Nanotechnology has vast applications in almost all fields of science and technology. The use of medicinal plants for the synthesis of metallic nanoparticles has gained much attention nowadays. In the current research work, six medicinal plants were used for the synthesis of gold nanoparticles (AuNPs) and iron nanoparticles (FeNPs). The synthesized nanoparticles were characterized by different techniques including UV-visible spectrophotometry, scanning electron microscopy (SEM), and Fourier transform infrared spectroscopy (FTIR). Furthermore, the activities of green synthesized nanoparticles were screened *in vitro* using, for example, antibacterial, antioxidant, cytotoxic, and DNA protection assays. Both FeNPs and AuNPs had spherical shapes with an average size less than 50 nm and were found to have good antimicrobial and nontoxic effects. Furthermore, FeNPs from *Ficus microcarpa* demonstrated high drug loading efficiency (65%) as compared to an anti-inflammatory drug (diclofenac potassium, DFP). We also evaluated the drug delivery potential, as well as anti-inflammatory and anticoagulant properties, of nanoparticles *in vivo*. Interestingly, AuNPs of *Syzygium cumini* exhibited strong anti-inflammatory potential as compared to DFP and diclofenac-loaded FeNPs of *Ficus microcarpa*. The results suggest potential pharmacological applications of biogenic synthesized AuNPs and FeNPs which can be explored further. The study revealed that the green synthesized AuNPs and FeNPs provide a promising approach for the synthesis of drug-loaded nanoparticles and consequently in the field of targeted drug delivery.

1. Introduction

Nanotechnology has gained much popularity nowadays in almost all fields of science and technology, because of its vast applications in medicine, chemistry, electronics, and engineering [1, 2]. Various chemical, physical, and biological approaches are now being used for the synthesis of metallic

nanoparticles [3, 4]. Chemical methods involve the use of toxic chemicals that not only pose a risk to the environment and human health but also have the problems of low stability and aggregation of particles [5]. Hence, the plant-based biological approach is considered ideal over other microbes-mediated biological methods due to low cost, high reproducibility, eco-friendliness, less reaction time, and

elimination of cell culture step [6–9]. Plant extracts contain many different kinds of phytochemicals that serve as strong reducing and stabilizing agents, which drive the synthesis of nanoparticles [10–12]. Therefore, the size, shape, and other properties of synthesized nanoparticles may vary depending on the nature and source of the plant being used [13]. Plant extract-based synthetic approach is widely reported in the literature [14, 15], but there is still a lot to be explored regarding the reduction potential of various phytochemicals because of the diversity and high potential of plants in producing nanoparticles of different sizes and shapes [16].

Phyllanthus emblica, *Syzygium cumini*, *Mentha piperita*, *Rosa indica*, *Mallotus philippensis*, and *Ficus microcarpa* are important medicinal plants of Pakistan. These plant extracts have been reported for significant pharmacologically effects, including anti-inflammatory, antitumor, hepatoprotective, antidiabetic, antioxidant, and antimicrobial activities [17–20]. Many studies have indicated that phytochemicals such as polyphenols, hydrolyzable tannins, flavonoids, alkaloids, terpenoids, and proteins present in these plant extracts are the major bioactive compounds responsible for their different biological activities [21, 22]. Phytochemicals are capable of reducing metal ions to nanoparticles but also help in their stabilization [23, 24].

In the present study six medicinal plants, *Phyllanthus emblica*, *Syzygium cumini*, *Mentha piperita*, *Rosa indica*, *Mallotus philippensis*, and *Ficus microcarpa*, were used to synthesize gold (AuNPs) and iron (FeNPs) nanoparticles of different morphology and biological activities. Nanoparticles were characterized by UV-visible spectrophotometry, scanning electron microscopy (SEM), and Fourier transform infrared spectroscopy (FTIR). Biological activities of AuNPs and FeNPs were evaluated *in vitro* by antibacterial assay, DPPH free radical scavenging assay. Nontoxic effects of nanoparticles were assessed by brine shrimp cytotoxicity assay and inhibition of hydroxyl free radical-induced DNA damage assay. To minimize the side effects, like gastric irritation due to high dose administration of nonsteroidal anti-inflammatory drugs like diclofenac potassium (DFP), we also developed a method to load DFP on green synthesized AuNPs and FeNPs coupled with folic acid for targeted diclofenac delivery. The efficacy of drug-loaded nanoparticles was assessed *in vivo* using the mouse model.

