Labeling of graphs has defined many variations in the literature, e.g., graceful, harmonious, and radio labeling. Secrecy of data in data sciences and in information technology is very necessary as well as the accuracy of data transmission and different channel assignments is maintained. It enhances the graph terminologies for the computer programs. In this paper, we will discuss multidistance radio labeling used for channel assignment problems over wireless communication. A radio labeling is a one-to-one mapping \( \varphi : V(G) \rightarrow \mathbb{Z}^+ \) satisfying the condition \( |\varphi(\mu) - \varphi(\mu')| \geq 1 \) for any pair of vertices \( \mu, \mu' \in V(G) \) with \( \mu \neq \mu' \), where \( k \) is an integer, \( k \geq 1 \). The span of labeling \( \varphi \) is the largest number that \( \varphi \) assigns to a vertex of a graph. Radio number of \( G \), denoted by \( rn(G) \), is the minimum span taken over all radio labelings of \( G \). In this article, we will find relations for radio number and radio mean number of a lexicographic product for certain families of graphs.

1. Introduction

The notion of graph labeling was first introduced in 1966 by Rosa in [1], and since then, many different graph labelings have been defined and studied. In the 19th century, for studying the channel assignment problem, the term graph labeling was used where the transmitters are used as the vertices of the graph. Two vertices (transmitters) are said to be adjacent if they are sufficiently close to each other. A distance-two labeling is a function \( \varphi : V(G) \rightarrow \mathbb{Z}^+ \) with span \( k \) having the maximum value \( k \) such that for any \( \mu, \mu' \in V(G), \mu \neq \mu' \), the following relations are satisfied:

\[
|\varphi(\mu) - \varphi(\mu')| \geq \begin{cases} 
2, & \text{if } d(\mu, \mu') = 1 \\
1, & \text{if } d(\mu, \mu') = 2 
\end{cases}.
\]

An assignment of positive integers to the vertices of \( G \) by \( \varphi \) of \( G \) is said to be a radio \( k \)-labeling if \( |\varphi(\mu) - \varphi(\mu')| \geq k + 1 - d(\mu, \mu') \), where \( k \) is an integer, \( k \geq 1 \). The span of labeling \( \varphi \), denoted by \( sp(\varphi) \), is the max \( \{ |\varphi(\mu) - \varphi(\mu')| : \mu, \mu' \in V(G) \} \). Radio number of \( G \), denoted by \( rn(G) \), is the minimum span taken over all radio labelings of \( G \). The radio \( k \)-labeling number of \( G \) is the minimum span among all radio \( k \)-labelings of \( G \).

The study of radio \( k \)-labelings was motivated by Chartrand et al. [5] where they found the radio \( k \)-labeling number for paths. In [5], the lower and upper bounds were given for the radio \( k \)-labeling number for paths which have been improved lately by Kchikech et al. [6]. The radio \( k \)-labeling becomes a radio labeling, when \( k = \text{diam}(G) \). A radio labeling is a mapping from the vertices of the graph to some subsets of positive integers. The task of radio labeling is to assign to each station a positive smallest integer such that the interference in the nearest channel should be minimized. In 2001, multilevel distance labeling problem was introduced by Chartrand et al. [7].
A radio labeling is a one-to-one mapping \( \varphi: V(G) \rightarrow \mathbb{Z}^+ \) satisfying the condition
\[
\left| \varphi(\mu) - \varphi(\mu') \right| \geq \text{diam}(G) + 1 - d(\mu, \mu') \quad \forall \mu, \mu' \in V(G).
\]

In [8], multilevel distance (or radio) labeling for paths and cycles are determined by Liu and Zhu. Rahim et al. in [9] discussed and determined the radio number of Helm graphs. In [8], Liu et al. calculated the radio number of path graph. The radio numbers of hypercube graphs and square cycles have been computed by Khennoufa [10] and Liu et al. [11], respectively. In [12], Naseem et al. gave a lower bound for the radio number of edge-joint graphs. Adefokun and Ajayi [13] determined the radio number of \( P_q \) with \( p \geq 4 \) and \( K_p \) with \( p \geq 3 \). Lower bound has been improved by Bantva [15] for the radio number of graphs which was earlier given by Das et al. in [16]. For more results, we have [17–21].

