In this work, computational analysis of generalized Burger’s-Fisher and generalized Burger’s-Huxley equation is carried out using the sixth-order compact finite difference method. This technique deals with the nonstandard discretization of the spatial derivatives and optimized time integration using the strong stability-preserving Runge-Kutta method. This scheme inculcates four stages and third-order accuracy in the time domain. The stability analysis is discussed using eigenvalues of the coefficient matrix. Several examples are discussed for their approximate solution, and comparisons are made to show the efficiency and accuracy of CFDM6 with the results available in the literature. It is found that the present method is easy to implement with less computational effort and is highly accurate also.

1. Introduction

The excerpt approximation of the Navier-Stokes equation is represented by a prominent nonlinear mathematical model known as Burger’s equation. It is the perfect combination of advection and diffusion terms. This equation was introduced by Bateman [1]. Later, Burger [2] extensively worked on this problem, considering the turbulence effect and the statistical aspects. Burger’s equation describes the process of simulating shock wave phenomena, dispersion in a porous medium, heat conduction, diffusion flow, modeling of gas dynamics, traffic flow, and reflection of the nonlinear fluid, boundary layer flow, electrohydrodynamics, sound waves, oil reservoir simulation, etc. The spreading of any species due to the favorable environment of the invasive species or predicting the pattern of spreading was an important issue in the early twenties. The great researcher Fisher [3] proposed a model for the temporal and spatial propagation, depicting the wave of increase in gene frequency in an infinite medium and termed it as Fisher’s equation. It represents the biological processes, ecological systems, pattern formation, etc. Petrovskii and Shigesada [4] combined both the models by assuming that the distribution of species is symmetrical and the environment is homogeneous. The following 1D equation was proposed:

$$\frac{\partial z}{\partial t} = \frac{\partial^2 z}{\partial x^2} + f(x, t, z, z_x), \quad \text{in } \Phi = \Phi_x \times \Phi_t, \quad (1)$$

with the initial and boundary conditions:

$$z = z^0, \quad \text{in } \Phi_x \times t_0,$$

$$\mathcal{B}z = \Omega, \quad \text{on } \partial \Phi_x \times \Phi_t, \quad (2)$$

where $\Phi_x = (a, b), \Phi_t = (0, t)$, and $\mathcal{B}$ is the boundary operator. A mathematical model for $f(x, t, z, z_x) = -\beta z^6 z_x + \gamma z(1 - z^6)$ in (1) with the above conditions is known as the generalized Burger’s-Fisher (gBF) equation and is expressed as follows:

$$\frac{\partial z}{\partial t} - \frac{\partial^2 z}{\partial x^2} + \beta z^6 \frac{\partial z}{\partial x} - \gamma z(1 - z^6) = 0, \quad 0 \leq x \leq 1, t \geq 0, \quad (3)$$

subject to the initial condition:
\[
\eta(x, 0) = \left[\frac{1}{2} + \frac{1}{2} \tanh \left( \frac{\beta \delta x}{2(1 + \delta)} \right) \right]^{1/\delta},
\]
and the boundary conditions:
\[
\eta(0, t) = \left(\frac{1}{2} + \frac{1}{2} \tanh \left( \frac{-\beta \delta}{2(1 + \delta)} \left( \frac{\beta^2 + \gamma(1 + \delta)^2}{\beta(1 + \delta)} t \right) \right) \right)^{1/\delta},
\]
\[
\eta(1, t) = \left(\frac{1}{2} + \frac{1}{2} \tanh \left( \frac{-\beta \delta}{2(1 + \delta)} \left( 1 - \frac{\beta^2 + \gamma(1 + \delta)^2}{\beta(1 + \delta)} t \right) \right) \right)^{1/\delta},
\]
where \(\beta, \gamma, \) and \(\delta\) are the constants. The choice of the value of these constants reduces the model to different forms of PDEs. For \(\gamma = 0\), it reduces to the generalized Burger’s equation. Taking \(\beta = 0\), it becomes the generalized Fisher’s equation. The exact solution of Equation (3) was given by Chen and Zhang [5] as follows:
\[
\eta(x, t) = \left[\frac{1}{2} + \frac{1}{2} \tanh \left( \frac{-\beta \delta}{2(1 + \delta)} \left( x - \frac{\beta^2 + \gamma(1 + \delta)^2}{\beta(1 + \delta)} t \right) \right) \right]^{1/\delta}.
\]

The significance and various applications motivated the researchers to compute the analytical and numerical solutions of the Burger’s-Fisher equation. Recently, the dynamical behaviour and exact parametric representations of the traveling wave solutions under different parametric conditions have been discussed by Li [16]. In the findings, the exact monotonic and nonmonotonic kink wave solutions, two-peak solitary wave solutions, and periodic wave solutions, as well as unbounded traveling wave solutions have been obtained. Onyejekwe et al. [17] applied a boundary integral element-based numerical technique, in which the boundary and domain values calculate the fundamental integral inside the domain. The domain integrals due to non-linearity are considered for computing the solution. Investigation of the global existence and uniqueness of a periodic wave solution has been conducted by Zhang et al. [18].

