As a generalization of the intuitionistic fuzzy number (IFN), the linguistic interval-valued intuitionistic fuzzy number (LIVIFN) is a flexible and superior tool to describe complex fuzzy uncertainty information. Heronian mean (HM) operator has the characteristic of considering the relationship between attributes. Extended copulas (ECs) and extended cocopulas (ECCs) are the promotion form of Archimedean $t$-norm and $t$-conorm (ATT). ECs and ECCs can generate versatile operational rules and can provide more choice for decision makers (DMs). Therefore, it is very necessary to take advantages of them. In this paper, ECs and ECCs, some specifics of ECs and ECCs, and score and accuracy functions of IVIFNs are gained first. Then, we propose the linguistic interval-valued intuitionistic fuzzy weighted copula Heronian mean (LIVIFWCHM) operator; also, some properties and five specific expressions of the LIVIFWCHM operator are discussed. Moreover, we also propose a new MAGDM approach based on the proposed LIVIFWCHM operator. Finally, a set of examples are used to demonstrate the effectiveness, generality, and flexibility of the proposed method.

1. Introduction

Decision-making problems (DMPs) exist in all aspects of people’s life, ranging from the development of national politics, economy, and culture to the decision-making at the enterprise level. The multiattribute decision-making (MADM) problem is based on the analysis of multiple influencing factors or indicators in the decision-making. It is necessary to judge or evaluate the limited scheme set from multiple attributes, give the corresponding evaluation information or preference information, and then rank the limited alternatives. With the rapid development of society and the increasingly complex social environment, it is difficult for a decision maker to consider all aspects of the problem, so multiattribute group decision-making (MAGDM) came into being. MAGDM combines the characteristics of MADM and group decision-making. It mainly refers to that many members of the group evaluate several fixed attributes of several alternatives, give the order of alternatives, and obtain the best scheme.

In the classic MADM problems, decision makers (DMs) usually use accurate values to evaluate the attributes of alternatives. However, in the practical application process, due to the complexity and fuzziness of the problem, the evaluation values given by DMs are usually not accurate values but in the form of linguistic values, such as “good,” “general,” or “poor.” Therefore, linguistic-based multiattribute decision-making has become the hot research content of MAGDM [1].

Since Zadeh put forward the concept of the linguistic variable in 1975 [2], the combination of the linguistic variable and other theories has been put forward constantly [3–5], such as linguistic hesitant fuzzy set (LHFS) [6, 7], linguistic neutrosophic set [8, 9], linguistic intuitionistic fuzzy set (LIFS) [10], and linguistic Pythagorean fuzzy set [11]. As an important extended linguistic fuzzy set, LIFS has drawn much more attention. Chen et al. [10] first introduced the concept of the LIFS by combining the linguistic term set (LTS) and the IFS in which the membership degree (MD) and nonmembership degree (NMD) are expressed by the
LTS. A LIFS \( A \) on a finite universe of discourse \( Z \) and CLTS \( \mathcal{F} = \{ s_a | s_0 \leq s_a \leq s_t, \alpha \in [0, t] \} \) can be denoted as \( A = \{ (s_a(z), s_0(z)) | z \in Z \} \), where \( s_a(z), s_0(z) \in \mathcal{F} \) with the condition \( \alpha + \beta = t \).

In order to better express fuzziness, Garg and Kumar [12] introduced the linguistic interval-valued IFS (LIVIFS). LIVIFS is a more general form of the LIFS. For example, selecting a suitable house from a certain number of alternatives is a typical decision problem. In this problem, factors affecting the house selection such as the direction of the house, unit price of area, area size, community environment, and credibility of the developer may be described by linguistic variables (LVs) such as “poor,” “medium,” and “good.” Under this condition, IFS and IVIFS are no longer suitable. Furthermore, in the LIVIFS, the MD and NMD are expressed by the interval LVs (ILVs). When the upper and lower bounds of ILVs are equal, the LIVIFS degenerates to the LIFS. Based on the LIVIFS, scholars have proposed some aggregation operators (AOs), such as a prioritised weighted averaging operator by Kumar and Garg [13], a weighted Maclaurin symmetric mean operator (LIVIFWMSM) by Liu and Qin [14], and a weighted aggregation operator (LIVIFAWPMM) by Qin [15].

There are two limitations among these AOs. Firstly, the aforementioned AOs are only obtained by special \( t \)-norms (TNs) and \( t \)-conorms (TCs), i.e., algebraic TN and algebraic TC. Secondly, it is assumed that there is no relationship between attributes. In order to address some of the aforementioned limitations, some improved linguistic interval-valued intuitionistic fuzzy AOs are developed to solve some DMPs. For example, Xu et al. proposed the interval-valued intuitionistic fuzzy (IVIF) weighted power Muirhead mean (IVIFWPPM) operator [16]; a LIVIF-based Archimedean power Muirhead mean operator by Qin [15], which can tackle DMPs more generally and flexibly; entropic combined weighted averaging operator by Xian et al. [17]; LIVIFS-based Maclaurin symmetric mean (MSM) operator by Liu and Qin [14]; interval-valued intuitionistic 2-tuple linguistic setting and Bonferroni mean by Du and Yuan [18]; Pythagorean fuzzy linguistic (dual) Muirhead mean (PFLMM) operators and their weighted form by Liu [19]; Dombi Heronian mean operators by Wu et al. [20]; and Hamy mean operators by Wu et al. [21]. Besides, some DMP approaches have been built [22–32].

For the AOs above, although they can do well in their specific circumstances, only a small part of them can provide desirable generality and flexibility while taking into account the correlation between attributes. In [33], Liu and Chen proposed generalized AOs for the intuitionistic 2-tuple linguistic information with three kinds of additive generator. In [34], Tan and Chen proposed generalized AOs for the Archimedean intuitionistic fuzzy information with five kinds of additive generator.

Among various kinds of TNs and TCs, copulas and cocopulas are classical examples of TNs and TCs. Copula [35] can not only reflect the dependence among variables but also prevent information losing in the aggregation process. Copula is a method to deal with the correlation of random variables in statistics. The basic idea of the copula function is to simplify the problem by transforming the marginal variable into a uniformly distributed variable without looking at many different marginal distributions and then define the correlation as a joint distribution on the uniform distribution. As a tool for describing the dependence mechanism between variables, the copula function contains almost all the dependence information of random variables, especially when it is impossible to determine whether the traditional linear correlation coefficient can correctly measure the correlation between variables.

