In this article, we analyze Bianchi type–II, VIII, and IX spatially homogeneous and anisotropic space-times in the background of the Brans–Dicke theory of gravity within the framework of viscous holographic dark energy. To solve the field equations, we have used the relation between the metric potentials as \( R \sim S \) and the relation between the scalar field \( \phi \) and the scale factor \( a \) as \( \phi \sim a^m \). Also, we have discussed some of the dynamical parameters of the obtained models, such as the deceleration parameter \( (q) \), the jerk parameter \( (j) \), the EoS parameter \( (\omega_{\text{vhd}}) \), the density parameter \( (\Omega_{\text{vhd}}) \), Om-diagnostic, squared speed of sound \( (v^2_s) \), EoS plane \( (\omega_{\text{vhd}} - \omega_{\text{vhd}}') \), and statefinder plane \( (r - s) \) through graphical representation, which are significant in the discussion of cosmology. Furthermore, all the models obtained and graphically presented shown an expanding and accelerating Universe, which is in better agreement with the latest experimental data. The viscous holographic dark energy models are compatible with explaining the present cosmic accelerated expansion.

1. Introduction

In 1905, the theory of Special Relativity (SR) [1–3] was put forward by A. Einstein, which shown the genesis of absolute space and absolute time by surpassing the single 4D space-time, which had only an absolute meaning [4]. The perception that the gravitational field in a small neighborhood of space-time is incomprehensible from a proper acceleration in the frame of reference (principle of equivalence), has taken an upturn from Special Relativity (SR) to General Relativity (GR), where the gravitation has been adjoined to SR (holds true only in the absence of gravitation), which eventually gives a curved space-time, as the SR is generalized for the accelerating observers. As an outcome of Mach’s limitation of absolute space, as Einstein had anticipated, the idea of general covariance (the absence of an advantaged frame of reference) develops [5] and by default obeys Mach’s principle. Apparently, this was not the case, since various anti-Machian elements were discovered in GR.

Although GR is undeniably an appealing theory [6–10], it fails to offer the ultimate interpretation of gravity (a paradigm of a perfect theory), disregarding all the advantages. The theory has several conceptual issues, most of which are often overlooked, in addition to its much-discussed incompatibility with quantum mechanics. If in space, consistent with the same old epitome, where 95% of the overall constituent material continues to be missing, its miles an intimidating sign for us to doubt back to the very foundations of the theory. A significant perspective with a prominent context of alternative theories of gravitation develops from a critical study of Mach’s principle, the equivalence principle, dark energy (DE) and dark matter (DM), and so on. Over the years, alternative theories of gravity have continued to draw considerable interest, leading to the discussion of numerous theories. These theories offered the first potentially feasible alternatives to the conventional general relativistic theory of gravity as proposed by Einstein. One of them is scalar–tensor theories of gravitation, where the dynamical DE component is introduced in the
right-hand side of the Einstein field equations, and the other
is modified theories of gravitation, where the left-hand side
of the Einstein field equations are modified. Scalar-tensor
theories have emerged as some of the most well-established
and well-studied alternatives to conservative gravity theories
in the literature.

The Brans–Dicke theory (BDT) [11] is the most natural
choice as the scalar-tensor generalization of GR, which can be
considered as a pioneer in the study of scalar-tensor
theories, and the inclusion of Mach’s Principle led to the
advent of this theory. This can be called the first-ever theory
of gravity, where the metric tensor represents the dynamics
of space-time and the scalar field describes the dynamics
of gravity. The BDT also gives a fair description of the early era,
as well as the present phases of cosmic evolution that gives a
proper explanation for the Universe’s accelerated expansion
[12], as this theory justifies the experiments in the Solar System
domain [13]. The gravitational constant G in this
theory is to be replaced with 1/ϕ, where ϕ purely depends on
the time and is coupled to gravity with a coupling parameter
ω. It is evident in the literature that GR can be retrieved from
the BDT if ϕ is a constant and ω → ∞ [14, 15]. As and
when the coupling constant ω takes huge values greater than
500, GR can be deduced from BDT [16], accounting for
the recent Universe’s expansion and accommodating the ob-
servational data as well [17–19]. There is a prominent po-
sition for BDT among theories of gravitation because it is
capable of accounting for the properties of cosmic expansion
since the early phases of inflation [20]. A generalized (or modified) version of BDT [21–23] supports the notion that
the parameter ω depends on the scalar field ϕ. Several
models, based on the BDT, have been perfectly able to
explain the properties of the expanding Universe with the
help of various cosmological parameters [24–27]. The
models based on the generalized BDT have an extremely
low value for the coupling parameter, unaccommodating the
findings during the implementation of the previous versions
of the theory [20, 28–30]. A recent study in the BDT [31] has
been made in the FRW models with a varying λ-term and a
dynamic deceleration parameter. Also, it has been recently
justified that for huge values of ω, the generalization of BDT
can explain the Universe’s accelerated expansion with the
interaction between matter and a scalar field [32].

The anisotropy and the spatial homogeneity are the two
major characterizations for the Bianchi type (BT) cosmo-
logical models. There are nine different models altogether,
and these have been classified into two classes [33]. The
class A represents the BT models I, II, VII, VIII, and IX, and
class-B consists of BT models III, IV, V, VI, and VII. These
models are known to describe the evolution of the Universe’s
early stages in the presence of various physical distributions
of matter, thereby explaining the structure and space
properties of all the Einstein field conditions along with
cosmological arrangements, and thus, rewriting the Einstein
equations in the Hamiltonian form. In this regard, Misner
[34, 35] and other authors have focused much of their efforts
on fabricating a fine Hamiltonian system. In spite of this,
these Hamiltonian forms could not be utilized to prove the
collapse speculations by Lin and Wald [36, 37]. These BT
models uncover the magnitude of anisotropy in the back-
ground radiation and provide a pragmatic picture of the past
eras in the history of the cosmos. Furthermore, the cos-
mological problem of Einstein field equations from a the-
etorical perspective can be addressed well through the
anisotropic models, as they tend to have greater generality
when compared with isotropic solutions. In particular, we
are involved in studying the BT-II, VIII, and IX cosmological
models in the presence of viscous holographic dark energy
(VHDE) in BDT. Diverse aspects of the BT-II, VIII, and IX
cosmological models have been explored by many authors
[38–41].

Present-time experimental and theoretical supernovae
type Ia (SNeIa) observations [42, 43], cosmic microwave
background radiation (CMBR) [44, 45], and large-scale
structures [45, 46] provide the most enthralling evidence for
the same. Many models of the Universe have been studied
assuming the existence of a mysterious component, so-called
DE, which generates huge negative pressure, imparting the
mechanism for the accelerated cosmic expansion. Planck’s
current measurements indicate that 68.3% of the Universe’s
total energy content is in the form of DE. In spite of the
success of standard cosmology, it is known that there are a
few unsolvable problems that include the search for ac-
commodating DE candidates, in which researches found the
cosmological constant as a primary candidate for DE that
not only describes the phenomenon of DE but also the ‘‘fine
tuning’’ and ‘‘cosmic coincidence’’. For this reason, various
dynamical DE models, which include a family of scalar fields
such as quintessence [47–50], phantom [51–54], quintom
[55, 56], tachyon [57–59], K-essence [60], and various
Chaplygin gas models like generalized Chaplygin gas, ex-
tended Chaplygin gas, and modified Chaplygin gas [61–75],
have been developed.

Way back then, viscosity played an influential role in the
study of cosmology, which has been extended in recent years
to include the study of an accelerating Universe and has
acquired an immense interest in present times for numerous
reasons. The idea of perfect fluid in the study of cosmic
models has shown no dissipation and helps in the study of
cosmic evolution. In the existent scenario, the study of
imperfect fluid models has been suggested by introducing
the concept of viscosity. In particular, the bulk viscous fluids
that are included in the discourse of inflation are competent
for explaining late-time cosmic acceleration. The increase in
the viscosity is attributed to a Universe that is expanding at a
rapid rate and can be understood as an accumulation of
states that are out of thermal equilibrium in a small fraction
of time. For these obvious reasons, the concept of viscosity
has gained popularity in the study of space.

