SIBLING SPECIES IN THE *EURYDICE* GROUP OF *LETHE* (LEPIDOPTERA: SATYRIDAE)

BY RING T. CARDÉ,¹ ARTHUR M. SHAPIRO,¹
AND HARRY K. CLENCH²

INTRODUCTION

We have uncovered a pair of sibling species in the comparatively well-known butterfly fauna of eastern North America: the common Grass Nymph or Eyed Brown, *Lethe eurydice* of recent authors, is actually two species, which are extensively sympatric.

Curiously, the distinctness of these two has been known since at least 1936, when W. D. Field discovered and characterized them as subspecies. He assigned names to them which we now know to be inapplicable. This was corrected in 1947 by R. L. Chermock, who named the presumably more southern "subspecies" *appalachia*. Neither of these authors was aware that the "subspecies" are sympatric.

The present investigation was first suggested when one of us (Clench) found both forms flying in the same area near Leesburg, Mercer Co., Pennsylvania in 1966. The conspicuous habitat difference between them implied that two species might be involved. In 1968 another of us (Shapiro) found the same situation in western and central New York and (with Cardé) investigated the immature stages and biology of the insects. The results of this study are partly reported elsewhere (Shapiro and Cardé, 1970).

Independently of us, C. F. dos Passos and his correspondents simultaneously made the same discovery. Several of the conclusions contained in the resulting paper (dos Passos, 1969) appear erroneous. Since the taxonomic situation is very complex, we here review the whole subject, nomenclatorially, morphologically, and distributionally.

In brief, we recognize two species in this group, as follows:

(1a) *Lethe eurydice eurydice* (Johansson), widely distributed from Labrador to Great Slave Lake and south to Delaware and Illinois, occurring in open marshes and sedge meadows.

(1b) *Lethe eurydice fumosa* (Leussler), scattered in small isolated colonies (many now extinct) in sedgy permanent marshes in the

Figs. 1-2. *Lethe appalachia* male, McLean Bogs Reserve, Tompkins Co., New York. Figs. 3-4. *Lethe eurydice* (male) neotype, Morris Arboretum, Philadelphia Co., Pennsylvania. Figs. 5-6. *Lethe eurydice fumosa* male, Sarpy Co., Nebraska.

prairie regions from Minnesota and South Dakota to Indiana, Nebraska and Colorado.

(2) *Lethe appalachia* R. L. Chermock, widely distributed from Maine to northern Florida, westward to South Dakota and Alabama, broadly sympatric with *L. e. eurydice* but occurring primarily in swamp forest, shrub swamps and forest-edge ecotones.

These forms have had a particularly extensive history in earlier literature, involving not just the above names but several others as well, as may be seen below.

TAXONOMY

In reviewing the taxa of the *Lethe eurydice* group, we have given the synonymies in strict chronological order, following the practice of some of the older authors. We hope this practice will add historical perspective to the discussions of these intricate synonymies.

The distributional data and maps (figs. 21, 22) were based on material examined in the following institutional collections: American Museum of Natural History, New York (AMNH); Academy of Natural Sciences of Philadelphia (ANSP); United States National Museum, Washington, D.C. (USNM); Carnegie Museum, Pittsburgh (CM); Cornell University, Ithaca, New York (CU); New York State Museum, Albany (NYSM); and Hope Department of Entomology, Oxford University, England (Oxon.). Also the following private collections: Robert H. Whittaker (RHW); David J. Horn (DJH); Arthur M. Shapiro (AMS). A few reliable printed or other records, based on specimens not seen, are given separately, along with a few which are queried.

The sexes of *Lethe* are very similar and may at times be difficult to determine in a superficial examination. We have therefore listed only the localities and dates of material examined. In the case of large series, only a range of dates may be given.

The characters differentiating the three entities recognized in this paper are summarized in Table 1 and in the accompanying section of the text. A brief summary of the most conspicuous characters of each is given following its taxonomic history.

Lethe eurydice eurydice (Johansson)

Papilio eurydice Johansson 1763, Amoen. Acad. 6: 406; type locality Philadelphia [Pennsylvania]; type formerly in the De Geer collection (Stockholm, Sweden), now lost; neotype designated below.

Papilio canthus Linnaeus 1767, Syst. Nat. (12th ed.): 768; type locality "in America septentrionali;" no type exists (replacement name for *Papilio eurydice*).

