In this paper a detailed derivation of the general transport equations for two-phase systems using a method based on nonlocal volume averaging is presented. The local volume averaging equations are commonly applied in nuclear reactor system for optimal design and safe operation. Unfortunately, these equations are limited to length-scale restriction and according with the theory of the averaging volume method, these fail in transition of the flow patterns and boundaries between two-phase flow and solid, which produce rapid changes in the physical properties and void fraction. The non-local volume averaging equations derived in this work contain new terms related with non-local transport effects due to accumulation, convection diffusion and transport properties for two-phase flow; for instance, they can be applied in the boundary between a two-phase flow and a solid phase, or in the boundary of the transition region of two-phase flows where the local volume averaging equations fail.

1. Introduction

The technique of local volume averaging of microscopic conservation equations of motion and transport has received numerous research and analysis [1–16], in order to obtain macroscopic balance equations applicable to multiphase systems. The approximation of local volume-averaged conservation equation of two-phase flow is valid when the following length-scale restriction is fulfilled [10]:

$$\ell \ll \Im, \quad (1)$$

where $\ell$ is the characteristic length of the dispersed phases, and $\Im$ is the characteristic length of the global system:

$$\frac{1}{\Im} = \frac{\text{MAX}_{x \in V_k} | \nabla \langle \psi_k \rangle(x, t) |}{\text{MAX}_{x \in V_k} \langle \psi_k \rangle(x, t)}. \quad (2)$$

In this equation $\psi_k$ is the intrinsic property and $\langle \psi_k \rangle$ represents the average and $V_k$ is the volume of k-phase. Then, $\ell$ is associated where $\psi_k$ varies significantly, and $\Im$ with the changes in $\langle \psi_k \rangle$.

The imposition of the guarantees good behavior of the averaged variables. However, the most well-known multiphase flow systems where the length-scale restriction given by (1) are not true: geological systems [17], fractionation of hydrocarbons [18], transport of contaminants [19–21], elimination of contamination in aqueous streams [22], cuttings transport [23–25], and concentration of pharmaceutics [26], among others that include extraction and separation processes [27]. Specifically, in nuclear systems of BWR type and other industrial applications that involve multiphase flow, the length-scale restriction is no longer satisfied following the transition to churn or slug flow regimes, where the number of bubbles is highly decreased and their size is increased to the length of the magnitude order of the averaging volume, including the whole system, that is, pipe diameter.

The local volume averaging of the conservation equations (mass, momentum, and energy) involves averaging the product of a volume-averaged variable $\langle \psi_k \rangle$ (in this paper it was sought to use the nomenclature defined by Lahey and Drew [10]), with the unaveraged variable $\psi_k$, that is,
\langle \phi_k (\psi_k) \rangle \) (here \( \psi_k \) and \( \phi_k \) are intensive properties associated with the k phase). The conditions necessary to bring a volume-averaged variable outside the volume integral are the imposing of the length-scale restriction given by (1), that is, \( \langle \phi_k (\psi_k) \rangle = \langle \phi_k \rangle \langle \psi_k \rangle \), with the idea of obtaining manipulated variables associated with the processes of two-phase flow.

Another common case of the local volume averaging of the conservation equations is the average product of two unaveraged variables, that is, \( \langle \phi_k \psi_k \rangle \). The traditional representation is \( \langle \phi_k \psi_k \rangle = \alpha_k \langle \phi_k \rangle \langle \psi_k \rangle + \langle \tilde{\phi}_k \tilde{\psi}_k \rangle \), where \( \tilde{\phi}_k \) and \( \tilde{\psi}_k \) represent the spatial deviations around averaged values of the local variables and are defined by the decomposition \( \phi_k = \langle \phi_k \rangle + \tilde{\phi}_k \) and \( \psi_k = \langle \psi_k \rangle + \tilde{\psi}_k \) [5]. The removal of averaged quantities from the volume integrals is consistent with the length-scale restriction given by (1). The mathematical consequence of this type of inequality can be expressed as \( \langle \tilde{\phi}_k \rangle = 0 \) and \( \langle \tilde{\psi}_k \rangle = 0 \).

