Nonlinear differential equations for an electromechanical integrated magnetic gear (EIMG) system are developed by considering the nonlinearity in the magnetic force of the system components. Expressions for the main resonances and superharmonic resonances are obtained for output wave frequencies close to the natural frequency and half the natural frequency of the derived EIMG system. The response laws are discussed in detail. The magnetic coupling stiffness among the components is found to exhibit distinct nonlinearity, leading to strong main resonances and superharmonic resonances. Smaller values of the magnetic coupling stiffness and damping result in larger response amplitudes and transient responses that slowly decay to zero. When the main resonances and superharmonic resonances occur, the dominant frequency of the response is the natural frequency of the derived EIMG system, and the amplitudes of different components of the resonance display large differences.

1. Introduction

Magnetic drives, and especially magnetic gear boxes, are extensively used in the medical, food, and chemical industries. These systems have the advantages of being contactless, wear-free, and lubrication-free, with low levels of vibration and noise, and built-in overload protection [1]. The field-modulated magnetic gear (FMMG) has a coaxial topology, which significantly improves the permanent magnet (PM) utilization rate and can generate much higher torque and torque density than traditional magnetic gears that use a parallel shaft topology [2]. Therefore, FMMGs are widely used in the vehicle, wind, marine, and aerospace fields [3–5]. Various high-performance FMMG-based systems have been proposed, such as axial-flux magnetic gears, linear magnetic gears, and intersecting axes magnetic gears [6–8]. Various direct current PM rotors and alternating current PM motors have been developed for use in electric vehicles and wind power systems [9, 10]. Together, these innovations have significantly promoted the development of magnetic gears.

Electrical and control techniques are widely used in mechanical engineering, resulting in the development of many cutting-edge composite drives such as the electromagnetic harmonic drive and electromechanical integrated toroidal drive. One of the authors has previously presented a drive system known as the electromechanical integrated magnetic gear (EIMG) [11]. This integrates power and control systems into FMMG. Thus, EIMG possesses the advantages of FMMG alongside a compact structure with torque and speed control. Compared with FMMG, EIMG can generate higher torque at lower speeds. EIMG can transmit torque by magnetic field coupling, unlike mechanical gears, which require direct contact to do so. The magnetic coupling stiffness of EIMG is much lower than the contact stiffness of mechanical gears [12, 13], and EIMG has different dynamic characteristics compared with mechanical gear systems. Because EIMG system has a lower magnetic coupling stiffness, its natural frequencies are much lower than those of mechanical gear systems. As a result, low-frequency resonance can easily occur. When such resonance occurs, the amplitudes of the EIMG system’s components slowly attenuate, degrading the dynamics of the system. To overcome this problem, Frank et al. added damper windings to synchronous generators to suppress the oscillations caused by transients [14]. Montague et al. used servo control in magnetic gears to overcome the disadvantages of low stiffness [15].
As EIMG is a relatively new type of magnetic gear, its dynamics should be thoroughly studied to control the behavior and improve the service performance of such a system. This study develops a dynamic model and differential equations for EIMG system by considering the nonlinearity of the magnetic coupling stiffness. The main resonances and superharmonic resonances produced by a torque wave are discussed, and these provide the foundation for the parameter optimization and performance improvement of the EIMG system.

2. Nonlinear Dynamic Model of EIMG

Figure 1 shows the inner rotor, inner and outer stator, and inner and outer ferromagnetic pole-pieces (FP) that comprise an EIMG system. All components are concentric, and the EIMG has four air gaps. Windings made of insulated wire are mounted in the dew-drop slot of the inner stator. PMs are positioned uniformly on the inner surface of the outer stator and the inner and outer surfaces of the inner rotor. The inner and outer FP comprise permeable and nonpermeable magnetic materials layered at regular intervals. FP modulate the magnetic fields in the two air gaps next to them, thus ensuring that the number of pole pairs of PMs on the inner rotor and outer stator agrees with the number of pole pairs of the space harmonic flux density of the air gaps.

A three-phase alternating current is supplied to the inner stator coils to generate a rotary magnetic field with a main harmonic of \( p_1 \). After being modulated by the inner FP, the main harmonic \( p_2 \) of the magnetic field in the second air gap is consistent with the number of pole pairs of PMs on the inner surface of the inner rotor. Therefore, the inner rotor can be actuated, thereby realizing the first drive. When the inner rotor runs, a magnetic field with a main harmonic of \( p_3 \) in the third air gap is generated and modulated by the outer FP. As a result, the main harmonic \( p_4 \) of the magnetic field in the fourth air gap becomes equal to the number of pole pairs of PMs on the outer stator. Then, the second drive is achieved.

To realize equal pole coupling among the EIMG components, \( p_1, p_2, p_3, \) and \( p_4 \) have the following constraint relations:

\[
\begin{align*}
p_{12} &= p_1 + p_2, \\
p_{34} &= p_3 + p_4, \\
\end{align*}
\]

where \( p_1 \) is the number of pole pairs of the three-phase alternating current and \( p_2, p_3, \) and \( p_4 \) are the number of pole pairs of PMs on the stator and the inner and outer surfaces of the inner rotor, respectively.

The magnetic coupling torques among the components are calculated as follows:

\[
\begin{align*}
T_1 &= T_{c1} \sin (p_1 \theta_{12} + \theta_{10}), \\
T_3 &= T_{c3} \sin (p_3 \theta_{23} + \theta_{10}) = T_{c3} \sin (p_3 \theta_{34} + \theta_{20}), \\
T_5 &= T_{c5} \sin (p_5 \theta_{5} + \theta_{20}),
\end{align*}
\]

where \( T_1, T_3, \) and \( T_5 \) are the torques on the inner stator, inner rotor, and outer stator, respectively; \( T_{c1}, T_{c3}, \) and \( T_{c5} \) are the maximum torques on the inner stator, inner rotor, and outer stator, respectively; \( \theta_{10} \) and \( \theta_{20} \) are the relative rotation angles between the inner stator and inner rotor and between the inner rotor and outer stator, respectively; and \( \theta_{12}, \theta_{23}, \theta_{34}, \) and \( \theta_{5} \) are the relative torsional displacements between the inner stator and inner FP, inner FP and inner rotor, inner rotor and outer FP, and outer FP and outer stator, respectively.

Figure 2 shows the dynamic model of the EIMG system. This model contains four subsystems: inner stator/inner FP subsystem, inner FP/inner rotor subsystem, inner rotor/outer FP subsystem, and outer FP/outer stator subsystem. Because the magnetic coupling stiffness is much lower than the supporting stiffness [12], only torsional displacements are considered, and transverse vibration displacements are assumed to be negligible.

