A new mathematical model of a 3DOF 2D mechanical system “transported cross-beam, two moving bridge cranes” has been proposed. Small system oscillations have been derived through the introduction of Lagrange equations. The numerical estimation of 3DOF system motion has been carried out with equation-based Modelica language. The present article uses the Lagrange method and numerical and optimization methods, realized with JModelica.org and Optimica freeware. The absolute swaying of the cross-beam with respect to the displacement of the two moving bridge cranes was estimated. The phase portraits of the 3DOF system for linear and angular coordinates were presented. An open loop optimal control problem was posed for the motion of the bridge cranes. A “bang-bang” control strategy was implemented for the derivation of an optimal control solution, which enables the travel of two bridge cranes at a prescribed distance for minimum time and minimum swaying of a heavy cross-beam. The derived results of the numerical simulation can be easily practically realized by crane operators with good agreement with simple engineering estimations. The proposed control strategy enables synchronous motion of two bridge cranes with a cross-beam that practically solves the posed problem of unwanted excessive oscillations of a heavy cross-beam during transportation.

1. Background and Introduction

Current civil engineering technologies often assume a modular concept for the assembly of buildings and other large structures. Individual modules are manufactured at specialized plants and plant departments with further transportation of modular sections to a storage warehouse. Further transportation routes of individual modules lead from the warehouse to the erecting yard at the construction site. Individual modules and modular sections are many times very heavy and bulky objects. Construction plant operation requires simultaneous usage of several cranes, working together at the various stages of transportation of these heavy modules [1, 2].

An example of modular unit construction would be the erection of the tower of a wind-powered generator with several modular sections, utilizing two boom cranes working together. This practical case of the two-crane assembly of a wind machine tower requires 3D turning and tumbling of cylindrical modular sections from a horizontal to a vertical position. In contrast to this example the present article (Figures 1, 2, 3, and 6) is focused on the solution of a problem of horizontal transportation of a finished heavy steel beam from a fabrication shop to a storage warehouse.

A shipbuilding example of collaborative working of two or more cranes would be the problem of transportation of a heavy bulk marine engine weighing in the range of 3–3000 tons to the installation site.
Other examples in civil engineering include the lifting-and-handling problems of modular building elements of construction, bays of a building, ceiling and floor slab panels, and spandrel walls. Construction problems of roofs, floors, and domes of roofed stadiums and shopping centers require preliminary manufacturing of the heavy bulk trussed frame modules with further transportation to building sites.

It is important to note that attempts to transport heavy bulk stores with a single crane are very undesirable because of the high probability of torsional oscillations of a heavy load. Moreover, usage of two cranes working together for heavy load transportation is a truly natural way for handling displacements in civil and mechanical engineering as nature itself has supplied humans with two hands and two legs for more efficient performance of lifting-and-handling operations.

Overhead crane dynamics has been studied in the research efforts of such scientists as Abdel-Rahman et al. (2003) [1], Deen Ali et al. (2005) [2], Arena et al. (2015) [3], Cartmell et al. (1998) [4], Castelli et al. (2014) [5], Cha et al. (2010) [6], Goodwin (1997) [7], Huang et al. (2015) [8], Lahouar et al. (2009) [9], Pigani and Gallina (2014) [10],
Sawodny et al. (2002) [11], Smoczek (2014) [12], Zi et al. (2008) [13].

Abdel-Rahman et al. (2003) have discussed mechanical design schemes and mathematical models of gantry cranes and bidirectional gantry cranes with translational displacements of payloads [1]. However, payload transportation by two overhead cranes with cross-beam usage is not addressed in [1].

Arena et al. (2015) have proposed several 3D kinematic and dynamic models of container cranes with constant distances between fixed points of supporting rigid and elastic cables [3]. However, some disadvantage of Arena’s model is associated with a prescribed imposition of geometric constraints on the distances between fixed points for supporting cables. A 2D kinematic model of the present article generalizes Arena’s model in the vertical plane [3].

Castelli et al. (2014) have studied a kinetostatic model of a Cartesian cable-suspended robot [5]. A kinematic model of Castelli et al. (2014) is focused on the transportation of a payload using double cables with variable lengths, which provide translational linear motion of the payload without obstacles. There is an analogy between a swaying Cartesian cable-suspended robot (Castelli, 2014) and the swaying cross-beam ED in our problem. However, during transportation the payload may have additional extraneous transverse oscillations. Moreover, successful payload transportation requires a synchronized change of lengths of both supporting cables.

Cha et al. (2010) have studied extra-heavy cargo lifting by two floating cranes with a barge ship connected between the two cranes [6].

Huang et al. (2015) have proposed a new double-pendulum mechanical model, describing the transportation of a large payload with distributed mass, which is attached to one trolley by one suspension cable and two rigging cables [8]. Huang et al. (2015) have suppressed payload vibration during transportation by control of trolley acceleration [8]. Mechanical disadvantage of Huang’s model is a usage of only one suspension cable. However, there are possible strong engineering benefits of using two suspension cables without rigging cables, which is beyond the scope of Huang’s research [8].

Kostikov et al. (2016) and Perig et al. (2014) have studied cargo transportation by crane with one slewing pivot point ([14–17]).

Analysis of references [1–18] clearly shows that the dynamics of transportation of the cross-beam by two overhead cranes is not fully addressed in available works [1–18]. This confirms the actuality, relevance, and industrial significance (Figure 1) of the present research.

2. Research Actuality and Prime Novelty of Research

The aim of the present research is the dynamic description of the transportation of a heavy cross-beam by two overhead cranes (Figures 1, 2, 3, and 6).

The objective of this research is a 3DOF 2D guided mechanical system “cross-beam ED, cables AE and BD, moving bridge crane A, moving bridge crane B.”

The subject of this research is the study of small oscillations of a heavy cross-beam, induced by the guided motion of two overhead cranes.

The prime novelty of the present research is the introduction of a new mathematical model of a 3DOF 2D mechanical system “cross-beam, two moving bridge cranes” with further dynamic and optimization analysis of small system oscillations and numerical evaluation of guided system motion in the first approach.

The main contribution of the present original research article to the field of engineering transportation is as follows. The 2D problem of horizontal transportation of a heavy steel structure by two bridge cranes, operating at different horizontal levels with different length hoisting cables, has been addressed.

The theoretical novelty of the research is the formulation of differential equations for the motion of a 2D mechanical
system “cross-beam, two moving bridge cranes,” determination of natural frequencies and periods of oscillations, and the numerical derivation of laws of system motion for coherent initial conditions. An open loop optimal control problem was formulated and solved with JModelica.org and Optimica freeware. The posed optimal control problem numerical solution provides minimization of transportation time for bodies of the mechanical system together with minimal swaying of the heavy bulk load.

The practical sphere of engineering applications of the present transportation problem is in lifting-and-handling machinery and civil engineering.

The plant photo in Figure 1 shows the two bridge cranes with crane operators’ cabins, which move along the different horizontal levels. The different lengths of supporting cables \(l_1\) and \(l_2\) for holding and carriage of heavy cross-beam by two bridge cranes are clearly observable in Figures 1, 2, 3, and 6.

Figure 1 contains an experimental plant photo of a cross-beam being transported with two independently moving cranes and provides a schematic illustration of the cross-beam inclination angles. The straight inclined line within the cross-beam, which passes through the fixing points of conjunction of the carrying cables’ roping to the cross-beam, forms a slope angle \(\gamma_0\) to the horizon. As a matter of engineering convenience, the present article introduces three interconnected angles \(\gamma,\gamma_0,\) and \(\delta,\) which uniquely determine the angle of rotation of the cross-beam. The angle \(\gamma\) in Figure 2 is the current angle of rotation of a cross-beam ED with respect to the horizontal \(x\), where cross-beam ED displacement occurs along the horizontal \(x\) direction. Factually the angle \(\gamma\) in Figure 2 is a kind of incidence angle, which characterizes the current angle of a cross-beam ED with the direction of the velocity vector of the horizontal displacements of the cranes. It will be shown further that the law of the change of angle \(\gamma\) will be a harmonic one with respect to a certain position of

\[ x_n = a \cos(\gamma_0) + x_2; \]
\[ z_n = b; \]
\[ x_n = x_1 + l_1 \cdot \sin(a) + a \cdot \cos(\gamma) - l_2 \cdot \sin(\beta); \]
\[ z_n = -l_1 \cdot \cos(a) + a \cdot \sin(\gamma) + l_2 \cdot \cos(\beta). \]

System (1) of transcendental equations, which determine the Cartesian coordinates of point \(B\), contains variables \(x_1; \ x_2;\) and \(a\). It is necessary to solve system (1) with respect to the unknown angles \(\beta, \gamma,\) that is, to derive \(\beta = f_\beta(x_1, x_2, a)\) and \(\gamma = f_\gamma(x_1, x_2, a)\) for \(\gamma = \gamma_0 + \delta,\) where the current angle \(\delta\) is counted off from the initial inclination angle \(\gamma_0\) in the direction of cross-beam ED motion in Figures 2 and 3. The simplest way to solve system (1) with respect to the \(\beta, \gamma,\) and \(\delta\) usage of a small angle assumption (Appendix A–D).

In order to calculate the initial inclination angle \(\gamma_0\) (Figures 1 and 3) of cross-beam ED with a horizon \(x\) it is possible to introduce an additional geometric parameter \(\Delta z_0 = a \cdot \sin(\gamma_0)\) in Figure 3 by substitution of the initial time moment \(t_0 = 0\) (s) into the second lower equations of system (1), which yields the following expression \(x_n = b = (-1) \cdot l_1 \cdot 1 + a \cdot \sin(\gamma_0) + l_2 \cdot 1,\) and \(\Delta z_0 = a \cdot \sin(\gamma_0) = b + l_1 - l_2\) or the sinus of \(\gamma_0\) angle is \(\sin(\gamma_0) = (b + l_1 - l_2)/a = \Delta z_0/a\) (Figure 3). These reasons confirm alternative results in formulae (A.2)–(A.4).

