The aim of this paper is to present another family of fractional symmetric α-η-contractions and build up some new results for such contraction in the context of $\mathcal{F}$-metric space. The author derives some results for Suzuki-type contractions and orbitally $T$-complete and orbitally continuous mappings in $\mathcal{F}$-metric spaces. The inspiration of this paper is to observe the solution of fractional-order differential equation with one of the boundary conditions using fixed-point technique in $\mathcal{F}$-metric space.

1. Preliminaries and Scope

Fixed-point theory has been promoted by a few particular works in the most recent decades [1–3]. One of the intriguing methodologies was presented in Karapinar et al.‘s work [4] which starts a thought of interpolative kind of contractions and sets up shiny new fixed-point results in partial metric space. Recently, Jleli and Samet [5] introduced a new generalization of metric space and named it as $\mathcal{F}$-metric space.

Definition 1 (see [5]). Let $\mathcal{F}$ be the set function $f: (0, +\infty) \to (−\infty, +\infty)$ that meets the following conditions:

\[
\text{(F}_1\text{)} f \text{ is nondecreasing; that is, for all } 0 < c < d, \text{ it implies } f(c) \leq f(d).
\]

\[
\text{(F}_2\text{)} \text{ For each iteration } \{d_n\} \subset (0, +\infty), \text{ we have } \lim_{n \to \infty} d_n = 0, \text{ if and only if } \lim_{n \to \infty} f(d_n) = -\infty.
\] (1)

The generalized notion of metric space is as follows.

Definition 2 (see [5]). Let $A \neq \emptyset$ with $D: A \times A \to [0, +\infty)$ be a given mapping. Suppose that there exists $(f, \mu) \in \mathcal{F} \times [0, +\infty)$ such that

\[
\text{(D}_1\text{)} (w, v) \in A \times A, \text{ } D(w, v) = 0 \iff w = v.
\]

\[
\text{(D}_2\text{)} D(w, v) = D(v, w) \text{ for all } (w, v) \in A \times A.
\]

\[
\text{(D}_3\text{)} \text{ Each } (w, v) \in A \times A, \forall N \in \mathbb{N}, N \geq 2, \text{ and for each } (u_i)_{i=1}^N \subset A \text{ with } (u_1, u_N) = (w, v), \text{ we have } \lim_{n \to \infty} d(u_i, u_{i+1}) = 0.
\]

\[
D(w, v) > 0 \implies f(D(w, v)) \leq f\left(\sum_{i=1}^{N-1} d(u_i, u_{i+1})\right) + \mu. \tag{2}
\]

Then, it is said that $D$ is an $\mathcal{F}$-metric on $A$.

Here, the pair $(A, D)$ is called an $\mathcal{F}$-metric space and it is abbreviated as $\mathcal{F}$-MS. A sequence $\{w_n\}$ in $(A, D)$ is $\mathcal{F}$-Cauchy, if $\lim_{m,n \to \infty} D(w_n, w_m) = 0$. Furthermore, $(A, D)$ is $\mathcal{F}$-complete, if every $\mathcal{F}$-Cauchy sequence is $\mathcal{F}$-convergent in $A$.

The following example is stated in [5].

Example 1 (see [5]). The set of natural numbers $\mathbb{N} = A$ is an $\mathcal{F}$-MS if we define $D$ by

\[
D(w, v) = \begin{cases} 
(w - v)^2, & \text{if } (w, v) \in [0, 3] \times [0, 3], \\
|w - v|, & \text{if } (w, v) \notin [0, 3] \times [0, 3],
\end{cases} \tag{3}
\]

for all $(w, v) \in A \times A$, $f(t) = \ln(t)$, and $\mu = \ln(3)$. Moreover, $D$ does not form a metric but it is an $\mathcal{F}$-MS.
Jleli and Samet proposed a simple Banach fixed-point theorem as follows.

**Theorem 1** (see [5]). Let \((A, D)\) be an \(\mathcal{T}\)-MS. Let \(g: A \rightarrow A\) be a self-mapping. Suppose that the following conditions are met:

(i) \((A, D)\) is \(\mathcal{T}\)-complete.

(ii) \(\exists\) a constant \(k \in (0, 1)\) such that

\[
D(g(w), g(v)) \leq k D(w, v), \quad (w, v) \in A \times A.
\]

Then, \(g\) attains a unique fixed-point \(w^* \in A\).

In 2012, Sameti et al. introduced a class of \(\alpha\)-admissible mappings as follows.

**Definition 3** (see [6]). Let \(T: A \rightarrow A\) and \(\alpha: A \times A \rightarrow \{0, +\infty\}\). \(T\) is said to be \(\alpha\)-admissible if \(w, v \in A\), and \(\alpha(w, v) \geq 1\) implies that \(\alpha(Tw, Tv) \geq 1\).

Next, Salimi et al. [7] modified the concept of \(\alpha\)-admissible mapping as follows.

**Definition 4** (see [7]). Let \(T: A \rightarrow A\) and \(\alpha, \eta: A \times A \rightarrow [0, +\infty)\) be two functions. \(T\) is called an \(\alpha\)-admissible mapping with respect to \(\eta\), if \(w, v \in A\), and \(\alpha(w, v) \geq \eta(w, v)\) implies that \(\alpha(Tw, Tv) \geq \eta(Tw, Tv)\).

If \(\eta(w, v) = 1\), then the above definition reduces to Definition 3. If \(\alpha(w, v) = 1\), then \(T\) is called an \(\eta\)-sub-admissible mapping.

**Definition 5** (see [8]). Consider a metric space \((A, d)\) and assume that \(T: A \rightarrow A\) and \(\alpha, \eta: A \times A \rightarrow [0, +\infty)\) are two functions. A mapping \(T\) is considered as \(\alpha\)-\(\eta\)-continuous mapping in \((A, d)\) whenever \(w \in A\) is given, and the sequence \(\{w_n\}\) is as follows:

\[
w_n \rightarrow w \text{ at } \infty,
\]

\[
\alpha(w_n, w_{n+1}) \geq \eta(w_n, w_{n+1}),
\]

\[\forall n \in \mathbb{N} \text{ implies } Tu_n \rightarrow Tw.\]

For more details, see, for example, [9, 10]. A mapping \(T: A \rightarrow A\) is called orbitally continuous in \(v \in A\) if \(\lim_{n \rightarrow \infty} T^n w = v\) implies that \(\lim_{n \rightarrow \infty} T^n w = Tv\). Mapping is orbitally continuous on \(A\) if \(T\) is orbitally continuous \(\forall v \in A\).

## 2. Fractional Symmetric \(\alpha\)-\(\eta\)-Contraction of Type-I

In this segment, first we present a new fractional symmetric \(\alpha\)-\(\eta\)-contraction of type-I.