There are two distinguishing features of copulas: (1) copulas and cocopulas are flexible because DMs can select different types of copulas to define the operations under the fuzzy environment, and the results obtained from these operations are close; (2) copula function is flexible to capture the correlations among attributes in DMPs. Based on the two obvious characteristics, copulas have been applied to some DMPs. For example, Nelsen [35] applied copulas in the aggregation function. Tao et al. [36] extended copulas to the IFS and applied it to DMPs. Basically, there are two types of copula: Archimedean copula and Gaussian copula. In this paper, we only discuss Archimedean copula. In the light of Archimedean copula, Tao et al. [37] studied a new computational model for unbalanced LVs. Chen et al. [38] defined new AOs in the linguistic neutrosophic set based on the copula and applied them to solve DMPs. Xu et al. [39] also proposed fuzzy copula power AOs to solve MAGDM problems based on linguistic interval-valued intuitionistic information; however, the authors did not consider the correlation between attributes.

In order to solve the relationship between attributes, Bonferroni [40] proposed the Bonferroni mean (BM) operator firstly, and then Yager [41] further expanded the BM operator and enhanced its modeling capabilities. By replacing simple average operators (ordered weighted average operators and Choquet operators) with other forms of average operators, Yager proposed some more efficient AOs. However, the BM operator ignores the relationship between each attribute and itself and with the nature of computation redundancy. Heronian mean (HM) operator was first proposed by Beliakov [42]. Heronian mean (HM) operator and BM operator have similar structures, and both consider the correlation between attribute values. However, the HM operator has obvious advantages over the BM operator and can make up for the two shortcomings of the BM operator. On this basis, a series of extension models have been proposed, such as the intuitionistic fuzzy geometric HM (IFGHM) operator [43], IVIF Heronian mean (IVIFHM) operator [44], uncertain linguistic HM operators [45], partitioned HM operators [46], unbalanced linguistic generalized HM operator [32], normal intuitionistic fuzzy HM operator [47], and picture fuzzy Dombi HM operator [48]. However, the HM is not applied to aggregate the linguistic interval-valued intuitionistic fuzzy information (LIVIFI).

Although the existing AOs can provide the most commonly used way to aggregate the LIVIFS, they lack a unique way in practical applications. What is it the form of AOs on the basis of the copula function and LIVIFS? What are the differences between copula-based AOs and existing AOs?
Considering the HM operator has the ability to interrelate among the attributes, what is the form of the weighted HM operator based on the LIVIFS and copula function? So, the goal and motivation of the present work are to synthesize ECs (ECCs), HM operator, and LIVIFS and to develop a MAGDM approach with LIVIFI.

Accordingly, the main intentions and contributions of this work are summarized as follows:

1. We propose a new version of copulas and cocopulas by extending the domain and the range of copulas and cocopulas from \([0,1]\) to \([0,t]\) \((t>0)\), which is called extended copulas (ECs) and extended cocopulas (ECCs)
2. We introduce several universal operational laws of LIVIFS and discuss some special instances
3. We develop the LIVIFWCHM operator, explore several characteristics, and give some particular cases
4. In addition, we propose a novel decision approach for MAGDM with LIVIFI and investigate the efficacy and superiorities of the propounded approach

In order to achieve the above goals, the organizational structure of this paper is as follows. In Section 2, some basic concepts of the LIVIFS, copulas, and cocopulas and some properties of the LIVIFS based on ECs and ECCs are introduced. Furthermore, we redefine several novel operations for LIVIFNs and discuss some special cases. In Section 3, based on these operation rules, we derive the LIVIFWCHM operator as well as explore several properties and particular examples. In Section 4, a new method for MAGDM is proposed based on the LIVIFWCHM operator under LIVIFI. In Section 5, a set of examples are provided to investigate the efficacy and superiorities of the propounded approach. The conclusion is obtained in Section 6.

## 2. Preliminaries

In this section, firstly, some basic concepts related to the LIVIFS, HM operator, and copulas and cocopulas are reviewed, which are the basis of the present work.

**Definition 1** (see [12]). Let \(X\) be a finite universal set and \(S_{[0,2]}\) be a continuous LTS. A LIVIFS \(A\) in \(X\) is defined as

\[
A = \{x, s_{\mu A(x)}, s_{\alpha A(x)}, \mid x \in X, \}
\]

where \(s_{\mu A(x)} = [s_{\mu A(x)}, s_{\alpha A(x)}]\), and \(s_{\alpha A(x)} = [s_{\alpha A(x)}, s_{\mu A(x)}]\) are all subsets of \([s_0, s_1]\) and represent linguistic MD and NMD of \(x\), respectively. For any \(x \in X, s_{\mu A(x)} + s_{\alpha A(x)} \leq s_t\). The pair \((s_{\mu A(x)}, s_{\alpha A(x)})\) is called the LIVIFN.

For convenience, we denote the LIVAIFN as \(\alpha = ([s_a, s_b], [s_c, s_d])\), where \(s_a, s_b, s_c, s_d \in S_{[0,2]}\), and also, \([s_a, s_b] \in [s_0, s_1], [s_c, s_d] \in [s_0, s_1], b + d \leq t\).

**Definition 2** (see [12]). Let \(\alpha = ([s_a, s_b], [s_c, s_d])\) be a LIVAIFN; a score function and accuracy function of \(\alpha\) are defined as

\[
S(\alpha) = s'_{(2t^2a^2c^2b^2d^2)'/4},
\]

\[
H(\alpha) = s'_{(a^2b^2c^2d^2)'/2}.
\]

Then, for any two different LIVAIFNs \(\alpha_1\) and \(\alpha_2\), we have the following:

1. If \(S(\alpha_1) < S(\alpha_2)\), then \(\alpha_1 < \alpha_2\)
2. If \(S(\alpha_1) = S(\alpha_2)\) and \(H(\alpha_1) = H(\alpha_2)\), then \(\alpha_1 < \alpha_2\)

**Definition 3** (see [33]). An extended \(t\)-norm \(\mathcal{T}\) is a mapping from \([0, t] \times [0, t]\) to \([0, t]\) if \(\mathcal{T}\) fulfills the following conditions: for all \(c, d, e \in [0, t]\),

1. \(\mathcal{T}(c, t) = c\)
2. \(\mathcal{T}(c, d) = \mathcal{T}(d, c)\)
3. \(\mathcal{T}(c, \mathcal{T}(d, e)) = \mathcal{T}(\mathcal{T}(c, d), e)\).

If \(T\) just satisfies (T1), then \(T\) is called a semicopula. With the help of extended TNs and extended TCs, we first introduce the concept of extended copulas (ECs) and extended cocopulas (ECCs) in order to handle some DMPs with LIFI.

**Definition 4** (see [35]). A binary function \(C: [0, t] \longrightarrow [0, t]\) is called an EC if \(C\) fulfills the following conditions: for all \(c, d, c', d' \in [0, t]\),

1. \(C(c, d) + C(c', d') \geq C(c, d') + C(c', d)\)
2. \(C(c, 0) = C(0, c) = 0\)
3. \(C(c, t) = C(t, c) = c\)

**Definition 5** (see [35]). Let \(\varphi: [0, 0] \longrightarrow [0, +\infty)\) and \(\psi: [0, +\infty) \longrightarrow [0, t]\). If \(\varphi, \psi\) satisfy the following conditions, for all \((c, d) \in [0, t]^2\),

1. \(\varphi\) is continuous.
2. \(\varphi\) is strictly decreasing.
3. \(\varphi(t) = 0\).
4. \(\psi(c) = \begin{cases} \varphi^{-1}(c), & c \in [0, \varphi(0)], \\ 0, & c \in [\varphi(0), +\infty)\end{cases}\)

\(C(c, d) = \psi(\varphi(c) + \varphi(d))\),

the copula \(C\) is called ECs.

