1. Introduction

The 3x + 1 problem, also known as the Collatz conjecture, had its beginnings in the University of Berlin in 1930 [1]. In particular, Dr. Collatz was interested in cycles that could be generated with number-theoretic functions. This study later evolved to what we know today as the 3x + 1 problem or Collatz function. It was not until the International Congress of Mathematics of 1950 that the problem began to spread [2]. Eventually, the problem gained sufficient attention and became something akin to American folklore.

Definition 1

\[
C(n) := \begin{cases} 
3n + 1, & n \equiv 1 \pmod{2}, \\
\frac{n}{2}, & n \equiv 0 \pmod{2}, 
\end{cases} \quad T(n) := \begin{cases} 
\frac{3n + 1}{2}, & n \equiv 1 \pmod{2}, \\
\frac{n}{2}, & n \equiv 0 \pmod{2}. 
\end{cases}
\] (1)

What makes this problem initially interesting is the fact that the conjecture itself is so difficult to prove. The problem has proven to be quite evasive to proof by all modern mathematical techniques tried thus far. Inasmuch that particular generalizations of the 3x + 1 problem have been demonstrated to be arithmetically undecidable [3–5]. The 3x + 1 problem stands on the same footing as the Riemann hypothesis being a Π2 problem with regard to complexity.
Defnition 4. Fix standpoint, there may be a solution that only resolves the 3x + 1 problem uniquely. This would be a pity, as the Collatz problem is only one of a vast collection of number-theoretical functions of its kind. More optimistically, a hypothetical method of proof could be generalized yielding new knowledge and tools to study other topics of mathematics. Such mathematical topics include but are not limited to exponential diophantine equations, discrete dynamical systems, mathematical logic, and Turing machines, among others [6].

The elusiveness of an answer belies the fact the Collatz conjecture touches nearly every branch of mathematics. In this paper, we study properties of integral loops in a generalized Collatz-like mapping. We make an improvement on the work performed regarding the set of rational cycles for the 3x + 1 problem. It has been proven that the parity sequence (characteristic sequence) associated with the trajectory of a starting integer is eventually periodic if and only if the trajectory eventually enters an integral loop [7, 8].

Previous proofs of this fact depend on the 2-adic nature of the parity sequence. Here, we present an alternative proof that is 2-adic invariant. We also provide examples.

2. Preliminary Definitions

2.1. Integral Loops

Definition 3. Fix $k \in \mathbb{Z}_{>0}$. Let $C_k : \mathbb{Z}_{>0} \rightarrow \mathbb{Z}_{>0}$ be defined as

$$C_k(n) = \begin{cases} 3n + k, & \text{if } n \equiv 1 \pmod{2}, \\ n, & \text{if } n \equiv 0 \pmod{2}. \end{cases}$$ (2)

Let $C_k^N(n) = n$. Furthermore, for $s \geq 0$, we denote function composition as $C_k^{s+1}(n) = C_k \circ C_k^s(n)$. Finally, if $k = 1$, then we write $C$ instead of $C_1$.

Definition 4. Fix $k \in \mathbb{Z}_{>0}$. Let $\chi_k : \mathbb{Z}_{>0} \rightarrow \{0, 1\}$ be defined as

$$\chi_k(n) = \begin{cases} 1, & \text{if } C_k(n) \equiv 1 \pmod{2}, \\ 0, & \text{if } C_k(n) \equiv 0 \pmod{2}. \end{cases}$$ (3)

Let $\chi_k^0(n) \equiv n \pmod{2}$. Furthermore, for $s \geq 0$, we denote function composition as $\chi_k^{s+1}(n) = \chi_k \circ \chi_k^s(n)$. Finally, if $k = 1$, then we write $\chi$ instead of $\chi_1$.

Definition 5. Fix $k \in \mathbb{Z}_{>0}$ and $n \in \mathbb{Z}_{>0}$. Let $\{C_k^0(n), C_k^1(n), \ldots\}$ denote the trajectory of $n$.