**Definition 6.** Let \(T: A \rightarrow A\) be an \(\mathcal{T}\)-metric space \((A, D)\) and two functions, \(\eta: A \times A \rightarrow [0, +\infty)\). We consider that \(T\) is a fractional symmetric \(\alpha\)-\(\eta\)-contraction of type-I along with constants \(\lambda \in [0, 1)\) and \(\beta, \tilde{\omega}, \gamma \in (0, 1)\) such that, whenever \(\alpha(w, v) \geq \eta(w, v)\), we have

\[
D(Tw, Tv)^{\beta} \leq \lambda \left(\tilde{S}_1(w, v)\right)^\gamma,
\]

where

\[
\tilde{S}_1(w, v) = D(w, v)^{\beta} \left[D(w, Tw)^{\beta\tilde{\omega}(\beta-\gamma)} + D(v, Tw)^{\beta\tilde{\omega}(\beta-\gamma)}\right] \left[D(w, Tw) + D(v, Tw)^{\beta\tilde{\omega}(\beta-\gamma)}\right]^{\beta\tilde{\omega}(\beta-\gamma)}
\]

and \(\alpha, \eta: A \times A \rightarrow [0, +\infty)\) by

\[
\alpha(w, v) = \begin{cases} 1, & \text{if } w, v \in A, \\ 0, & \text{otherwise} \end{cases}
\]

\[
\eta(w, v) = \begin{cases} \frac{1}{2}, & \text{if } w, v \in A, \\ 0, & \text{otherwise}. \end{cases}
\]

If \(w, v \in A\), clearly \(\alpha(w, v) \in A \geq \eta(w, v)\) such that
By taking any value of constants \( \lambda \in [0,1) \) and \( \beta, \tilde{\omega}, \gamma \in (0,1) \), clearly, (6) holds for all \( p \in [1,\infty) \), \( w, v \in A \setminus \text{Fix}(T) \). Point out that \( T \) has two fixed points, which are 0 and 1.

Now, we initiate brand new fixed-point theorems for fractional symmetric \( \alpha-\eta \)-contraction of type-I in the configuration of \( \mathcal{F} \)-complete \( \mathcal{F} \)-MS.

**Theorem 2.** Let \((A,D)\) be a complete \( \mathcal{F} \)-metric space and \( T \) is a fractional symmetric \( \alpha-\eta \)-contraction of type-I satisfying the following statements:

(i) \( T \) is an \( \alpha \)-admissible mapping concerning \( \eta \)
(ii) There exists \( w_0 \in A \) to such an extent that \( \alpha(w_0,Tw_0) \geq \eta(w_0,Tw_0) \)
(iii) \( T \) is \( \alpha-\eta \)-continuous

At that point, \( T \) possesses a fixed point at \( A \).

Proof. Consider \( w_0 \) in \( A \) with the goal that \( \alpha(w_0,Tw_0) \geq \eta(w_0,Tw_0) \). For \( w_0 \in A \), we build a chain \( \{w_n\}_{n=1}^{\infty} \) in such a way that \( w_1 = Tw_0 \) and \( w_n = Tw_{n-1} = T^2w_0 \). Proceeding with this exercise, \( w_n = Tw_n = T^{n+1}w_0 \) for every \( n \in \mathbb{N} \).

Presently, as long as mapping \( T \) is \( \alpha \)-admissible with respect to \( \eta \), at that time \( \alpha(w_0,w_1) = \alpha(w_0,Tw_0) \geq \eta(w_0,Tw_0) = \eta(w_0,w_1) \). Carrying on in this way, we get \( \alpha(w_n,w_{n+1}) \geq \eta(w_n,Tw_{n-1}) \), for all \( n \in \mathbb{N} \).

Provided that \( w_{n+1} = w_n \) for some \( n \in \mathbb{N} \), then \( w_n = w^* \) is a fixed point of \( T \). So, we assume that \( w_n \neq w_{n+1} \) accompanied by

\[
D(Tw_{n-1},Tw_n) = D(w_n,Tw_n) > 0, \quad \text{for all } n \in \mathbb{N}. \tag{13}
\]

As \( T \) is fractional symmetric \( \alpha-\eta \)-contraction of type-I, a part of \( n \in \mathbb{N} \), we have

\[
D(w_n,w_{n+1}) = D(Tw_{n-1},Tw_n) \leq \lambda \left[ D(w_{n-1},w_n) \cdot D(w_n,Tw_{n-1}) \cdot D(w_{n-1},Tw_n) \right] \leq \lambda \left[ D(w_{n-1},w_n)^p \cdot D(w_n,Tw_{n-1})^{p(\beta-\tilde{\omega})} \cdot D(w_{n-1},Tw_n) \right] \leq \lambda \left[ D(w_{n-1},w_n) \cdot D(w_n,Tw_{n-1})^{p(\beta-\tilde{\omega})} \cdot D(w_{n-1},Tw_n) \right],
\]

where \( \lambda \) is a fixed positive number.

\[
D(w_{n-1},w_n) \leq \lambda \left[ D(w_{n-1},w_n) \cdot D(w_n,Tw_{n-1})^{p(\beta-\tilde{\omega})} \cdot D(w_{n-1},Tw_n) \right] \tag{14}
\]
which implies that
\[ D(w_n, w_{n+1})^p \leq \lambda D(w_{n-1}, w_n)^p, \]
and we deduce that
\[ D(w_n, w_{n+1}) \leq \lambda D(w_{n-1}, w_n). \]  

(16)

We conclude that \( \{D(w_{n-1}, w_n)\} \) is a nonincreasing sequence with nonnegative terms. Thus, there is a non-negative constant \( \rho \) such that \( \lim_{n \to \infty} D(w_{n-1}, w_n) = \rho \). Note that \( \rho \geq 0 \). From (16), we have
\[ D(w_n, w_{n+1}) \leq \lambda D(w_{n-1}, w_n) \leq \lambda^n D(w_0, w_1). \]  

(17)

This provides
\[ \sum_{i=n}^{m-1} D(w_i, w_{i+1}) \leq \frac{\lambda^n}{1 - \lambda} D(w_0, w_1), \quad m > n. \]  

(18)

Considering for as much as
\[ \lim_{n \to \infty} \frac{\lambda^n}{1 - \lambda} D(w_0, w_1) = 0, \]
there subsist some \( N \in \mathbb{N} \) corresponding to
\[ 0 < \frac{\lambda^n}{1 - \lambda} D(w_0, w_1) < \delta, \quad n \geq N. \]  

(20)

Let \( \epsilon > 0 \) be fixed and let \( (f, \mu) \in \mathcal{F} \times [0, \infty) \) be cognate and \( (D_3) \) is satisfied. By \((\mathcal{F}_2)\), there exists \( \delta > 0 \) which connotes that
\[ 0 < t < \delta \text{ implies } f(t) < f(\epsilon) - \mu. \]  

(21)

Hence, by (21) and \((\mathcal{F}_1)\), we get
\[ f(D(Tw^*, w^*)) \leq f(\lambda D(w^*, w_n)^p \cdot D(Tw^*, w^*)^{(p/(\beta - \tilde{\omega})(\beta - y))} \cdot D(w_n, Tw_n)^{(p/(\tilde{\omega} - \beta)(\beta - y))} \cdot [D(Tw^*, w^*) + D(w_n, Tw_n)]^{(1/p) - (\beta - y)(\tilde{\omega} - \beta)} + D(w_n + 1, w^*)^p) + \mu, \]

for all \( n \in \mathbb{N} \). In other words, by using \((\mathcal{F}_2)\) and (25), we get
\[ \lim_{n \to \infty} f\left(\frac{\lambda}{1 - \lambda} D(w_n, w_n)^p + D(w_n, w_n)^p\right) + \mu = -\infty, \]
which gives a contradiction. Therefore \( D(Tw^*, w^*) = 0 \), hence \( w^* \) possesses a fixed point of \( T \).