However, for more realistic problems, this length-scale restriction given by (1) is not true. In general, this length-scale restriction is not valid within the boundary region (e.g., transition region in two-phase flows) due to significant spatial variations of the two-phase flow structure. The classical length-scale restriction which is implicit in the average transport equations are not satisfied.

In this paper a detailed derivation of the general transport equations for two-phase systems using a method based on nonlocal volume averaging, that is, without length-scale restriction is presented. The nonlocal volume averaging equations derived in this work contain new terms related to nonlocal transport effects due to accumulation, convection diffusion, and transport properties for two-phase flow heat transfer. The nonlocal terms were evaluated considering that these are a function of the local terms, which yield new coefficients or closure relationships.

### 2. Preliminaries

The two-phase flow is a system formed by a fluid mixture of 1 (liquid) and g (gas) phases flowing through a region V as is illustrated in Figure 1. Phase k (= l, g) has a variable volume \( V_k \) with a total interfacial area of \( A_k \) in the averaging volume V, which has an enveloping surface area (A) with a unit normal vector (\( \hat{n} \)) pointing outward. A portion of \( A_k \) is made of a liquid-gas interphase \( A_{lg} \) and a fluid-solid interface \( A_{kw} \). The unit normal vector \( \hat{n}_k \) of \( A_k \) is always drawn outwardly from phase k, regardless whether it is associated with \( A_{lg} \) or \( A_{kw} \).

**Local averaging volume**

\[
V = V_l(t) + V_g(t). 
\]  
(3)

**Volume fraction g phase in fluid mixture**

\[
\alpha_g = \frac{V_g(t)}{V}. 
\]  
(4)

The method of volume averaging is a technique that can be used to rigorously derive continuum equations for multiphase systems. This means that the equations valid for a particular phase can be spatially smoothed to produce equations that are valid everywhere, except in the boundaries which contain the multiphase systems.

The volume average operator or superficial volume average \( \langle \psi_k \rangle \) of some property \( \psi_k \) (scalar, vector, or tensor) associated with the k phase is given by

\[
\langle \psi_k \rangle = \frac{1}{V} \int_{V_k(x,t)} \psi_k (x + \sum_{k,t} \frac{dV}{V}) \, dV, \quad (5)
\]

where \( V \) is the averaging volume, \( V_k \) is the volume of the k phase (contained \( V \)), \( \hat{z} \) is the position vector locating the centroid of the averaging volume, \( \hat{z}_k \) is the position vector at any point in the k phase relative to the centroid, as is illustrated in Figure 1, and \( dV \) indicates that the integration is carried out with respect to the components of \( \hat{z}_k \). Then, (5) indicates that the volume-averaged quantities are associated with the centroid. In order to simplify the notation, we will avoid the precise nomenclature used and represent the superficial average of \( \psi_k \) as

\[
\langle \psi_k \rangle = \frac{1}{V_k} \int_{V_k} \psi_k \left| \frac{\hat{z}}{\sum_{k,t} \frac{dV}{V}} \right| \, dV. \quad (6)
\]

The intrinsic average is expressed in the form

\[
\langle \psi_k \rangle = \frac{1}{V_k} \int_{V_k} \psi_k \left| \frac{\hat{z}}{\sum_{k,t} \frac{dV}{V}} \right| \, dV. \quad (7)
\]

![Figure 1: Schematic figure of a two-phase flow with a transition region, showing the position vectors and the averaging volume.](image-url)
These averages will be used in the theoretical development of the two-phase flow transport equations and are related by

$$
\langle \psi_k \rangle^s = a_k \langle \psi_k \rangle.
$$

(8)

With $\psi_k = 1$, the result leads to

$$
\langle 1 \rangle^s = a_k.
$$

(9)

As mentioned above $V$ is a constant, which is invariant in both space and time as illustrated in Figure 1. In this case the volumes of each phase of the flow may change with the position and time, that is, $V_k(x,t)$. It should be clear that the volume fraction $a_k$ is a function of the position and time.