- ? *Papilio canthus*: Fabricius 1775 (*partim*), Syst. Ent.: 486.
Argus canthus: Scopoli 1777, Introd. Hist. Nat.: 432.
Satyrus canthus: Godart 1821, Encycl. Meth. 9: 465, 493.
Neonympha canthus: Westwood 1851, in Doubleday, Westwood, and Hewitson, Gen. Diurn. Lep. 2: 375.
Neonympha cantheus (*nec* Godart 1821, see below): Morris 1860, Cat. Lepid. N. Amer.: 10.
Hipparchia boisduvallii Harris 1862, Ins. Inj. Veg. (Flint ed.): 305, fig. 128; type locality "this State" (Massachusetts), type now lost; no neotype designated.
Debis canthus: Herrich-Schaeffer 1865, Correspbl. Zool.-Min. Ver. Regensburg 19: 72.
Pararge canthus: Butler 1868, Cat. Satyridae Br. Mus.: 123.
Euptychia canthus: Kirby 1871, Syn. Cat. Diurn. Lep.: 55.
Pararge boisduvallii: Edwards 1872, Synopsis N. Amer. Butt.: 26.
Argus eurydice: Scudder 1872, Syst. Rev. Amer. Butt.: 6.
Satyrodes eurydice: Scudder 1875, Bull. Buffalo Soc. Nat. Sci. 2: 243.
Satyrodes canthus: Smith 1884, Bull. Brooklyn Ent. Soc. 6: 119.
? *Satyrodes canthus* ab. *boweri* F. H. Chermock 1927, Bull. Brooklyn Ent. Soc. 22: 118; type locality Port Hope, Ontario; type not located, stated by dos Passos to be in Carnegie Museum, but not found. (Infrasubspecific name with no standing in nomenclature.)
Satyrodes eurydice transmontana Field 1936, J. Ent. Zool. (Pomona) 28: 22; type locality Compton, Quebec; no type designated.
Satyrodes eurydice transmontana f. ♀ *rawsoni* Field 1936, J. Ent. Zool. (Pomona) 28: 22; type locality Bloomfield, Michigan; type deposited in U. S. National Museum. (Infrasubspecific name with no standing in nomenclature.)
Lethe (*Enodia*) *eurydice*: R. L. Chermock 1947, Ent. News 58: 29.

The descriptions of both *eurydice* Johansson and *canthus* Linnaeus are too scanty to restrict on internal evidence to either of the sympatric northeastern species, both of which occur at the type locality (Shapiro, 1970a). If that locality (Philadelphia) is accurate, there can be no doubt that Johansson's description applies only to a member of this group, even though no mention is made of eyespots on the forewing above (an objection to this usage, raised by Harris, 1862 and Edwards, 1897). No type of *eurydice* or *canthus* (which was proposed explicitly as a replacement name for *eurydice* and hence has the same type) exists in the British Museum (Natural History) or in the De Geer collection at the Naturhistoriska Riksmuseum, Stockholm.

When *appalachia* (see below) was described as the southern subspecies of *eurydice*, the latter name became firmly associated with the assumed "northern" subspecies whose color and pattern were contrasted with *appalachia* by Chermock. It seems desirable to

stabilize the nomenclature by preserving this usage through a neotype designation. This removes the possibility that a specimen of Chermock's *appalachia* might eventually be selected as neotype of *eurydice*, leaving the familiar "northern" insect's name in question. The only Philadelphia specimens of *eurydice* auct. with full data which we have found were collected by one of us (Shapiro). Several of these were placed in the United States National Museum two years ago, and we designate one such specimen the neotype of *Papilio eurydice* Johansson.

Neotype. — A male deposited in the U.S. National Museum bearing the manuscript label "eurydice ♂/Morris Arboretum/Phila. Co. Pa./29 June 1967/A. M. Shapiro" (fig. 1). We have added a label identifying the specimen as the neotype of *Papilio eurydice* Johansson. The U.S.N.M. also contains a second specimen with the same locality and collection date.

Taxonomic History: the Euptychia names. — The taxonomy of *L. eurydice* is complicated by confusion with *Ypthimoides* (= *Euptychia*) *argulus* (Godart). This problem was not noted by dos Passos, and is reviewed here.

Fabricius (1775) reworked the description of *canthus*, adding "immaculatis" to the upperside diagnosis and altering various details. The "immaculatis" may have been by inference from the lack of reference to spots in the earlier descriptions, but it seems more likely that Fabricius was working from some other insect he confused with the Linnean one. In 1779 Cramer described and figured a species from Surinam as *Papilio argante*. This name is a junior homonym of *Papilio argante* Fabricius 1775 (now *Phoebis argante*, Pieridae). Fabricius synonymized *argante* Cramer to *canthus* (Fabricius, 1781), improperly emending it to *arganthe* in synonymy. (*Arganthe* is not available as a replacement name because it was proposed in synonymy.) He repeated this usage in 1787 and 1793. His own descriptions of "*canthus*" do not fit Cramer's figure well. Godart (1821) recognized that three species were included in the Fabrician concept "*canthus*" and attempted to end the confusion by redescribing the true *canthus* (translating Linnaeus), and naming two new entities, *argulus* and *cantheus*. Godart's *argulus* is a replacement name for the preoccupied *argante* and is the oldest valid name for this taxon. *Cantheus* is a renaming of the entity Fabricius first thought was *canthus*, theretofore without a valid name. The identity of this animal cannot be determined if, as appears, Fabrician specimens of "*canthus*" do not exist.

Figs. 7-8. *Lethe appalachia* female, McLean Bogs Reserve, Tompkins Co., New York. Figs. 9-10. *Lethe eurydice eurydice* female, McLean Bogs Reserve, Tompkins Co., New York. Figs. 11-12. *Lethe eurydice fumosa* female, Sarpy Co., Nebraska.

Butler (1868) described *Euptychia perfuscata* and subsequently (1869) synonymized it to *argante*. We have not seen his specimens (which should be in the British Museum), nor any specimen definitely determinable under any of these names. The most recent discussion of *argulus* is by Weymer (1907, p. 202). The leading North American authority on *Euptychia* and its allies, L. D. Miller, advises us (*in litt.*) that he does not know the species, but from Cramer's description and figure would place it near *Yphthimoides grimon*. The partial synonymy of *argante* = *argulus* is thus:

Papilio argante Cramer 1779 (*nec Papilio argante* Fabricius 1775), De Uitlandsch. Kapell. 3: 19, pl. 204; type locality Surinam; type not investigated.