\[ \square \]

**Theorem 3.** Let \((A, D)\) be an \( \mathcal{F} \)-complete \( \mathcal{F} \)-metric space and let \( T \) be a fractional symmetric \( \alpha \)-\( \eta \)-contraction of type-I fulfilling the accompanying affirmations:

(i) \( T \) is an \( \alpha \)-admissible mapping concerning \( \eta \)

(ii) There exists a \( w_0 \in A \) to such extent that \( \alpha(w_0, Tw_0) \geq \eta(w_0, Tw_0) \)

(iii) An iteration \( \{w_n\} \) in \( A \) is such that \( \alpha(w_n, w_{n+1}) \geq \eta(w_n, w_{n+1}) \) escorted by \( w_n \to w^* \) at the same time \( n \to \infty \) after that \( \alpha(w_n, w^*) \geq \eta(w_n, w^*) \) holds for each \( n \in \mathbb{N} \).

Afterwards, \( T \) possesses a fixed point in \( A \).

**Proof.** On closing lines of the proof of Theorem 2, we acquire \( \alpha(w_n, w^*) \geq \eta(w_n, w^*) \) for each \( n \in \mathbb{N} \). Using \((D_3)\), we have
\[ f(D(Tw^*, w^*)) \leq f(D(Tw^*, Tw_n)^p + D(w_n, w^*)^p) + \mu. \]  

(29)

From (6) connecting \((\mathcal{F}_1)\), we have
\[ f\left(D(Tw^*, w^*)^p\right) \leq f\left(D(Tw, Tw_n)^p\right) + D(Tw_n, w^*)^p + \mu \]
\[ \leq f\left(\lambda (D(w^*, w_n)^p) \cdot D(Tw^*, w^*)^p (p/(\beta - \tilde{\omega}(\beta - \gamma))) \cdot D(w_n, Tw_n) (p/(\beta - \tilde{\omega}(\beta - \gamma))) \right. \]
\[ \cdot \left. [D(Tw^*, w^*) + D(w_n, Tw_n)] (p/(\beta - \tilde{\omega}(\beta - \gamma))) \right) \]
\[ \cdot \left. [D(Tw_n, w^*) + D(w_n, Tw_n)] (p/(\beta - \tilde{\omega}(\beta - \gamma))) + D(w_{n+1}, w^*)^p \right) + \mu. \] (30)

Employ (25) with certitude that
\[ \lim_{n \to \infty} D(w_n, w^*) = 0, \quad \text{together with} \quad \lim_{n \to \infty} D(w_{n+1}, w^*) = 0, \]
and we obtain
\[ f\left(D(w^*, Tw^*)^p\right) \leq f\left(D(w^*, Tw^*)^p\right) + \mu, \] (31)
and making use of (F_2), we have
\[ \lim_{n \to \infty} f\left(D(w^*, Tw^*)^p\right) + \mu = -\infty, \] (32)
which is a contradiction. Therefore, \( D(w^*, Tw^*) = 0; \) in other words, \( w^* \) possesses a fixed point of \( T. \)

Example 3. Let \( A = (0, 1] \subseteq \mathbb{R} \) with an \( \mathcal{F} \)-metric \( D: A \times A \to [0, \infty) \) by
\[ D(w, v) = \begin{cases} (w - v)^2, & \text{if} \ (w, v) \in A \times A, \\ |w - v|, & \text{if} \ (w, v) \notin A \times A. \end{cases} \] (33)

(iii) By taking constant \( \lambda \in [0, 1], \) and \( \beta, \tilde{\omega}, \gamma \in (0, 1), \)
for all \( w, v \in A \backslash \text{Fix}(T). \)
(iv) Case III. If any \( w, v \notin A, \) then we have
\[ D(Tw, Tw) = 0 \leq \lambda \left[ |v - w| \cdot |w|^{(1/(\beta - \tilde{\omega}(\beta - \gamma)))} \cdot |v|^{(1/(\beta - \tilde{\omega}(\beta - \gamma)))} \right. \]
\[ \cdot \left. (|w| + |v|)^{1/(\tilde{\omega} - \beta)(\tilde{\omega} - \gamma))} \cdot (|w| + |v|)^{(1/(\gamma - \beta)(\gamma - \tilde{\omega}))} \right], \] (37)

Therefore, whole constraints of Theorem 2 are satisfied. Hence, \( T \) is fractional symmetric \( \alpha - \eta \)-contraction of type-I.

Definition 7. Consider an \( \mathcal{F} \)-metric space \((A, D)\) and two functions \( \alpha, \eta: A \times A \to [0, +\infty). \) Then an \( \mathcal{F} \)-metric space on \( A \) is said to be \( \alpha - \eta \)-complete if and only if every \( \mathcal{F} \)-Cauchy sequence \( \{w_n\} \), along with
\[ \alpha(w_n, w_{n+1}) \geq \eta(w_n, w_{n+1}) \] each one of the \( n \in \mathbb{N}. \) (38)

\( \mathcal{F} \)-converges in \( A. \)
Remark 1. Theorems 2 and 3 also hold for $\alpha$-$\eta$-complete $\mathcal{M}$-metric space instead of $\mathcal{M}$-complete $\mathcal{S}$-metric space (for details, see [10]).

3. Fractional Symmetric $\alpha$-$\eta$-Contraction of Type-II

In this section, a fractional symmetric $\alpha$-$\eta$-contraction of type-II is introduced and in the structure of $\mathcal{S}$-complete $\mathcal{S}$-metric space. Using this notion, we shall provide a fixed-point theorem.

\[
S_2(w, v) = \left\{ \begin{array}{l}
D(w, v) \cdot [D(w, T(w))]^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \cdot [D(v, T(w))]^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \\
[D(w, T(w)) + D(v, T(w))]^{\left(\frac{p\bar{w}(\alpha-\beta)(\beta-\gamma)}{1-p}\right)} \cdot [D(w, T(w)) + D(v, T(w))]^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} 
\end{array} \right.
\]

where $p \in (1, \infty)$, for all $w, v \in A \setminus \text{Fix}(T)$.

Now we show and demonstrate our next theorem.

**Theorem 4.** Let $(A, D)$ be an $\mathcal{S}$-complete $\mathcal{S}$-metric space and let $T$ be a fractional symmetric $\alpha$-$\eta$-contraction of type-II fulfilling the accompanying affirmations:

(i) $T$ is an $\alpha$-admissible mapping concerning $\eta$

(ii) There exists $w_0 \in A$ to such an extent that $\alpha(w_0, T(w_0)) \geq \eta(w_0, T(w_0))$

(iii) $T$ is $\alpha$-$\eta$-continuous

After that, $T$ possesses a fixed point in $A$.