Definition 6. Fix $k \in \mathbb{Z}_{>0}$ and $n \in \mathbb{Z}_{>0}$. Let $\{\chi_k^0(n), \chi_k^1(n), \ldots\}$ denote the characteristic trajectory of $n$. Let $\{0, 1\}^*$ denote the set of binary sequences of infinite length.

Definition 7. Fix $k \in \mathbb{Z}_{>0}$ and $n \in \mathbb{Z}_{>0}$. We say $B \in \{0, 1\}^*$ is associated with the characteristic trajectory of $n$ if $B = (\chi_k^i(n))_{i \geq 0}$.

Proposition 8. Fix $k \in \mathbb{Z}_{>0}$, $n \in \mathbb{Z}_{>0}$, and $N \in \mathbb{Z}_{>0}$. Let $B \in \{0, 1\}^*$ such that $B = (\chi_k^i(n))_{i \geq 0}$. Let $\rho$ and $\nu$ be the count of the number of zeros and ones, respectively, in $B$ for all $i$ between zero and $N - 1$ inclusive. For $1 \leq j \leq \nu - 1$, let $m_j$ denote the number of zeros between $(j - 1)th$ and $j$th one.

1. If $n$ is odd, let $m_0 = 0$ and $m_r$ be the remaining zeros after the last one.

2. If $n$ is even, let $m_0$ be the number of leading zeros.

Then, $n$ satisfies the following equality:

$$C_k^N(n) = 3^\nu n + k 2^\nu \left(3^{\nu - 1} + \sum_{r=1}^{\nu - 1} 3^{\nu - 1 - r} 2 \sum_{r=1}^{m_r} \right).$$ (4)

Proof. Let us assume first that $n$ is odd, which implies that $m_0 = 0$. Therefore, equation (4) reduces to the form,

$$C_k^N(n) = 3^\nu n + k \left(3^{\nu - 1} + \sum_{r=1}^{\nu - 1} 3^{\nu - 1 - r} 2 \sum_{r=1}^{m_r} \right).$$ (5)

By construction of $\rho$ and $\nu$, we make the substitution $N = \rho + \nu$. We know that $C_k^N(n)$ represents $N$ compositions of the $C_k$ mapping with starting integer $n$. Therefore, we can advance the trajectory of $n$ by one and subtract one step from $N$ in the following manner:

$$C_k^N(n) = C_k^{\rho + \nu}(n) = C_k^{\rho + \nu - 1} \circ C_k(n) = C_k^{\rho + \nu - 1}(3n + k).$$ (6)

Both the terms $3n$ and $k$ are odd. Therefore, their sum is even. We can divide by two, $m_1$ number of times yielding the following expression:

$$C_k^N(n) = C_k^{\rho - m_1 + \nu - 2} \circ C_k \left( \frac{3n + k}{2^{m_1}} \right) = C_k^{\rho - m_1 + \nu - 2} \left( \frac{3n + 3k + 2^m k}{2^{m_1}} \right).$$ (7)

By hypothesis, this expression is again odd. Therefore, we can apply the $C_k$ map for one more step.

$$C_k^N(n) = C_k^{\rho - m_1 + \nu - 2} \circ C_k \left( \frac{3n + k}{2^{m_1}} \right) = C_k^{\rho - m_1 + \nu - 2} \left( \frac{3n + 3k + 2^m k}{2^{m_1}} \right).$$ (8)
In turn, this expression is again even. Therefore, we can divide by \(m_1\) powers of two. Following this, we can reduce the expression again,

\[
C_k^N(n) = \frac{3n + k + 2^{m_1}}{2^{m_1 + m_2}} \left( \frac{3^2 n + 3k + 2^{m_1} k}{2^{m_1 + m_2}} \right) 
\]

(9)

We proceed to follow this process inductively until the length of the entire finite subsequence of \(B\) is exhausted.