The tangential magnetic coupling forces among the components are calculated as follows:

\[
\begin{align*}
F_{c1} &= \frac{T_{c1}}{R_1} = \frac{T_{c1}}{R_1} \sin (p_1 \theta_{12} + \theta_{10}), \\
F_{c3} &= \frac{T_{c3}}{R_3} = \frac{T_{c3}}{R_3} \sin (p_3 \theta_{23} + \theta_{10}), \\
F_{c5} &= \frac{T_{c5}}{R_5} = \frac{T_{c5}}{R_5} \sin (p_5 \theta_{5} + \theta_{20}),
\end{align*}
\]

where \( F_{c1}, F_{c3}, \) and \( F_{c5} \) are the tangential magnetic coupling forces between the inner stator and inner FP, inner FP and inner rotor, inner rotor and outer FP, and outer FP and outer stator, respectively; \( R_1, R_3, \) and \( R_5 \) are the equivalent radius of gyration of the inner stator, inner rotor, and outer stator, respectively; and \( \theta_{k} (k = 1, 2, 3, 4, 5) \) is the torsional angular displacement of the inner stator, inner FP, inner rotor, outer FP, and outer stator, respectively.

For convenience, the torsional angular displacements are all replaced by their corresponding torsional displacements as

\[
x = [x_1 \ x_2 \ x_3 \ x_4 \ x_5]^T,
\]

where \( x_k (k = 1, 2, 3, 4, 5) \) is the torsional displacement of the inner stator, inner FP, inner rotor, outer FP, and outer stator, respectively, and \( x_k = R_k \theta_k \).
The magnetic coupling forces among the components are functions of the relative torsional displacements. When \( t = 0 \), namely, \( x_i = 0 \), the magnetic coupling forces are expanded using the Taylor series as

\[
\begin{align*}
F_{\text{II}} &= h_1 + a_1x_1 + b_1x_2 + c_1x_1^2 + d_1x_2^2 + e_1x_1x_2, \\
F_{\text{III}} &= h_2 + a_2x_2 + b_2x_3 + c_2x_2^2 + d_2x_3^2 + e_2x_2x_3, \\
F_{\text{IO}} &= h_3 + a_3x_3 + b_3x_4 + c_3x_3^2 + d_3x_4^2 + e_3x_3x_4, \\
F_{\text{OO}} &= h_4 + a_4x_4 + b_4x_5 + c_4x_5^2 + d_4x_5^2 + e_4x_4x_5,
\end{align*}
\]

(5)

where \( h_1 = T_{\text{c}}\sin\theta_{10}/R_1 \), \( a_1 = T_{\text{c}}p_1 \cos\theta_{10}/R_1^2 \), \( b_1 = -T_{\text{c}}p_1 \cos^2\theta_{10}/R_1R_2^2 \), \( c_1 = T_{\text{c}}p_1^2 \cos^2\theta_{10}/2R_1R_2^2 \), \( d_1 = T_{\text{c}}p_1^3 \cos^2\theta_{10}/2R_1^3 \), \( e_1 = -T_{\text{c}}p_1^4 \cos\theta_{10}/R_1^4 \), \( h_2 = T_{\text{d}}\sin\theta_{10}/R_3 \), \( a_2 = T_{\text{d}}p_2 \cos\theta_{10}/R_3R_4^2 \), \( b_2 = -T_{\text{d}}p_2 \cos\theta_{10}/R_3^3 \), \( c_2 = T_{\text{d}}p_2^2 \cos\theta_{10}/2R_3R_4^2 \), \( d_2 = T_{\text{d}}p_2^3 \cos\theta_{10}/2R_3^3 \), \( e_2 = -T_{\text{d}}p_2^4 \cos\theta_{10}/R_3^4 \), \( h_3 = T_{\text{d}}\sin\theta_{20}/R_3 \), \( a_3 = T_{\text{d}}p_3 \cos\theta_{20}/R_3R_4^2 \), \( b_3 = -T_{\text{d}}p_3 \cos\theta_{20}/R_3R_4^2 \), \( c_3 = T_{\text{d}}p_3^2 \cos\theta_{20}/2R_3R_4^2 \), \( d_3 = T_{\text{d}}p_3^3 \cos\theta_{20}/2R_3^3 \), \( e_3 = T_{\text{d}}p_3^4 \cos\theta_{20}/R_3^4 \), \( h_4 = T_{\text{co}}\sin\theta_{20}/R_5 \), \( a_4 = T_{\text{co}}p_4 \cos\theta_{20}/R_5^2 \), \( b_4 = -T_{\text{co}}p_4 \cos\theta_{20}/R_5^3 \), \( c_4 = T_{\text{co}}p_4^2 \cos\theta_{20}/2R_5^3 \), \( d_4 = T_{\text{co}}p_4^3 \cos\theta_{20}/2R_5^4 \), \( e_4 = -T_{\text{co}}p_4^4 \cos\theta_{20}/R_5^4 \).

Figure 2: Nonlinear dynamic model of electromechanical integrated magnetic gear.
The magnetic coupling forces among the components are nonlinear functions of the relative torsional displacements. The constant components of the Taylor series expansions of the magnetic coupling forces will lead to relative static displacements rather than dynamic displacements. Therefore, \( h_i \) is neglected. Based on Newton's second law of motion, the nonlinear dynamic differential equations of an EIMG system can be expressed as follows:

\[
M_i \ddot{x}_i + c_i \dot{x}_i + a_i x_i + b_i x_2 + c_i x_i^2 + d_i x_i^4 + e_i x_i x_2 = k_i x_i = 0,
\]

\[
M_2 \ddot{x}_2 + c_0 \dot{x}_2 - (a_1 x_1 + b_1 x_2 + c_1 x_1^2 + d_1 x_2^2 + e_1 x_1 x_2) + (a_2 x_2 + b_2 x_3 + c_2 x_3^2 + d_2 x_3^4 + e_2 x_2 x_3) + k_{ii} x_2 = 0,
\]

\[
M_3 \ddot{x}_3 + c_3 x_3 - (a_3 x_2 + b_3 x_4 + c_3 x_3^2 + d_3 x_4^2 + e_3 x_3 x_4) + (a_4 x_4 + b_4 x_5 + c_4 x_4^2 + d_4 x_4^3 + e_4 x_4 x_5) = 0,
\]