**Proof.** Consider $w_1$ in $A$ correspondent to $\alpha(w_0, T(w_0)) \geq \eta(w_0, T(w_0))$. For $w_n \in A$, we build an iteration $[w_n]_{n=0}^{\infty}$ in such a way that $w_1 = T(w_0)$ and $w_{n+1} = T(w_n)$.

\[
D(w_n, w_{n+1}) = D(Tw_{n-1}, Tw_n) \leq \lambda \left[ D(w_{n-1}, w_n) \cdot D(w_{n-1}, Tw_n) \right]^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \cdot D(w_n, Tw_n)^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)}
\]

\[
= \lambda \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, Tw_n) \left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right) \cdot D(w_n, Tw_n)^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \right]
\]

\[
\leq \lambda \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, Tw_n) \left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right) \cdot D(w_n, Tw_n)^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \right]
\]

\[
= \lambda \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, Tw_n) \left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right) \cdot D(w_n, Tw_n)^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \right]
\]

\[
\leq \lambda \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, Tw_n) \left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right) \cdot D(w_n, Tw_n)^{\left(\frac{p\beta(\beta-\bar{w})(\beta-\gamma)}{1-p}\right)} \right]
\]

Providing with this exercise, $w_{n+1} = Tw_n = T^{n+1}w_0$, for all $n \in \mathbb{N}$. Now, as long as mapping $T$ is $\alpha$-admissible with respect to $\eta$, at that time $\alpha(w_0, w_1) = \alpha(w_0, Tw_0) \geq \eta(w_0, T(w_0)) = \eta(w_0, w_1)$. Carrying on in this way, we own

\[
\alpha(w_{n-1}, w_n) \geq \eta(w_{n-1}, w_n) = \eta(w_{n-1}, Tw_{n-1}), \quad \text{for all } n \in \mathbb{N}.
\]

As $T$ is fractional symmetric $\alpha$-$\eta$-contraction of type-II, a part of $n \in \mathbb{N}$, we own

\[
D(Tw_{n-1}, Tw_n) = D(w_n, Tw_n) > 0, \quad \text{every } n \in \mathbb{N}.
\]
which implies that
\[ D(w_n, w_{n+1})^p \leq \lambda D(w_{n-1}, w_n)^p, \tag{45} \]
and we deduce that
\[ D(w_n, w_{n+1}) \leq \lambda D(w_{n-1}, w_n). \tag{46} \]

We conclude that \{D(w_{n-1}, w_n)\} is a nonincreasing sequence with nonnegative terms. As a result, there is a nonnegative constant \( \rho \) such that \( \lim_{n \to \infty} D(w_{n-1}, w_n) = \rho \). We shall indicate that \( \rho > 0 \). Indeed, from (46), we derive that
\[ D(w_n, w_{n+1}) \leq \lambda D(w_{n-1}, w_n) \leq \lambda^n D(w_0, w_1). \tag{47} \]

The rest of the test follows the same lines of Theorem 2. \( \square \)

**Theorem 5.** Consider an \( \mathcal{F} \)-complete \( \mathcal{F} \)-metric space \((A, D)\) and let \( T \) be a fractional symmetric \( \alpha, \eta \)-contraction of type-II meeting the following assertions:

\[ f(D(Tw^*, w^*))^p \leq f((D(Tw^*, Tw_n)^p) + D(Tw_n, w^*)^p) + \mu \]
\[ \leq f\left( \lambda \left( D(w^*, w_n)^p \cdot D(Tw^*, w^*)^{(p\beta/\beta-\bar{\omega})(\beta-\gamma)} \cdot D(Tw_n, Tw_n)^{(p\beta/\beta-\bar{\omega})(\beta-\gamma)} \right) \right) \]
\[ \cdot \left( D(Tw^*, w^*) + D(w_n, Tw_n)^{p\gamma/\gamma-\bar{\omega}} \right) \]
\[ \cdot \left( D(Tw_n, w^*) + D(w_n, Tw^*)^{p\gamma/\gamma-\bar{\omega}} \right) + D(w_{n+1}, w^*)^p \right) + \mu. \tag{49} \]

Making use of (25), we get
\[ \lim_{n \to \infty} D(w_n, w^*) = 0 \text{ together } \lim_{n \to \infty} D(w_{n+1}, w^*) = 0, \tag{50} \]
and we procure
\[ f(D(w^*, Tw^*)) \leq f(D(w^*, Tw_n)) + \mu. \tag{51} \]

Using (\( \mathcal{F}_2 \)), we have
\[ \lim_{n \to \infty} f(D(w^*, Tw^*)) + \mu = -\infty, \tag{52} \]
which is a logical inconsistency. Along these lines \( D(w^*, Tw^*) = 0 \); that is, \( w^* \) possesses a fixed point of \( T \). \( \square \)

### 4. Fractional Symmetric \( \alpha, \eta \)-Contraction of Type-III

In this section, fractional symmetric \( \alpha, \eta \)-contraction of type-III is considered in the environment of \( \mathcal{F} \)-complete \( \mathcal{F} \)-metric space. After stating a fixed-point theorem for such maps, we set up fractional symmetric \( \alpha, \eta \)-contraction of type-III as follows.

**Definition 9.** Consider an \( \mathcal{F} \)-metric space \((A, D)\) with a self-map \( T: A \to A \) and two functions \( \alpha, \eta: A \times A \to [0, +\infty) \). We say that \( T \) is fractional symmetric \( \alpha, \eta \)-contraction of type-III along with constants \( \lambda \in [0, 1) \) and \( \beta, \bar{\omega}, \gamma \in (0, 1) \), such that, whenever \( \alpha(w, v) \geq \eta(w, v) \), we have
\[ D(Tw, Tv)^p \leq \lambda \left( \tilde{S}_3(w, v) \right), \tag{53} \]
where

\[ \tilde{S}_3(w, v) = \lambda \max \left\{ D(u, v), \left[ D(w, Tw) \right]^{p\beta/\beta-\bar{\omega}} \right\} \cdot [D(u, Tv)]^{p\beta/\beta-\bar{\omega}} \cdot [D(w, Tw) + D(v, Tv)]^{p\gamma/\gamma-\bar{\omega}} \cdot \left[ D(w, Tv) + D(u, Tw) \right]^{p\gamma/\gamma-\bar{\omega}} \right\}, \tag{54} \]
where \( p \in [1, \infty) \), for all \( w, v \in A \setminus \text{Fix}(T) \).

Now we declare and demonstrate our next theorem.

**Theorem 6.** Let an \( F \)-complete \((A, D)\) be an \( F \)-metric space along with \( T \) being a fractional symmetric \( \alpha \eta \)-contraction of type-III which meets the following assertions:

(i) \( T \) is an \( \alpha \eta \)-admissible mapping concerning \( \eta \)

(ii) There exists \( w_0 \in A \) such that \( \alpha(w_0, T w_0) \geq \eta(w_0, T w_0) \)

(iii) \( T \) is \( \alpha \eta \)-continuous

After that, \( T \) possesses a fixed point in \( A \).

