Terahertz (THz) radiation from a plasma cylinder with embedded radial electric and axial magnetic fields is investigated. The plasma density and the electric and magnetic fields are such that the electron plasma frequency is near the electron cyclotron frequency and in the THz regime. Two-dimensional particle-in-cell simulations show that the plasma electrons oscillate not only in the azimuthal direction but also in the radial direction. Spectral analysis shows that the resulting oscillating current pattern has a clearly defined characteristic frequency near the electron cyclotron frequency, suggesting resonance between the cyclotron and plasma oscillations. The resulting far-field THz radiation in the axial direction is also discussed.

1. Introduction

The frequency regime of Terahertz (THz) radiation lies between that of microwaves and optical waves. Because of shortage of effective sources, the THz regime was often considered as a gap in the usable electromagnetic-wave spectrum. Generation and manipulation of THz radiation (or T-rays) have been extensively investigated because of its relevance in many areas of basic science and application. In particular, it has potential use in medical and security-detection imaging and communication, as well as in investigating molecular dynamics in matter in the condensed phase.

Many approaches have been proposed for generating T-rays, including synchrotron radiation [1], optical transition radiation [2, 3], and nonlinear frequency upconversion [4]. Optical transition radiation is produced by relativistic electrons as they cross the interface of different dielectric

media. Frequency up- or downconversion of electromagnetic radiation can be realized through nonlinear wave-matter and wave-wave interaction. THz radiation can also be produced in intense laser interaction with matter [3, 5, 6–14]. T-rays can also be produced by the oscillating electrons in laser-induced wakefields [15–17], Smith–Purcell effect of the electron beams in laser-matter interactions [18], two-color laser gas-plasma interaction [19, 20], transition-Cherenkov effect from laser filaments [21], laser-driven wire-guided helical undulators [22], and linear and nonlinear mode conversion [23], as well as laser interaction with strongly magnetized plasmas [24–27]. However, most such sources of T-rays are rather complex and inconvenient to realize in practice.

We consider in this paper an unusual but simple source of T-rays, namely, a plasma cylinder with embedded axial magnetic electric and radial fields. Two-dimensional (2D) particle-in-cell (PIC) simulations show that electrons in the

plasma cylinder oscillate in the azimuthal as well as radial directions. The evolution of the oscillating current distribution is investigated. It is found that resonance-like behavior between the electron oscillations near the plasma and cyclotron frequencies can take place, and the resulting current pattern can produce T-rays in the axial direction.

This paper is organized as follows. In Section 2, the proposed scheme and simulation parameters are described. Section 3 presents the simulation results at the initial stage, and Section 4 considers the long-time behavior. The far-field power of the T-ray emitted from the plasma cylinder is given in Section 5. Section 6 gives the summary.

2. Proposed Scheme and Simulation Parameters

We consider here an unusual source of THz radiation, namely, from a plasma cylinder with external radial electric field and axial magnetic field, as shown in Figure 1. The electric field producing the plasma could be from a radial capacitor discharge and the magnetic field from a solenoid coil outside the cylinder. The electron motion is governed by

$$d_t(\gamma u) = -e\left(E + \frac{1}{c}u \times B\right), \quad (1)$$

$$d_t\gamma = \frac{e}{mc^2}u \times B, \quad (2)$$

where u is the electron velocity, γ is the relativistic factor, and e , m , and c are the electron charge and mass, and the speed of light, respectively. The dynamics of both electrons and (hydrogen) ions are fully included in the PIC simulations [28]. However, as expected, within the picosecond time of interest here, the electron motion is dominant. The constant embedded electric and magnetic fields are $E_0 = E_0\hat{r}$ and $B_0 = B_0\hat{z}$, where $E_0 = 3.4 \times 10^{10}$ V/m and $B_0 = 11.4$ T, which we note are readily realizable. The cylindrical plasma cylinder is of radius $R = 3286 \mu\text{m}$ and initially of uniform density $n_0 = 1.26 \times 10^{20} \text{m}^{-3}$. The temperature of the electrons and ions is 300 eV. The parameters have been chosen such that the electron cyclotron frequency $\omega_c = eB_0/mc$ and plasma frequency $\omega_{pe} = (4\pi e^2 n_0/m)^{1/2}$ are both in the THz regime, so that resonance of the electron oscillations can be expected.

To investigate the evolution of such a plasma cylinder, we use the 2D3V (two-dimensional in space and three-dimensional in velocity) PIC simulation code LAPINE [28]. The size of the simulation box is $9418 \mu\text{m} \times 9418 \mu\text{m}$. The spatial mesh has 1024×1024 cells, containing 4×10^7 each of electrons and ions, and the simulation time step is 13 fs. As mentioned, the ion dynamics is fully included, as they might play a role in the long-time behavior of the system.