‡ *Papilio canthus* (*nec* Linnaeus 1767): Fabricius 1781 (*partim*), Spec. Ins. 2: 64 (*arganthe* in synonymy); 1787, Mant. Ins. 2: 31; 1793, Ent. Syst. 3(1): 157.

Satyrus argulus Godart 1821, Encyl. Meth. 9: 463, 488; type locality Surinam; type never existed (replacement name for *argante*).

? *Euptychia perfuscata* Butler 1868, Cat. Satyridae Br. Mus.: 18; type locality Para, Brazil; type probably in British Museum, not investigated.

? *Euptychia argante*: Butler 1869, Cat. Diurn. Lep. Fabr. Br. Mus. 13.

Cantheus, which is the unknown animal Fabricius confounded first with *canthus* and then with *argante*, usually appears in the synonymy of *eurydice* = *canthus*, but its only proper claim there is its mistaken use in synonymy by Morris (1860). We have removed *cantheus* Godart from the synonymies of the other entities and regard it as a *nomen dubium*, presumably a species of *Euptychia sens. lat.* Its synonymy is:

‡ *Papilio canthus* (*nec* Linnaeus 1767): Fabricius 1775 (*partim*), Syst. Ent.: 486; 1781, Spec. Ins. 2: 64; 1787, Mant. Ins. 2: 31; 1793, Ent. Syst. 3(1): 157.

Satyrus cantheus Godart 1821, Encyl. Meth. 9: 465, 493; type locality "l'Amerique septentrionale"; type not investigated, probably never existed.

Godart's description of *cantheus* erroneously cites Fabricius, "Species Insectorum" for "Mantissa Insectorum." The name is misspelled "cautheus" in the heading on page 465.

Taxonomic History: other names.—Gosse (1841) attributes the name *Hipparchia transmontana* to Say, but it does not appear in any extant work by that author. It usually appears in the synonymy of *eurydice* attributed to Gosse 1840. Apparently Gosse believed it was described elsewhere, since his "description" (1840, p. 247) is

13

14

Fig. 13. Male genitalia of *Lethe appalachia*.

Fig. 14. Male genitalia of *Lethe eurydice eurydice*.

inadequate to associate it with any biological entity. It could apply to any of several Quebec Satyridae, which are not exhausted by the other species enumerated in the text. His statement that "this is likewise described by the American naturalists as very rare, and is found only beyond the Rocky Mountains . . ." makes no sense when applied to any species of *Lethe*. We regard this as a *nomen nudum* and have omitted it from the synonymy.

Field (1936) resurrected *transmontana* as the northern subspecies of *eurydice*, describing it adequately and giving as the type locality Gosse's base at Compton, Quebec. This is the oldest valid publication of the name, which should thus be credited to Field 1936. This subspecific distinction was grounded in confusion over the entities now called *eurydice* and *appalachia*. Observing differences between northern *eurydice* and specimens from near the type locality, Philadelphia, which he took as typical of that taxon but which were really *appalachia*, Field felt that a subspecific name was warranted. This is clear from his article, particularly the citation of Clark's (1932) figures of Beltsville, Maryland *appalachia* which Field (like Clark) calls typical *eurydice*. Thus *transmontana* becomes a junior subjective synonym of *eurydice*. We can see no subspecific differences among eastern populations of *eurydice* as here restricted. Field's female form *rawsoni* is based on specimens faded in life; such specimens occur throughout the range of *eurydice*. The name is infrasubspecific and therefore has no formal standing.

The name *boisduvallii* was attributed by dos Passos (1964) to Morris (1862), an error corrected later (dos Passos, 1969). Morris published the name in synonymy, spelled *boisduvalli*. The first valid publication was in the posthumous (1862) edition of Harris's "Insects Injurious to Vegetation," edited by Flint. The editor's preface makes clear that the name should be attributed to Harris. It was emended to *boisduvalii* by Scudder (1889) in synonymy; this spelling is used by Forbes (1960) and dos Passos (1964). Dos Passos (1969) has further emended it to *boisduvali*. Although not the preferred form, the double "i" is acceptable in taxonomy as the genitive of the Latinized name, i.e. "Boisduvalius." While Boisduval spelled his name with only one "l" and there is no orthographic reason to double it in forming the Latin genitive, the fact that the

Fig. 15. Male genitalia of *Lethe eurydice fumosa* (valve in slightly different position than valves of figs. 13 and 14). Fig. 16. Ventral view of *Lethe appalachia* valve. Fig. 17. Ventral view of *Lethe eurydice eurydice* valve. Fig. 18. Ventral view of *Lethe eurydice fumosa* valve.

name is spelled *boisduvallii* in both the text and index of Harris (1862) indicates that the double "l" was the form used in the Harris manuscript, and this is confirmed by its use in Morris's (1862) citation from that manuscript. Unfortunately, then, *boisduvalli* is technically a "correct original spelling" and cannot be emended under the Code.

Summary of Characters.—*Lethe eurydice eurydice* is relatively pale, pinkish brown above, somewhat yellowish beneath, with the postmedial line deeply indented beneath on all wings. The male valve is strongly 4-sided when viewed laterally, and the tegumen is dorsally rounded. The larva appears superficially to have dark side-stripes on the head capsule, extending from near the tip of the horns to the ocelli. These and other characters are discussed more completely under the headings "Diagnostic Characters" and "Biological Differences," after the taxonomic treatment of *Lethe appalachia*, below.