In [22], Ali et al. proposed a formula for finding a lower bound for \( rn(G) \), for graphs with small diameter. It is sometimes very useful to determine how many pairs \( (\mu, \mu) \) with \( \varphi(\mu) = \varphi(\mu) = 1 \) we can have. If there can be at most \( y \) such pairs in a graph \( G \), then
\[
rn(G) \geq y + 2(q - 1 - y) + 1.
\]

In this paper, firstly, we determine the radio number and then radio mean number for the lexicographic product of path with path, path with cycle, and cycle with cycle. Finally, we present computer programs for finding such radio labelings of these families of graphs.

### 2. Applications

Labeling of graphs is one of the most popular parameters due to its diverse applications in real life. Radio labeling process proved as an efficient way of determining the time of communication for sensor networks. For giving valuable mathematical models, it has a wide scope of applications such as coding theory, electrical switchboards, circuit design, communication network addressing, channel assignment process, social networks, astronomy, demand and supply scenario, radar, database management, X-ray crystallography, and data security.

### 3. Lexicographic Product of Graphs

The lexicographic product was first studied by Hausdorff in 1914 [23]. The lexicographic product of two graphs \( G_1 \) and \( G_2 \) is denoted by \( G_1[G_2] \) which is a graph with (Figure 1)

1. The vertex set of the Cartesian product \( V(G_1) \times V(G_2) \), and
2. Distinct vertices \( (\mu, \mu') \) and \( (\mu_0, \mu_0) \) are adjacent in \( G_1[G_2] \) if
   - (a) \( \mu_0 \in E(G_1) \), or
   - (b) \( \mu = \mu_0 \) and \( \mu' \neq \mu_0 \in E(G_2) \).

### 4. Main Results

In this section, we discuss the radio labelings and compute the radio number for the lexicographic product of path with path \( P_p[P_q] \) and path with cycle \( P_p[C_q] \) for \( p = 2, 3 \). Moreover, we also presented a computer program for computing the radio number of these families of graphs.

#### 4.1. Results of Radio Labeling

Let \( P_q \) be the path with \( q \) vertices. The lexicographic product of \( P_1 \) with \( P_q \) is isomorphic to graph \( P_q \). The radio number of paths is investigated by Liu et al. in [8] as stated in the following result.

**Theorem 4.1** (see [8]). For any \( q \geq 3 \),
\[
rn(P_1[P_q]) = \begin{cases} 2k(q - 1) + 1, & \text{if } q = 2k, \\ 2k^2 + 2, & \text{if } q = 2k + 1, 
\end{cases}
\]

We have a result for lower bound of \( rn(P_p[P_q]) \) for \( p = 2, 3 \) and \( q \geq 4 \).

**Theorem 4.2.** For all \( q \geq 4 \), \( rn(P_p[P_q]) \geq pq + 1 \).

*Proof.* In order to prove that the value stated above is a lower bound for the radio number, we will use the idea of distance-two labeling, i.e., expression 1.

The order of the graph \( P_1[P_q] \) is \( pq \) for \( p = 2, 3 \) and there exists \( pq - 2 \), such pairs with labeling difference equals to 1. So, 3 implies that
\[
rn(P_1[P_q]) \geq (pq - 2) + 2[(pq - 1) - (pq - 2)]
\]
\[= pq - 2 + 2[pq - 1 - pq + 2] + 1
\]
\[= pq - 2 + 2pq - 2 - 2pq + 4 + 1
\]
\[= pq + 1,
\]
\[rn(P_1[P_q]) \geq pq + 1.
\]

**Theorem 4.3.** For all \( q \geq 4 \), \( rn(P_2[P_q]) \leq 2q + 1 \).

*Proof.* The vertex set is partitioned in two disjoint sets \( V_l \) and \( V_r \). Each partition is given as \( V_l = V_l^1 \cup V_l^2 \) and \( V_r = V_r^1 \cup V_r^2 \). For \( t = l, r \), \( V_t^1 = \{v_1, v_2, v_3, \ldots, v_{[q^2]}\} \) and \( V_t^2 = \{v_{[q^2] + 1}, v_{[q^2] + 2}, v_{[q^2] + 3}, \ldots, v_{[q^2]}\} \). Define a mapping \( \varphi: V(P_2[P_q]) \rightarrow \mathbb{N} \) as follows:
Case 2.1: Let \( \mu \) and \( \eta \) be any two distinct vertices in \( V_1^c \), then \( \mu = v_k \) and \( \eta = v_i, 1 \leq k \neq i \leq [q/2] \); therefore, \( \varphi(\mu) = 2k \) and \( \varphi(\eta) = 2l \). Also, we note that \( d(\mu, \eta) \geq 1 \); hence, \( d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3 \).