The holographic dark energy (HDE) models have seen
success in recent years, with many considering them as the
appropriate candidates to explain the problems of modern
cosmology. The concept of HDE was initially introduced by
Li [76] in 2004 with respect to the holographic principle
[77–83] to elucidate the late-time Universe’s accelerated
expansion. The holographic principle, as stated by black hole
thermodynamics [84, 85], says that a hologram can be
completely represented as a volume of space, which agrees
with a theory related to the boundary of that space [86] and the AdS/CFT (anti-de Sitter/Conformal field theory) correspondence, as it can be observed in the seminal reference [87]. In [76], a holographic principle-based cosmic acceleration model was developed for the first time. As such, the reduced Plank mass and a cosmological length scale, taken as the future event horizon of the Universe, are the two physical quantities of the boundary of the Universe on which a DE model relies on. As a consequence of an ultraviolet cutoff (Λ) for a region of size L, where the mass of a black hole of the similar size is not exceeded by the total energy, HDE density can be stated as \( \rho_{\text{hde}} = 3C^2M_p/L^2 \), with C being a constant, \( M_p = 1/\sqrt{8\pi G} \) being the reduced Plank mass, and G being the Newtonian gravitational constant. The holographic principle is considered as a central principle of quantum gravity because of its applications in various fields of physics, viz. cosmology [88] and nuclear physics [89] in the present era. All the generalized HDE models known as of now are the suggested ones by [90], which came only after Li. Moreover, the Nojiri–Odintsov HDE gives a detailed description of covariant theories different from Li’s HDE [91]. A more dynamical scenario for HDE in the BDT along with matter creation has been suggested instead of Einstein relativity. Recently, Singh and Srivastava [102] have considered VHDE for FRW space-time. The unification of viscosity and HDE is a mathematical attempt in the light of the holographic principle. Moreover, it is hypothesized that DE is pervading the whole Universe, with bulk viscosity giving the accelerated expansion of phantom types in the late time evolution of the Universe. Here, we have assumed pressure less DM and that the effective pressure of VHDE is a sum of the pressure of HDE and bulk viscosity. Eckart [101] has proposed a type of effective pressure in the context of general relativity. Recently, Singh and Srivastava [102] have considered VHDE for FRW space-time.

Now, with the help of equation (6), the field equations (3) and (4) for the metric in equation (1) can be written as

\[
S = \int d^4x \sqrt{-g} \left( -\phi \bar{\mathcal{R}} + \frac{\omega}{\phi} \phi \nabla \phi \nabla \phi + L_m \right),
\]

where \( \phi \) is the Brans–Dicke scalar field representing the inverse of Newton’s constant, which is allowed to vary with space and time, \( \bar{\mathcal{R}} \) is the scalar curvature, and \( \omega \) is the Brans–Dicke constant. Varying the action in (2) with respect to the metric tensor \( g_{ij} \) and the scalar field \( \phi \), the field equations are obtained as

\[
G_{ij} = -8\pi \rho_{\text{hde}} + \omega \phi^{-2} \left( \phi_i \phi_j - \frac{1}{2} g_{ij} \phi^k \phi_k \right) - \phi^{-1} (\phi_{ij} - g_{ij} \phi^k \phi_k),
\]

\[
\phi^k \phi_k = 8\pi (3 + 2\omega)^{-1} T^i,\]

where \( G_{ij} = \bar{\mathcal{R}}_{ij} - 1/2 \bar{\mathcal{R}} g_{ij} \) is an Einstein tensor, \( T_{ij} \) is the stress-energy tensor of the matter, and \( \bar{\mathcal{R}}_{ij} \) is the Ricci curvature tensor.

The conservation equation

\[
T^i_{\text{ij}} = 0,
\]

is a consequence of the field equations (3) and (4).

The energy momentum tensor for the VHDE is taken as

\[
T_{ij} = T^m_{ij} + T^h_{ij},
\]

Here, \( T^m_{ij} \) and \( T^h_{ij} \) represent matter and VHDE tensors, which are given as

\[
T^h_{ij} = (\bar{\mathcal{P}}_{\text{hde}} + \rho_{\text{hde}}) U^j_i U^h_j - \bar{\mathcal{P}}_{\text{hde}} g_{ij},
\]

\[
T^m_{ij} = \rho_m U^m_i U^m_j,
\]

where \( \rho_m \) is the energy density of the matter, \( \bar{\mathcal{P}}_{\text{hde}} \) and \( \rho_{\text{hde}} \), respectively, represent the pressure and energy density of the VHDE; \( U^i_j \) denotes the comoving velocity vector of the matter and VHDE, satisfying \( U^i_i U^j_j = 1 \). The VHDE pressure satisfies the relation \( \bar{\mathcal{P}}_{\text{hde}} = P_{\text{hde}} - 3\chi H \), where \( \chi \) is the bulk viscosity coefficient. Equation of state parameters for VHDE and HDE, respectively, are defined as \( \omega_{\text{hde}} = P_{\text{hde}}/\rho_{\text{hde}} \) and \( \omega_{\text{hde}} = P_{\text{hde}}/\rho_{\text{hde}} \). The unification of viscosity and HDE is a mathematical attempt in the light of the holographic principle. Moreover, it is hypothesized that DE is pervading the whole Universe, with bulk viscosity giving the accelerated expansion of phantom types in the late time evolution of the Universe. Here, we have assumed pressure less DM and that the effective pressure of VHDE is a sum of the pressure of HDE and bulk viscosity. Eckart [101] has proposed a type of effective pressure in the context of general relativity. Recently, Singh and Srivastava [102] have considered VHDE for FRW space-time.

Advances in Astronomy
The energy conservation equation of the matter is

\[ \frac{R^2}{R} + \frac{S^2}{S} + \frac{2R'}{R} \frac{S'}{S} = \frac{S^4}{4} + \frac{\omega \phi'^2}{2\phi^2} + \frac{\phi'}{\phi} + \frac{\phi''}{\phi} = -8\pi (P_{\text{vhde}} - 3\zeta H) \phi \]

Also, the energy conservation equation leads to

\[ \rho_m' + \rho_{\text{vhde}}' + \left( \frac{S'}{S} + \frac{2R'}{R} \right) (\rho_m + \rho_{\text{vhde}} + P_{\text{vhde}} - 3\zeta H) = 0. \]

The conservation equation of the matter is

\[ \rho_m' + \left( \frac{S'}{S} + \frac{2R'}{R} \right) \rho_m = 0, \]

and for VHDE, the conservation equation is

\[ \rho_{\text{vhde}}' + \left( \frac{S'}{S} + \frac{2R'}{R} \right) (\rho_{\text{vhde}} + P_{\text{vhde}} - 3\zeta H) = 0. \]

Here, the over-head dash denotes differentiation with respect to "T." Hence, to find a determinate solution to these highly nonlinear differential equations, we need at least three physically viable conditions:

We assume that the relation between the metric potentials (Collins et al., [103]) as

\[ R = S^n, \]

where \( n > 1 \).

We consider the relation between scale factor \( a \) and scalar field \( \phi \) (Tripathy et al., [104]) as

\[ \phi = a^m, \]

where \( m \) is a positive constant.

