We consider the unbounded parallel batch scheduling with deterioration, release dates, and rejection. Each job is either accepted and processed on a single batching machine, or rejected by paying penalties. The processing time of a job is a simple linear increasing function of its starting time. The objective is to minimize the sum of the makespan of the accepted jobs and the total penalty of the rejected jobs. First, we show that the problem is NP-hard in the ordinary sense. Then, we present two pseudopolynomial time algorithms and a fully polynomial-time approximation scheme to solve this problem. Furthermore, we provide an optimal $O(n \log n)$ time algorithm for the case where jobs have identical release dates.

1. Introduction

The parallel batch scheduling problem has been extensively studied in the literature over the last decade. The fundamental model of the parallel batch scheduling problem was first introduced by Lee et al. [1] with the restriction that the number of jobs in each batch is bounded by a number $b$. This bounded model is motivated by the burn-in operations in semiconductor manufacturing. Brucker et al. [2] provided an extensive discussion of the unbounded version of the parallel batch scheduling problem. This unbounded model can be applied, for example, to situations where the batch contents are heated in a sufficiently large kiln. Cheng et al. [3], Deng et al. [4, 5], and Liu et al. [6, 7] presented new complexity results and approximation algorithms for the parallel batch scheduling problem subject to release dates. In addition, more recent developments of this topic can be found in [8].

In classical scheduling problems, it is assumed that the processing times of jobs are fixed parameters. In practice, however, we often encounter situations in which processing time increases over time. Examples can be found in financial management, steel production, firefighting, and so forth, where any delay in processing a job may increase its completion time. Such problems are generally known as scheduling with deterioration effects. Browne and Yechiali [9] first considered scheduling problem with linear deterioration. They provided the optimal solution for the single machine when the objective is to minimize makespan. In addition, they solved a special case when the objective function is to minimize the total weighted completion time. Mosheiov [10] considered single machine scheduling problems with simple linear deteriorating jobs. He showed that most commonly scheduling objectives, such as the makespan, the total flow time, the sum of weighted completion times, the maximum lateness, the total lateness, the maximum tardiness, and the number of tardy jobs, remain solvable in polynomial time. Alidaee and Womer [11] presented an extensive survey of different deteriorating models and scheduling problems. Cheng et al. [12] provided an updated survey of scheduling problems with time-dependent processing times. Li et al. [13] considered the problem of scheduling of deteriorating jobs with release dates on a single batching machine. Miao et al. [14] studied the scheduling problems with deteriorating jobs and release dates on a single (batching) machine to minimize the maximum lateness. Zou et al. [15] considered several uniform parallel machine scheduling problems with linear deteriorating jobs.
On the other hand, it is always assumed in traditional scheduling research that all the jobs have to be processed on some machines. In real applications, however, things may be more complicated. For example, due to limited resources, the scheduler may reject some jobs and thereby incur job-dependent penalties for each rejected job. Bartal et al. [16] first introduced the notion of rejection. They considered both the offline and online versions of scheduling problem and studied the multiprocessor scheduling problem to minimize the sum of the makespan of the accepted jobs and the total rejection penalty of the rejected jobs. Subsequently, the machine scheduling problem with rejection has received increasing research attention. Hoogeveen et al. [17] considered the offline multiprocessor scheduling problem with rejection where preemption is allowed. They provided a pseudopolynomial time algorithm for each problem. Lu et al. [18] considered the unbounded parallel batch machine scheduling problem with release dates and rejection. Engels et al. [19] studied the single machine scheduling with rejection where preemption is allowed. They provided a fully polynomial-time approximation scheme for the problem and discuss one special case. In Section 4, we study the problem of minimizing the sum of the makespan of the accepted jobs (i.e., $C_{\text{max}}(R)$) and the total penalty of the rejected jobs. Using the three-field notation of Graham et al. [23], we denote the problem by $1\{p\text{-batch},r,\text{rej},b\geq n\}C_{\text{max}}(R)+\sum_{j\in R} e_j$.