Case 2.2: Let \( \mu \) and \( \eta \) be any two distinct vertices in \( V_2^c \), then \( \mu = v_k \) and \( \eta = v_i, 1 \leq k \neq l \leq [q/2] \); therefore, \( \varphi(\mu) = 2(q + k) \) and \( \varphi(\eta) = 2(q + l) \). Also, we note that \( d(\mu, \eta) \geq 1 \); hence, \( d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3 \).

Case 3: Suppose \( \mu \) and \( \eta \) are any two vertices in \( V_r \), then two subcases can be obtained.

Case 3.1: Let \( \mu \) and \( \eta \) be any two distinct vertices in \( V_1^l \), then \( \mu = v_k \) and \( \eta = v_i, 1 \leq k \neq l \leq [q/2] \); therefore, \( \varphi(\mu) = 2(q + k) \) and \( \varphi(\eta) = 2(q + l) \). Also, we note that \( d(\mu, \eta) \geq 1 \); hence, \( d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3 \).

Case 3.2: Let \( \mu \) and \( \eta \) be any two distinct vertices in \( V_2^l \), then \( \mu = v_k \) and \( \eta = v_i, 1 \leq k \neq l \leq [q/2] \); therefore, \( \varphi(\mu) = 2(q + k) + 1 \) and \( \varphi(\eta) = 2(q + l) + 1 \). Also, we note that \( d(\mu, \eta) \geq 1 \); hence, \( d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3 \).

Theorem 4.4

\[
\begin{align*}
\text{rn}(P_3[C_q]) &= \begin{cases} 
3(q + 1), & \text{if } q = 3, \\
3q + 2, & \text{if } q = 4, \\
3q + 1, & \text{if } q \geq 5,
\end{cases}
\end{align*}
\]

Theorem 4.5

For all \( q \geq 4 \), \( \text{rn}(P_3[C_q]) \leq 3q + 1 \).
Claim: the mapping $\rho$ is a valid radio labeling. We must show that condition 2 for radio labeling holds for all pair of vertices $\mu, \eta \in V(\mathbb{P}_3[P_3])$.

Case 1: suppose $\mu$ and $\eta$ are any two vertices in $V_1$, then two subcases can be obtained.

Case 1.1: let $\mu$ and $\eta$ be any two distinct vertices in $V^1_1$, then $\mu = v_k$ and $\eta = v_l$,  $1 \leq k \neq l \leq \lfloor q/2 \rfloor$, therefore, $\varphi(\mu) = q + 2k$ and $\varphi(\eta) = q + 2l$. Also, we note that $d(\mu, \eta) \geq 1$; hence, $d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3$.

Case 1.2: let $\mu$ and $\eta$ be any two distinct vertices in $V^2_1$, then $\mu = v_k$ and $\eta = v_l$, $1 \leq k \neq l \leq \lfloor q/2 \rfloor$; therefore, $\varphi(\mu) = q + 1 + 2k$ and $\varphi(\eta) = q + 1 + 2l$. Also, we note that $d(\mu, \eta) \geq 1$; hence, $d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3$.

Case 2: suppose $\mu$ and $\eta$ are any two vertices in $V_r$, then two subcases can be obtained.

Case 2.1: let $\mu$ and $\eta$ be any two distinct vertices in $V^1_r$, then $\mu = v_k$ and $\eta = v_l$, $1 \leq k \neq l \leq \lfloor q/2 \rfloor$; therefore, $\varphi(\mu) = 2(k - 1)$ and $\varphi(\eta) = 2l - 1$. Also, we note that $d(\mu, \eta) \geq 1$; hence, $d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3$.

Case 2.2: let $\mu$ and $\eta$ be any two distinct vertices in $V^2_r$, then $\mu = v_k$ and $\eta = v_l$, $1 \leq k \neq l \leq \lfloor q/2 \rfloor$; therefore, $\varphi(\mu) = 2k$ and $\varphi(\eta) = 2l$. Also, we note that $d(\mu, \eta) \geq 1$; hence, $d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3$.

Case 3: suppose $\mu$ and $\eta$ are any two vertices in $V_r$, then two subcases can be obtained.