We take the bulk viscosity coefficient in the following form (Ren and Meng [105]; Meng et al., [106])

\[ \zeta = \zeta_0 + \zeta_1 H, \]

where \( \zeta_0 \) and \( \zeta_1 \) are positive constants and \( H \) is the Hubble parameter.
Now, using conditions (20) and (21) in field equations (13) and (14), we get
\[
\frac{S''}{S} + \left( \frac{m(2n + 1) - 3}{3} \right) \frac{S'}{S} = \frac{\delta S^{3n+2} - S^4}{1 - n} \tag{23}
\]

3.1. Bianchi Type-II ($\delta = 0$) Cosmological Model. If $\delta = 0$, equation (23) can be written as
\[
\frac{S''}{S} + \left( \frac{m(2n + 1) - 3}{3} \right) \frac{S'}{S} = -\frac{S^4}{1 - n} \tag{24}
\]

On solving equation (24), we get
\[
S = [2\beta_1 - 2\gamma_1 T]^{-1/2}, \quad R = [2\beta_1 - 2\gamma_1 T]^{-n/2}. \tag{25}
\]

\[
Y_1 = \left( 64 \left[ 3 + \left( n + \frac{1}{2} \right) m \right] (T\gamma_1 - \beta_1)^3 \gamma_1^3 \left( n + \frac{1}{2} \right) m (2\beta_1 - 2T\gamma_1)^{(-2n+1)m+12n-12/6}
- 144n^2 \gamma_1^2 (T\gamma_1 - \beta_1)^2 (2\beta_1 - 2T\gamma_1)^{(-2n-1)m+12n-6/6}
+ 8(T\gamma_1 - \beta_1) \left[ \frac{-27}{8} + \left( n + \frac{1}{2} \right) m^2 \gamma_1^2 \left( n^2 - 3m - \frac{27n}{2} + 9n \right) \right] (2\beta_1 - 2T\gamma_1)^{(-2n-1)m+12n/6}
- 576 \left[ (T\zeta_0 - \frac{\zeta_1 n}{3} - \frac{\zeta_1}{6}) \gamma_1 (n + \frac{1}{2}) \right]\right),
\]

The energy density of the matter is
\[
\rho_m = \beta_2 (2\beta_1 - 2\gamma_1 T)^{2n+1/2}, \tag{31}
\]

where $\beta_2$ is the constant of integration.

The energy density of the VHDE is
\[
Y_2 = \left( 9 + \left( 8\omega n + \frac{1}{2} \right)^2 m^2 - 48 \left( n + \frac{1}{2} \right)^2 m - 36n^2 - 72n \right) (2\beta_1 - 2T\gamma_1)^{(-2n-1)m+12n/6 - 576n\beta_2 (2\beta_1 - 2T\gamma_1)^{n+1/2} (T\gamma_1 - \beta_1)}\right)\right), \tag{33}
\]

The viscosity coefficient is given by
\[
\zeta = \zeta_0 + \frac{\zeta_1}{3} \left( 2n + 1 \right) \tag{34}
\]

Now the metric (1) can be written as
\[
ds^2 = dt^2 - [2\beta_1 - 2\gamma_1]^{-n} [d\theta^2 + d\phi^2]
- [2\beta_1 - 2\gamma_1]^{-1} [d\psi + \theta d\phi]^2. \tag{35}
\]
\[
S^2 = \beta_3^2 S^6 + \gamma^2 S^2, \quad (37)
\]
where \( \beta_3^2 = \frac{1}{2}k_2 - 6 \) and \( \gamma^2 = \frac{1}{2}k_2 - 2 \) with \( k_2 = m + 3/3 \).

From the equation (37), we get
\[
S = \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{1/2}, \quad (38)
\]
\[
R = \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{-1/2}.
\]

The spatial volume and an average scale factor are given by
\[
V = \cosh \theta \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{-1/2}, \quad (39)
\]
\[
a = (\cosh \theta)^3 \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{-1/6}. \quad (40)
\]

From equations (40) and (21), the scalar field \( \phi \) is given by
\[
\phi = \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{-m/6} (\cosh \theta)^{m/3}. \quad (41)
\]
The pressure of the VHDE is
\[
P_{vhde} = \frac{Y_3}{-144\pi\beta_3^3 \sinh^3(2\gamma T)}, \quad (42)
\]
where
\[
Y_3 = \left( \frac{m}{\cosh^3(\theta) \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^6} \right)^{-m/6} \left( -18 + (18 + (\omega + 2)m^2 + 6m)\gamma^2 \beta_3^2 \cosh^2(2\gamma T) + (18 + (-12m + 72)\gamma^2 \beta_3^2 - \frac{27\gamma^2}{2}) \right), \quad (43)
\]
\[
-144\beta_3^3 \left( \cosh(2\gamma T) \sinh(2\gamma T) \frac{\gamma^2}{3} + \cosh^2(2\gamma T) \zeta_0 - \zeta_0 \cosh(2\gamma T) \pi \right) \gamma^2 \right) \right].
\]

The energy density of the matter has the following expression:
\[
\rho_m = \beta_4 \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{1/2}, \quad (44)
\]
where \( \beta_4 \) is an integration constant.

The energy density of the VHDE is obtained as
\[
\rho_{vhde} = \frac{Y_4}{288\pi\beta_3^3 \sinh^3(2\gamma T)}, \quad (45)
\]
where
\[
Y_4 = \left( -2\gamma^2 \cosh^{m/3}(\theta) \left( 18 + (m^2 - 6m + 18)\gamma^2 \beta_3^2 \cosh^2(2\gamma T) - 18\beta_3^2 + \frac{9\gamma^2}{2} \right) \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{-m/6} \right. \quad (46)
\]
\[
-288\beta_3^3 \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{1/2} \sinh(2\gamma T) \pi \beta_3^2 \left( \cosh^2(2\gamma T) - 1 \right) \right].
\]

The viscosity coefficient is given by
\[
\zeta = \zeta_0 + \frac{\zeta_1 \gamma \coth(2\gamma T)}{3}. \quad (47)
\]

Hence, the metric (1) takes the following form:
\[
ds^2 = dt^2 - \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right]^{-1} \left[ d\theta^2 + \cosh \theta d\psi^2 \right] - \left[ \frac{\gamma^2}{\beta_3} \cosech(2\gamma T) \right] \left[ d\psi + \sinh \theta d\phi \right]^2. \quad (48)
\]
3.3. Bianchi Type-IX (δ = 1) Cosmological Model. If δ = 1, equation (23) can be written as

\[
\frac{S''}{S} + \left(\frac{m(2n + 1) - 3}{3}\right) \frac{S''}{S} = \frac{S^{2n+2} - S^4}{1 - n} \tag{49}
\]

We can solve the above equation and get the deterministic solution only for \( n = -1 \).

So, from equation (49), we get

\[
S^2 = \gamma_3^2 S_0^2 - \beta_5^2 S^6, \tag{50}
\]

where, \( \beta_5^2 = 1/6 - 2k_3 \) and \( \gamma_3^2 = 1/2 - 2k_3 \) with \( k_3 = m + 3/3 \).

From equation (49), we get

\[
S = \left[ \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right]^{1/2}, \tag{51}
\]

\[
R = \left[ \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right]^{-1/2}.
\]

The spatial volume and average scale factor are given by

\[
V = \sin\theta \left[ \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right]^{-1/2}, \tag{52}
\]

\[
a = (\sin\theta)^{1/3} \left[ \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right]^{-1/6}. \tag{53}
\]

From equations (21) and (53), the scalar field \( \phi \) is given by

\[
\phi = \left[ \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right]^{-m/6} (\sin\theta)^{m/3}. \tag{54}
\]

The pressure of the VHDE is as follows:

\[
P_{\text{vhde}} = \frac{Y_5}{144\pi\beta_5^3 \cosh^3(2\gamma_3 T)} \tag{55}
\]

where

\[
Y_5 = \left( -18 + \left( 18 + (\omega + 2)m^2 + 6m \right) \gamma_3^2 \beta_5^3 \cosh^2(2\gamma_3 T) - \gamma_3^2 \left( \frac{27}{2} + \left( -54 + (\omega + 2)m^2 - 6m \right) \beta_5^3 \right) \gamma_3^3 \sin^m \left( \theta \left( \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right) \right) \right) \gamma_3^5.
\]

The energy density of the matter is obtained as

\[
\rho_m = \beta_5 \left[ \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right]^{1/2}, \tag{57}
\]

the energy density of the VHDE has the following expression:

\[
Y_6 = \left( -2\sin^{-m/3} \left( \theta \right) \gamma_3 \left( -18 + \left( m^2 \omega - 6m + 18 \right) \gamma_3^2 \beta_5^3 \cosh^4(n(2\gamma_3 T)q) - n \gamma_3^2 \left( \frac{9}{2} + \left( m^2 \omega - 6m + 18 \right) \beta_5^3 \right) \gamma_3^3 \left( \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \right) \right) \right) \gamma_3^5.
\]

The viscosity coefficient is

\[
\zeta = \zeta_0 + \frac{\zeta_3 \gamma_3 \text{tanh}(2\gamma_3 T)}{3}. \tag{60}
\]