Equation (A.12) establishes a simplified linear dependence between swing angles \(\alpha\) and \(\beta.\) So one gets from (A.12) that the small angle \(\beta\) in Figure 2 can be estimated on the basis of (A.12) in the following way:

\[ \beta \approx \left(\frac{l_2}{l_1}\right) \cdot (x_1 - x_2 + l_1 \alpha). \]

Equation (2) determines the swing angle \(\beta\) as the simplified linear function of the variables \(x_1, x_2, \alpha;\) that is, \(\beta = f_\beta(x_1, x_2, \alpha).\)

The rate of change of the swing angle \(\beta,\) that is, the small angular velocity \(\omega_\beta = (d\beta/dt),\) can be estimated on the basis of (2) in the following way:

\[ \left(\frac{d\beta}{dt}\right) = \left(\frac{l_2}{l_1}\right) \cdot \left(\frac{dx_1}{dt} - \frac{dx_2}{dt} + l_1 \frac{d\alpha}{dt}\right). \]

Equation (B.9) determines the small inclination angle \(\delta\) to be a simplified linear function of the variables \(x_1, x_2, \alpha;\) that is, \(\delta = f_\delta(x_1, x_2, \alpha).\) Algebraic expression (B.9) accurately proves the correctness of statement (A.9) concerning the second order of infinitely small \(\delta\) (infinitesimality of \(\delta = O(\alpha^2))\) for a small inclination angle \(\delta,\) which determines the current motion of the mechanical system will be derived using the Lagrange equations [14, 16–18] for generalized coordinates \(x_1, x_2,\) and \(\alpha.\) So it is necessary to determine kinetic and potential energies of the mechanical system as functions of our chosen generalized coordinates. For this purpose we have to calculate the coordinates of bodies \(A,\) \(B,\) and material point \(C_3\) of the cross-beam body DE.

The Cartesian coordinates of point \(B,\) which coincides with the point \(C_2,\) are as follows:

3. Kinematics of the Mechanical System:

Geometric Constraints, Coordinates, and Velocities

The mechanical model of the present problem (Figure 1) is shown in Figures 2, 3, and 6. Dynamic equations for the
inclination of the cross-beam ED in Figure 2. Equation (B.9) allows the development of an alternative approximate expression for the small angle $\gamma$ for cross-beam ED inclination in Figure 2:

$$\gamma = \gamma_0 + \delta \approx \gamma_0 + \left( \frac{1}{2} \cdot a \cdot l_2 \cdot \cos(\gamma_0) \right) \left( (x_1 - x_2 + l_1 \alpha)^2 - l_1 \cdot l_2 \cdot \alpha \right)^2$$ \hspace{1cm} (4)

The derived alternative equations (B.9) and (4) provide a way for the estimation of the value of the angular velocity $\omega_\delta = (d\delta/dt)$ and $\omega_\gamma = (d\gamma/dt)$ by the following expression:

$$\frac{d\gamma}{dt} = \frac{1}{2} \cdot (a \cdot l_2 \cdot \cos(\gamma_0)) \left( (x_1 - x_2 + l_1 \alpha)^2 - l_1 \cdot l_2 \cdot \alpha \right)^2$$ \hspace{1cm} (5)

Algebraic expression (5) also proves the correctness of statement (A.9) concerning the second order of infinitely small $\omega_\delta$ (infinitesimal of $\omega_\delta = (d\delta/dt) = \omega_\gamma = (d\gamma/dt) = O(\alpha^2)$) for the angular velocity of the cross-beam ED in Figure 2.

After simplifications (C.4) yields that

$$z_{C_3} = \left( \left( \frac{1}{2} \right) \cdot l_1 \right) \cdot \alpha^2$$

Estimation of potential energy enables calculation of the generalized forces $Q_{x_1}, Q_{x_2},$ and $Q_\alpha,$ which can be calculated as partial derivatives of potential energy $\Pi$ with respect to the general coordinates $x_1, x_2,$ and $\alpha$ (Appendix E). Substitution of (E.2), (E.4), and (E.9) into a one-column matrix yields the following vector of generalized forces:

$$\{Q\} = (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} \begin{pmatrix} -x_1 + x_2 - l_1 \alpha \\ x_1 - x_2 + l_1 \alpha \\ -\left(l_1 \cdot l_2 + l_1^2\right) \cdot \alpha - x_1 \cdot l_1 + x_2 \cdot l_1 \end{pmatrix}.$$ \hspace{1cm} (9)

Simplification of (F.7) results in the following approximated expression:

$$T \approx \frac{1}{2} \cdot (m_1 + m_3) \cdot \left( \frac{d^2 x_1}{dt^2} \right)^2 + \frac{1}{2} \cdot m_2 \cdot \left( \frac{d^2 x_2}{dt^2} \right)^2 + \frac{1}{2} \cdot m_3 \cdot l_1^2 \cdot \left( \frac{d^2 \alpha}{dt^2} \right)^2 + m_3 \cdot l_1 \cdot \left( \frac{d^2 x_1}{dt^2} \right) \cdot \left( \frac{d\alpha}{dt} \right).$$ \hspace{1cm} (10)

The matrix form of the left-hand sides of Lagrange equations (G.1), (G.7), and (G.13) or (G.5), (G.11), and (G.17) yields the following matrix expression:

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}} \right) - \frac{\partial T}{\partial q} = \begin{pmatrix} (m_1 + m_3) \cdot 0 \cdot (m_3 \cdot l_1) \\ 0 \cdot m_2 \cdot 0 \\ (m_3 \cdot l_1) \cdot 0 \cdot (m_3 \cdot l_1^2) \end{pmatrix}$$ \hspace{1cm} (11)

The vector form of Lagrange equations is as follows:

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}} \right) - \frac{\partial T}{\partial q} = \{Q\},$$ \hspace{1cm} (12)

where the left-hand side of (12) is determined by matrix product (11) and the right-hand side of (12) is determined by the vector-column (9).
Substitution of (11) and (9) into (12) results in the following matrix form of Lagrange equations for the motion of the system in Figures 2 and 3:

\[
\begin{pmatrix}
  (m_1 + m_3) & 0 & (m_3 \cdot l_1) \\
  0 & m_2 & 0 \\
  (m_3 \cdot l_1) & 0 & (m_3 \cdot l_1^2)
\end{pmatrix}
\begin{pmatrix}
  \frac{d^2 x_1}{dt^2} \\
  \frac{d^2 x_2}{dt^2} \\
  \frac{d^2 \alpha}{dt^2}
\end{pmatrix}
\approx (m_3 g) \cdot \frac{1}{(2 \cdot l_2)}
\begin{pmatrix}
  -x_1 + x_2 - l_1 \alpha \\
  x_1 - x_2 + l_1 \alpha \\
  -(l_1 \cdot l_2 + l_1^2) \cdot \alpha - x_1 \cdot l_1 + x_2 \cdot l_1
\end{pmatrix}.
\]

Derived equation (G.6), (G.12), (G.18), or (13) allows the determination of natural periods of system oscillations, natural frequencies of mechanical system, and deriving motion equations for each of the three bodies of studied mechanical system for different initial conditions in Figures 1–3. The numerical solution of Lagrange equation (G.6), (G.12), (G.18), or (13) enables the determination of motion patterns and formulating applied engineering recommendations concerning motion of the system.

5. First Computational Example of Numerical Integration of Derived Lagrange Equations for the Studied Mechanical System with JModelica.org Freeware

Both Figure 3 and formulae (2)-(3) yield that at the initial time moment \( t_0 = 0 \) (s), (2) results in \( \beta_1 \approx ((x_1)_0 - (x_2)_0 + l_1 \cdot (\alpha_0))/l_2 \approx 0 \). The time derivative of this expression provides an analogical algebraic equation for initial velocities \( \omega_2(0) = d(\beta_2)/dt \approx ((V_1)_0 - (V_2)_0 + l_1 \cdot (d(\alpha_0))/dt)/l_2 \) of system in Figures 1–3, which results in the following equations: \( l_2 \cdot \omega_2(0) = (V_1)_0 - (V_2)_0 \), \( (V_2)_0 = (V_2)_0 \), and \( \omega_2(0) = d(\alpha_0)/dt = (l_1 \cdot (\alpha_0))/l_2 \). Additional assumption \( \omega_2(0) = 0 \) results in \( \omega_2(0) = d(\beta_2)/dt \approx ((-1) \cdot (V_1)_0)/l_2 = ((-1) \cdot (V_2)_0)/l_2 \). The derivation of numerical solutions of inverse dynamic problems for mechanical system in Figures 1–3 requires the assignment of different initial values of system coordinates and velocities, which satisfy the abovementioned constraint equations for initial coordinates \( \beta_0 \approx ((x_1)_0 - (x_2)_0 + l_1 \cdot (\alpha_0))/l_2 \approx 0 \) and initial velocities \( \omega_2(0) = d(\alpha_0)/dt = (l_1 \cdot (\alpha_0))/l_2 \approx ((V_2)_0 - (V_2)_0 + l_1 \cdot (\omega_2(0))/l_2 \). These questions concerning the influence of initial conditions were properly addressed by the
Figure 5: JModelica.org-derived numerical plots for angular coordinates $\alpha = \alpha(t)$ (a); $\beta = \beta(t)$ (b); $\delta = \delta(t)$ (c); $\gamma = \gamma(t)$ (d); $\omega_\gamma = \omega_\gamma(\gamma)$; that is, $(d(\gamma(t))/dt) = f(\gamma)$ (f), computed for system (13) with nonzero initial velocities $V_B(0) = 0.5$ (m/s) and $\omega_\beta(0) \approx -0.083$ (rad/s).
coordinates with respect to motion time \( t \); computational results are shown in Figures 4 and 5.

It is useful to get the numerical solution of system (13) of Lagrange equations (G.6), (G.12), and (G.18) with freeware code JModelica.org [14, 15, 19] for the following numerical values of parameters of the mechanical system in Figure 2: gravity acceleration is \( g = 9.81 \text{ (m/s}^2) \); masses of movable carts \( A \) and \( B \) are \( m_1 = m_2 = 1000 \text{ (kg)} \); mass of the cross-beam ED is \( m_3 = 10000 \text{ (kg)} \); length of the left cable AE is \( l_1 = 6 \text{ (m)} \); length of the right cable BD is \( l_2 = 5 \text{ (m)} \); vertical distance between the carts is \( b = 2 \text{ (m)} \); length of the cross-beam ED is \( a = 4 \text{ (m)} \).

