In this paper, we design and investigate a higher order $\varepsilon$-uniformly convergent method to solve singularly perturbed parabolic reaction-diffusion problems with a large time delay. We use the Crank–Nicolson method for the time derivative, while the spatial derivative is discretized using a nonstandard finite difference approach on a uniform mesh. Furthermore, to improve the order of convergence, we used the Richardson extrapolation technique. The designed scheme converges independent of the perturbation parameter ($\varepsilon$-uniformly convergent) and also achieves fourth-order convergent in both time and spatial variables. Two model examples are considered to demonstrate the applicability of the suggested method. The proposed method produces better accuracy and a higher rate of convergence than some methods that appear in the literature.

1. Introduction

Many practical problems which are modelled by parameter dependent differential equations and delay singularly perturbed differential equations have many application in engineering and applied mathematics such as the effect of various physical parameter on heat and mass transfer [1, 2], heat transport in the presence of magnetic field and modulation [3, 4], ground water flow, extraction of oil from reservoirs, population dynamics, and fluid flow. The solution of time delayed singularly perturbed partial differential equation is not only determined by its present state but also by a certain past state. One of the difficulties in solving singularly perturbed problems is developing $\varepsilon$- uniformly convergent methods. As far as finite difference methods are concerned, two approaches have ordinarily been used by numerical analysis to obtain $\varepsilon$- uniformly convergent methods for solving singularly perturbed problems, and these are namely fitted operator and fitted mesh finite difference methods [5].

The majority of researchers focused on the numerical solution of singularly perturbed partial differential equations without a delay parameter [6-10]. Numerical approaches for solving singularly perturbed parabolic time delay reaction-diffusion equations that are $\varepsilon$- uniformly convergent are not well established. Gowrisankar and Natesan [11] presented a numerical scheme for singularly perturbed parabolic delay convection diffusion equation using piecewise fitted mesh approach, and the method have first-order in time and first-order up to a logarithmic factor in space. Singh et al. [12] analyzed a domain decomposition method for solving singularly perturbed parabolic reaction-diffusion problems with time delay, and the method have rate of convergence one. Yulan et al. [13] examined time delayed singularly perturbed reaction-diffusion problem using the barycentric interpolation collocation method but they did not show the convergence analysis. Kumar and Kumari [14] introduced a cubic B-spline method overfitted mesh for a class of singularly perturbed delay parabolic partial differential equations first-order in time and second-order accurate in space. Dagnachew et al. [15] designed a fitted operator method for singularly perturbed parabolic convection diffusion equation with small space delays, and the method have second order in both spatial and temporary variables. Kumar [16] developed a collocation method consisting of cubic B-spline basis functions over piecewise-uniform mesh for singularly
perturbed parabolic convection diffusion problems with a time delay. Govindarao et al. [17] presented for the solution of singularly perturbed delay parabolic reaction-diffusion initial-boundary-value problem using Shishkin mesh strategy. Mesfin and Gemechis [18] introduced numerical solution for singularly perturbed parabolic PDEs with shift parameter using the Crank–Nicholson method in the temporal discretization and nonstandard finite difference method in the spatial discretization, and the method have order of convergence $O((\Delta t)^{2})$. Fasica and Gemechis [19] proposed a nonstandard finite difference method for singularly perturbed parabolic reaction-diffusion problems with a large time delay. We applied a nonstandard finite difference method (Mickens rule) over the Crank–Nicholson finite difference method. To accelerate the order of convergence, the Richardson extrapolation technique is applied. The current method is more accurate and has faster rate of convergence than those methods that appear in the literature. The present method has a fourth-order of convergence in both the spatial and temporal variables after Richardson extrapolation technique applied.

Notation. Throughout this work, $M$ and $C$ are positive constants that are independent of the perturbation parameter $\epsilon$ and $m$ and $n$. The norm $\| \cdot \|$ denotes the maximum norm.