Another important nonlinear equation, describing the interaction between reaction mechanism, convection effect, and diffusion transport is the 1D generalized Burguer’s-Huxley (gBH) equation, for which \(f(x, t, z, z_\gamma) = -\beta z^\delta z_x + \gamma z(1 - z^\delta)(z^\delta - \eta)\). The equation is expressed as follows:
\[
\frac{\partial z}{\partial t} - \frac{\partial^2 z}{\partial x^2} + \beta z^\delta \frac{\partial z}{\partial x} = \gamma z(1 - z^\delta)(z^\delta - \eta), \quad a \leq x \leq b, t \geq 0.
\]

The parameters \(\beta, \gamma, \) and \(\delta\) are the constants and parameter \(\eta \in (0, 1)\). The initial and boundary conditions are as follows:
\[
z(x, 0) = \left[\frac{\eta}{2} + \frac{\eta}{2} \tanh \left( A_1 x \right) \right]^{1/\delta},
\]
\[
z(a, t) = \left[\frac{\eta}{2} + \frac{\eta}{2} \tanh \left( A_1 (a - A_2 t) \right) \right]^{1/\delta} ,
\]

The exact solution derived by Wang [19], using nonlinear transformations, is reproduced hereunder:
\[
z(x, t) = \left[\frac{\eta}{2} + \frac{\eta}{2} \tanh \left( A_1 (x - A_2 t) \right) \right]^{1/\delta},
\]
where
\[
A_1 = \eta \delta \left( -\beta + \sqrt{\beta^2 + 4\gamma(1 + \delta)} \right), A_2 = \frac{\beta \eta}{\delta + 1} - \frac{(1 - \eta + \delta) \left( -\beta + \sqrt{\beta^2 + 4\gamma(\delta + 1)} \right)}{2(\delta + 1)}.
\]

For \(\gamma = 0\), the above model conforms to the generalized Burger’s equation, and considering \(\beta = 0\) and \(\delta = 1\), the Huxley equation [20] is obtained. For \(\beta = 0, \gamma = 1, \) and \(\delta = 1,\) it corresponds to the Fitzhugh-Nagoma equation [21]. Yefimova and Kudryashov [22] applied the Hopf-Cole transformation for solving the gBH equation. The Adomian decomposition method was implemented by Ismail et al. [23]. Gao and Zhao [24] proposed the Exp-function method for a series of exact solutions of the gBH equation. A high-order difference scheme using Taylor’s series expansion was presented by Sari et al. [25]. Celik [26] introduced a numerical method based on the Haar wavelet approach.
Zhang et al. [27] reduced the Burger’s-Huxley and Burger’s-Fisher equations into first-order systems and then applied the discontinuous Galerkin method. A numerical scheme based on the finite differences for time integration and cubic B-spline for space integration was proposed by Mohammadi [28]. A fourth-order finite difference method was implemented by Bratos [29] in a two-time level recurrence relation for the solution of the gBH equation. El-Kady et al. [30] discussed the methods based on cardinal Chebyshev and Legendre basis functions with the Galerkin method, Gauss quadrature formula, and El-Gendi method to convert the problem into ordinary differential equations. Technique based on modified cubic B-spline as the basis function with differential quadrature method was discussed by Singh et al. [31]. The nonstandard finite difference method was analyzed by Zibaei et al. [32], Bukhari [33] applied local radial basis function differential collocation method. Macias-Díaz [34] used the hyperbolic-trigonometric tension B-spline method. Macias-Díaz [34] used the cardinal B-spline wavelet numerical method was used by Lele [42] proposed well-regulated compact schemes in which the constructed error function is minimized. Many researchers have extended the compact schemes, Lele [42] proposed well-regulated compact schemes in which the constructed error function is minimized. Many researchers have extended the compact schemes, Lele [42] proposed well-regulated compact schemes in which the constructed error function is minimized.

In this work, a numerical scheme based on the sixth-order finite difference method was analyzed by Zibaei et al. The paper is organized as follows: in Section 2, first- and second-order spatial derivatives of the CFDM6 are derived. In Section 3, the proposed method is implemented followed by SSP-RK43. In Section 4, convergence is discussed. In Section 5, stability analysis for the proposed scheme is presented. In Section 6, several test problems are discussed to demonstrate and justify the applicability of the proposed scheme. In Section 7, the concluding explaining the efficiency of CFDM6 is given.

### 2. Compact Finite Difference Method

The spatial domain \( \phi_x = (a, b) \) is divided into uniform mesh with step iteration \( x_i = a + ih, i = 0, 1, 2, \ldots, N, h = (b-a)/N \) and for time domain \( \phi_t = (t_0, t), \) with \( t_0 = 0, \) a uniform step of size \( \Delta t = t^{i+1} - t^i \) such that \( t^i = t_0 + j\Delta t, j = 0, 1, 2, \ldots, \) is followed. The method for calculating first-order and second-order derivatives using the compact finite difference scheme is given hereunder.