ALBERTA: Rivercourse, near Lloydminster, vii.6.41 (R. J. Fitch) (CU)

Other records: Dos Passos (1969) erroneously records *eurydice* from "south to Colorado and east of the Rocky Mountains to Georgia and Florida." The Colorado records represent *L. e. fumosa* (see below). At present the southernmost record of true *L. e. eurydice* is northern Delaware.

Scudder (1889) records *L. eurydice* from Rupert's Fort, Quebec (east shore Hudson's Bay); Mingan, Labrador; and Great Slave Lake, NWT. All of these are plotted on the map.

The western distribution of *eurydice* is unclear. Puckering and Post (1960) record it from Cass, Cavalier, Dickey, Grand Forks, and Pembina Cos., North Dakota. These are entered on the map. We have seen no South Dakota records. However, Leussler (1938), who was well acquainted with *L. e. fumosa*, reported typical *eurydice* in Sioux Co., northwestern Nebraska. This record seems to require special confirmation, and has not been plotted.

The "*eurydice*" reported from Monroe Co., Tennessee (Mather, 1961) was *appalachia* (W. Reinthal, pers. comm.). The latter species was found at Jackson, Tenn. by Roever (Mather and Mather, 1958).

Lethe eurydice fumosa (Leussler)

Satyroides canthus n.v. *fumosus* Leussler 1916, Ent. News 27: 99, pl. iv, figs. 1, 2; type locality Sarpy County, Nebraska; type reportedly deposited in Ohio State University, not seen.

Lethe fumosus: dos Passos 1969 (*partim*), J. New York Ent. Soc. 77: 120.

Taxonomic History. — Described from 17 males and 8 females, all labeled "Omaha" by Leussler, as are various later topotypes. Although it was described as a "variety," the geographic nature of *fumosa* was clearly expressed.

The Greek noun *λήθη* is feminine and retains its gender in the Latinized form *Lethe*. Both the species names in this group are also feminine. We have adopted the spelling *fumosa* to make this subspecies agree in gender, as provided by the Code.

Summary of Characters. — *Lethe eurydice fumosa* resembles *L. eurydice* in most respects, but the males and some females are darker above. The four eyespots on the forewing are consistently graded in size, from the smallest on top to the largest at the bottom; this is especially obvious beneath. The male valves have far fewer setae than in *L. e. eurydice*. The early stages are unknown.

Distribution (fig. 21). — Material examined:

NEBRASKA: Sarpy Co.: "Omaha" vi.28.13, vii.1.15 (R. A. Leussler) (cotypes) (ANSP); vii.12.13, vi.14.13, vi.27.14 (cotype), vii.7.17 (R. A. Leussler) (USNM); vi.27.14 ("topotype"), vii.5.13, vi.28.13, vi.26.15 (cotype), vii.7.17 (R. A. Leussler) (AMNH); vi.27.14 (paratype), vii.1.16 (figured by Holland, pl. 63, fig. 11) (R. A. Leussler) (CM); County undetermined: "Nebraska," no date (J. Angus coll.) (AMNH)

IOWA: Dickinson Co.: Lake Okoboji, vi.25.21 (R. A. Leussler) (USNM); Hancock Co.: 1 mi. W Klemme, vii.24.60 (L. D. Miller) (CM); Poweshiek Co.: Grinnell, vii.4.81 (AMNH); County undetermined: "Ia." no date (H. Skinner) (CM)

WISCONSIN: Kenosha Co.: Twin Lakes, vi.1-4.11 (A. Kwiat) (USNM); County undetermined: "Wis." no date (E. T. Owen coll.) (USNM)

MINNESOTA: Hennepin Co.: Lake Minnetonka, no date (USNM), St. Anthony Park, vii.15.91 (USNM)

INDIANA: County undetermined: Tremont, vii.24.48 (O. Buchholz) (AMNH)

SOUTH DAKOTA: Brookings Co.: Volga, no date (P. C. Truman) (CM)

COLORADO: Larimer Co.: Loveland, no date (W. H. Edwards coll.) (CM); County undetermined: "Colo." not date (David Bruce) (CM), "Colorado" no date (E. T. Owen coll.) (USNM), "Colorado" no date (H. S. Burnett) (USNM)

Bruce collected *fumosa* at Estes Park, Larimer Co., Colorado (Edwards 1897, p. 197). The identities of the Indiana, Minnesota, and Wisconsin specimens noted above were not checked by the genitalia, and are somewhat uncertain.

Lethe appalachia R. L. Chermock

Lethe (Enodia) eurydice appalachia R. L. Chermock 1947, Ent. News 58: 29; type locality Conestee Falls, North Carolina; type in R. L. Chermock collection, not seen.

Lethe fumosus appalachia: dos Passos 1969, J. New York Ent. Soc. 77: 121.

Taxonomic History.—Unmistakable figures of *appalachia* appear in three older works under other names. None of these has any taxonomic significance. Boisduval and Le Conte (1829) figure a male *appalachia* with an ambiguous female as *Satyrus canthus* (pl. 60). Edwards (1897) figures a female *appalachia* (pl. 26, figs. 3, 4) with a normal male *eurydice* (figs. 1, 2) as *Satyrodes canthus*, along with a dark male which is probably also *eurydice* but might be *fumosa* (fig. 5). Denton (1900) figures an ambiguous specimen (p. 217), an *eurydice* (p. 218), and an *appalachia* (p. 219), all as *Neonympha canthus*.