Hence, the metric (1) can be written as

\[
ds^2 = \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T)^{1/2} \left[ d\theta^2 + \sin\theta d\varphi^2 \right] - \frac{\gamma_3}{\beta_5} \text{sech}(2\gamma_3 T) \left[ d\psi + \cos\theta d\varphi \right]^2. \tag{61}
\]

Thus, equations (35), (48), and (61) represent spatially homogeneous and anisotropic BT-II, VIII, and IX VHDE cosmological models, respectively, in the Brans–Dicke scalar theory of gravitation. For graphical representation we consider the following values: \( n = 1.9, m = 0.97 \) for BT-II, \( m = 0.011 \) for BT-VIII, \( m = 3.999 \) for BT-IX, \( \gamma_1 = -0.099, \)
\[ \beta_1 = 0.145, \beta_2 = -1045, \omega = 958899, \zeta_1 = 9.15, 018.3, \zeta_0 = 0.35, 02, \gamma_2 = 0.099, \beta_3 = -9995, \gamma_3 = 0.095, \beta_5 = 0.011, \beta_0 = -999, a_0 = 1.5, H_0 = 85. \] 
The plots of VHDE pressure \((P_{\text{vhde}})\) against redshift respectively for BT-II, VIII, and IX models have been represented in Figures 1–3 for different values of \(\zeta_0\) and \(\zeta_1\). Here, we observe that the behavior of \(P_{\text{vhde}}\) for three different values of \(\zeta_0\) and \(\zeta_1\) is the increasing with redshift and varies in the negative region, which indicates the cosmic expansion. Moreover, as increasing the values of \(\zeta_0\) and \(\zeta_1\), we get more acceleration of the Universe. Also, we have depicted the energy density of VHDE \((\rho_{\text{vhde}})\) versus redshift in Figures 4–6 for BT–II, VIII, and IX models, respectively, and we observe that the trajectory varies in the positive region, which indicates an accelerated expansion of the cosmos. The bulk viscous coefficient has been plotted against redshift with various values of \(\zeta_0\) and \(\zeta_1\) for BT-II, VIII, and IX models, respectively, and we observe that the trajectory varies in positive regions throughout the evolution of all the three models for various values of \(\zeta_0\) and \(\zeta_1\), which indicates an accelerated expansion of the Universe.

Some of the cosmological properties of the models are discussed as follows:

The mean Hubble parameter \(H\) is given by

\[ H = \frac{H_1 + H_2 + H_3}{3}, \quad (62) \]

where \(H_1 = H_2 = \dot{R}/R, H_3 = \dot{S}/S\) are directional Hubble’s parameters, which express the expansion rates of the Universe in the directions of \(x, y_1\), and \(z\), respectively. The mean Hubble’s parameter of BT-II, VIII, and IX VHDE cosmological models are, respectively, given by

\[ H = \frac{\gamma_1 (2n + 1)}{3(2\beta_1 - 2\gamma_1 T)}, \]

\[ H = \frac{\gamma_2 \coth(2\gamma_2 T)}{3}, \quad (63) \]

\[ H = \frac{\gamma_3 \tanh(2\gamma_3 T)}{3}. \]

The anisotropic parameter of the BT-II VHDE model is given by

\[ A_b = \frac{1}{3} \sum_{i=1}^{3} \left( \frac{H_i - H}{H} \right)^2 = \frac{2(n - 1)^2}{(2n + 1)^2}, \quad (64) \]

and for the BT-VIII and IX VHDE cosmological models, we get

\[ A_b = 8. \quad (65) \]

From equations (64) and (65), we can observe that \(A_b \neq 0\), which indicates that the BT-II, VIII, and IX models are always anisotropic throughout the evolution of the Universe with respect to VHDE.

The expansion scalar \((\theta)\) has been defined as

\[ \theta = \frac{2\dot{R}}{R} + \frac{\dot{S}}{S}, \quad (66) \]

whose expressions for the BT-II, VIII, and IX VHDE models are, respectively, given as

\[ \theta = \frac{\gamma_1 (2n + 1)}{(2\beta_1 - 2\gamma_1 T)}, \]

\[ \theta = \gamma_2 \coth(2\gamma_2 T), \]

\[ \theta = \gamma_3 \tanh(2\gamma_3 T). \quad (67) \]

The shear scalar \((\sigma^2)\) is defined by the following equation and is followed by the expressions of \(\sigma^2\) for BT–II, VIII, and IX VHDE models, respectively, as

\[ \sigma^2 = \frac{1}{2} \delta_{ij} \sigma_{ij} = \frac{1}{2} \left( \sum_{i=1}^{3} (H_i - \frac{\dot{\theta}^2}{3}) \right), \quad (68) \]

\[ \sigma^2 = \frac{\gamma_1 (2n + 1)}{(2\beta_1 - 2\gamma_1 T)} (n - 1)^2, \quad (69) \]

\[ \sigma^2 = \frac{4\gamma_2 \coth^2(2\gamma_2 T)}{3}, \quad (70) \]

\[ \sigma^2 = \frac{4\gamma_3 \tanh^2(2\gamma_3 T)}{3}. \quad (71) \]
4. Some Other Important Properties of the Models

Now we compute the following dynamical parameters, which are significant in the physical discussion of the cosmological models presented in equations (35), (48), and (61).

4.1. Deceleration Parameter ($q$). The parameter is defined as

$$q = -\frac{a \dddot{a}}{a^2},$$

that depends upon the scale factor and its derivatives. It is considered to describe the transition phase of the Universe.
and basically computes the expansion rate of the cosmos. Whenever the deceleration parameter shows a positive curve, it indicates the decelerated expansion of the Universe. Whereas, the negative curve implies that there is an accelerated expansion of the cosmos and at $q = 0$ there exists the marginal inflation. The deceleration parameters of the BT-II, VIII, and IX models are, respectively, given by

$$q = \frac{-6}{2n+1} - 1,$$

$$q = 6\text{sech}^2(2\gamma_2T) - 1,$$

$$q = -6\text{cosech}^2(2\gamma_3T) - 1.$$ 

\text{(73)}
The behavior of the deceleration parameter \(q\) for BT-VIII and IX models has been depicted against the redshift \(z\) in Figures 10 and 11, respectively. From Figure 10, it is observed that the path of the BT-VIII curve travels from the deceleration to the acceleration phase while passing through the transition line. Whereas, from Figure 11, it is clear that the curve for BT-IX varies in an accelerated phase. However, the deceleration parameter of BT-II is independent of time. Some of the authors, namely, Berman [107], Bishi et al. [108], Santhi et al. [109], Santhi and Naidu [110], Samanta [111], Kumar and Singh [112], have attained a constant \(q\) in their research.

4.2. Jerk Parameter \((j)\)

The cosmic jerk,

\[
j = \frac{1}{aH^2} \frac{d^3a}{dt^3},
\]

(74)

can be accounted for by the transition of the Universe from the decelerating to the accelerating phase. For various models of the cosmos, there is a variation in the transition of the Universe whenever the jerk parameter lies in the positive region and the deceleration parameter lies in the negative region (Visser [113]). Rapetti et al. [114] showed that for the flat ΛCDM model, the value of jerk becomes unity.

The Jerk parameter of the BT-II, VIII, and IX models is, respectively, given by

\[
j = \frac{4n + 40n + 91}{(2n + 1)^2},
\]

\[
j = 54 \text{sech}^2(2\gamma_2 T) + 1,
\]

\[
j = 1 - 54 \text{cosech}^2(2\gamma_1 T).
\]

Figures 12 and 13 represent the variations of the jerk parameter plotted against redshift \(z\) for the models BT-VIII and IX, respectively. The trajectory of the jerk parameter for the BT-VIII model in Figure 12 varies in the positive region, whereas for the BT-IX model in Figure 13, the trajectory varies in the negative region, both of which approach unity in late times. However, the jerk parameter for BT-II is independent of time. Santhi and Naidu [115], Rao et al. [116], Santhi et al. [117], Rao and Prasanthi [118], and Shaikh et al. [119] are some of the researchers who have acquired a constant jerk parameter in their work.