2. Description of the Problem

We consider the singularly perturbed parabolic reaction-diffusion initial boundary value problem with time delay over $D = D_x \times D_t$, with $D_x = (0, 1)$, $D_t = (0, T]$, and $\Omega = \Omega_l \cup \Omega_{b} \cup \Omega_r$ of the form:

\begin{equation}
\begin{aligned}
u_x &= p(x,t)u_x(x,t) + q(x,t)u(x,t) - g(x,t), \\
u(x,t) &= \psi_b(x,t), \\
u(0,t) &= \psi_l(t), \\
u(1,t) &= \psi_r(t),
\end{aligned}
\end{equation}

where $0 < \epsilon \ll 1$ and $\tau > 0$ are the given constants. The functions $p(x,t), q(x,t), g(x,t)$ over $\overline{D}$ and $\psi_b(x,t), \psi_l(t), \psi_r(t)$ over $\overline{\Omega}$ are sufficiently smooth and bounded functions that satisfy

\begin{equation}
p(x,t) \geq \alpha > 0, \quad (x,t) \in \overline{D}.
\end{equation}

For some positive integer $b$, the terminal time $T$ is considered to satisfy the condition $T = b\tau$. The existence of a unique solution of equation (1) is guaranteed with the assumption that the data are smooth and satisfy appropriate compatibility conditions at the corner points $(0, 0), (1, 0), (0, -\tau)$, and $(1, -\tau)$. The delay terms and the required compatibility condition at the corner points are $\psi_b(0, 0) = \psi_l(0), \psi_r(1, 0) = \psi_r(0), (0,t)$ and $\psi_b(0, 0) \geq \psi_l(0), \psi_r(1, 0) = \psi_r(0), (0,t)$ and

\begin{equation}
\begin{aligned}
\frac{\partial \psi_b(0,0)}{\partial t} - \epsilon \frac{\partial^2 \psi_b(0,0)}{\partial x^2} + p(0,0)\psi_b(0,0) + q(0,0)\psi_b(0,-\tau) &= g(0,0), \\
\frac{\partial \psi_b(0,0)}{\partial t} - \epsilon \frac{\partial^2 \psi_b(1,0)}{\partial x^2} + p(1,0)\psi_b(1,0) + q(1,0)\psi_b(1,-\tau) &= g(1,0).
\end{aligned}
\end{equation}

Equation (1) admits a unique solution under the above assumptions and compatibility conditions, and the solution exhibits boundary layers along $x = 0, x = 1$ in [20].

\begin{equation}
\begin{aligned}
&|\nu(x,t) - \psi_b(x,t)| \leq C\epsilon, \quad (x,t) \in \overline{D}, \\
&|\nu(x,t)| \leq C, \quad (x,t) \in \overline{\Omega},
\end{aligned}
\end{equation}

where $C$ is the positive real constant. For the proof of equation (4), see Govindarao and Mohapatra [21].

Lemma 1. The solution of the equation (1) satisfies the following estimate:

Lemma 2. Continuous maximum principle: we assume that $\theta(x,t)$ is any sufficiently smooth function satisfying $\theta(x,t) \geq 0, \quad \forall (x,t) \in \partial D$. Then, $L^t\theta(x,t) \geq 0, \forall (x,t) \in \overline{D}$ implies that $\theta(x,t) \geq 0, \forall (x,t) \in \overline{D}$, where $L^t\theta(x,t) = \theta_t(x,t) - \epsilon \theta_{xx}(x,t) + p(x,t)\theta(x,t)$.

Proof. We assume $(x^*, t^*) \in \overline{D} - \partial D$ such that $\theta(x^*, t^*) = \min \{\theta(x,t) : (x,t) \in \overline{D}\}$ and suppose $\theta(x^*, t^*) < 0$. This gives that $\theta_t(x^*, t^*) = 0, \int_{(x,t) \in \overline{D}}$, and this implies

\begin{equation}
L^t\theta(x^*, t^*) = \theta_t(x^*, t^*) - \epsilon \theta_{xx}(x^*, t^*) + p(x^*, t^*)\theta(x^*, t^*) \leq 0.
\end{equation}

We have $L^t\theta(x,t) \leq 0$ which contradicts our assumption.

Thus, $\theta(x^*, t^*) \geq 0$ which leads to $\theta(x,t) \geq 0, \forall (x,t) \in \overline{D}$.

