Potassium (K^+) plays key roles in plant growth and development. However, molecular mechanism studies of K^+ nutrition in forest plants are largely rare. In plants, SKOR gene encodes for the outward rectifying Shaker-type K^+ channel that is responsible for the long-distance transportation of K^+ through xylem in roots. In this study, we determined a Shaker-type K^+ channel gene in purple osier (*Salix purpurea*), designated as *SpuSKOR*, and determined its function using a patch clamp electrophysiological system. *SpuSKOR* was closely clustered with poplar *PtrSKOR* in the phylogenetic tree. Quantitative real-time PCR (qRT-PCR) analyses demonstrated that *SpuSKOR* was predominantly expressed in roots, and expression decreased under K^+ depletion conditions. Patch clamp analysis via HEK293-T cells demonstrated that the activity of the *SpuSKOR* channel was activated when the cell membrane voltage reached at -10 mV, and the channel activity was enhanced along with the increase of membrane voltage. Outward currents were recorded and induced in response to the decrease of external K^+ concentration. Our results indicate that *SpuSKOR* is a typical voltage dependent outwardly rectifying K^+ channel in purple osier. This study provides theoretical basis for revealing the mechanism of K^+ transport and distribution in woody plants.

1. Introduction

Plants need to absorb the required K^+ from the soil through plant roots and, then, distribute them to different organs to meet the normal growth and development [1–6]. Previous studies demonstrated that there are two kinds of mechanisms of K^+ uptake in plants. Mechanism I is the high-affinity K^+ absorption system, which plays a major role when the external K^+ concentration is less than $200 \mu\text{mol}\cdot\text{L}^{-1}$. Mechanism II is the low affinity K^+ absorption system, which plays key role when the external K^+ concentration is more than $1 \text{ mmol}\cdot\text{L}^{-1}$

[1, 7, 8]. The long-distance distribution and dynamic balance of K^+ in plants are mainly mediated by various K^+ channels located in the plasma membrane. According to the sequence, structure, and function of these channel proteins, they can be divided into three categories: Shaker family channels, TPK family channels, and other potassium channels [2, 4, 6, 9]. Among them, Shaker-type K^+ channels are the most thoroughly studied. The affinity constant of Shaker-type K^+ channels to substrate K^+ is about tens of millimoles, which is a typical low affinity and high-throughput K^+ channel, and plays an important role in plant K^+ nutrition efficiency [2, 3, 5, 6].

Since Anderson et al. [10] and Sentenac et al. [11] reported the Shaker-type K^+ channels KAT1 and AKT1 in *Arabidopsis thaliana*, more than 40 Shaker-type K^+ channels have been found in different plants during the recent 30 years [2, 3, 12–16]. According to the voltage dependence and the different movement direction of K^+ in the transmembrane, Shaker-type K^+ channels can be divided into three types: inward rectifier, outward rectifier, and weak rectifier (bidirectional rectifier). In *Arabidopsis*, the inward rectifying K^+ channels include AKT1, SPIK, KAT1, and KAT2 [10, 11, 17, 18]. SKOR and GORK are typical outward rectifier K^+ channels [9, 14], and AKT2/3 is a typical weak rectifier K^+ channel [19, 20].

In particular, SKOR gene encodes a class of outward rectifying Shaker-type K^+ channel. In *Arabidopsis*, the molecular mechanism of the SKOR channel physiological function is more detailed: AtSKOR is mainly located in the columella and pericycle parenchyma cells of the root, which is responsible for the K^+ release into the xylem sap, thus realizing the long-distance transportation of K^+ ions through the xylem. Meanwhile, it was found that the lack of AtSKOR channel function could reduce the K^+ content in the shoot by about 50% and the plant growth and development [9]. In recent years, SKOR has been widely studied in rice [14], muskmelon [15], *Puccinellia tenuiflora* [21], and *Zygophyllum Xanthoxylum* [22]. However, the function of SKOR channels in woody plants is largely rare.

As one of the most popular diploid willow plants, purple osier plays an important role in soil and water conservation, shelter forest, and biomass energy, and its genome has been successfully sequenced [23, 24]. The molecular basis and mechanisms of K^+ nutrition and homeostasis in willow are still unknown. In this study, we isolated a Shaker-like K^+ channel gene, *SpuSKOR*, from purple osier, and analyzed their function via patch clamp electrophysiological system, which provided a theoretical basis for revealing the mechanism of K^+ transport and distribution in woody plants.