#### 2.1. Spatial Derivatives of First Order

The first-order spatial derivatives for CFDM6 at the inner nodes are calculated as follows [42]:

\[
\phi x'_{i-1} + \phi x'_{i+1} + \phi x'_{i} = \chi \left( \frac{\phi_x^{i+1} - \phi_x^{i-1}}{4h} \right) + \psi \left( \frac{\phi_x^{i+1} - \phi_x^{i-1}}{2h} \right). \tag{13}
\]

For the optimality of the scheme with higher-order accuracy, consider \( \psi = 1/3 \) representing the implicit form of the first-order derivative. The unknown parameters on the other side are calculated by the relation \( \chi = (1/3)(4\psi - 1) \) and \( \psi = (2/3)(2 + \phi). \) By simple calculation, Equation (13) reduces to a sixth-order tridiagonal matrix as a linear system of equations given below with truncation error (4/\( 7! \))\( h^6 \phi_x'^{i(??)}: \)

\[
\phi x'_{i-1} + 3\phi x'_{i} + \phi x'_{i+1} = \frac{-\phi_x^{i+1} - 28\phi_x^{i-1} + 8\phi_x^{i-2} + 12\phi_x^{i+2}}{12h}, \quad i = 2, 3, \ldots, N - 2. \tag{14}
\]

For the value of the derivative at \( x_0, x_1, x_{N-1}, \) and \( x_N, \) one-sided forward and backward schemes have been implemented, which produce following results:

\[
5\phi_x'^{i+1} = \frac{1}{60h} (-197\phi_x^{i+2} - 25\phi_x^{i+1} + 300\phi_x^{i+0} - 100\phi_x^{i-1} + 25\phi_x^{i-2} - 3\phi_x^{i-3}),
\]

\[
2\phi_x'^{i+1} + 11\phi_x'^{i+2} + 2\phi_x'^{i+3} = \frac{1}{12h} (-80\phi_x^{i+4} - 35\phi_x^{i+3} + 136\phi_x^{i+2} - 28\phi_x^{i+1} + 8\phi_x^{i} - \phi_x^{i-1}),
\]

\[
2\phi_x'^{N-2} + 11\phi_x'^{N-1} + 2\phi_x'^{N} = \frac{1}{12h} (3\phi_x^{N-4} - 8\phi_x^{N-3} + 28\phi_x^{N-2} - 136\phi_x^{N-1} + 35\phi_x^{N} + 80\phi_x^{N+1}),
\]

\[
5\phi_x'^{N-1} + \phi_x'^{N} = \frac{1}{60h} (3\phi_x^{N-5} - 25\phi_x^{N-4} + 100\phi_x^{N-3} - 300\phi_x^{N-2} + 25\phi_x^{N-1} + 197\phi_x^{N}). \tag{15}
\]

The relations (14) and (15) can be represented in the form of a matrix system as

\[
A\phi_x' = \Xi\phi_x,
\]

where \( A, \) and \( \Xi \) are the matrices and vectors that represent the differential operators and the boundary conditions, respectively.
where

\[
A = \begin{bmatrix}
1 & 5 & \ldots & \ldots & 1 & 3 & 1 \\
2 & 11 & 2 & \ldots & \ldots & 2 & 11 & 2 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
1 & 3 & 1 & \ldots & \ldots & 1 & 3 & 1 \\
2 & 11 & 2 & \ldots & \ldots & 2 & 11 & 2 \\
\end{bmatrix}
\]

\[
D = \begin{bmatrix}
197 & 25 & 300 & 100 & 25 & 3 & 0 \\
60 & 60 & 60 & 60 & 60 & 60 & 60 \\
80 & 35 & 136 & 28 & 8 & 1 & 12 \\
12 & 12 & 12 & 12 & 12 & 12 & 12 \\
-1 & 28 & 0 & 28 & 1 & 12 & 12 \\
-1 & 28 & 0 & 28 & 1 & 12 & 12 \\
-1 & 28 & 0 & 28 & 1 & 12 & 12 \\
1 & 28 & 0 & 28 & 1 & 12 & 12 \\
3 & 25 & 100 & 300 & 25 & 197 & 60 & 60 & 60 & 60 \\
\end{bmatrix}
\]

\[
\overline{D} = \frac{1}{h^2}
\]

\[
\overline{D} = \frac{12}{h^2}
\]

2.2. Spatial Derivatives of Second Order. Similarly, the second-order derivative is calculated as

\[
\tau z_{i+1}'' + z_i' + \tau z_i'' = \sigma \left( \frac{z_{i+2} - 2z_i + z_{i-2}}{4h^2} \right) + \varsigma \left( \frac{z_{i+1} - 2z_i + z_{i-1}}{h^2} \right).
\]

For \(\tau = 0\), this equation represents the explicit method to calculate the derivative, and for \(\tau = 1/10\), it will represent the implicit scheme of the second-order derivative. The unknown constants on the R.H.S. are calculated as \(\varsigma = (4/3)(1 - \tau)\) and \(\sigma = (1/3)(1 + 10\tau)\). This reduces Equation (18) to a tridiagonal system as follows:

\[
\tau z_i'' + z_{i+1}' + z_{i-1}' = \frac{12}{h^2} \left( z_{i+1} - 2z_i + z_{i-1} \right).
\]

