Option pricing is always one of the critical issues in financial mathematics and economics. Brownian motion is the basic hypothesis of option pricing model, which questions the fractional property of stock price. In this paper, under the assumption that the exchange rate follows the extended Vasicek model, we obtain the closed form of the pricing formulas for two kinds of power options under fractional Brownian Motion (FBM) jump-diffusion models.

## 1. Introduction

The pricing of exotic options is often an optimal stochastic problem, in which the stochastic process sometimes follows jump-diffusion process. The issue gets more complicated because the distribution of the maximum is difficult to derive. There is no doubt that we should use jump-diffusion process to describe the changing behaviors of financial markets, instead of diffusion process, but the pricing process is more complex. Market quotations, trade practices, and information dissemination are three important factors which effect trade speed and transaction volume. Therefore, a reasonable pricing is the premise which will active the exchange market.

In recent years, with the exception of European and American options, a large number of new financial derivatives are derived in the international financial derivative market. Among them, the power option is one of the new typical options. The research of the power options has significant meanings both theoretical and practical. The BS [1] model has become an indispensable tool for option pricing and hedging in the finance industry. However, it is well documented that the Geometric Brownian Motion (GBM) assumption for the underlying asset's price dynamics in the BS model fails to reflect the real facts: market return data display excess kurtosis (peaked and fat-tailed distributions), skewness, volatility clustering, long-range dependence and large, sudden movements, and so forth. These observations reveal that a simple GBM assumption misses some

important features of the data. Therefore, many different option valuation models with realistic price dynamics have been currently proposed and tested. Some of these models include jump-diffusion model, subordinated processes, pure jump processes, Lévy processes, stochastic volatility model, regime-switching model, GARCH model, processes driven by FBM, and others. Except for FBM, these models give rise to incomplete market. Hu and Oksendal [2] and Elliott and van der Hoek [3] have proved that there is no arbitrage in the FBM market if the wick product is used in the definition of stochastic integration. Compared with the traditional efficient market theory, use the fractional market theory to describe that the movement of the actual market is more appropriate and accurate. Pricing options with stochastic interest rate under jump-diffusion models are an important field in recent years.

In the FBM market, very little work on the options valuation is considered. Hu and Oksendal [2] have derived a formula for the price at time  $t = 0$  of a European option. Necula [4] has extended the formula in [2] for every time  $t \in [0, T]$ . Liu and Yang [5, 6] considered the European contingent claim and compound option for the ease of a nonconstant but deterministic volatility using the quasiconditional expectation. Xue and Wang [7] also consider the pricing of the extremum options for the two risky assets type. Elliott and Chan [8] have obtained a closed-form solution for perpetual American options whose maturity goes to

infinity by applying quadratic approximation. Peng [9] has also obtained an explicit price of perpetual American put for a fractional O-U model. Deng and Lin [10] have considered approximate valuation for the American put option with finite maturity date using compound option approach.

In this paper, under the assumption that the exchange rate obeys the expanding Vasicek models, we obtain the pricing formulas of two kinds of power options under fractional jump-diffusion models.

## 2. The Fundamental Theorem and Lemma

In this section, we state several theorems and lemmas presented in [11].

**Theorem 1.** Let  $X \sim N(0, 1)$ ,  $Y \sim N(0, 1)$ ,  $\text{Cov}(X, Y) = \rho$ . Then, we have

$$\begin{aligned} & E[\exp(cX + dY) \chi_{aX+bY \geq k}] \\ &= \exp\left(\frac{1}{2}(c^2 + d^2 + 2\rho cd)\right) \\ & \times N\left(\frac{ac + bd + \rho(ad + bc) - k}{\sqrt{a^2 + b^2 + 2\rho ab}}\right), \end{aligned} \quad (1)$$

where  $a, b, c, d, k \in \mathbb{R}$ .