\[
C_k^N(n) = \frac{3^2 n + 3k + 2^{m_1} k + \ldots}{2^{m_1 + m_2 + \ldots}}
\]

(10)

On the other hand, we suppose that \(n\) is even. Then, \(m_0 > 0\) and by hypothesis \(n = 2^m \bar{n}\) for an odd integer \(\bar{n}\). Starting from equation (4), we find by taking \(m_0\) steps,

\[
C_k^N(n) = C_k^{n^{m_0} + n} \circ C_k^{m_0} (n) = C_k^{n^{m_0} + n} \left( \frac{n}{2^{m_0}} \right)
\]

(11)

Recalling by hypothesis \(n = 2^m \bar{n}\) implies that \(n/2^{m_0} = \bar{n}\). Substituting this quantity in equation (11) yields

\[
C_k^N(n) = C_k^{n^{m_0} + n} \left( \frac{n}{2^{m_0}} \right) = C_k^{n^{m_0} + n} (\bar{n}).
\]

(12)

We then consider the previous argument starting with \(\bar{n}\), \(\bar{\rho} = \rho - m_0\), and \(\nu\) unchanged.

\[
C_k^N(n) = C_k^{n^{m_0} + n} (\bar{n}) = \frac{3^\nu n + k 2^{m_0}}{2^{\rho - \nu}} \left( \frac{3^\nu n + k 2^{m_0}}{2^{\rho - \nu}} \right)^{(\nu - 1) 2^{\nu - (\rho - \nu)}}
\]

(13)

Therefore, we find that

\[
C_k^N(n) = C_k^{n^{m_0} + n} (\bar{n}) = \frac{3^\nu n + k 2^{m_0}}{2^{\rho - \nu}} \left( \frac{3^\nu n + k 2^{m_0}}{2^{\rho - \nu}} \right)^{(\nu - 1) 2^{\nu - (\rho - \nu)}}
\]

(14)

Proposition 9. Fix \(k \in \mathbb{Z}_{odd}^{\geq 0}\) and \(n \in \mathbb{Z}_{> 0}\). Let \(B \in \{0, 1\}^*\) such that \(B = (\chi_k^{(n)}(i))_{i \geq 0}\). We suppose that \(N\) is the smallest positive integer such that \(C_k^N(n) = n\). Let \(\rho \) and \(\nu\) be the count of the number of zeros and ones, respectively, in \(B\) for all \(i\) between 0 and \(N\) inclusive. For \(1 \leq j \leq \nu\), let \(m_j\) denote the number of zeros between \((j - 1)\)th and \(j\)th one.

(1) If \(n\) is odd, let \(m_0 = 0\) and \(m_j\) be the remaining zeros after the last one.

(2) If \(n\) is even, let \(m_0\) be the number of leading zeros. Observe that \(n = 2^{m_0} \bar{n}\) for \(\bar{n}\) being odd. So, we obtain \(m_1, \ldots, m_{\nu - 1}\) by (1) and \(\bar{n}\).

Then, \(n\) satisfies the following equality:

\[
n = \frac{k 2^{m_0}}{2^{\rho - \nu}} \left( \frac{3^\nu n + k 2^{m_0}}{2^{\rho - \nu}} \right)^{(\nu - 1) 2^{\nu - (\rho - \nu)}}
\]

(15)
Proof. Equation (15) can be derived from equation (4) by setting $C_k^n(n) = n$.

We will refer to equation (15) as the integral loop formula.

$$n = \frac{175\left(3^{4-1} + 3^{4-2} \times 2^1 + 3^{4-3} \times 2^{1+3} + 3^{4-4} \times 2^{1+3+2}\right)}{2^8 - 3^4},$$

$$= \frac{175(27 + 9 \times 2 + 3 \times 16 + 1 \times 64)}{175} = 157.$$  \hspace{1cm} (16)

2.2. Rational Cycles

**Definition 10.** Let $B \in \{0, 1\}^\ast$. We say that $B$ is a rational 2-adic if it can be written $a = p/q$ for some integers $p, q$ with $q$ odd [8].