For the boundary points, one-sided forward and backward schemes have been implemented, which gives the following results:

\[
10z_{i+1}' + z_i'' = \frac{12}{h^2} \left( \frac{115}{36} z_{i+1} - \frac{555}{144} z_i + \frac{89}{6} z_{i-1} - \frac{773}{72} z_{i-2} + \frac{151}{36} z_{i-3} - \frac{11}{16} z_{i-4} \right).
\]

The second-order derivative can be written in the matrix form as

\[
Cz_i'' = Dz_i,
\]

\[
\frac{\partial z_i}{\partial t} = C^{-1}Dz_i - \beta z_i^4 A^{-1}Bz_i + \gamma z_i \left( 1 - z_i^4 \right) \equiv \mathcal{L}(z_i).
\]

3. Implementation of CFDM6

By substituting the values of first-order and second-order derivatives in Equations (3) and (8), a linear system of equations are obtained for \(i = 0, 1, \ldots, N\):

(i) **Model-I**: generalized Burger’s-Fisher equation:

\[
\frac{\partial z_i}{\partial t} = C^{-1}Dz_i - \beta z_i^4 A^{-1}Bz_i + \gamma z_i \left( 1 - z_i^4 \right) \equiv \mathcal{L}(z_i).
\]

(ii) **Model-II**: generalized Burger’s-Huxley equation:

\[
\frac{\partial z_i}{\partial t} = C^{-1}Dz_i - \beta z_i^4 A^{-1}Bz_i + \gamma z_i \left( 1 - z_i^4 \right) \left( z_i^4 - \eta \right) \equiv \mathcal{L}(z_i).
\]
3.1. SSP-RK43 Scheme. Let

\[ \frac{dz_i}{dt} = \mathcal{L}(z_i), \quad i = 0, 1, 2 \cdots, N, \]

where \( \mathcal{L} \) represents the nonlinear differential operator as defined above. In order to solve this system of ODE’s from the \( t^j \) to \( t^{j+1} \) time level, SSP-RK43 is applied using the following operations:

\[
\begin{align*}
    z^{(1)} &= z^j + \frac{\Delta t}{2} \mathcal{L}(z') \\
    z^{(2)} &= z^{(1)} + \frac{\Delta t}{2} \mathcal{L}(z^{(1)}) \\
    z^{(3)} &= \frac{2}{3} z^j + \frac{1}{3} z^{(2)} + \frac{\Delta t}{6} \mathcal{L}(z^{(2)}) \\
    z^{j+1} &= z^{(3)} + \frac{\Delta t}{2} \mathcal{L}(z^{(3)}). 
\end{align*}
\] (25)

By using the initial condition, \( z(x, t) \) at every required time level can be calculated.

4. Convergence Analysis

Convergence of the model is investigated below for the desired Equations (22) and (23).

**Theorem 1.** It is an assumption that the given initial value problem \( dz/dt = \mathcal{L}(z) \) has a unique solution if \( \mathcal{L}(z) \) satisfies the following conditions:

1. \( \mathcal{L}(z) \) is a real function
2. \( \mathcal{L}(z) \) is well defined and continuous in the domain of \( t \in \Phi_i \) and \( z \in (-\infty, \infty) \)
3. There exists a constant called the Lipschitz constant \( \kappa \) such that \( |\mathcal{L}(z, t, \Delta t) - \mathcal{L}(\hat{z}, t, \Delta t)| \leq \kappa |z - \hat{z}| \), where \( t \in \Phi_i \) and \( z \) and \( \hat{z} \) be any two different points

It is clearly seen that \( \mathcal{L}(z) \) for the generalized Burger’s-Fisher equation and generalized Burger’s-Huxley equation is real, well defined, and continuous. Hence, above theorem is satisfied.

**Lemma 2.** A single-step method (25) is said to be regular, if the incremental function \( \phi(z, t, \Delta t) \) satisfies the following conditions:

1. The function is well defined and is continuous in the given time and space domain
2. For every \( t \in \Phi_i \) and \( z, \hat{z} \in (-\infty, \infty) \), there exist a constant \( \kappa \) such that

\[ |\phi(z, t, \Delta t) - \phi(\hat{z}, t, \Delta t)| \leq \kappa |z - \hat{z}|. \] (26)

**Lemma 3.** Any single-step method is consistent if \( \phi(z, t, 0) = \mathcal{L}(z, t) \).

**Theorem 4.** The consistency is the necessary and sufficient condition for the convergence of a regular single-step method with the order (say) \( p \geq 1 \).

**Proof.** This theorem ensures that the approximate solution converges to the exact solution. For the proof, consider the specific incremental function \( \phi(z, t, \Delta t) \). Assume that the given differential equation \( z_{i+1} = \mathcal{L}(z) \) has a unique solution \( z(t) \) on \( \Phi_i \) and also \( z(t) \in C^{p+1} \Phi_i \) for \( p \geq 1 \). Using Taylor’s series expansion about any point \( t^{j+1} \),

\[
\begin{align*}
    z(t) &= z(t^j) + (t - t^j)z'(t^j) + \frac{(t - t^j)^2}{2!} z''(t^j) + \cdots + \frac{(t - t^j)^p}{p!} z^p(t^j) + (t - t^j)^{p+1} \xi(t^j),
\end{align*}
\] (27)

where \( \xi \in (t^j, t) \). Taking \( t = t^{j+1} \), one gets

\[
\begin{align*}
    z(t^{j+1}) - z(t^j) &= \Delta t z'(t^j).
\end{align*}
\] (28)

