High levels of urokinase receptor (uPAR) in tissue and serum of patients with chondrosarcoma correlate with poor prognosis. First, we analyzed the uPAR levels in tissues and plasma of five patients affected by chondrosarcoma. Interestingly, very high levels of uPAR and its soluble forms (SuPAR) were found on tumor cell surfaces and plasma, respectively, of two patients with lung metastases. Therefore, to investigate the role of SuPAR in chondrosarcomas, we generated a primary cell culture from a chondrosarcoma tissue overexpressing uPAR on cell surfaces. We found that chondrosarcoma-like primary culture cells release a large amount of SuPAR in the medium. *In vitro*, SuPAR elicits chondrosarcoma cell migration likely through its uPAR<sub>88–92</sub> sequence, since the DII<sub>88–183</sub> or DIIDIIR<sub>88–284</sub> uPAR domains retain motogen effect whereas DI<sub>1–87</sub> or DIII<sub>184–284</sub> domains, both lacking the uPAR<sub>88–92</sub> sequence, are ineffective. Chondrosarcoma cells cross matrigel in response to SuPAR, and their invasion capability is abrogated by RERF peptide which inhibits uPAR<sub>88–92</sub> signalling. These findings assign a role to uPAR in mobilizing chondrosarcoma cells and suggest that RERF peptide may be regarded as a prototype to generate new therapeutics for the chondrosarcoma treatment.

## 1. Introduction

Chondrosarcomas are a heterogeneous group of neoplasms having in common the production of cartilage matrix by the tumor cells [1]. Chondrosarcoma accounts for approximately 20% of bone sarcomas with a peak incidence in the fifth to seventh decade of life. Because there are no effective treatments for patients with unresectable or metastatic disease, there is a pressing need to develop new targeted approaches [2].

Chondrosarcomas can progress from low grade to high grade, which is reflected by increased cellularity, nuclear atypia, mucomyxoid matrix changes, and increased vascularization [3, 4]. Low-grade chondrosarcomas are locally aggressive but rarely metastasize [5]. By contrast, high-grade

chondrosarcomas often metastasize and are lethal in most patients [3]. The molecular mechanisms involved in the progression to high-grade chondrosarcoma are beginning to be unravelled [1]. Furthermore, processes such as tumor cell attachment, migration, and invasion, which are known to be fundamental in carcinoma, have not been similarly explored in chondrosarcoma.

Proteolytic degradation of the extracellular matrix constituents and modification of cell adhesion properties are required for tumor invasion and metastasis. The urokinase plasminogen activator (uPA) system have an important role in tumorigenesis, extracellular matrix degradation, and migration and invasion of tumor cells [6–10]. Upon binding to uPA, the cell-surface urokinase receptor (uPAR) elicits a variety of cell responses, including cell migration

and invasion [11]. Many malignant cultured cell lines and human neoplasms have been characterized by their increased uPAR expression [12, 13], thus suggesting that the inhibition of uPAR activity could be a promising strategy to prevent cancer invasion and metastasis.

uPAR is a glycosylated glycosylphosphatidylinositol-anchored protein [14] formed by three domains DI, DII, and DIII connected by short linker regions [15]. The Ser<sup>88</sup>-Arg-Ser-Arg-Tyr<sup>92</sup> (uPAR<sub>88-92</sub>) linker region between DI and DII domains is a protease sensitive region which retains chemotactic activity, even in the form of an isolated SRSRY peptide [16, 17]. The flexibility of this region enables its interaction with a wide variety of ligands [18]. uPAR engagement with uPA favours the exposure of the uPAR<sub>88-92</sub> sequence which, in turn, promotes cytoskeletal rearrangements and directional cell migration by binding to the G-protein-coupled formyl-peptide receptors (FPRs) [16, 17, 19]. By a drug-design approach based on the conformational analysis of the uPAR<sub>88-92</sub> sequence, we have recently developed a family of peptides which revealed to be uPAR antagonists in virtue of their ability to prevent uPAR/FPR interaction. Among these, we found that RERF peptide potently inhibits *in vitro* and *in vivo* cell migration and invasion of highly invasive human fibrosarcoma HT1080 cells [20].

In tumor tissues, shedding and/or enzymatic cleavage of uPAR generate truncated forms of uPAR (SuPAR), which are secreted in the extracellular milieu [21–24]. Soluble forms of uPAR have been identified, *in vitro*, in conditioned cell culture medium and, *in vivo*, in serum and urine of patients affected by several type of solid tumors, including sarcomas and chondrosarcomas, and have been significantly associated to a bad prognosis [21–25]. In particular, codetection of a high expression level of uPA, uPAR, and PAI-1 in tumour tissue and of SuPAR in serum of patients affected by soft-tissue sarcoma has been reported to significantly correlate with a shortened overall survival [25]. To gain some insight on the role of soluble forms of uPAR in determining an aggressive phenotype of chondrosarcoma, we have analysed the effects of SuPAR on a primary cell culture derived from an uPAR expressing chondrosarcoma case.

## 2. Materials and Methods

**2.1. Patients, Tissue and Plasma Collection.** Six patients with chondrosarcoma were studied. Surgical removed tumors were routinely processed for the histopathological diagnosis performed according to the WHO classification [26]. A representative sample from each tumor excision was immediately frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$  until used for immunocytochemistry. A sample from the tumor excision of patient no. 6 was immediately processed for preparation of a primary cell culture. Plasma samples were obtained just before surgery and were stored at  $-80^{\circ}\text{C}$  until assayed.