3. Main Results

3.1. NP-Hardness Proof. We first give a lemma, which will be used in what follows.

Lemma 1 (see [10]). For the problem $1|r_j=t_0, p_j=b_j|C_{\text{max}}$, the maximum completion time of the jobs is equal to $C_{\text{max}} = t_0\prod_{j\in J} (1+b_j)$ and it does not depend on the processing order of the jobs.

Theorem 2. The problem $1|p\text{-batch}, r_j, p_j = b_j, \text{rej}, b \geq n|C_{\text{max}}(R)+\sum_{j\in R} e_j$ is binary NP-hard.

Proof. The decision version of the scheduling problem is clearly in NP. We use a reduction from the Equal Products Problem, which is NP-hard (see [24]).

An instance $I$ of the Equal Products Problem is formulated as follows. Given a set $Q = \{1,2,\ldots,m\}$ and positive integers $a_i$ for each $i \in Q$ such that $\prod_{i \in Q} a_i = A^2$ for a certain positive integer $A$, does there exist a subset $S \subset Q$ such that $\prod_{i \in S} a_i = A$?

For any given instance $I$ of the Equal Products Problem, we construct a corresponding instance $II$ of our problem as follows.

(i) There are $n = 2m + 1$ jobs.

(ii) For $i = 1$, there exist job $J_1$ with $(r_1,b_1,e_1) = (1,A^{2m-1}2^{2m+1} + A)$ and job $J_2$ with $(r_2,b_2,e_2) = (1,A^{2m}a_1 - 1, \ln a_1)$.

(iii) For each $2 \leq i \leq m$, there exist job $J_{2i-1}$ with $(r_{2i-1},b_{2i-1},e_{2i-1}) = (A^{\sum_{j=1}^{i-1} 2^{2m-2j}}, A^{2m-2i+1} - 1, 2A^{m+1} + A)$ and job $J_{2i}$ with $(r_{2i},b_{2i},e_{2i}) = (A^{\sum_{j=1}^{i-1} 2^{2m-2j}}, A^{2m-2i+1} - 1, \ln a_i)$.
(iv) For $i = 2m + 1$, there exists only a job $J_{2m+1}$ with $(r_{2m+1}, b_{2m+1}, e_{2m+1}) = (A^{m+1}, 1, 2A^{m+1} + A)$.

(v) The threshold value is given by $Y = 2A^{m+1} + \ln A$.

The decision asks whether there is a schedule such that $C\max(R) + \sum_{j \in S} e_j \leq Y$.

It is clear that the reduction can be done in polynomial time, and it is easy to verify that $b_i > 0$ for $i = 1, \ldots, m + 1$. Assume first that the Equal Products Problem has a solution $S$ such that $\prod_{j \in S} a_j = A$. Then, we construct a schedule in the following way. If $i \in S$, we assign the jobs $J_{2i-1}$ and $J_{2i}$ as a batch $B_i$. If $i \notin S$, we assign the job $J_{2i-1}$ as a batch $B_i$. We assign the job $J_{2m+1}$ as the last batch $B_{m+1}$. The jobs are processed on the batch machine in the order of $B_1, \ldots, B_{m+1}$. All other jobs are rejected. It is easy to verify that

$$C\max(R) + \sum_{j \in R} e_j = \max \left\{ A^{m+1} \prod_{j \in S} a_j, r_{m+1} \right\} + (1 + b_{m+1}) + \sum_{i \notin S} \ln a_i$$

$$= 2A^{m+1} + \ln A = Y.$$ 

Conversely, suppose that there is a schedule $\pi$ with $C\max(R) + \sum_{j \in R} e_j \leq Y$. We need to show that there is a subset $S$ for the Equal Products Problem with $\prod_{j \in S} a_j = A$. We have the following claims.