2. Material and Methods

2.1. Plant Material and Growth Condition. Purple osier plants used throughout this study were collected as previously described in Liang et al. [25]. 1-year-old female purple osier cutting asexual cloning plants were grown in advance in 1/2MS liquid medium (the control, [26]) in a growth chamber with 12 h light at 25°C followed by 12 h dark at 20°C (with 60% relative humidity) for 2 weeks and, then, transferred into the plastic containers that being suffered to different treatments, based on 1/2MS liquid medium. Leaf, stem, root, full blooming flower, and mature fruit tissues were collected from the same plant and frozen immediately in liquid nitrogen for further quantitative real-time PCR (qRT-PCR) analyses.

K^+ deficiency treatment was carried out as previously described in Liang et al. [25]. 1-year-old female purple osier cutting asexual cloning plants were subjected to K^+ deficiency and collected at 0 h, 4 h, 12 h, 36 h, and 72 h before qRT-PCR analysis.

2.2. Identification of *SpuSKOR* Gene. Genome information of purple osier willow was screened from The Plant Genomics

Resource of Phytozome 12 (<https://phytozome.jgi.doe.gov/pz/portal.html>). BLAST searches against the genome database were carried out with the full-length of *Arabidopsis* SKOR (AT3G02850) protein sequence as reference, to obtain the SKOR gene from purple osier. The amino acid sequence of the candidate purple osier SKOR protein was verified using the Pfam (<http://pfam.xfam.org>) and InterProScan 4.8 (<http://www.ebi.ac.uk/Tools/pfa/iprscan/>), to confirm the existence of typical K^+ channel domains. Gene ID, location, coding sequence, amino acid sequence, and intron numbers were gathered on Phytozome Genomics Resources.

2.3. Phylogenetic Analysis of Known Plant SKOR Proteins. The full-length SKOR protein sequences of purple osier, *Arabidopsis*, rice, maize, soybean, tomato, grape, peach, apple, and poplar were downloaded from the Phytozome Genomics Resources, respectively, and pear SKOR protein was downloaded from Pear Genome Project (<http://peargenome.njau.edu.cn/>). A neighbor-joining method phylogenetic tree was constructed as previously described in Tamura et al. [27, 28], via using the ClustalX2.1 and MEGA7.0 software.

2.4. RNA Extraction and Quantitative Real-Time PCR Assay. As previously described in Liang et al. [25], RNA extraction was carried out using MiniBEST Plant RNA Extraction Kit (TaKaRa, Dalian, China), and the 1st cDNA was synthesized using PrimeScript™ RT reagent Kit (TaKaRa, Dalian, China). Specific primers for *SpuSKOR* and Ubiquitin control gene were designed from NCBI/Primer-BLAST online server (Table 1). qRT-PCR was performed on 7500 Real-Time PCR System (Applied Biosystems, New York, USA) as described by Liang et al. [25] and You et al. [28]. Using SYBR Premix Ex Taq reaction kit (TaKaRa, Dalian, China), qRT-PCR efficiency and the starting template concentration were calculated according to the description of Song et al. [28–30]. The relative expression levels of *SpuSKOR* were presented after normalization to the internal control *SpuUbiquitin* from three independent biological repeats [25].

2.5. Patch Clamping Analysis. The recombinant plasmid pTracer-CMV3-SKOR was constructed by cloning the CDS region of *SpuSKOR* gene into pTracer-CMV3 vector [12], using the forward primer (Table 1, *Kpn* I site was introduced and underlined) and reverse primer (Table 1, *Not* I site was introduced and underlined). The electrophysiological function of *SpuSKOR* was carried out by patch clamp system as described by Su et al. [12]. The purified and concentrated pTracer-CMV3-SKOR plasmid was transfected into HEK293-T cells (ATCC company, USA). The cells labeled with green fluorescence were selected and being detected by PCLAMP 10.0 device (Axon, USA). The current signal of *SpuSKOR* channel was collected by PCLAMP 10.0 and then being analyzed via the Sigmaplot 10.0 software. The external K^+ concentration in the extracellular fluid was set of 0, 10, 50, and 100 mmol·L⁻¹, each concentration with 6 cells.