4.3. Statefinder Pair \((r, s)\).

As mentioned earlier, a mysterious force, the DE, may be responsible for the cosmos to undergo an accelerated expansion into the current era. But as of now, there is no adequate information about DE. Hence, it becomes necessary to identify and understand the various properties of DE and its importance in various kinds of cosmographic models. Ratra and Peebles [47], Kamenshik et al. [61], Armendariz Picon et al. [60] Dvali et al. [120] have proposed various studies to realize that different DE forms, such as quintessence, Chaplygin gas, k-essence, and brane world models, give several families of curves for scale factor \(a(t)\). As a way of categorizing the various types of DE, Sahni et al. [121] have proposed a diagnostic pair known as the “statefinder diagnostic,” defined as

\[
r = \frac{\dot{a}}{aH^3} \quad \text{and} \quad s = \frac{r - 1}{3(q - 1/2)},
\]

(76)

that is based upon the derivatives of the scale factor \(a(t)\) and the deceleration parameter \(q\). We have obtained expressions for the statefinder diagnostic pair \((r, s)\) for the models BT-II, VIII, and IX, which are respectively given by

\[
r = \frac{(2n + 7)(2n + 13)}{(2n + 1)^2} \quad \text{and} \quad s = \frac{-4}{(2n + 1)}
\]

\[
r = 54 \text{sech}^2(2\gamma_2 T) + 1 \quad \text{and} \quad s = \frac{-12}{\text{cosh}^2(2\gamma_2 T) - 4}
\]

\[
r = 1 - 54 \text{cosech}^2(2\gamma_1 T) \quad \text{and} \quad s = \frac{12}{\text{cosh}^2(2\gamma_1 T) + 3}
\]

The interpretation of the statefinder pair from Figures 14 and 15 says that the \((r, s)\) plane for BT-VIII and IX models starts its evolution from the quintessence and phantom regions and reaches the ΛCDM model\((r = 1, s = 0)\). Also, for the BT-II Universe, the statefinder plane is independent of time. Shanti et al. [122], Samanta and Mishra [123], Katore and Gore [124], and Shaikh et al. [119] are some of the authors who have obtained the statefinder parameters independent of time.

4.4. EoS Parameter \((\omega_{\text{vhde}})\). To classify the phases of the inflating Universe, viz., the transition from decelerated to accelerated phases containing DE and radiation dominated eras, the EoS parameter \(\omega_{\text{vhde}}\) can be broadly used, whose expression is given by \(\omega_{\text{vhde}} = P_{\text{vhde}}/\rho_{\text{vhde}}\).

It categorizes various epochs as follows:

Decelerated phase:

(i) stiff fluid (\(\omega_{\text{vhde}} = 1\)),

(ii) the radiation dominated phase (\(0 < \omega_{\text{vhde}} < 1/3\)) and

(iii) dust fluid phase or cold dark matter (\(\omega_{\text{vhde}} = 0\)).

Accelerated phase:

(i) the quintessence phase (\(-1 < \omega_{\text{vhde}} < -1/3\)),

(ii) cosmological constant/vacuum phase (\(\omega_{\text{vhde}} = -1\))

(iii) quintom era and phantom era (\(\omega_{\text{vhde}} < -1\)).

The EoS Parameter for the BT-II VHDE cosmological model is given by

\[
\omega_{\text{vhde}} = \frac{Y_7}{Y_5},
\]

(78)

where
Figure 10: Deceleration parameter ($q$) versus redshift ($z$) for BT-VIII.

Figure 11: Deceleration parameter ($q$) versus redshift ($z$) for BT-IX.

Figure 12: Jerk ($j$) versus redshift ($z$) for BT-VIII.
Figure 13: Jerk ($j$) versus redshift ($z$) for BT-IX.

Figure 14: Statefinder plane ($r - s$) for BT-VIII.

Figure 15: Statefinder plane ($r - s$) for BT-IX.
\[ Y_9 = \frac{1}{576} \left( -64 \left( 3 + (n + \frac{1}{2})m \right) (T \gamma_1 - \beta_1)^3 \gamma_1^2 m \left( n + \frac{1}{2} \right) \left( -2T \gamma_1 + 2\beta_1 \right) \left( -2n - 1 \right) m + 6n - 12 \right) \frac{(-2n - 1) m + 6 n - 12}{6}, \]

\[ + 144 \gamma_1^2 n^2 \left( T \gamma_1 - \beta_1 \right)^2 \left( -2T \gamma_1 + 2\beta_1 \right) \frac{(-2n - 1) m + 6 n - 6}{6}, \]

\[ - 8 \left( T \gamma_1 - \beta_1 \right) \left( \frac{-27}{8} + \left( \left( n + \frac{1}{2} \right) \omega m^2 + \left( -3n - \frac{3}{2} \right) m - \frac{27 n^2}{2} + 9n \right) \gamma_1^2 \right) \left( -2T \gamma_1 + 2\beta_1 \right) \frac{(-2n - 1) m + 6 n}{6}, \]

\[ + 576 (-2T \gamma_1 + 2\beta_1)^{-n} \gamma_1 \left( T \xi_0 - \frac{\xi n}{3} - \frac{\xi}{6} \right) \gamma_1 - \xi_0 \beta_1 \left( n + \frac{1}{2} \right) \right) \right), \]

\[ Y_8 = \left( T \gamma_1 - \beta_1 \right) \left( \frac{-1}{64} \left( \left( n + \frac{1}{2} \right) \omega m^2 + \frac{1}{12} \left( n + \frac{1}{2} \right) m + \frac{n^2}{16} + \frac{n}{8} \right) \gamma_1 \right) \left( -2T \gamma_1 + 2\beta_1 \right) \frac{(-2n - 1) m + 6 n}{6}, \]

\[ + (-2T \gamma_1 + 2\beta_1) \left( n - \frac{1}{2} \gamma_2 \left( T \gamma_1 - \beta_1 \right) \right) \right) \right). \]

The EoS parameter for the BT-VIII VHDE cosmological model is given by

\[ \omega_{\text{shde}} = \frac{Y_9}{Y_{10}} \quad (80) \]

\[ Y_8 = \left( 8 \left( \cosh^m (\theta \left( -18 + (m^2 + 6m) \gamma_1^2 \right) \beta_1 \cosh^2 (\gamma_1) + (n + \frac{1}{2}) \omega m^2 + \frac{1}{12} \left( n + \frac{1}{2} \right) m + \frac{n^2}{16} + \frac{n}{8} \right) \gamma_1 \right) \left( -2T \gamma_1 + 2\beta_1 \right) \frac{(-2n - 1) m + 6 n}{6}, \]

\[ + 576 (-2T \gamma_1 + 2\beta_1)^{-n} \gamma_1 \left( T \xi_0 - \frac{\xi n}{3} - \frac{\xi}{6} \right) \gamma_1 - \xi_0 \beta_1 \left( n + \frac{1}{2} \right) \right) \right), \]

\[ Y_9 = \left( 8 \left( \cosh^m (\gamma_1) + \frac{1}{2} \left( \gamma_1 \cosh (\gamma_1) \sinh (\gamma_1) + \frac{1}{2} \left( \gamma_1 \cosh (\gamma_1) \sinh (\gamma_1) + \frac{3}{10} \gamma_1 \cosh (\gamma_1) \sinh (\gamma_1) \sinh (\gamma_1) \sinh (\gamma_1) \right) \gamma_1 \right) \gamma_1 \right) \gamma_1 \right) \left( -2T \gamma_1 + 2\beta_1 \right) \frac{(-2n - 1) m + 6 n}{6}, \]

\[ + 8 \left( \cosh^m (\theta \left( 18 + (m^2 + 6m) \gamma_1^2 \right) \beta_1 \cosh (\gamma_1) + (n + \frac{1}{2}) \omega m^2 + \frac{1}{12} \left( n + \frac{1}{2} \right) m + \frac{n^2}{16} + \frac{n}{8} \right) \gamma_1 \right) \left( -2 \left( \cosh (\gamma_1) \tanh (\gamma_1) + 1 \right) \right) \right) \right), \]

\[ \omega_{\text{shde}} = \frac{Y_{11}}{Y_{12}} \quad (82) \]