The initial conditions for system (13) of Lagrange equations (G.6), (G.12), and (G.18) are as follows: it is possible to assume that at the initial time moment \( t = 0 \text{ (s)} \) the right upper cart B in Figure 2 moves rectilinearly to the right; that is, initial coordinate of the left cart A is \( x_A(0) = 0 \text{ (m)} \); initial velocity of the left cart A is \( V_A(0) = (dx_A(0)/dt) = 0 \text{ (m/s)} \); initial coordinate of the right cart B is \( x_B(0) = 0 \text{ (m)} \); initial velocity of the right cart B, which moves to the right, is \( V_B(0) = V'_B(0) = (dx_B(0)/dt) = 0.5 \text{ (m/s)} \neq 0 \); initial swing angle of the left rope AE is \( \alpha(0) = 0 \text{ (rad)} \); initial angular velocity of the left cable AE is \( \omega_A(0) = (d\alpha(0)/dt) = 0 \text{ (rad/s)} \). The aforementioned constraint equations yield that \( \omega_B(0) = d(\beta_B)/dt = ((-1) \cdot (V_B(0))/l_2 = ((-1) \cdot (V_B(0))/l_2 = (-1) \cdot 0.5 \text{ (m/s)}/6 \text{ (m)} \approx -0.083 \text{ (rad/s)} \). The corresponding computational results are shown in Figures 4 and 5.

Computational Figures 4 and 5 show the increase of carts' coordinates with respect to motion time \( t \). The computational curves in Figures 4 and 5 also show the additional harmonic oscillations. Computational dependencies of the angular coordinates in Figure 5 are harmonic curves. The computational amplitudes in Figure 5 confirm the correctness of small angle assumption in the present article.

Computational Figure 5(f) shows an unstable focus at the phase plane \((\gamma(t), d(\gamma(t))/dt)\) that means a certain increase in amplitude during cross-beam oscillations. However it is possible to neglect some increase of \( \gamma \) amplitude by taking into account the fact that both \( \gamma(t) \) and \( (d(\gamma(t))/dt) \) are second-order infinitesimal quantities. So from an engineering standpoint some small increase in \( \gamma(t) \) during a cross-beam transportation is negligible and not essential. Moreover Figure 5(f) shows the necessity of application of additional damping devices for suppression of a \( \gamma(t) \) oscillations.

6. Dynamics of the Guided Mechanical System

The formulation of the optimal control problem for guided motion of bridge cranes \( A \) and \( B \) requires the application of two independent external control forces to moving carts \( A \) and \( B \) with magnitudes \( F_1 = u_1(t) \text{ [N]} \) and \( F_2 = u_2(t) \text{ [N]} \) of variable forces in Figure 6.

Substitution of (1.9), (1.14), and (1.19) into the one-column matrix yields the following vector of generalized forces for the guided mechanical system:

\[
\{Q_3\} \approx (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} \cdot \begin{pmatrix}
-x_1 + x_2 - l_1 \alpha \\
-x_1 + x_2 + l_1 \alpha \\
-x_1 + x_2 + l_1 \alpha
\end{pmatrix}
\]

Substitution of (11) and (14) into (12) results in the following matrix form of the Lagrange equations for the motion of the guided mechanical system in Figure 6:
where $F_1 = u_1(t) [N]$ and $F_2 = u_2(t) [N]$ in Figure 6.

Matrix equation (15) shows that the addition of control forces $F_1 = u_1(t) [N]$ and $F_2 = u_2(t) [N]$ in the form of the additional vector components for control forces $\mathbf{F} = \begin{pmatrix} N \\ N \end{pmatrix}$ in the right-hand side of equation (15), which provide minimization of the objective function $J = t_f + \int_0^{t_f} (\alpha(t))^2 \, dt$, where $\alpha(t) [\text{rad}]$ is the variable angle of the cable AE with the vertical axis $z$ and $t_f [s]$ is the time of travel of the bridge cranes $A$ and $B$ of the prescribed desired distance $S$.

Minimization of the objective function $J$ (16) has to be done for the following constraints:

$$ \frac{d}{dt} (x_1(t)) = x_{1p}(t); $$

(17)

$$ \frac{d}{dt} (x_2(t)) = x_{2p}(t); $$

(18)

$$ \frac{d}{dt} (\alpha(t)) = \alpha_p(t); $$

(19)

$$ (m_1 + m_3) \cdot \left( \frac{d}{dt} (x_{1p}(t)) \right) + m_3 \cdot l_1 \cdot \left( \frac{d}{dt} (\alpha_p(t)) \right) $$

$$ = u_1(t) - (m_3 g) \cdot \frac{1}{2 \cdot l_2} $$

$$ \cdot (x_1(t) - x_2(t) + l_1 \cdot \alpha(t)); $$

(20)

$$ m_2 \cdot \left( \frac{d}{dt} (x_{2p}(t)) \right) $$

$$ = u_2(t) + (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} $$

$$ \cdot (x_1(t) - x_2(t) + l_1 \cdot \alpha(t)); $$

(21)

$$ m_3 \cdot l_1 \cdot \left( \frac{d}{dt} (x_{1p}(t)) \right) + m_3 \cdot l_2^2 \cdot \left( \frac{d}{dt} (\alpha_p(t)) \right) $$

$$ = (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} $$

$$ \cdot (x_1(t) - x_2(t) + l_1 \cdot \alpha(t)); $$

(22)

$$ x_1(0) = 0; $$

(23)

$$ x_{1p}(0) = 0; $$

$$ x_1(0) = 0; $$

$$ x_{2p}(0) = 0; $$

$$ \alpha(0) = 0; $$

$$ \alpha_p(0) = 0; $$

$$ x_1(t_f) = S; $$

(24)

$$ x_{1p}(t_f) = 0; $$

$$ x_2(t_f) = S; $$

$$ x_{2p}(t_f) = 0; $$

$$ \alpha(t_f) = 0; $$

$$ \alpha_p(t_f) = 0; $$

$$ |u_1(t)| \leq u_{1\text{max}}; $$

(25)

$$ |u_2(t)| \leq u_{2\text{max}}. $$

Introduction of control $\left( u_1(t); u_2(t); 0 \right)^T$ into equations (J.4), (J.5), (J.6), and (15) provides possibility of deriving an optimal control in dependence from the form of a minimized functional $J$ (16) with equal weight coefficients.

7. Second Computational Example of a Numerical Solution of Derived Governing Equations for the Studied Guided Mechanical System with JModelica.org and Optimica Freeware

It is possible to achieve a numerical solution of system (16)–(25) for minimized functional (16), governing equations (17)–(22), initial conditions (23), terminal conditions (24), and limitations on the control forces (25) with module Optimica of freeware code JModelica.org [14, 15, 19] for the following numerical values of parameters of the mechanical system in Figure 6.
Figure 6: gravity acceleration is \( g = 9.81 \text{ (m/s}^2) \); masses of movable carts \( A \) and \( B \) are \( m_1 = m_2 = 1000 \text{ (kg)} \); mass of the cross-beam \( ED \) is \( m_3 = 10000 \text{ (kg)} \); length of the left rope \( AE \) is \( l_1 = 6 \text{ (m)} \); length of the right rope \( BD \) is \( l_2 = 5 \text{ (m)} \); vertical distance between the carts is \( b = 2 \text{ (m)} \); length of the cross-beam \( ED \) is \( a = 4 \text{ (m)} \); prescribed desired transportation distance for bridge cranes \( A \) and \( B \) is \( S = 40 \text{ (m)} \); the maximum value of the first control force is \( u_{1\max} = 100 \text{ (N)} \); and the maximum value of the second control force is \( u_{2\max} = 100 \text{ (N)} \). Derived plots of motion of guided system with zero initial conditions (23) are shown in Figure 7.

8. Discussion of Derived Results

The present problem is a new and mathematically complex research problem. Complexity of the problem is connected with the imposition of essentially nonlinear geometric constraints that cause a lot of issues and problems with the derivation of differential equations of motion.

Development of the governing equations was based on the application of a small parameter linearization method. The numerical solution of the problem confirmed the correctness of applying linearization techniques. Derived simulation results were in good agreement with the basic conservation laws of classical mechanics.

The linear momentum of the system at the initial time \( t = 0 \text{ (s)} \) is determined by the linear momentum of cart \( B \) and can be calculated as \( m_3 \cdot V_B(0) = 1000 \text{ (kg)} \cdot 0.5 \text{ (m/s)} = 500 \text{ (kg.m/s)} \). The total mass of the whole system is \( (m_1 + m_2 + m_3) = 12000 \text{ (kg)} \). It is possible to determine the linear velocity of the center of gravity of the mechanism at an arbitrary time with the introduction of a theorem defining center-of-gravity motion conservation as \( V_C = \frac{(m_2 \cdot V_B(0))/(m_1 + m_2 + m_3)}{500 \text{ (kg.m/s)/}12000 \text{ (kg)} = 0.042 \text{ (m/s)}} \). The derived value of \( V_C \) determines the average velocity for the entire system in Figure 2. So it is possible to estimate the traversed path of the carts \( A \) and \( B \) in Figure 4(a) for the moment of time \( \tau = 10 \text{ (s)} \) with the formula \( S = V_C \cdot \tau \approx 0.042 \text{ (m/s)} \cdot 10 \text{ (s)} = 0.42 \text{ (m)} \).

It is necessary to note that, in addition to the motion due to the velocity of the center of gravity, there are additional system motions with natural frequencies \( k_1 = 1021 \text{ (1/s)} \) and \( k_2 = 3.794 \text{ (1/s)} \) (Appendix H), and the corresponding natural periods \( \tau_1 = 2 \cdot \pi / k_1 \approx 6.155 \text{ (s)} \) and \( \tau_2 = 2 \cdot \pi / k_2 \approx 1.656 \text{ (s)} \). These two natural periods and amplitudes are clearly observable in Figures 4 and 5.