Lemma 3. Stability estimate: let $\nu(x,t)$ be the solution of the continuous problem for equation (1), and we have

\begin{equation}
\|\nu(x,t)\| \leq \alpha - \|L^t u\| + \|u\|_{\Omega_l},
\end{equation}

where $L^t u = u_t - \epsilon u_{xx} + p(x,t) u(x,t)$.
Let the two barrier function $\pi^\pm$ be defined as 
\[\pi^\pm = \alpha^{-1}\|L^\pm u\| + \|u\|_{\Omega} \pm u(x,t), \quad (x,t) \in \bar{\Omega},\]
we have
\[
\pi^+(0,t) = \alpha^{-1}\|L^+ u\| + \|u\|_{\Omega} \pm u(0,t) \geq \|u\|_{\Omega} \pm u(0,t) \geq 0,
\]
\[
\pi^+(1,t) = \alpha^{-1}\|L^+ u\| + \|u\|_{\Omega} \pm u(1,t) \geq \|u\|_{\Omega} \pm u(1,t) \geq 0.
\]

Also, for $(x,t) \in \Omega_b$,
\[
\pi^+(x,t) = \alpha^{-1}\|L^+ u\| + \|u\|_{\Omega} \pm u(x,t) \geq \|u\|_{\Omega} \pm u(x,t) \geq 0.
\]

Furthermore, $\forall (x,t) \in D$
\[
L^\pm \pi^\pm(x,t) = \alpha^{-1}\|L^\pm u\| + \|u\|_{\Omega} \pm L^\pm u(x,t)
\geq \|L^\pm u\| + \alpha\|u\|_{\Omega} \pm L^\pm u(x,t)
\geq \|L^\pm u\| \pm L^\pm u(x,t) \geq 0.
\]

Therefore, using Lemma 2, we obtained the desired outcome. \qed

3. Derivation of the Numerical Method

In this section, we develop a nonstandard finite difference method over Crank–Nicolson scheme to solve equation (1).

3.1. Time Discretization. We first perform a semi-discretization of the problem in time direction by using the average of implicit and explicit Euler method with uniform time-steps $k = (T/n)$ in the time-interval $[0,T]$. This results a time-mesh $D^k_j = t_j = jk, \ j = 0, 1, 2, \ldots, n$, and the method results in a system of boundary value problems.

\[
\begin{align*}
\frac{u^{i+1}(x) - u^i(x)}{k} &= -\frac{e}{2} \left[ u^{j+1}_{xx}(x) + u^i_{xx}(x) \right] + \frac{1}{2} \left[ p^{i+1}(x) u^{i+1}(x) + p^i(x) u^i(x) \right] \\
&= -\frac{1}{2} \left[ q^{i+1}(x) \psi_b(x, t^{i+1}) - 1 \right] + q^i(x) \psi_b(x, t^i - 1) + \frac{1}{2} \left[ g^{i+1}(x) + g^i(x) \right],
\end{align*}
\]

for $0 < x < 1$ and $0 \leq j \leq \frac{n}{b}$,

\[
\begin{align*}
\frac{u^{i+1}(x) - u^i(x)}{k} &= -\frac{e}{2} \left[ u^{j+1}_{xx}(x) + u^i_{xx}(x) \right] + \frac{1}{2} \left[ p^{i+1}(x) u^{i+1}(x) + p^i(x) u^i(x) \right] \\
&= -\frac{1}{2} \left[ q^{i+1}(x) u^{j+1-(n/b)}(x) + q^i(x) u^{i-(n/b)}(x) \right] + \frac{1}{2} \left[ g^{i+1}(x) + g^i(x) \right],
\end{align*}
\]

for $0 < x < 1$ and $\frac{n}{b} < j \leq n$. 

where \( u(x, t^{j+1}) = u^{j+1}(x), \) \( p(x, t^{j+1}) = p^{j+1}(x), \) \( q(x, t^{j+1}) = q^{j+1}(x), \) \( g(x, t^{j+1}) = g^{j+1}(x), \) and \( b = (T/t). \)

Rearranging equation (10), we get

\[
\begin{cases}
-\epsilon u^{j+1}_{xx}(x) + \overline{p}^{j+1}(x)u^{j+1}(x) \\
= \epsilon u^{j+1}_{xx}(x) - \overline{p}^{j}(x)u^{j}(x) + \overline{g}^{j+1}(x) + \overline{g}^{j}(x), \\
\text{for } 0 < x < 1 \text{ and } 0 \leq j \leq \frac{n}{b} \\
-\epsilon u^{j+1}_{xx}(x) + \overline{p}^{j+1}(x)u^{j+1}(x) = \epsilon u^{j+1}_{xx}(x) - \overline{p}^{j}(x)u^{j}(x) \\
+ q^{j+1}(x)u^{j+1-nb}(x) + q^{j}(x)u^{j-nb}(x) + g^{j+1}(x) + g^{j}(x), \\
\text{for } 0 < x < 1 \text{ and } \frac{n}{b} < j \leq n,
\end{cases}
\]  