**Definition 11.** Let $B \in \{0, 1\}^\ast$. We say that $B$ is eventually periodic if there exists a positive integer $K$ such that $B^{k+1} = B^k$ for all sufficiently large $k$. If $B^{k+1} = B^k$ for all $k$, then $B$ is called periodic [8].

**Theorem 12.** There is a one-to-one correspondence between rational numbers $a = p/q$, where $q$ is odd, and eventually periodic sequences $B$, which associates with each such rational number $a$ the bit sequence $(B^0, B^1, \ldots)$ of its 2-adic expansion. The sequence $B$ is strictly periodic if and only if $|a| < 0$ and $|a| < 1$. [9].

**Example 1.** We consider the integral loop induced by $n = 157$ and $k = 175$. With respect to equation (15), we find that

$$a = M + p'/q', \text{ where } p' \leq 0 \text{ and } |p'| < q.$$ Thus, the 2-adic expansion for $p'/q'$ is periodic. It follows that the 2-adic expansion for the sum $a = M + p'/q'$ is eventually periodic.

Conversely, an eventually periodic sequence $B = (B^0, B^1, \ldots)$ corresponds to a rational number $a = \sum_{i=0}^\infty B^i2^{-i}$ because it is given by a finite transient term $\sum_{i=0}^{K-1} B^i2^{-i}$ for some nonnegative integer $K$ plus a periodic term, $\sum_{i=K}^\infty B^i2^{-i} = 2^K\sum_{i=0}^{\infty} B^i2^{-i}$, both of which are rational numbers.

**Proposition 13.** Fix $k \in \mathbb{Z}_{odd}$ and $n \in \mathbb{Z}_{p}$. Let $B^* \in \{0, 1\}^\ast$ such that $B = (\chi_k^N(n))_{n=0}^\infty$. We assume that the trajectory of $n$ is bounded above. Then, there exists some $N'$ contained in the trajectory of $n$ and the smallest $N$ in $\mathbb{Z}_{p}$ such that $C_k^n(n') = n'$ and only if $B$ is a rational 2-adic.

**Proof.** We suppose that first in the trajectory of $n$, there exists an $n'$, $N \in \mathbb{Z}_{p}$ so that $C_k^n(n') = n'$. We assume further that $N$ is the smallest positive integer which satisfies this equality. Then, $B$ has a repeating period of length $N$ and is rational.

Now, we assume that $B$ is a rational 2-adic. Let $\chi_k$ be the starting value whose characteristic trajectory generates the repeating period of $B$. Let us define the symbol $\sigma$ as follows:

$$\sigma = 3^{-1} + \sum_{i=1}^{\infty} 3^{-1-i} \sum_{j=1}^{m_i} 2^j,$$

where $\Sigma m_i = \tilde{p}$. We observe immediately that $\sigma$ is finite as both $\tilde{p}$ and $\tilde{v}$ are finite. We have the following sequence of values by continuous application of the Collatz map $C_k^n$ generating values $x_1, x_2, \ldots, x_n$:

$$2\tilde{v}x_1 = 3\tilde{v}x_0 + k\sigma,$$

$$2\tilde{v}x_2 = 3\tilde{v}x_1 + k\sigma,$$

$$\ldots$$

$$2\tilde{v}x_n = 3\tilde{v}x_{n-1} + k\sigma.$$  \hspace{1cm} (20)

We can consolidate the terms into an expression that includes only $x_n$ and $x_0$ as follows:
Thus, solving for $x_0$ yields

$$x_0 = \left( \frac{2^n}{3^m} \right)^n \left( x_0 - \frac{k\alpha}{2^p - 3^q} \right) + \frac{k\alpha}{2^p - 3^q}.$$  

(21)