where
\[ Y_{11} = \left( \sin^2 \theta \left( -18 + (w + 2m^2 + 6m)\beta^2 \right) \right) \beta \sinh(yT) - \left( -18 + (w + 2m^2 + 6m)\beta^2 \right) \beta \cosh(yT) + \left( -\frac{27}{8} + (3m + 18)\beta^2 \right) \beta \cosh (2yT) \right)^{\text{min}} \]

\[ -96\cosh(yT) \left( \beta \cosh(yT) \right) + 3\cosh(yT) \sinh(yT) \cosh(yT) - \frac{3\beta^2}{2} \sinh(yT) \right) \beta \cosh(yT) \left( -\frac{1}{2} \right) \beta \cosh(yT) \]

\[ Y_{12} = \left( 2304\beta^6 \left( \beta \sinh(yT) - \frac{1}{2} \right) \left( \frac{\beta}{\sinh^2(yT) - 1} \right) \right)^{1/2} + 8\beta^2 \sinh^2 \theta \left( \frac{1}{\beta} \cosh(2yT) \right)^{\text{min}} \left( \left( -18 + (m^2 - 6m + 18)\beta^2 \right) \beta \cosh(yT) \right) \]

\[ -\left( -18 + (m^2 - 6m + 18)\beta^2 \right) \beta \cosh(yT) \left( \frac{9\beta^2}{2} + \frac{9\beta^4}{2} \right) \right) \right] \right). \]

(83)

Figures 16–18 show the behavior of the EoS parameter \( \omega_{\text{vhde}} \) taken against redshift \( z \) with different values of \( \zeta_0 \) and \( \zeta_1 \) for all the three models of BT-II, VIII, and IX, respectively. Here, we notice that the curves of \( \omega_{\text{vhde}} \) for BT-II and IX models for different values of \( \zeta_0 \) and \( \zeta_1 \) begin from the quintessence region \((-1 < \omega_{\text{vhde}} < -1/3)\) and cross the nonrelativistic matter \( \omega_{\text{vhde}} = -1 \) then reaching the phantom region \( \omega_{\text{vhde}} < -1 \), whereas for BT-VIII, in the presence of null viscosity (i.e., \( \zeta_0 = 0 \) and \( \zeta_1 = 0 \)), the curve of \( \omega_{\text{vhde}} \) varies in the quintessence region and as the values of \( \zeta_0 \) and \( \zeta_1 \) are increased, we get the quintessence to the phantom region by crossing the phantom divided line, varying more in the phantom region, which indicates accelerated expansion of the Universe. According to the obtained models, the observed EoS parameters match the 2018 Planck data [125], where the EoS parameter limits are as follows:

\[ \omega_{\text{vhde}} = \begin{cases} 
-1.56^{+0.01}_{-0.01} \text{ (Planck + TT + ioE),} \\
-1.58^{+0.01}_{-0.01} \text{ (Planck + TT, EE + ioE),} \\
-1.57^{+0.01}_{-0.01} \text{ (Planck + TT, TE, EE + ioE + lensing),} \\
-1.04^{+0.01}_{-0.01} \text{ (Planck + TT, TE, EE + ioE + lensing + BAO).} 
\end{cases} \]

(84)

For the BT-VIII VHDE cosmological model,

\[ \omega'_{\text{vhde}} = \frac{Y_{15}}{Y_{16}}. \]

(87)

where
Figure 16: EoS parameter ($\omega_{vhde}$) versus redshift ($z$) for BT-II.

Figure 17: EoS parameter ($\omega_{vhde}$) versus redshift ($z$) for BT-VIII.
For the BT-IX VHDE cosmological model,

\[ \omega'_{\text{vde}} = \frac{Y_{17}}{Y_{18}} \]  

(89)

where
The evolutionary trajectories of $\omega_{\text{vhde}} - \omega_{\text{vhde}}'$ plane for the BT-II, VIII, and IX models are plotted with different values of $\zeta_0$ and $\zeta_1$ in Figures 19–21, respectively and we notice that the $\omega_{\text{vhde}} - \omega_{\text{vhde}}'$ plane for the BT-II and IX models vary in the freezing region (i.e., $\omega_{\text{vhde}} < 0$ and $\omega_{\text{vhde}}' < 0$) whereas, the $\omega_{\text{vhde}} - \omega_{\text{vhde}}'$ plane of the BT-VIII model varies in thawing region (i.e., $\omega_{\text{vhde}} < 0$ and $\omega_{\text{vhde}}' > 0$) for small values of $\zeta_0$ and $\zeta_1$. However, by increasing the values of $\zeta_0$ and $\zeta_1$ we get the freezing region for the BT-VIII model. Hence, the $\omega_{\text{vhde}} - \omega_{\text{vhde}}'$ plane of our obtained models is in accordance with the present observational data [127, 128] as follows:

$$\omega_{\text{vhde}} = -1.17^{+0.13}_{-0.12},$$

$$\omega_{\text{vhde}}' = 0.85^{+0.50}_{-0.45} \text{ (WMAP + eCAMB + BAO + H}_0 + \text{ SNe),}$$

$$\omega_{\text{vhde}} = -1.13^{+0.24}_{-0.25},$$

$$\omega_{\text{vhde}}' = 1.32 \text{ (Planck + WP + BAO),}$$

$$\omega_{\text{vhde}} = -1.34^{+0.18}_{-0.18},$$

$$\omega_{\text{vhde}}' = 0.85 \pm 0.7 \text{ (WMAP + eCAMB + BAO + H}_0).$$

(91)

4.6. Stability of the Model. To examine the stability of any DE model, we utilize the squared speed of sound ($v_s^2$). The models with $v_s^2 < 0$ shows instability whereas as models with $v_s^2 > 0$ shows stability. Hence, the $v_s^2$ is determined as follows [129]:

$$v_s^2 = \frac{P_{\text{vhde}}'}{\rho_{\text{vhde}},}$$

(92)

where $P_{\text{vhde}}'$ and $\rho_{\text{vhde}}'$ are the differentiation of pressure and density of VHDE w.r.t cosmic time $T'$, respectively.

The squared speed of the sound for the BT-II VHDE model is given by

$$v_s^2 = \frac{Y_{19}}{Y_{20}},$$

(93)

where

$$Y_{19} = \frac{-1}{32} \left( (T_{Y_1} - \beta_1)^2 \left( \left( \frac{n+1}{2} \right) m - 6n + 3 \right) y_1^2 \left( \frac{n+1}{2} \right) m \left( 3 + \left( \frac{n+1}{2} \right) m \right) \left( -2T_{Y_1} + 2\beta_1 \right) \right) \left( \frac{2m - 6n + 12}{6} \right),$$

$$-\frac{9n^2}{2} \left( T_{Y_1} - \beta_1 \right)^2 \left( \frac{n+1}{2} \right) m - 6n + 3 \right) y_2^2 \left( -2T_{Y_1} + 2\beta_1 \right) \left( \frac{2m - 6n + 12}{6} \right) + \frac{1}{8} \left( T_{Y_1} - \beta_1 \right) \left( \frac{n+1}{2} \right) m - 6n + 3 \right),$$

$$-\frac{27}{8} \left( \left( \frac{n+1}{2} \right)^2 \omega m^2 + \left( -3n - \frac{3}{2} \right) m - \frac{27m^2}{2} + 9n \right) y_2^2 \left( -2T_{Y_1} + 2\beta_1 \right) \left( \frac{-2m - 6n + 12}{6} \right),$$

$$-27 \left( -2T_{Y_1} + 2\beta_1 \right) n \gamma_1 \left( \frac{2m - 6n + 12}{6} \right) y_1 - \frac{\left( T_{\zeta_0} - \frac{2m - 6n + 12}{6} \right) y_1 - \zeta_0 \beta_1 \right) \left( -2T_{Y_1} + 2\beta_1 \right) \left( \frac{2m - 6n + 12}{6} \right),$$

$$-27 \left( -2T_{Y_1} + 2\beta_1 \right) n \gamma_1 \left( \frac{2m - 6n + 12}{6} \right) y_1 - \frac{\left( T_{\zeta_0} - \frac{2m - 6n + 12}{6} \right) y_1 - \zeta_0 \beta_1 \right) \left( -2T_{Y_1} + 2\beta_1 \right) \left( \frac{2m - 6n + 12}{6} \right),$$

$$Y_{20} = \left( T_{Y_1} - \beta_1 \right) \left( \frac{-1}{32} \left( \left( \frac{n+1}{2} \right) m - 6n + 3 \right) y_1^2 \left( \frac{n+1}{2} \right) m \left( 3 + \left( \frac{n+1}{2} \right) m \right) \left( -2T_{Y_1} + 2\beta_1 \right) \right) \left( \frac{2m - 6n + 12}{6} \right),$$

$$\left( -2T_{Y_1} + 2\beta_1 \right) \left( \frac{-2m + 6n - 3n + 12}{6} \right) + \left( T_{Y_1} - \beta_1 \right) n \gamma_1 \left( \frac{n+1}{2} \right) m - 6n + 3 \right) y_2^2 \left( -2T_{Y_1} + 2\beta_1 \right) \left( \frac{-2m + 6n - 3n + 12}{6} \right).$$