\[
M_4 \ddot{x}_4 + c_{of} \dot{x}_4 - (a_5 x_3 + b_5 x_4 + c_5 x_4^2 + d_5 x_4^2 + e_5 x_3 x_4) + (a_6 x_4 + b_6 x_5 + c_6 x_4^2 + d_6 x_4^3 + e_4 x_4 x_5) = \frac{\Delta T \cos \omega_c t}{R_4},
\]

\[
M_{of} \ddot{x}_5 + c_{of} x_5 - (a_7 x_4 + b_7 x_5 + c_7 x_5^2 + d_4 x_4^3 + e_4 x_4 x_5) + k_{of} x_5 = 0,
\]

where \( m_1 \) and \( m_2 \) are the masses of the inner stator and inner FP; respectively; \( M_1 \) (\( M_1 = I_1 / R_1^2 \)) and \( M_2 \) (\( M_2 = I_2 / R_2^2 \)) are the equivalent masses of the inner stator and inner FP along their torsional vibration direction, respectively; \( I_1 \) (\( I_1 = m_1 \cdot R_1^2 / 2 \) and \( I_2 \) (\( I_2 = m_2 \cdot R_2^2 / 2 \)) are the mass moments of inertia of the inner stator and inner FP, respectively; \( m_3 \) and \( M_3 \) (\( M_3 = I_3 / R_3^2 \)) are the mass and equivalent mass of the inner rotor, respectively; \( I_3 \) (\( I_3 = m_3 \cdot R_3^2 / 2 \)) is the mass moment of inertia of the inner rotor; \( m_4 \) and \( M_4 \) (\( M_4 = I_4 / R_4^2 \)) are the mass and equivalent mass of the outer FP, respectively; \( I_4 \) (\( I_4 = m_4 \cdot R_4^2 / 2 \)) is the mass moment of inertia of the outer FP; \( m_5 \) and \( M_5 \) (\( M_5 = I_5 / R_5^2 \)) are the mass and equivalent mass of the outer FP, respectively; \( I_5 \) is the mass moment of inertia of the outer stator; \( k_s, k_{ot}, k_{of} \) and \( k_0 \) are the torsional support stiffness values of the inner stator, inner FP, and outer stator, respectively; \( c_s, c_{ot}, c_{of}, \) and \( c_o \) are the damping coefficients of the inner stator, inner FP, inner rotor, outer rotor, and outer FP, respectively.

Equation (6) can be rewritten in matrix form as

\[
[M] \ddot{x} + [c] \dot{x} + [k] x = [F] + \Delta [F].
\]

The constant components of the Taylor series expansions of the magnetic coupling forces will lead to relative static displacements rather than dynamic displacements. Therefore, \( h_i \) is neglected. Based on Newton's second law of motion, the nonlinear dynamic differential equations of an EIMG system can be expressed as follows:

\[
M_i \ddot{x}_i + c_i \dot{x}_i + a_i x_i + b_i x_2 + c_i x_i^2 + d_i x_i^4 + e_i x_i x_2 = k_i x_i = 0,
\]

\[
M_2 \ddot{x}_2 + c_0 \dot{x}_2 - (a_1 x_1 + b_1 x_2 + c_1 x_1^2 + d_1 x_2^2 + e_1 x_1 x_2) + (a_2 x_2 + b_2 x_3 + c_2 x_3^2 + d_2 x_3^4 + e_2 x_2 x_3) + k_{ii} x_2 = 0,
\]

\[
M_3 \ddot{x}_3 + c_3 x_3 - (a_3 x_2 + b_3 x_4 + c_3 x_3^2 + d_3 x_4^2 + e_3 x_3 x_4) + (a_4 x_4 + b_4 x_5 + c_4 x_4^2 + d_4 x_4^3 + e_4 x_4 x_5) = 0,
\]

\[
M_4 \ddot{x}_4 + c_{of} \dot{x}_4 - (a_5 x_3 + b_5 x_4 + c_5 x_4^2 + d_5 x_4^2 + e_5 x_3 x_4) + (a_6 x_4 + b_6 x_5 + c_6 x_4^2 + d_6 x_4^3 + e_4 x_4 x_5) = \frac{\Delta T \cos \omega_c t}{R_4},
\]

\[
M_{of} \ddot{x}_5 + c_{of} x_5 - (a_7 x_4 + b_7 x_5 + c_7 x_5^2 + d_4 x_4^3 + e_4 x_4 x_5) + k_{of} x_5 = 0,
\]

where \( \Delta T \) is the amplitude of the torque fluctuation and \( \omega_c \) is the excitation frequency of the torque wave.

Equation (7) can be normalized as

\[
\ddot{x}_N + \frac{c_N}{M_{of}} \dot{x}_N + \frac{k_N}{M_{of}} x_N = F_N,
\]

where \( \dot{x}_N, k_N, \) and \( F_N \) are the normal displacement vector, normal stiffness matrix, and normal equivalent load vector, respectively; these are expressed as follows:

\[
x_N = [x_{N1} \ x_{N2} \ x_{N3} \ x_{N4} \ x_{N5}]^T,
\]

\[
k_N = \text{diag} \{ (k_{N1} 0 0 0 0) \},
\]

\[
F_N = \left[ F_{N1} \ F_{N2} \ F_{N3} \ F_{N4} \ F_{N5} \right]^T,
\]

\[
F_N = A_{N4k} \frac{\Delta T \cos \omega_c t}{R_4} + A_{N4k} F_1 + A_{N2k} F_2 + A_{N3k} F_3 + A_{N4k} F_4 + A_{N5k} F_5,
\]

where \( \omega_c \) is the natural frequency of the linear system derived for the EIMG.

Because the damping matrix \( c \) is diagonal, the elements on the primary diagonal of the normal damping matrix \( c_N \) are much larger than the other elements. Therefore, the normal...
damping matrix $c_N$ in (9) is simplified into the following diagonal matrix:

$$c_N = \text{diag } [(c_{N1}, c_{N2}, c_{N3}, c_{N4}, c_{N5})].$$

(11)

### 3. Main Resonance

A multiscale method is used to solve (9). To balance the effects of the damping forces and nonlinear elements and express them in the same perturbation equation, the following assumptions are made:

$$x_{Nk} = x_{Nk0} (T_0, T_1) + \varepsilon x_{Nk1} (T_0, T_1) + \cdots,$$

$$\Delta T = \epsilon \Delta T',$$

(12)

$$c_{Nk} = \varepsilon c_{Nk}.'$$

When the wave frequency of the output torque is close to the natural frequency of the outer FP rotational mode, the following assumption is introduced:

$$\omega_c = \omega_k + \varepsilon \sigma_1.$$  

(13)

By substituting (12) and (13) into (9) and setting the power coefficients of the small parameters $\varepsilon$ on both sides of the equations to be equal, the following differential equations are obtained:

Zero power

$$D_0^2 x_{Nk0} + \omega_k^2 x_{Nk0} = 0$$

(14)

First power

$$D_0^2 x_{Nk1} + \omega_k^2 x_{Nk1} = -c_{N1} D_0 x_{Nk0} - 2 D_0 D_1 x_{Nk0} + F_{Nk0},$$

(15)

where

$$F_{Nk0} = \frac{A_{Nk4} \Delta T' \cos \omega_T t}{R_4} + A_{Nk1} F_{10} + A_{Nk2} F_{20} + A_{Nk3} F_{30} + A_{Nk4} F_{40} + A_{Nk5} F_{50},$$

$$F_{10} = \left(-c_1 x_{10} + d_1 x_{20}^2 + e_1 x_{10} x_{20}\right),$$

$$F_{20} = c_1 x_{10} + d_1 x_{20}^2 + e_1 x_{10} x_{20} - \left(c_2 x_{30}^2 + d_2 x_{20} x_{30} + e_2 x_{20} x_{30}\right),$$

$$F_{30} = c_2 x_{30} + d_2 x_{20} + e_2 x_{20} x_{30} - \left(c_3 x_{50}^2 + d_3 x_{40} + e_3 x_{50} x_{40}\right),$$

$$F_{40} = c_3 x_{50}^2 + d_3 x_{40} + e_3 x_{50} x_{40} - \left(c_4 x_{70}^2 + d_4 x_{60} + e_4 x_{70} x_{60}\right),$$

$$F_{50} = c_4 x_{70}^2 + d_4 x_{60} + e_4 x_{70} x_{60}.$$

(16)

Under the normal coordinate system, the general solution of (14) is expressed as

$$x_{Nk0} = A_k (T_1) e^{i \omega_k T_0} + \text{cc}.$$  

(17)

Under the regular coordinate system, the solutions of (14) are

$$x_{10} = \alpha_1 A_1 (T_1) e^{i \omega_k T_0} + \alpha_2 A_2 (T_1) e^{i \omega_k T_0} + \alpha_3 A_3 (T_1) e^{i \omega_k T_0} + \alpha_4 A_4 (T_1) e^{i \omega_k T_0} + \alpha_5 A_5 (T_1) e^{i \omega_k T_0} + \text{cc},$$

$$x_{20} = \beta_1 A_1 (T_1) e^{i \omega_k T_0} + \beta_2 A_2 (T_1) e^{i \omega_k T_0} + \beta_3 A_3 (T_1) e^{i \omega_k T_0} + \beta_4 A_4 (T_1) e^{i \omega_k T_0} + \beta_5 A_5 (T_1) e^{i \omega_k T_0} + \text{cc},$$

$$x_{30} = \gamma_1 A_1 (T_1) e^{i \omega_k T_0} + \gamma_2 A_2 (T_1) e^{i \omega_k T_0} + \gamma_3 A_3 (T_1) e^{i \omega_k T_0} + \gamma_4 A_4 (T_1) e^{i \omega_k T_0} + \gamma_5 A_5 (T_1) e^{i \omega_k T_0} + \text{cc},$$

$$x_{40} = \mu_1 A_1 (T_1) e^{i \omega_k T_0} + \mu_2 A_2 (T_1) e^{i \omega_k T_0} + \mu_3 A_3 (T_1) e^{i \omega_k T_0} + \mu_4 A_4 (T_1) e^{i \omega_k T_0} + \mu_5 A_5 (T_1) e^{i \omega_k T_0} + \text{cc},$$

$$x_{50} = \eta_1 A_1 (T_1) e^{i \omega_k T_0} + \eta_2 A_2 (T_1) e^{i \omega_k T_0} + \eta_3 A_3 (T_1) e^{i \omega_k T_0} + \eta_4 A_4 (T_1) e^{i \omega_k T_0} + \eta_5 A_5 (T_1) e^{i \omega_k T_0} + \text{cc},$$

(18)

where $\alpha_1 = A_{N11}$, $\alpha_2 = A_{N12}$, $\alpha_3 = A_{N13}$, $\alpha_4 = A_{N14}$, and $\alpha_5 = A_{N15}$; $\beta_1 = A_{N21}$, $\beta_2 = A_{N22}$, $\beta_3 = A_{N23}$, $\beta_4 = A_{N24}$, and $\beta_5 = A_{N25}$; $\gamma_1 = A_{N31}$, $\gamma_2 = A_{N32}$, $\gamma_3 = A_{N33}$, $\gamma_4 = A_{N34}$, and $\gamma_5 = A_{N35}$; $\mu_1 = A_{N41}$, $\mu_2 = A_{N42}$, $\mu_3 = A_{N43}$, $\mu_4 = A_{N44}$, and $\mu_5 = A_{N45}$; and $\eta_1 = A_{N51}$, $\eta_2 = A_{N52}$, $\eta_3 = A_{N53}$, $\eta_4 = A_{N54}$, and $\eta_5 = A_{N55}$. Here, $A_{Nkj}$ denotes the element in the $k$th row and $j$th column of the normal modal matrix $A_N$:

$$A_N = \begin{bmatrix} A_{N11} & A_{N12} & A_{N13} & A_{N14} & A_{N15} \\ A_{N21} & A_{N22} & A_{N23} & A_{N24} & A_{N25} \\ A_{N31} & A_{N32} & A_{N33} & A_{N34} & A_{N35} \\ A_{N41} & A_{N42} & A_{N43} & A_{N44} & A_{N45} \\ A_{N51} & A_{N52} & A_{N53} & A_{N54} & A_{N55} \end{bmatrix}.$$  

(19)

By substituting (18), (15) can be rewritten as

$$D_0^2 x_{Nk1} + \omega_k^2 x_{Nk1} = -c_{N1} D_0 x_{Nk0} - 2 (A_k e^{i \omega_k T_0} + i \omega_k A_k e^{i \omega_k T_0}) + \frac{A_{Nk4} \Delta T' \cos \omega_T t}{R_4}.$$

(20)
\[ + \sum_{k=1}^{5} \sum_{j=1}^{5} G_{kj} A_k \left[ A_j e^{i(\omega_k \tau) T_0} + A_j^* e^{i(-\omega_k \tau) T_0} \right] + \text{cc}, \]  