The numerical solution of an optimal control problem (16)–(25) allows determination of the control variables \( u_1(t) \) and \( u_2(t) \) for control forces \( F_1 = u_1(t) \text{ [N]} \) and \( F_2 = u_2(t) \text{ [N]} \) in Figure 7(b), which enable transportation of a cross-beam from the initial to the final position with minimum time and minimum swaying in Figures 7(c) and 7(d). These control variables \( u_1(t) \) and \( u_2(t) \) are the control forces \( F_1 = u_1(t) \) and \( F_2 = u_2(t) \), applied to the first and second bridge cranes \( A \) and \( B \). Optimica-derived derived Figure 7(b) shows that it is possible to provide an optimal motion in the abovementioned sense by the following strategy, when at the first half of motion time the control forces \( u_1(t) \) and \( u_2(t) \) should be constant and positive and at the second half of motion time the control forces \( u_1(t) \) and \( u_2(t) \) should be negative. As a result, in the beginning, acting forces provide maximum acceleration of the bridge cranes and then deceleration. This control strategy is a "bang-bang" control method with the switching point in the time moment \( t^* = t_f/2 \), where \( t_f \) is the time of travel of bridge cranes from one position to another. It is shown in Figure 7(b) that during the last 2-3 seconds the control forces have negative values because it is necessary to provide slowing-down (deceleration) of the system motion. In this case the values of control forces are \( 0.25 \cdot \max[u_1(t), u_2(t)] \). This kind of a control strategy enables travel to the final position with near-zero-values of velocities \( V_{x_1} = V_{x_2} = V_{y_3} = 0 \text{ (m/s)} \) and near-zero-values of swaying angles \( \alpha = \beta = 0 \). An easy practical realization of these recommendations by bridge crane operators is the real advantage of the found control strategy. Really, in the first half of the way, crane operators have to accelerate bridge cranes, and in the second half of the movement, crane operators have to decelerate bridge cranes. This control strategy is relatively easy for realization in manual mode using available crane control mechanisms. The proposed control strategy reduces transportation time and partially decreases intensity of the labor of crane operators.

Analysis of Figure 7(a) indicates that the proposed control strategy enables synchronous motion of bridge cranes with quite small and negligible oscillations of a heavy cross-beam. Analysis of Figure 7(c) shows that deviation of a cross-beam from equilibrium position in the horizontal direction does not exceed 0.002 (rad), and in the vertical direction the cross-beam deviation is much smaller and does not exceed \( 4 \cdot 10^{-6} \text{ (rad)} \).

It is easy to confirm the correctness of the proposed optimal control with engineering estimation. According to the law of variation of momentum along the horizontal direction, the impulse of control forces for \( F_1 = u_1(t) \text{ [N]} \) and \( F_2 = u_2(t) \text{ [N]} \) is \( (u_1 + u_2) \cdot (t_f/2) \approx (100 + 100) \cdot 49 \text{ (Ns)} = 9800 \text{ (Ns)} \). Moreover, it follows from Figure 7(e) that the linear momentum of the system to this time moment 49 s is \( (m_1 + m_2 + m_3) \cdot V_C \approx (1000 + 1000 + 1000) \cdot 0.8 \text{ (kg.m/s)} = 9600 \text{ (Ns)} \). The results are approximately the same in the deceleration region. These simple engineering estimations confirm the correctness of the derived optimal control strategy.

Further research directions are associated with dynamic analysis of internal forces, reactions of constraints, introduction of additional elastic-damping devices, development and analysis of other modes of optimal control, introduction of additional elastic-damping devices, and search for other natural frequencies in 3D problem.

9. Final Conclusions

The present problem is a truly new problem of lifting-and-handling machinery.

This problem has arisen from applied engineering assignments, associated with civil engineering and transportation problems in plant departments and in field environment conditions.
Figure 7: JModelica.org- and Optimica-derived numerical plots for linear coordinates $x_1 = x_1(t)$; $x_2 = x_2(t)$; and $x_3 = x_3(t)$ (a); control forces $F_1 = u_1(t)$ [N] and $F_2 = u_2(t)$ [N] (b); angular coordinates $\alpha = \alpha(t)$ and $\beta = \beta(t)$ (c); angular coordinate $\delta = \delta(t)$ (d); synchronized velocities $V_{x_1}(t) = (d(x_1(t))/dt)$, $V_{y_1}(t) = (d(y_1(t))/dt)$, and $V_{c_3}(t) = (d(x_{c_3}(t))/dt)$ of points $C_1$, $C_2$, $C_3$ during guided system motion (e); and $\omega_\gamma = \omega_\gamma(t)$; that is, $(d(\gamma(t))/dt) = f(\gamma)$, obtained for synchronous motion of the mechanical system with an open loop control.
There are previously known studies of vertical lifting, space canting, and 3D rotation of the load up to 90 deg with two boom cranes, working together. But there is a lack of relevant and specific information concerning horizontal transportation of the load with two bridge cranes.

The present original research article is focused on the development of a mathematical model, describing the horizontal transportation of the load (cross-beam) in the vertical plane.

Transportation dynamics of heavy cross-beam moved by two overhead cranes was addressed with the introduction of the Lagrange equations using small angle assumptions. A 3DOF mechanical system “heavy cross-beam, two moving carts” was studied. One of the methodologies of the search of optimal control was proposed. An optimal control strategy with angles of cross-beam oscillations around the center of mass. The algebraic equation (A.2) yields

\[
\Delta z_0 = l_1 - l_2 + b.
\]  

Equations (A.2) and (A.3) enable calculation of the initial angle \(\gamma_0\):

\[
\sin (\gamma_0) = \frac{\Delta z_0}{a} = \frac{(l_1 - l_2 + b)}{a};
\]

\[
\cos (\gamma_0) = \sqrt{1 - \sin^2 (\gamma_0)}.
\]

Further linearization of (1) requires the derivation of simplified trigonometric expressions for the current angle \(\gamma\) using the formulae for sine and cosine of angular sum, where \(y = \gamma_0 + \delta\) (Figure 2):

\[
\cos (y) = \cos (\gamma_0 + \delta) = \cos (\gamma_0) \cos (\delta) - \sin (\gamma_0) \sin (\delta);
\]

\[
\sin (y) = \sin (\gamma_0 + \delta) = \sin (\gamma_0) \cos (\delta) + \cos (\gamma_0) \sin (\delta).
\]

It is possible to make a linearization of (A.5) for the small angle \(\delta\) assuming that

\[
\sin (\delta) \approx \delta; \quad \cos (\delta) \approx 1.
\]

After substitution of (A.6) into (A.5) one obtains

\[
\cos (y) = \cos (\gamma_0 + \delta) \approx \cos (\gamma_0) - \delta \cdot \sin (\gamma_0); \quad \quad \quad \text{(A.7)}
\]

\[
\sin (y) = \sin (\gamma_0 + \delta) \approx \sin (\gamma_0) + \delta \cdot \cos (\gamma_0). \quad \quad \quad \text{(A.8)}
\]

As will subsequently be shown in further equations (4), (B.9), and (5), the angle \(\delta\) and the angular velocity of the cross-beam ED are the second-order infinitesimal quantities with respect to \(\alpha\); that is,

\[
\delta = O (\alpha^2); \quad \quad \quad \text{(A.9)}
\]

Substitution of (A.9) into (A.7) approximately results in

\[
\cos (y) = \cos (\gamma_0). \quad \quad \quad \text{(A.10)}
\]

Combined usage of (A.1) and (A.10) provides a way to linearize (1) for the abscissa \(x_B\) of point B. Substitution of (A.1) and (A.10) into the upper lines of (1) yields that

\[
x_B = a \cos (\gamma_0) + x_2 = x_1 + l_1 \cdot \alpha + a \cos (\gamma_0) - l_2 \cdot \beta. \quad \quad \quad \text{(A.11)}
\]

Approximate equation (A.11) results in

\[
x_2 - x_1 \approx l_1 \cdot \alpha - l_2 \cdot \beta. \quad \quad \quad \text{(A.12)}
\]
**B. Estimation of Small Inclination Angles**

Now it is necessary to find a simplified expression for \( y = f_\gamma(x_1, x_2, \alpha) \), where \( y = y_0 + \delta \). For this purpose it is necessary to address system (1) for the applicable \( z_B \) of point B. Substitution of the second equations of system (A.1) and (A.8) into the lower lines of (1) yields

\[
z_B = b \\
\approx -l_1 \cdot \left(1 - \left(\frac{1}{2}\right) \cdot \alpha^2\right) + a \cdot \sin(y_0) + a \cdot \delta \\
\cdot \cos(y_0) + l_2 \cdot \left(1 - \left(\frac{1}{2}\right) \cdot \beta^2\right)
\]

where the second term on the right-hand side of (B.1) is determined by expression (A.4). Therefore, the substitution of (A.4) into (B.1) produces

\[
b \approx -l_1 \cdot \left(1 - \left(\frac{1}{2}\right) \cdot \alpha^2\right) + (l_1 - l_2 + b) + a \cdot \delta \\
\cdot \cos(y_0) + l_2 \cdot \left(1 - \left(\frac{1}{2}\right) \cdot \beta^2\right);
\]

\[
b \approx -l_1 + \left(\frac{1}{2}\right) \cdot l_1 \cdot \alpha^2 + l_1 - l_2 + b + a \cdot \delta \cdot \cos(y_0)
\]

\[
+ l_2 - \left(\frac{1}{2}\right) \cdot l_2 \cdot \beta^2.
\]

It is obvious that components \( b, l_1, \) and \( l_2 \) with opposite signs in (B.3) result in zero-sum terms of (B.3). So (B.3) yields

\[
a \cdot \delta \cdot \cos(y_0) = \left(\frac{1}{2}\right) \cdot l_2 \cdot \beta^2 - \left(\frac{1}{2}\right) \cdot l_1 \cdot \alpha^2.
\]

After transformation (B.4) yields the small angle \( \delta \) expression:

\[
\delta \approx \left(\frac{\beta^2 - l_1 \cdot \alpha^2}{2 \cdot a \cdot \cos(y_0)}\right).
\]