**Proof.** Consider \( w_0 \) in \( A \) with the aim that \( \alpha(w_0, T w_0) \geq \eta(w_0, T w_0) \). Take any \( w_n \in A \); we erect a recapitulate \( \{w_n\}_{n=1}^{\infty} \) in such a way that \( w_1 = T w_0 \) and \( w_2 = T^2 w_0 \). Continuing with this practice, \( w_{n+1} = T^{n+1} w_0 \), every \( n \in \mathbb{N} \). As long as mapping \( T \) is \( \alpha \eta \)-admissible with respect to \( \eta \), at that time \( \alpha(w_0, w_1) = \alpha(w_0, T w_0) \geq \eta(w_0, T w_0) = \eta(w_0, w_1) \). Carrying on in this way, we find

\[
\alpha(w_{n-1}, w_n) \geq \eta(w_{n-1}, T w_{n-1}), \quad \text{for all } n \in \mathbb{N}.
\]

(55)

Provided that \( w_{n+1} = w_n \) for some \( n \in \mathbb{N} \), then \( w_n = w^* \) is a fixed point of \( T \). So, we assume that \( w_n \neq w_{n+1} \) accompanied by

\[
D(T w_{n-1}, T w_n) = D(w_n, T w_n) > 0, \quad \text{each } n \in \mathbb{N}.
\]

(56)

As \( T \) is a fractional symmetric \( \alpha \eta \)-contraction of type-III, a part of \( n \in \mathbb{N} \), we own

\[
D(w_n, w_{n+1})^p = D(T w_{n-1}, T w_n)^p \leq \lambda \max \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\left[ D(w_{n-1}, T w_{n-1}) + D(w_n, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_{n-1}, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma)) \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
= \lambda \max \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\leq \lambda \max \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\leq \lambda \max \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\leq \lambda \max \left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

\[
\left[ D(w_{n-1}, w_n)^p \cdot D(w_{n-1}, T w_n) \right]^{(p \beta^2/(\beta - \omega)(\beta - \gamma))} \cdot D(w_n, T w_n)^p(\beta^2/(\beta - \omega)(\beta - \gamma))
\]

Provided that \( \max[D(w_{n-1}, w_n), D(w_{n-1}, w_n)] = D(w_n, w_{n+1}) \), at that time,

\[
D(w_n, w_{n+1}) \leq \lambda D(w_n, w_{n+1}),
\]

(58)

which is a contradiction. We deduce that

\[
D(w_n, w_{n+1}) \leq \lambda D(w_n, w_{n+1}).
\]

(59)
Theorem 7. Consider an $\mathcal{F}$-complete $\mathcal{F}$-metric space $(A, D)$ and let $T$ be a fractional symmetric $\alpha$-$\eta$-contraction of type-III meeting the following assertions:

(i) $T$ is an $\alpha$-admissible mapping with respect to $\eta$
(ii) There exists $w_0 \in A$ such that $\alpha(w_0, Tw_0) \geq \eta(w_0, Tw_0)$
(iii) An iteration \{w_n\} in $A$ is such that $\alpha(w_n, w_{n+1}) \geq \eta(w_n, w_{n+1})$ escorted by $w_n \rightarrow w^*$ at the same time $n \rightarrow \infty$; after that $\alpha(w_n, w^*) \geq \eta(w_n, w^*)$ holds for each $n \in \mathbb{N}$.

Afterwards, $T$ possesses a fixed point in $A$.

Proof. Similar to the same lines of Theorem 3, considering (iii), $\alpha(w_n, w^*) \geq \eta(w_n, w^*)$ for all $n \in \mathbb{N}$. By $(D_3)$, we have

$$f(D(Tw^*, w^*)) \leq f(D(Tw^*, Tw_n) + D(w_n, w^*)) + \mu.$$  

Using (40) along with $(\mathcal{F}_1)$, we have

\[
\lim_{n \rightarrow \infty} D(w_n, w^*) = 0 \quad \text{as long as} \quad \lim_{n \rightarrow \infty} D(w_{n+1}, w^*) = 0, \tag{63}
\]

and we obtain

$$f(D(w^*, Tw^*)) \leq f(D(w^*, Tw_n)) + \mu. \tag{64}$$

Utilizing $(\mathcal{F}_2)$, we have

$$\lim_{n \rightarrow \infty} f(D(w^*, Tw_n)) + \mu = -\infty, \tag{65}$$

which is a logical inconsistency. Along these lines, $D(w^*, Tw^*) = 0$; that is, $w^*$ possesses a fixed point of $T$. □

5. Fractional Symmetric $\alpha$-$\eta$-Contraction of Type-IV

In this part, we propose a new notion, fractional symmetric $\alpha$-$\eta$-contraction of type-IV, in the framework of $\mathcal{F}$-complete $\mathcal{F}$-metric space.

$$\lim_{n \rightarrow \infty} f(D(w^*, Tw_n)) + \mu = -\infty, \tag{65}$$

where $p \in [1, \infty)$, for all $w, v \in A \setminus \text{Fix}(T)$.

Now we declare and demonstrate our next theorem.

Theorem 8. Let an $\mathcal{F}$-complete $(A, D)$ be an $\mathcal{F}$-metric space along with $T$ being a fractional symmetric $\alpha$-$\eta$-contraction of type-IV that meets the following assertions:

(i) $T$ is an $\alpha$-admissible mapping concerning $\eta$
(ii) There exists $w_0 \in A$ which connotes that $\alpha(w_0, Tw_0) \geq \eta(w_0, Tw_0)$
(iii) $T$ is $\alpha$-$\eta$-continuous.

Definition 10. Consider an $\mathcal{F}$-metric space $(A, D)$ with a self-map $T; A \rightarrow A$ and two functions $\alpha, \eta; A \times A \rightarrow [0, +\infty)$. We say that $T$ is a fractional symmetric $\alpha$-$\eta$-contraction type-IV along with constants $\lambda \in [0, 1)$ and $\beta, \bar{\omega}, \gamma \in (0, 1)$ with $\beta + \bar{\omega} + \gamma < 1$ such that, whenever $\alpha(w, v) \geq \eta(w, v)$, we have

$$D(Tw, Tw^*)^p \leq \lambda(S_3(w, v)), \tag{66}$$

where

$$\tilde{S}_3(w, v) = \lambda \left\{ D(w, v) \left( \frac{\beta}{\frac{1}{\beta} - \bar{\omega}} \right) \cdot D(w, Tw) \left( \frac{1}{\beta} - \bar{\omega} \right) \cdot \left[ D(w, Tw) + D(v, Tw) \right] \left( \frac{\beta}{\frac{1}{\beta} - \bar{\omega}} \right) \cdot \left[ D(w, Tw) + D(v, Tw) \right] \right\}, \tag{67}$$

After that, $T$ possesses a fixed point in $A$.

Proof. Consider $w_0$ in $A$ with the aim that $\alpha(w_0, Tw_0) \geq \eta(w_0, Tw_0)$. Take any $w_0 \in A$; we build a chain \{\{w_n\}\} in such a way that $w_1 = Tw_0$ and $w_2 = Tw_1 = T^2w_0$. }
Proceeding with this exercise, \( w_{n+1} = T w_n = T^{n+1} w_0 \), for every \( n \in \mathbb{N} \). As long as mapping \( T \) is \( \alpha \)-admissible with respect to \( \eta \), at that time \( \alpha(w_0, w_1) = \alpha(w_0, T w_0) \geq \eta(w_0, T w_0) = \eta(w_0, w_1) \). Carrying on in this way, we get \( \alpha(w_{n-1}, w_n) \geq \eta(w_{n-1}, w_n) = \eta(w_{n-1}, T w_{n-1}) \), each \( n \in \mathbb{N} \).