Dos Passos (1969) erred in sinking *appalachia* to "*fumosus*." There is no evidence for his statement that "*fumosus* and *appalachia* occur at opposite ends of a cline."

Dos Passos lists ab. *boweri* F. H. Chermock under *appalachia*. It cannot be identified to species by the description, and the type has not been found; it is not in the Carnegie Museum, where dos Passos recorded it. We have placed *boweri* provisionally in the synonymy of *eurydice* because that species is considered more likely from the type locality, Port Hope, Ontario. However, a specimen of *appalachia* with no ocelli on the forewings above, labeled "Bowie, Md./ v-29-45/DDT experiment," is in the U.S. National Museum. At any rate, the name is clearly infrasubspecific and has no standing.

Summary of Characters.—*Lethe appalachia* differs from both subspecies of *eurydice* in being grayish or mousy brown above (blackish when fresh) and somewhat purplish or lilac-tinged beneath; the postmedial lines rounded, with only slight indentations. The male valve is less clearly 4-sided in lateral view, and the tegumen is dorsally flattened. The larval head capsule bears side-stripes not reaching below the bases of the horns.

Distribution (fig. 22).—Material examined:

FLORIDA: Jefferson Co.: Monticello, x.4.14 (paratype) (AMNH)

We regard the South Dakota and Missouri records of *L. appalachia* as somewhat dubious, but they are shown on the map.

Other records: The following are probably accurate, although the specimens have not been seen. They are included on the map:

GEORGIA: Thomas Co.: Linton Lake, viii.9.67, viii.29.67; Fulton Co.: Atlanta (Harris Trail), vii.29.60, viii.20-26.61; De Kalb Co.: Avondale Estates, vi.16.44; Union Co.: Copper Creek State Park, vi.6.58, vii.16.61, vi.18.62, vii.18.62, viii.22.59; White Co.: Cleveland, vi.13.57 (all from L. Harris, unpublished MS, p. 244)

MINNESOTA: Anoka Co.: Bald Eagle Lake, 1966 (Masters, 1967)

INDIANA: Steuben Co.: Hogback Lake, vii.17.42 (Price and Shull, 1969)

TENNESSEE: Madison Co.: Jackson (Mather and Mather, 1958)

ALABAMA: Tuscaloosa Co.: vic. Tuscaloosa (Chermock, 1949)

MICHIGAN: Montcalm Co.: Sidney, vii.26.50 (F. Rutkowski)

PENNSYLVANIA: Fayette Co.: Markleysburg Bog, 2 mi. N Markleysburg (H. K. Clench)

DIAGNOSTIC CHARACTERS

Color and Pattern.—*Lethe e. eurydice* and *L. e. fumosa* differ subtly but consistently from *L. appalachia*. Nearly all specimens can be assigned to the correct species by color and pattern alone. The most useful characters separating the two species are the ground color above and beneath, and the waviness of the postmedial line beneath. The two subspecies of *eurydice* differ most consistently in the relative sizes of the forewing ocelli. All of the observed differences are given in Table 1.

We have not seen a truly fresh specimen of *L. e. fumosa*. Leussler (1916) describes the ground color of fresh specimens as "a very dark smoky grey . . . even a blackish appearance." This sounds very much like the color of newly emerged *appalachia*. Old specimens of the two are very different, however: *fumosa* males are an even, somewhat purplish or reddish brown, while *appalachia* is grayish or mousy brown. Some female *fumosa*, particularly from Colorado, are nearly identical in color to nominate female *eurydice*, but the ground color of the males is nearly always distinctive. A few male *eurydice* from the northeast are dark purplish brown when

fresh, and fade to an even dark reddish brown. Their spot-sizes are normal and they lack the *fumosa* tendencies to "high angledness" of the forewing and blind and rimless ocelli above. A specimen of this dark form of nominate *eurydice* is probably represented by Edwards' figure 5 (1897, pl. 26).

Specimens of the three taxa are shown in figs. 1-12.

Male Genitalia.—Chermock (1947) and dos Passos (1969) reported no genitalic differences between *L. e. eurydice* and *L. appalachia*. However, we have found that they do differ slightly but significantly. The tegumen of *appalachia* is flattened dorsally, while that of *eurydice* (both subspecies) is rounded. The valves of *appalachia* are shorter and narrower dorso-ventrally, and from the side appear less quadrilateral than those of the *eurydice* subspecies. The male genitalia of *L. e. eurydice* and *L. e. fumosa* are substantially similar, but differ from each other and from *appalachia* in the density and arrangement of setae on the valves. See Table 1 and figs. 13-18.

Female Genitalia.—There seem to be no useful characters here. Some minor differences in the sclerotization of the genital plate were found among all three taxa.

Early Stages.—The larvae of *L. e. eurydice* and *L. appalachia* from central New York differ consistently in the maculation and tubercles of the head capsule. In *L. e. eurydice* the red side stripes become darker below the bases of the horns, extending to the ocelli. The darker part of the stripe consists of small, heavily pigmented, regularly arranged tubercles on a less heavily pigmented ground. In *L. appalachia* the stripe does not extend below the horn, and its lower end contains several large, pale, irregularly placed tubercles which contrast with the red ground (figs. 19, 20).

The early stages of *L. e. fumosa* are completely unknown.