When the local instantaneous transport equations are averaged over the volume, terms arise which are averages of derivatives. In order to interchange differentiation and integration in the averaging transport equations, two special averaging theorems are needed. The first one is the spatial theorem [1, 28, 29]

$$
\langle \nabla \psi_k \rangle^s = \nabla \langle \psi_k \rangle + \frac{1}{V} \int_{A_k} \psi_k |_{x+y} n_k dA,
$$

(10)

where $\psi_k$ is a quantity associated with the $k$ phase, $n_k$ is the unit normal vector directed from the $k$ phase towards the $f$ phase, and $A_k$ is the area of the $k-f$ interface contained within $V$.

The second integral theorem is a special form of the Leibniz rule known as the transport theorem [10, 30]:

$$
\left\langle \frac{\partial \psi_k}{\partial t} \right\rangle^s = \frac{\partial}{\partial t} \langle \psi_k \rangle^s + \frac{1}{V} \int_{A_k} \psi_k |_{x+y} W_k \cdot n_k dA,
$$

(11)

where $W_k$ is the velocity of the $k-f$ interface in $V$,

$$
A_k = A_{kw} + A_{kb}.
$$

(12)

If $\psi_k = 1$, the previous theorems lead to

$$
\nabla a_k = -\frac{1}{V} \int_{A_k} n_k dA,
$$

(13)

$$
\frac{\partial a_k}{\partial t} = \frac{1}{V} \int_{A_k} W_k \cdot n_k dA.
$$

(14)

In these theorems $\psi_k$ should be continuous within the $k$ phase.

It is important to note that these theorems are not restricted to the inequality given by (1).

In order to eliminate the point or local variable $\psi_k$ in the spatial averaging theorem given by (10) we use the spatial decomposition $\langle \psi_k \rangle = \langle \psi_k \rangle + \tilde{\psi}_k$ [5],

$$
\langle \nabla \psi_k \rangle^s = \nabla \langle \psi_k \rangle^s + \frac{1}{V} \int_{A_k} \langle \psi_k \rangle |_{x+y} n_k dA
$$

$$
+ \frac{1}{V} \int_{A_k} \tilde{\psi}_k |_{x+y} n_k dA.
$$

(15)

In the homogeneous regions of the system, the following length-scale restriction given by (1) is usually satisfied, and the following simplification is considered:

$$
\langle \psi_k \rangle |_{x+y} \equiv \langle \psi_k \rangle, \quad \text{for } \frac{\ell}{5} \ll 1.
$$

(16)

Then, the second term on the right side of (15) can be written as

$$
\frac{1}{V} \int_{A_k} \langle \psi_k \rangle |_{x+y} n_k dA
$$

$$
= \left\{ \frac{1}{V} \int_{A_k} n_k dA \right\} \langle \psi_k \rangle
$$

$$
= -\{ \nabla a_k \} \langle \psi_k \rangle, \quad \text{for } \frac{\ell}{5} \ll 1.
$$

(17)

In general, the averaged terms evaluated in the centroid can be removed from the integrals, where this result was obtained using the lemma given by (13). Then, (15) can be rewritten as follows:

$$
\langle \nabla \psi_k \rangle^s = a_k \nabla \langle \psi_k \rangle + \frac{1}{V} \int_{A_k} \tilde{\psi}_k |_{x+y} n_k dA, \quad \text{for } \frac{\ell}{5} \ll 1.
$$

(18)

The similar form, the theorem given by (11) can be rewritten as

$$
\left\langle \frac{\partial \psi_k}{\partial t} \right\rangle^s = a_k \frac{\partial}{\partial t} \langle \psi_k \rangle^s
$$

$$
- \frac{1}{V} \int_{A_k} \tilde{\psi}_k |_{x+y} W_k \cdot n_k dA, \quad \text{for } \frac{\ell}{5} \ll 1,
$$

(19)

where this result was obtained using the lemma given by (14).

The local average volume in principle cannot describe significant variations or sudden changes where the characteristic length $\ell$ can be of the order of $5$. Then, it is necessary to extend the scope of the theorems given by (18) and (19), which is the goal of the next section.

3. Nonlocal Averaged Volume

The spatial decomposition given by $\psi_k = \langle \psi_k \rangle + \tilde{\psi}_k$ represents a decomposition of length scales, that is, the average $\langle \psi_k \rangle$ undergoes significant change only over the large length scale, while that the spatial deviation $\tilde{\psi}_k$ is dominated by the small length scale $\ell$. However, this idea considered that the nonlocal effects are negligible.