(68)

\[
D(w_n, w_{n+1})^p = D(T w_{n-1}, T w_n)^p \leq \lambda \left[ D(w_{n-1}, w_n)^p + \left( \frac{\alpha}{\beta}(\omega - \omega) \right) \left( \frac{\alpha}{\beta}(\omega - \omega) \right) \right].
\]

\[
0 = \lambda \left[ D(w_{n-1}, w_n) \left( \frac{\alpha}{\beta}(\omega - \omega) \right) \right] - D(w_n, w_{n+1})^p \leq \lambda \left[ D(w_{n-1}, w_n) \left( \frac{\alpha}{\beta}(\omega - \omega) \right) \right] - D(w_n, w_{n+1})^p.
\]

(69)

Provided that \( w_{n+1} = w_n \) for some \( n \in \mathbb{N} \), then \( w_n = w^* \) is a fixed point of \( T \). So, we assume that \( w_n \neq w_{n+1} \) accompanied by

\[
D(T w_{n-1}, T w_n) = D(w_n, T w_n) > 0, \quad \text{for all} \ n \in \mathbb{N}.
\]

As \( T \) is fractional symmetric \( \alpha \)-\( \eta \)-contraction of type-IV, a part of \( n \in \mathbb{N} \), we have

On condition that \( \max\{D(w_n, w_{n+1}), D(w_{n+1}, w_n)\} = D(w_n, w_{n+1}) \), at that time,

\[
D(w_n, w_{n+1}) \leq \lambda D(w_n, w_{n+1}), \quad \text{(71)}
\]

which is a contradiction. We deduce that

\[
D(w_n, w_{n+1}) \leq \lambda D(w_n, w_{n+1}). \quad \text{(72)}
\]

Let up the closing lines of Theorem 2.

\[ \square \]

Theorem 9. Consider an \( F \)-complete \( F \)-metric space \( (A, D) \) and suppose that \( T \) is a fractional symmetric \( \alpha \)-\( \eta \)-contraction of type-IV fulfilling the accompanying affirmations:

(1) \( T \) is an \( \alpha \)-admissible mapping concerning \( \eta \)

(ii) There exists \( w_0 \in A \) to such an extent that \( \alpha(w_0, T w_0) \geq \eta(w_0, T w_0) \)

(iii) An iteration \( \{w_n\} \) in \( A \) is analogous to \( \alpha(w_n, w_{n+1}) \geq \eta(w_n, w_{n+1}) \) escorted by \( w_n \to w^* \) at the same time \( n \to \infty \); after that \( \alpha(w_n, w^*) \geq \eta(w_n, w^*) \) holds for each \( n \in \mathbb{N} \)

Afterwards, \( T \) possesses a fixed point in \( A \).

Whether \( \eta(w, w) = 1 \), in Theorems 2, 3, 4, and 5, we introduce the following corollaries.

Corollary 1. Consider an \( F \)-complete \( F \)-metric space \( (A, D) \) and suppose that \( T \) is a fractional symmetric \( \alpha \)-\( \eta \)-contraction of type-I fulfilling the accompanying affirmations:
Corollary 3. Consider an \( \mathcal{F} \)-complete \( \mathcal{F} \)-metric space \((A, D)\) and let \( T \) be fractional symmetric \( \alpha \eta \)-contraction of type-II fulfilling the accompanying affirmations:

(i) \( T \) is an \( \alpha \)-admissible mapping
(ii) There subsist \( w_0 \in A \) parallel to \( \alpha(w_0, Tw_0) \geq 1 \)
(iii) \( T \) is \( \alpha \eta \)-continuous

Afterwards, \( T \) possesses a fixed point in \( A \).

Corollary 4. Let an \( \mathcal{F} \)-complete \((A, D)\) be \( \mathcal{F} \)-metric space and let \( \beta \) be a fractional symmetric \( \alpha \eta \)-contraction of type-II meeting the accompanying affirmations:

(i) \( T \) is an \( \alpha \)-admissible mapping
(ii) There subsist \( w_0 \in A \) parallel to \( \alpha(w_0, Tw_0) \geq 1 \)
(iii) An iteration \( \{w_n\} \) in \( A \) is analogous to \( \alpha(w_n, w_{n+1}) \geq 1 \) escorted by \( w_n \to w^* \) at the same time \( n \to \infty \);

after that \( \alpha(w_n, w^*) \geq 1 \) holds for each \( n \in \mathbb{N} \)

Afterwards, \( T \) possesses a fixed point in \( A \).

In similar fashion, we can deduce Corollaries 1, 2, 3, and 4 for fractional symmetric \( \alpha \eta \)-contraction of type-III and that of type-IV, respectively.

6. Consequences

As a consequence of our results, we derive some effect for Suzuki-type fractional symmetric contractions and orbitally \( T \)-complete and orbitally continuous mappings in \( \mathcal{F} \)-metric spaces.

Theorem 10. Consider an \( \mathcal{F} \)-metric space \((A, D)\) and let \( T \) be a continuous self-mapping on \( A \). Assume that there exists \( r \in [0, 1) \) in addition to \( \beta, \tilde{\mu}, \gamma \in (0, 1) \) such that

\[
D(w, Tw) \leq D(w, v) \text{ implies } D(Tw, Tv)^p \leq r\left(\tilde{S}_1(w, v)\right),
\]

where

\[
\tilde{S}_1(w, v) = D(w, v)^p \cdot D(w, Tw)^{p(\beta - \tilde{\mu})} \cdot D(v, Tv)^{p(\beta - \tilde{\mu})} \cdot D(w, Tw) + D(v, Tv)^{p(\tilde{\mu} - \gamma)} \cdot [D(w, Tw) + D(v, Tv)]^{p(\tilde{\mu} - \gamma)}.
\]

Finally, every constraint of Theorem 2 holds true. Hence, \( T \) possesses a fixed point in \( A \).

Theorem 11. Consider an \( \mathcal{F} \)-metric space \((A, D)\) and let \( T \) be a self-mapping of \( A \). Suppose that the following assertions hold:

(i) \((A, D)\) is an orbitally \( T \)-complete \( \mathcal{F} \)-metric space.
(ii) There exists \( r \in [0, 1) \) in addition to \( \beta, \tilde{\mu}, \gamma \in (0, 1) \) such that

\[
D(Tw, Tv)^p \leq r\left(\tilde{S}_1(w, v)\right),
\]

(i) where
\[ S_1(w, v) = D(w, v)^p \cdot D(w, Tw)^{(p/(\beta - \tilde{\omega})(\beta - \gamma))} \cdot D(v, Tu)^{(p/(\beta - \tilde{\omega})(\beta - \gamma))} \cdot (D(w, Tw) + D(v, Tu))^{(p/\tilde{\omega})(\beta - \gamma)}. \]

(ii) \( p \in [1, \infty) \), for all \( w, v \in O(\omega) \) for some \( \omega \in A \), where \( O(\omega) \) is an orbit of \( \omega \).