Thus, the incremental function is defined as

\[
\begin{align*}
    \phi(z(t^j), t^j, \Delta t) &= (\Delta t) z'(t^j) + \frac{(\Delta t)^2}{2!} z''(t^j) + \cdots + \frac{(\Delta t)^p}{p!} z^p(t^j) + (\Delta t)^{p+1} \xi(t^j).
\end{align*}
\] (29)

It is computed using the approximate value of \( z^j \) where the exact value \( z(t^j) \) is required. Hence, \( z^{j+1} = z^j + \Delta t \phi(z(t^j), t^j, \Delta t) \), \( j = 0, 1, 2 \cdots, m - 1 \). To compute the error using Taylor’s series,

\[
\begin{align*}
    z^{j+1} &= z^j + \Delta t z'(t^j) + \frac{(\Delta t)^2}{2!} z''(t^j) + \cdots + \frac{(\Delta t)^p}{p!} z^p(t^j) + (\Delta t)^{p+1} \xi(t^j).
\end{align*}
\] (30)

The approximate value using the SSP-RK43 scheme is

\[
\begin{align*}
    z^{j+1} &= z^j + \Delta t \mathcal{L}(z^j) + \frac{(\Delta t)^2}{2!} \mathcal{L}^2(z^j) + \cdots + \frac{(\Delta t)^p}{p!} \mathcal{L}^p(z^j).
\end{align*}
\] (31)

The following relation is obtained:

\[
\begin{align*}
    \Delta t \phi(z(t^j), t^j, \Delta t) &= \Delta t z'(t^j) + \frac{(\Delta t)^2}{2!} \mathcal{L}^2(z^j) + \cdots + \frac{(\Delta t)^p}{p!} \mathcal{L}^p(z^j).
\end{align*}
\] (32)
The value of $\Delta t \phi(z_j, t_j, \Delta t)$ is obtained from $\Delta t \phi(z(t_j), t_j, \Delta t)$ by using the exact approximate value of $z_j$ in place of the exact value of $z(t_j)$. According to the SSP-RK43, the approximate value of $z(t_j+1)$ is obtained as follows:

$$z_{j+1} = z_j + \Delta t \phi(z_j, t_j, \Delta t) + \frac{(\Delta t)^2}{2!} \phi'(z_j, t_j, \Delta t) + \frac{(\Delta t)^3}{3!} \phi''(z_j, t_j, \Delta t) + \cdots.$$  \hfill (33)

For the above relation, compute the values of $z(t_j)$, $z'(t_j)$, $z''(t_j)$ as follows:

$$z'(t_j) = \mathcal{D}(z(t_j), t_j),$$

$$z''(t_j) = \mathcal{D}_t + \mathcal{D}_z,$$

$$z'''(t_j) = \mathcal{D}_{tt} + 2\mathcal{D}_z^2 + \mathcal{D}_z^3 + \mathcal{D}(\mathcal{D}_t + \mathcal{D}_z).$$ \hfill (34)

Thus, from these computed values taking $t = t_j$, the error term is obtained as follows:

$$\frac{\Delta t^{p+1}}{(p+1)!} \xi^{p+1}(t_j) < \varepsilon.$$ \hfill (35)

Hence, on simplification,

$$\Delta t^{p+1} \xi^{p+1}(t_j) < \varepsilon(p+1)!. \hfill (36)$$

In other words,

$$\Delta t^{p+1} \mathcal{L}^p(t_j) < \varepsilon(p+1)!. \hfill (37)$$

Thus, the given value of $p$ will give the upper bound, and for the computational purpose, the value of $\mathcal{L}^p(t_j)$ in Equation (37) is replaced with the max $|\mathcal{L}^p(t_j)|$ in the temporal domain $\Phi_t$. The SSP-RK43 as discussed above is rewritten as

\[\text{Figure 1: Plot of eigenvalues corresponding to gBF equation with } \Delta t = 0.0001 \text{ and } \delta = 8.\]
From the Theorem 1, the proof for convergence is elaborated as follows:

\[ Q_1 - Q_1^* = z' + \frac{\Delta t}{2} \mathcal{L}(z', t') - z'^* + \frac{\Delta t}{2} \mathcal{L}(z'^*), \]

\[ Q_2 = Q_1 + \frac{\Delta t}{2} \mathcal{L}(Q_1), \]

\[ Q_3 = \frac{2}{3} z' + \frac{1}{3} Q_2 + \frac{\Delta t}{6} \mathcal{L}(Q_2), \]

\[ z^{i+1} = Q_3 + \frac{\Delta t}{2} \mathcal{L}(Q_3). \]

The iterated value of \( z^{i+1} \) can be written as

\[ z^{i+1} = z' + c_1 Q_1 + c_2 Q_2 + c_3 Q_3. \]  

Using Taylor's series expansion, the incremental function becomes

\[ \phi(z', t', \Delta t) = (\Delta t)^{-1} (c_1 Q_1 + c_2 Q_2 + c_3 Q_3). \]  