Equation (B.5) determines the small inclination angle \( \delta \) as the simplified linear function of the variables \( \alpha \) and \( \beta \); that is, \( \delta = f_\delta(\alpha, \beta) \). Equation (B.5) provides the possibility of calculating an approximate expression for the small angle \( y \) for cross-beam ED inclination in Figure 2:

\[
y = y_0 + \delta \approx y_0 + \left(\frac{l_2 \cdot \beta^2 - l_1 \cdot \alpha^2}{2 \cdot a \cdot \cos(y_0)}\right).
\]

The derived equations (B.5) and (B.6) provide a way to estimate the value of the angular velocity \( \omega_\delta = \frac{dy}{dt} = \omega_y = (dy/dt) \) by the following expression:

\[
\left(\frac{dy}{dt}\right) = \left(\frac{d\delta}{dt}\right) = \frac{1}{(a \cdot \cos(y_0))} \left( l_2 \cdot \beta \cdot \left(\frac{d\beta}{dt}\right) - l_1 \cdot \alpha \cdot \left(\frac{d\alpha}{dt}\right) \right).
\]

It is possible to make further transformations of (B.5) and to derive the small inclination angle \( \delta \) as the simplified linear function of the variables \( x_1, x_2, \alpha \), that is, to get an expression for \( \delta = f_\delta(x_1, x_2, \alpha) \) by substitution of (2) into (B.5):

\[
\delta \approx \frac{1}{(2 \cdot a \cdot \cos(y_0))} \left( l_2 \cdot \left(\frac{1}{l_2}\right)^2 \cdot (x_1 - x_2 + l_1 \alpha)^2 - l_1 \cdot \alpha^2 \right)
\]

\[
\approx \frac{1}{(2 \cdot a \cdot \cos(y_0))} \left( (x_1 - x_2 + l_1 \alpha)^2 - l_1 \cdot l_2 \cdot \alpha^2 \right).
\]

\[
\delta = \frac{1}{(2 \cdot a \cdot \cos(y_0))} \left( (x_1 - x_2 + l_1 \alpha)^2 - l_1 \cdot l_2 \cdot \alpha^2 \right).
\]

**C. Linearized Coordinates of Cross-Beam Center**

Now it is necessary to address the coordinates and displacements of the point \( C_3 \), which is located at the center of the cross-beam ED. The coordinates of the point \( C_3 \) are necessary for determination of kinetic (Appendix F) and potential energies of the cross-beam ED, as well as for calculation of the generalized forces (Appendix E) in the Lagrange equations (Appendix G). The horizontal and vertical Cartesian coordinates of point \( C_3 \) in Figure 2 are determined by the following formulæ:

\[
x_{C_3} = x_1 + l_1 \cdot \sin(\alpha) + \left(\frac{a}{2}\right) \cdot \cos(y)\;
\]

\[
z_{C_3} = -l_1 \cdot \cos(\alpha) + \left(\frac{a}{2}\right) \cdot \sin(y).
\]

Further linearization of (C.1) is possible through the application of the previous expressions (A.1) and (A.7)-(A.8). Substitution of (A.1) and (A.7)-(A.8) yields

\[
x_{C_3} \approx x_1 + l_1 \cdot \alpha + \left(\frac{a}{2}\right) \cdot (\cos(y_0) - \delta \cdot \sin(y_0)) ;
\]

\[
z_{C_3} \approx -l_1 \cdot \left(1 - \left(\frac{1}{2}\right) \cdot \alpha^2\right) + \left(\frac{a}{2}\right) \cdot (\sin(y_0) + \delta \cdot \cos(y_0)).
\]

It is possible to expand the brackets in (C.2) to get the following simplified expressions:

\[
x_{C_3} \approx x_1 + l_1 \cdot \alpha - \left(\frac{a}{2}\right) \cdot \sin(y_0) \cdot \delta
\]

\[
+ \left(\frac{a}{2}\right) \cdot \cos(y_0);
\]

\[
z_{C_3} \approx \left(\frac{1}{2}\right) \cdot l_1 \cdot \alpha^2 + \left(\frac{a}{2}\right) \cdot \cos(y_0) \cdot \delta
\]

\[
+ \left(\frac{a}{2}\right) \cdot \sin(y_0) - l_1 \cdot \alpha \cdot \delta.
\]
Substitution of (A.4) and (B.9) into the second equation of system (C.3) results in the following expression for the vertical location applicable of the point $C_3$:

$$z_{C_3} \approx \left( \frac{1}{2} \right) \cdot l_1 \cdot \alpha^2 + \left( \frac{a}{2} \right) \cdot \cos (\gamma_0) - \frac{1}{2 \cdot a \cdot l_2 \cdot \cos (\gamma_0)} \left( x_1 - x_2 + l_1 \alpha \right)^2 - l_1 \cdot l_2 \cdot \alpha^2 \cdot \left( \frac{1}{2} \right) \cdot \left( l_1 - l_2 + b - l_1 \right).$$ (C.4)

**D. Linearized Velocities of Cross-Beam Center**

The further calculation of kinetic energy of the cross-beam ED requires an estimation of velocity of the point $C_3$. The first time derivatives of system (C.1) give to one the system of equations for $\mathbf{V}_{C_3}$ projections:

$$\frac{d(x_{C_3})}{dt} = \left( \frac{dx_1}{dt} \right) + \left( l_1 \cdot \cos (\alpha) \right) \cdot \left( \frac{d\alpha}{dt} \right) - \left( \frac{a}{2} \right) \cdot \sin (\gamma) \cdot \left( \frac{dy}{dt} \right);$$

$$\frac{d(z_{C_3})}{dt} = \left( l_1 \cdot \sin (\alpha) \right) \cdot \left( \frac{d\alpha}{dt} \right) + \left( \frac{a}{2} \right) \cdot \cos (\gamma) \cdot \left( \frac{dy}{dt} \right).$$ (D.1)

It is more useful to linearize system (D.1) through differentiation of system (C.3) with respect to the time $t$:

$$\frac{d(x_{C_3})}{dt} = \left( \frac{dx_1}{dt} \right) + l_1 \cdot \left( \frac{d\alpha}{dt} \right) - \left( \frac{a}{2} \right) \cdot \sin (\gamma_0) \cdot \left( \frac{d\delta}{dt} \right);$$

$$\frac{d(z_{C_3})}{dt} = \left( \frac{1}{2} \right) \cdot l_1 \cdot \left( 2 \cdot \alpha \right) \cdot \left( \frac{d\alpha}{dt} \right) + \left( \frac{a}{2} \right) \cdot \cos (\gamma_0) \cdot \left( \frac{d\delta}{dt} \right).$$ (D.2)

The system of expressions (D.2) can be further simplified by taking into account equation (5) that $\omega_3 = \omega_0 = (d\delta/dt) = \omega_\gamma = (dy/dt) = O(\alpha^2) \approx 0$:

$$\frac{d(x_{C_3})}{dt} = \left( \frac{dx_1}{dt} \right) + l_1 \cdot \left( \frac{d\alpha}{dt} \right);$$

$$\frac{d(z_{C_3})}{dt} = \left( l_1 \cdot \alpha \right) \cdot \left( \frac{d\alpha}{dt} \right).$$ (D.3)

It is possible to further simplify (D.3) by taking into account the fact that the product $\alpha \cdot (d\alpha/dt)$ is the second-order infinitesimal quantity; that is,

$$\alpha \cdot \left( \frac{d\alpha}{dt} \right) = O(\alpha^2).$$ (D.4)

Substitution of (D.4) into (D.3) yields

$$\frac{d(x_{C_3})}{dt} = \left( \frac{dx_1}{dt} \right) + l_1 \cdot \left( \frac{d\alpha}{dt} \right);$$

$$\frac{d(z_{C_3})}{dt} = 0.$$ (D.5)

**E. Generalized Forces**

The first generalized force $Q_{x_1}$, which corresponds to the generalized linear coordinate $x_1$, is as follows:

$$Q_{x_1} = -\frac{\partial \Pi}{\partial x_1} \approx \left( -1 \right) \cdot (m_3 g) \cdot \frac{1}{4 \cdot l_2} \cdot \left( x_1 - x_2 + l_1 \alpha \right).$$ (E.1)

After simplifications the previous equation (E.1) for the first generalized force $Q_{x_1}$ takes the form

$$Q_{x_1} \approx \left( -1 \right) \cdot (m_3 g) \cdot \frac{1}{2 \cdot l_2} \cdot \left( x_1 - x_2 + l_1 \alpha \right).$$ (E.2)

The second generalized force $Q_{x_2}$, which corresponds to the generalized linear coordinate $x_2$, can be calculated as

$$Q_{x_2} = -\frac{\partial \Pi}{\partial x_2} \approx \left( -1 \right) \cdot (m_3 g) \cdot \frac{1}{4 \cdot l_2} \cdot \left( x_1 - x_2 + l_1 \alpha \right) \cdot \left( -1 \right).$$ (E.3)

After simplifications (E.3) for the second generalized force $Q_{x_2}$ yields

$$Q_{x_2} \approx \left( +1 \right) \cdot (m_3 g) \cdot \frac{1}{2 \cdot l_2} \cdot \left( x_1 - x_2 + l_1 \alpha \right).$$ (E.4)

It is possible to calculate the third generalized force $Q_\alpha$, which corresponds to the generalized angular coordinate $\alpha$, by the following expression:

$$Q_\alpha = -\frac{\partial \Pi}{\partial \alpha} \approx \left( -1 \right) \cdot (m_3 g) \cdot \left( \left( \frac{1}{2} \right) \cdot l_1 \right) \cdot \left( 2 \cdot \alpha \right) + \frac{1}{4 \cdot l_2} \cdot \left( 2 \cdot \left( x_1 - x_2 + l_1 \alpha \right) \cdot l_1 \cdot l_2 \cdot 2 \cdot \alpha \right).$$ (E.5)
After simplifications (E.5) produces

\[ Q_\alpha = \left(-1\right) \cdot (m_3 g) \cdot \left( l_1 \cdot \alpha \right) + \frac{1}{2 \cdot l_2} \left( (x_1 - x_2 + l_1 \alpha) \cdot l_1 - l_1 \cdot l_2 \cdot \alpha \right). \]  

(E.6)

Reducing a right-hand side fraction of (E.6) to a common denominator yields

\[ Q_\alpha \approx (m_3 g) \cdot \frac{1}{2 \cdot l_2} \cdot (-l_1 \cdot l_2 \cdot \alpha - (x_1 - x_2 + l_1 \alpha) \cdot l_1). \]  

(E.7)

Expanding the brackets in (E.7) leads to the following expression:

\[ Q_\alpha \approx (m_3 g) \cdot \frac{1}{2 \cdot l_2} \cdot \left(-l_1 \cdot l_2 \cdot \alpha - x_1 \cdot l_1 + x_2 \cdot l_1 - l_1^2 \cdot \alpha \right). \]

Equation (E.8) finally produces

\[ Q_\alpha \approx (m_3 g) \cdot \frac{1}{2 \cdot l_2} \cdot \left(\left( l_1 + l_1^2 \right) \cdot \alpha - x_1 \cdot l_1 + x_2 \cdot l_1 \right). \]  

(E.9)

F. System Kinetic Energy

Calculation of kinetic energy of the mechanical system in Figure 2 requires some additional comments.