3. Initial Stage of the Evolution

Figure 2 shows the self-consistently induced electric field ΔE_r at $t = 13.18$ ps and $t = 16.11$ ps. In this beginning stage of the evolution, besides the cyclotron motion, the plasma electrons are driven radially by external electric field E_0 and

FIGURE 1: The plasma cylinder with external radial electric field E_0 and axial magnetic field B_0 , where $E_0 = 3.4 \times 10^{10}$ V/m and $B_0 = 11.4$ T. The (hydrogen) plasma density is $n_0 = 1.26 \times 10^{20} \text{m}^{-3}$.

acquire a radial velocity v_r . The induced electric field ΔE_r , of order hundreds V/m, is much weaker than E_0 . The Lorentz force from B_0 and v_r also cause the electrons to move in the azimuthal direction, and the resulting azimuthal velocity in turn causes the electrons to move in the radial direction, leading to the oscillations. The much heavier ions have hardly moved (not shown).

The evolution of the current density distribution in the early stage, involving about two oscillation periods, is shown in Figure 3. Figure 3(a) shows that, at $t = 11.72$ ps, the current density near the cylinder center is larger than that near the boundary. Furthermore, the local current vectors (black arrows) indicate that the stronger current is in the anticlockwise direction (note that the electrons near the center rotate in the clockwise direction). For $t = 13.18$ ps, Figure 3(b) shows that the outward-moving electrons approach the boundary of the circular column. They are then reflected by the sheath there and move inwards toward the center, as can be seen in Figure 3(c). Roughly, Figures 3(a) and 3(c) correspond to near-minimum amplitudes and Figures 3(b) and 3(d) to near-maximum amplitudes, of the current oscillations. The evolution of the current density in Figure 3 shows that besides rotating in the anticlockwise direction, the electrons oscillate in a rather complicated manner.

4. Long-Time Behavior

Figure 3 shows the electron dynamics in the initial two oscillation cycles. To see the behavior at longer times, we now focus on a fixed location inside the plasma cylinder. Figures 4(a) and 4(c) show the evolution of the radial and azimuthal currents at $(x, y) = (7346.04 \mu\text{m}, 7346.04 \mu\text{m})$. One can see that, during the 80 ps long interval, the electron currents J_r and J_ϕ have undergone many oscillation cycles. Figures 4(b) and 4(d) show the

FIGURE 2: Snapshots of the induced electric field ΔE_r at (a) $t = 13.18$ ps and (b) $t = 16.11$ ps. Note that the induced electric field is much weaker than the embedded electric field.

