the hollow, spiny, chitinous object that an insect or bird foe would seize when attacking the tree-hopper could be no possible incentive toward further efforts. In the above cited instance, this adaptation certainly saved two individuals from me, and without doubt in nature is often used successfully, and may be considered as a sort of adaptive self mutilation, or autotomy.

The accompanying plate will give an idea of the appearance of the insect, with and without the pronotal development.

THE SPECIES OF THE COLEOPTEROUS FAMILY TEMNOCHILIDÆ COLLECTED ON THE EXPEDITION.

BY CHAS. SCHAEFFER,
Museum of the Brooklyn Institute, Brooklyn, N. Y.

Temnochila chalcea Kirsch

Eleven specimens collected at Abuná and Porto Velho, Rio Madeira.

The females of this species, which is widely distributed in Central and South America, have the last ventral segment more or less deeply and broadly triangularly impressed, a rather unusual female character in this genus.

Tenebroides bipustulata Fab.

Seven specimens collected at Porto Velho and Abuná, Rio Madeira.

The middle and hind tibiae are armed with one or two small
spines on the upper edge, which is rather unusual in this genus and apparently overlooked by every author dealing with this species.

**Tenebroides bipustulata** var. *impressifrons* Reit.

Differs from *bipustulata* only in the absence of the red elytral spots.

**Tenebroides subcostata** sp. nov.

Elongate, feebly convex, color of upper surface brown, under side, antennae and legs castaneous. Head moderately coarsely, not densely punctuate, a narrow space near clypeus almost smooth, with at most only a few very fine punctures. Antennal club abrupt and relatively large, sensitive space of joints large, occupying about half the width of the joint. Prothorax transverse, lateral margin crenulate, scarcely rounded at sides and feebly obliquely narrowing to base at about basal third; hind angles obtuse; anterior margin rather deeply emarginate, anterior angles prominent; basal marginal line almost entire, only narrowly interrupted at middle, surface rather coarsely and densely punctate at sides, less densely at middle. Scutellum small, smooth, shining. Elytra almost parallel, striae replaced by very narrow, smooth and more or less distinctly elevated lines; intervals wide and very densely irregularly punctate. Underside of head smooth, shining with a few sparse punctures. Prothorax below densely and rather coarsely punctate. Abdominal segments irregularly transversely impressed and rather coarsely punctate. Length 7 mm.

Judging from the descriptions this species seems to be related to *anceps* Lev. and *lineolata* Reit. Both have also the elytral striae replaced by narrow elevated lines but have the intervals distinctly uni- or biseriately punctured, while the intervals in *subcostata* are very densely, confusedly punctate.

**Tenebroides vittata** sp. nov.

Form short, feebly convex. Color above subeneous, shining, anterior margin of head, lateral margin of prothorax, an almost entire vitta on each elytron, occupying the fifth and sixth intervals and lateral margin narrowly red. Under-side, antennae and legs reddish. Head rather sparsely and finely punctate. Prothorax about twice as wide as long; sides arcuate but feebly narrowing towards base and not sinuate before basal angles; base scarcely narrower than the thorax at apical angles; basal margin almost straight with the angles rectangular, basal line entire; apical margin moderately deeply emarginate, angles acute, surface
rather sparsely and finely punctate, punctures a little coarser towards the lateral margin. Elytra slightly wider than the prothorax at base; humeral angles prominent but rounded; lateral margin slightly sinuate below humeral angles; the punctures representing the striae feebly impressed on the disk but stronger at sides; intervals with a few, scarcely visible punctures. Antennæ rather short, the club nearly as long as the preceding joints. Submentum and gula almost smooth, with only a few coarse punctures at sides. Prosternum very sparsely punctate. Abdominal segments finely alutaceous, not densely punctate. Length 5 mm.

Madeira-Mamoré R. R. Co. Camp 43. One specimen.

I was unable to find a description that would fit this distinct little species.

STUDIES AMONGST THE COCCINELLIDÆ. NO. 3.

By F. W. NUNENMACHER,
Piedmont, California.

The following paper consists of a list of the Coccinellidæ taken by the Stanford Expedition to Brazil in 1911. The Coccinellid material of their collection was entrusted to the writer and among the species taken I find two new to science which are described in their proper places in the list.

Genus Epilachna Chevr.

*Epilachna gossypiata* Muls. Rio Madeira, Brazil, 2 specimens.

Genus Psyllobora Muls.

*Psyllobora confluenta* Fab. Ceará, Brazil, 8 specimens.

Genus Cycloneda Cr.

*Cycloneda sanguinea* L. Abuná, Bolivia, 1 specimen.

Genus Exocomus Redt.

*Exocomus bimaculosus* Muls. Independencia, Parahyba, Brazil (Mann and Heath).