(iii) if \( \{v_n\} \) is a sequence such that \( \{v_n\} \subseteq O(\omega) \) with \( v_n \to v^* \) as \( n \to \infty \), then \( v^* \in O(\omega) \).

Then, \( T \) possesses a fixed point.

**Proof.** Describe \( \alpha, \eta : A \times A \to [0, +\infty) \), by \( \alpha(w, v) = 3 \) on \( O(\omega) \times O(\omega) \) and \( \alpha(w, v) = 0 \); otherwise, \( \eta(w, v) = 1 \) for all \( w, v \in A \) (see Remark 6 [11]). Then \( (A, D) \) is an \( \alpha, \eta \)-complete \( F \)-metric and \( T \) is an \( \alpha \)-admissible mapping with respect to \( \eta \). Let \( \alpha(w, v) \geq \eta(w, v) \); then \( w, v \in O(\omega) \), and then, from (ii), we have

\[ D(Tw, Tu)^p \leq r(S_1(w, v)), \]

where

\[ (i) \text{ For all } w, v \in O(\omega), \text{ there exists } r \in [0, 1) \text{ along with } \beta, \tilde{\omega}, \gamma \in (0, 1), \text{ such that } \]

\[ D(Tw, Tu)^p \leq r(S_1(w, v)), \]

(ii) where

\[ \beta, \tilde{\omega}, \gamma \in (0, 1), \text{ such that } \]

\[ \text{and aforesaid } T \text{ is a fractional symmetric } \alpha, \eta \text{-contraction of type-I. Hence, each constraint of Theorem 2 holds true. Thus, } T \text{ gets a fixed point.} \]
(i) \((A, D)\) is an orbitally \(T\)-complete \(\mathcal{F}\)-metric space;

(ii) there exist \(r \in [0, 1)\) parallel to \(\beta, \bar{w}, \gamma \in (0, 1)\) such that

\[
D(Tw, Tw)^p \leq r\left(\tilde{S}_2(w, v)\right),
\]

where

\[
\tilde{S}_2(w, v) = D(w, v)^p \cdot D(w, Tw)^{(p\beta/\beta - \bar{w})(\beta - \gamma)} \cdot D(v, Tu)^{(p\beta/\beta - \bar{w})(\beta - \gamma)} \cdot [D(w, Tw) + D(v, Tv)]^{(p\bar{w}(\bar{w} - \beta)(\bar{w} - \gamma))},
\]

(iii) \(p \in [1, \infty)\), for all \(w, v \in O(\omega)\) for some \(\omega \in A\), where \(O(\omega)\) is an orbit of \(\omega\);

(iv) if \(\{v_n\}\) is a sequence such that \(\{v_n\} \subseteq O(\omega)\) with \(v_n \rightarrow v^*\) as \(n \rightarrow \infty\), then \(v^* \in O(\omega)\).

Then, \(T\) possesses a fixed point.

**Theorem 14.** Consider an \(\mathcal{F}\)-metric space \((A, D)\) and let \(T\) be a self-mapping of \(A\). Suppose that the following assertions hold:

\[
\tilde{S}_2(w, v) = D(w, v)^p \cdot D(w, Tw)^{(p\beta/\beta - \bar{w})(\beta - \gamma)} \cdot D(v, Tu)^{(p\beta/\beta - \bar{w})(\beta - \gamma)} \cdot [D(w, Tw) + D(v, Tv)]^{(p\bar{w}(\bar{w} - \beta)(\bar{w} - \gamma))},
\]

(iii) \(p \in [1, \infty)\), for some \(\omega \in A\);

(iv) the operator \(T\) is orbitally continuous.

Afterwards, \(T\) possesses a fixed point.

Theorems 10, 11, and 12 can be derived easily for fractional symmetric contraction of type-III and that of type-IV, respectively.

**7. Application to Fractional-Order Differential Equations**

The local and nonlocal fractional differential equations have recently proved to be significant tools in the modeling of many phenomena in numerous fields of science and building. The fractional-order differential equations have numerous applications in viscoelasticity, electrochemistry, control, porous media, electromagnetism, and so forth. For more details, see [2, 13-19]. Our aim is to give the existence and uniqueness of bounded solution of local fractional-order differential equation given in (93). Consider a function \(f: (0, \infty) \rightarrow \mathbb{R}\). The conformable derivative of order \(\alpha\) of \(f\) at \(t > 0\) is defined by [20]

\[
D^{-\alpha} f(t) = \lim_{\epsilon \to 0} \frac{f(t + \epsilon t^{-\alpha}) - f(t)}{\epsilon},
\]

The conformable fractional integral associated with (91) is defined by [20, 21]

\[
I^\alpha_0 f(t) = \int_0^t s^{\alpha-1} f(s) ds.
\]

We consider the following boundary value problem of a conformable fractional-order differential equation:

\[
D^\alpha w(t) = \lambda f(t, w(t)), \quad t \in (0, 1), 1 < \alpha < 2,
\]

with \(w(0) = 0, w(1) = \int_0^1 w(s) ds\).

The integral representation of the solution to the boundary value problem (93) is

\[
w(t) = \lambda \int_0^1 G(t, s) f(s, w(s)) ds,
\]

where \(G(t, s)\) is a Green’s function defined by

\[
G(t, s) = \begin{cases} 
-2ts^n + s^{\alpha-1}, & 0 \leq s \leq t \leq 1, \\
-2ts^n, & 0 \leq t \leq s \leq 1,
\end{cases}
\]

and \(\int_0^1 w(s) ds\) denotes the Riemann integrable of \(w\) with respect to \(s\) and \(f: [0, 1] \times \mathbb{R} \rightarrow \mathbb{R}\) is a continuous function.
\[ w(t) = c_0 + c_1 t + \lambda \int_0^t s^{\alpha-1} f(s, w(s)) ds, \]
\[ w(0) = 0 \Rightarrow c_0 = 0, \]
\[ w(1) = c_1 + \lambda \int_0^1 s^{\alpha-1} f(s, w(s)) ds, \]
\[ \int_0^1 w(s) ds = \int_0^1 c_1 ds + \lambda \int_0^1 \int_0^z (s^{\alpha-1} f(z, w(z)) dz \]
\[ = \frac{1}{2} c_1 + \lambda \int_0^1 z^{\alpha-1} f(z, w(z)) dz \]
\[ = \frac{1}{2} c_1 + \lambda \int_0^1 (1-z) z^{\alpha-1} f(z, w(z)) dz \]
\[ = \frac{1}{2} c_1 + \lambda \int_0^1 (z^{\alpha-1} - s^{\alpha}) f(s, w(s)) ds, \]
\[ \frac{1}{2} c_1 = -\lambda \int_0^1 s^{\alpha-1} f(s, w(s)) ds + \lambda \int_0^1 (z^{\alpha-1} - s^{\alpha}) f(s, w(s)) ds \]
\[ = -\lambda \int_0^1 s^{\alpha} f(s, w(s)) ds \]
\[ c_1 = -2\lambda \int_0^1 s^{\alpha} f(s, w(s)) ds. \]