**Lemma 2.** Let  $X \sim N(0, \sigma_X^2)$ ,  $Y \sim N(0, \sigma_Y^2)$ ,  $\text{Cov}(X, Y) = \rho$ . Then, we have

$$\begin{aligned} & E[\exp(cX + dY) \chi_{aX+bY \geq k}] \\ &= \exp\left(\frac{1}{2}(c^2 \sigma_X^2 + d^2 \sigma_Y^2 + 2\rho cd \sigma_X \sigma_Y)\right) N(D), \end{aligned} \quad (2)$$

where  $a, b, c, d, k \in \mathbb{R}$  and

$$D = \frac{ac\sigma_X^2 + bd\sigma_Y^2 + \rho(ad + bc)\sigma_X\sigma_Y - k}{\sqrt{a^2\sigma_X^2 + b^2\sigma_Y^2 + 2\rho ab\sigma_X\sigma_Y}}. \quad (3)$$

**Definition 3.** We have some assumptions as follows:

$$\begin{aligned} F(w) &= \sum_{\alpha \in I} a_\alpha H_\alpha(w) \in (S)_H^*, \\ G(w) &= \sum_{\beta \in I} b_\beta H_\beta(w) \in (S)_H^*. \end{aligned} \quad (4)$$

We define wick integral as follows:

$$F \diamond G(w) = \sum_{\alpha, \beta \in I} a_\alpha b_\beta H_{\alpha+\beta}(w). \quad (5)$$

**Definition 4.** We define the function  $Y : \mathbb{R} \rightarrow (S)_H^*$ , s.t.  $Y(t) \diamond W_H(t)$  is integrated in  $(S)_H^*$ . Then we can define the stochastic integration of  $Y$  about  $\{B_H(t), t \in \mathbb{R}, H \in (0, 1)\}$  as follows:

$$\int_{\mathbb{R}} Y(t) dB_H(t) = \int_{\mathbb{R}} Y(t) \diamond W_H(t) dt, \quad (6)$$

where  $W_H(t)$  means fractional noise and  $\diamond$  means wick integral.

## 3. Our Models

**3.1. Interest Rate Model.** We assume that the interest rate follows the extended Vasicek model in this paper. That means it has the following form:

$$dr(t) = (a(t) - b(t)r(t))dt + \sigma_r(t)dB^Q(t), \quad (7)$$

where  $a(t)$  affects long-term average interest rate;  $b(t)$  is the average recovery rate which adjusts the relationship of short-term and long-term; and  $\sigma_r(t)$  is fluctuation ratio.

As we all know, if we want to find out the discounted factor, firstly we need to find out the discount rate  $\int_t^T r(s)ds$ . By the Itô theorem, we have

$$d(e^{n(s)}r(s)) = e^{n(s)}(a(s)ds + \sigma_r(s)dB^Q(s)), \quad (8)$$

where  $n(s) = \int_0^s b(u)du$ . Then by the integral both sides of the equation above on  $[t, s]$ , we have

$$\begin{aligned} r(s) &= r(t)e^{n(t)-n(s)} + \int_t^s e^{n(t)-n(s)}a(u)du \\ &+ \int_t^s e^{n(t)-n(s)}\sigma_r(u)dB^Q(u). \end{aligned} \quad (9)$$

Further,

$$\begin{aligned} & \int_t^T r(s)ds \\ &= r(t) \int_t^T e^{n(t)-n(s)}ds + \int_t^T \int_t^s e^{n(t)-n(s)}a(u)du ds \\ &+ \int_t^T \int_t^s e^{n(t)-n(s)}\sigma_r(u)dB^Q(u) \\ &= r(t) \int_t^T e^{n(t)-n(s)}ds + \int_t^T a(u) \int_t^s e^{n(t)-n(s)}ds du \\ &+ \int_t^T \sigma_r(u) \int_t^s e^{n(t)-n(s)}ds dB^Q(u) \\ &= r(t)m(t, T) + \int_t^T a(u)m(u, T)du \\ &+ \int_t^T \sigma_r(u)m(u, T)dB^Q(u) \\ &= G(t, T, r_t) + \int_t^T \sigma_r(u)m(u, T)dB^Q(u), \end{aligned} \quad (10)$$

where

$$m(u, v) = \int_u^v e^{n(t)-n(s)}ds, \quad (11)$$

$$G(t, T, r_t) = r(t)m(t, T) + \int_t^T a(u)m(u, T)du. \quad (12)$$

**3.2. Jump-Diffusion Model.** We assume the market is a full market with continuous time, and there exist two kinds of continuous trading assets, one of which is risk-free bonds. The price process of bonds  $M(t)$  satisfies the following equation:

$$\frac{dM(t)}{M(t)} = r(t) dt, \quad M(0) = 1, \quad (13)$$

where  $r(t)$  is a continuous function of time  $t$ . The other trading asset is the risk asset  $S(t)$ ; the price process of  $S(t)$  satisfies the following equation:

$$dS(t) = S(t) [\mu(t) dt + \sigma(t) dB(t) + (e^{J(t)} - 1) dQ_t], \quad (14)$$

where  $B(t)$  is Brownian motion;  $Q_t$  is the number of random jumps of underlying asset price within  $[0, t]$  and it follows the Poisson process with the parameter  $\lambda$ ;  $J(t)$  is the random variable which follows the normal distribution  $N(-\sigma_J^2/2, \sigma_J^2)$ ;  $e^{J(t)} - 1$  is the height of the stock price jump;  $\mu(t)$  is the expected rate of return; and  $\sigma^2(t)$  is the volatility.

Solving (14), we have

$$S(t) = S_0 \exp \left[ \int_0^t \left( \mu(t) - \frac{\sigma^2(t)}{2} \right) ds + \int_0^t \sigma(t) dB(t) + \sum_{i=1}^{Q_t} J(i) \right]. \quad (15)$$

In addition, jump-diffusion model is independent of the risk appetite, so risk-free interest rate  $r(t)$  can be used to take place of the expected rate of return  $\mu(t)$  according to the risk-neutral valuation principles. Consequently, the formula (15) can be rewritten as follows:

$$S(t) = S_0 \exp \left[ \int_0^t \left( r(t) - \frac{\sigma^2(t)}{2} \right) ds + \int_0^t \sigma(t) dB(t) + \sum_{i=1}^{Q_t} J(i) \right]. \quad (16)$$

**3.3. Fractional Jump-Diffusion Model.** Fractional jump-diffusion model is the extension of jump-diffusion model because of the replacement of Brownian motion  $B(t)$  with fractional Brownian motion  $B_H(t)$  in the model. The risk-neutral dynamics of the underlying asset is given as

$$dS(t) = S(t) [(r(t) - \lambda\theta) dt + \sigma(t) dB_H(t) + J(t) dQ_t], \quad (17)$$

where  $\{B_H(t), 0 \leq t \leq T\}$  is the fractional Brownian motion in probability space  $(\Omega, F, P)$ ;  $Q_t$  is the number of random jumps of underlying asset price within  $[t, T]$ , which follows Poisson process with the parameter  $\lambda$ ;  $J(t)$  is the height of the jump on stock price, satisfying  $\ln(1 + J(t)) \sim N(\ln(1 + \theta) - (\sigma^2/2), \sigma^2)$ ;  $r(t)$  is the expected rate of return; and  $\sigma^2(t)$  is the volatility.

From (17), we have

$$\frac{dS(t)}{S(t)} = (r(t) - \lambda\theta) dt + \sigma(t) dB_H(t) + J(t) dQ_t. \quad (18)$$

According to the definitions and properties of stochastic calculus and function  $\exp \diamond (X)$ , we get

$$\begin{aligned} S(t) &= S_0 \exp \diamond \left[ \int_0^t (r(s) - \lambda\theta) ds + \int_0^t \sigma(s) dB_H(s) + \sum_{i=1}^{Q_t} \ln(1 + J(i)) \right] \\ &= S_0 \prod_{i=1}^{Q_t} (1 + J(i)) \\ &\quad \times \exp \diamond \left[ \int_0^t (r(s) - \lambda\theta) ds + \int_0^t \sigma(s) dB_H(s) \right] \\ &= S_0 \prod_{i=1}^{Q_t} (1 + J(i)) \\ &\quad \times \exp \left[ \int_0^t (r(s) - \lambda\theta - H\sigma^2(s) s^{2H-1}) ds + \int_0^t \sigma(s) dB_H(s) \right]. \end{aligned} \quad (19)$$

#### 4. Pricing of Two Kinds of Power Options under FBM, Stochastic Rate, and Jump-Diffusion Models

In this section, we obtain pricing formulas of two kinds of power options.

**4.1. Pricing of the First Kind of Power Option.** From (11), we have

$$\int_t^T r(s) ds = G(t, T, r_t) + \int_t^T \sigma_r(u) m(u, T) dB^Q(u), \quad (20)$$

where  $m(u, v)$ ,  $G(t, T, r_t)$  are given by (12), (23), respectively.