2.6. Statistical Analysis. All data were statistically analyzed using independent samples *t*-test in the SPSS 13.0 software (SPSS Chicago, Illinois, USA). Asterisks indicate statistical

differences between plants under control and stress treatment (* $P < 0.05$, ** $P < 0.01$).

3. Results

3.1. Identification of *SpuSKOR* in Purple Osier Willow. By BLAST searching of the Phytozome Genomics Resources of Purple Osier Willow, a putative *SKOR* channel encoding gene was identified, entitled as *SpuSKOR*, which contains a coding sequence of 3099bp in nucleotides that encodes 1032 amino acids. Protein domain verification analyses showed that all of them contain six ion transmembrane domains (PF00520), three ankyrin domain (PF12796), one cyclic nucleotide-binding domain (PF00027), and one KHA dimerisation domain (PF11834), which belongs to the classic plant potassium channels (Figure 1(a)). Gene structure analysis showed that *SpuSKOR* had 16 introns that varied distinctly in length (Figure 1(b)).

3.2. Phylogenetic and Protein Motif Analysis of *SKOR* Proteins. To confirm the evolutionary relationship of *SKOR* proteins of 11 sequenced plants, a maximum likelihood (ML) phylogenetic tree was generated. The amino acid sequences of 11 *SKOR* proteins share an overall identity of 53.39% (data not shown). Notably, purple osier willow and poplar belong to the same family of Salicaceae; *SpuSKOR* was closely clustered with *PtrSKOR* from poplar in the phylogenetic tree (Figure 2). Rice and maize belong to the same

family of Gramineae; *OsaSKOR* and *ZmaSKOR* were closely clustered together. Moreover, all Roseaceae orthologs from apple (*MdoSKOR*), pear (*PbrSKOR*), peach (*PpeSKOR*), and strawberry (*FveSKOR*) have the closest genetic relationships (Figure 2).

3.3. Expression Profiles of *SpuSKOR*. The transcriptomic data of purple osier was obtained from Phytozome online database. In general, the percentages of *SpuSKOR* expression in different tissues and organs are as follows: the maximum expression was detected in roots (64%), followed by leaf (17%), xylem (7%), pistil (5%), petal (3%), pollen (2%), catkin (1%), and female receptive (1%) (Figure 3). qRT-PCR was further performed to determine the expression profiles of *SpuSKOR* in different tissues of 1-year-old female purple osier. Results showed that *SpuSKOR* was unevenly expressed in the tested organs, and mainly expressed in roots, followed by leaves, phloem, catkin, pistil, pollen, and female receptive (Figure 4), which was consistent with the transcriptomic expression status.

To investigate the role of *SpuSKOR* in maintaining K^+ homeostasis in purple osier, we analyzed the expression profiles of *SpuSKOR* in roots, leaves, and stems of 1-year-old purple osier seedlings under K^+ depletion. Results showed that expression of *SpuSKOR* in roots was consistently decreased until 12 h and, then, kept the same. Although expression level was largely low in stems and leaves,

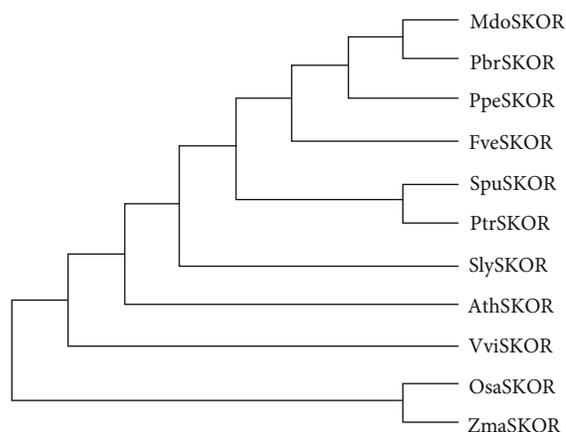

FIGURE 2: Phylogenetic tree of SKOR proteins from different plants. A maximum likelihood (ML) tree was constructed by multiple alignment of SKOR proteins in purple osier, *Arabidopsis*, rice, maize, soybean, tomato, grape, peach, apple, and poplar using the ClustalX2.1 and MEGA7.0 software. Information of SKOR proteins from sequenced plant was listed in Supplemental Table 1. The *SpuSKOR* protein was labeled with red dot.