**2.2. Immunohistochemistry.** Frozen sections, corresponding to the largest cross-sectional area of the tumor, were cut, placed on glass slides and subjected to immunostaining

with the streptavidin-biotin-peroxidase method, as previously described [27]. Briefly, sections were fixed with 2.5% formaldehyde in phosphate buffered saline (PBS) and incubated overnight at  $4^{\circ}\text{C}$  with diluents (negative control), or  $2\ \mu\text{g}/\text{mL}$  R4 anti-uPAR monoclonal antibody (mAb), kindly provided by G. Hoyer-Hansen (Finsen Institute, Copenhagen, Denmark). After several washes in PBS, 1:200 diluted biotinylated goat anti-mouse immunoglobulins were applied to sections at  $23^{\circ}\text{C}$  for 60 min. Thereafter, sections were incubated with streptavidin-biotinylated horseradish peroxidase complex for additional 30 min and the peroxidase-dependent staining was developed by diaminobenzidine. Slides were counterstained with Mayer's haematoxylin.

**2.3. Primary Cell Culture.** A representative sample from the tumor excision ( $\sim 1\ \text{cm} \times 1\ \text{cm}$ ) from patient no. 6 was immediately minced by scalpel under sterile conditions and incubated with  $1.0\ \text{mg}/\text{mL}$  collagenase XI (Sigma) for 3 h at  $37^{\circ}\text{C}$  under gentle agitation, as previously described [28]. Cells, recovered by centrifugation at 1500 rpm, were cultured in 6-well multidish plates in Dulbecco Modified Essential Medium (DMEM) with the addition of 10% foetal bovine serum (FBS), 100 IU/mL penicillin and  $50\ \mu\text{g}/\text{mL}$  streptomycin. Isolated cell clusters were further amplified in growth medium until an adherent, homogeneous cell population was obtained.

**2.4. Cell Lines and Conditioned Media.** Mouse fibroblast LB6, LB6 cells stably transfected with cDNA encoding human SuPAR (LB6/hSuPAR) [12], and human fibrosarcoma HT1080 cell line were grown in DMEM supplemented with 10%FBS, 100 IU/mL penicillin and  $50\ \mu\text{g}/\text{mL}$  streptomycin. To prepare conditioned media, LB6, LB6/hSuPAR, or chondrosarcoma cells were grown to 80% confluence on  $10\ \text{cm}$   $\emptyset$  plates. Growth medium was removed and cells, after extensive washing with PBS, were incubated in serum-free medium. After 18 h, the medium was recovered, cleared by centrifugation, and analysed for the SuPAR content applying a commercially available enzyme-linked immunosorbent assay kit (ELISA) purchased by R&D System, as previously described [12]. Antigen concentrations were expressed as ng analyte per  $\mu\text{g}$  proteins.

**2.5. Immunofluorescence.** Chondrosarcoma cells, plated on glass slides (30%–40% confluence), were fixed and permeabilized with 2.5% formaldehyde-0.2% Triton X-100 in PBS for 10 min at  $4^{\circ}\text{C}$ , then incubated overnight at  $4^{\circ}\text{C}$  with  $5\ \mu\text{g}/\text{mL}$  anti-vimentin (Dako), anti-cytokeratin (Zymed Laboratories Inc.) or  $2\ \mu\text{g}/\text{mL}$  R4 anti-uPAR mAbs. A subset of experiments was performed on fixed with 2.5% formaldehyde, nonpermeabilized cells. Immunofluorescence was carried out by incubating slides with 1:100 diluted Alexa 488-conjugated F(ab')<sub>2</sub> fragment of rabbit anti-mouse IgG (Molecular Probes) for 1h at  $22^{\circ}\text{C}$ . After nuclear staining with 4'-diamidino-2-phenylindole dye (DAPI), cells were analysed by a fluorescence inverted microscope connected to a videocamera (Carl Zeiss), as described [20].

**2.6. Flow Cytometry.** Cells were detached using 200 mg/L EDTA, 500 mg/L trypsin (Cambrex). Nonspecific binding sites, possibly due to any Fc receptor, were blocked by normal rat serum. Cells ( $0.5 \times 10^6$  cells/sample) were incubated with 1:40 normal rat serum added to PBS (CTL) or 2  $\mu$ g/mL R4 anti-uPAR mAb for 30 min at 4°C. After extensive washing with PBS, cells were incubated with Alexa 488-conjugated F(ab')<sub>2</sub> fragment of rabbit anti-mouse IgG and finally resuspended in 0.6 mL PBS. Samples were analysed by flow cytometry using a FACS Vantage cell sorter (Becton & Dickinson). All data were analysed using CellQuest software.

**2.7. Immunoprecipitation.** Conditioned medium of LB6, LB6/hSuPAR or chondrosarcoma cells (500  $\mu$ L/sample) were precleared with 10  $\mu$ L Protein G-Sepharose (Ge-Healthcare) for 1 hr at 4°C, immunoprecipitated with 100  $\mu$ L rabbit 399 anti-uPAR conjugated to sepharose beads (0.5 mg IgG per mL of beads) diluted 1:1 for 18 h at 4°C. Beads were washed and then boiled in SDS-PAGE sample buffer. Proteins were separated by a 12.5% SDS-PAGE followed by Western blotting with 2  $\mu$ g/mL R4 anti-uPAR mAb.