Claim 1. All jobs $J_{2i-1}$ for each $1 \leq i \leq m + 1$ are accepted and $C\max(R) \geq 2A^{m+1}.$

Proof. If there exists some job $J_{2i-1}$ ($1 \leq i \leq m + 1$) being rejected, then we have $C\max(R) + \sum_{j \in R} e_j \geq e_{2i-1} = 2A^{m+1} + A > Y$. It is a contradiction. Since job $J_{2m+1}$ is accepted, we have $C\max(R) \geq r_{2m+1} + (1 + b_{2m+1}) \geq 2A^{m+1}.$

From Claim 1, we can obtain that only the jobs $\{J_{2i} : 1 \leq i \leq m\}$ can be rejected.

Claim 2. Only job $J_{2m+1}$ is processed in the last batch.

Proof. If there exists a job $J_i$ ($1 \leq i \leq 2m$) with $J_{2m+1}$ processed in the same batch $B$, then we have

$$C\max = r_{2m+1} + (1 + b(B))$$

$$= r_{2m+1} + (1 + b_i) \geq A^{m+1} + (1 + A^2 - 1)$$

$$= A^{m+1} > Y.$$ 

Then, we denote by $B_{m+1}$ the last batch containing only job $J_{2m+1}$.

Claim 3. Each batch contains either a single job $J_{2i-1}$ or two jobs $\{J_{2i-1}, J_{2i}\}$ for $1 \leq i \leq m$.

Proof. For job $J_{2m-1}$, if there exists a job $J_1$ ($1 \leq i \leq 2m - 2$) with $J_{2m-1}$ which are processed in the same batch $B$, then we have $C\max = r_{2m-1} + (1 + b(B)) = r_{2m-1} + (1 + b_i) \geq A^{m+1} + (1 + A^2 - 1) = A^{m+1} > Y.$

Thus, we denote by $B_m$ the new batch containing job $J_{2m-1}$.

For job $J_{2m-3}$, if there exists a job $J_i$ ($1 \leq i \leq 2m - 4$) with $J_{2m-3}$ which are processed in the same batch $B_{m-1}$, then we have the completion time of the batch as

$$C(B_{m-1}) \geq r_{2m-3} + (1 + b(B_{m-1}))$$

$$= r_{2m-3} + (1 + b_i) \geq A^{m+1} - 1 + A^2 - 1$$

$$= A^{m+1}.$$ 

The completion time of batch $B_m$ is

$$C(B_m) = \max \{C(B_{m-1}), r_{2m-1}\} + (1 + b(B_m))$$

$$\geq A^{m+1} > Y.$$ 

Therefore, batch $B_{m-1}$ can only contain either job $J_{2m-3}$ or jobs $\{J_{2m-3}, J_{2m-4}\}$. Repeat this deduction, we have the correctness of Claim 3. Let $B_i$ be the batch containing job $J_{2i-1}$ for $1 \leq i \leq m$.

By Claims 2 and 3, we have batch $B_i = \{J_{2i-1}, J_{2i}\}$ if $J_{2i}$ is accepted and batch $B_i = \{J_{2i-1}\}$ if $J_{2i}$ is rejected. Let $S = \{i : J_{2i} \text{ is rejected for } 1 \leq i \leq m\}$. Next, we are ready to show that $S$ is a solution of the Equal Products Problem.

Since $C\max(R) \geq 2A^{m+1}$ and $C\max(R) + \sum_{j \in R} e_j \leq Y = 2A^{m+1} + \ln A$, we have $\sum_{j \in S} \ln a_j = \sum_{j \in R} e_j \leq \ln A$. If $\prod_{j \in S} a_j = X < A$, we have

$$C\max(R) + \sum_{j \in R} e_j = \max \left\{ r(B_{m-1}), C(B_m) \right\} + (1 + b_{m+1}) + \sum_{j \in S} \ln a_j$$

$$= 2A^{m+1} + \prod_{j \in S} a_j + \ln X > 2A^{m+1} + \frac{A}{X} + \ln X > Y.$$ 

It is a contradiction. Hence, we have $\prod_{j \in S} a_j = A$ and $S$ is a solution of the Equal Products Problem. This completes the proof.