Case 3.1: let $\mu$ and $\eta$ be any two distinct vertices in $V^1_r$, then $\mu = v_k$ and $\eta = v_l$, $1 \leq k \neq l \leq \lfloor q/2 \rfloor$; therefore, $\varphi(\mu) = 2(q + k)$ and $\varphi(\eta) = 2(q + l)$. Also, we note that $d(\mu, \eta) \geq 1$; hence, $d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3$.

Case 3.2: let $\mu$ and $\eta$ be any two distinct vertices in $V^2_r$, then $\mu = v_k$ and $\eta = v_l$, $1 \leq k \neq l \leq \lfloor q/2 \rfloor$; therefore, $\varphi(\mu) = 2(q + k) + 1$ and $\varphi(\eta) = 2(q + l) + 1$. Also, we note that $d(\mu, \eta) \geq 1$; hence, $d(\mu, \eta) + |\varphi(\mu) - \varphi(\eta)| \geq 1 + 2 = 3 d(\mu, \eta) + |2(k - l)| \geq 3$. □

4.2. Computing Radio Number of Lexicographic Product of Graphs by Using Computer Language. This computer code has been composed by using Python language.

```python
import numpy as np
import math as mt

def main():
    m = int(input('m = Enter the number of vertices (either 2 or 3) = '))
    n = int(input('n = Enter the number of vertices (n > 5) = '))

    name3 = input('Type rnPP for lexic of two path graphs, Type rnPC for radio number of path and cycles, Type exist to quit the program = ')
    name3 ! = 'exit':
    if name3 = = 'rnPP':
        print('Executing rnPP
        rnpp(n, m)
        elif name3 = = 'rnPC':
        print('Executing rnPC
        rnpc(n, m)
    else:
        print('Input error: Enter the correct input value
        name3 = input('Enter rnPP for lexico of two path graphs, rnPC for radio number of path and cycles, or exist to quit the program = ')
    def rnpp(n, m):
        if m = = 2:
            q1 = mt.ceil(n/2)
            l = np.zeros(n, dtytpe = int)
            r = np.zeros(n, dtytpe = int)
            for i in range(0, q1, 1):
                if m = 2:
                    r[n-j] = n+2* j
                elif m = 3:
                    q2 = mt.ceil(n/2)
                    l = np.zeros(n, dtytpe = int)
                    r = np.zeros(n, dtytpe = int)
                    for j in range(1, n-q1+1, 1):
                        if m = 2:
                            r[n-j] = n+2* j
                        elif m = 3:
                            q2 = mt.ceil(n/2):
                            l[n-j] = n+2* j
                            r[n-j] = n+2* j

    for l, c, r in zip(l, c, r):
        print(l, c, r)
    elif m = = 3:
        q2 = mt.ceil(n/2):
        l[n-j] = n+2* j
        r[n-j] = n+2* j

        for l, c, r in zip(l, c, r):
            print(l, c, r)
    else:
        print('Try again! Enter either 2 or 3 for the value of m
        exit()
    def rnpc(n, m):
        if m = = 2:
            q1 = mt.ceil(n/2)
            l = np.zeros(n, dtytpe = int)
        elif m = = 3:
            q2 = mt.ceil(n/2):
            l[n-j] = n+2* j
            r[n-j] = n+2* j
            for l, c, r in zip(l, c, r):
                print(l, c, r)
        else:
            print('Input error: Enter the correct input value
            name3 = input('Enter rnPP for lexico of two path graphs, rnPC for radio number of path and cycles, or exist to quit the program = ')
    def main():
        m = int(input('m = Enter the number of vertices (either 2 or 3) = '))
        n = int(input('n = Enter the number of vertices (n > 5) = '))
```

5. Results of Radio Mean Labeling

Ponraj et al. [24] discussed the radio mean labeling. In this section, we discuss the radio mean labeling and compute the radio mean number for the lexicographic product of path with path $P_\mu[P_q]$ and path with cycle $P_p[C_q]$ for $p = 2, 3$. Moreover, we also presented a computer program for computing the radio number of these families of graphs.

**Definition 5.1.** Radio mean labeling of a connected graph $G$ is a one-to-one map $\varphi$ from the vertex set $V(G)$ to the set of natural numbers $\mathbb{N}$ such that for two distinct vertices $\mu$ and $\mu'$ of $G$,

$$d(\mu, \mu') + \frac{\varphi(\mu) + \varphi(\mu')}{2} \geq 1 + \text{diam}(G).$$

The radio mean number of $\varphi$, denoted by $\text{rmn}(\varphi)$, is the maximum number assigned to any vertex of $G$. The radio mean number of $G$, $\text{rmn}(G)$ is the minimum value of $\text{rmn}(\varphi)$ taken over all radio mean labeling $\varphi$ of $G$.