**2.8. Cell Migration and Invasion Assays.** Cell migration and invasion assays were performed using Boyden chambers and 8  $\mu$ m pore size polyvinyl-pyrrolidone-free polycarbonate filters (Nucleopore) as previously described [20, 27]. The ability of primary cell culture to migrate or to cross matrigel was assessed between the VI and the IX passage. For cell invasion assays, filters were coated with 50  $\mu$ g/mL matrigel, a reconstituted basement membrane (BD Biosciences). Cells were preincubated with DMEM, 2  $\mu$ g/mL normal rabbit serum (NRS), blocking 399 anti-uPAR Ab [29, 30], or anti-uPAR<sub>84-95</sub> Ab which specifically recognizes the uPAR chemotactic Ser<sup>88</sup>-Arg-Ser-Arg-Tyr<sup>92</sup> sequence [31] for 1 h at 37°C, prior to seeding in the upper chamber at  $3 \times 10^4$  cells/well. In a subset of experiments, cells were exposed to 10 nM RERF or ERFR peptides (Primm) which we have previously reported to inhibit uPAR<sub>88-92</sub>-dependent signalling without affecting cell proliferation [20]. The indicated chemoattractants were placed in the bottom well. Recombinant uPAR domains (Calbiochem) were employed at 10 nM concentration. Cells were allowed to migrate or invade matrigel at 37°C in humidified air with 5% CO<sub>2</sub> for 4 h or 18 h, respectively. At the end of the assay, cells in the upper chamber and on the upper filter surface were removed whereas cells on the lower filter surface were fixed with ethanol and stained with haematoxylin. The number of migrating or invading cells was determined by counting cells in 10 random fields/filter at 200x magnification. HT1080 cells were employed as an internal control. Data were calculated as a percentage of migrated or invading cells in the absence of chemoattractant, considered as 100%.

**2.9. Statistical Analysis.** The data were analysed for significance using Student's *t*-test. Differences were considered statistically significant at a level of  $P < .05$ .

### 3. Results and Discussion

**3.1. uPAR Expression and SuPAR Release in Chondrosarcomas.** The age of the patients at diagnosis ranged from 34 to 72 years. Surgical removed tumors were routinely processed for the histopathological diagnosis performed according to the WHO classification [26]. Table 1 reports the pathological findings of 6 primary chondrosarcomas: 5 were primary bone lesions including femur (3) and sternum (2) and 1 was extraskelatal lesion involving pelvis (Table 1). The main *clinical* features at diagnosis are summarized in Table 2. To investigate the molecular mechanisms underlying the activity of uPAR in chondrosarcoma, we first analysed the uPAR expression on chondrosarcoma tissues by immunohistochemistry, using R4 anti-uPAR mAb. The intensity of uPAR staining of tumor cells was graded as faint (grading 1), moderate (grading 2), or intense (grading 3) (Table 2). Except for the benign/low grade lesion which did not show any reactivity to R4 anti-uPAR mAb, all tumors, although at a different extent, exhibit a heterogeneous pattern of staining, mainly localized on tumor plasma cell membranes (Figure 1). Several tumor cells have been reported to shed soluble forms of uPAR [21–25]. Therefore, we performed a quantitative analysis of the of SuPAR content in the plasma of patients using a commercially Elisa Kit. As shown in Table 2, an appreciable amount of SuPAR was detected in all the plasma tested. Interestingly, patients with lung metastases (#3 and #4) exhibited higher levels of SuPAR (Table 2). These data encouraged us to further analyze the role of SuPAR in chondrosarcoma invasiveness.

The patient no. 6 underwent a surgery for an extensive sternal mass (Table 1). Preoperative workup showed bilateral nodules suspicious for pulmonary metastases. Following multidisciplinary consultation, it was decided to submit the patient to complete sternal resection and pulmonary metastasectomy. For the reconstruction of the anterior chest wall defect, three cadaveric cryopreserved ribs were used. The resected tumor measured 18  $\times$  15  $\times$  8 cm. Histology of the primary tumor yielded a diagnosis of grade 2, focally grade 3 chondrosarcoma, characterized by frank hypercellularity, with elongated hyperchromatic and sometimes binucleated nuclei (Figure 2(a)). The pulmonary lesions were confirmed to be pulmonary metastases from chondrosarcoma. The patient was followed up to 8 months after primary surgery, when multiple extraskelatal metastases were detected. At this point, he received chemotherapy, but died soon after due to chemotherapy-related complications.