(94)
For the BT-VIII VHDE cosmological model,

\[ v_s^2 = \frac{\gamma_{21}}{\gamma_{22}} \]  \hspace{1cm} (95)
\[ Y_{21} = \left\{ 4 \left( \cosh^3(\theta) \left( \cosh^2(y_2 T) - \frac{1}{2} \right) \left( -18 + (18 + (\omega + 2)m^2 + 6m)\frac{\beta^2}{3} \right) \right) + (m - 6)\beta_3^2 \cosh^4(y_2 T) \right\} \]

\[ \left( -18 + (18 + (\omega + 2)m^2 + 6m)\frac{\beta^2}{3} \right) \]

\[ (m - 6)\beta_3^2 \cosh^2(y_2 T) + \frac{1}{4} (m - 18)\frac{\beta^2}{3} \left( \frac{27}{2} + (-54 + (\omega + 2)m^2 - 6m)\beta_3^2 \right) \]

\[ \left( \frac{\cosh^2(y_2 T)}{6} \right) \] \[ + 288 \left( \cosh^2(y_2 T) \sinh(y_2 T)\frac{\beta^2}{3} \right) \]

\[ + \frac{3}{2} \cosh^2(y_2 T) - \frac{\beta^2}{3} \sinh(y_2 T)\frac{\beta^2}{3} - \frac{3}{2} \cosh(y_2 T) \]

\[ \frac{\beta^2}{3} \left( \frac{\cosh(y_2 T)}{6} \right) \]

\[ \left\{ \frac{\beta^2}{3} \right\} \]

\[ Y_{22} = \left\{ \cosh(2y_2 T) \left( \cosh^3(\theta) \left( \frac{\cosh^2(y_2 T)}{6} \right) \right) \right\} \]

\[ \left\{ \frac{\beta^2}{3} \right\} \]

\[ \sqrt{2} \left( (m - 6)(18 + (m^2\omega - 6m + 18)\frac{\beta^2}{3})^2 \right) \]

\[ \cosh^4(y_2 T) - (m - 6)\left( 18 + (m^2\omega - 6m + 18)\frac{\beta^2}{3} \cosh^2(y_2 T) + \frac{1}{4} (m - 18)\left( \frac{9}{2} + (m^2\omega - 6m + 18)\frac{\beta^2}{3} \right) y_2 \right) \]

\[ \left( \frac{\beta^2}{3} \cosh(y_2 T) \right) \]

\[ \left\{ \frac{\beta^2}{3} \right\} \]

\[ \left\{ \frac{\beta^2}{3} \cosh^2(y_2 T) \left( \cosh^2(y_2 T) - 1 \right) \right\} \]

For the BT-IX VHDE cosmological model, where

\[ \frac{v_s^2}{y_{24}} = \frac{Y_{23}}{Y_{24}} \]
We have plotted the squared speed of the sound \((v_s^2)\) versus redshift for three different values of \(\zeta_0\) and \(\zeta_1\) for BT-II, VIII, and IX models in Figures 22–24. The \(v_s^2\) of BT-II and VIII models show the unstable behavior for three values of \(\zeta_0\) and \(\zeta_1\). Whereas, \(v_s^2\) of BT-IX gives the stable to unstable behavior. Also, by increasing the values of \(\zeta_0\) and \(\zeta_1\), i.e., increasing bulk viscosity, the models indicate the unstable behavior of the Universe.

### 4.7. Density Parameter \((\Omega_{\text{vhde}})\)

The dimensionless density parameter of DE \((\Omega_{\text{vhde}})\) is defined as

\[
Y_{25} = \left\{\left(-18 \pm (18 + \omega + 2\beta_1 + 6\beta_2 - 6n + 18)\right)c_0^2 + (18 \pm \omega + 2\beta_1 + 6\beta_2 - 6n + 18)\right\}^{\frac{1}{2}}
\]

\[
\Omega_{\text{vhde}} = \frac{\sqrt{Y_{26}}}{96y_2^2\beta_2^3\sinh(2y_2T)\cosh^2(2y_2T)}
\]

where

\[
Y_{26} = \left\{-2y_2(\cosh(\theta))^m\left(\frac{y_2}{\beta_3}\cosh(2y_2T)\right)^{-m/6}\left(18 + (m^2\omega - 6m + 18)y_2^3\beta_3^2\cosh^2(2y_2T) - 18\beta_3^2 + \frac{9y_2^2}{2}\right)\right\}^{\frac{1}{2}}
\]

\[
\Omega_{\text{vhde}} = \frac{\sqrt{Y_{27}}}{96y_2^2\cosh(2y_2T)\beta_3^2\sinh^2(2y_2T)}
\]

where
\[ Y_{27} = \left\{ -2 \left( -18 + (m^2 \omega - 6m + 18) \gamma_s \beta^2 \cosh^2(2 \gamma_s T) - \gamma_s \left( \frac{-9}{2} + (m^2 \omega - 6m + 18) \beta^2 \right) \right) \gamma_s \left( \frac{\gamma_s}{\beta_s} \sech^2(2 \gamma_s T) \right) \right\}^{ -m/6 } \]

\[ -288 \beta_s \left( \frac{\gamma_s}{\beta_s} \sech^2(2 \gamma_s T) \right)^{1/2} \pi \beta_s \cosh^3(2 \gamma_s T) \}

Figure 22: Squared speed of sound \((v^2)\) versus redshift \((z)\) for BT-II.

Figure 23: Squared speed of sound \((v^2)\) versus redshift \((z)\) for BT-VIII.

The density parameter \(\Omega_{\text{rde}}\) for BT-II, VIII, and IX VHDE models against redshift \((z)\) is seen in Figures 25–27,
respectively. It can be seen that the trajectories of $\Omega_{vhde}$ are decreasing against redshift ($z$) for all the three models and are varying in the positive region.

4.8. Om-Diagnostic ($Om(z)$). To discriminate different phases of the Universe, Sahni et al., [130] have introduced another tool called the Om-diagnostic. It is also used to distinguish the $\Lambda$CDM for the nonminimally coupled scalar field, quintessence model, and phantom field through the trajectories of the curves. The phantom DE era corresponds to the positive trajectory, whereas the negative trajectory indicates that the DE constitutes quintessence. The om-diagnostic function is defined as

$$Om(z) = \frac{H^2(z) - H_0^2}{H_0^2(z^3 - 1)}$$  \hspace{1cm} (106)

The Om-diagnostic for models which are in Equations (35), (48), and (61) are, respectively, given by

$$Om(z) = \frac{\gamma_1(2n + 1) - 3H_0^2((1 + z)/a_0)^{(6/2n+1)}}{3H_0^2((1 + z)/a_0)^{(6/2n+1)}(z^3 - 1)},$$

$$Om(z) = \frac{\left(\gamma_2/9\right)\left(1 + \left(\beta_2/\gamma_2\right)\cos^2(\theta)(1 + z)/a_0^6\right)^2}{H_0^2(z^3 - 1)},$$

$$Om(z) = \frac{\left(\gamma_3/9\right)\left(1 + \left(\beta_3/\gamma_3\right)\sin^2(\theta)(1 + z)/a_0^6\right)^2}{H_0^2(z^3 - 1)},$$  \hspace{1cm} (107)

The plots of the Om-diagnostic against redshift ($z$) are represented for the BT–II, VIII, and IX models in Figures 28–30, respectively, which depict the quintessence behavior of the DE, as the trajectories for the three models vary in the negative region.