(20)

where \( \text{cc} \) is the complex conjugate of the right-hand-side expression in (20) and \( c_{ij} \) is a constant associated with \( A_N \), \( c_k \), \( d_k \), and \( e_k \), and it is expressed as follows:

\[
G_{kj} = -A_{N1k} \left( c_4 \alpha_k \alpha_j + d_3 \beta_k \beta_j + e_3 \alpha_k \beta_j \right) \\
+ A_{N2k} \left[ (c_2 \gamma_k \gamma_j + d_3 \beta_k \beta_j + e_2 \gamma_k \beta_j) \right] \\
- \left( c_3 \beta_k \beta_j + d_2 \Delta_k \mu_j + e_3 \gamma_k \mu_j \right) \\
+ A_{N3k} \left[ (c_2 \gamma_k \gamma_j + d_2 \beta_k \beta_j + e_2 \gamma_k \beta_j) \right] \\
- \left( c_3 \beta_k \beta_j + d_2 \Delta_k \mu_j + e_3 \gamma_k \mu_j \right) \\
+ A_{N4k} \left[ (c_2 \gamma_k \gamma_j + d_3 \Delta_k \mu_j + e_3 \gamma_k \mu_j) \right] \\
+ A_{N5k} \left[ (c_3 \beta_k \beta_j + d_3 \Delta_k \mu_j + e_3 \gamma_k \mu_j) \right].
\]

There are multiple frequency components in the right-hand-side expressions of (20), such as \( \pm 2 \omega_k, \pm (\omega_k \pm \omega_j) \), and \( \pm \omega_j \), where \( m = 1, 2, 3, 4, 5 \) and \( k \neq j \). When there is no internal resonance, the secular terms can be eliminated to obtain

\[ -c_{ij} \Delta_T e_{m0} A_m - 2 \dot{A}_m = 0, \]

\[ -c_{ij} \omega_4 A_4 - 2i \omega_4 \dot{A}_4 + \frac{A_{N4k} \Delta_T^2 e^{\gamma m \tau}}{R_4} = 0, \]  

(22)

where \( m = 1, 2, 3, \) and 5.

Solutions of (22) are obtained as follows:

\[ A_m = E_m e^{-\gamma m t / 2}, \]

\[ A_4 = E_4 e^{-\gamma m t / 2} - \frac{A_{N4k} \Delta_T^2 e^{j(\sigma m + \theta) t}}{R_4 \omega_4 \sqrt{c_2^2 + 4 \sigma_1^2}}, \]  

(23)

where \( E_k \) and \( E_4 \) are constants related to the output torque, \( \varphi_j \), is a constant related to \( \varepsilon \) and \( \sigma \), \( \cos \varphi_j = 2 \sigma_1 / \sqrt{c_2^2 + 4 \sigma_1^2} \), and \( \sin \varphi_j = c_2 / \sqrt{c_2^2 + 4 \sigma_1^2} \).

Under the normal coordinate system, the zero-order approximate analytical solution of the EIMG system is expressed as

\[ x_{N0m} = E_{m0} e^{-\gamma m t / 2} e^{j \omega_0 t} + \text{cc}, \]

\[ x_{N04} = E_{44} e^{-\gamma m t / 2} e^{j \omega_4 t} - \frac{A_{N4k} \Delta_T^2 e^{j(\omega m + \theta) t}}{R_4 \omega_4 \sqrt{c_2^2 + 4 \sigma_1^2}} + \text{cc}. \]  

(24)

After eliminating the secular terms, the first-order approximate solutions are obtained by substituting (23) and (24) into (20):

\[ x_{N1m} = \frac{A_{N4k} \Delta_T^2 e^{j(\omega_m + \theta) t}}{R_4 (\omega_m^2 - \omega_0^2)} + x_{N41}, \]

\[ x_{N41} = \sum_{m=1,2,3,5} \sum_{j=1,2,3,5} G_{m1} E_m E_j e^{-c_{ij} e_{m0} h / 2} e^{j(\omega_m - \omega_j) t} \]

\[ \cdot \frac{e^{j(\omega_m - \omega_j) t}}{\omega_m^2 - (\omega_m \pm \omega_j)^2} \]

\[ + \sum_{m=1,2,3,5} G_{m4} E_m \left[ \frac{E_j e^{-c_{ij} e_{m0} h / 2} e^{j(\omega_m - \omega_j) t}}{\omega_m^2 - (\omega_m \pm \omega_j)^2} \right] \]

\[ - \frac{X_4 E_j e^{-c_{ij} e_{m0} h / 2} e^{j(\omega_m - \omega_j) t}}{\omega_m^2 - (\omega_m + \omega_4)^2} \]  

\[ + \frac{F_4^2 e^{-c_{ij} e_{m0} h / 2} e^{j(\omega_m - \omega_j) t}}{\omega_m^2 - (\omega_m + \omega_4)^2} \]  

\[ \left. - \left( \frac{X_4 E_j e^{-c_{ij} e_{m0} h / 2} e^{j(\omega_m + \omega_4) t}}{\omega_m^2 + (\omega_m - \omega_4)^2} \right) \right) \]  

\[ - \frac{X_4 e^{-c_{ij} e_{m0} h / 2} e^{j(\omega_m + \omega_4) t}}{\omega_m^2 - (\omega_m + \omega_4)^2} \]  

\[ + \frac{X_4 e^{c_{ij} e_{m0} h / 2} e^{j(\omega_m - \omega_4) t}}{\omega_m^2 - (\omega_m + \omega_4)^2} \]  

\[ - \frac{X_4 e^{c_{ij} e_{m0} h / 2} e^{j(\omega_m + \omega_4) t}}{\omega_m^2 - (\omega_m - \omega_4)^2} \]  

\[ - \frac{X_4 e^{c_{ij} e_{m0} h / 2} e^{j(\omega_m - \omega_4) t}}{\omega_m^2 - (\omega_m - \omega_4)^2} \]  

\[ + \text{cc}, \]

where

\[ X_4 = \frac{A_{N4k} \Delta_T^2 e^{j(\omega_4 t + \theta) t}}{R_4 \omega_4 \sqrt{c_2^2 + 4 \sigma_1^2}}, \]

\[ G_{m1} = -A_{N1i} \left( c_4 \alpha_m \alpha_j + d_3 \beta_m \beta_j + e_4 \alpha_m \beta_j \right) \]

\[ + A_{N2i} \left[ (c_2 \gamma_m \gamma_j + d_3 \beta_m \beta_j + e_2 \gamma_m \beta_j) \right] \]

\[ - \left( c_3 \beta_m \beta_j + d_2 \Delta_m \mu_j + e_3 \gamma_m \mu_j \right) \]

\[ + A_{N3i} \left[ (c_2 \gamma_m \gamma_j + d_2 \beta_m \beta_j + e_2 \gamma_m \beta_j) \right] \]

\[ - \left( c_3 \beta_m \beta_j + d_2 \Delta_m \mu_j + e_3 \gamma_m \mu_j \right) \]

\[ + A_{N4i} \left[ (c_3 \beta_m \beta_j + d_2 \Delta_m \mu_j + e_3 \gamma_m \mu_j) \right] \]

\[ + A_{N5i} \left[ (c_4 \gamma_m \gamma_j + d_4 \Delta_m \mu_j + e_4 \gamma_m \mu_j) \right] \]

\[ - \left( c_3 \beta_m \beta_j + d_2 \Delta_m \mu_j + e_3 \gamma_m \mu_j \right) \]  