From the Theorem 1, the proof for convergence is elaborated as follows:

\[ |Q_1 - Q_1^*| \leq |z' - z'^*| + \frac{\Delta t}{2} \mathcal{L}(z') - \mathcal{L}(z'^*) \leq (1 + \frac{\Delta t}{2} \mathcal{L}) |z' - z'^*|. \]

\[ Q_2 - Q_1^* = Q_1 + \frac{\Delta t}{2} \mathcal{L}(Q_1) - Q_1^* - \frac{\Delta t}{2} \mathcal{L}(Q_1^*), \]

\[ Q_2 - Q_1^* \leq |Q_1 - Q_1^*| + \frac{\Delta t}{2} \mathcal{L}(Q_1) - \mathcal{L}(Q_1^*), \]

\[ = |Q_1 - Q_1^*| + \frac{\Delta t}{2} \mathcal{L}(z') - \mathcal{L}(z'^*) \leq (1 + \frac{\Delta t}{2} \mathcal{L}) |z' - z'^*|. \]

\[ \leq (1 + \frac{\Delta t}{2} \mathcal{L}) |z' - z'^*| + \frac{\Delta t}{2} \mathcal{L}(z') - \mathcal{L}(z'^*), \]

\[ + \cdots \mathcal{L}(z''') - \mathcal{L}(z'^*) \mathcal{L}(z''') - \cdots \mathcal{L}(z'^*)^2 \mathcal{L}(z''') \]

\[ \leq (1 + \frac{\Delta t}{2} \mathcal{L}) |z' - z'^*| + \frac{\Delta t}{2} \mathcal{L}(z') - \mathcal{L}(z'^*), \]

\[ + \frac{\Delta t}{2} \mathcal{L}(z') \mathcal{L}(z') - \mathcal{L}(z'^*) \mathcal{L}(z'^*), \]

\[ + \cdots \cdots \mathcal{L}(z''') \mathcal{L}(z''') - \mathcal{L}(z'^*) \mathcal{L}(z'^*) \mathcal{L}(z'^*), \]

\[ \leq (1 + \Delta t \mathcal{L}) |z' - z'^*| + \mathcal{L}(z'^*)^2 |z' - z'^*|, \]

\[ = (1 + \Delta t \mathcal{L}) \frac{1}{2} |z' - z'^*|. \]

(a) Comparison of numerical and exact solution

(b) Surface plot of numerical solution

Figure 3: Graphical representation of solutions corresponding to Example 1 with $N = 10$ and $\Delta t = 0.001$.

As discussed by [47], the free parameters are largely taken according to the range of absolute stability. The other possibility is minimizing the sum of the absolute value of the coefficients of the truncation error. Thus $\mathcal{L}_x < \kappa$ and $\mathcal{L}_zz < \kappa^2/M$ where $M$ is the upper bound of convergence. For the incremental function,

$$
|\phi(z', t', \Delta t) - \phi(z'', t', \Delta t)|
$$

$$
= (\Delta t)^{-1} c_1 Q_1 + c_2 Q_2 + c_3 Q_3 - c_1 Q_1^* - c_2 Q_2^* - c_3 Q_3^* 
$$

$$
= (\Delta t)^{-1} (c_1 |Q_1 - Q_1^*| + c_2 |Q_2 - Q_2^*| + c_3 |Q_3 - Q_3^*|)
$$

$$
\leq (\Delta t)^{-1} \left( c_1 \left(1 + \frac{\Delta t}{2}\kappa\right) |z'| - |z''| + c_2 \left(1 + \Delta t \kappa + \frac{\Delta t^2}{2}\kappa^2\right) |z' - z''| \right)
$$

$$
+ c_3 \left( |z' - z''| + \frac{3\Delta t}{2} + 2 \frac{\Delta t}{2} \kappa \right) |z' - z''|
$$

$$
\leq \left(3\Delta t + \frac{3\Delta t}{2} + 2 \frac{\Delta t}{2} \kappa \right) |z' - z''|.
$$

(42)

The backward substitution of (38) and its comparison with general Taylor’s series [47] gives $c_1 = 1/4, c_2 = 1/2, c_3 = 1/4$. Hence, these values generate the inequality as

$$
|\phi(z', t', \Delta t) - \phi(z'', t', \Delta t)| \leq \kappa \left(1 + \frac{1}{2} \Delta t \kappa + \frac{1}{6} (\Delta t \kappa)^2 \right) |z' - z''|.
$$

(43)
The eigenvalue-based technique is followed to establish the stability of the system.

The stability analysis of both the models is discussed below.

5. Stability Analysis

The stability analysis of both the models is discussed below by taking nonlinearity coefficient \( z = m \) (say), where \( m = \max z \), in the entire process to handle the nonlinear term in Equations (22) and (23). The eigenvalue-based technique [45] is followed to establish the stability of the system.