2. Material and Methods

2.1. Preparation of Gold and Iron Nanoparticles. A volume of 500 μL , 1 mL, 2 mL, and 4 mL of the aqueous leaf extract (2 g/100 mL) was carefully added to 25 mL of 1 mM aqueous chloroauric acid (HAuCl_4) and ferrous sulfate heptahydrate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$) (Sigma Aldrich Chemical Co., St. Louis, Mo, USA) solution. The flasks containing the mixture of extract and corresponding salts were incubated at 50°C for 24 h in the dark.

2.2. Characterization of Nanoparticles. All synthesized nanoparticles were characterized by the following techniques.

2.3. UV-Visible Spectroscopy Analysis. UV-visible spectrum of gold and iron nanoparticles was monitored by UV-visible spectroscopy (Agilent UV-visible spectrophotometer). Respective plant extract and salt solutions were used as controls. The measurement was carried out at wavelength ranges of 400–800 nm and 200–400 nm for characterization of gold and iron nanoparticles, respectively.

2.4. Scanning Electron Microscopy (SEM). The shape and size of nanoparticles were evaluated by SEM using an analytical scanning electron microscope (JSN, 6490A, Tokyo, Japan). Thin films of the nanoparticles were prepared on a carbon-coated copper grid by simply dropping a very small amount of the sample on the grid, and excess solution was removed by blotting paper.

2.5. Fourier Transform Infrared Spectroscopy (FTIR). FTIR spectra of gold and iron nanoparticles were recorded in KBr pellets using a PerkinElmer spectrophotometer (Thermo Scientific, USA). The wavenumber range was selected in the range of middle infrared of 4000–400 cm^{-1} . The peaks obtained were plotted as wavenumber (cm^{-1}) in X-axis and as percentage transmittance in Y-axis.

2.6. Temperature Dependent Stability of Nanoparticles. The biosynthesized nanoparticles were stored at 4°C and analyzed through UV-visible spectrophotometer for eight months for stability.

2.7. Antibacterial Assay. The antibacterial activity of green synthesized nanoparticles was evaluated by the disc diffusion method as described previously [25]. Seven bacterial strains, i.e., *Bacillus subtilis* (*B. subtilis*), *Salmonella typhi* (*S. typhi*), *Enterobacter aerogenes* (*E. aerogenes*), *Pseudomonas septic* (*P. septic*), *Staphylococcus aureus* (*S. Aureus*), *Micrococcus luteus* (*M. Luteus*), and *Escherichia coli* (*E. coli*), were used on nutrient agar plates. Sterile filter paper discs impregnated with 5 μL of each nanoparticle solution with 20 $\mu\text{g}/\text{mL}$, 10 $\mu\text{g}/\text{mL}$, 5 $\mu\text{g}/\text{mL}$, and 2.5 $\mu\text{g}/\text{mL}$ final concentration were placed on the seeded plates. Disc infused with Kanamycin (standard antibacterial) served as a positive control. Plates were incubated at 37°C for 24 h. After incubation, the diameter of the zone of inhibition was measured with the help of the vernier caliper. Nanoparticles producing an inhibitory concentration (MIC) were determined by standard threefold broth microdilution method. A stock solution of each active nanoparticle was serially diluted in 96-well plates with Mueller Hinton broth. A standardized inoculum for each bacterial strain was prepared as an inoculum size of 5×10^4 CFU/mL in each well. Then, plates were incubated at 37°C overnight. The MIC was calculated as the lowest concentration of the nanoparticles inhibiting the growth of bacterial strain by measuring OD at 600 nm, and the assay was performed as triplicated analysis.