The generator \(\varphi\) of an EC is if a mapping from \([0, t]\) to \(R^+\) and \(\varphi^{-1}\) is the mapping from \(R^+\) to \([0, t]\) with \(\varphi(0) = +\infty\) and \(\varphi(t) = 0\). According to Genest and Mackay [49], \(C\) can be rewritten as

\[
C(c, d) = \varphi^{-1}(\varphi(c) + \varphi(d)).
\]

**Definition 6.** Let \(C\) be an EC, for all \((c, d) \in [0, t]^2\); then, ECCs are expressed as

\[
C^\ast(c, d) = t - C(t - c, t - d).
\]
Theorem 1. For all \( c_1, c_2, d_1, d_2 \in [0, t] \), if \( c_i + d_i \leq t \) \((i = 1, 2)\), then \( 0 \leq C(c_1, c_2) + C^*(d_1, d_2) \leq t \).

Proof. It follows easily from the definitions of EC and ECC that \( 0 \leq C(c_1, c_2) + C^*(d_1, d_2) \). So, we just need to prove

\[
C(c_1, c_2) + C^*(d_1, d_2) = (e^{-1}(c_1) + e(c_2)) + t - e^{-1}(e(t - d_1) + e(t - d_2)).
\]

(7)

As \( e \) is strictly decreasing and \( c_i + d_i \leq t \) \((i = 1, 2)\), it follows that

\[
e^{-1}(e(c_1) + e(c_2)) \geq e(t - d_1) + e(t - d_2).
\]

(8)

Therefore,

\[
\begin{align*}
(L1)_{\alpha_c} & \oplus_{C} \alpha_c = \left( \left[ s_{c}(e^{-1}(e(t-a)) + e(\omega(t-a))) \right] + s_{c}(e^{-1}(e(t-b)) + e(\omega(t-b))) \right)
\end{align*}
\]

(12)

\[
(L2)_{\alpha_c} \oplus_{C} \alpha_c = \left( \left[ s_{\omega_c}(e(t-a)) + e(\omega(t-a))) \right] + s_{\omega_c}(e(t-b)) + e(\omega(t-b)) \right)
\]

(11)

It is easy to verify that \( \Theta_{c} \) and \( \Theta_{c} \) satisfy the associative law, that is, for all three LIVIFNs \( A, B, \) and \( C, \)

\[
(1) (A \Theta_{C} B) \Theta_{C} C = A \Theta_{C} (B \Theta_{C} C),
\]

\[
(2) A \Theta_{C} (B \Theta_{C} C) = A \Theta_{C} B \Theta_{C} C.
\]

Theorem 2. Let \( \alpha = ([s_a, s_b], [s_a, s_d]) \) be a LIVIFN; for \( n \in \mathbb{N}^* \), we have \( n\alpha \) is still a LIVIFN, and

\[
n\alpha = \left( \left[ s_{c}(e^{-1}(n(e(t-a))) + e(\omega(t-a))) \right] + \left[ s_{\omega_{c}}(n(e(t-b))) + e(\omega(t-b)) \right] \right).
\]

(13)

where \( n\alpha = \oplus_{c} \oplus_{c} \oplus_{c} \cdots \oplus_{c} \alpha \).

\[
(k + 1)\alpha = k \oplus_{c} \alpha
\]

(16)

</tr>
</tbody>
</table>

So, equation (13) holds for all $n \in \mathbb{N}^*$. Similarly, the following theorem can be obtained easily. \hfill $\square$

$$
(L3)\alpha = \left[ \sum_{i=1}^{n} \alpha_i \right]^\theta_{\lambda_1}, \lambda_2 > 0, \\
(L4)\alpha^\lambda = \left[ \sum_{i=1}^{n} \alpha_i \right]^\theta_{\lambda_1}, \lambda_2 > 0.
$$

It is easy to verify that the operational laws hold for all three LIVIFNs $\alpha_1, \alpha_2, \alpha_3$ and $\lambda_1, \lambda_2 > 0$:

\begin{align*}
(3) & \lambda_1 \alpha \oplus \lambda_2 \alpha = (\lambda_1 + \lambda_2) \alpha, \\
(4) & \alpha^\lambda_1 \odot \alpha^\lambda_2 = (\alpha_1 \odot \alpha_2)^\lambda, \\
(5) & \alpha^\lambda_1 \odot \alpha^\lambda_2 = \alpha^{1+2\lambda_2}.
\end{align*}

**Theorem 3.** Let $\alpha = ([s_{\lambda_1}, s_{\lambda_2}], [s_{\lambda_3}, s_{\lambda_4}])$ be a LIVIFN; for all $n \in \mathbb{N}^*$, we have $\alpha^n$ is still a LIVIFN, and

$$
(L3)\alpha^n = \left[ \sum_{i=1}^{n} \alpha_i \right]^\theta_{\lambda_1, \lambda_2 > 0}, \\
(L4)\alpha^{\lambda^n} = \left[ \sum_{i=1}^{n} \alpha_i \right]^\theta_{\lambda_1, \lambda_2 > 0}.
$$

3. LIVIF Heronian Mean Operator Based on ECs and ECCs

Under this part, we proposed the LIVIFWCHM operator through the novel operational laws. The particular cases of the proposed operator are explored, and several desired properties are proved in detail.

**Definition 9.** Let $\alpha = ([s_{\lambda_1}, s_{\lambda_2}], [s_{\lambda_3}, s_{\lambda_4}])$ be a collection of LIVIFNs and $p, q > 0$; then, the linguistic interval-valued intuitionistic fuzzy weight copula Heronian mean (LIVIFWCHM) operator is expressed as

$$
\text{LIVIFWCHM}^p_q(\alpha_1, \ldots, \alpha_n) = \left( \sum_{i=1}^{n} \omega_i \alpha_i^p \odot \left( \omega_j \alpha_j^q \right)^{1/p} \right)^{1/(p+q)},
$$

where $\omega_i$ is the weight vector (WV) of $\alpha_i$, $\omega_i \geq 0$, and $\sum_{i=1}^{n} \omega_i = 1$. 