(26)
$E_m$ will approach zero with increasing time because of the damping among components. The stable responses of the first-order approximate analytic solution of the EIMG system can be obtained by substituting (24) and (25) into (12):

$$x_{Nj} = \frac{e A_{Nj} A_{\Delta T} e^{i \omega_j t}}{R_4 (\omega_j^2 - \omega_0^2)} + \frac{e X_j^2 e^{2 (i \omega_0 + 2 \omega_j t + 2 \eta_j)}}{\omega_0^2 - (2 \omega_0 + 2 \omega_0 t)^2} + \text{cc},$$

$$x_{Nk} = \frac{-A_{Nj} \Delta T e^{i (2 \omega_0 + 2 \omega_j t + 2 \eta_j)}}{R_4 \omega_0 \sqrt{c_{Nj}^2 + 4 \epsilon^2 \sigma_1^2}} + \frac{e X_j^2 e^{2 (i \omega_0 + 2 \omega_j t + 2 \eta_j)}}{\omega_0^2 - (2 \omega_0 + 2 \omega_0 t)^2} + \text{cc},$$

(27)

where $x_k = A_{Nk} \Delta T / R_4 \omega_0 \sqrt{c_{Nk}^2 + 4 \epsilon^2 \sigma_1^2}$.

4. Superharmonic Resonance

When the wave frequency approaches a certain frequency $\omega_k$ of the derived EIMG system, resonance will occur. In this situation, stable responses of the EIMG system under the normal coordinate system are calculated as

$$x_{Nj} = \frac{e A_{Nj} A_{\Delta T} e^{i \omega_j t}}{R_4 (\omega_j^2 - \omega_0^2)} + \frac{e X_j^2 e^{2 (i \omega_0 + 2 \omega_j t + 2 \eta_j)}}{\omega_0^2 - (2 \omega_0 + 2 \omega_0 t)^2} + \text{cc},$$

(29)

with $x_k = A_{Nk} \Delta T / R_4 \omega_0 \sqrt{c_{Nk}^2 + 4 \epsilon^2 \sigma_1^2}$.

First power

$$D_0^2 x_{Nj0} + \omega_0^2 x_{Nj0} = -c_{Nj} \omega_0 A_k e^{i \omega_0 t} - 2 (A_k e^{i \omega_0 t} + i \omega_0 A_k e^{i \omega_0 T_0} + L_k e^{2 i \omega_0 T_0})$$

$$+ L_k \sum_{m=1}^{5} H_k (A_m e^{i (\omega_m + \omega_0) T_0} + A_m e^{i (-\omega_m + \omega_0) T_0})$$

$$+ \sum_{k=1}^{5} \sum_{j=1}^{5} G_{kj} A_k [J e^{i (\omega_j + \omega_0) T_0} + A_j e^{i (\omega_j - \omega_0) T_0}] + \text{cc},$$

(32)

where

$$F_{Nj0} = A_{Nj} \Delta T \cos \omega_0 t,$$

$$F_{Nj0}'' = A_{Nj} F_{10} + A_{Nj} F_{20} + A_{Nj} F_{30} + A_{Nj} F_{40} + A_{Nj} F_{50},$$

$$H_k = A_{Nk} \{c_1 \alpha_m + d_1 \beta_m \rho_2 + e_1 (\beta_m \rho_1 + \alpha_m \rho_2)\}$$

$$+ A_{Nk} \{c_2 \alpha_m + d_2 \beta_m \rho_2 + e_2 (\beta_m \rho_1 + \alpha_m \rho_2)$$

$$- c_3 \gamma_m \rho_3 - d_3 \delta_m \rho_3 - e_3 (\beta_m \rho_3 + \gamma_m \rho_3)\}$$

$$+ A_{Nk} \{c_3 \gamma_m \rho_3 + d_3 \delta_m \rho_3 + e_3 (\gamma_m \rho_3 + \mu_m \rho_3)$$

$$- c_4 \mu_m \rho_5 - d_4 \mu_m \rho_5 - e_4 (\eta_m \rho_5 + \mu_m \rho_5)\}$$

$$+ A_{Nk} \{c_4 \mu_m \rho_5 + d_4 \mu_m \rho_5 + e_4 (\eta_m \rho_5 + \mu_m \rho_5)\},$$

(33)

$$L_k = A_{Nk} \{c_1 \rho_1^2 + d_1 \rho_5^2 + e_1 \rho_1 \rho_3\} + A_{Nk} \{c_1 \rho_1^2$$

$$+ d_1 \rho_5^2 + e_1 \rho_1 \rho_3 - (c_2 \rho_3^2 + d_2 \rho_5^2 + e_2 \rho_3 \rho_5)\}$$

$$+ A_{Nk} \{c_3 \rho_3^2 + d_3 \rho_5^2 + e_3 \rho_3 \rho_5$$

$$- (c_3 \rho_3^2 + d_3 \rho_5^2 + e_3 \rho_3 \rho_5)\} + A_{Nk} \{c_3 \rho_3^2 + d_3 \rho_5^2 + e_3 \rho_3 \rho_5$$

$$+ d_4 \rho_5^2 + e_4 \rho_3 \rho_5\},$$

Under the normal coordinate system, the general solution of (31) is expressed as

$$x_{Nj0} = A_j (T_1) e^{i \omega_0 T_0} + B_j e^{i \omega_0 T_0} + \text{cc},$$

(34)

where $B_j = A_{Nj} \Delta T / R_4 (\omega_j^2 - \omega_0^2)$. 