Returning to (10) and (11), it clearly indicates that is a nonlocal spatial averaging theorem since the dependent variable $\langle \psi_k \rangle$ is evaluated at other points than the centroid (which is indicated by $\langle \psi_k \rangle |_{x+y}$). In this context, we use nonlocal in the sense that it does not involve the use of length-scale restriction in its derivation [31, 32].

3.1. Nonlocal Averaged Volume Approximation. The area integral of $\langle \psi_k \rangle |_{x+y} n_k$ is evaluated in the $k$ phase indicated by position vector $y_k$ shown in Figure 1. Then,

$$
\frac{1}{V} \int_{A_k} \langle \psi_k \rangle |_{x+y} n_k dA,
$$

(20)

which is essentially a nonlocal term since that the dependent variable $\langle \psi_k \rangle$ is not evaluated at the centroid, $\bar{x}$ (Figure 1).
The nature of the volume-averaged variable \( \langle \psi_k \rangle \mid_{Z^2} \) can be known applying a Taylor series expansion about the centroid of the averaging volume \[33\]:

\[
\langle \psi_k \rangle \mid_{Z^2} = \langle \psi_k \rangle + \nabla \cdot \langle \psi_k \rangle + \frac{1}{2} \sum_{\ell=2}^n \nabla^\ell \langle \psi_k \rangle + \cdots.
\]

The second, third, and following terms on the left side correspond to nonlocal effects. Then, this equation can be approximate by

\[
\langle \psi_k \rangle \mid_{Z^2} = \langle \psi_k \rangle + \langle \psi_k \rangle_{NL},
\]

where \( \langle \psi_k \rangle_{NL} = \psi_k \cdot \Delta \langle \psi_k \rangle + \frac{1}{2} \sum_{\ell=2}^n \nabla^\ell \langle \psi_k \rangle + \cdots \). Inclusive can be treated as source term formed by \( \langle \psi_k \rangle \mid_{Z^2} - \langle \psi_k \rangle \). It is important to emphasize that the presence of the term \( \langle \psi_k \rangle_{NL} \) involves that the nonlocal representation avoids imposing length-scale restrictions. Then, the general representation of nonlocal term is

\[
\langle \psi_k \rangle_{NL} = \begin{cases} \langle \psi_k \rangle \mid_{Z^2} - \langle \psi_k \rangle, & \text{without length-scale restrictions}, \\ 0, & \text{for } \frac{\ell}{\delta} \ll 1. \end{cases}
\]

The physical interpretation of \(23\) indicates that the nonlocal contribution is negligible in the homogeneous region, that is, those portions of the two-phase flow that are not influenced by the rapid changes in the structure which occur in the boundary region. Therefore, nonlocal term can be important in the boundary region, where \( \langle \psi_k \rangle \mid_{Z^2} - \langle \psi_k \rangle \) is important and the length-scale constraints given by \(1\) are not valid.

Applying these ideas the theorems can be expressed in nonlocal terms:

\[
\nabla \langle \psi_k \rangle = \alpha_k \nabla \langle \psi_k \rangle + \frac{1}{V} \int_{A_k} \langle \psi_k \rangle_{NL} W_k \cdot \mathbf{n} dA + \frac{1}{V} \int_{A_k} \psi_k \mid_{Z^2} W_k \cdot \mathbf{n} dA,
\]

\[
\left( \frac{\partial \langle \psi_k \rangle}{\partial t} \right)^s = \alpha_k \frac{\partial \langle \psi_k \rangle}{\partial t} - \frac{1}{V} \int_{A_k} \langle \psi_k \rangle_{NL} W_k \cdot \mathbf{n} dA - \frac{1}{V} \int_{A_k} \psi_k \mid_{Z^2} W_k \cdot \mathbf{n} dA.
\]

The forms of these integral theorems are applied in this work to obtain nonlocal volume-averaged conservation equation for two-phase flow, that is, without restriction of the length scale.