2.8. DPPH Free Radical Scavenging Assay. The free radical scavenging activity of samples was determined by the reported method with some modifications [26]. Each nanoparticle sample (10 μL) with final concentration of 100 $\mu\text{g}/\text{mL}$, 50 $\mu\text{g}/\text{mL}$, 25 $\mu\text{g}/\text{mL}$, and 12.5 $\mu\text{g}/\text{mL}$ was mixed with 0.1 mM DPPH (190 μL) in 96-well plate. Deionized water and ascorbic acid were used as negative and positive controls, respectively. The reaction was carried out in triplicate, and mixtures were incubated in the dark at 37°C for 30 min. Following incubation, the absorbance of samples was measured at 517 nm using a microplate reader. IC_{50} was calculated by TableCurve software (version 4), and the free radical scavenging potential of the sample was calculated with the help of the following formula:

$$\text{scavenging activity (\%)} = \left(\frac{1 - \text{absorbance of sample}}{\text{absorbance of control}} \right) \times 100. \quad (1)$$

2.9. Brine Shrimp Cytotoxicity Assay. Brine shrimp cytotoxic assay was used to assess the toxicity of nanoparticles [27]. *Artemia salina* (brine shrimp) eggs (Ocean Star Inc., USA) were hatched in seawater (34 g/L). After 24 h, shrimps were transferred to vials, with almost 15 in each vial. The test samples with the final concentrations of 50 $\mu\text{g}/\text{mL}$, 25 $\mu\text{g}/\text{mL}$, and 12.5 $\mu\text{g}/\text{mL}$ were added, and the final volume was made up to 5 mL. The whole procedure was carried out in triplicate. The vials were kept under light at 25–28°C for 24 h of incubation. After 24 h, surviving brine shrimps were counted by 3x magnifying glass. Percentage viability was calculated using the following formula:

$$\text{percentage viability} = \left(\frac{\text{control} - \text{test}}{\text{control}} \right) \times 100. \quad (2)$$

2.10. Inhibition of Hydroxyl Free Radical-Induced DNA Damage Assay. DNA protection ability of nanoparticles against hydroxyl free radical-induced DNA damage was determined *in vitro* using a DNA protection assay [27]. The reaction was performed in PCR tubes with 16 μL of the total volume having 4 μL of pBR322 DNA (0.5 μg), 3 μL of 2 mM FeSO_4 , 4 μL of 30% H_2O_2 , and 5 μL of nanoparticles with 1000, 100, and 10 $\mu\text{g}/\text{mL}$ final concentrations. DNA of pBR322 treated with 2 mM FeSO_4 and 30% H_2O_2 was used as positive control while untreated pBR322 DNA served as negative control (P). To check the effects of samples on DNA, prooxidant control containing the sample and untreated pBR322 was used. The mixtures were then incubated at 37°C for 1 h. Reaction mixtures were run on 0.8% agarose gel electrophoresis in 1x TBE buffer using 1 Kb ladder (L). The gel was visualized by using gel documentation system (Bio-Rad Laboratories, California, USA).

2.11. Preparation of Drug-Loaded Nanoparticles. DFP was loaded on green synthesized AuNPs and FeNPs of *Syzygium cumini* and *Ficus microcarpa* according to the reported method [28]. A stock solution of DFP (10 mg/mL) was prepared, in addition to further serial dilutions, i.e., 4 mg/mL, 2 mg/mL, and 1 mg/mL. The concentration of drug to be used for loading was optimized by carrying out reactions of drug loading at the above concentrations. 2 mL of optimized concentration (e.g., 2 mL of 2 mg/mL drug) of the drug was added to 6 mL of AuNPs and FeNPs (1 mg/mL), and the mixture was allowed to stir for 24 h and then centrifuged at 14,000 rpm for 30 min. Drug-loaded nanoparticles were washed twice with deionized water. The pellet (that contains drug-loaded nanoparticles) was again dispersed in deionized water for characterization. Drug loading was evaluated by measuring the absorbance of supernatant and standard drug solution at 276 nm. The efficiency of drug adsorption was calculated using the following formula:

$$\% \text{ loading efficiency} = \left(\frac{\text{drug added during preparation} - \text{drug in the supernatant}}{\text{amount of drug added during preparation}} \right) \times 100. \quad (3)$$

