CASE REPORT

A Different Method of Hepaticojejunostomy for Proximal Biliary Injuries

(Received 28 October 1993)

The management of proximal biliary injuries presents a surgical challenge. Anastomoses can be difficult to perform and can have poor results. We describe a method of hepaticojejunostomy done from within the Roux-en-Y loop, which can be utilized in this situation.

KEY WORDS: Biliary Injury bile ducts

CASE REPORT

A 23-year-old white female underwent cholecystectomy at an out-of-state hospital. Several days postoperatively, she was noted to have bile draining from a Penrose drain, and was referred to St. John's Mercy Medical Center for further management. Percutaneous transhepatic cholangiogram revealed complete transection of the right and left hepatic ducts near the hilum. This finding was confirmed at operation. The injury had occurred just below the exit of the right and left hepatic ducts from the liver, only a few mm of each duct being visible. A large segment of biliary tree was absent, the other end comprising the distal common bile duct, thus making a primary anastomosis impossible.

The repair was performed in the following manner: A Roux-en-Y limb was created and brought up to the hilum. An enterotomy was created, to which the hepatic ducts would be sutured (Figure 1). Another enterotomy was made opposite to the first incision, taking care to avoid the mesentery. The hepaticojejunostomy was created using interrupted, absorbable sutures in a mucosa to mucosa fashion. The anasto-

mosis was sewn from within the bowel and could be visualized easily through the opposite incision (Figure 2). The completed anastomosis is seen in Figure 3. Stents were left in place in both ducts prior to closure of the other enterotomy.

DISCUSSION

Bismuth has divided injuries and strictures of the bile ducts into five categories.¹ Destruction of the hilar confluence with separation of the right and the left hepatic ducts is termed a Type 4 injury. The higher the stricture, the more difficult reconstruction becomes and good results become less likely. It is generally agreed that Roux-en-Y hepaticojejunostomy is the best method of reconstruction for high injuries.¹⁻³ Exposure of adequate length of the hepatic ducts can be challenging. Where the injury is so high, as in this case, a liver split may be necessary.¹ The technique described results in good mucosa to mucosa approximation.

Without the need to perform a liver split, Smith has published a similar technique of anastomosis to the common bile duct through the still-open end of the Roux-en-Y⁴, but no such technique has been described for injuries to the hepatic duct.