By substituting (30) into (9) and setting the power coefficients of the small parameters $\epsilon$ on both sides of the equation to be equal, the following differential equations are obtained:

Zero power

$$D_0^2 x_{Nj0} + \omega_0^2 x_{Nj0} = F_{Nj0}$$

(31)}

Shock and Vibration

7
Under the regular coordinate system, solutions of Eq. (31) are calculated as

\[
x_{10} = \alpha_1 A_1 (T_1) e^{i\omega T_0} + \alpha_2 A_2 (T_1) e^{i\omega T_0} + \alpha_3 A_3 (T_1) e^{i\omega T_0} + \alpha_4 A_4 (T_1) e^{i\omega T_0} + \alpha_5 A_5 (T_1) e^{i\omega T_0} + \rho_1 e^{i\omega T_0} + \cdots,
\]

\[
x_{20} = \beta_1 A_1 (T_1) e^{i\omega T_0} + \beta_2 A_2 (T_1) e^{i\omega T_0} + \beta_3 A_3 (T_1) e^{i\omega T_0} + \beta_4 A_4 (T_1) e^{i\omega T_0} + \beta_5 A_5 (T_1) e^{i\omega T_0} + \rho_2 e^{i\omega T_0} + \cdots.
\]

\[
x_{30} = \gamma_1 A_1 (T_1) e^{i\omega T_0} + \gamma_2 A_2 (T_1) e^{i\omega T_0} + \gamma_3 A_3 (T_1) e^{i\omega T_0} + \gamma_4 A_4 (T_1) e^{i\omega T_0} + \gamma_5 A_5 (T_1) e^{i\omega T_0} + \rho_3 e^{i\omega T_0} + \cdots
\]

\[
x_{40} = \delta_1 A_1 (T_1) e^{i\omega T_0} + \delta_2 A_2 (T_1) e^{i\omega T_0} + \delta_3 A_3 (T_1) e^{i\omega T_0} + \delta_4 A_4 (T_1) e^{i\omega T_0} + \delta_5 A_5 (T_1) e^{i\omega T_0} + \rho_4 e^{i\omega T_0} + \cdots
\]

\[
x_{50} = \varepsilon_1 A_1 (T_1) e^{i\omega T_0} + \varepsilon_2 A_2 (T_1) e^{i\omega T_0} + \varepsilon_3 A_3 (T_1) e^{i\omega T_0} + \varepsilon_4 A_4 (T_1) e^{i\omega T_0} + \varepsilon_5 A_5 (T_1) e^{i\omega T_0} + \rho_5 e^{i\omega T_0} + \cdots
\]

where \( \rho_1 = A_{N11} B_1 + A_{N12} B_2 + A_{N13} B_3 + A_{N14} B_4 + A_{N15} B_5, \)

\( \rho_2 = A_{N21} B_1 + A_{N22} B_2 + A_{N23} B_3 + A_{N24} B_4 + A_{N25} B_5, \)

\( \rho_3 = A_{N31} B_1 + A_{N32} B_2 + A_{N33} B_3 + A_{N34} B_4 + A_{N35} B_5, \)

\( \rho_4 = A_{N41} B_1 + A_{N42} B_2 + A_{N43} B_3 + A_{N44} B_4 + A_{N45} B_5, \)

\( \rho_5 = A_{N51} B_1 + A_{N52} B_2 + A_{N53} B_3 + A_{N54} B_4 + A_{N55} B_5. \)

After substituting (35) into (32), there are multiple frequency components such as \( 2\omega_1 \pm \omega_1, \pm \omega_2, \) and \( \pm \omega_2 \pm \omega_3, \) where \( k = 1, 2, 3, 4, 5 \) and \( k \neq j. \) When there is no internal resonance, the secular terms can be eliminated from (32) to obtain

\[
-c_{N1} m \omega_2 = 2 A_m = 0,
\]

\[
-c_{N2} i\omega_3 A_1 e^{i\omega t} - 2i\omega_3 A_2 e^{i\omega t} + L_4 e^{2i\omega t} = 0.
\]

The solutions of (36) are written as

\[
A_m = E_m e^{-c_{N1} t/2},
\]

\[
A_4 = E_4 e^{-c_{N2} t/2} - \frac{L_4 e^{i(\sigma \tau + \varphi_2)}}{\omega_4 \sqrt{c_{N4}^2 + 4\epsilon^2 \sigma_2^2}}.
\]

where \( \varphi_2 \) is a constant related to \( \epsilon \) and \( \sigma, \) \( \cos \varphi_2 = 2\epsilon \sigma_2 / \sqrt{c_{N4}^2 + 4\epsilon^2 \sigma_2^2}, \) and \( \sin \varphi_2 = c_{N4} / \sqrt{c_{N4}^2 + 4\epsilon^2 \sigma_2^2}. \)

Because of the damping in the ELMG system, the initial vibration displacements will decrease to zero. Under the normal coordinate system, the zero-order stable analytical solutions are given by

\[
x_{N0} = B_m e^{i\omega_0 t} + \frac{V e^{i\omega t}}{\omega_m^2 - \omega_0^2} e^{i(\omega_0 t + \varphi_2)} + B e^{i\omega T_0} + \cdots
\]

(38)

After eliminating the secular terms, the first-order approximate solutions are obtained by substituting (38) into (32):

\[
x_{N1} = \frac{V e^{i\omega t}}{\omega_m^2 - \omega_0^2} e^{i(\omega_0 t + \varphi_2)} + \frac{T_l e^{2i(\omega_0 + \varphi_2) t}}{\omega_4 \sqrt{c_{N4}^2 + 4\epsilon^2 \sigma_2^2}} e^{i(\omega_0 t + \varphi_2) + \cdots}
\]

(39)

\[
x_{N1} = \frac{V e^{i\omega t}}{\omega_4 \sqrt{c_{N4}^2 + 4\epsilon^2 \sigma_2^2}} e^{i(\omega_0 t + \varphi_2)} + \frac{T_l e^{2i(\omega_0 + \varphi_2) t}}{\omega_4 \sqrt{c_{N4}^2 + 4\epsilon^2 \sigma_2^2}} e^{i(\omega_0 t + \varphi_2) + \cdots}
\]

(40)
When the wave frequency of the torque wave is close to half of the natural frequency of the EIMG system, namely, 
$2\omega_0 = \omega_1 + \omega_2$, the approximate solutions of the EIMG system under the normal coordinate system are

$$x_{\text{Ns}} = B_4e^{i\omega_0 T_0} + \frac{\varepsilon U_4 L_4}{\omega_4 \sqrt{c_{N4}^2 + 4e^2 \sigma_4^2}} \left[ e^{i[(\omega_1 + \omega_2 + \omega_3) + \phi_3]} \omega_4^2 - (\omega_4 + \omega_2 + e\sigma_2)^2 \right] + \text{cc},$$

$$x_{\text{Nn}} = B_4e^{i\omega_0 T_0} + \frac{\varepsilon U_4 L_4}{\omega_4 \sqrt{c_{N4}^2 + 4e^2 \sigma_4^2}} \left[ e^{i[(\omega_1 + \omega_2 + \omega_3) + \phi_3]} \omega_4^2 - (\omega_4 + \omega_2 + e\sigma_2)^2 \right] + \text{cc}. \tag{41}$$

The superharmonic resonance responses of the EIMG system under the regular coordinate system are calculated using (28).