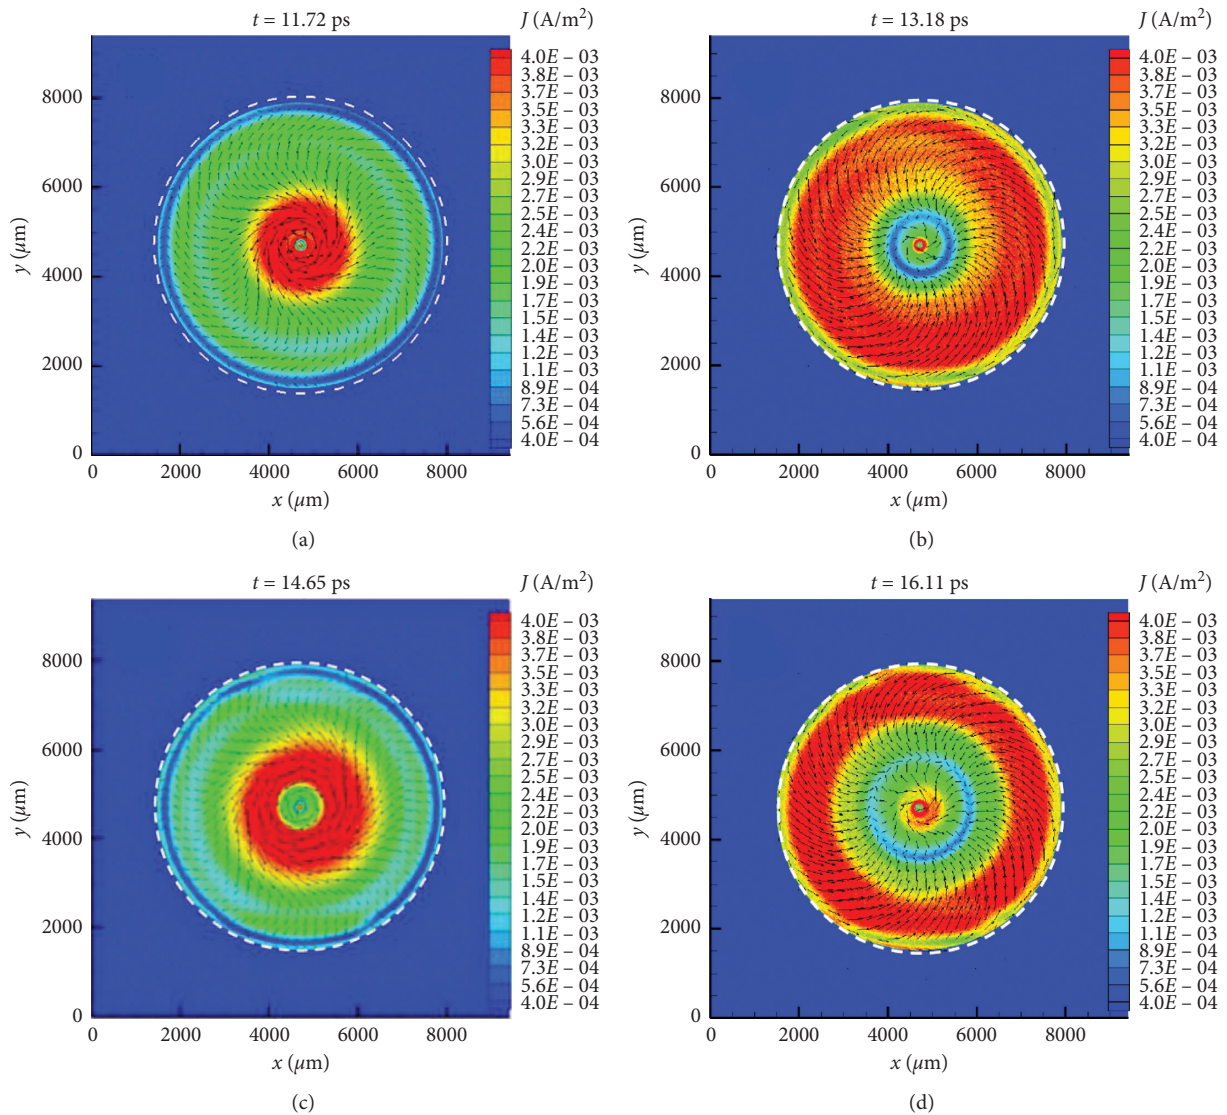

FIGURE 3: Snapshots of the current distribution at (a) $t = 11.72$, (b) $t = 13.18$, (c) $t = 14.65$, and (d) $t = 16.11$ ps. The black arrows represent local current vectors. Close inspection shows that the currents oscillate both radially and azimuthally. The white dashed circles mark the boundary of the initial plasma cylinder.

FIGURE 4: Evolution of the (a) radial current density J_r and (c) azimuthal current density J_ϕ at $(x, y) = (7346.04 \mu\text{m}, 7346.04 \mu\text{m})$. (b, d) The corresponding frequency spectra.

FIGURE 5: Evolution of the (a) total current density $\sum |J(x)|$ and (b) its frequency spectrum.

FIGURE 6: The frequency spectrum of the THz radiation. The peak is at ~ 0.35 THz, and the bandwidth is $\sim 5.7\%$.

corresponding frequency spectra. We can see in both the radial and azimuthal spectra a dominant peak at $f \sim 0.35$ THz (or $\omega \sim 2.2$ rad/sec). In fact, their overall spectral profiles are almost identical, suggesting that a 2D normal-mode-like structure has formed.

Figure 5 shows the evolution of the total current density $\sum |J(x)|$ in the simulation box. Figure 5(a) shows that the initial oscillations of the total current density are of large amplitude (to be expected since the initial plasma and fields do not form a self-consistent system), and the corresponding rate of decrease of the envelope is -4.9 A/m²/ps. At later times, the rate of decrease becomes -0.0012 A/m²/ps. Figure 5(b) shows the corresponding frequency spectrum, showing that the characteristic frequency of the current oscillations at this location is also ~ 0.35 THz.

5. Terahertz Radiation

Using the temporal and spatial current density from the simulation, one can obtain the far-field radiation. The total electromagnetic energy per unit solid angle Ω per unit frequency is given by the following equation [15, 29]:

$$\frac{d^2 I}{d\omega d\Omega} \approx \frac{\omega^2}{4\pi^2 c^3} \left| \int dt \int d^3 x \hat{n} \times [\hat{n} \times J(x, t)] e^{i\omega(t - \hat{n} \cdot x/c)} \right|^2, \quad (3)$$

where \hat{n} is the direction of the observer with respect to the radiating body. The intensity distribution of the radiation in the z -direction is then [15]

$$\frac{d^2 I}{d\omega d\Omega} \approx \frac{\omega^2}{4\pi^2 c^3} \left| \int dt J(t) e^{i\omega t} \right|^2, \quad (4)$$

where $J(t) = \int d^3 x J(x, t)$. The corresponding result is shown in Figure 6. We can see that the radiation spectrum has a broad peak centered at $f_0 \sim 0.35$ THz, as to be expected in view of the current density spectra discussed above. The full-width-at-half-maximum bandwidth $\Delta f/f_0$ is about 0.057.

6. Summary

In this paper, we have shown that a bounded plasma cylinder with embedded radial electric and axial magnetic fields can emit T-rays if the parameters of the plasma and the electric and magnetic fields are such that the electron plasma and cyclotron frequencies nearly match and are in the THz regime. As a result, resonance-like behavior of the electrons can occur. The electrons not only rotate in the azimuthal direction but also oscillate in both the radial and azimuthal directions. The resulting currents can emit THz radiation. Finally, it may be of interest to note that, in a nonperturbative analysis of the cold fluid and Maxwell equations, where all the electric and magnetic fields are self-consistent, similar coupled oscillation behavior of the charged particles can exist in an unbounded and self-consistently expanding plasma [30].