(11)

where \( \overline{p}^{j+1}(x) = p^{j+1}(x) + (2/k), \) \( \overline{p}^{j}(x) = p^{j}(x) - (2/k), \) and \( \overline{g}^{j+1}(x) = g^{j+1}(x) - q^{j+1}(x)\psi_b(x, t^{j+1} - 1). \)

In the operator form, equation (11) can be written as

\[
\begin{cases}
L^* u^{j+1}(x) = g_j(x, t^{j+1}), \quad 0 < x < 1 \text{ and } 0 \leq j \leq \frac{n}{b} \\
L^* u^{j+1}(x) = g_j(x, t^{j+1}), \quad 0 < x < 1 \text{ and } \frac{n}{b} < j \leq n,
\end{cases}
\]

(12)

with initial and boundary condition

\[
\begin{cases}
u(x, 0) = \psi_b(x, 0), \\
u(0, t) = \psi_l(t), u(1, t) = \psi_r(t),
\end{cases}
\]

(13)

where

\[
L^* u^{j+1}(x) = -\epsilon u^{j+1}_{xx}(x) + \overline{p}^{j+1}(x)u^{j+1}(x),
\]

\[
g_j(x, t^{j+1}) = \epsilon u^{j+1}_{xx}(x) - \overline{p}^{j}(x)u^{j}(x) + \overline{g}^{j+1}(x) + \overline{g}^{j}(x),
\]

\[
g_j(x, t^{j+1}) = \epsilon u^{j+1}_{xx}(x) - \overline{p}^{j}(x)u^{j}(x) - q^{j+1}(x)u^{j+1-nb}(x) - q^{j}(x)u^{j-nb}(x) + g^{j+1}(x) + g^{j}(x).
\]

(14)

Since \( \theta^{j+1}(0) \geq 0, \theta^{j+1}(1) \geq 0, \) then \( x^* \notin [0, 1] \) and \( x^* \in D_x. \)

The differential operator \( L^* \theta^{j+1}(x) \) at the point \( x^* \) value becomes

\[
L^* \theta^{j+1}(x^*) = -\epsilon \theta^{j+1}_{xx}(x^*) + \overline{p}^{j+1}(x^*)\theta^{j+1}(x^*),
\]

(16)

which contradicts our assumption.

Therefore, \( \theta^{j+1}(x) \geq 0, \forall x \in \overline{D}_x. \)

The local truncation error of the semidiscretization method of equation (11) is given by \( e^{j+1} = u^{j+1} - \overline{u}^{j+1}, \) where \( \overline{u}^{j+1} \) is the computed solution of the boundary value problem.

**Lemma 5 (Estimation of local error).** Suppose that

\[
\left| \frac{\partial^n}{\partial t^n} u(x, t) \right| \leq C, \quad (x, t) \in \overline{D}, \quad 0 \leq n \leq 2.
\]

The local error estimate in the temporal direction is given by

\[
\|e^{j+1}\|_{\infty} = C_k^k.
\]

(18)

**Proof.** Using Taylor series expansion, we have

\[
u(x, t^{j+1}) = u(x, t^{j+1/2}) + \frac{k}{2} u_t(x, t^{j+1/2}) + \frac{k^2}{8} u_{tt} + O(k^2),
\]

(19)

\[
u(x, t^j) = u(x, t^{j+1/2}) - \frac{k}{2} u_t(x, t^{j+1/2}) + \frac{k^2}{8} u_{tt} + O(k^3).
\]

(20)
Subtracting equations (19) and (20), we have

\[
\left\{ \begin{array}{l}
\frac{u(x, t^{(i)}) - u(x, t^i)}{k} = e^{u(x, t^i)} - p(x, t^i) + O(k^2) \\
\frac{u(x, t^{(i+1)}) - u(x, t^{i+1})}{k} = e^{u(x, t^{i+1})} - p(x, t^{i+1}) + O(k^2) \\
\end{array} \right.
\]

\[+ g(x, t^i) + g(x, t^{i+1}), \quad 0 < x < 1, 0 \leq i < j \leq n. \tag{21}\]

where

\[
u(x, t^i) + u(x, t^{i+1}) + O(k^2), \tag{22}\]

\[
g(x, t^i) + g(x, t^{i+1}) + O(k^2). \tag{23}\]

The solution to the local error is

\[
L \cdot e^{i+1} = O(k^2), \quad e^{i+1}(0) = 0 = e^{i+1}(1). \tag{24}\]

Thus, using the maximum principle, the required result is satisfied.

