To protect against oxidative stress-induced apoptosis in lens epithelial cells is a potential strategy in preventing cataract formation. The present study aimed at studying the protective effect and underlying mechanisms of p-coumaric acid (p-CA) on hydrogen peroxide- (H2O2-) induced apoptosis in human lens epithelial (HLE) cells (SRA 01–04). Cells were pretreated with p-CA at a concentration of 3, 10, and 30 μM before the treatment of H2O2 (275 μM). Results showed that pretreatment with p-CA significantly protected against H2O2-induced cell death in a dose-dependent manner, as well as downregulating the expressions of both cleaved caspase-3 and cleaved caspase-9 in HLE cells. Moreover, p-CA also greatly suppressed H2O2-induced intracellular ROS production and mitochondrial membrane potential loss and elevated the activities of T-SOD, CAT, and GSH-Px of H2O2-treated cells. As well, in vitro study showed that p-CA also suppressed H2O2-induced phosphorylation of p-38, ERK, and JNK in HLE cells. These findings demonstrate that p-CA suppresses H2O2-induced HLE cell apoptosis through modulating MAPK signaling pathways and suggest that p-CA has a potential therapeutic role in the prevention of cataract.

1. Introduction

Age-related cataracts are the leading causes of blindness among the elderly population, affecting nearly 50% of 180 million visually impaired people in the world [1]. Although the surgery has proved effective for cataracts, it still exists in many risks and complications [2]. It is estimated that if the onset of clinical cataract can be delayed for 10 years, half of the cataract surgeries will not be necessary [3]. Thus, to delay or prevent cataract development would be important both for increasing the well-being of older adults and for reducing medical care costs. Oxidative stress caused by reactive oxygen species (ROS) has long been recognized as the major contributor to the formation of cataract, and hydrogen peroxide (H2O2) is the main intracellular ROS in the aqueous humor, which can activate multiple signaling events such as the activation of the caspases, the Bcl-2 family, the mitogen-activated protein kinases (MAPKs), and NF-κB pathways to induce lens epithelial cell (HLE) apoptosis and cause lens opacification, resulting in subsequent cataract development [4–7]. Therefore, to protect human lens epithelial cells from oxidative stress-induced apoptosis is an important strategy in preventing and delaying cataract formation.

p-Coumaric acid (p-CA) is a phenolic acid which is widely distributed in many plants and human diets such as cereals, fruits, and vegetables, possessing versatile medicinal activities including antioxidant, cardioprotective, antimelanogenic, antimutagenic, antiplatelet, anti-inflammatory, and immunomodulatory actions [8–13]. Previous studies reported that p-CA is effective to protect the cornea from
UVB-induced oxidation damage in vivo and in vitro [14–16]. Other studies also proposed that p-CA could prevent cells from oxidative stress-induced apoptosis [17, 18]. However, the molecular mechanisms behind its protection against oxidative stress remain unknown. In our preliminary work, we screened the protective effects of natural compounds on H₂O₂-induced oxidative damage in human lens epithelial cells and found that p-CA exerts a potent protective effect on H₂O₂-induced oxidative stress in human lens epithelial cells (SRA 01–04). In the present study, we therefore investigated the effect of p-CA on H₂O₂-induced apoptosis in human lens epithelial (HLE) cells and its molecular mechanisms involved.

2. Materials and Methods

2.1. General. Fetal bovine serum (FBS), 0.25% trypsin, and DMEM/F12 medium were obtained from Gibco (Grand Island, NY, USA). Dimethyl sulfoxide (DMSO), H₂O₂, cocktail of protease inhibitors, and 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) were purchased from Sigma Chemical Co. (St. Louis, MO, USA). Quick start Bradford 1x dye reagent was from Bio-Rad Laboratories Inc. (Beverly, California, USA). Anti-cleaved caspase-3, anti-cleaved caspase-9, anti-p-p38, anti-p-ERK, anti-p-JNK, anti-β-actin, U0126, LY2228820, and SP600125 were obtained from Cell Signal Technology (Beverly, MA, USA). The annexin V/FITC kit was purchased from eBioscience (Bender MedSystems GmbH, Vienna, Austria). T-SOD, CAT, and GSH-Px activities were all measured as previously described using a colorimetric assay kit according to the manufacturers’ instructions [20].

2.6. Measurement of Mitochondrial Membrane Potential (Δψm) and the Activities of Antioxidant Enzymes. The mitochondrial membrane potential was tested using Rhodamine123 (Rh123) as previously described [20]. As well, T-SOD, CAT, and GSH-Px activities were all measured as previously described using a colorimetric assay kit according to the manufacturers’ instructions [20].