**Theorem 4.** Let $\alpha = ([s_{\lambda_1}, s_{\lambda_2}], [s_{\lambda_3}, s_{\lambda_4}])$ be a collection of LIVIFNs and $p, q > 0$; then, the aggregated result form is still LIVIFNs and has
LIVIFWCHM^{p,q}(a_1,\ldots,a_n) = ([s_i,s_j],[s_i,s_j]).

\[
a = q^{-1} \left( \frac{1}{p+q} \right) t - q^{-1} \left( \frac{2}{p+q} \right) \sum_{j=1}^{m} p \left( t - \left( q^{-1}(\omega_{\rho}(t-a_j)) \right) \right) + qe(t-\left( q^{-1}(\omega_{\rho}(t-a_j)) \right)) \right),
\]

\[
b = q^{-1} \left( \frac{1}{p+q} \right) t - q^{-1} \left( \frac{2}{p+q} \right) \sum_{j=1}^{m} p \left( t - \left( q^{-1}(\omega_{\rho}(t-b_j)) \right) \right) + qe(t-\left( q^{-1}(\omega_{\rho}(t-b_j)) \right)) \right),
\]

\[
c = t - q^{-1} \left( \frac{1}{p+q} \right) t - q^{-1} \left( \frac{2}{p+q} \right) \sum_{j=1}^{m} p \left( t - \left( q^{-1}(\omega_{\rho}(t-c_j)) \right) \right) + qe(t-\left( q^{-1}(\omega_{\rho}(t-c_j)) \right)) \right),
\]

\[
d = t - q^{-1} \left( \frac{1}{p+q} \right) t - q^{-1} \left( \frac{2}{p+q} \right) \sum_{j=1}^{m} p \left( t - \left( q^{-1}(\omega_{\rho}(t-d_j)) \right) \right) + qe(t-\left( q^{-1}(\omega_{\rho}(t-d_j)) \right)) \right).
\]

(21)

**Proof.** Since

\[
\omega_i\alpha_i = \left[ s_{t-q^{-1}(\omega_{\rho}(t-a))}, s_{t-q^{-1}(\omega_{\rho}(t-b))} \right],
\]

\[
(\omega_i\alpha_i)^p = \left[ s_{t-q^{-1}(p\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))}, s_{t-q^{-1}(p\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))} \right],
\]

(22)

and similarly, we have

\[
(\omega_i\alpha_i)^q = \left[ s_{t-q^{-1}(q\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))}, s_{t-q^{-1}(q\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))} \right],
\]

(23)

Then,

\[
(\omega_i\alpha_i)^p \otimes (\omega_j\alpha_j)^q
\]

\[
= \left[ s_{t-q^{-1}(p\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))} \otimes s_{t-q^{-1}(q\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))}, s_{t-q^{-1}(p\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))} \otimes s_{t-q^{-1}(q\left( t-q^{-1}(\omega_{\rho}(t-a)) \right))}, \right]
\]

(24)
\[
\sum_{j=1}^{n} \sum_{i=1}^{n} (\omega_i \alpha_i)^p \otimes (\omega_j \alpha_j)^q \\
= \left( \left[ t \omega^{-1} \left( \frac{2}{n(n+1)} \Sigma_{j=1}^{n} \Sigma_{i=1}^{n} \left( t - q^{-1}(p_0(t, \omega(t-a))) + q_0(t, \omega(t-b))) \right) \right] \right)^{(1/p+1/q)} \\
\left( \sum_{j=1}^{n} \sum_{i=1}^{n} (\omega_i \alpha_i)^p \otimes (\omega_j \alpha_j)^q \right)^{(1/(p+q))}
\]
Theorem 5 (monotonicity). Let \( a_i = ([s_{a_i}, s_{b_i}], [s_{c_i}, s_{d_i}]) \) and \( b_i = ([s_{r_i}, s_{d_i}], [s_{n_i}, s_{v_i}]) \) be a collection of LIVIFNs; if \( a_i \leq \tau_i, b_i \leq \theta_i, c_i \geq \eta_i, d_i \geq \nu_i \) for all \( i \), then
\[
LIVIFWCHM^{p,q}(a_1, \ldots, a_n) \leq LIVIFWCHM^{p,q}(b_1, \ldots, b_n).
\]
(26)

Proof. On the one hand, since \( a_i \leq \tau_i, b_i \leq \theta_i, c_i \geq \eta_i, d_i \geq \nu_i \) for all \( i \), we have \( t - a_i \geq t - \tau_i \) and \( t - b_i \geq t - \theta_i \). As \( a \) and \( \rho^{-1} \) are monotonicity decreasing, \( \rho(t - a_i) \leq \rho(t - \tau_i) \) and \( \rho(t - b_i) \leq \rho(t - \theta_i) \); furthermore,
\[
\left( e^{-1}(\omega(t - a_i)) \right) \geq \left( e^{-1}(\omega(t - \tau_i)) \right).
\]
(27)

and so,

\[
\begin{align*}
& \frac{1}{p+q} e^{-1} \left( t - e^{-1} \left( \frac{2}{n(n+1)} \sum_{i=1}^{n} \rho(t - e^{-1}(\omega(t - a_i))) \right) \right) \\
& \quad + q \left( e^{-1}(\omega(t - a_i))) \right)
\end{align*}
\]

(28)

Similarly, we have

\[
\begin{align*}
& \frac{1}{p+q} e^{-1} \left( t - e^{-1} \left( \frac{2}{n(n+1)} \sum_{i=1}^{n} \rho(t - e^{-1}(\omega(t - b_i))) \right) \right) \\
& \quad + q \left( e^{-1}(\omega(t - b_i))) \right)
\end{align*}
\]

(29)
On the other hand, as \( c_i \geq \eta_i \) and \( d_i \geq \gamma_i \), we have
\[ \varphi(c_i) \leq \varphi(\eta_i), \quad \varphi^{-1}(\omega_\varphi(c_i)) \geq \varphi^{-1}(\omega_\varphi(\eta_i)) \]
and \( p_\varphi(t - \varphi^{-1}(\omega_\varphi(\eta_i))) \geq p_\varphi(t - \varphi^{-1}(\omega_\varphi(\eta_i))) \).

\[ \begin{aligned}
\left( \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(c_i)))) \right) &\leq \left( \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(\eta_i)))) \right), \\
\left( \sum_{i=1}^{n} \sum_{j=1}^{2} \varphi(t - \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(c_i))))) \right) &\leq \left( \sum_{i=1}^{n} \sum_{j=1}^{2} \varphi(t - \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(\eta_i))))) \right), \\
\left( t - \varphi^{-1}\left( \frac{1}{p+q} \varphi \left( t - \varphi^{-1}\left( \frac{2}{n(n+1)} \sum_{j=1}^{n} \varphi(t - \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(d_i)))) \right) \right) \right) \right) &\geq \left( t - \varphi^{-1}\left( \frac{1}{p+q} \varphi \left( t - \varphi^{-1}\left( \frac{2}{n(n+1)} \sum_{j=1}^{n} \varphi(t - \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(v_i)))) \right) \right) \right) \right), \\
\left( t - \varphi^{-1}\left( \frac{1}{p+q} \varphi \left( t - \varphi^{-1}\left( \frac{2}{n(n+1)} \sum_{j=1}^{n} \varphi(t - \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(v_i)))) \right) \right) \right) \right) &\geq \left( t - \varphi^{-1}\left( \frac{1}{p+q} \varphi \left( t - \varphi^{-1}\left( \frac{2}{n(n+1)} \sum_{j=1}^{n} \varphi(t - \varphi^{-1}(p_\varphi(t - \varphi^{-1}(\omega_\varphi(v_i)))) \right) \right) \right) \right).
\end{aligned} \]