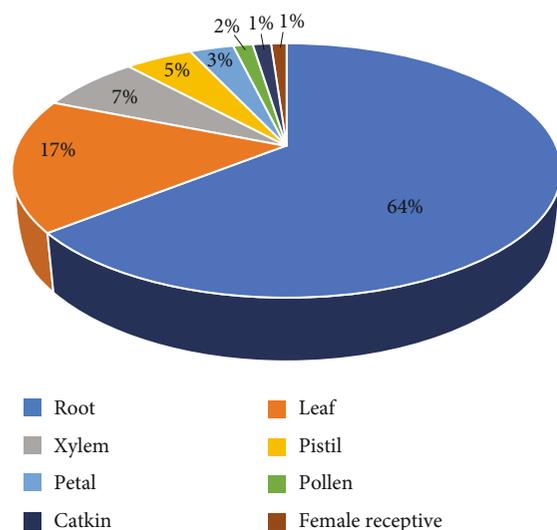

FIGURE 3: In silico transcriptomic expression pattern of *SpuSKOR* in different tissues/organs of purple osier. The expression levels (RPKM) of *SpuSKOR* were directly downloaded from Phytozome Genomic Resources (purple osier).

SpuSKOR in stems was steadily reduced until 72 h, while *SpuSKOR* in leaves was not affected under K^+ deficiency (Figure 5).

3.4. Patch Clamp Determination of *SpuSKOR* in HEK293-T Cells. Taking HEK293-T cells transfected with pTracer-CMV3 empty vector were used as the control, pCLAMP 10.0 patch clamp system was used to record the characteristic curves of current and membrane voltage of pTracer-CMV3-SKOR under different extracellular K^+ concentrations. Results showed that cells expressing pTracer-CMV3-SKOR exhibited outward rectifying currents, without deducting

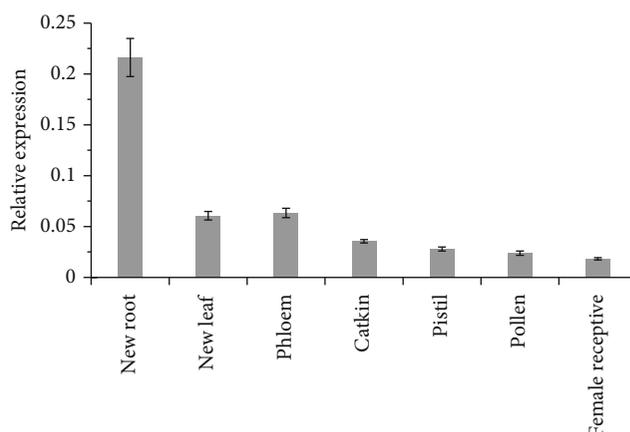

FIGURE 4: qRT-PCR analysis of *SpuSKOR* in different tissues/organs of purple osier. 1-year-old female purple osier plants were grown in 1/2MS liquid medium in a growth chamber with 12 h light at 25°C followed by 12 h dark at 20°C (with 60% relative humidity). Different tissues/organs were collected from the same plant on April 20, 2019, and frozen immediately in liquid nitrogen for RNA extraction and quantitative real-time PCR. Data are the means of values obtained from three independent replicates \pm SE.

the control background currents, and the outward current increased with the decrease of extracellular K^+ concentration (Figure 6). Notably, the lowest current was recorded when the extracellular K^+ concentration was set at 100 $mmol \cdot L^{-1}$, while the highest current was recorded when the extracellular K^+ concentration was set at 0 $mmol \cdot L^{-1}$ (Figure 6).

In addition, when the cell membrane voltage was at -10 mV, the *SpuSKOR* channel was activated and the outward rectifying current appeared. The more positive the voltage was, the stronger the outward rectifier current was (Figure 6).

4. Discussion

As one of the most important cation elements in plant cells, K^+ is closely related to plant growth and development [1–4, 6]. K^+ fertilizer favorably contributes to plant growth, flowering, wood quality, and yield [2–6]. Molecular mechanisms towards K^+ nutrition in perennial forest plants are largely rare.