2.12. Preparation of Diclofenac-Loaded Folic Acid Attached Nanoparticles. 150 mg of 1-ethyl-3-(3-dimethyl amino-propyl)carbodiimide (EDC) was dissolved in 2.5 mL of 0.1 M NaOH, and 150 mg of folic acid (FA) was added to the mixture and then activated for 3 h. Casein (500 mg) dissolved in 10 mL of 0.1 M NaOH was added to it and stirred for 24 h. It was then dialyzed against water to obtain casein-folic acid conjugate and to remove unreacted EDC and folic acid from that conjugate. 1 mL of the conjugate was added to drug-loaded nanoparticles (5 mg/mL) and stirred for 12 h, followed by centrifugation to synthesize drug-loaded folic acid attached nanoparticles. The free drug in the supernatant was determined by measuring its absorbance at 276 nm.

2.13. Anti-Inflammatory Assay. The anti-inflammatory potential of nanoparticles was assessed by the carrageenan-induced mouse paw edema test as reported previously [29]. Rats were divided according to weight and marked with a specific number. Drug dose was given according to the weight of the rat. All samples were dissolved in DMSO at a concentration of 1 mg/mL, DFP was used as the positive control, and DMSO was used as the negative control. Weighed rats were divided into groups ($n = 7$). Animals were fed orally by feeding tubes 60 min before carrageenan injection. 100 μL of freshly prepared carrageenan was injected into sub-planar tissues of the left hind paw of each rat. Plethysmometer (Ugo Basile 7140) calculated the paw volume instantly before and after the carrageenan injection at 0,

1, and 3 h intervals. Three readings were recorded at each time interval. The increase in paw volume for subsequent time intervals was calculated by the following formula:

$$\text{percentage inhibition} = \left[\left(\frac{A - B}{A} \right) \times 100 \right], \quad (4)$$

where A is edema of control rats and B is edema of treated rats.

2.14. Anticoagulant Assay. Nanoparticles were screened for their anticoagulant activity by the rat capillary method used previously to determine the time delay in clot formation after the treatment [30]. After 1 h of dosage, the rat-tail was pierced with the help of a lancet, and the tail blood was filled in capillary tubes and placed in a water bath at 37°C. After 60 s, the small parts of the capillary tube were fragmented each 10 s until the thread of fibrin is visualized between the pierced ends of the tube. Aspirin was used as the positive control, and saline in 10% DMSO served as the negative control. Clot formation time was measured in seconds, and the ratios were calculated using International Normalized Ratios [31]. The INR values were calculated by the following formula:

$$\text{INR} = \left(\frac{\text{PT sample}}{\text{PT control}} \right)^{\text{ISI}}. \quad (5)$$

In this equation, PT represents the prothrombin time (clotting time) and ISI represents the international sensitivity index as per WHO guidelines.

2.15. Statistical Analysis. The data were analyzed statistically by one-way analysis of variance (ANOVA) followed by Tukey's test using GraphPad Prism 8.0 software. Results are expressed as mean \pm SD, and $p < 0.05$ is considered significant.

3. Results and Discussion

3.1. Biosynthesis and Characterization of Gold and Iron Nanoparticles. In this study, gold and iron nanoparticles were synthesized from six different medicinal plants, i.e., *Phyllanthus emblica*, *Syzygium cumini*, *Mentha piperita*, *Rosa indica*, *Mallotus philippensis*, and *Ficus macrocarpa*, to check the comparative potential and efficacy of these strong antioxidant plants in the synthesis of nanoparticles. We already evaluated the comparative antioxidant activities of the plants [32]. In the current study, different concentrations of each plant extract were mixed with the solution of HAuClO₄ and FeSO₄·7H₂O, incubated for 12–24 h. Change in color of solution, purple/violet and black/brown, indicated the synthesis of gold and iron nanoparticles, respectively (Figures 1(a) and 1(b)). UV-visible spectrophotometric analysis revealed characteristic peaks of gold nanoparticles at 541 nm and iron nanoparticles at 215 nm (Figure 1(c)). Metal salts and extracts (used as controls) did not show peak at characteristic nanoparticle wavelength. Sharp