BIOLOGICAL DIFFERENCES

Developmental Rate.—Larvae of *L. e. eurydice* and *L. appalachia* from McLean, N.Y. reared *ex ovo* at 24°C on late summer photoperiods showed developmental differences. *Eurydice* larvae invariably entered diapause in the third or fourth instar. *Appalachia* larvae usually developed without diapause, the entire life cycle requiring about 60 days. *Lethe appalachia* is at least double-brooded in its southern range; apparently it has the potential to breed continuously

Table 1. Differences separating taxa of the *Lethe eurydice* group. Color terminology follows Kornerup and Wanscher (1963) and Ridgway (1912).

character	<i>L. e. eurydice</i>
I. COLOR AND PATTERN	
postmedial line of forewing beneath	projects marginad into teeth at M ₃ , Cu ₂
postmedial line of hindwing beneath	projects marginad into teeth at Cu ₁ , Cu ₂
ground color beneath (fresh males)	red-haired (6C4) = wood brown
ground color beneath (fresh females)	greyish orange (5B5) = clay color
ground color above (fresh males)	sunburn (6D5) = snuff brown
ground color above (fresh females)	clay (5D5) = Saccardo's umber
color between ocelli and subterminal line beneath	darker than ground, tinged with orange
color marginad of postmedial line on hindwing beneath	lighter than ground, yellowish especially in M ₃
contrast between discal and limbal areas on forewing above	moderate to strong
rings around ocelli above	usually strong
ocelli of forewing beneath	variable, subequal, 4 usually largest
ocelli 4, 5 on hindwing above	usually pupilled
apex of forewing	tending to be "low angled" ^d
II. MALE GENITALIA	
valve shape	4-sided in lateral view
valve costa	inner lip larger
valve setae	valve tip heavily armed; many setae on sacculus
tegumen	dorsally rounded
III. LARVAL HEAD CAPSULE	
red stripe	top of horns to ocelli
tubercles in red stripe	red, small, regularly arranged
IV. HABITAT	
	open sedge marshes

^aonly old specimens seen

^bfades in life to Van Dyke brown (6F6) = bistre

^cfades in life to brown (6E5) = brownish olive

*L. e. fumosa**L. appalachia*

as in <i>L. e. eurydice</i>	smoother, only slightly wavy
as in <i>L. e. eurydice</i>	smoother, only slightly wavy
cinnamon (6D6) = Rood's brown	dark blonde (5D4) = buffy brown
greyish orange (5B5) = clay color	topaz (5C5) = avellaneous
cocoa brown (6E6) = cinnamon brown ^a	teak (6F5) = mummy brown ^b
sahara (6C5) = sayal brown ^a	teak (6F5) = mummy brown ^c
as in <i>L. e. eurydice</i>	paler, not orange-tinted
as in <i>L. e. eurydice</i>	lighter than ground, with violet iridescence
slight (♂) to moderate (♀)	moderate to strong
weak to strong	weak to strong
usually 4>3>2>1	usually 1 and 4 largest
frequently unpupilled	frequently unpupilled
"high angled" in ♂♂ only	frequently "high angled" (both sexes)
as in <i>L. e. eurydice</i>	less 4-sided; short; narrower dorso-ventrally
as in <i>L. e. eurydice</i>	inner lip smaller
few setae on valve tip or sacculus	some setae distally and on sacculus
as in <i>L. e. eurydice</i>	dorsally flattened
unknown	horns only
unknown	irregular, large, pale
permanent marshes within prairie region	swamp forest, shrub swamp, forest-edge ecotones

^a"high angled": ratio of length of forewing (base to apex): outer margin < 1.5.

(without diapause) elsewhere as well. So far as is known, *eurydice* is single-brooded everywhere. Larvae of both species turn from yellow green to straw yellow when in diapause, and are capable of changing color in either direction overnight.

A usually small emergence of fresh *eurydice* occurs in some localities in New York, New Jersey and Pennsylvania in the first half of August, four to five weeks after the principal emergence. Males of this late "brood" are frequently of the dark form noted above. It is very unlikely that these butterflies are descendants of those which emerged a month earlier. There may be a genetic basis for the emergence times; a bimodal emergence of *Hyalophora cecropia* (L.) (Saturniidae) was recently reported by Sternburg and Waldbauer (1969), with no genetic data. We do not believe the late *eurydice* are identical with *fumosa*, but the slight possibility exists that they represent another sibling species, unrecognizable in the adult except by its flight period and a statistical color difference. We have not obtained ova from these insects.

Food Plants.—Dos Passos (1969) speculates that a food plant difference between *L. eurydice* and *L. appalachia* is likely. However, our observations suggest that both are sedge-feeders and that neither is species- or group-specific within *Carex*. Female *appalachia* occur near sedges in shrub swamp or forest habitats where observation is difficult. One oviposition was seen in the field, on *Carex lacustris* Willd. (Cyperaceae) at Texas Hollow, Schuyler Co., N.Y. Other sedges commonly associated with this species in New York, all of which were completely acceptable in the laboratory, are *Carex gracillima* Schwein., *C. lanuginosa* Michx., and *Scirpus georgianus* Harp. Wild hosts of *L. e. eurydice* in central New York include *C. lacustris*, *C. stricta* Lam., *C. rostrata* Stokes, and *C. trichocarpa* Michx. All of these sedges were fully acceptable to both species, as are some dozen other species tested (mostly undetermined). We reared both species from egg to adult on *Carex torta* Boott. Neither species would accept any of the following grasses (Gramineae): *Festuca ovina* L.; *Elymus riparius* L.; *Brachyelytrum erectum* (Schreb.) Beauv.; *Muhlenbergia schreberi* Gmel.; *Agrostis alba* L.; *Phalaris arundinacea* L.; *Leersia oryzoides* (L.) Sw.; *Echinochloa crus-galli* (L.) Beauv. (*B. erectum* and *P. arundinacea* are wild food plants of *Lethe portlandia anthedon* A. H. Clark, and *M. schreberi* is acceptable in the laboratory; Shapiro and Cardé, 1970.)