Lemma 5 at each time step plays significant role to the global error in the temporal discretization which is defined in the following lemma.

**Lemma 6 (Global error estimate).** The global error estimate at \(j^{th}\) time level is given by

\[
\[\|E\|_\infty \leq C_j k^2. \tag{25}\]

Proof. Using Lemma 5, the global error estimate at \((j)^{th}\) time level is given by

\[
\|E\|_\infty = \left\{ \begin{array}{l}
\|e_i^j\|_\infty + \|e_{i+1}^j\|_\infty + \cdots + \|e_{n}^j\|_\infty \\
\leq C(jk)k^2, \quad \text{using Lemma 5} \\
\leq C(jk)k^2, \quad \text{since } jk \leq T \\
= C_4 k^2, \quad \text{where } C_4 \text{ is the positive real constant independent of } e \text{ and } k. \tag{26}\end{array} \right.
\]

**Lemma 7 (Stability estimate for semidiscretization).** Let \(y(x)\) be the solution of the continuous problem for equation (11). Then, we have

\[
\|y(x)\| \geq \alpha^{-1} \|L^* y(x)\| + \|y(x)\|_{\Omega}. \tag{27}\]

Proof. This lemma can be proved using the same approach as Lemma 3.

**3.2. Spatial Discretization with NSFD.** The development of the exact finite difference approach led to the discovery of a nonstandard discrete modeling method. Let \(D^x_m\) be the partition of the spatial domain \([0, 1]\) into \(m\) subintervals such that

\[
x_i = i h, \quad \text{for } i = 0, 1, 2, \ldots, m, \tag{28}\]

where \(h = (1/m)\) is the step length in spatial direction such that \(h > \epsilon\). The resulted boundary value problems (11) are treated using the nonstandard finite difference scheme rules of Mickens in [22] to find the solution as follows:
with initial and boundary conditions

\[
\begin{align*}
\{ u(x_i, 0) &= \varphi_i(x_i, 0), \\
u(0, t^j) &= \varphi_j(t^j), u(1, t^j) &= \psi_j(t^j),
\end{align*}
\]

(29)

where for \( i = 1, 2, \ldots, m - 1 \) and \( j = 1, 2, \ldots, n \).

\[
\phi^2(i, j) = \frac{4}{\rho^2(i, j)} \sinh^2 \left( \frac{\rho(i, j) h}{2} \right), \quad \text{with} \quad \rho(i, j) = \frac{\sqrt{p_i^j}}{\epsilon}
\]

(30)

The scheme (28) results in a tridiagonal system of linear equations

\[
E_i^{j+1} u_{i-1}^{j+1} + F_i^{j+1} u_i^{j+1} + G_i^{j+1} u_{i+1}^{j+1} = H_i^{j+1},
\]

(31)

where

\[
\begin{aligned}
E_i^{j+1} &= \frac{-\epsilon}{\phi^2(i, j + 1)}, \\
F_i^{j+1} &= \frac{2\epsilon}{\phi^2(i, j + 1)} + \frac{p_i^{j+1}}{\epsilon}, \\
G_i^{j+1} &= \frac{-\epsilon}{\phi^2(i, j + 1)} \\
H_i^{j+1} &= \begin{cases}
\epsilon \left[ u_{i-1} - 2u_i + u_{i+1} \right] / \phi^2(i, j) - \frac{\xi^j_i}{\pi_i^j} u_i^{j+1} + \xi_i^{j+1} + \epsilon_j, & \text{for } 0 \leq j \leq n \frac{h}{b}, \\
\epsilon \left[ u_{i-1} - 2u_i + u_{i+1} \right] / \phi^2(i, j) - \frac{\xi^j_i}{\pi_i^j} u_i^{j+1} - q_i^{j+1} u_i - g_i^{j+1} + q_i^j, & \text{for } n \frac{h}{b} < j \leq n.
\end{cases}
\end{aligned}
\]

(32)
Lemma 8 (Discrete maximum principle). Suppose that $L^{mn}$ is the discrete operator of the scheme (31) and $\omega^j_l$ be any mesh function satisfying, $\omega^0_l \geq 0$, $\omega^j_l \geq 0$, $\omega^j_m \geq 0$, $\forall l$, $j$. If $L^{mn}\omega^j_l \geq 0$ in $D_m^n$, then $\omega^j_l \geq 0$ in $D_m^n$.