Suppose that underlying assets jump  $m$  times during  $[t, T]$ , then

$$\begin{aligned} S_T &= S_t \prod_{i=1}^m (1 + J(i)) \\ &\quad \times \exp \left[ \int_t^T (r(s) - \lambda\theta - H\sigma^2(s) s^{2H-1}) ds + \int_t^T \sigma(s) dB_H(s) \right]. \end{aligned} \quad (21)$$

**Theorem 5.** The formula of the first kind of call power option with exercise price  $K$  at exercise date  $T$  is

$$\begin{aligned} C(t, r_t, S_t, K) &= \sum_{m=0}^{\infty} \left[ \exp(-\lambda(T-t)) \frac{(\lambda(T-t))^m}{m!} (I_c - II_c) \right], \end{aligned} \quad (22)$$

where

$$\begin{aligned}
 I_c &= S_t^n \prod_{i=1}^m (1 + j(i)) \exp(s_1) \cdot N(d_1), \\
 II_c &= K \exp\left[\frac{\sigma_X^2}{2} - G(t, T, r_t)\right] \cdot N(d_2), \\
 s_1 &= \frac{(n-1)^2}{2} \sigma_X^2 + \frac{n^2 - n}{2} \sigma_Y^2 + (n-1) G(t, T, r_t) \\
 &\quad - n \int_t^T \lambda \theta ds, \\
 d_1 &= \left( \ln \left[ S_t \cdot \sqrt{\frac{\prod_{i=1}^m (1 + j(i))}{K}} \right] + G(t, T, r_t) - \int_t^T \lambda \theta ds \right. \\
 &\quad \left. + (n-1) \sigma_X^2 + \frac{2n-1}{2} \sigma_Y^2 \right) \left( \sqrt{\sigma_X^2 + \sigma_Y^2} \right)^{-1}, \\
 d_2 &= \left( \ln \left[ S_t \cdot \sqrt{\frac{\prod_{i=1}^m (1 + j(i))}{K}} \right] + G(t, T, r_t) \right. \\
 &\quad \left. - \int_t^T \lambda \theta ds - \sigma_X^2 - \frac{\sigma_Y^2}{2} \right) \left( \sqrt{\sigma_X^2 + \sigma_Y^2} \right)^{-1}.
 \end{aligned} \tag{23}$$

*Proof.* According to the No-Arbitrage pricing theory, we get

$$\begin{aligned}
 C(t, r_t, S_t, K) &= E \left[ \exp \left( - \int_t^T r(s) ds \right) (S_T^n - K) \chi_{S_T^n > K} \right] \\
 &= \sum_{m=0}^{\infty} \left[ \exp(-\lambda(T-t)) \frac{(\lambda(T-t))^m}{m!} I_c - II_c \right].
 \end{aligned} \tag{24}$$

Let

$$\begin{aligned}
 X &= \int_t^T \sigma_r(u) m(u, T) dB(u), \\
 Y &= \int_t^T \sigma(s) dB_H(s),
 \end{aligned} \tag{25}$$

then

$$\begin{aligned}
 X &\sim N \left( 0, \int_t^T \sigma_r(u) m(u, T) du \right) = N(0, \sigma_X^2), \\
 Y &\sim \left( 0, 2H \int_t^T \sigma^2(u) u^{2H-1} du \right) = N(0, \sigma_Y^2).
 \end{aligned} \tag{26}$$

Then we have

$$I_c = E \left[ \exp \left( - \int_t^T r(s) ds \right) S_T^n \chi_{S_T^n \geq K} \right]. \tag{27}$$