Fig. 21. Distribution of *Lethe eurydice eurydice* (solid circles) and *Lethe eurydice fumosa* (solid triangles).

Adult Behavior.—The most striking difference between *L. e. eurydice* and *L. appalachia*, and the one leading to the discovery of their sympatry, is their differential habitat selection (Shapiro and Cardé, 1970). At the McLean Bogs Reserve, Tompkins Co., New York, these two species are frequently found flying within a few feet of each other, but do not mix. The preference of *L. appalachia* for shaded habitats often results in its association with *L. p. anthedon* upland or *L. p. portlandia* on the Coastal Plain. We have found *L. e. eurydice* only in relatively open sedge marshes or, rarely, in drier meadows; it never enters dense shrub swamp or woods. We have seen *L. eurydice* and *L. p. anthedon* in copula in their usual habitats, once each (3 p.m. and 3:30 p.m., respectively).

DISCUSSION

Although the term "sibling species" has been in the literature for nearly thirty years and the concept is even older, it still seems necessary to point out that excessive dependence on morphological

Fig. 22. Distribution of *Lethe appalachia*.

differences can hinder the recognition of such biologically interesting species as those of the *Lethe eurydice* group. Despite abundant museum evidence of sympatry, these species went unrecognized for twenty years after Chermock (1947) was unable to find genitalic differences between them.

As usually happens with sibling species, recognition on biological grounds has led to discovery of morphological characters hitherto overlooked. These, however, are of a magnitude which would not be considered diagnostic of species in most groups of Lepidoptera. In fact, the genitalia seem to be among the most conservative characters in *Lethe*. Chermock found only very minor genitalic differences between *L. portlandia* and *L. creola* Skinner in the other American species group, and circumstantial evidence suggests that *portlandia* itself is really a pair of (largely allopatric) sibling species. Many Asiatic *Lethe* we have examined also show only slight differences among themselves and from their close American relatives. We consider it likely that what we are calling *Lethe eurydice fumosa* may also prove specifically distinct when its biology

— particularly the early stages — becomes better known. Similar cases recently uncovered in the Lepidoptera include the tortricid moths *Archips argyrosphilus* and *A. mortuanus*, which differ only in sex attractant and in some characters of the last-instar larva (Roelofs and Comeau, 1969), and the papilionid butterflies *Papilio zelicaon* and *P. gothica*, said to differ consistently only in host-plant specificity but to behave as species in genetic tests (Remington, 1968). The *Holomelina aurantiaca* complex (Arctiidae), often thought to consist of two species, actually includes at least ten, exceedingly similar in genitalic morphology, color and pattern, but differing in chromosome number (Cardé, unpublished).

The seemingly inevitable problem with sympatric sibling pairs such as *Lethe eurydice* and *appalachia* is to account evolutionarily for the “elegant” manner in which they coexist. The view that reproductive isolating mechanisms and ecological differences evolve in response to deleterious hybridization and competition in secondary sympatry (Brown and Wilson, 1956) is now very widely accepted. It was recently challenged by Ehrlich and Raven (1969), who proposed that isolating mechanisms usually develop during the genetic differentiation of allopatric populations under different selective regimes. This is in effect a reformulation of the view of most nineteenth- and early twentieth-century evolutionists. Attempting to explain the ecological relationship of a given set of sibling species requires consideration of the following points:

1. The apparent absence of ecological interaction (e.g., competition) or gene flow between presently sympatric populations does not rule out such events in the past, nor for competition, in the future. Furthermore, intermittent large-scale gene flow between normally allopatric populations, associated with fluctuations in population sizes, has probably been an important component of speciation (Brown, 1957). Such fluctuations could also result in episodes of competition between otherwise non-competing species.
2. Biogeographical evidence may offer important clues to episodes of prior sympatry or allopatry in the evolution of species differences (cf. Mengel, 1964).
3. In the absence of evidence for character displacement, it cannot be assumed that biological differences which appear to prevent competition evolved in response to the adverse effects of competition.

The ecological differences among the American species of *Lethe* can be resolved into two parts: that involving the *eurydice* group alone and that concerning the *eurydice* and *portlandia* groups. The

species *eurydice*, *appalachia*, and *portlandia* (in the broad sense, including *anthedon*) divide neatly into "non-competing" pairs: the two sedge feeders (*eurydice* and *appalachia*) differ in habitat; the two woodland species (*appalachia* and *portlandia*) differ in larval food plant. (Similarly, in sexual behavior, *eurydice* and *appalachia* are essentially non-territorial; *portlandia* is strongly territorial.)

Lethe and the genera closely related to it are hypothesized to have originated in southeast Asia (Miller, 1968), a region with many forest-dwelling, grass- (mostly bamboo-) feeding representatives of both the *eurydice* and *portlandia* groups. It seems reasonable that the ancestors of both these groups migrated to North America via the Bering land bridge in the Arcto-Tertiary forest, and were forced southward by the events of the Pleistocene.