**3.2. Isolation and Characterization of Chondrosarcoma Cells.** As described in the methods, a representative sample from the tumor excision was minced and subjected to enzymatic digestion; cell suspension was recovered and cultured in multidish plates until to the third passage (Figure 2(b)). Subcloning of the isolated cell clusters (Figure 2(c)) and seven further passages resulted in an adherent, homogeneous cell population mainly characterized by small chondrosarcoma-like cells (Figure 2(d)), resembling, in shape and size, those observed on haematoxylin/eosin stained section (Figures 3(a) and 3(b)). Immunocytochemical analysis of cells grown on

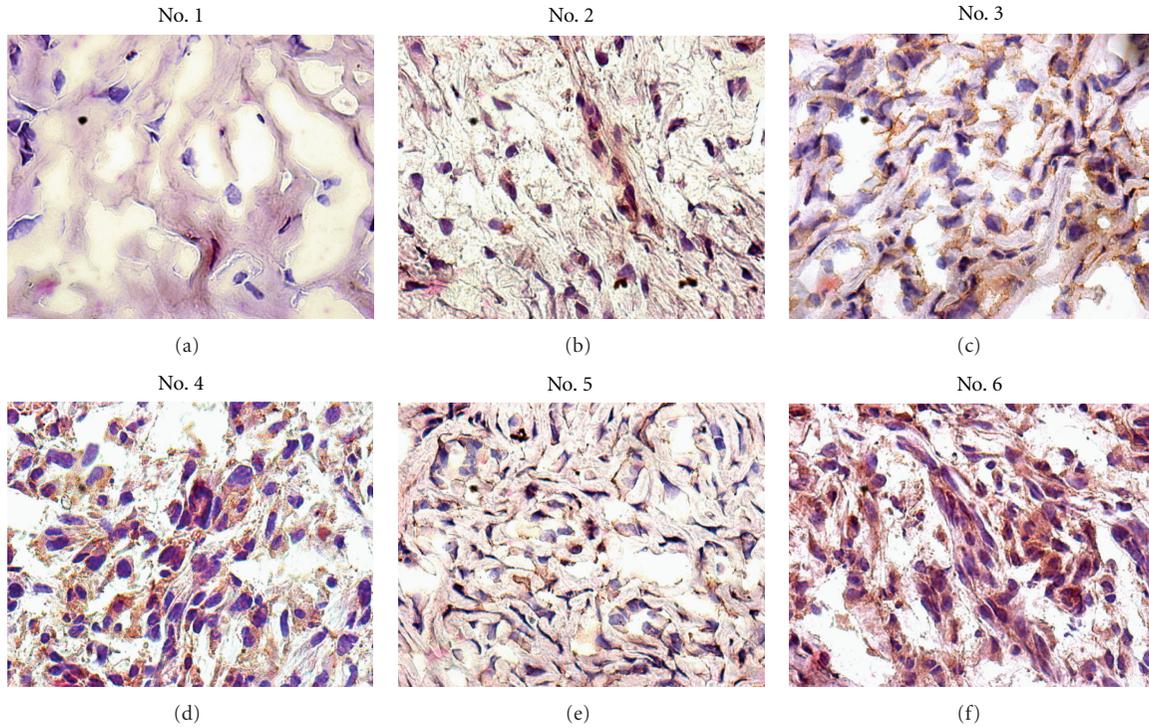

FIGURE 1: uPAR protein is expressed in chondrosarcoma tissues. Immunohistochemistry was performed on frozen sections with the streptavidin-biotin-peroxidase method using 2  $\mu\text{g}/\text{mL}$  R4 anti-uPAR mAb. Sections were counterstained with haematoxylin. Original magnifications:  $\times 400$ .

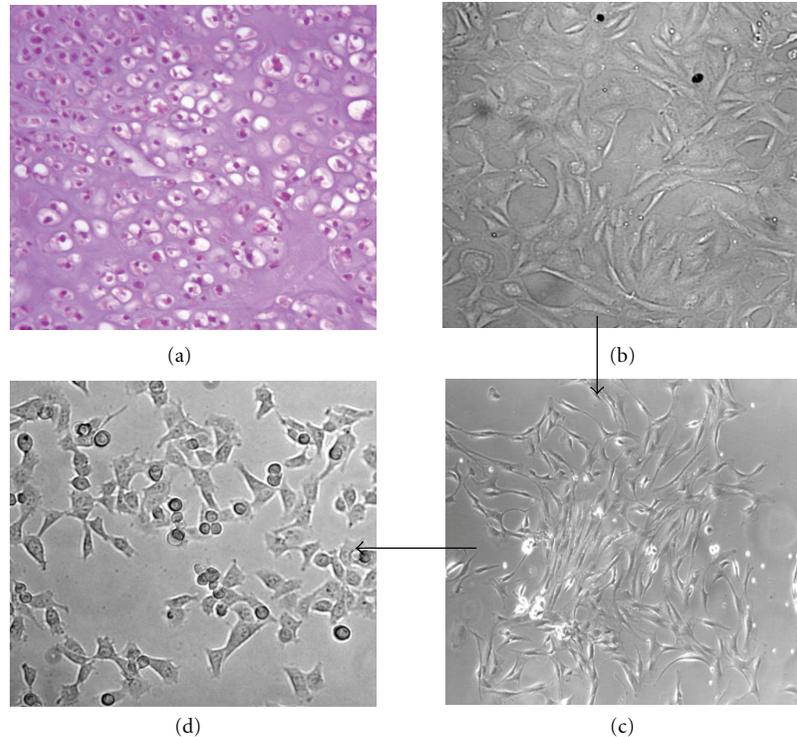

FIGURE 2: Generation of a primary cell culture from a chondrosarcoma tissue. (a) Haematoxylin/eosin stained section of a human primary grade 2, focally grade 3 chondrosarcoma of sternum (patient no. 6). (b–d) A representative sample from the tumor excision was subjected to enzymatic digestion. The isolated cells, recovered by centrifugation at 1500 rpm, were cultured in DMEM 10% FBS until to the third passage. At this passage, cell population showed an evident cellular heterogeneity (b). Subcloning of the isolated cell clusters (c) and amplification for six further passages resulted in an adherent, homogeneous cell population characterized by small, chondrosarcoma-like cells (d). Images were captured by an inverted microscope connected to a video camera. Original magnification: x200 (a and c), x400 (b and d).

glass slides revealed the total absence of epithelial (cytokeratin) cell marker whereas a strong staining was observed in the 95% of cells exposed to anti-vimentin mAb (Figures 3(c) and 3(d)).