2.2. Cell Culture. Human lens epithelial (HLE) cells SRA 01/04 were purchased from the Chinese Academy of Medical Sciences (Beijing, China). The HLE cells were cultured as a monolayer in DMEM/F12 medium supplemented with 15% heat-inactivated FBS, penicillin (100 U/mL), and streptomycin (100 μg/mL) and were maintained under standard cell culture conditions at 37°C in a humidified atmosphere of 5% CO₂. The cells were routinely subcultured every 2-3 days.

2.3. Cell Viability. The cells were cultured in 96-well microplates with a density of 1x10⁵ cells/well and incubated with different concentrations of p-CA (0–100 μM), respectively, with or without the exposure of H₂O₂. After 24 h incubation, the culture medium was removed and cell viability was measured using the MTT method as previously described [19].

2.4. Detection of Cell Apoptosis. The percentage of apoptotic cells was assayed using the annexin V/FITC apoptosis detection kit according to the manufacturer’s directions. Briefly, cells were plated and incubated in 6-well plates at a density of 1x10⁶ cells/well. After exposure to H₂O₂ (275 μM) and/or indicated concentrations of p-CA for 6 h, the cells were harvested by 0.25% trypsin and washed twice with ice-cold PBS. The cell pellets were resuspended in binding buffer (1x) prior to the addition of 5 μL FITC-labeled annexin V and 10 μL propidium iodide (PI) for 15 min at room temperature in the dark. The level of cell apoptosis was immediately analyzed on a flow cytometer (Becton Dickinson, San Jose, CA, USA).

2.5. Reactive Oxygen Species (ROS) Generation Assay. The intracellular ROS levels were evaluated using the ROS-specific fluorescent dye H2DCF-DA. After indicating treatments, cells were washed with PBS for three times and stained with H2DCF-DA, incubated at 37°C for 30 min in the darkness. Furthermore, cells were harvested and the generation of ROS was quantified by measuring the intracellular fluorescence intensity by a flow cytometer. The samples were then analyzed with FlowJo 7.6.1.

2.7. Immunoblotting. Cells were incubated in 6-well plates at a density of 1x10⁶ cells/well. After exposure to H₂O₂ (275 μM) and/or indicated concentrations of p-CA for 24 h, the cells were washed twice with ice-cold PBS and then lysed using RIPA buffer for 30 min on ice. Protein concentrations were quantified using the BCA protein assay kit [21]. And then, protein from each sample (50 μg) was separated by 12% SDS-PAGE gels and transferred onto nitrocellulose membranes. After incubation with primary antibodies against cleaved caspase-3, cleaved caspase-9, p-p38, p-ERK, p-JNK, and β-actin, followed by incubations with the appropriate secondary antibodies conjugated with HRP as our previously described method [22], the blots were detected by enhanced chemiluminescence (ECL), and then protein bands were quantified by densitometric analysis using Image-Pro Plus® software (Media Cybernetics Inc., USA).

2.8. Statistical Analysis. The data are presented as the mean value ± standard error of the mean (SEM). The difference between the mean values was evaluated using one-way ANOVA, followed by Duncan’s multiple range tests. Comparisons were performed using GraphPad Prism 5.0 software (GraphPad Software Inc., San Diego, CA, USA). A P value < 0.05 was considered statistically significant.

3. Results and Discussion

It is well-known that the apoptosis of lens epithelial cells plays a vital role in cataract formation, and oxidative stress induced by ROS such as O₂⁻ and H₂O₂ has been recognized as an important mediator to induce apoptosis of lens epithelial cells [3, 5, 6]. Therefore, in the study, H₂O₂ was used to induce oxidative injury of lens epithelial cells. After H₂O₂ exposure, the cells showed a high cell apoptosis rate and 275 μM H₂O₂ was set as the working concentration (Figure 1(b)). In parallel, HLE cells were treated with
different concentrations of p-CA (0, 0.3, 1, 3, 10, 30, and 100 μM) for 24 h and no significant cytotoxicity was observed (Figure 1(c)). And then, the dose response of p-CA was assayed on H2O2-treated HLE cells, and the result showed that pretreatment with p-CA (3–100 μM) significantly prevented H2O2-induced cell death in a dose-dependent manner (Figure 1(d)). To quantitatively examine the protective potential of p-CA against H2O2-induced cell death in HLE cells, the percentage of apoptotic cells was detected by the annexin V/PI double staining method. As shown in Figure 2(a), the percentage of total apoptotic cells (the sum of early-stage apoptotic cells (annexin V+/PI− cells) and late-stage apoptotic cells (annexin V+/PI+)) was significantly increased after the exposure of 275 μM H2O2. Compared to the cells treated with H2O2 alone, pretreatment with p-CA (3, 10, and 30 μM) resulted in a significant decrease of apoptotic cells in the total population of cells in a dose-dependent manner. Caspases are the main initiators and executors of apoptosis [23, 24]. As one of the key effectors, caspase-3 is activated through cleavage by caspase-9 and involved in the mitochondria-mediated pathway. We thus examined the expressions of cleaved caspase-3 and cleaved caspase-9 using Western blot. As shown in Figure 2(b), the expressions of cleaved caspase-3 and cleaved caspase-9 were markedly upregulated after H2O2 treatment. In contrast, pretreatment with p-CA (3, 10, and 30 μM) significantly inhibited the upregulation of cleaved caspase-3 and cleaved caspase-9. Collectively, these results suggested that p-CA exhibits a potent protective effect against H2O2-induced apoptosis in HLE cells.