It is obvious that the first cart A (point \( C_1 \)) is involved in the translational motion along the horizontal axis \( OX \). Hence, the kinetic energy of a 2D model of the bridge crane A can be calculated by the following expression:

\[ T_1 = \left( \frac{1}{2} \right) \cdot m_A \cdot \left( \vec{V}_{C_1} \right)^2 = \left( \frac{1}{2} \right) \cdot m_A \cdot \left( \vec{V}_{C_1} \right)^2 \]  

(F.1)

\[ = \left( \frac{1}{2} \right) \cdot m_A \cdot \left( \frac{dx_1}{dt} \right)^2. \]

It is clearly shown in Figure 2 that the second cart B (point \( C_2 \)) is involved in the translational motion along the upper horizontal axis, which is parallel to axis \( OX \) and is located from \( OX \) at the distance \( b \). Therefore, the kinetic energy of a 2D model of the bridge crane B can be analogously calculated by the same formula for kinetic energy of translational motion as

\[ T_2 = \left( \frac{1}{2} \right) \cdot m_B \cdot \left( \vec{V}_{C_2} \right)^2 = \left( \frac{1}{2} \right) \cdot m_B \cdot \left( \vec{V}_{C_2} \right)^2 \]  

(F.2)

\[ = \left( \frac{1}{2} \right) \cdot m_B \cdot \left( \frac{dx_2}{dt} \right)^2. \]

It is shown in Figures 1 and 2 that the heavy cross-beam ED can be considered as a solid rod, which is involved in parallel-plane motion. It is well known from the course of mechanics that the kinetic energy of the cross-beam ED in parallel-plane motion can be calculated with König’s theorem as

\[ T_3 = \left( \frac{1}{2} \right) \cdot m_{ED} \cdot \left( \vec{V}_{C_3} \right)^2 + \left( \frac{1}{2} \right) \cdot I_{C_3} \cdot \left( \vec{\omega}_{ED} \right)^2, \]  

(F.3)

where \( m_{ED} = m_3 \) is the mass of the cross-beam ED, \( \vec{V}_{C_3} = \vec{V}_{C_3x} + \vec{V}_{C_3z} \) is the vector of the linear velocity of the point \( C_3 \) (see formulae (D.1)–(D.5) of Appendix D), where point \( C_3 \) is the center of mass of the cross-beam ED, \( I_{C_3} = ((1/12) \cdot m_3 \cdot a^2) \) is the moment of inertia of the cross-beam ED with respect to the cross-beam central point \( C_3 \), and \( \vec{\omega}_{ED} = \vec{\omega}_3 \) is the vector of an angular velocity of the cross-beam ED, which is determined by formulae (B.7) and (5).

Substitution of scalar quantities into König’s theorem results in the following equation:

\[ T_3 = \left( \frac{1}{2} \right) \cdot m_3 \cdot \left( \left( \frac{dx_{C_3}}{dt} \right)^2 + \left( \frac{dz_{C_3}}{dt} \right)^2 \right) \]  

(F.4)

\[ + \left( \frac{1}{2} \right) \cdot \left( \frac{1}{12} \cdot m_3 \cdot a^2 \right) \cdot \left( \frac{dy}{dt} \right)^2, \]

where approximate values of time derivatives \( (dx_{C_3}/dt) \), \( (dz_{C_3}/dt) \) and \( (dy/dt) \) are determined by (5) and (D.5).

It was shown above that the first time derivatives \( (dz_{C_3}/dt) \) and \( (dy/dt) \) are second-order infinitesimal quantities. Therefore substitution of (5) and (D.5) into (F.4) results in zero-values of the following two terms of (F.4):

\( (dz_{C_3}/dt)^2 \approx 0 \) and \( (dy/dt)^2 \approx 0 \). Substitution of (5) and (D.5) into (F.4) proves the possibility of reducing the parallel-plane motion of the heavy cross-beam ED to planar motion.

Simplified formula (F.4) after linearization with (5) and (D.5) yields that

\[ T_3 \approx \left( \frac{1}{2} \right) \cdot m_3 \cdot \left( \frac{dx_{C_3}}{dt} \right)^2. \]  

(F.5)

Substitution of (D.5) into (F.5) results in

\[ T_3 \approx \left( \frac{1}{2} \right) \cdot m_3 \cdot \left( \left( \frac{dx_3}{dt} \right) + l_1 \cdot \left( \frac{dx_1}{dt} \right) \right)^2. \]  

(F.6)

It is possible to calculate the kinetic energy of mechanical system by substitution of (F.1), (F.2), and (F.6) into algebraic expression for the total kinetic energy:

\[ T = T_1 + T_2 + T_3 \]

\[ = \left( \frac{1}{2} \right) \cdot m_1 \cdot \left( \frac{dx_1}{dt} \right)^2 + \left( \frac{1}{2} \right) \cdot m_2 \cdot \left( \frac{dx_2}{dt} \right)^2 \]

\[ + \left( \frac{1}{2} \right) \cdot m_3 \cdot \left( \frac{dx_3}{dt} \right)^2 + \left( \frac{1}{2} \right) \cdot m_3 \cdot l_1^2 \cdot \left( \frac{da_1}{dt} \right)^2 \]  

(F.7)

\[ + \left( \frac{1}{2} \right) \cdot m_3 \cdot 2 \cdot \left( \frac{dx_1}{dt} \right) \cdot l_1 \cdot \left( \frac{dx_1}{dt} \right). \]
**G. System Lagrange Equations**

The first Lagrange equation for the generalized coordinate $x_1$ is as follows:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_1} \right) - \frac{\partial T}{\partial x_1} = Q_{x_1},
$$  \hspace{1cm} (G.1)

where $T$ and $Q_{x_1}$ are approximately determined by (10) and (E.2).

The partial derivative of the kinetic energy with respect to the first generalized velocity ($dx_1/dt$) yields

$$
\frac{\partial T}{\partial x_1} \approx \left( \frac{1}{2} \right) \cdot (m_1 + m_3) \cdot 2 \cdot \left( \frac{dx_1}{dt} \right) + m_3 \cdot l_1.
$$  \hspace{1cm} (G.2)

The full derivative of expression (G.2) with respect to time $t$ is as follows:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_1} \right) \approx \left( m_1 + m_3 \right) \cdot \left( \frac{d^2 x_1}{dt^2} \right) + m_3 \cdot l_1 \cdot \left( \frac{d^2 \alpha}{dt^2} \right).
$$  \hspace{1cm} (G.3)

It follows from (10) that the partial derivative of the kinetic energy with respect to the first generalized coordinate $x_1$ has a zero-value

$$
\frac{\partial T}{\partial x_1} = 0.
$$  \hspace{1cm} (G.4)

Substitution of (G.3) and (G.4) into (G.1) results in the following approximate expression of the left-hand side of the first Lagrange equation:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_1} \right) - \frac{\partial T}{\partial x_1} \approx \left( m_1 + m_3 \right) \cdot \left( \frac{d^2 x_1}{dt^2} \right) + m_3 \cdot l_1 \cdot \left( \frac{d^2 \alpha}{dt^2} \right).
$$  \hspace{1cm} (G.5)

Substitution of (G.5) and (E.2) into (G.1) gives the first simplified Lagrange equation:

$$(m_1 + m_3) \cdot \left( \frac{d^2 x_1}{dt^2} \right) + m_3 \cdot l_1 \cdot \left( \frac{d^2 \alpha}{dt^2} \right) = (-1) \cdot (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} \cdot (x_1 - x_2 + l_1 \alpha).
$$  \hspace{1cm} (G.6)

The second Lagrange equation for the generalized coordinate $x_2$ is as follows:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_2} \right) - \frac{\partial T}{\partial x_2} = Q_{x_2},
$$  \hspace{1cm} (G.7)

where $T$ and $Q_{x_2}$ are approximately determined by (10) and (E.4).

The partial derivative of the kinetic energy with respect to the second generalized velocity ($dx_2/dt$) yields

$$
\frac{\partial T}{\partial x_2} \approx \left( \frac{1}{2} \right) \cdot m_2 \cdot 2 \cdot \left( \frac{dx_2}{dt} \right).
$$  \hspace{1cm} (G.8)

The full derivative of expression (G.8) with respect to time $t$ is as follows:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_2} \right) \approx m_2 \cdot \left( \frac{d^2 x_2}{dt^2} \right).
$$  \hspace{1cm} (G.9)

It follows from (10) that the partial derivative of the kinetic energy with respect to the second generalized coordinate $x_2$ has a zero-value

$$
\frac{\partial T}{\partial x_2} = 0.
$$  \hspace{1cm} (G.10)

Substitution of (G.9) and (G.10) into (G.7) results in the following approximate expression of the left-hand side of the second Lagrange equation:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_2} \right) - \frac{\partial T}{\partial x_2} \approx m_2 \cdot \left( \frac{d^2 x_2}{dt^2} \right).
$$  \hspace{1cm} (G.11)

Substitution of (G.11) and (E.4) into (G.7) gives the second simplified Lagrange equation:

$$
m_2 \cdot \left( \frac{d^2 x_2}{dt^2} \right) = (+1) \cdot (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} \cdot (x_1 - x_2 + l_1 \alpha).
$$  \hspace{1cm} (G.12)

The third Lagrange equation for the generalized coordinate $\alpha$ is as follows:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\alpha}} \right) - \frac{\partial T}{\partial \alpha} = Q_{\alpha},
$$  \hspace{1cm} (G.13)

where $T$ and $Q_{\alpha}$ are approximately determined by (10) and (E.9).