Therefore, \( \text{LIVIFWCHM}^{p,q}(\alpha_1,\ldots,\alpha_n) \leq \text{LIVIFWCHM}^{p,q}(\beta_1,\ldots,\beta_n) \).

\[ \text{Theorem 6 (boundness).} \quad \text{Let} \quad \alpha_i = ([s_{\alpha_i}, s_{\beta_i}), [s_{\gamma_i}, s_{\delta_i}]) \quad \text{and} \quad \alpha_i^{-1} = ([\min(s_{\alpha_i}), \max(s_{\beta_i})], [\min(s_{\gamma_i}), \min(s_{\delta_i})]) \quad \text{for all} \quad i. \quad \text{Then} \]

\[ \text{LIVIFWCHM}^{p,q}(\alpha^{-}, \ldots, \alpha^{-}) \leq \text{LIVIFWCHM}^{p,q}(\beta_1, \ldots, \beta_n) \leq \text{LIVIFWCHM}^{p,q}(\alpha^{+}, \ldots, \alpha^{+}). \]

\[ \text{Proof.} \quad \text{According to Theorem 5, the conclusion is obvious, so we omitted it here.} \]

According to formula (20) and Theorem 4, it is easy to know that operators do not satisfy idempotency.

\[ \text{Now, we can discuss some special cases of the LIVIFWCHM}^{p,q} \text{ operator with respect to the parameters} \quad p \quad \text{and} \quad q. \]

\[ (1) \quad \text{When} \quad q \to 0, \quad \text{the formula reduces to} \]
LIVIFWCHM^{p,q}(a_1,\ldots, a_n) = ([s_a, s_b], [s_c, s_d]),
\begin{align*}
a &= q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-a_i)))\right)\right)\right), \\
a &= q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-b_i)))\right)\right)\right), \\
c &= t - q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-c_i)))\right)\right)\right), \\
c &= t - q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-d_i)))\right)\right)\right).
\end{align*}
(33)

(2) When \( p \to 0 \), the formula reduces to

LIVIFWCHM^{p,q}(a_1,\ldots, a_n) = ([s_a, s_b], [s_c, s_d]),
\begin{align*}
a &= q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-a_i)))\right)\right)\right), \\
a &= q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-b_i)))\right)\right)\right), \\
c &= t - q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-c_i)))\right)\right)\right), \\
c &= t - q^{-1}\left(1-p\left(t-q^{-1}\left(\frac{2}{n(n+1)} \sum_{i=1}^{n} q^{-1}(n+1-i)(t-q^{-1}(ω_i(0, t-d_i)))\right)\right)\right).
\end{align*}
(34)

(3) When \( p = q = \frac{1}{2} \), the formula reduces to an interval-valued intuitionistic fuzzy basic Heronian operator.
(4) When \( p = q = 1 \), the formula reduces to an interval-valued intuitionistic fuzzy basic line Heronian mean operator.

Some different types of LIVIFWCHM^{p,q} are as follows:

Case 1: Gumbel type: when \( q(c) = (-\ln(c/t))^p \), \(q^{-1}(c) = t e^{-c/(t^p)}\), and \( t \geq 1 \), we have
\[ G \equiv \text{LIVIFWCHM}^{p,q}(a_1,\ldots, a_n) = ([s_a, s_b], [s_c, s_d]), \] (35)
where

\[
a = \text{te} - \frac{1}{p + q} \left( -\ln \left(1 - e^{-a_t^{(1,0)}} \right) \right)^\theta, \\
b = \text{te} - \frac{1}{p + q} \left( -\ln \left(1 - e^{-b_t^{(1,0)}} \right) \right)^\theta, \\
c = t - \text{te} - \frac{1}{p + q} \left( -\ln \left(1 - e^{-c_t^{(1,0)}} \right) \right)^\theta, \\
d = t - \text{te} - \frac{1}{p + q} \left( -\ln \left(1 - e^{-d_t^{(1,0)}} \right) \right)^\theta,
\]

\[
a_4 = \frac{2}{n(n+1)} \sum_{i=1}^n \sum_{j=1}^i \left( -\ln \left(1 - e^{-a_t^{(1,0)}} \right) \right)^\theta, \\
b_4 = \frac{2}{n(n+1)} \sum_{i=1}^n \sum_{j=1}^i \left( -\ln \left(1 - e^{-b_t^{(1,0)}} \right) \right)^\theta, \\
c_4 = \frac{2}{n(n+1)} \sum_{i=1}^n \sum_{j=1}^i \left( -\ln \left(1 - e^{-c_t^{(1,0)}} \right) \right)^\theta, \\
d_4 = \frac{2}{n(n+1)} \sum_{i=1}^n \sum_{j=1}^i \left( -\ln \left(1 - e^{-d_t^{(1,0)}} \right) \right)^\theta,
\]

\[
a'_4 = p \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( t - a_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta + q \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( t - a_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta, \\
b'_4 = p \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( t - b_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta + q \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( t - b_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta, \\
c'_4 = p \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( c_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta + q \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( c_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta, \\
d'_4 = p \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( d_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta + q \left( -\ln \left(1 - e^{-\left( w_i \left( -\ln \left( d_i^t \right) \right) \right)^{\theta} } \right) \right)^\theta.
\]

Case 2: Clayton type: when \( \varphi(c) = (c/t)^{-\theta} - 1 \), where \( \varphi^{-1}(c) = t(c + 1)^{-\frac{1}{\theta}} \), \( \theta \geq -1 \), and \( \theta \neq 0 \), we have

\[
C-\text{LIVFWCHM}^{p,q}(\alpha_1, \alpha_2, \ldots, \alpha_n) = ([s_a, s_b], [s_c, s_d]),
\]