The initial displacements $x_0$ are obtained from the static solution of the linear differential equations derived for the EIMG system. The linear differential equations in (7) are expressed as

$$Mx + kx = F_0, \tag{42}$$

where $F_0 = [T_3/R_2 T_2/R_2 T_1/R_1 T_0/R_0]_T^T$ and $T_2$, $T_1$, $T_3$ are the output torques on the inner and outer FP, respectively.

By setting the mass matrix in (42) equal to zero and only considering the static loads, the static displacement equations can be expressed under the assumption that the deformations of components caused by gravity and the stiffness waves are negligible. In this case, we have

$$kx_0 = F_0, \tag{43}$$

where $x_0 = [E_1 E_2 E_3 E_4]_T^T$.

5. Resonance of Example EIMG

System and Discussion

A finite element model (FEM) of the example EIMG system described in Table 1 can be built using Ansys; a diagram of the system is presented in Figure 3. In this model, the inner stator and the permeable magnetic of the inner and outer FP consist of silicon steel (23TW250) sheets. The back irons of the inner rotor and outer stator are also made of 23TW250. The nonpermeable magnets of the inner and outer FP are made of epikote, which has similar material characteristics to air. The remanence and coercivity of the PMs on the inner rotor and outer stator are coincident (see Table 1). In this study, we consider linear and unsaturated magnetic circuits. The air gaps have denser grids because these areas have greater magnetic reluctance and higher variation gradients of magnetic flux density than the PMs and back irons. The torque profiles calculated for all components are displayed in Figure 4.

Figure 4 indicates that the torques on all components vary sinusoidally with respect to the phase angle. The wave period is determined by the number of pole pairs of the currents on the inner stator or the number of pole pairs of the PMs on the inner rotor and outer stator; that is, $T_p = \frac{2\pi}{n_p}$. The torque profiles can be expressed as $T_{\text{rel}} = \sin(\phi \theta_{ij} + \theta_\phi)$, where $\theta_{ij}$ is the relative torsional displacement between two adjacent components. When the outer torque on the outer FP is less than the maximum $T_{\text{rel}}$ and takes a constant value, $\theta_\phi$ is also constant. As such, $T_{\text{rel}}$ is a (nonlinear) sinusoidal function of the relative torsional displacements.

Table 2 shows the corresponding dynamic parameters of the example EIMG system.

By substituting the dynamic parameters of the example system into (25) and (28), the main resonance responses of the EIMG system can be determined. When the wave frequency is close to the natural frequency of the outer FP

Rotational mode, the transient responses of the components are shown in Figure 5.

Figure 5 indicates that the output torque causes larger initial static displacements among the components of the EIMG system. The system damping ensures that the transient responses will gradually transition to the steady state. This process takes approximately 6 s. When resonance occurs, there are multiple frequency components in the transient responses, and the steady-state responses have a particular frequency.
Figure 6: Continued.
Because of the magnetic coupling among components in the EIMG system, the magnetic coupling stiffness is much smaller than the mechanical support stiffness. Moreover, because there is no contact among the components (namely, no frictional damping), the resonance amplitudes of the transient responses will be larger and will slowly decay to zero. This results in some deterioration in the dynamic characteristics.

Considering the effects of damping, the resonance will gradually be close to stabilization. When the wave frequency $\omega_e$ is close to the natural frequency $\omega_i$ and half of the corresponding frequency $\omega_i/2$ of the derived nonlinear EIMG system, the steady-state response curves are as shown in Figures 6 and 7.

Figures 6 and 7 show that strong resonance will occur when the wave frequency is close to the natural frequency or half of the natural frequency of the derived EIMG system. The dominant frequency in the superharmonic resonance is the natural frequency, rather than the wave frequency or half of the natural frequency. The resonance amplitudes are much larger when the wave frequency is close to the natural frequency of the inner rotor rotational mode and outer FP rotational mode than when the wave frequency is close to the natural frequency of the inner FP rotational mode and inner stator rotational mode.

When resonance occurs and the displacement of a certain degree of freedom reaches its maximum, the resonance amplitudes are very different. For instance, when the wave frequency is close to the natural frequency of the outer FP rotational mode, the torsional displacements of the outer FP attain their maximum. Furthermore, the displacements of the adjacent components, namely, the inner rotor and outer
Figure 7: Continued.
stator, will also be larger; however, the displacements of the interval components, namely, the inner FP and stator, will be much smaller.

Similarly, when the wave frequency is close to twice the natural frequency of the derived EIMG system, strong subharmonic resonance will occur because of the nonlinear magnetic coupling stiffness. The dynamic behavior is similar to the superharmonic response. When the outer stator outputs torque with a wave frequency close to the natural frequency of the derived EIMG system, strong resonance will occur. Furthermore, the amplitudes of the various components will be very different.

Because there is no contact among the components, the relative influences among adjacent (interval) components are larger (smaller) than those in a mechanical gear system. Because of the output torque on the outer FP waves, the equivalent load is greatest on the outer FP. Therefore, the largest resonance occurs when the wave frequency is close to the natural frequency of the outer FP rotational mode. Because the magnetic coupling stiffness is much smaller than the support stiffness, the natural frequencies of the inner rotor and outer FP rotational mode are much larger. When the current frequency is smaller, the EIMG can be used in applications that easily admit low frequencies, high torque, and low-frequency resonance. When the current frequency is larger, low-frequency main resonances may not occur; however, superharmonic resonances can easily occur.

6. Conclusion

EIMG systems output torque as a result of the magnetic coupling among components. The magnetic coupling stiffness is much smaller than the mesh stiffness of mechanical gear systems and exhibits distinct nonlinearity. Thus, there
are quadratic nonlinearities in the EIMG dynamic system. When the wave frequency is close to the natural frequency or twice/half the natural frequency of the derived EIMG system, strong resonance will occur. The dominant frequency is the natural frequency, and the resonance amplitudes exhibit large differences when superharmonic resonance occurs. Because of the smaller magnetic coupling stiffness and damping, the transient responses slowly decay to zero. In order to accelerate the decay rate of the transient responses and avoid the resonances, the vibration control strategy of the EIMG system should be analyzed. These can provide the foundation for the parameter optimization and performance improvement of the EIMG system.