**3.3. Identification of Membrane-Anchored uPAR on Chondrosarcoma Cells.** First, uPAR expression was analysed in chondrosarcoma cells by immunofluorescence and cytofluorimetry. Accordingly to immunohistochemical findings (Figure 1), chondrosarcoma cells express high levels of uPAR mainly localized on plasma cell membranes (Figure 4(a)). In permeabilized cells, a discrete, intracytoplasmic amount of uPAR was also found, thus indicating that chondrosarcoma cells effectively synthesize uPAR (Figure 4(b)). Interestingly, flow cytometry revealed that chondrosarcoma cells express higher levels of uPAR as compared to HT1080 cells (25 and 23.9 mean fluorescence intensity, resp., in the 98% of total cells) (Figure 4(c)).

**3.4. Chondrosarcoma Cells Shed Soluble Forms of uPAR into the Medium.** We investigated whether soluble forms of uPAR are produced and released by chondrosarcoma cells in the culture medium. To this purpose, we took advantage by employing, as a negative and a positive controls, conditioned medium of uPAR lacking wild-type LB6 and transfected

LB6/hSuPAR cells, respectively. We measured by Elisa the amount of SuPAR antigen released in the conditioned medium of LB6, LB6/hSuPAR and chondrosarcoma cells. As expected, LB6/hSuPAR cells released a large amount of SuPAR as compared to the wild-type LB6 cells [12]. In keeping with the expression of high levels of uPAR on plasma cell membranes, chondrosarcoma cells released a very large amount of SuPAR in the medium as compared to that produced by LB6/hSuPAR cells (10.3 ng/ $\mu$ g and 5.2 ng/ $\mu$ g of proteins, resp.) (Figure 4(d)). To ascertain the occurrence of cleaved forms of SuPAR in the conditioned medium of chondrosarcoma cells, serum-free medium was subjected to immunoprecipitation with rabbit 399 anti-uPAR Ab which recognizes all soluble forms of SuPAR, followed by Western blotting with R4 anti-uPAR mAb which recognizes full-length DIIDIII and DIII cleaved forms of uPAR [24]. LB6 and LB6/hSuPAR conditioned media were employed as negative and positive control, respectively. According to Sidenius et al. [24], we found in the conditioned medium of both chondrosarcoma and LB6/hSuPAR, but not LB6 cells, a fragment with an approximate 45 kDa molecular weight, comigrating with the purified full-length SuPAR (Figure 4(d)). R4 anti-uPAR mAb specifically recognized in the conditioned medium of LB6/hSuPAR but not LB6 cells an additional fragment having molecular weight of about 35 kDa, compatible with the cleaved DIIDIII fragment

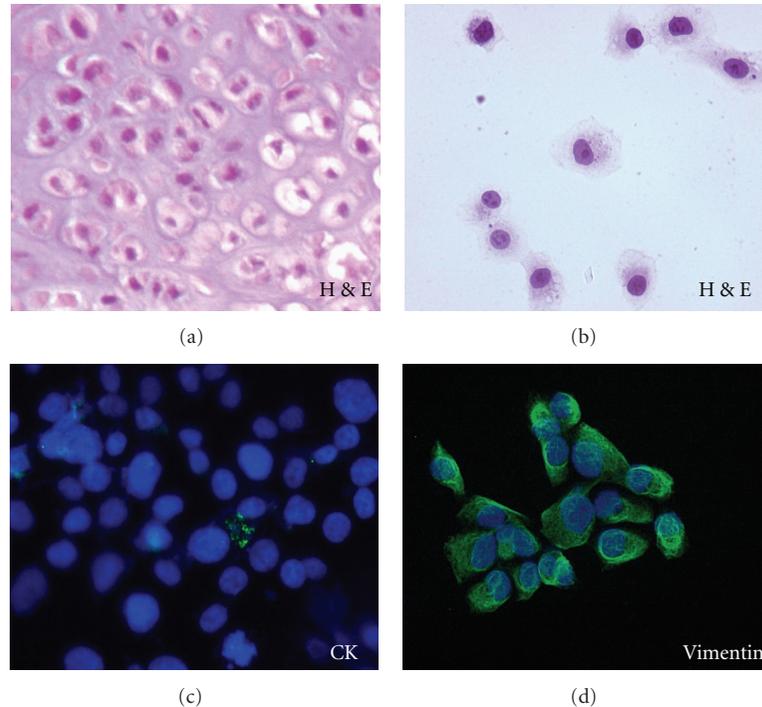

FIGURE 3: Immunophenotyping of chondrosarcoma cells. (a, b) haematoxylin/eosin stained chondrosarcoma cells resemble in shape and size those of chondrosarcoma tissue section. (c, d) chondrosarcoma cells grown on glass slides to semiconfluence were stained with anti-cytokeratin (CK) or anti-vimentin mAbs and with Alexa 488-conjugated F(ab')<sub>2</sub> fragment of rabbit anti-mouse IgG (green). Nuclei were stained blue with DAPI. Original magnification: x400.

of SuPAR. As shown in Figure 4(e), a fragment with an approximate 35 kDa molecular weight, comigrating with the DIIDIII fragment of SuPAR was found in the conditioned medium of chondrosarcoma cells. Although we can not assess whether other fragments of SuPAR do exist in the chondrosarcoma cell medium, this findings indicate that at least two fragments, both containing the chemotactic sequence of uPAR, may influence cell behaviour.