The partial derivative of the kinetic energy with respect to the third generalized velocity ($d\alpha/dt$) yields

$$
\frac{\partial T}{\partial \alpha} \approx \left( \frac{1}{2} \right) \cdot m_3 \cdot l_1^2 \cdot 2 \cdot \left( \frac{d\alpha}{dt} \right) + m_3 \cdot l_1 \cdot \left( \frac{dx_1}{dt} \right).
$$  \hspace{1cm} (G.14)

The full derivative of expression (G.14) with respect to time $t$ is as follows:

$$
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\alpha}} \right) \approx m_3 \cdot l_1^2 \cdot \left( \frac{d^2 \alpha}{dt^2} \right) + m_3 \cdot l_1 \cdot \left( \frac{d^2 x_1}{dt^2} \right).
$$  \hspace{1cm} (G.15)
It follows from (10) that the partial derivative of the kinetic energy with respect to the third generalized coordinate \( \alpha \) has a zero-value
\[
\frac{\partial T}{\partial \alpha} \approx 0.
\] (G.16)

Substitution of (G.15) and (G.16) into (G.13) results in the following approximate expression of the left-hand side of the third Lagrange equation:
\[
d\left(\frac{\partial T}{\partial \dot{\alpha}}\right) + \frac{\partial T}{\partial \alpha} \approx m_3 \cdot l_1 \cdot \left(\frac{d^2 \alpha}{dt^2}\right) + m_3 \cdot l_1 \cdot \left(\frac{d^2 x_1}{dt^2}\right).
\] (G.17)

Substitution of (G.17) and (E.9) into (G.13) gives the third simplified Lagrange equation:
\[
m_3 \cdot l_1 \cdot \left(\frac{d^2 \alpha}{dt^2}\right) + m_3 \cdot l_1 \cdot \left(\frac{d^2 x_1}{dt^2}\right) \approx (m_3 g) \cdot \left(\frac{1}{2 \cdot l_2}\right) \cdot \left(- (l_1 \cdot l_2 + l_2^2) \cdot \alpha - x_1 \cdot l_1 + x_2 \cdot l_1\right).
\] (G.18)

**H. Numerical Estimation of Natural Frequencies for the Mechanical System**

It is possible to estimate the natural frequencies of the mechanical system with the system (13) of Lagrange equations (G.6), (G.12), and (G.18). After generation of the determinant of the natural frequencies matrix for system (13) it is possible to write the following characteristic biquadratic equation for system (13) of Lagrange equations (G.6), (G.12), and (G.18) in the form:
\[
\left|\begin{array}{ccc}
\frac{m_1 + m_3}{m_3} \cdot \lambda^2 + \frac{g}{2 \cdot l_2} & -\frac{g}{2 \cdot l_2} & \lambda^2 + \frac{g}{2 \cdot l_2} \\
-\frac{g}{2 \cdot l_2} & \frac{m_2}{m_3} \cdot \lambda^2 + \frac{g}{2 \cdot l_2} & -\frac{g}{2 \cdot l_2} \\
\lambda^2 + \frac{g}{2 \cdot l_2} & -\frac{g}{2 \cdot l_2} & (l_1 \cdot \lambda^2 + \frac{g}{2 \cdot l_2} \cdot (l_1 + l_2))
\end{array}\right| = 0.
\] (H.1)

The determinant (H.1) yields the following characteristic secular equation of sixth order for the above determined numerical values in Section 5:
\[
0.560 \cdot \lambda^6 + 7.073 \cdot \lambda^4 - 15.879 \cdot \lambda^2 - 23.602 = 0.
\] (H.2)

The numerical solution of the secular equation (H.2) gives the following set of roots:
\[
\lambda = \{\pm 1.676; \pm 1.021 \cdot i; \pm 3.794 \cdot i\}.
\] (H.3)

**I. Generalized Forces of the Guided Mechanical System**

Calculation of the generalized forces \( Q_{\delta (x_1)} \), \( Q_{\delta (x_2)} \), and \( Q_{\delta (\alpha)} \) in (I.1)–(I.3) requires the estimation of isochronous variation \( \delta (z_{C_3}) \) of the vertical coordinate \( z_{C_3} \) on the basis of approximate formula (D.2). The second equation of formulae (D.2) yields the following approximate expression for total ordinary differential of the vertical coordinate \( z_{C_3} \):
\[
d (z_{C_3}) \approx (l_1 \cdot \alpha) \cdot d (\alpha) + \left(\frac{a}{2}\right) \cdot \cos (\gamma_0) \cdot d (\delta). \quad (I.1)
\]

It is possible to get an approximate expression for total ordinary differential \( d (\delta) \) in (I.1) on the basis of the previously derived formula (5), which produces the following equation:
\[
d (\delta) = \frac{1}{(a \cdot l_2 \cdot \cos (\gamma_0))} \cdot \left((x_1 - x_2 + l_1 \alpha) \cdot (d (x_1) - d (x_2) + l_1 \cdot d (\alpha)) - l_1 \cdot l_2 \cdot \alpha \cdot d (\alpha)\right). \quad (I.2)
\]

Substitution of (I.2) into (I.1) results in the following expression:
\[
d (z_{C_3}) \approx (l_1 \cdot \alpha) \cdot d (\alpha) + \left(\frac{(a/2)}{a \cdot l_2 \cdot \cos (\gamma_0)}\right) \cdot \left((x_1 - x_2 + l_1 \alpha) \cdot (d (x_1) - d (x_2) + l_1 \cdot d (\alpha)) - l_1 \cdot l_2 \cdot \alpha \cdot d (\alpha)\right). \quad (I.3)
\]

The formal change of differential symbol \( d \) to the symbol of virtual displacement \( \delta \) in (I.3) corresponds to imaginary freezing of time variable \( t \) and gives the following expression for the isochronous variation \( \delta (z_{C_3}) \) of the vertical coordinate \( z_{C_3} \):
\[
\delta (z_{C_3}) \approx (l_1 \cdot \alpha) \cdot \delta (\alpha) + \frac{1}{(2 \cdot l_2)} \cdot \left((x_1 - x_2 + l_1 \alpha) \cdot (\delta (x_1) - \delta (x_2) + l_1 \cdot \delta (\alpha)) - l_1 \cdot l_2 \cdot \alpha \cdot \delta (\alpha)\right). \quad (I.4)
\]
where \(\delta(x_1); \delta(x_2); \) and \(\delta(\alpha)\) are the three independent isochronous variations of the three generalized coordinates \(x_1; x_2; \) and \(\alpha,\) which determine the current position of a 3DOF mechanical system in Figures 2 and 6.

Calculation of the first generalized force \(Q_{\delta(x_1)}\) requires the imposition of the first independent virtual displacement \(\delta(x_1) \neq 0\) to the mechanical system in Figure 6 with simultaneous "freezing" or "sticking down" of cart \(B\) to the upper rails and "freezing" or "sticking to the left" of cable \(AE\) to the vertical axis \(z\) factually assuming zero-values of another two virtual displacements \(\delta(x_2) = 0\) and \(\delta(\alpha) = 0:\)

\[
Q_{\delta(x_1)} = \left( \frac{1}{\delta(x_1)} \right) \cdot \left( \sum_k \delta A_k \delta(x_1) \right)_{\delta(x_1) = 0; \delta(\alpha) = 0} \quad \text{(I.5)}
\]

\[
= F_1 \cdot \delta(x_1) + (\delta A_1 (m_3g))_{\delta(x_1) = 0} \quad \text{(I.5)}
\]

\[
Q_{\delta(x_1)} = \frac{F_1 \cdot \delta(x_1) + (\delta A_1 (m_3g))_{\delta(x_1) = 0}}{\delta(x_1)} \quad \text{(I.6)}
\]

where the virtual work of the force \(F_2\) in (I.5)-(I.6) at the virtual displacement \(\delta(x_1) \neq 0\) has a zero-value because in our imagination we made "freezing" or "sticking down" of the cart \(B\) to the upper rails with \(\delta(x_2) = 0\).

The second term \((\delta A_1 (m_3g))\) in the numerator of (I.5) is the virtual work of the gravity force \(m_3g\) of the cross-beam \(ED\) in the case of \(\delta(x_1) \neq 0\) with \(\delta(x_2) = 0\) and \(\delta(\alpha) = 0.\) The minus sign in the numerator of (I.6) shows that gravity force \(m_3g\) has negative work due to lifting up the point \(C_3\) in this case in Figure 6. It is possible to calculate the algebraic expression of the isochronous variation \((\delta z_{C_3})\) in the present case through the substitution of \(\delta(x_2) = 0\) and \(\delta(\alpha) = 0\) into (1.4):

\[
(\delta z_{C_3})_{\delta(x_1)} = (\delta z_{C_3})_{\delta(x_1) = 0; \delta(\alpha) = 0} \approx \frac{1}{2 \cdot l_3} \cdot ((x_1 - x_2 + I_1 \alpha) \cdot (\delta x_1)) \quad \text{(I.7)}
\]

Substitution of (I.7) into (I.6) results in the following expression:

\[
Q_{\delta(x_1)} = \frac{F_1 \cdot \delta(x_1) + (-1) \cdot (m_3g) \cdot \frac{1}{2 \cdot l_3} \cdot ((x_1 - x_2 + I_1 \alpha) \cdot (\delta x_1))}{\delta(x_1)} \quad \text{(I.8)}
\]

After simplifications (I.8) produces that

\[
Q_{\delta(x_1)} \approx F_1 - (m_3g) \cdot \frac{1}{2 \cdot l_3} \cdot (x_1 - x_2 + I_1 \alpha) \quad \text{(I.9)}
\]

Derived expression (I.9) generalizes previous formula (E.2) in the case of \(F_1 \neq 0.\) Formula (I.9) has been independently derived through virtual displacements. Similarity of expressions (E.2) and (I.9) proves the correctness of the proposed mathematical model. Substitution of \(F_1 = 0\) into (I.9) again yields (E.2) that proves and confirms the correctness of (E.2).