3.2. Dynamic Programming Algorithms

Lemma 3. For problem 1|p-batch, $r_j, p_j = b_j, t, r, b \geq n|C\max(R) + \sum_{j \in R} e_j$, there exists an optimal schedule such that the accepted jobs are processed in a nonincreasing order of deteriorating rates.
Proof. Otherwise, there exist two accepted jobs $J_i$ and $J_j$ such that $J_j$ is processed later than $J_i$, but $b_i < b_j$. Since $b \geq n$, there is no limit on the number of jobs in a batch and we can put job $J_i$ into the batch containing job $J_j$. This does not delay the completion time of any batch. A finite number of repetitions of this procedure yields an optimal schedule of the required form.

Based on Lemma 3, we only consider the schedules in which the accepted jobs are processed in a nonincreasing order of deterioration rates. Assume that jobs are indexed such that $b_1 \geq \cdots \geq b_n$.

Let $F(j, k, E)$ denote the optimal objective function value of the following scheduling problem:

(i) the jobs in consideration are $J_1, \ldots, J_j$;

(ii) $J_k$ is the job with the minimum index in the last batch;

(iii) the total penalty of rejected jobs is $E$.

In any such schedule, there are two possible cases: either $J_i$ is rejected or $J_i$ is accepted and processed on the batching machine. We distinguish two cases in the following discussion.

Case 1. Job $J_i$ is rejected. Since $J_i$ is rejected, in the corresponding optimal schedule for $J_1, \ldots, J_{j-1}$, $J_k$ is still the job with the minimum index in the last batch and the total rejection penalty among $J_1, \ldots, J_{j-1}$ is $E - e_j$. Therefore, we have $F(j, k, E) = F(j - 1, k, E - e_j) + e_j$.

Case 2. Job $J_i$ is accepted. In this case, we consider this problem in the following two cases.

Case 2.1. If $k = j$, then job $J_j$ starts a new batch. The starting time of job $J_j$ is $\max\{F(j - 1, k', E) - E, r_j\}$. Therefore, we have $F(j, k, E) = \min_{0 \leq k' \leq j-1} \{\max\{F(j - 1, k', E) - E, r_j\}(1 + b_k) + E\}$.

Case 2.2. If $k < j$, then job $J_j$ can be assigned to the last batch containing job $J_k$. Therefore, $F(j, k, E) = \max\{F(j - 1, k, E) - E, r_j\}(1 + b_k) + E$.

Combining the above two cases, we design the following dynamic programming algorithm.

**Algorithm D1.** Consider the following steps.

Step 1 (initialization). Consider $F(1, 1, 0) = r_1(1 + b_1)$ and $F(1, k, E) = \infty$ for $(k, E) \neq (1, 0)$.

Consider $F(1, 0, e_1) = t_0 + e_1$ and $F(1, k, E) = \infty$ for $(k, E) \neq (0, e_1)$.

Step 2 (recursion). If $k = j$,

$$F(j, k, E) = \min \left\{ \min_{0 \leq k' \leq j-1} \{\max\{F(j - 1, k', E) - E, r_j\}\right. \times (1 + b_j) + E, F(j - 1, k, E - e_j) + e_j \} \right\}.$$  \hfill (6)

If $k < j$,

$$F(j, k, E) = \min \left\{ \max \left\{ F(j - 1, k, E) - E, r_j \right\} \times (1 + b_k) ight.$$

$$+ E, F(j - 1, k, E - e_j) + e_j \} \right\}.$$ \hfill (7)

Step 3 (optimal solution). The optimal value is given by $\min\{F(n, k, E) : 0 \leq k \leq n, 0 \leq E \leq \sum_{j=1}^{n} e_j\}$.