**3.5. SuPAR Promotes In Vitro Migration of Human Chondrosarcoma Cells.** Soluble forms of uPAR, including the DIIDIII fragment, have been shown to strongly chemoattract a variety of cell types [16, 17, 20, 32]. We investigated whether chondrosarcoma cells specifically respond to soluble forms of uPAR. In these experiments, we took advantage by employing the uPAR expressing human fibrosarcoma HT1080 cells as an internal control. Cell migration assays were carried in Boyden chambers using conditioned media of wild-type LB6 or LB6/hSuPAR cells. We found that similarly to HT1080, chondrosarcoma cells exhibited a strong ability to migrate toward the LB6/hSuPAR conditioned medium, reaching  $363 \pm 26\%$  of the random cell migration (Table 3). On the contrary, wild-type LB6 conditioned medium did not exert any effect, indicating that chondrosarcoma cells specifically respond to SuPAR. Interestingly, 10 nM recombinant DII<sub>88-183</sub> or DIIDIII<sub>88-284</sub> uPAR domains as well as full length DIDIIDIII<sub>1-284</sub> triggered an appreciable cell migration ( $215\% \pm 5$ ,  $221\% \pm 13$ , and  $240\% \pm 10$ ,

resp.) whereas recombinant DI<sub>1-87</sub> or DIII<sub>184-284</sub> uPAR domains, both lacking the uPAR<sub>88-92</sub> sequence, were ineffective at 10nM (Table 3). These findings suggest that SuPAR is able to mobilize chondrosarcoma cells through its uPAR<sub>88-92</sub> sequence. To further investigate the role of the uPAR<sub>88-92</sub> sequence in mobilizing chondrosarcoma cells, a subset of experiments was performed in the presence of 399 anti-uPAR Ab or a polyclonal antibody which specifically recognized the uPAR<sub>84-95</sub> sequence [30, 31]. As shown in Table 3, in the presence of 399 anti-uPAR or anti- uPAR<sub>84-95</sub> Abs, both HT1080 and chondrosarcoma cells failed to respond to the conditioned medium of LB6/hSuPAR cells or to recombinant uPAR domains containing the chemotactic sequence. The inhibition was specific, as the presence of nonimmune serum did not abrogate cell motility. All together, these results clearly indicate that soluble forms of uPAR containing the uPAR<sub>88-92</sub> sequence are able to mobilize chondrosarcoma cells.

**3.6. uPAR Promotes In Vitro Invasion of Human Chondrosarcoma Cells.** Cell migration is a prerequisite for cancer invasion. Therefore, we performed *in vitro* matrigel invasion assays [33] to quantify, the relative invasive potential of chondrosarcoma cells. In these assays, 10% FBS was employed as a source of chemoattractants and the basal cell invasion, assessed in the absence of any chemoattractant, was taken as 100%. We employed the uPAR expressing human fibrosarcoma HT1080 cells as an internal control. According