Calculation of the second generalized force \(Q_{\delta(x_2)}\) requires the imposition of the second independent virtual displacement \(\delta(x_2) \neq 0\) to the mechanical system in Figure 6 with simultaneous "freezing" or "sticking down" of cart \(A\) to the lower rails and "freezing" or "sticking to the left" of cable \(AE\) to the vertical axis \(z\) factually assuming zero-values of another two virtual displacements \(\delta(x_1) = 0\) and \(\delta(\alpha) = 0:\)

\[
Q_{\delta(x_2)} = \left( \frac{1}{\delta(x_2)} \right) \cdot \left( \sum_k \delta A_k \delta(x_2) \right)_{\delta(x_2) = 0; \delta(\alpha) = 0} \quad \text{(I.10)}
\]

\[
= F_2 \cdot \delta(x_2) + (\delta A_2 (m_3g))_{\delta(x_2) = 0} \quad \text{(I.10)}
\]

\[
Q_{\delta(x_2)} = \frac{F_2 \cdot \delta(x_2) + (\delta A_2 (m_3g))_{\delta(x_2) = 0}}{\delta(x_2)} \quad \text{(I.11)}
\]

where the virtual work of the force \(F_1\) in (I.10)-(I.11) at the virtual displacement \(\delta(x_2) \neq 0\) has a zero-value because in our imagination we made "freezing" or "sticking down" of the cart \(A\) to the lower rails with \(\delta(x_1) = 0.\)

The second term \((\delta A_2 (m_3g))\) in the numerator of (I.10) is the virtual work of the gravity force \(m_3g\) of the cross-beam \(ED\) in the case of \(\delta(x_2) \neq 0\) with \(\delta(x_1) = 0\) and \(\delta(\alpha) = 0.\) The minus sign in the numerator of (I.11) shows that gravity force \(m_3g\) has negative work due to lifting up the point \(C_3\) in this case in Figure 6. It is possible to calculate the algebraic expression of the isochronous variation \((\delta z_{C_3})\) in the present case through the substitution of \(\delta(x_1) = 0\) and \(\delta(\alpha) = 0\) into (1.4):

\[
(\delta z_{C_3})_{\delta(x_2)} = (\delta z_{C_3})_{\delta(x_2) = 0; \delta(\alpha) = 0} \approx \frac{1}{2 \cdot l_3} \cdot ((x_1 - x_2 + I_1 \alpha) \cdot (\delta x_2)) \quad \text{(I.12)}
\]
Substitution of (I.12) into (I.11) results in the following expression:

\[
Q_{\delta(x_2)} = \frac{F_2 \cdot \delta (x_2) + (-1) \cdot (m_3 g) \cdot 1/ (2 \cdot l_2) \cdot (x_1 - x_2 + l_1 \alpha) \cdot (-1) \cdot \delta (x_2)}{\delta (x_2)}. \tag{1.13}
\]

After simplifications (1.13) produces that

\[
Q_{\delta(x_2)} = F_2 + (m_3 g) \cdot \frac{1}{(2 \cdot l_2)} \cdot (x_1 - x_2 + l_1 \alpha). \tag{1.14}
\]

Derived expression (1.14) generalizes previous formula (E.4) in the case of \( F_2 \neq 0 \). Formula (1.14) has been independently derived through virtual displacements. Similarity of expressions (E.4) and (I.14) proves the correctness of proposed mathematical model. Substitution of \( F_2 = 0 \) into (I.14) yields again (E.4) that proves and confirms the correctness of (E.4).

Calculation of the third generalized force \( Q_{\delta(\alpha)} \) requires the imposition of the third independent virtual displacement \( \delta(\alpha) \neq 0 \) to the mechanical system in Figure 6 with simultaneous “freezing” or “sticking down” of cart A to the lower rails and “freezing” or “sticking down” of cart B to the upper rails factually assuming zero-values of another two virtual displacements \( \delta(x_1) = 0 \) and \( \delta(x_2) = 0 \):

\[
Q_{\delta(\alpha)} = \left( \frac{1}{\delta (\alpha)} \right) \cdot \left( \left( \sum_k \delta A^k_{\delta(\alpha)} \right) \right)_{\delta(x_1)=0, \delta(x_2)=0}.
\tag{1.15}
\]

The derived expression (1.15) is completely identical to previous formula (E.6). Formula (1.15) has been independently derived through virtual displacements. Coincidence of expressions (E.6) and (1.15) proves the correctness of the proposed mathematical model.

J. Lagrange Equations of the Guided Mechanical System

Application of independent control forces \( F_1 = u_1(t) \) [N] and \( F_2 = u_2(t) \) [N] requires the estimation of new values of three generalized forces \( Q_{\delta x_1}, Q_{\delta x_2}, \) and \( Q_{\delta \alpha} \) in the right-hand sides of the following Lagrange equations for Figure 6:

\[
a \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_1} \right) - \frac{\partial T}{\partial x_1} = Q_{\delta x_1}; \tag{1.1}
\]

\[
a \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_2} \right) - \frac{\partial T}{\partial x_2} = Q_{\delta x_2}; \tag{1.2}
\]

\[
a \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\alpha}} \right) - \frac{\partial T}{\partial \alpha} = Q_{\delta \alpha}. \tag{1.3}
\]
where magnitudes of generalized forces $Q_8(x_1)$, $Q_8(x_2)$, and $Q_8(\delta x)$ are determined by the action of three independent external forces $F_1 = u_1(t)$ [N], $F_2 = u_2(t)$ [N], and $m_3g$ [N] (Figure 6). The left-hand sides of Lagrange equations (1.1–(1.3) are determined by (G.5), (G.11), and (G.17).

Substitution of (G.5) and (I.9) into (J.1) results in the following first Lagrange equation for the guided mechanical system:

$$
(m_1 + m_3) \cdot \left( \frac{d^2 x_1}{dt^2} \right) + m_3 \cdot l_1 \cdot \left( \frac{d^2 \alpha}{dt^2} \right) = F_1 - (m_3g) \cdot \frac{1}{(2 \cdot l_2)} \cdot (x_1 - x_2 + l_1 \alpha) \quad (J.4)
$$

Substitution of (G.11) and (I.14) into (J.2) results into the following second Lagrange equation for the guided mechanical system:

$$
m_2 \cdot \left( \frac{d^2 x_2}{dt^2} \right) = F_2 + (m_3g) \cdot \frac{1}{(2 \cdot l_2)} \cdot (x_1 - x_2 + l_1 \alpha) \quad (J.5)
$$

Substitution of (G.17) and (I.19) into (J.3) results into the following third Lagrange equation for the guided mechanical system:

$$
m_3 \cdot \left( \frac{d^2 \alpha}{dt^2} \right) + m_3 \cdot l_1 \cdot \left( \frac{d^2 x_1}{dt^2} \right) = (-1) \cdot (m_3g) \cdot \left( l_1 \cdot \alpha \right) + \frac{1}{(2 \cdot l_2)} \cdot (l_1 \cdot (x_1 - x_2 + l_1 \alpha) - l_1 \cdot l_2 \cdot \alpha) \quad (J.6)
$$

### Nomenclature

**DOF:** Degree of freedom  
**ODE:** Ordinary differential equation  
**point A:** Point of bridge crane 1 position  
**point B:** Point of bridge crane 2 position  
**DE:** Cross-beam 3  
**point C:** Point of gravity center of cross-beam 3  
**g:** Scalar value of gravitational acceleration (m/s²)  
**t:** Current time (s)  
**l₁:** Length of the left cable AE, that is, $l_{AE} = l_1$ (m)  
**l₂:** Length of the right cable BD, that is, $l_{BD} = l_2$ (m)  
**a:** Length of cross-beam DE (m)  
**b:** Vertical distance between the carts A and B (m)  
**x₁:** The horizontal coordinate of bridge crane p. A (m)  
**dx₁/dt:** The horizontal projection of bridge crane p. A velocity (m/s)  
**x₂:** The horizontal coordinate of bridge crane p. B (m)  
**dx₂/dt:** The horizontal projection of bridge crane p. B velocity (m/s)  
**x₃:** The horizontal projection of p. C₃ (m)  
**dx₃/dt:** The horizontal projection of p. C₃ velocity (m/s)  
**y:** The inclination angle of cross-beam DE with horizontal line (rad)  
**dy/dt:** The angular velocity of cross-beam DE around horizontal line or around p. E (rad/s)  
**d²y/dt²:** The angular acceleration of cross-beam DE around horizontal line or around p. E (rad/s²)  
**m₁:** Mass of bridge crane p. A (kg)  
**m₂:** Mass of bridge crane p. B (kg)  
**m₃:** Mass of cross-beam DE (kg)  
**T:** Kinetic energy of the system “heavy cross-beam, two moving carts” (J = N-m)  
**Π:** Potential energy of the system “heavy cross-beam, two moving carts” (J = N-m)  
**Q₈:** Generalized forces (N)  
**λₗ:** Roots of the secular equation  
**k₁; k₂:** First and second natural frequencies of system oscillations (1/s)  
**τ₁; τ₂:** First and second natural periods of system oscillations (s).

### Additional Points

**Highlights.** A new 2D model of a 3DOF system “two moving bridge cranes, transported cross-beam” was proposed. A new open loop optimal control problem was formulated and solved with JModelica.org freeware. Simple engineering methodology for optimal control realization was proposed.
Disclosure

The submission of the authors' paper implies that it has not been previously published, that it is not under consideration for publication elsewhere, and that it will not be published elsewhere in the same form without the written permission of the editors.

Competing Interests

The authors Alexander V. Perig, Alexander N. Stadnik, Alexander A. Kostikov, and Sergey V. Podlesny declare that there is no conflict of interests regarding the publication of this paper.

Authors’ Contributions

All authors participated in the design of this work and performed equally. All authors read and approved the final manuscript.