**Theorem 4.** Algorithm D1 solves the problem $1|p$-batch, $r_j, p_j = b_j, t_0, b \geq n|C_{\text{max}}(\mathcal{R}) + \sum_{j \in \mathcal{E}} e_j$ in $O(n^2 \sum_{j=1}^{n} e_j)$ time.

Proof. The correctness of Algorithm D1 is guaranteed by the above discussion. The recursive function has at most $O(n^2 \sum_{j=1}^{n} e_j)$ states; each iteration takes a constant time to execute. Hence, the running time of Algorithm D1 is $O(n^2 \sum_{j=1}^{n} e_j)$.

Next, we give another dynamic programming Algorithm D2. Let $f(j, k, E)$ denote the minimum value of the maximum completion time satisfying the following conditions.

(i) The jobs in consideration are $J_1, \ldots, J_j$.

(ii) $J_k$ is the job with the minimum index in the last batch.

(iii) The total penalty of rejected jobs is $E$.

In any such schedule, there are two possible cases: either $J_i$ is rejected or $J_i$ is accepted and processed on the batching machine.

Case 1. If job $J_i$ is rejected, we have $f(j, k, E) = f(j - 1, k, E - e_j)$.

Case 2. Job $J_i$ is accepted.

Case 2.1. If $k = j$, then job $J_j$ starts a new batch; the starting time of job $J_j$ is $\max\{f(j - 1, k', E), r_j\}$. Therefore, we have $f(j, k, E) = \min_{0 \leq k' \leq j-1} \{\max\{f(j - 1, k', E), r_j\}(1 + b_k)\}$.

Case 2.2. If $k < j$, then job $J_j$ can be assigned to the last batch containing job $J_k$. Therefore, $f(j, k, E) = \max\{f(j - 1, k, E)\}(1 + b_k)$.

Combining the above two cases, we design the dynamic programming algorithm as follows.

**Algorithm D2.** Consider the following steps.

Step 1 (initialization). Consider $f(1, 1, 0) = r_1(1 + b_1)$ and $f(1, k, E) = \infty$ for any $(k, E) \neq (1, 0)$.

Consider $f(1, 0, e_1) = t_0$ and $f(1, k, E) = \infty$ for any $(k, E) \neq (0, e_1)$.
Step 2 (recursion). If \( k = j \),
\[
\begin{align*}
f(j, k, E) &= \min_{0 \leq k' \leq j-1} \left\{ \max \left\{ f(j - 1, k', E), r_j \right\} (1 + b_j) \right\}, \\
n_j &= \min_{0 \leq k' \leq j-1} \left\{ \max \left\{ f(j - 1, k', E), r_j \right\} (1 + b_j) \right\}.
\end{align*}
\]
If \( k < j \),
\[
f(j, k, E) = \min \left\{ \max \left\{ \frac{f(j - 1, k, E)}{1 + b_k}, r_j \right\} (1 + b_k), \\
\quad \left\{ f(j - 1, k, E - e_j) \right\} \right\}.
\]

Step 3 (optimal solution). The optimal value is determined by
\[
\min f(n, k, E) + E : 0 \leq k \leq n, 0 \leq E \leq \sum_{j=1}^{n} e_j.
\]

**Theorem 5.** Algorithm DP2 solves the problem \(1|p\text{-batch}, r_j, p_j = b_j \cdot t_j, b_j \geq n|C_{\text{max}}(\overline{R}) + \sum_{j \in R} e_j\) in \(O((n^4/\varepsilon^2) \log^2 \sum_{j=1}^{n} e_j)\) time.

### 3.3. An FPTAS

An FPTAS is a \(p\)-approximation algorithm for a minimization problem if it produces a solution that is at most \(p\) times the optimal solution. If \(p = 1\) the algorithm is called a fully polynomial-time approximation scheme (FPTAS). Algorithm \(\mathcal{A}_\varepsilon\) is a \((1 + \varepsilon,p)\)-approximation algorithm running in polynomial time in the input size and \(1/\varepsilon\). In the sequel, we assume \(0 < \varepsilon < 1\).