1. **Model-I**: generalized Burger’s-Fisher equation:

\[
\frac{\partial z^i}{\partial t} = \mathcal{C}^{-1}\mathcal{D}z^i - \beta m^\delta A^{-1}Bz^i + \gamma \left(1 - m^\delta\right)z^i,
\]

\[
z^i = \left(\mathcal{C}^{-1}\mathcal{D} - \left(\beta m^\delta A^{-1}B + \gamma \left(1 - m^\delta\right)\right)I\right)z^i \equiv \mathfrak{T}z^i; \tag{44}
\]

2. **Model-II**: generalized Burger’s-Huxley equation:

\[
\frac{\partial z^i}{\partial t} = \mathcal{C}^{-1}\mathcal{D}z^i - \beta m^\delta A^{-1}Bz^i + \gamma \left(1 - m^\delta\right)\left(m^\delta - \eta\right)z^i, \tag{45}
\]

It is observed that \(|\phi(z^i, t^i, \Delta t)|\) satisfies the Lipschitz condition in \( z^i \) and is a continuous function in \( \Delta t \). Thus, it is concluded that SSP-RK43 is convergent.

The matrix \( \mathfrak{T} \) is constant for both the Model-I and Model-II with the assumption that it has distinct or possibly complex eigenvalues with a negative real part. Using the given initial condition for the analytic solution, the relation becomes

\[
z(t) = \exp(\mathfrak{T}t)z^0, \tag{47}
\]

whereas on expanding the exponent as a matrix function where \( I \) is the identity matrix,

\[
\exp(\mathfrak{T}t) = I + \mathfrak{T}t + \frac{(\mathfrak{T}t)^2}{2!} + \frac{(\mathfrak{T}t)^3}{3!} + \cdots. \tag{48}
\]

For Model-I and Model-II, consider the transformation matrix \( P \) such that \( P^{-1}\mathfrak{T}P = \mathfrak{D} \) where \( \mathfrak{D} \) is the diagonal matrix; thus, the relation becomes

\[
P^{-1}\exp(\mathfrak{T}t)P = \exp(\mathfrak{D}t), \tag{49}
\]

Numerical solution

(a) Comparison of numerical and exact solution

(b) Surface plot of numerical solution
\[ D = \eta_1 \eta_2 \cdots \eta_n \]

Similarly, as discussed above, the solution of Equation (52) is \( v = \exp(\mathcal{D}t)\psi \), and the recursive relation is

\[ v^{i+1} = E(\mathcal{D}t)\psi^i. \]  

In this diagonal matrix, \( E(\mathcal{D}t) \) is an approximate matrix of \( \exp(\mathcal{D}t) \). The diagonal elements of the approximated matrix are \( E'(\eta^i \Delta t) \). Implementing Equation (25) on the scalar Equation (44),

\[ z' = \eta^i z. \]  

Thus, the method discussed in Equation (25) is absolutely stable if

\[ |E'(\eta^i \Delta t)| < 1, \]  

where \( \text{Re}(\eta) < 0 \). The stability of the system exclusively depends on the eigenvalues of the coefficient matrix \( \mathfrak{T} \) of the form \( \sum_{m=0}^{\infty}(\mathfrak{T}\Delta t)^m/m! \) which should satisfy Equation (54). The necessary conditions that eigenvalues of \( \mathfrak{T} \) should satisfy are given below [47]:
respectively. It can be clearly observed that the eigenvalues of the given equations in Figures 1 and 2, therefore, the proposed technique is unconditionally stable.

(i) For real $\eta^i : -2.78 < \Delta t \eta^i < 0$
(ii) For pure imaginary $\eta^i : -2\sqrt{2} < \Delta t \eta^i < 2\sqrt{2}$
(iii) For complex $\eta^i : \Delta t \eta^i$ should lie in the region as given by [48]

For different values of parameters, eigenvalues corresponding to gBF and gBH equations are given in Figures 1 and 2, respectively. It can be clearly observed that the eigenvalues of all the considered problems satisfy the above defined conditions; therefore, the proposed technique is unconditionally stable.

6. Numerical Experiments

The accuracy of compact finite difference scheme is measured using the $L_2$ and $L_{\infty}$ error norms, which are defined as follows:

$$L_{\infty} = \max_{0 \leq i \leq N} |z_i - Z_i|, L_2 = \sqrt{\sum_{i=0}^{N} (z_i - Z_i)^2},$$

Figure 7: Error and solution profile of Example 5 with $N = 50$ and $\Delta t = 0.01$. (a) Absolute error at different time levels (b) Surface plot of numerical solution
where $z_i$ and $Z_i$ represent the exact and numerical solutions, respectively, at the node point $x_i$ for some fixed time.

**Example 1.** Consider gBF Equation (3) with the parameters $\beta = 0.001$ and $\gamma = 0.001$ for the initial condition as Equation (4) and the boundary conditions as (5) and (6). The exact solution is given by Equation (7). Table 1 gives a comparison of the absolute error for fixed spatial step size $h = 0.1$ and temporal step size $\Delta t = 0.0001$. Absolute error is calculated at time levels $t = 0.001, 0.010, 0.100$ with $\delta = 1$ and $\delta = 4$. The results are found to be more accurate in comparison to the Adomian decomposition method [23], compact FDM [25],
and exponential time differencing method of lines [29]. Figure 3(a) compares numerical and exact solution at different time levels, and Figure 3(b) presents the 3D behaviour of the numerical solution with $N = 10$, $\Delta t = 0.01$, and $\delta = 8$.