Proposition 15. Fix $\alpha, \beta, k \in \mathbb{Z}_{>0}$ so that $\alpha, \beta$, and $k$ are pairwise coprimes. Then, there exists a pair of integers $x, y \in \mathbb{Z}$ satisfying the following linear Diophantine equation:

$$ax + by = -k.$$  

(26)

Lemma 14. Fix $a, \beta, k \in \mathbb{Z}_{>0}$ so that $\alpha, \beta$, and $k$ are pairwise coprimes. Then, there exists a pair of integers $x, y \in \mathbb{Z}$ satisfying the following linear Diophantine equation:

$$ax + by = -k.$$  

(26)

Proof. A necessary and sufficient condition that a linear Diophantine equation is solvable is that $k$ is a multiple of the greatest common denominator of $\alpha$ and $\beta$ [10]. By hypothesis, $\gcd(\alpha, \beta) = 1$. Thus, $k$ is necessarily a multiple. We conclude that the linear Diophantine equation is always solvable. \hfill \Box

Proposition 15. Fix $\alpha, \beta, k \in \mathbb{Z}_{>0}$ so that $\alpha, \beta$, and $k$ are pairwise coprimes. Then, there exists a pair of integers $x, y \in \mathbb{Z}$ satisfying the following linear Diophantine equation:

$$ax + by = -k.$$  

(26)

Proof. A necessary and sufficient condition that a linear Diophantine equation is solvable is that $k$ is a multiple of the greatest common denominator of $\alpha$ and $\beta$ [10]. By hypothesis, $\gcd(\alpha, \beta) = 1$. Thus, $k$ is necessarily a multiple. We conclude that the linear Diophantine equation is always solvable. \hfill \Box

3. Generalizations

3.1. Two-State System with Halting Condition. We would like to consider first a generalization of the two-state system given in Definition 3. To begin, we need the following lemma:

$$2^m x_n = 3^m x_0 + k\alpha \sum_{i=0}^{n-1} 3^{(n-1-i)} 2^i. \tag{21}$$

We suppose first that $2^p/3^q > 1$. Following from equation (21), we distribute the first term, yielding the following:

$$x_0 = \left( \frac{2^n}{3^m} \right)^n \left( x_0 - \frac{k\alpha}{2^p - 3^q} \right) + \frac{k\alpha}{2^p - 3^q}. \tag{23}$$

Then, there exists an $N$ such that for all $n > N$, $x_n = k\alpha/2^p - 3^q$. We find a new $x_N$, which maybe different from $x_0$, such that $x_N$ generates an integral loop coinciding with the original rational loop.

If conversely we suppose $2^p/3^q < 1$, we simply reverse equation (21) to solve for $x_n$ in terms of $x_0$:

$$x_n = \left( \frac{3^q}{2^p} \right)^n \left( x_0 - \frac{k\alpha}{2^p - 3^q} \right) + \frac{k\alpha}{2^p - 3^q}. \tag{24}$$

We suppose first that $x_0 = k\alpha/2^p - 3^q$, then it follows that $x_1 = k\alpha/2^p - 3^q$. This equality is true for all, and thus, we have an integral loop. So, assume instead that $x_0 \neq k\alpha/2^p - 3^q$. Then, we can write Equation (22) in the form of a ratio exhibited in equation:

$$\frac{x_n - k\alpha/2^p - 3^q}{x_0 - k\alpha/2^p - 3^q} = \left( \frac{3^q}{2^p} \right)^n. \tag{25}$$

However, recall $x_0$ and $k\alpha/2^p - 3^q$ are both fixed values. Thus, the left hand side has a fixed denominator. However, as the right hand side is the quotient of two primes, the denominator expands with irreducible powers of two. If $x_n$ is a trajectory of integers, then there would be some index $N$ of which the denominator on the right hand side would be larger than the left hand side. This would be a contradiction.

Finally, as $\gamma = \ln(2)/\ln(3)p$, as an irrational ratio cannot be expressed with a finite binary sequence.