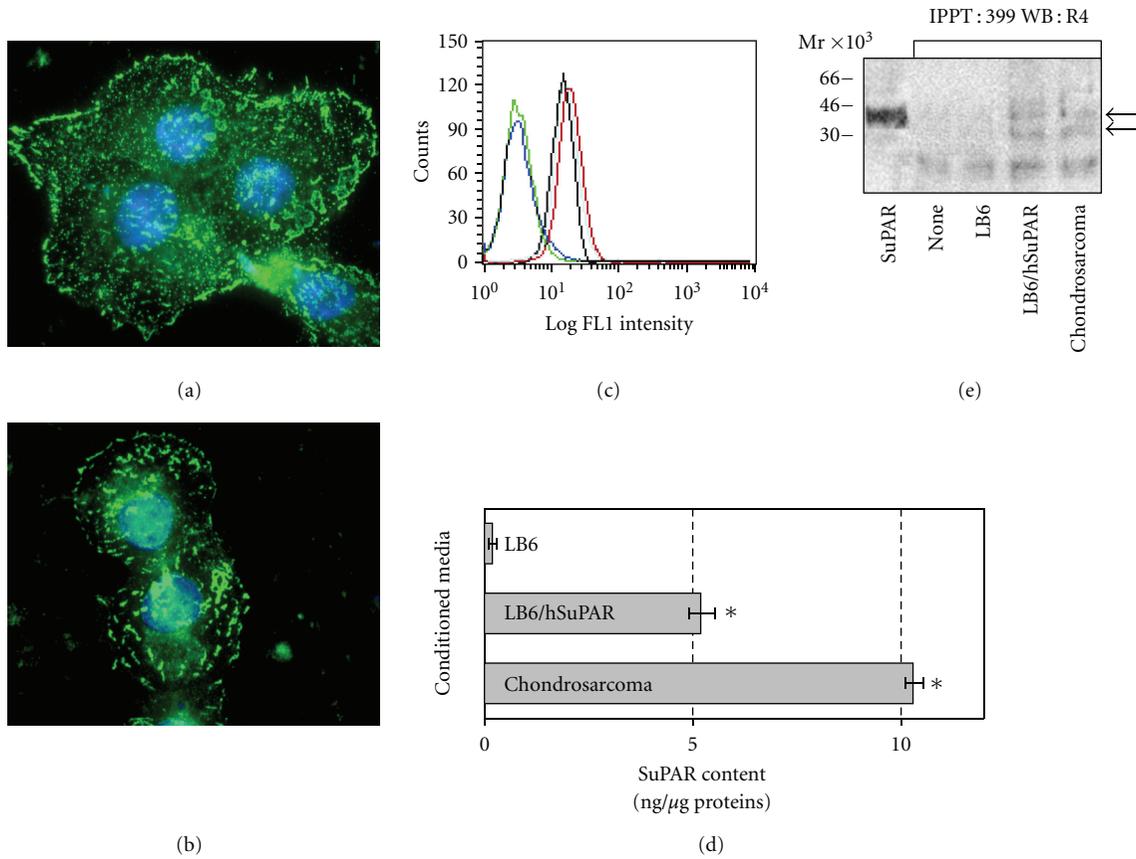

FIGURE 4: Chondrosarcoma cells express uPAR and release its soluble forms in the medium. Chondrosarcoma cells were fixed with 2.5% formaldehyde (a) or fixed with 2.5% formaldehyde and permeabilized with 0.2% Triton X-100 (b) for 10 min at 4°C, incubated overnight at 4°C with 2 μg/mL R4 anti-uPAR mAb and then exposed to Alexa 488-conjugated F(ab')<sub>2</sub> fragment of rabbit anti-mouse IgG (green). Nuclei were stained blue with DAPI. Original magnification: x1000. (c) Flow cytometry analysis of uPAR on chondrosarcoma and HT1080 cell surfaces. HT1080 and chondrosarcoma cells were harvested, incubated with normal rat serum added to PBS (green and blue curves, resp.) or 2 μg/mL R4 anti-uPAR mAb (black and red curves, resp.), stained with Alexa 488-conjugated F(ab')<sub>2</sub> rabbit anti-mouse IgG and analyzed by FACS. (d) Chondrosarcoma cells release soluble forms of uPAR in the medium. LB6, LB6/hSuPAR, or chondrosarcoma cells were grown to 80% confluence. Growth medium was removed, cells were extensively washed with PBS and then incubated in serum-free medium for 18 h. The medium was recovered, cleared by centrifugation, and analysed for SuPAR content by ELISA. Antigen concentrations were expressed as ng SuPAR per μg proteins. Columns, mean of two independent experiments; bars, ±SD, \**P* < .001 against the control (conditioned medium of LB6 wild-type cells). (e) 500 μL conditioned media of LB6, LB6/hSuPAR or chondrosarcoma cells were immunoprecipitated with 100 μL rabbit 399 anti-uPAR Ab conjugated to sepharose beads for 18 h at 4°C. The eluted proteins were separated by a 12.5% SDS-PAGE and analysed by Western blot using R4 anti-uPAR mAb. 1 μg purified SuPAR or 10 μL 399 anti-uPAR conjugated to sepharose beads (none) were loaded as a control. Arrows indicate the full-length SuPAR and the DIIDIII fragment of SuPAR.

to their previously reported highly invasive capability [20], HT1080 cells exhibited a strong ability to cross matrigel ( $597 \pm 30\%$  of the basal level). Chondrosarcoma cells exhibited a very high ability to invade matrigel as compared to HT1080 cells, reaching  $721 \pm 91\%$  of the basal level (Figure 5(a)). Interestingly, cell exposure to blocking 399 anti-uPAR or anti-uPAR<sub>84-95</sub> Abs strongly reduced cell invasion ability of both HT1080 and chondrosarcoma cells. To further elucidate the role of uPAR in promoting cell invasiveness, a subset of experiments were performed in the presence of RERF peptide which we have previously reported to specifically inhibit uPAR<sub>88-92</sub>-dependent signalling without affecting cell proliferation [20]. We found that cell exposure to 10 nM

RERF strongly reduced the ability of both HT1080 and chondrosarcoma cells to cross matrigel whereas the ERERF control peptide failed to exert any inhibitory effect. These findings strongly support the role of uPAR in promoting cell invasion. To assess whether also soluble forms of uPAR may be involved in cell invasion capability, experiments were performed using conditioned medium of LB6/hSuPAR cells as a source of intact and DIIDIII uPAR fragment, or conditioned medium of LB6 cells as a negative control. We found that both HT1080 and chondrosarcoma cells respond to LB6/hSuPAR conditioned medium, the effect being prevented by 399 anti-uPAR as well as by anti-uPAR<sub>84-95</sub> Abs (Figure 5(b)).

TABLE 3: SuPAR-dependent migration of chondrosarcoma cells.

Supplements	Effector	Cell migration (%)	
		HT1080 cells	Chondrosarcoma cells
DMEM	DMEM	100	100
	CM LB6	110 ± 5	112 ± 8

Cells incubated with diluents (DMEM) or 5 µg/mL the indicated antibody for 1 h at 37°C were seeded in Boyden chambers for cell migration assays as described in the Material and Method section, in the presence or absence of the indicated effectors. Conditioned medium (CM) of LB6/hSuPAR cells was used as a source of SuPAR. For quantitative analysis of cell migration, the basal value (DMEM) was taken as 100% and all values were reported relative to that. Data are the means ± SD of two independent experiments, performed in duplicate. Statistical significance with *P* values was calculated against the control DMEM.