characteristic peaks of nanoparticles were observed at the optimal concentration of each extract. Stability studies of nanoparticles showed that most of the green synthesized gold and iron nanoparticles were found to be stable for eight months (Figure 1(d)). Only *Phyllanthus emblica* and *Syzygium cumini* gold nanoparticles showed a redshift indicating poor stability, while in the case of iron nanoparticles there was some change in the peak wavelength of *Mallotus philippensis* and *Ficus microcarpa*. Any redshift in surface plasmon resonance band may be due to an increase in either nanoparticle size, particle aggregation, or both. Moreover, the poor stability of these particles may be due to an increase in particle size and aggregation over time [33, 34]. SEM analysis of green synthesized gold and iron nanoparticles revealed the uniform texture, small size (less than 50 nm), and spherical shape of nanoparticles (Figure 2(a)). The AuNPs of *Mallotus philippensis* and FeNPs of *Rosa indica* exhibited the smallest size (i.e., 29 nm and 28 nm, respectively). This is because of the different reduction capacities of each plant extract. The volume of extract used for nanoparticle synthesis also affects nanoparticle size [24, 33, 35]. SEM images also revealed that AuNPs have less agglomeration than FeNPs. This might be due to the magnetic behavior of iron nanoparticles and their larger surface area to volume ratio, as they tend to aggregate to reduce surface energy. These particles can be coated with a biocompatible polymer to remove agglomeration [36, 37]. The major plant biomolecules responsible for the reduction, stabilization, and capping of AuNPs and FeNPs were further verified by FTIR spectroscopy. The disappearance of characteristic functional group peak of plant extract in spectra of nanoparticles (both gold and iron) showed that these functional groups are involved in the synthesis of nanoparticles [38, 39]. Any shift in the peak of functional groups shows their involvement in the capping of nanoparticles. Considering this, FTIR spectra of all green synthesized nanoparticles were interpreted as shown in Table 1. Results showed the involvement of phytochemicals of plant extracts such as phenolics, alkaloids, flavonoids, and proteins in the synthesis and stability of nanoparticles. Some representative FTIR spectra are shown in Figure 2(b).

3.2. Antibacterial Activity. Antibacterial activity of green synthesized AuNPs and FeNPs was assessed by using disc diffusion assay. Plant extracts and metal salts used for metallic nanoparticles synthesis were used as controls. Initial screening was done at 20 $\mu\text{g}/\text{mL}$. To calculate minimum inhibitory concentration (MIC), 10 $\mu\text{g}/\text{mL}$, 5 $\mu\text{g}/\text{mL}$, and 2.5 $\mu\text{g}/\text{mL}$ concentrations of nanoparticles were used. Our results showed that most of the AuNPs and FeNPs exhibited strong antibacterial activity against two Gram-positive strains (*S. aureus* and *M. luteus*) and one gram -ve strain (*E. aerogenes*) with very low MIC value, i.e., 2.5 $\mu\text{g}/\text{mL}$ (Figure 3(a)). At high concentrations, gold nanoparticles of *Ficus microcarpa* and *Phyllanthus emblica* significantly inhibited the growth of *E. coli* (gram -ve strain). Previous

reports showed that AuNPs and FeNPs have more bactericidal effects for gram -ve bacteria than for gram +ve ones due to the thick peptidoglycan cell wall [40, 41]. In the current study, green synthesized nanoparticles showed more or less the same antibacterial effect against both strains. The effect might be due to their small size, which enabled them to penetrate into the thicker wall of gram +ve bacteria, as well. Literature shows that gold nanoparticles may kill bacteria either by changing the membrane permeability, decreasing ATP levels by inhibition of ATP synthase, or inhibiting the binding of tRNA ribosomal subunit [42, 43]. On the other hand, iron nanoparticles might exhibit bactericidal effects by inducing reactive oxygen species that may cause damage in the protein and DNA of the bacteria through oxidative stress [44, 45].