Oxidative stress can be defined as the imbalance between prooxidant/antioxidant that can occur as a result of an increase in free radical production and/or a decrease in radical scavenging capability of antioxidant defense systems. We therefore detected the production of intracellular free radical ROS in H2O2-induced HLE cells, as shown in Figure 3(a). When the cells were exposed to H2O2, the generation of ROS increased significantly, whereas pretreatment with p-CA (3, 10, and 30 μM) significantly inhibited H2O2-induced production of intracellular ROS in a dose-dependent manner. The mitochondria are the major location to produce intracellular ROS, and ROS overload would result in lysosomal leakage through the mitochondrial outer membrane and mitochondrial dysfunction. A significant reduction of mitochondrial membrane potential (∆ψm) is a symbolic feature of early apoptosis. We further determined the loss of ∆ψm in H2O2-induced HLE cells. As shown in Figure 3(b), exposure of HLE cells to H2O2 for 6 h could significantly
increase the percentage of cells with Δψm loss, which is up to 29.0%, and pretreatment with p-CA (3, 10, and 30 μM) could significantly reduce the percentage of cells with Δψm loss to 23.7%, 21.2%, and 15.8% in a dose-dependent manner. In parallel, we also detected the radical scavenging capability of antioxidant defense systems of HLE cells, such as the activities of T-SOD, GSH-Px, and CAT enzymes. Compared to the untreated control, H₂O₂ decreased the activities of T-SOD, CAT, and GSH-Px near 2-fold. In H₂O₂-treated HLE cells, pretreatment with p-CA (3, 10, and 30 μM) could significantly enhance the activities of T-SOD, CAT, and GSH-Px in dose-dependent manners as shown in Figure 4. These results indicated that p-CA possesses potent antioxidant activities against H₂O₂-induced impairment in HLE cells.

**Figure 2:** p-CA prevented H₂O₂-induced cell apoptosis in HLE cells. (a) HLE cells were pretreated with p-CA (3, 10, and 30 μM) for 2 h before 275 μM H₂O₂ treatment for 6 h. The apoptotic cells were detected by flow cytometry after staining with both FITC annexin V and PI. (b) HLE cells were pretreated with p-CA (3, 10, and 30 μM) for 2 h before 275 μM H₂O₂ treatment for 24 h. Cleaved caspase-3 and cleaved caspase-9 expressions were measured by Western blot. Data are expressed as the mean ± SEM (n = 3). *P < 0.05, **P < 0.01, and ***P < 0.001, compared with the untreated control group; #P < 0.001, compared with the treated group.
To explore the molecular mechanisms involved in the protective effects of p-CA against H₂O₂-induced apoptosis, we evaluated the possible influence of this compound on the expression of mitogen-activated protein kinases (MAPKs), namely, ERK, JNK, and p38, which play important roles in the regulation of intracellular metabolism and responding...
to external stress [6]. Several previous investigations reported that p-CA reduced the oxidative stress of various cells via the inhibition of the MAPK signaling cascade [25–27]. Our data showed that (Figure 5(a)) incubation with H2O2 led to a massive increase of p-p38, p-ERK, and p-JNK. As expected, increased p-p38, p-JNK, and p-ERK were significantly rescued by p-CA in a dose-dependent manner. To further confirm the role of the MAPK signaling pathway to mediate the inhibitory effect of p-CA on H2O2-induced apoptosis in HLE cells, we have detected the cell viability of cells exposed to H2O2 with the ERK inhibitor (U0126) or p-38 inhibitor (PD169316) or JNK inhibitor (SP600125), respectively. As shown in Figure 5(b), compared to cells treated with p-CA alone in the presence of H2O2, HLE cells treated with p-CA combined with LY2228820 or U0126 or SP600125 in the exposure of H2O2 exhibited a much higher cell viability, which displayed the protective effect of p-CA on H2O2-induced apoptosis in HLE cells via affecting MAPK signaling pathways.

4. Conclusion

In conclusion, the data from this study demonstrate that p-CA, a natural compound, could protect HLE cells from oxidative stress-induced apoptosis through modulating MAPK signaling pathways. Our findings suggest a potential use of p-CA in the prevention of cataractogenesis.