Proof. Let $\omega^j_l = \min \omega^j_l$, for all $\omega^j_l \in D_m^n$ and $\omega^j_l < 0$. It follows that $\omega^j_{l+1} = \omega^j_l > 0$ and $\omega^{j-1}_l = \omega^j_l > 0$. Thus, $L^{mn}\omega^j_l < 0$, which contradicts our assumptions.

Therefore, $\omega^j_l \geq 0 \in D_m^n$. □

4. Convergence Analysis

We shall omit the time level index for the sake of simplicity. The following is how we get the local truncation error of the present nonstandard finite difference method from equation (28):

$$L^{mn}_c (U_i - u_i) = (L_{xx} - L^{mn}_{xx})u_i,$$

(33)

using nonstandard finite difference method.
Using Taylor series expansion of $u_{i-1}$ and $u_{i+1}$ in (34), we have that
\[
L^{m,n}_ε \left(U_n - u_n \right) = -ε u_n^n + \frac{ε}{2} \left[ \frac{u_{i-1} - 2u_i + u_{i+1}}{h_i^2} \right].
\] (34)

The truncated Taylor series expansion of $(1/\phi_i^n)$ is given by
\[
\frac{1}{\phi_i^n} = \frac{\rho_i^2}{4} \left( \frac{4}{\rho_i^2 h^2} - \frac{1}{3} + \frac{\rho_i^2 h^2}{60} \right).
\] (36)

Using equation (36), equation (34) becomes
\[
L^{m,n}_ε \left(U_n - u_n \right) = -ε u_n^n + \frac{ε}{2} \left[ \frac{u_{i-1} - 2u_i + u_{i+1}}{h_i^2} + \frac{1}{\phi_i^n} \right], \quad \xi_i \in (x_{i-1}, x_{i+1}).
\] (35)
Theorem 2. Let \( u(x, t) \) be the solution of (1) and \( u(x, t) \) be the solution of (11) both at time level \( j \). Then,
\[
\max_{0 \leq i \leq m} |U_i^j - u^j| \leq M h^2.
\]

Therefore, the nonstandard finite difference method is a second order uniformly convergent scheme in space variable.

Theorem 3. Let \( U_i^j \) be the numerical solution of (31) and \( u(x, t) \) be the solution of (1). Then,
\[
\max_{0 \leq i \leq m, 0 \leq j \leq n} |U_i^j - u| \leq M (h^2 + k^2).
\]

Therefore, the nonstandard finite difference method is a second order uniformly convergent scheme in both space and time variables.

5. Richardson Extrapolation Method

The Richardson extrapolation method is intended to increase the accuracy of the basic scheme’s computed solutions. From Theorem 2, we have
\[
|u(x, t^{j+1}) - U_i^{j+1}| \leq M (h^2 + k^2),
\]
where \( u(x, t^{j+1}) \) and \( U_i^{j+1} \) are the exact and approximate solution for \( D_n^m \) mesh interval, respectively, and \( M \) is a constant independent of \( e, k, \) and \( h \).

Let \( D_{2m}^n \) be the mesh found by doubling the mesh interval of \( D_m^n \) and approximate solution using \( D_{2m}^n \) mesh interval is \( U_i^{j+1} \). Equation (41) with mesh size \( h, k \neq 0 \) becomes
\[
u(x, t^{j+1}) - U_i^{j+1} = M (h^2 + k^2) + R_m^n (x_i, t^{j+1}) \in D_m^n, \quad (42)
\]
and equation (41) with mesh size \( (h/2), (k/2) \neq 0 \) becomes
\[
u(x, t^{j+1}) - U_i^{j+1} = M \left( \frac{h^2}{4} + \frac{k^2}{4} \right) + R_{2m}^{2n} (x_i, t^{j+1}) \in D_{2m}^{2n}, \quad (43)
\]
where the remainders \( R_m^n \) and \( R_{2m}^{2n} \) are \( O(h^4 + k^4) \). Subtracting equation (42) from equation (43) and obtained extrapolation formula,
\[
\left( U_i^{j+1} \right)^{\text{ext}} = \frac{4U_i^{j+1} - U_i^{j+1}}{3},
\]
where \( (U_i^{j+1})^{\text{ext}} \) is the approximate solution of \( u(x, t^{j+1}) \) using the Richardson extrapolation method with truncation error.
\[
|u(x, t^{j+1}) - (U_i^{j+1})^{\text{ext}}| \leq M (h^4 + k^4),
\]

Therefore, after the Richardson extrapolation method applied, the proposed method becomes fourth order uniformly convergent scheme in both space and time variables.