For any \(\varepsilon > 0\) and any \(x \geq 1\), if \((1 + \varepsilon)^{k-1} < x < (1 + \varepsilon)^k\), then we define \([x]_{\varepsilon} = (1 + \varepsilon)^{k-1}\). If \(x\) is an exact power of \((1 + \varepsilon)\), then \([x]_{\varepsilon} = (1 + \varepsilon)^k\). Note that \([x]_{\varepsilon} \leq (1 + \varepsilon)^x\) for any \(x \geq 1\).

For any \(\varepsilon > 0\), let \(l = \varepsilon/2n\) and let \(R = \{J_{i_1}, J_{i_2}, \ldots, J_{i_m}\}\) be the set of rejected jobs, where \(i_1 < i_2 < \cdots < i_m\). We inflate the rejection penalty of the set \(R\) with respect to any \(\varepsilon > 0\) as defined in
\[
\phi_{\varepsilon'}(R) = \left\lceil \frac{\phi_{\varepsilon}(R - J_{i_m})}{\varepsilon'} \right\rceil, \quad \text{if } m \geq 1, \quad \text{if } R = \emptyset.
\]

**Lemma 6** (see [25]). For any set \(R\) of jobs and any \(\varepsilon' > 0\),
\[
\phi_{\varepsilon'}(R) \leq (1 + \varepsilon')^{|R|} \sum_{j \in R} e_j.
\]

**Lemma 7** (see [19]). For any \(0 < x \leq 1\) and for any integer \(n \geq 1\), \((1 + (x/n))^n \leq 1 + 2nx\) holds.

Based on Lemmas 6 and 7, we have the following theorem.

**Theorem 8.** For any \(0 < \varepsilon \leq 2\), the optimal objective function value for \(1|p\text{-batch}, r_j, p_j = b_j \cdot t_j, b_j \geq n|C_{\text{max}}(\overline{R}) + \phi_{\varepsilon}(R)\)

is at most \((1 + \varepsilon)\) times the optimal objective function value for \(1|p\text{-batch}, r_j, p_j = b_j \cdot t_j, b_j \geq n|C_{\text{max}}(\overline{R}) + \sum_{j \in R} e_j\).

Assume that the jobs have been indexed such that \(b_1 \geq \cdots \geq b_n\) and define
\[
\tau_i = \begin{cases} 
(1 + \varepsilon')^i, & \text{if } i \neq 0, \\
0, & \text{if } i = -1.
\end{cases}
\]

Let \(f(j, k, l)\) denote the minimum value of the maximum completion time satisfying the following conditions.

(i) The jobs in consideration are \(J_1, \ldots, J_j\).

(ii) In the last batch, \(J_k\) is the job with the minimum index.

(iii) The inflated rejection penalty of the rejected jobs is \(\tau_i\).

We design a dynamic programming algorithm as follows.

**Algorithm \(\mathcal{A}_\varepsilon\).** Consider the following steps.

**Step 1 (initialization).** Consider
\[
f(1, k, l) = \begin{cases} 
t_0, & \text{if } \tau_i = [e_i]_{\varepsilon'}, \\
\tau_i, & \text{if } i = -1, \\
+\infty, & \text{otherwise}.
\end{cases}
\]

**Step 2 (recursion).** If \(k = j\), then
\[
f(j, k, l) = \min \left\{ \min_{0 \leq k' \leq j-1} \left\{ \max \left\{ f(j - 1, k', l), r_j \right\} (1 + b_j) \right\}, \\
\min_{-1 \leq s \leq l} f(j - 1, k, l') \right\}.
\]

If \(k < j\), then
\[
f(j, k, l) = \min \left\{ \max \left\{ \frac{f(j - 1, k, l)}{1 + b_k}, r_j \right\} (1 + b_k), \\
\min_{-1 \leq s \leq l} f(j - 1, k, l') \right\},
\]
where \(l\) is given by \((1 + \varepsilon')^l = [1 + (1 + \varepsilon') \cdot e_j]_{\varepsilon'}\).