3.3. DPPH Free Radical Scavenging Activity. Free radical scavenging potential of nanoparticles was evaluated by DPPH assay at concentrations of 100 $\mu\text{g}/\text{mL}$, 50 $\mu\text{g}/\text{mL}$, 25 $\mu\text{g}/\text{mL}$, and 12.5 $\mu\text{g}/\text{mL}$. Among plant extracts and metal salts, *Phyllanthus emblica* extract and iron salt showed significant free radical scavenging potential having IC_{50}

values of 10.6 $\mu\text{g}/\text{mL}$ and 18.9 $\mu\text{g}/\text{mL}$, respectively. Gold nanoparticles synthesized in this study have not shown free radical scavenging potential except *Phyllanthus emblica* and *Syzygium cumini* gold nanoparticles, which showed antioxidant potential at a higher concentration of 200 $\mu\text{g}/\text{mL}$ (Figure 3(b)). This is contrary to most of the reported studies, which showed the good antioxidant potential of gold nanoparticles [42, 46]. This may be because of some structural differences in these gold nanoparticles [40]. It is quite interesting to note that, among the six iron nanoparticles, *Phyllanthus emblica* and *Syzygium cumini* iron nanoparticles possess good free radical scavenging power with IC_{50} values $\leq 100 \mu\text{g}/\text{mL}$. This may be due to the very low IC_{50} values of these extracts as compared to other extracts. The antioxidant property of iron nanoparticles could be due to capping antioxidants (from extract) as well as due to ferrous salt being a good antioxidant.

3.4. Cytotoxic Activity. To evaluate nontoxic behavior, the investigated nanoparticles were subjected to brine shrimp cytotoxic assay. The results indicated a nontoxic effect of gold and iron nanoparticles with 100% viability

Data represent the mean of triplicate with statistical significance a: $p < 0.001$, b: $p < 0.01$.

(Figure 3(c)). The results are consistent with the reported findings that metal oxide nanoparticles (such as iron oxide particles) form agglomerates of size up to 400 nm that cannot be ingested by *Artemia salina* larvae, and thus these particles accumulate in the gut but do not cause mortality for exposure of 24 h [47, 48].

3.5. Inhibition of Hydroxyl (OH) Free Radical-Induced DNA Damage Assay. The prooxidant or antioxidant potential of nanoparticles was assessed through an OH free radical scavenging assay. When OH radicals attack DNA, the supercoiled form of DNA changes into an open circular form if there is a single-strand break. On the other hand, in the case of a double-strand break, a linear form is produced moving between the above two forms [49]. Our

results showed that all gold nanoparticles were good oxidants, but when these particles were mixed with H₂O₂ and FeSO₄, complete DNA damage was seen, demonstrating the neutral behavior of gold nanoparticles (Figure 3(d)A). Iron nanoparticles in prooxidant control showed light damage to DNA giving both open circular and supercoiled bands (i.e., single-strand break) (Figure 3(d)B). When these iron nanoparticles were mixed with H₂O₂ and FeSO₄, they completely damaged DNA at all concentrations. This may be due to the release of iron from nanoparticles that have the potential to cause the conversion of H₂O₂ and superoxide anions to OH radicals. Furthermore, free iron ions can cause OH-induced modifications of purine and pyrimidine and could give the surplus amount of iron, thus causing the production of highly reactive hydroxyl radicals by the Fenton

FIGURE 4: UV-visible spectra of diclofenac potassium and drug-loaded nanoparticles of (a) diclofenac potassium (DFP), (b) *Syzygium cumini* AuNPs, (c) *Ficus microcarpa* AuNPs, (d) *Syzygium cumini* FeNPs, (e) *Ficus microcarpa* FeNPs.

reaction [50]. We observed that the extracts of *Phyllanthus emblica* (at conc. of 1000 $\mu\text{g}/\text{mL}$ and 100 $\mu\text{g}/\text{mL}$), *Rosa indica*, *Syzygium cumini*, *Mallotus philippensis*, and *Ficus microcarpa* (only at conc. of 1000 $\mu\text{g}/\text{mL}$), used a control, showed slight protection.