**Example 2.** Consider Equation (3) for $\beta = \gamma = 1$ with the initial condition (4) and boundary conditions (5) and (6). The absolute error is compared in Table 2 with those of previous investigators Ismail et al. [23], Sari et al. [25], and Bratsos.
Example 3. Consider Equation (3) for the initial and boundary conditions (4) and (6) with \( \beta = 0.1 \) and \( \gamma = -0.0025 \). Table 3 depicts the accuracy of the results obtained by CFDM6, by comparing the absolute error with literature data for \( h = 0.1, \Delta t = 0.0001, \) and \( \delta = 2, 4, 8 \). Figure 5(a) compares the numerical and exact solution at different time levels, and Figure 5(b) represents the 3D behaviour of the numerical solution with \( N = 10, \Delta t = 0.01, \) and \( \delta = 8 \).

Example 4. Consider gBH Equation (8) with the initial and boundary conditions (9) and (10) for parametric values \( \beta = \gamma = 1 \) and \( \eta = 0.001 \). The exact solution is given by (11). The absolute error at node points \( x = 0.1, 0.5, 0.9 \) is given in Table 4 at \( t = 0.1 \) and \( t = 1 \) for \( h = 0.1, \Delta t = 0.0001, \) and \( \delta = 2. \) Comparison shows that results are better than exponential finite difference scheme [49], hybrid B-spline [50], and tension B-spline collocation method [37]. Table 5 gives a comparison of \( L_\infty \) error norm for \( \delta = 1, 4, 8 \). Table 6 gives a comparison of \( L_2 \) and \( L_\infty \) error norms with \( \delta = 2, h = 0.1, \eta = 0.001, \Delta t = 0.01 \) at \( t = 0.05, 0.1, 1.5 \). Figure 6(a) represents the absolute error at different time levels with \( N = 10 \), and Figure 6(b) gives the 3D profile of numerical solution with \( N = 50, \Delta t = 0.01, \) and \( \delta = 8 \).

Example 5. The gBH Equation (8) is considered for the initial and boundary conditions (9) and (10). The CFDM6 results are evaluated for \( \beta = 0.1, \gamma = 0.001, \) and \( \eta = 0.0001 \), \( h = 0.1, \Delta t = 0.0001, \) and \( \delta = 2 \) at different node points for time \( t = 0.2, 0.5, \) and 0.8. Tables 9 and 10 give a comparison of absolute error for \( \eta = 0.0001 \) and \( \eta = 0.00001 \), respectively. Remarkable closeness of numerical and exact solutions can be seen in the tables. Figure 8(a) represents the absolute error at different time levels with \( N = 10, \) and Figure 8(b) gives the 3D profile of numerical solution with \( N = 50, \Delta t = 0.01, \) and \( \delta = 8 \).

Example 6. Consider gBH Equation (8) with initial and boundary conditions (9) and (10). The absolute error is compared with the schemes discussed by [37, 49, 50] for \( \beta = 5, \gamma = 10, \eta = 0.0001, \Delta t = 0.0001, \) and \( \delta = 2 \) at different node points for time \( t = 0.2, 0.5, \) and 0.8. Tables 9 and 10 give a comparison of absolute error for \( \eta = 0.0001 \) and \( \eta = 0.00001 \), respectively. Remarkable closeness of numerical and exact solutions can be seen in the tables. Figure 8(a) represents the absolute error at different time levels with \( N = 10, \) and Figure 8(b) gives the 3D profile of numerical solution with \( N = 50, \Delta t = 0.01, \) and \( \delta = 8 \).

Example 7. The gBH Equation (8) is subjected to initial and boundary conditions (9) and (10) for \( \beta = 0, \gamma = 1, \) and \( \eta = 0.001 \). Table 11 compares absolute error of CFDM6 with the Adomian decomposition method (ADM) [23], fourth-order numerical scheme (FDS4) [29], Gauss Chebyshev Galerkin (GCG) [30], and modified cubic B-spline differential quadrature method (MCSDQM) [31] at \( \delta = 2, h = 0.1, \) and \( \Delta t = 0.0001 \). Table 12 gives the comparison of absolute error for \( \delta = 3 \). The efficiency of the numerical solution to approach the exact solution can be easily seen, and the results are better than those of other methods. Figure 9(a) represents the absolute error at different time levels with \( N = 10, \) and Figure 9(b) gives the 3D profile of the numerical solution with \( N = 50, \Delta t = 0.01, \) and \( \delta = 8 \).

7. Conclusion

Compact FDM along with the SSP-RK43 scheme has been implemented to solve gBF and gBH equations. Several examples of both the equations are successfully solved with the proposed technique. Absolute error and \( L_2 \) and \( L_\infty \) error norms are calculated and compared with the previous results. The results with CFDM6 are found to be better than those with many techniques like the Adomian decomposition method, exponential time differencing method of lines, cubic B-spline collocation method, exponential finite difference scheme, hybrid B-spline collocation, tension B-spline collocation, multiscale Runge-Kutta Galerkin method, and modified cubic B-spline differential quadrature method. Comparison shows that the technique is providing highly accurate results with ease in implementation and less computational effort.

Data Availability

The complete data is in the manuscript.

Conflicts of Interest

The authors declare that they have no conflicts of interest.