With the vast majority of the many Asian *Lethe* feeding on grasses, the evolution of sedge feeding in North America by the ancestor of the *eurydice* group is a tempting hypothesis. Evolution of this trait by proto-*eurydice* independent of competition with proto-*portlandia* or by character displacement in sympatry with it are both possibilities. T. Shirôzu (pers. comm.) informs us that *Lethe marginalis* Motschulsky, which seems to be a member of the *eurydice* group, feeds on non-bamboo grasses and on sedges in Japan, as does *Kirinia epaminondas* Staudinger, formerly placed in *Lethe*. *Ninguta* ("*Lethe*") *schrenckii* Menetries is an obligate sedge feeder.

On the other hand, the speciation of *eurydice* and *appalachia* may have occurred when one of the Pleistocene glaciations isolated some populations of proto-*eurydice* in prairie to the west of populations in the eastern Austral forests. Virtually the entire range of *eurydice* was glaciated, and the distribution is therefore of recent origin. The same can be said for the northern portions of the ranges of *appalachia* and *portlandia*, but the southern portions are characteristic of many organisms which presumably survived the Wisconsin (and earlier glaciations) in the southeast. The lack of recorded relict populations of *eurydice* south of Pennsylvania in the Appalachians, if not due to inadequate collecting, suggests that the species did not have a Wisconsin refugium in the forested Austral Zone of the southeast; its habitat preference and developmental rate support this interpretation. (We do know of species of Hesperiidæ, e.g. *Euphyes bimacula*, with ranges and biologies substantially similar to *L. eurydice*, which have relict populations in the southeast; Shapiro, 1970b.) Its most probable refugium, then, was in glacial Transition Zone somewhere west of the Appalachians. The existence of *L. e. fumosa* also supports

a prior western distribution for *eurydice*, but does not help in dating it. We have no grounds for estimating evolutionary rates in this group; all that can be said now with some confidence is that *eurydice* and *appalachia* were more likely allopatric than sympatric in the Wisconsin (and *appalachia* and *portlandia* more likely sympatric).

The critical evidence concerns character displacement. We have found no morphological character displacement in sympatric *vs.* allopatric populations of *Lethe eurydice* and *L. appalachia*. One of us (Clench) believes he has observed behavioral character displacement between them in Pennsylvania, within the area of general sympatry; in certain localities where only one species occurs, it appears that the habitat selection is not so rigorous as elsewhere. This needs additional study and quantification. Another geographic area also bears close investigation in this connection. Specimens of *eurydice* from southeastern New York (Orange, Rockland, and Westchester Counties) are somewhat anomalous, tending to vary in color and pattern (but not genitalia) toward *appalachia*. We have seen very few specimens from outside this small area which we would hesitate to classify to species by color and pattern. The area is completely surrounded by normal, sympatric, well-differentiated populations of both. It is thus critical to determine the ecology of these anomalous insects. Should *appalachia* be rare or absent, and *eurydice* occupying its niche at least in part, one would have a powerful argument for character displacement as the origin of the habitat difference. (There is a chance of natural hybridization due to man's extensive disturbance of *Lethe* habitats in southeastern New York.)

There are, then, two basic questions: Did the behavioral and food plant differences between the American *eurydice* and *portlandia* groups evolve independently, or largely as a result of competition? Did the sharp habitat selection between *eurydice* and *appalachia* in close sympatry evolve in isolation, or was it intensified by behavioral character displacement?

On the first point, any evolutionary scenario will require much more comparative data on the Asiatic species than is readily available. Only a comprehensive revision, identifying the closest relatives of the American species and comparing their biologies, will allow a convincing argument.

On the second point, field studies in areas of allopatry will be critical. It should be noted that while we suspect the *eurydice* - *appalachia* habitat difference may have evolved to prevent competition

for larval food, it also may function, and have evolved, as a reproductive isolating mechanism. Greater knowledge of mating behavior in this group (Shapiro and Cardé, 1970), as well as more information on the southeastern New York populations, may be able to distinguish the correct hypothesis.

Our current state of knowledge does not allow us to choose between independent evolution and character displacement in accounting for the differences between the American *eurydice* and *portlandia* groups. But character displacement is an attractive hypothesis for the *eurydice* - *appalachia* habitat selection difference.

ACKNOWLEDGMENTS

We wish to thank William D. Field of the U.S. National Museum and Dr. Alexander B. Klots of the American Museum of Natural History for their advice and cooperation; Dr. Michael Emsley for the loan of specimens of *Lethe eurydice fumosa* from the Philadelphia Academy of Natural Sciences; N. D. Riley of the British Museum (Natural History) and Dr. T. Nyholm of the Naturhistoriska Riksmuseum (Stockholm) for aiding in the search for the early types; Dr. Lee D. Miller for information on *Euptychia* spp.; Lucien Harris, Jr. and Frank Rutkowski for field notes and unpublished locality data; Edward L. Rittershausen for specimens from southeastern New York; Dr. Takashi Shirôzu, Kyushu University, Japan, for data on Asiatic *Lethe*; and Dr. Peter A. Hyypio for determining species of sedges. Dr. John G. Franclemont of Cornell University provided invaluable assistance in the taxonomic research. Mrs. Adrienne R. Shapiro assisted in color determinations and in the preparation of the manuscript. Dr. John Burns made several helpful suggestions.

This research received partial support from National Science Foundation Grant GB 7757 (Environmental Biology) and from the Grace Griswold Memorial Illustrations Fund, Department of Entomology and Limnology, Cornell University. To both we extend our thanks.