3.6. Analysis of Drug-Loaded Nanoparticles. Due to small size and good *in vitro* activities, AuNPs and FeNPs of *Syzygium cumini* and *Ficus microcarpa* were selected for drug loading. The highest percentage of drug loading was seen in *Ficus microcarpa* FeNPs, i.e., 65%. After drug loading, supernatant (containing free drug) and pellet (containing drug-loaded nanoparticles) were compared with standard drug. UV-visible peak analysis indicated good folic acid attachment only in the case of FeNPs (Figure 4). The redshift (from 238 nm to 275 nm) was seen only in the case of iron nanoparticles when they interacted with casein-folic acid conjugate. This may be because ligand attachment, as well as drug loading, depends on nanoparticle

surface properties, such as structure and charge [51]. FTIR spectrum of drug-loaded nanoparticles was compared with DFP (Figure 5(e)). *Ficus microcarpa* diclofenac-loaded iron nanoparticles (with 65% loading) showed two characteristic peaks of diclofenac potassium at 3285.54 cm^{-1} and 2920.81 cm^{-1} (Figure 5(d)). These peaks show the drug binding with phenols, alcohol, and carboxylic acids groups capped on the surface of nanoparticles. *Ficus microcarpa* gold nanoparticles and *Syzygium cumini* gold nanoparticles showed characteristic peaks of diclofenac at 2919.5 cm^{-1} and 2921.3 cm^{-1} (Figures 5(a) and 5(b)). *Syzygium cumini* iron nanoparticles showed no diclofenac peaks at all (Figure 5(c)). This may be due to the lowest diclofenac loading efficiency of *Syzygium cumini* iron nanoparticles, i.e., 27%.

3.7. Anti-Inflammatory Activity. *In vivo* anti-inflammatory potential of AuNPs and FeNPs was assessed by carrageenan-induced rat hind paw edema test. Results showed that

FIGURE 5: FTIR spectra of (a) *Syzygium cumini* diclofenac potassium loaded gold nanoparticles (AuNPs), (b) *Ficus microcarpa* diclofenac potassium loaded AuNPs, (c) *Syzygium cumini* diclofenac potassium loaded iron nanoparticles (FeNPs), (d) *Ficus microcarpa* diclofenac potassium loaded FeNPs, (e) diclofenac potassium (DFP).

Syzygium cumini gold nanoparticles exhibited strong anti-inflammatory activity as compared to control (Figure 6). These particles might show anti-inflammatory effects by inducing the level of proinflammatory cytokines, i.e., TNF- α , which is the reported anti-inflammatory mechanism for gold nanoparticles [52]. This strong anti-inflammatory activity may be due to some capping agents of *Syzygium cumini* extract. *Ficus microcarpa* gold nanoparticles did not exhibit significant inhibition to edema. This might be because the generation of proinflammatory cytokines depends on the material and size of nanoparticles [53]. Iron nanoparticles exhibited less anti-inflammatory activity as compared to gold nanoparticles. Results of FeNPs are consistent with the previous studies; these particles are known to induce inflammation via oxidative stress [54]. The exact mechanism is

not known but it may be because inflammatory response also depends on nanoparticle composition [55].

Diclofenac-loaded *Ficus microcarpa* gold nanoparticles have not shown any anti-inflammatory activity. Diclofenac-loaded *Syzygium cumini* gold nanoparticles exhibited less activity than *Syzygium cumini* gold nanoparticles (without any drug), which shows that either drug was not loaded properly or folic acid attachment to drug-loaded particles might cause such drastic change to nanoparticle surface that it could not reduce edema to such an extent. The same case was observed for drug-loaded *Syzygium cumini* iron nanoparticles. *Ficus microcarpa* drug-loaded iron nanoparticles showed higher edema inhibition than DFP and *Ficus microcarpa* FeNPs (without any drug). These results correlate with the highest loading efficiency of *Ficus microcarpa* drug-loaded iron nanoparticles, i.e., 65%. This

FIGURE 6: Percentage edema inhibition of different nanoparticles by carrageenan-induced rat paw edema test (S. cumini AuNPs: Syzygium cumini gold nanoparticles, S. cumini FeNPs: Syzygium cumini iron nanoparticles, F. microcarpa AuNPs: Ficus microcarpa gold nanoparticles, F. microcarpa FeNPs: Ficus microcarpa iron nanoparticles). Data represent the mean with statistical significance a: $p < 0.001$, b: $p < 0.01$, c: $p < 0.05$, ns: nonsignificance.

shows that diclofenac-loaded folic-acid-coupled iron nanoparticles can be used for drug delivery systems as they enhanced the effect of the drug possibly by lowering the side effects and increasing the specificity of the drug towards the target cell. The above results indicate the increase of anti-inflammatory activity and decrease in paw swelling over time. The highest anti-inflammatory activity was recorded at 3rd h.