\*Statistical significance with *P* < .05. \*\*Statistical significance with *P* < .001.

#### 4. Conclusions

uPAR plays a key role in pathological processes sustained by an altered cell migration [11]. High levels of uPAR and SuPAR in tissue and serum of patients with sarcoma, including chondrosarcoma, correlate with a poor prognosis [25]. We generated a primary cell culture derived from a uPAR overexpressing chondrosarcoma tissue. We found that chondrosarcoma-like primary culture cells express high level of uPAR on plasma cell membranes and release a large amount of intact SuPAR as well as DIIDIII uPAR fragment in the medium. Our findings revealed that, *in vitro*, SuPAR: (i) elicits chondrosarcoma cell migration through its uPAR<sub>88-92</sub> sequence and (ii) promotes chondrosarcoma cell invasion, the effect being reduced to the basal level by anti-uPAR blocking antibody. Taken together, our findings raises the possibility that soluble uPAR released by chondrosarcoma cells in the extracellular matrix may generate a chemotactic gradient which, in turn, stimulates tumor cells to migrate and invade

the surrounding tissues. There are few studies investigating the clinical impact of uPAR expression and its correlation to prognosis in chondrosarcoma [25]. Our findings suggest that the determination of plasmatic SuPAR content in patients with chondrosarcoma could be helpful for a prognostic evaluation. Furthermore, there are currently no universally effective therapies for unresectable or metastasized chondrosarcomas [1]. It can be envisaged that the inhibition of uPAR activity could be a promising strategy to prevent chondrosarcoma invasion and metastasis. We found that, *in vitro*, the chondrosarcoma cell invasion ability may be abrogated by RERF peptide which specifically inhibits the uPAR<sub>88-92</sub>-dependent signalling by preventing its interaction with the G-protein coupled formyl-peptide receptor [20]. In conclusion, our data indicate that uPAR is required for the cell migration and invasion machinery of chondrosarcoma cells and suggest that RERF peptide may be regarded as a prototype to generate new therapeutic agents for the treatment of unresectable or metastasized chondrosarcoma.

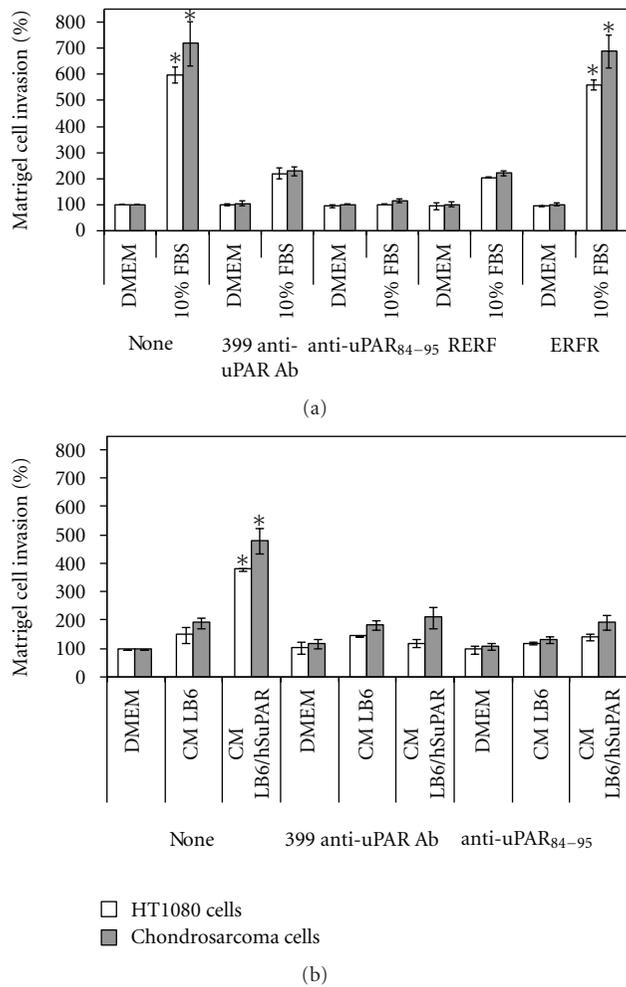

FIGURE 5: uPAR-dependent matrigel invasion of chondrosarcoma. Cells human fibrosarcoma HT1080 and chondrosarcoma cells were subjected to cell invasion assays. Cells were preincubated with DMEM (none), 2  $\mu$ g/mL indicated anti-uPAR antibodies, 10 nM RERF peptide or 10 nM ERFR peptide, plated in Boyden chambers and allowed to cross matrigel-coated filters for 18 h at 37°C in humidified air with 5% CO<sub>2</sub>. 10% FBS (a), LB6, or LB6/hSuPAR conditioned media (b) were employed as chemoattractants. In all cases, data are reported as a percentage of invading cells in the absence of chemoattractant, considered as 100% (DMEM), and represent the average of two experiments, performed in duplicate. Columns, mean of two independent experiments; bars,  $\pm$ SD, \* $P$  < .001 against the control (DMEM).