5. Interpretations of the Models

To understand the cosmological mysteries of accelerated expansion, we have constructed the field equations of BDT for BT–II, VIII, and IX Universe in the context of VHDE. The exact solutions of the Brans–Dicke field equations are obtained by considering the relations between the metric potentials, the relation between scalar field and scale factor, and by taking bulk viscosity as proposed by Ren and Meng [105] and Meng et al., [106]. Furthermore, we have discussed the evolution of the Universe by studying various...
geometrical and physical parameters. We have plotted VHDE pressure, EoS parameter, EoS plane, and the squared speed of the sound by taking various values of $\zeta_0$ & $\zeta_1$. Also, a comparison study has been conducted by considering some isotropic and homogeneous cosmological models. Now, we summarize the results of the obtained models as follows:

For the Bianchi type-II cosmological model, we observe that the Universe shows a rapid expansion, as the VHDE pressure and energy density vary in negative and positive regions, respectively. This is further justified by the bulk viscosity coefficient ($\zeta$) as, it is varying in the positive region throughout the cosmic evolution. We have constructed plots for various parameters and have observed that the deceleration parameter ($q$), the jerk parameter ($j$), and the statefinder plane ($r - s$) behave independently of time. The Universe shows a quintom-like nature, which is interpreted with the help of the EoS parameter; and the EoS plane varies in the freezing region. This behaviors of the EoS parameter and the EoS plane represents the accelerated expansion of the cosmos. The squared speed of sound ($v_s^2$) varies in the negative region, depicting an unstable Universe model. Also, the density parameter ($\Omega_{vhde}$) is decreasing and varying in the positive region and the $\Omega_m(z)$ differs in the negative region, depicting the quintessence behavior of the Universe.

For the Bianchi type-VIII cosmological model has an accelerated cosmic expansion as the VHDE pressure and energy density vary in the negative and positive regions, respectively. Also, $\zeta$ is varying in the positive region, indicating an accelerated expansion of the Universe. The deceleration parameter ($q$) shows a transition from an early
decelerating phase to a late accelerating phase, and the jerk parameter differs in a positive region approaching to one as \( z \rightarrow 0 \). Moreover, the statefinder pair \((r, s)\) starts its evolution from the quintessence and phantom regions and reaches the \( \Lambda \) CDM model (for \( r = 1, s = 0 \)). The model shows an unstable behavior, as \( v^2 \) is varying in the negative region. The plot of the EoS parameter states that the model varies in the phantom region and the EoS plane differs in the freezing region. The density parameter is decreasing and varying in the positive region and the \( \Omega_m \) varies in the negative region depicting, the quintessence behavior of the Universe.

For the Bianchi type-IX cosmological model, the plots for VHDE pressure, energy density, and viscosity coefficients indicate an accelerated cosmic expansion as they vary in negative, positive, and positive regions respectively. The curve of deceleration parameter \((q)\) varies in the accelerated phase, whereas the jerk parameter \((j)\) varies in the negative region, approaching to one in the near future as \( z \rightarrow 0 \). The squared speed of sound varies in positive to negative region, depicting the stable to an unstable behavior of the Universe. Also, the statefinder pair starts its evolution from the quintessence and phantom regions and reaches the \( \Lambda \) CDM model (for \( r = 1, s = 0 \)). The Universe shows the quintom region and is distinguished in the freezing region as the EoS parameter and EoS plane are varying in the negative region, respectively. The density parameter \((\Omega_{\text{vhde}})\) and \(\Omega_m\) have the same behavior as the other two models.

Now, it will be interesting to compare our BT-II, VIII, and IX VHDE models in BDT along with the other dark energy models in the literature with regard to the energy density of the VHDE \((\rho_{\text{vhde}})\) EoS parameter \((\omega_{\text{vhde}})\) plane, the deceleration parameter \((q)\), the density parameter of the VHDE \((\Omega_{\text{vhde}})\) Om diagnostic, and bulk viscosity \((\zeta)\). We have considered some isotropic and homogeneous models for comparison study. Singh and Srivastava [102] have studied a flat FRW Universe filled with DM and viscous new HDE and they present four possible solutions for the model depending on the choice of the viscous term. Also, they have discussed the evolution of the cosmological quantities such as scale factor, deceleration parameter, and transition redshift to observe the effect of viscosity in the evolution. Srivastava and Singh [131] have investigated the new HDE model in modified \( f(R, T) \) gravity theory within the framework of a flat FRW model with bulk viscous matter content and found the solution for nonviscous and viscous new HDE models. Also, they have analyzed a new HDE model with constant bulk viscosity \((i.e., \zeta_1 = \zeta_0 = \text{constant})\) to explain the present accelerated the expansion of the Universe. Singh and Kumar [132] have examined Ricci dark energy model with bulk viscosity to observe the cosmic accelerating expansion phenomena, and they analyzed the model with deceleration parameter \((q)\), EoS parameter \((\omega_{\text{vhde}})\), bulk viscosity \((\zeta)\), and \(\Omega_m\). Singh and Kaur [133] have explored a matter-dominated model with a bulk viscosity in BDT to interpret the observed cosmic accelerating expansion phenomena with flat FRW line element. Kumar and Beesham [134] have studied the concept of HDE in the frame work of BDT in the formalism of the flat FRW metric, and they have shown that the VHDE can play the role of an interacting HDE as it is able to explain the phase transition of the Universe. Rahman and Ansari [135] have studied the interacting generalized ghost polytropic gas model of DE with a specific Hubble parameter in the spatially homogeneous and anisotropic LRS BT-II Universe in GR and also discuss the physical and geometrical properties of the Universe, which are found to be consistent with recent observations. Maurya et al., [136] have studied DE models in LRS BT-II space-time in a new perspective of time-dependent deceleration parameters in GR where various parameters of DE models are also calculated, and it is found that these are consistent with the recent observations. Naidu [137] has investigated the spatially homogeneous and totally anisotropic BT-II cosmological model filled with pressure less matter and anisotropic modified Ricci dark energy in the presence of an attractive massive scalar field in GR. It seems that the deceleration parameter \((q)\) of our BT-VIII model coincides with the results of Singh and Srivastava [102], Singh and Kumar [132], Singh and Kaur [133], Kumar and Beesham [134], Rahman and Ansari [135], and Maurya et al. [136]. Also, the deceleration parameter \((q)\) of our BT-IX model coincides with the results of Kumar and Beesham [134] and Maurya et al., [136]. The state finder parameters \((r - s)\) of the BT-VIII & IX models coincide with the results of Singh and Srivastava [102], Srivastava and Singh [131], Singh and Kaur [133], Singh and Kumar [132], and Rahman and Ansari [135]. The energy density of the VHDE of our BT-II, VIII, and IX VHDE models agree with the results of Maurya et al., [136] and Naidu [137]. Whereas, at null viscosity, the EoS parameter of our BT-VIII model agrees with the results of Singh and Kumar [132], Singh and Kaur [133], and Rahman and Ansari [135]. The density parameter of our BT-II, VIII, and IX VHDE models agrees with the results of Rahman and Ansari [135] and Naidu [137]. The Om-diagonistics of our BT-II, VIII, and IX VHDE models correspond with the results of Singh and Srivastava [102], Srivastava and Singh [131], Singh and Kumar [132], and Singh and Kaur [133]. The energy density of the VHDE of our BT-II, VIII, and IX models agree with the results of Rahman and Ansari [135] and Maurya et al., [136]. The bulk viscosity of our models coincides with the results of Singh and Kumar [132]. The above results lead to the conclusion that our BT-II, VIII, and IX VHDE models in BDT are in good agreement with the observational data. Also, we hope that the above investigations will help to have a deep insight into the behavior of bulk viscosity with VHDE Universes.