### 3.2. Average Volume of the Product of Two Local Variables \( \varphi_k \psi_k \)

The explicit representation of the average volume of the product of two local variables is given by

\[
\langle \varphi_k \psi_k \rangle^s = \frac{1}{V} \int_{V_k} \langle \varphi_k \psi_k \rangle \mid_{Z^2} dV.
\]

Substituting the correspondent spatial deviations for the local variables \( \varphi_k \) and \( \psi_k \) leads to

\[
\langle \varphi_k \psi_k \rangle^s = \alpha_k \langle \varphi_k \rangle \langle \psi_k \rangle + \langle \varphi_k \rangle \langle \psi_k \rangle^s + \langle \varphi_k \rangle \langle \widetilde{\varphi}_k \psi_k \rangle^s,
\]

This is rewritten as

\[
\langle \varphi_k \psi_k \rangle^s = \langle \varphi_k \psi_k \rangle_{NL} + \alpha_k \langle \varphi_k \rangle \langle \psi_k \rangle + \langle \widetilde{\varphi}_k \psi_k \rangle^s,
\]

where \( \langle \varphi_k \psi_k \rangle_{NL} \) is a nonlocal term, since it involves, indirectly, values of \( \langle \varphi_k \rangle \) and \( \langle \psi_k \rangle \) that are not associated with the centroid of the averaging volume illustrated in Figure 1. The nonlocal contribution is given by

\[
\langle \varphi_k \psi_k \rangle_{NL} = \langle (\varphi_k) (\psi_k) \rangle^s + \langle (\varphi_k \widetilde{\psi}_k) \rangle^s \\
+ \langle (\varphi_k \widetilde{\varphi}_k) \rangle^s - \alpha_k \langle \varphi_k \rangle \langle \psi_k \rangle.
\]

It can be demonstrated that

\[
\langle \varphi_k \psi_k \rangle_{NL} = 0, \quad \text{for } \frac{\ell}{\delta} \ll 1.
\]

### 3.3. Operators Applied to Two Local Variables \( \varphi_k \psi_k \)

The typical expressions in the transport phenomena in a two-phase flow involve an average differential operator with two local variables,

\[
\nabla \langle \varphi_k \psi_k \rangle = \nabla \langle \varphi_k \rangle \langle \psi_k \rangle + \frac{1}{V} \int_{A_k} \varphi_k \psi_k \mid_{Z^2} W_k \cdot \mathbf{n} dA,
\]

\[
\left( \frac{\partial \langle \varphi_k \psi_k \rangle}{\partial t} \right)^s = \frac{\partial \langle \varphi_k \psi_k \rangle}{\partial t} - \frac{1}{V} \int_{A_k} \varphi_k \psi_k \mid_{Z^2} W_k \cdot \mathbf{n} dA.
\]
With the previous ideas we obtain expanded form of the
theorems for the product of two-local variables
\[
\langle \nabla \varphi_k \psi_k \rangle^s = \nabla \langle \varphi_k \psi_k \rangle^{NL} + \nabla \langle \varphi_k \psi_k \rangle + \nabla \langle \varphi_k \tilde{\psi}_k \rangle^s
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \varphi_k \psi_k \rangle \right) \eta_k dA \right\}_{NL}
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \varphi_k \tilde{\psi}_k \rangle \right) \eta_k dA \right\}_{D}
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \varphi_k \tilde{\psi}_k \rangle \right) \eta_k dA \right\}_{D}
\] (32)

\[
\frac{\partial \langle \varphi_k \psi_k \rangle^s}{\partial t} = \alpha_k \frac{\partial \langle \varphi_k \psi_k \rangle}{\partial t} + \frac{\partial \langle \varphi_k \psi_k \rangle^{NL}}{\partial t} + \frac{\partial \langle \varphi_k \tilde{\psi}_k \rangle^s}{\partial t}
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \varphi_k \psi_k \rangle \right) N_k dA \right\}_{NL}
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \varphi_k \tilde{\psi}_k \rangle \right) N_k dA \right\}_{D}
\] (33)

Equations for Two-Phase Flow

The starting point for the development of the nonlocal volume-averaged conservation equations is the point con-
servation equations. In order to illustrate the application of
theorems and related definitions, we considered
the general balance equation for some \( \psi \) properties in the \( k \) phase:
\[
\frac{\partial \langle \rho_k \psi_k \rangle}{\partial t} + \nabla \cdot \langle \rho_k U_k \psi_k \rangle + \nabla \cdot \langle D_k \psi_k \rangle = \rho_k f,
\] (34)

where \( \psi_k \) is the quantity conserved, \( D_k \) is the molecular flux, and \( f \) is a volumetric source. As summarized in Table 1, depending on the choice of the quantity to be conserved, either of these equations can be used to quantify the mass, momentum, and energy conservation of each phase.