Since

$$\begin{aligned}
 &\exp \left[ - \int_t^T r(s) ds \right] S_T^n \\
 &= \exp \left[ - \int_t^T r(s) ds \right] S_t^n \prod_{i=1}^m (1 + j(i)) \\
 &\quad \cdot \exp \left[ n \int_t^T (r(s) - \lambda \theta - H \sigma^2(s) s^{2H-1}) ds \right. \\
 &\quad \left. + n \int_t^T \sigma(s) dB_H(s) \right] \\
 &= S_t^n \prod_{i=1}^m (1 + j(i)) \\
 &\quad \times \exp \left[ (n-1) \int_t^T r(s) ds \right. \\
 &\quad \left. + n \int_t^T (-\lambda \theta) ds - \frac{n}{2} \sigma_Y^2 \right] \cdot e^{nY} \\
 &= S_t^n \prod_{i=1}^m (1 + j(i)) \\
 &\quad \times \exp \left\{ (n-1) \left[ G(t, T, r_t) \right. \right. \\
 &\quad \left. \left. + \int_t^T \sigma_r(u) m(u, T) dB(u) \right] \right. \\
 &\quad \left. + n \int_t^T (-\lambda \theta) ds - \frac{n}{2} \sigma_Y^2 \right\} \cdot e^{nY} \\
 &= S_t^n \prod_{i=1}^m (1 + j(i)) \\
 &\quad \times \exp \left[ (n-1) G(t, T, r_t) \right. \\
 &\quad \left. + n \int_t^T (-\lambda \theta) ds - \frac{n}{2} \sigma_Y^2 \right] \cdot e^{(n-1)X + nY}, \\
 &S_T^n > K \\
 &\implies S_t^n \prod_{i=1}^m (1 + j(i)) \\
 &\quad \times \exp \left\{ n \cdot \left[ \int_t^T r(s) ds + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} \right] \right\} \\
 &\quad \cdot e^{nY} > K \\
 &\implies S_t \cdot \sqrt{\prod_{i=1}^m (1 + j(i))} \\
 &\quad \times \exp \left[ \int_t^T r(s) ds + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} \right] \cdot e^Y > \sqrt[n]{K}
 \end{aligned}$$

$$\begin{aligned}
 & \Rightarrow \exp \left[ \int_t^T \sigma_r(u) m(u, T) dB(u) + G(t, T, r_t) \right. \\
 & \quad \left. + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} \right] \cdot e^Y \\
 & > \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \\
 & \Rightarrow G(t, T, r_t) + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} + X + Y \\
 & > \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \right] \\
 & \Rightarrow X + Y > \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \right] \\
 & \quad - G(t, T, r_t) - \int_t^T (-\lambda \theta) ds + \frac{\sigma_Y^2}{2}
 \end{aligned} \tag{28}$$

which means

$$\begin{aligned}
 & \chi_{S_T^n > K} \\
 & = \chi_{X+Y > \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \right] - G(t, T, r_t) - \int_t^T (-\lambda \theta) ds + \sigma_Y^2/2}
 \end{aligned} \tag{29}$$

then we obtain

$$\begin{aligned}
 I_c & = E \left[ S_t^n \prod_{i=1}^m (1+j(i)) \right. \\
 & \quad \times \exp \left[ (n-1) G(t, T, r_t) + n \int_t^T (-\lambda \theta) ds - \frac{n}{2} \sigma_Y^2 \right] \\
 & \quad \cdot e^{(n-1)X+nY} \\
 & \quad \cdot \chi_{X+Y > \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \right] - G(t, T, r_t) - \int_t^T (-\lambda \theta) ds + \sigma_Y^2/2} \Bigg] \\
 & = S_t^n \prod_{i=1}^m (1+j(i)) \\
 & \quad \times \exp \left[ (n-1) G(t, T, r_t) + n \int_t^T (-\lambda \theta) ds - \frac{n}{2} \sigma_Y^2 \right] \\
 & \quad \cdot E \left[ e^{(n-1)X+nY} \right. \\
 & \quad \cdot \chi_{X+Y > \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \right] - G(t, T, r_t) - \int_t^T (-\lambda \theta) ds + \sigma_Y^2/2} \Bigg] \\
 & = S_t^n \prod_{i=1}^m (1+j(i))
 \end{aligned}$$

$$\begin{aligned}
 & \times \exp \left[ (n-1) G(t, T, r_t) + n \int_t^T (-\lambda \theta) ds - \frac{n}{2} \sigma_Y^2 \right] \\
 & \cdot \exp \left( \frac{(n-1)^2 \sigma_X^2 + n^2 \sigma_Y^2}{2} \right) \cdot N(d_1) \\
 & = S_t^n \prod_{i=1}^m (1+j(i)) \exp(s_1) \cdot N(d_1), \\
 & \quad \Pi_c = E \left[ \exp \left( - \int_t^T r(s) ds \right) K \chi_{S_T^n \geq K} \right], \\
 & \exp \left( - \int_t^T r(s) ds \right) \\
 & = \exp \left( -G(t, T, r_t) - \int_t^T \sigma_r(u) m(u, T) dB^Q(u) \right) \\
 & = \exp(-G(t, T, r_t)) \cdot \exp(-X).
 \end{aligned} \tag{30}$$