In plants, SKOR genes encode a class of outward rectifying Shaker-like K^+ channel proteins, which play an important role in plant growth and development [4, 9, 30]. To date, there are more than 650 species of *Salicaceae* in the world. However, no SKOR channel protein in *Salicaceae* has been reported. Although the core transmembrane regions of SKOR homologous proteins in woody plants of different families and genera have very high sequence consistency (data not shown), there are differences in the genetic evolution relationship (Figure 2). SKOR homologous proteins of the same family and genus have relatively high consistency and are more similar in genetic evolution distance (Figure 2). In particular, *SpuSKOR* and poplar *PtrSKOR* are closely clustered in the phylogenetic tree, and they have high amino acid sequence identity of 94.54% (Supplemental

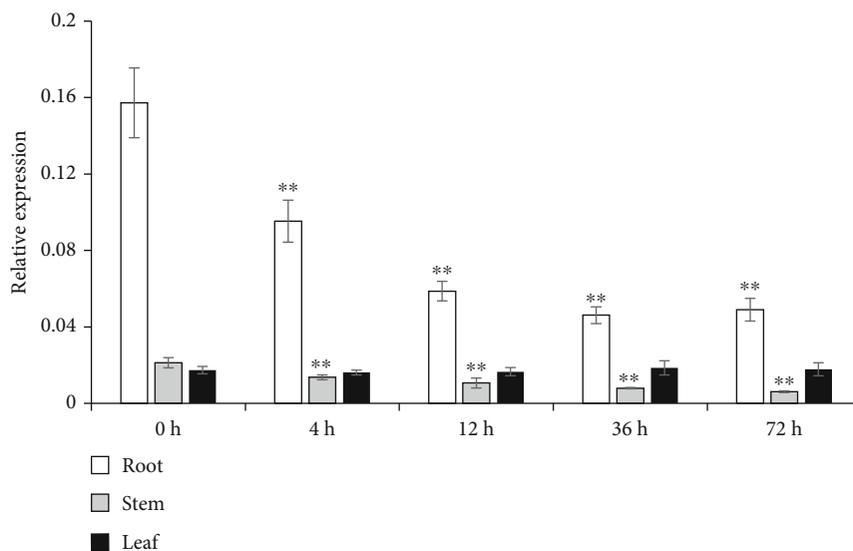

FIGURE 5: Expression changes of *SpuSKOR* under K^+ deficiency. 1-year-old purple osier plants were exposed to K^+ deficiency for 4 h, 12 h, 36 h, and 72 h, respectively, before examination. The relative expression level of *SpuSKOR* was presented after normalization to the internal control. Data are the means of values obtained from three independent replicates \pm SE.

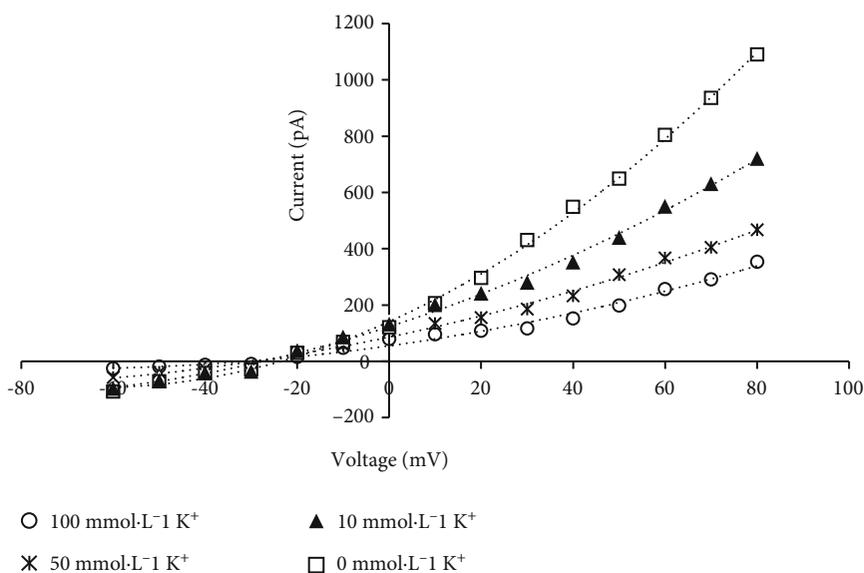

FIGURE 6: Curves of the current-voltage relation in response to different extracellular K^+ concentrations via patch clamp system. Green fluorescence-labeled HEK293-T cells were selected and being detected by PCLAMP 10.0 device. The current signal of the *SpuSKOR* channel was collected by PCLAMP 10.0 and then being analyzed via the Sigmaplot 10.0 software. The external K^+ concentration in the extracellular fluid was set of 0, 10, 50, and 100 $\text{mmol}\cdot\text{L}^{-1}$. Data are shown as the means of values obtained from 6 independent cells.