The volume averaged of the general balance equation can be expressed as
\[
\frac{\partial \langle \rho_k \psi_k \rangle}{\partial t}^s + \nabla \cdot \langle \rho_k U_k \psi_k \rangle^s + \nabla \cdot \langle D_k \psi_k \rangle^s = \langle \rho_k f_k \rangle^s
\] (35)

<table>
<thead>

<td>( P_k )</td>
<td>( \frac{K_k}{\rho_k} )</td>
</tr>
<tr>
<td>Energy</td>
<td>( e_k )</td>
<td>( \frac{\rho_q}{\rho_k} )</td>
<td>( \frac{\rho_q}{\rho_k} )</td>
</tr>
</tbody>
</table>

Note: \( e_k = h_k + U_k^2/2 \) is the total specific energy for the \( k \) phase, where \( h_k \) is the enthalpy. \( q'' \) denotes the heat flux vector for the \( k \) phase.

The nonlocal transport theorem of the product of two variables derived in this work given by (33) with \( \psi_k = \rho_k \) is used in order to express the first term of this equation:
\[
\langle \nabla \cdot \rho_k U_k \psi_k \rangle^s = \alpha_k \nabla \cdot \langle \rho_k U_k \psi_k \rangle + \nabla \cdot \langle \rho_k U_k \psi_k \rangle^{NL} + \nabla \cdot \langle \rho_k \tilde{\psi}_k \rangle^s
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \rho_k \psi_k \rangle \right) N_k dA \right\}_{NL}
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \rho_k \tilde{\psi}_k \rangle \right) N_k dA \right\}_{D}
\] (36)

The nonlocal averaging theorem for the product of three variables can be developed following the same procedure given by (32). Then, the second term in (35) is given by
\[
\langle \nabla \cdot \rho_k D_k \psi_k \rangle^s = \alpha_k \nabla \cdot \langle \rho_k D_k \psi_k \rangle + \nabla \cdot \langle \rho_k D_k \psi_k \rangle^{NL} + \nabla \cdot \langle \rho_k \tilde{\psi}_k \rangle^s
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \rho_k \psi_k \rangle \right) N_k dA \right\}_{NL}
\]
\[
+ \left\{ \frac{1}{V} \int_{A_k} \left( \langle \rho_k \tilde{\psi}_k \rangle \right) N_k dA \right\}_{D}
\] (37)

The nonlocal averaging theorem given by (24) with \( \psi_k = D_k \) is used in order to obtain the diffusive term
\[
\langle \nabla \cdot D_k \psi_k \rangle^s = \alpha_k \nabla \cdot \langle D_k \psi_k \rangle + \frac{1}{V} \int_{A_k} \langle D_k \psi_k \rangle^{NL} N_k dA
\]
\[
+ \frac{1}{V} \int_{A_k} \langle \rho_k \psi_k \rangle N_k dA
\] (38)

(39)
The terms \( \langle \rho_k f_k \rangle^s \) are obtained with the application of (28)

\[
\langle \rho_k f_k \rangle^s = \langle \rho_k f_k \rangle_{\text{NL}} + \alpha_k \langle \rho_k \rangle \langle f_k \rangle + \langle \tilde{\rho}_k \tilde{f}_k \rangle^s. \tag{40}
\]

In order to simplify the previous equations, the following representations are proposed:

\[
\frac{\partial \langle \rho_k \psi_k \rangle_{\text{NL}}}{\partial t} = \eta a_k \frac{\partial \langle \rho_k \rangle \langle \psi_k \rangle}{\partial t}, \quad \text{nonlocal accumulation,} \tag{41}
\]

\[
\frac{\partial \langle \tilde{\rho}_k \tilde{\psi}_k \rangle^s}{\partial t} = \delta_a a_k \frac{\partial \langle \rho_k \rangle \langle \psi_k \rangle}{\partial t}, \quad \text{dispersion for accumulation,} \tag{42}
\]