Step 3 (output). The optimal value is determined by
\[
\min \{ f(n, k, l) + \tau_i : 0 \leq k \leq n, -1 \leq l \leq L \},
\]
where \(L\) is the smallest integer such that \((1 + \varepsilon')^L \geq (1 + \varepsilon)^n \sum_{j=1}^{n} e_j\).

**Theorem 9.** There exists an FPTAS for problem \(1|p\text{-batch}, r_j, p_j = b_j \cdot t_j, b_j \geq n|C_{\text{max}}(\overline{R}) + \sum_{j \in R} e_j\) which runs in \(O((n^4/\varepsilon^2) \log^2 \sum_{j=1}^{n} e_j)\) time.
The correctness of Algorithm $\mathcal{A}_\varepsilon$ is guaranteed by the above discussion. We need to compute exactly $O(n^2(L + 2))$ values $f(j,k,l)$ and computation of each value takes $O(L)$ time, where $L = O((n/\varepsilon) \log \sum_{j=1}^n e_j)$.

Hence, the running time of Algorithm $\mathcal{A}_\varepsilon$ is $O(n^2L^2) = O(n^2\varepsilon^2 \log \sum_{j=1}^n e_j)$.

\section{An Optimal Algorithm of One Special Case}

The special case where all jobs have the same release dates is considered in this subsection, that is, the problem $1|p\text{-batch}, r_j = t_0, p_j = b_jt, rej, b \geq n|C_{\max} = n|C_{\max}(R) + \sum_{j \in R} e_j$.

We first reindex the jobs in nonincreasing order of their deteriorating rates such that $b_1 \geq \cdots \geq b_n$.

\textbf{Lemma 10.} For problem $1|p\text{-batch}, r_j = t_0, p_j = b_jt, rej, b \geq n|C_{\max}(R) + \sum_{j \in R} e_j$, in any optimal schedule, if job $J_j$ ($1 \leq j \leq n$) is accepted, then the jobs set $\{J_i: i \geq j\}$ is also accepted.

\textbf{Proof.} If job $J_j$ is accepted, since $b \geq n$, there is no limit on the number of jobs in a batch; the jobs $\{J_{j+1}, \ldots, J_n\}$ can be accepted and assigned to the current last batch. Obviously, this does not increase the value of the objective function. This completes the proof.

\textbf{Theorem 11.} For problem $1|p\text{-batch}, r_j = t_0, p_j = b_jt, rej, b \geq n|C_{\max}(R) + \sum_{j \in R} e_j$, the optimal function value is $\min \{t_0(1 + b_1), \sum_{j=1}^{n-1} e_j, \min_{2 \leq j \leq n} \{t_0(1 + b_j) + \sum_{i=1}^{j-1} e_i\}\};$ the optimal solution can be found in $O(n \log n)$ time.

\section{Conclusion}

In this paper, we focus on the unbounded parallel batch scheduling of deteriorating jobs with release date and rejection. The objective is to minimize the makespan of the accepted jobs plus the total penalty of rejected jobs. We show that it is binary NP-hard; we provide two pseudopolynomial time algorithms and also propose a fully polynomial-time approximation scheme for the problem $1|p\text{-batch}, r_j = b_jt, rej, b \geq n|C_{\max}(R) + \sum_{j \in R} e_j$. Furthermore, we show that this problem can be solvable in $O(n \log n)$ time when jobs have identical release dates. For future research, it would be interesting to focus on scheduling deteriorating jobs with other objectives. Analysis of the other models of scheduling with rejection is also an interesting research direction.