In the similar way, we have

$$\begin{aligned}
 & E \left[ \exp \left( - \int_t^T r(s) ds \right) K \chi_{S_T^n \geq K} \right] \\
 & = K \cdot \exp(-G(t, T, r_t)) \\
 & \cdot E \left[ \exp(-X) \right. \\
 & \quad \times \chi_{X+Y > \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1+j(i))}} \right] - G(t, T, r_t) - \int_t^T (-\lambda \theta) ds + \sigma_Y^2/2} \Bigg] \\
 & = K \exp \left( \frac{\sigma_X^2}{2} - G(t, T, r_t) \right) \cdot N(d_2).
 \end{aligned} \tag{31}$$

□

**Theorem 6.** The formula of the first kind of put power option with exercise price  $K$  at exercise date  $T$  is

$$\begin{aligned}
 & P(t, r_t, S_t, K) \\
 & = \sum_{m=0}^{\infty} \left[ \exp(-\lambda(T-t)) \frac{(\lambda(T-t))^m}{m!} (I_p - \Pi_p) \right],
 \end{aligned} \tag{32}$$

where

$$\begin{aligned}
 I_p & = K \exp \left[ \frac{\sigma_X^2}{2} - G(t, T, r_t) \right] \cdot N(-d_2), \\
 \Pi_p & = S_t^n \prod_{i=1}^m (1+j(i)) \exp(s_1) \cdot N(-d_1),
 \end{aligned} \tag{33}$$

*Proof.* Similar to the proof procedure in the first kind of call power option, we have

$$I_p = E \left[ \exp \left( - \int_t^T r(s) ds \right) K \chi_{S_T^n < K} \right]. \tag{34}$$

Since

$$\begin{aligned}
S_T^n &< K \\
&\Rightarrow S_t^n \prod_{i=1}^m (1 + j(i)) \\
&\quad \times \exp \left\{ n \cdot \left[ \int_t^T r(s) ds + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} \right] \right\} \\
&\quad \cdot e^{nY} < K \\
&\Rightarrow S_t \cdot \sqrt[n]{\prod_{i=1}^m (1 + j(i))} \\
&\quad \times \exp \left[ \int_t^T r(s) ds + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} \right] \cdot e^Y < \sqrt[n]{K} \\
&\Rightarrow \exp \left[ \int_t^T \sigma_r(u) m(u, T) dB(u) + G(t, T, r_t) \right. \\
&\quad \left. + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} \right] \cdot e^Y \\
&< \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1 + j(i))}} \\
&\Rightarrow G(t, T, r_t) + \int_t^T (-\lambda \theta) ds - \frac{\sigma_Y^2}{2} + X + Y \\
&< \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1 + j(i))}} \right] \\
&\Rightarrow X + Y < \ln \left[ \frac{\sqrt[n]{K}}{S_t \cdot \sqrt[n]{\prod_{i=1}^m (1 + j(i))}} \right] - G(t, T, r_t) \\
&\quad - \int_t^T (-\lambda \theta) ds + \frac{\sigma_Y^2}{2}, \\

\end{aligned} \tag{55}$$

□

## 5. Conclusions

In this paper, we investigate the issue of pricing the reset option in FBM model, closed-form formulas for the reset option with a single reset date, and the phenomena of delta of the reset jumps existing in the reset option during the reset date. Under the assumption that the exchange rate follows the extended Vasicek model, we obtain the closed form of the pricing formulas for two kinds of power options under fractional Brownian motion (FBM) jump-diffusion models.

## Conflict of Interests

The authors declare that there is no conflict of interest regarding the publication of this paper.

## Acknowledgments

Thanks are due to the referees whose meaningful suggestions are very helpful to revise the paper. This work is supported by the Fundamental Research Funds for the Central Universities (JBK140924, JBK130401).