(37)
where

\[ a = t \left( \frac{1}{p+q} \left( \frac{t - t(a_4 + 1)^{-(1/\theta)}}{t} \right)^{-\theta} - 1 \right) + 1 \]^{-\theta} - 1, \]

\[ b = t \left( \frac{1}{p+q} \left( \frac{t - t(b_4 + 1)^{-(1/\theta)}}{t} \right)^{-\theta} - 1 \right) + 1 \]^{-\theta} - 1, \]

\[ c = t - t \left( \frac{1}{p+q} \left( \frac{t - t(c_4 + 1)^{-(1/\theta)}}{t} \right)^{-\theta} - 1 \right) + 1 \]^{-\theta} - 1, \]

\[ d = t - t \left( \frac{1}{p+q} \left( \frac{t - t(d_4 + 1)^{-(1/\theta)}}{t} \right)^{-\theta} - 1 \right) + 1 \]^{-\theta} - 1, \]

\[ a_4 = \frac{2}{n(n+1)} \sum_{i=1}^{n} \sum_{j=1}^{i} \left( \frac{t - t(a_i')^{-(1/\theta)}}{t} \right)^{-\theta} - 1, \]

\[ b_4 = \frac{2}{n(n+1)} \sum_{i=1}^{n} \sum_{j=1}^{i} \left( \frac{t - t(b_i')^{-(1/\theta)}}{t} \right)^{-\theta} - 1, \]

\[ c_4 = \frac{2}{n(n+1)} \sum_{i=1}^{n} \sum_{j=1}^{i} \left( \frac{t - t(c_i')^{-(1/\theta)}}{t} \right)^{-\theta} - 1, \]

\[ d_4 = \frac{2}{n(n+1)} \sum_{i=1}^{n} \sum_{j=1}^{i} \left( \frac{t - t(d_i')^{-(1/\theta)}}{t} \right)^{-\theta} - 1, \]

\[ a_i' = p \left( t - t(w_i((t - a_i)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} \]^{-\theta} + q \left( t - t(w_i((t - a_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} - 2,

\[ b_i' = p \left( t - t(w_i((t - b_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} \]^{-\theta} + q \left( t - t(w_i((t - b_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} - 2,

\[ c_i' = p \left( t - t(w_i((c_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} \]^{-\theta} + q \left( t - t(w_i((c_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} - 2,

\[ d_i' = p \left( t - t(w_i((d_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} \]^{-\theta} + q \left( t - t(w_i((d_i/t)^{-\theta} - 1) + 1) \right)^{-(1/\theta)} - 2.
Case 3: Frank type: when \( \varrho(c) = \ln(e^{-\theta(c)/\theta} - 1) \), \( \varrho^{-1}(c) = (-t/\theta) \ln(e^{\theta} - 1) + 1 \), and \( \theta \neq 0 \), we have
\[
F \sim \text{LIVIFWCHM}_{p,q}(\alpha_1, \alpha_2, \ldots, \alpha_n) = ([s_a, s_b], [s_c, s_d]),
\]
(39)

\[
a = t + \frac{t}{\theta} \ln \left( \left( e^{-\theta(\alpha_i/\cdot)} - 1 \right) (e^{\theta} - 1) \right), b
\]
\[
c = t + \frac{t}{\theta} \ln \left( \left( e^{-\theta(\alpha_i/\cdot)} - 1 \right) (e^{\theta} - 1) \right), d
\]
\[
a_d = t + \frac{t}{\theta} \ln \left( \left( \prod_{i=1}^{n} \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \right) (e^{\theta} - 1) \right),
\]
\[
b_d = t + \frac{t}{\theta} \ln \left( \left( \prod_{i=1}^{n} \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \right) (e^{\theta} - 1) \right),
\]
\[
c_d = t + \frac{t}{\theta} \ln \left( \left( \prod_{i=1}^{n} \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \right) (e^{\theta} - 1) \right),
\]
\[
d_d = t + \frac{t}{\theta} \ln \left( \left( \prod_{i=1}^{n} \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \right) (e^{\theta} - 1) \right),
\]
(40)

\[
a_{dij} = t + \frac{t}{\theta} \ln \left( \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \frac{\theta(\alpha_j/\cdot)}{e^{\theta} - 1} \right)(e^{\theta} - 1),
\]
\[
b_{dij} = t + \frac{t}{\theta} \ln \left( \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \frac{\theta(\alpha_j/\cdot)}{e^{\theta} - 1} \right)(e^{\theta} - 1),
\]
\[
c_{dij} = t + \frac{t}{\theta} \ln \left( \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \frac{\theta(\alpha_j/\cdot)}{e^{\theta} - 1} \right)(e^{\theta} - 1),
\]
\[
d_{dij} = t + \frac{t}{\theta} \ln \left( \left( \frac{\theta(\alpha_i/\cdot)}{e^{\theta} - 1} \right) \frac{\theta(\alpha_j/\cdot)}{e^{\theta} - 1} \right)(e^{\theta} - 1),
\]
Case 4: Ali-Mikhail-Haq type: when \( \varphi(c) = \ln \left( t - \theta (t - c) \right) \), \( \varphi^{-1}(c) = (t(1-\theta)/c^\theta - \theta) \), and \( \theta \in [-1,1) \), we have

\[
A_{-\text{LIVIFWCHM}^p}(a_1, a_2, \ldots, a_n) = \left( [s_a, s_b], [s_c, s_d] \right),
\]

(41)

\[
a = \frac{t(1-\theta)}{(t - \theta a_i/t - a_i)}^{(1/p+q)} - \theta b
da_i = \frac{t(1-\theta)}{(t - \theta a_i/t - a_i)}^{(1/p+q)} - \theta b_i
\]

where

\[
a = \frac{t(1-\theta)}{(t - \theta a_i/t - a_i)}^{(1/p+q)} - \theta b
\]

\[
c = \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d
da_i = \frac{t(1-\theta)}{(t - \theta a_i/t - a_i)}^{(1/p+q)} - \theta b_i
\]

\[
\begin{align*}
a &= \frac{t(1-\theta)}{(t - \theta a_i/t - a_i)}^{(1/p+q)} - \theta b \\
a_i &= \frac{t(1-\theta)}{(t - \theta a_i/t - a_i)}^{(1/p+q)} - \theta b_i \\
b &= \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d \\
b_i &= \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d_i \\
c &= \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d \\
c_i &= \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d_i \\
d &= \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d \\
d_i &= \frac{t(1-\theta)}{(t - \theta c_i/t - c_i)}^{(1/p+q)} - \theta d_i \\
\end{align*}
\]
Case 5: Joe type: when \( \varrho(c) = -\ln(1 - (1 - (c/t)^q)) \) and \( \varrho^{-1}(c) = t - t(1 - 1/c)^{1/q} \), where \( q \geq 1 \), we have

\[
J = \text{LIVIFWCHM}^p,q(\alpha_1, \alpha_2, \ldots, \alpha_n) = \left( [s_{at}, s_{bt}], [s_{ct}, s_{dt}] \right),
\]

(43)

\[
a = t - t \left( 1 - \left( 1 - \left( 1 - a'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)},
b = t - t \left( 1 - \left( 1 - \left( 1 - b'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)},
c = t \left( 1 - \left( 1 - \left( 1 - c'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)},
d = t \left( 1 - \left( 1 - \left( 1 - d'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)},
a'_d = \left( 1 - \left( 1 - \left( 1 - \left( 1 - a'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)} \right)^{1/(p+q)},
b'_d = \left( 1 - \left( 1 - \left( 1 - \left( 1 - b'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)} \right)^{1/(p+q)},
c'_d = \left( 1 - \left( 1 - \left( 1 - \left( 1 - c'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)} \right)^{1/(p+q)},
d'_d = \left( 1 - \left( 1 - \left( 1 - \left( 1 - d'_d \right)^{\theta} \right)^{1/(p+q)} \right)^{1/(p+q)} \right)^{1/(p+q)},
\]

(44)

4. LIMADM Approach

In this part, we will give an approach for MAGDM. In general, a MAGDM problem consists of the following parts: (1) alternative set: \( \Psi = \{\Psi_1, \ldots, \Psi_m\} \); (2) attribute set: \( A = \{a_1, \ldots, a_n\} \); (3) \( \text{WV} \) of attribute \( W = (w_1, \ldots, w_n) \) satisfies \( w_i \in [0, 1] \) and \( \sum_{i=1}^{n} w_i = 1 \); and (4) \( D = \{D_1, D_2, \ldots, D_p\} \) is the set of DMs.