**Theorem 5.2.** For $p = 2, 3$ and $q \geq 1$, $\text{rmn}(P_\mu[P_q]) = pq$.

**Proof.** Let $V(P_\mu[P_q]) = \bigcup_{p=1}^P V_p$ for $p = 2, 3$ and $1 \leq s \leq q$ and $E(P_\mu[P_q]) = \{V_i^\mu V_i^{s+1}; 1 \leq t \leq p; 1 \leq s \leq q \} \cup V_i^s V_i^{s+1}; 1 \leq s, s' \leq q$. It is clear that $\text{diam}(P_\mu[P_q]) = 2$. We define a vertex labeling $\varphi: V(P_\mu[P_q]) \rightarrow \mathbb{N}$ as follows: $\varphi(v_i^s) = ps - pt + t$ for $1 \leq t \leq p$ and $1 \leq s \leq q$. Now, we check the radio mean condition.

$$d(\mu, \mu') + \frac{\varphi(\mu) + \varphi(\mu')}{2} \geq 1 + \text{diam}(P_\mu[P_q]),$$

for all $\mu, \mu' \in V(P_\mu[P_q]).$

Case 1: the vertex labeling for the pair $(v_i^s, v_i^{s+1})$ for a fixed $t$, $1 \leq t \leq p$ and $1 \leq s \leq q - 1$, is given as $\varphi(v_i^s) = ps - pt + t$ and $\varphi(v_i^{s+1}) = p(s + 1) - pt + t$. Here, $d(v_i^s, v_i^{s+1}) = 1$. So, $d(v_i^s, v_i^{s+1}) + \lfloor ps - pt + t + 2t \rfloor = 1 + \lfloor 2ps - pt + 2t \rfloor \geq 1 + 2t \geq 3$.

Case 2: check the pair $(v_i^s, v_i^t)$ for a fixed $t$, $1 \leq t \leq p - 1$ and $1 \leq s, s' \leq q$. $\varphi(v_i^s) = ps - p + t$, $\varphi(v_i^{s+1}) = ps - p + t - 1$, and $d(v_i^s, v_i^{s+1}) = 1$. So, $d(v_i^s, v_i^{s+1}) + \lfloor ps - p + t + (ps' - p + t + 1) \rfloor = 1 + \lfloor p(s + s' - 2) + 2t \rfloor \geq 1 + 2t \geq 3$.

Case 3: check the pair $(v_i^s, v_i^{s+1})$ for a fixed $t$, $1 \leq t \leq p$ and $s' = s + 2$, for $1 \leq s \leq q - 2$, $\varphi(v_i^s) = ps - p + t$, $\varphi(v_i^{s+1}) = ps' - p + t$, and $d(v_i^s, v_i^{s+1}) = 2$. So, $d(v_i^s, v_i^{s+1}) + \lfloor ps - p + t + (ps' - p + t) \rfloor = 1 + \lfloor p(s + s') - 2(p - t) \rfloor \geq 1 + 2t \geq 3$.\hfill $\square$

5.1. Computing Radio Mean Number of Lexicographic Product of Graphs by Using Computer Language. This computer code has been composed by using Python language.

```python
import numpy as np
n = int(input('n= Enter the number of vertices (n> = 1)='))
m = int(input('m = Enter the number of vertices (either 2 or 3)='))

if m = = 2:
    lt = np.zeros(n, dtype = int)
    rt = np.zeros(n, dtype = int)
for j in range(1, n+1, 1):
    if j = = 1:
        for i in range(1, n+1, 1):
            lt[i-1] = m*i + m + j.
    else:
        for i in range(1, n+1, 1):
            rt[i-1] = m*i + m + j.
    print(lt, rt)
```
6. Conclusion

In this paper, we have discussed the radio number and radio mean number of lexicographic product of graphs, namely, \(P_2[P_q]\), \(P_3[P_q]\), \(P_2[C_q]\), and \(P_3[C_q]\) for \(q \geq 5\). We also computed the exact value of radio number and radio mean number of these families. Moreover, in this paper, we have presented their computer codes and also two open problems for future work have been given.

7. Open Problems

1. Determining the radio number of \(P_p[P_q]\) for \(p \geq 4\).
2. Determining the radio mean number of \(P_p[P_q]\) for \(p \geq 4\).