6. Numerical Examples and Results

To determine the efficacy of the current scheme, we looked at model problems that had been addressed in the literature and had approximate solutions that could be compared.

We used the double mesh principle to estimate the absolute maximum error of the current approach when the exact solution for the given problem is unknown [23]. We use the following formula to approximate the absolute maximum error at the selected mesh points:

Case 1. If the exact solution is known,
\[
L_{\epsilon}^{m,n} = \max_{(x, t) \in t} |u(x, t) - (u_i)_{\text{ext}}|.
\]
Case 2. If the exact solution is unknown,

\[ E_e^{m,n} = \max_{(i,j)\in\Omega} \left| (u_i^j) - (u_{2i-1}^{2j-1})^\text{ext} \right|. \]  

where \((u_i^j)\) is the approximation solution obtained by using \(m\) and \(n\) number of subintervals of space and time variables, respectively, and \((u_{2i-1}^{2j-1})^\text{ext}\) is the approximation solution obtained by using \(2m\) and \(2n\) number of subintervals of space and time variables, respectively, after applying the Richardson extrapolation method.

We also evaluate the corresponding rate of convergence:

\[ R_e^{m,n} = \frac{\log E_e^{m,n} - \log E_e^{2m,2n}}{\log 2}. \]

Example 1. We consider the following singularly perturbed parabolic delay initial-boundary-value problem:

\[
\begin{aligned}
&u_t(x,t) - \epsilon u_{xx}(x,t) + (1 + x^2) - u(x,t-1) = t^3, \quad (x,t) \in (0,1) \times (0,2], \\
&u(x,t) = 0, \quad (x,t) \in [0,1] \times [-1,0], \\
&u(0,t) = 0 = u(1,t), \\
&u(x,0) = 0 = u(1,0), \\
\end{aligned}
\]

whose exact solution is unknown.

Example 2. We consider the following singularly perturbed parabolic delay initial-boundary-value problem in [24]:

\[
\begin{aligned}
&u_t(x,t) - \epsilon u_{xx}(x,t) + \frac{(1 + x)^2}{2} = -u(x,t-1) + t^3, \quad (x,t) \in (0,1) \times (0,2], \\
&u(x,t) = 0, \quad (x,t) \in [0,1] \times [-1,0], \\
&u(0,t) = 0 = u(1,t), \\
&u(x,0) = 0 = u(1,0), \\
\end{aligned}
\]

whose exact solution is unknown.

### 7. Discussion and Conclusion

We proposed a nonstandard finite difference method for solving singularly perturbed parabolic delay partial differential equations of the reaction-diffusion type. The considered problems’ solution exhibits twin boundary layers on the right and left sides of the spatial domain. The basic mathematical procedures are defining the model problem, approximating the time variable using the Crank–Nicolson method, approximating the spatial variable using nonstandard finite difference scheme using Mickens rule, and reducing it into a tridiagonal systems of equation; this can be solved by using the Thomas algorithm. Lastly, to enhance the accuracy of the method, we use the Richardson extrapolation technique.

To validate the applicability of the proposed method, we used two model examples. The maximum absolute error and rate of convergence are shown in Tables 1 and 2 with different values of \(\epsilon, m,\) and \(n\). Comparison of maximum absolute error and rate of convergence with other methods that appear in the literature are shown in Tables 3 and 4. The behavior of maximum absolute error is shown in Figure 1. The physical behavior of the solution is shown in Figures 2 and 3.

The convergence of proposed scheme is insensitive to the perturbation parameter. After applying the Richardson extrapolation technique, the present method has order of four rate of convergence. The performance of the proposed scheme is assessed by comparing the results, and it is demonstrated that the numerical results are more accurate than that of existing difference schemes in the literature.

As future directions of this research, we will apply the scheme for nonlinear singularly perturbed parabolic reaction and convection diffusion problems.