DMs evaluate the attribute value of alternative \( \Psi_i \) under the attribute \( a_j \) which can be expressed by LIVIFNs: \( \gamma_{ij} = \left( [s_{at}, s_{bt}], [s_{ct}, s_{dt}] \right) \). Then, an algorithm and process of MAGDM will be designed and given as follows:

Step 1: A revised decision matrix \( \tilde{R}_k = (\tilde{Y}_{ij})_{m \times n} \) is obtained by normalizing the original decision matrix \( R \) in terms of the following equations:

\[
\tilde{Y}_{ij} = \begin{cases} 
\tilde{s} \left( [s_{at}, s_{bt}], [s_{ct}, s_{dt}] \right) & \text{for benefit type} \\
\tilde{s} \left( [s_{at}, s_{bt}], [s_{ct}, s_{dt}] \right) & \text{for cost type}.
\end{cases}
\]

(45)

Step 2: All attribute values \( \tilde{Y}_{ij}^{k} (i = 1, \ldots, m; j = 1, \ldots, n; k = 1, \ldots, p) \) are aggregated to a
comprehensive value $Z_i^k$ by the $G - \text{LIVIFWCHM}^{\rho,q}$ operator.

Step 3: the supports are calculated:

$$\text{Sup}(Z_i^k, Z_i^l) = 1 - |K_F(Z_i^k) - K_F(Z_i^l)|,$$

$$K_F(Z_i^k) = \frac{\sum_{m=0}^{d}(m_i^n)^k + (a_i^n + c_i^n)^k + (b_i^n + d_i^n)^k}{4},$$

(46)

Step 4: $T(Z_i^k)$ and weights $w_i^k$ are calculated:

$$T(Z_i^k) = \sum_{t=1,t\neq i}^{P} \text{Sup}(Z_i^k, Z_t^l),$$

(48)

$$w_i^k = \frac{\lambda_k(1 + T(Z_i^k))}{\sum_{k=1}^{P} \lambda_k(1 + T(Z_i^k))},$$

(49)

where $w_i^k \geq 0$, and $\sum_{k=1}^{P} w_i^k = 1$.

Step 5: the $G - \text{LIVIFWCHM}^{\rho,q}$ operator is used to obtain the collective preference values $Z_i$.

Step 6: the alternatives are ranked, and the desirable one is selected by equation (2).

The flow chart is shown in Figure 1.

5. Case Analysis

This example is from [12]. In the selection of companies for investment in the rural areas, there are four companies $\Psi_1, \Psi_2, \Psi_3,$ and $\Psi_4$ as candidates. The following four attributes $(c_1, \ldots, c_4)$ should be considered: $c_1$: project cost; $c_2$: technical capability; $c_3$: financial status; and $c_4$: company background.

The experts use LVs $\Psi = \{s_0: \text{extremely poor}, s_1: \text{very poor}, \ldots, s_4: \text{extremely good}\}$ to evaluate the companies in terms of LIVIFNs. The decision matrix can be found in Table 2.

5.1. Determining the Optimal Company

Example 1. In this section, we use $G - \text{LIVIFWCHM}^{\rho,q}$ operators to solve this MAGDM problem, where $\rho = 1$ and $\theta = 1$.

Let $\lambda = (0.243, 0.514, 0.243)$ be the WV of the three experts and $w = (0.4, 0.25, 0.2, 0.15)$ be the WV of the attributes.

Step 1: since all attributes are of the same type, the normalization procedure is omitted.

Step 2: the proposed $G - \text{LIVIFWCHM}^{\rho,q}$ operator is employed to aggregate the evaluation values of each attribute into the integrated matrices $Z_i^k$, as shown in Table 3.

Step 3: the supports $S_i^k = \text{Sup}(Z_i^k, Z_i^l)$ are obtained according to equation (46): $S_i^{12} = S_i^{21} = 0.9715$, $S_i^{13} = S_i^{31} = 0.9663$, $S_i^{14} = S_i^{41} = 0.9948$, $S_i^{23} = S_i^{32} = 0.9602$, $S_i^{24} = S_i^{42} = 0.9537$, $S_i^{34} = S_i^{43} = 0.9936$, $S_i^{13} = S_i^{31} = 0.9625$, $S_i^{14} = S_i^{41} = 0.9774$, $S_i^{12} = S_i^{21} = 0.9851$, $S_i^{23} = S_i^{32} = 0.9657$, $S_i^{34} = S_i^{43} = 0.9640$, and $S_i^{14} = S_i^{41} = 0.9982$.

Step 4: the supports $T_i^k = T(Z_i^k)$ and the weights $w_i^k$ are obtained according to equations (47) and (48):

$$T_i^1 = \sum_{t=1,t\neq 1}^{3} \text{Sup}(Z_i^1, Z_t^l) = \text{Sup}(Z_i^1, Z_t^1) + \text{Sup}(Z_i^1, Z_t^3) = 1.9378,$$

(50)

$$T_i^2 = 1.9663,$$

$$T_i^3 = 1.9610,$$

$$T_i^4 = 1.9640,$$

$$T_i^1 = 1.9399,$$

$$T_i^2 = 1.9477,$$

$$T_i^3 = 1.9625,$$

$$T_i^4 = 1.9297,$$

$$T_i^2 = 1.9622$$

Similarly, we have

$$\omega_i^1 = 0.5154,$$

$$\omega_i^2 = 0.2432,$$

$$\omega_i^3 = 0.2406,$$

$$\omega_i^4 = 0.2406,$$

$$\omega_i^5 = 0.5160,$$

$$\omega_i^6 = 0.2434,$$

$$\omega_i^7 = 0.2422,$$

$$\omega_i^8 = 0.5157,$$

$$\omega_i^9 = 0.2441,$$

$$\omega_i^{10} = 0.2409.$$  

(51)
Step 5: the collective preference values $Z_i$ are obtained according to the $G$–LIVIFWCHM operator:

\[
Z_1 = ([s_{3.3828}, s_{5.5831}], [s_{7.7725}, s_{7.1946}]), \\
Z_2 = ([s_{2.2704}, s_{4.4453}], [s_{6.9295}, s_{7.3946}]), \\
Z_3 = ([s_{3.3408}, s_{5.5389}], [s_{6.8444}, s_{7.2586}]), \\
Z_4 = ([s_{3.3786}, s_{4.4738}], [s_{7.0047}, s_{7.2643}]).
\]

(52)

Step 6: computing the score values of every alternative on the basis of Definition 2, we have

\[
S(\Psi_1) = 0.7497, \\
S(\Psi_2) = 0.5979, \\
S(\Psi_3) = 0.6942, \\
S(\Psi_4) = 0.6458.
\]

(53)
The rank of alternatives is $\Psi_1 > \Psi_3 > \Psi_4 > \Psi_2$, and so $\Psi_1$ is the best alternative.