Figure 1). The highly similar amino acid sequence and protein structure (Supplemental Figure 2) indicating that they might have similar physiological functions. Analyzing the function of *SpuSKOR* channel in purple osier provides theoretical support for studying the function of *SKOR* homologous proteins in *Salicaceae*.

The cell-specific expression patterns of these *SKOR* genes may be essential for the specific functions of the channels and plant growth. In *Arabidopsis* and rice, *SKOR* is specifically expressed in roots [9, 14, 19], while in muskmelon and *Zygo-phyllum xanthoxylum*, *SKOR* is ubiquitously expressed and the maximum expression was observed in roots [15, 22]. In

this study, *SpuSKOR* was mainly expressed in the roots but slightly expressed in the other parts of purple osier (Figure 4), which was consistent with previous reports in other plants [15, 21, 22], but was slightly differed from *Arabidopsis* and rice [9, 14]. Nonetheless, our findings confirmed again that *SKOR* genes mainly play indispensable roles in K^+ nutrition and ion dynamics in plant roots.

Favorably, electrophysiological studies may explain the functional characteristics and regulatory mechanisms of plant K^+ channels measured in vitro. In particular, patch clamp and two electrode voltage clamp are the two most effective systems to record the characteristic curves of

current, under distinct membrane voltage, and to determine the physiological function of ion channels [2, 3, 9, 14, 15, 17, 18, 19, 21, 22]. In terms of physiological function, plant SKOR proteins belong to a typical outward rectifying Shaker-type K^+ channel with K^+ selectivity. It has been confirmed in *Arabidopsis* [9, 19] and muskmelon [15] by using *Xenopus* oocytes and double electrode voltage clamp technology, patch clamping studies of SKOR channels are rare. In the model organism *Arabidopsis*, Shaker-like outwards rectifying channel *AtSKOR* is expressed in the pericycle and the xylem parenchyma in roots. The activity of the *AtSKOR* channel is modulated by membrane potential, along with external K^+ concentration. The *AtSKOR* channel opens at depolarized membrane potential [9]. In this study, patch clamp determination revealed that *SpuSKOR* had the characteristics of outward rectifying channel: K^+ efflux current and voltage-dependent gated channel activity, and the channel activity is regulated by extracellular K^+ concentration (Figure 6), which is similar to the K^+ current characteristics of *Arabidopsis AtSKOR* and muskmelon *CmSKOR* [9, 13, 19]. However, there were significant differences in current intensity, current, and membrane potential curves, suggesting that the functions of woody plant SKOR channels are quite different from those of annual plants. Notably, *SpuSKOR* current is recorded at negative membrane voltage (-10 mV) (Figure 6); this was because these recorded currents are nonnormalized currents that without deducting the control background currents. Although the characteristics and regulation mechanism of *SpuSKOR* channel for K^+ transport have not been carried out, this work provides theoretical basis and technical support for the study of the function of SKOR homologous proteins in woody plants.

Shaker-type channels play an important role in K^+ homeostasis, osmotic regulation, and proton regulation and are regulated by abiotic stresses, including external K^+ supply levels [5, 9, 14, 15, 19, 21, 22]. Purple osier plants have strong adaptability and play important roles in water and soil conservation, bioenergy, and shelter forest system construction [23, 24]. In this study, K^+ deficiency significantly reduced the expression level of *SpuSKOR* (Figure 5), which was consistent with the previous studies in *Arabidopsis* [9], *Zygophyllum Xanthoxylum* [22], and muskmelon [15]. Therefore, we speculate that there is not sufficient K^+ that could be transported to the upper part of the plant roots, under the condition of K^+ deficiency, which reduces the demand of SKOR genes and causes the decrease of SKOR expression levels. Nonetheless, *SpuSKOR* is a typical voltage-dependent outward rectifying K^+ channel in purple osier plants.

5. Conclusions

A Shaker-type K^+ channel gene, *SpuSKOR*, was isolated and determined in purple osier. *SpuSKOR* was mainly expressed in roots and was downregulated by K^+ deficiency. *SpuSKOR* is a typical voltage-dependent outward rectifying K^+ channel in purple osier.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

We declare that we do not have any commercial or associative interest that represents a conflict of interest with the work submitted.