So,

\[ w(t) = -2t\lambda \int_0^1 s^{\alpha} f(s, w(s)) ds + \lambda \int_0^t s^{\alpha-1} f(s, w(s)) ds, \]
\[ = -2t\lambda \int_0^1 s^{\alpha} f(s, w(s)) ds - 2t\lambda \int_0^t s^{\alpha} f(s, w(s)) ds + \lambda \int_0^1 s^{\alpha-1} f(s, w(s)) ds \]
\[ = \lambda \int_0^1 (-2ts^{\alpha} + s^{\alpha-1}) f(s, w(s)) ds + \lambda \int_0^1 (-2ts^{\alpha}) f(s, w(s)) ds \]
\[ = \lambda \int_0^1 G(t, s) f(s, w(s)) ds. \]

Let \( C(I) \) be the linear space of all continuous functions defined on \( I = [0, 1] \), and let \( D(u, v) = \|u - v\|_{C(I)} = \max_{t \in I} |u(t) - v(t)| \) for all \( u, v \in C(I) \). Then, \( (C(I), D) \) is an \( \mathcal{F} \)-complete metric space.

We consider the following conditions:

(a) There exists \( r \in [0, 1] \), and \( \zeta: \mathbb{R}^2 \rightarrow \mathbb{R} \) is a function for each \( a, b \in \mathbb{R} \) with \( \zeta(a, b) \geq \xi(a, b) \), such that

\[ |f(s, w(s)) - f(s, v(s))| 
\[ \leq |w(s) - v(s)| \cdot |w(s) - T w(s) + T v(s)|^{\beta |(u - v)(b - w)(\beta - \gamma)|} \cdot |v(s) - T v(s)|^{\beta |(u - v)(b - w)(\beta - \gamma)|} \]
\[ \cdot |u(s) - T u(s)|^{\beta |(u - v)(b - w)(\beta - \gamma)|} \cdot |u(s) - T u(s)|^{\beta |(u - v)(b - w)(\beta - \gamma)|}, \]

(98)
Theorem 15. Suppose that conditions (a)-(d) are satisfied. Then, (93) has at least one solution $w^* \in C(I)$.

Proof. We know that $w \in C(I)$ is a solution of (93) if and only if $w \in C(I)$ is a solution of the fractional-order integral equation

$$w(t) = \lambda \int_0^t G(t, s)f(s, w(s))ds, \quad \text{for all } t \in I. \quad (102)$$

We define a map $T: C(I) \longrightarrow C(I)$ by

$$Tw(t) = \lambda \int_0^t G(t, s)f(s, w(s))ds, \quad \text{for all } t \in I. \quad (103)$$

Then, problem (93) is equivalent to finding $w^* \in C(I)$, that is, a fixed point of $T$. Let $w, v \in C(I)$, such that $\zeta(w(t), v(t)) \geq 0$, for all $t \in I$. For using (a), we get

$$\zeta(w(t), v(t)) = \zeta(w(t), v(t)) \geq \zeta(w(t), v(t)),$$

for all $t \in I$;

(c) For each $w, v \in C(I)$, there exists $w_1, v_1 \in C(I)$ such that

$$\frac{\lambda}{101} \int_0^1 G(t, s)f(s, w_1(s))ds \leq \frac{\lambda}{102} \int_0^1 G(t, s)f(s, v_1(s))ds.$$
Thus,
\[
D(Tw, Tv) < \left\{ |w(s) - v(s)| \cdot |w(s) - Tw(s)|^{\beta/\alpha} \cdot |v(s) - Tv(s)|^{\beta/\alpha} \right. \\
\left. \cdot \left| |w(s) - Tw(s)| + |v(s) - Tv(s)| \right|^{\gamma/\alpha - \beta} \cdot \left| |w(s) - Tv(s)| + |v(s) - Tw(s)| \right|^{\gamma/\alpha - \beta} \right\},
\]
for all \( w, v \in C(I) \) such that \( \zeta(w(t), v(t)) \geq \xi(w(t), v(t)) \) for all \( t \). We define \( \alpha: C(I) \times C(I) \rightarrow [0, \infty) \) by
\[
\alpha(w, v) = \begin{cases} 
1, & \text{if } \zeta(w(t), v(t)) \geq 0, t \in I, \\
0, & \text{otherwise.}
\end{cases}
\]
\[
\eta(w, v) = \begin{cases} 
\frac{1}{2}, & \text{if } \zeta(w(t), v(t)) \geq 0, t \in I, \\
0, & \text{otherwise.}
\end{cases}
\]
Then, for all \( w, v \in C(I) \), \( \alpha(w, v) \geq \eta(w, v) \), we have
\[
D(Tw, Tv) \leq |w(s) - v(s)| \cdot |w(s) - Tw(s)|^{\beta/\alpha} \cdot |v(s) - Tv(s)|^{\beta/\alpha} \left| |w(s) - Tw(s)| + |v(s) - Tv(s)| \right|^{\gamma/\alpha - \beta} \left| |w(s) - Tv(s)| + |v(s) - Tw(s)| \right|^{\gamma/\alpha - \beta}.
\]
Obviously, \( \alpha(w, v) \geq \eta(w, v) \) for all \( w, v \in C(I) \). If \( \alpha(w, v) \geq \eta(w, v) \) for each \( w, v \in C(I) \), then \( \zeta(w(t), v(t)) \geq \xi(w(t), v(t)) \). From (c), we have \( \zeta(Tw(t), Tv(t)) \geq \xi(Tw(t), Tv(t)) \) and so \( \alpha(Tw, Tv) \geq \eta(Tw, Tv) \). Thus, \( T \) is an \( \alpha \)-admissible map concerning \( \eta \). From (d), we have that, for any cluster point \( w \) of a sequence \( \{w_n\} \) of points in \( C(I) \) with \( \alpha(w_n, w_{n+1}) = \eta(w_n, w_n) \), \( \lim_{n \to \infty} \inf \alpha(w_n, w) = \lim_{n \to \infty} \inf \eta(w_n, w) \). By applying Theorem 2, if \( T \) has a fixed point in \( C(I) \), there exists \( w^* \in C(I) \) such that \( Tw^* = w^* \), and \( w^* \) is a solution of (93).

7.1. Applications. The fractional-order differential equations emerge in various areas of engineering and scientific disciplines as the mathematical modeling of systems and processes in the fields of physics, chemistry, control theory, biology, economics, blood flow phenomena, signal and image processing, biophysics, aerodynamics, and fitting of experimental data.

7.2. Open Problem. What are the conditions for making a power of the contraction a nonnegative real number for fixed point and coincidence fixed point for two or more maps in various spaces?

8. Conclusion
The aim of this paper is to produce four new classes of type contractions. This research focuses on new idea of fractional symmetric \( \alpha-\eta \)-contractions of type-I, type-II, type-III, and type-IV in the structure of \( \mathcal{F} \)-metric space, which is different from and more general than ordinary metric. This paper will open a new conspiracy of fractional fixed-point theory. We develop here Suzuki-type fixed point results in orbitally complete \( \mathcal{F} \)-metric space. These new investigations and applications would enhance the impact of new setup.