The ordering results of alternatives use other ECs proposed in the present work which are listed in Table 4.

5.2. Sensitivity Analysis. The following two aspects reflect the flexibility of this method: firstly, DMs can select different types of ECs and ECCs with parameter $\theta$; secondly, the HM operator contains two important parameters, which can reflect the correlation between attributes. Therefore, different ranking results may be obtained according to different parameters.

In the following, the influence of parameters $p, q$, and $\theta$ on the results will be analyzed. Without loss of generality, the following analysis adopts the $G - LIVIFWCHM^{p,q}$ operator. Firstly, we assign different values to $\theta$ with fixed $p$ and $q$, and the results are listed in Table 5. In addition, we explore the effect of parameters $p$ and $q$ on the ultimate ranking results which can be found in Table 6 and Figures 2–9.

From Table 5, we can find out that when $p$ and $q$ are fixed, $\theta$ has little influence on the sorting result. From Figures 2–9 and Table 6, it is easy to derive the following conclusions: (1) The scores and ranking order will be different with respect to different parameters $p$ and $q$. (2) The optimal candidate will change when $\theta$ is small, and the absolute value of $p$ minus $q$ is large. (3) The best and worst alternatives are always the same when $\theta \geq 2$, and $q = 1, or q = 1$.

In application, the larger the value of $p$ or $q$, the more prominent the interaction between attributes, and if one of the parameters is zero, the relationship between attributes is not considered. For the actual applications, we can choose a simple integral number for $p$ and $q$ to simplify the process.

5.3. Comparative Analysis. In the following, the proposed approach will be analyzed and compared with other existing methods.

Example 2. This example is to select a new management information system. There are four alternatives $A_i (i = 1, 2, 3, 4)$ to be considered. Following this, there are four attributes $C_1$, $C_2$, $C_3$, and $C_4$ to be evaluated by three DMs using LIVIFI, where $C_1$: the costs; $C_2$: the reliability of software development from outsourcing enterprise; $C_3$: the contribution to the enterprise performance; and $C_4$: the effort to transition to a new system from the old systems.

For the decision matrices, see Tables III–V in [50]. The score values and rankings of alternatives are separately displayed in Table 7. From it, we can draw a conclusion that the orders are almost the same, and the optimal selections are all $A_1$, so we can see the proposed approach is workable and efficient.

Example 3. This is a MADM problem which is from [14]. In the example, a company wants to establish a new subsidiary on four potential sites $\Psi = \{\Psi_1, \Psi_2, \Psi_3, \Psi_4\}$, and there are five attributes $C = \{c_1, c_2, c_3, c_4, c_5\}$ that affect decision-making, and the weight of attributes is $w = \{0.2, 0.25, 0.15, 0.18, 0.22\}$. The evaluation value is expressed by the IVLIFN which is shown in Table 8. The proposed method used the LIVIFWCHM operator (see equation (21)), and also, the same score function proposed by Garg and Kumar [12] (equation (2)) was used for easy comparison. The comparison results with the recent existing work are listed in Table 9.

In the comparison, the WA operator in [12] and PWA operator in [13] were chosen which ignored the interaction.
between attributes. However, the YWMSM operator in [14] and WPMM operator in [15] considered the interaction between attributes. As can be seen from Table 9, the ranking order of the proposed method is exactly the same with Liu and Qin [14] and Qin [15]. Therefore, it can be concluded that the method proposed in this paper is feasible and effective for dealing with MAGDM problems based on LIVIFNs. In addition, the ranking results of the WA operator and PWA operator are different from those of other methods. The reason is that the former methods assume that all attributes are independent. Furthermore, compared with the YWMSM operator in [14] and WPMM operator in [15], the proposed method is based on ECs and ECCs, which have 5 different generator functions, so it can provide DMs more options. Therefore, this method is more flexible.

Figure 8: Scores of $A_i (i = 1, 2, 3, 4)$ when $p = 1$ and $q \in [0, 10]$ ($\theta = 2$).
In the following, the proposed approach will be analyzed and compared with other existing method approaches:

1. Chen et al.’s LIFWA operator [10], Zhang’s LIFWA operator [52], and Liu and Wang’s ILIFWA operator [53] are all based on the LIFS. In our proposed method, when \( t = 1, \theta = 1, p = 1 \), and \( q = 0 \) and only \( s_{(a+b)/2} \) and \( s_{(c+d)/2} \) are considered, LIVIFWCHM\(^{p,q} \) reduces to LIFWCHM\(^{p,q} \). In those methods mentioned above, the operational rules are based on algebraic TN and algebraic TC, which are special forms of EC and ECC. So, our method can also be applied to intuitionistic fuzzy DMPs. Therefore, our proposed method is effective and feasible. Furthermore, the proposed approach will provide more choice for the decision maker in real DMPs.

2. Compared with Tao et al.’s method [36], if \( t = 1, p = 1 \), and \( q = 0 \) and only \( s_{(a+b)/2} \) and \( s_{(c+d)/2} \) are considered, LIFWCHM\(^{p,q} \) reduces to IFCAA\(_w \). Therefore, compared with IFCAA\(_w \) [36], the proposed method is the generalization of Tao et al.
A detailed comparative analysis for the aforementioned approaches is displayed in Table 10.

6. Conclusions

In this paper, we propose a LIVIFWCHM operator to deal with MAGDM problems under LIVIFNs. We establish a new version of copulas and cocopulas and several universal operational laws of LIVIFNs and study some special instances of them based on dissimilar copulas. Then, we give the generalized expression of the LIVIFWCHM operator and explore several characteristics and five specific expressions of the LIVIFWCHM operator. On this basis, we bring forward an approach to solve MAGDM problems based on the LIVIFN. Then, a detailed numerical example has been given to show how it works, and a set of experiments have been carried out to verify the efficacy and superiority of the proposed method. The results also show that the proposed method is more general and flexible and can consider the correlation between attributes. In future, we shall focus, especially, on the correlation between attributes and incomplete attribute information, as well as the large-scale decision-making algorithm based on linguistic assessment theory and methodology.