\[
\nabla \cdot \langle \rho_k U_k \psi_k \rangle_{\text{NL}} = \eta a_k \nabla \cdot (\langle \rho_k \rangle \langle U_k \rangle \langle \psi_k \rangle), \quad \text{nonlocal convection,} \tag{43}
\]

\[
\nabla \cdot \langle \rho_k U_k \psi_k \rangle_D = \delta_a a_k \nabla \cdot (\langle \rho_k \rangle \langle U_k \rangle \langle \psi_k \rangle), \quad \text{dispersion for convection,} \tag{44}
\]

\[
\langle \rho_k f_k \rangle_{\text{NL}} = \eta \alpha_k \langle \rho_k \rangle \langle f_k \rangle, \quad \text{nonlocal source,} \tag{45}
\]

\[
\langle \tilde{\rho}_k \tilde{f}_k \rangle^s = \delta \alpha_k \langle \rho_k \rangle \langle f_k \rangle, \quad \text{dispersion for source,} \tag{46}
\]

where \( \eta \) and \( \delta \) are dimensionless parameters. The parameter \( \eta \) is the nonlocal nature, while the \( \delta \) parameter agglutinates the dispersion effects. Now, the diffusive flux of (39) can be expressed as

\[
\langle \nabla \cdot D_k \rangle^s = \alpha_k \nabla \cdot \langle D_k \rangle + M_{\text{NL}} + \tilde{M}_k. \tag{47}
\]

In this equation the following definitions were used:

\[
M_{\text{NL}} = \frac{1}{V} \int_{A_k} \langle D_k \rangle_{\text{NL}} \cdot \hat{n}_k dA, \quad \text{interfacial Nonlocal diffusion}, \tag{48}
\]

\[
\tilde{M}_k = \frac{1}{V} \int_{A_k} \tilde{D}_k \cdot \hat{n}_k dA, \quad \text{interfacial Diffusion due to dispersion}. \tag{49}
\]

Finally, substituting (41)–(49), the nonlocal volume-averaged of the general balance equation (without length-scale restriction) finally is obtained:

\[
\lambda a_k \frac{\partial \langle \rho_k \rangle \langle \psi_k \rangle}{\partial t} + \lambda \delta a_k \nabla \cdot (\langle \rho_k \rangle \langle U_k \rangle \langle \psi_k \rangle) + \alpha_k \nabla \cdot \langle D_k \rangle
= \lambda \alpha_k \langle \rho_k \rangle \langle f_k \rangle - M_{\text{NL}} - \tilde{M}_k - M_{\text{LD}} - M_{\text{NL}}, \tag{50}
\]

where

\[
\lambda = \eta + \delta + 1, \quad \text{and} \quad M_{\text{LD}} = \frac{1}{V} \int_{A_k} \langle \tilde{D}_k \tilde{\psi}_k \rangle \bigg|_{x^\perp} \cdot \hat{n}_k dA \bigg|_D
\]

\[
M_{\text{NL}} = \frac{1}{V} \int_{A_k} \langle \tilde{\rho}_k \tilde{\psi}_k \rangle \bigg|_{x^\perp} \cdot \hat{n}_k dA \bigg|_{\text{NL}}, \tag{52}
\]

\[
M_{\text{NL}} = \frac{1}{V} \int_{A_k} \langle \tilde{\rho}_k \rangle \langle \psi_k \rangle \bigg|_{x^\perp} \cdot \hat{n}_k dA \bigg|_{\text{NL}}. \tag{53}
\]

Recalling that a portion of \( A_k \) is made of a liquid-gas interphase and a fluid-solid interphase \( A_{\text{kw}} \), Then, \( M_{\text{LD}} \) (and \( M_{\text{NL}} \)) consider the transport phenomena related with interfacial mass transfer between fluid-fluid and fluid-solid interphase, that is, \( M_{\text{LD}} = M_{\text{LD}} + M_{\text{NL}} \) (with \( E = D, NL \)).