3.8. Anticoagulant Assay. The anticoagulant activity of nanoparticles was checked by the capillary tube method. Table 2 shows that all nanoparticles do not have anticoagulant activity as blood clotting time is decreased in all samples concerning negative control. These results are consistent with the reported findings that nanoparticles can find an escape from the normal defense system, rapidly enter the systemic circulation, and cause platelets aggregation [56]. Nanoparticles effect on platelets aggregation also depends on particle size, shape, and surface (i.e., electrical properties and surface charge). Nonsteroidal anti-inflammatory drug (DFP) is known to inhibit platelet aggregation and increase bleeding time. In the present study, diclofenac-loaded nanoparticles exhibited a better blood coagulation effect as compared to control. This may be due to the attachment of DFP on the surface of the nanoparticles. However, it can be seen that diclofenac-loaded *Ficus microcarpa* iron nanoparticles (with 65% drug loading efficiency) showed increased clotting time as compared to *Ficus microcarpa* iron nanoparticles (without diclofenac).

TABLE 2: Effect of nanoparticles on blood clotting time.

SN	Sample	Clotting time (sec)
1	Negative control	101 ± 1.15 ^b
2	<i>S. cumini</i> AuNPs	35 ± 7.5 ^a
3	<i>S. cumini</i> AuNPs (drug loaded)	30 ± 9.8 ^b
4	<i>F. microcarpa</i> AuNPs	29 ± 3.5 ^b
5	<i>F. microcarpa</i> AuNPs (drug loaded)	29 ± 7.9 ^a
6	<i>S. cumini</i> FeNPs	47 ± 7.5 ^b
7	<i>S. cumini</i> FeNPs (drug loaded)	43 ± 5.5 ^b
8	<i>F. microcarpa</i> FeNPs	17 ± 18.3 ^a
9	<i>F. microcarpa</i> FeNPs (drug loaded)	30 ± 24.4 ^b
10	Positive control	12 ± 1.2

Data represent the mean of triplicate measurements with statistical significance a: $p < 0.001$, b: $p < 0.01$; ± shows standard deviation. *S. cumini* AuNPs: *Syzygium cumini* gold nanoparticles, *S. cumini* FeNPs: *Syzygium cumini* iron nanoparticles, *F. microcarpa* AuNPs: *Ficus microcarpa* gold nanoparticles, *F. microcarpa* FeNPs: *Ficus microcarpa* iron nanoparticles.

4. Conclusion

In conclusion, an eco-friendly, green chemistry-based approach has been devised to synthesize metallic nanoparticles coupled with folic acid for targeted delivery of DFP to inflamed cells. The synthesized gold and iron nanoparticles were stable at refrigerated temperature and showed a small size range (i.e., less than 50 nm). Both gold and iron nanoparticles proved to be good antibacterial agents against gram +ve and gram -ve bacteria. Among all synthesized

nanoparticles, *Phyllanthus emblica* and *Syzygium cumini* synthesized iron nanoparticles served as DPPH free radical scavengers, while gold nanoparticles did not show antioxidant potential. Gold nanoparticles were protective while iron nanoparticles did not show any protection against DNA damage. Among gold and iron nanoparticles, only *Syzygium cumini* synthesized gold nanoparticles showed strong anti-inflammatory potential. The biological activity of synthesized gold and iron nanoparticles was more than their corresponding salts and extracts. As a result, it is possible that these stable and nontoxic metallic nanoparticles can be used for targeted drug delivery and disease therapy.

Data Availability

The data used to support the findings of this study are included within the article.

Ethical Approval

Animals were housed at the Quaid-i-Azam University primate facility. The Institutional Ethics and Biosafety Committee approved the study design, and all safety precautions were taken to minimize animal suffering.

Conflicts of Interest

The authors declare no conflicts of interest.

Acknowledgments

The authors would like to extend their sincere appreciation to Taif University Researchers Supporting Project (no. TURSP-2020/309), Taif University, Taif, Saudi Arabia. The authors are also grateful to the Higher Education Commission of Pakistan for the support of this research work.