5. Discussion

The volume averaged of the balance equation with length-scale restriction can be obtained starting from the nonlocal averaging equation (50), which contains local and nonlocal terms of the averaged volume. When \( \eta \to 0, \langle \rho_k U_k \psi_k \rangle_{\text{NL}} \to 0, \langle \rho_k f_k \rangle_{\text{NL}} \to 0, M_{\text{NL}} \to 0, \) and \( M_{\text{NL}} \to 0, \) the local averaging volume equation is recovered. Then, (46) simplifies to

\[
(\delta_a + 1) a_k \frac{\partial \langle \rho_k \rangle \langle \psi_k \rangle}{\partial t} + \alpha_k \nabla \cdot (\langle \rho_k \rangle \langle U_k \rangle \langle \psi_k \rangle) + \alpha_k \nabla \cdot \langle D_k \rangle - \frac{1}{3} \ll 1. \tag{54}
\]

The fundamental difference between local and nonlocal equations is that (50) involves, indirectly, values of the variables that are not associated with the centroid of the averaged volume as illustrated in Figure 1, while in (54) all the values of the volume-averaged variables are associated with the centroid of the averaged volume. The physical interpretation indicates that (54) describes the homogeneous two-phase flow. In this work the homogeneous term is used to indicate that the two-phase flow system has a behavior close to that of a homogeneous system; then to ensure homogeneity the system under study is based in length-scale restriction used to perform the upscaling in the two-phase flow system. However, (50) has not length-scale restriction and in principle it can describe regions of a two-phase flow, where drastic changes occur in the void fraction and transport properties (e.g., diffusivity).

The nonlocal volume-averaged equations derived in this work contain new terms related to nonlocal transport effects due to accumulation, convection diffusion, and transport properties for two-phase flow. In general, the nonlocal terms
were evaluated considering them as a function of the local terms, yielding new coefficients ($\eta'$s) that can be called nonlocal coefficients due to its nature these coefficients were defined through (41), (43), and (45) along with (48) and (53). It is important to note that these last two equations can also be expressed in terms of the local terms.

The nonlocal coefficients ($\eta'$s) are new closure relationships of the present novel formulation. For the application in a two-phase flow it is necessary as a first approximation to perform an analysis of order of magnitude, with the idea of identifying the predominant effects where the coefficients are not negligible (i.e., the temporal and diffusive effects are negligible). Then, the significant nonlocal coefficients can be evaluated with new or existing procedures in the experimental field, theoretical deduction, or numerical simulation, for instance.

The physical meaning of the nonlocal coefficients is related to the scaling process, that is, in the transition region as it can be observed in Figure 1. These coefficients act as coupling elements among the phenomena occurring in at least two different length scales. Outside of the interregion the length scales are smaller compared with those near the interregion (Figure 1).

Some examples where nonlocal general equation (50) can be applied are where $\alpha_0$ presents abrupt changes [33, 34], in particular transitions of flow patterns, interface with stratified or annular flow drops and bubbles, and others as in the boundary region of the two-phase flow and solid, where the length-scale restriction given by (1) is not valid.

6. Conclusions

In this paper a derivation of the general transport equations for two-phase systems using a method-based on nonlocal volume averaging was presented. The nonlocal volume averaging equations derived in this work (50) contain new terms related to nonlocal transport effects due to accumulation, convection diffusion, and transport properties for two-phase flow.

The nonlocal terms were evaluated as a first approximation considering that these are a function of the local terms (41), (43), and (45), given as result of the nonlocal volume averaging equations (50) for practical applications. The nonlocal coefficients ($\eta'$s) are new closure relationships of the present novel formulation. The significant nonlocal coefficients can be evaluated with new or existent procedures: theoretical, numerical, and experimental. These coefficients act as coupling elements among the phenomena occurring in at least two different length scales, during the scaling process for pragmatic applications.

To illustrate the application of the representations of the nonlocal theorems and related definitions, the general balance equation for some $\psi$ property in the k phase was considered, where it was demonstrated that a nonlocal volume balance equation was obtained with meaningful averages. This general balance equation can be applied generally where $\alpha_0$ presents abrupt changes [34, 35], such as transitions of flow patterns, interfaces with stratified or annular flow drops and bubbles, and others such as in the boundary region of the multiphase system, where the length-scale restriction (1) are not valid.

The nonlocal averaging model derived in this work represents a novel proposal and its framework could be the beginning of extensive research, both theoretical and experimental, as well as numerical simulation.