Thus, we have shown that no rational cycle apart from an integral loop exists for any $3x + k$ mapping. \hfill \Box

We define the trajectory and characteristic trajectory of $n$ in a similar manner to Definitions 5 and 6, respectively. Furthermore, we associate $B \in \{0, 1\}^*$ with $n$ in a similar manner to Definition 7.

Proposition 18. Fix $\alpha, \beta, k \in \mathbb{Z}_{>0}$ so that $\alpha, \beta$, and $k$ are pairwise coprimes. Let $\rho \in \{0, 1\}^{*}$ such that $B = (\chi_{(\alpha, \beta, k)}(n))_{i \geq 0}$. Let $\rho$ and $\nu$ be the count of the number of
zeros and ones, respectively, in $B$ for all $i$ between zero and $N - 1$ inclusive. For $1 \leq j \leq v - 1$, let $m_j$ denote the number of zeros between $(j - 1)\text{th}$ and $j\text{th}$ one. We assume that the halting condition for $C_{(a,b,k)}$ is not met for all $0 \leq i \leq N$.

1. If $n \equiv t \pmod{\beta}$, let $m_0 = 0$ and $m_i$ be the remaining zeros after the last one.
2. If $n \equiv 0 \pmod{\beta}$, let $m_i$ be the number of leading zeros. We observe that $n = \beta^{m_i} \bar{n}$ for $\bar{n} \equiv t \pmod{\beta}$.

So, we obtain $m_1, \ldots, m_{v-1}$ by (1) and $\bar{n}$.

Then, $n$ satisfies the following equality:

$$C_{(a,b,k)}^{N}(n) = \frac{a^{n} + k\beta^{m_0}\left(a^{v-1} + \sum_{r=1}^{v-1} a^{v-1-r} \beta^{m_r} \right)}{\beta^v - a^v}.$$  \hspace{1cm} (30)

**Proof.** By hypothesis, the halting condition is not met. Thus, every step of the characteristic trajectory associated with $n$ is nonempty. In that context, the proof is essentially identical to Proposition 8. \hfill \square

**Proposition 19.** Fix $\alpha, \beta, k \in \mathbb{Z}_{>0}$ so that $\alpha, \beta$, and $k$ are pairwise coprimes. Let $t \in \{1, \ldots, \beta - 1\}$ satisfying $at + k \equiv 0 \pmod{\beta}$. Let $B \in \{0, 1\}$ such that $B = (\chi'_{(a,b,k)}(n))_{n \leq 0}$. Suppose that $N$ is the smallest positive integer such that $C_{(a,b,k)}^{N+1}(n) = n$. Let $p$ and $v$ be the count of the number of zeros and ones, respectively, in $B$ for all $i$ between 0 and $N$ inclusive. For $1 \leq j \leq v - 1$, let $m_j$ denote the number of zeros between $(j - 1)\text{th}$ and $j\text{th}$ one. We assume that the halting condition for $C_{(a,b,k)}$ is not met for all $0 \leq i \leq N$.

1. If $n \equiv t \pmod{\beta}$, let $m_0 = 0$ and $m_i$ be the remaining zeros after the last one.
2. If $n \equiv 0 \pmod{\beta}$, let $m_i$ be the number of leading zeros. We observe that $\bar{n} \equiv t \pmod{\beta}$.

So, we obtain $m_1, \ldots, m_{v-1}$ by (1) and $\bar{n}$.

Then, $n$ satisfies the following equality:

$$n = \frac{a^{n} + k\beta^{m_0}\left(a^{v-1} + \sum_{r=1}^{v-1} a^{v-1-r} \beta^{m_r} \right)}{\beta^v - a^v}.$$  \hspace{1cm} (31)

**Proof.** This follows from Proposition 18, where we derive equation (31) from equation (30) by setting $C_{(a,b,k)}^{N}(n) = n$. \hfill \square

**Example 2.** Fix $\alpha = 7$ and $\beta = 5$. We consider that the integral loop is induced by $k = 282$ and $n = 109$. The mapping $C_{(7,5,282)}$ appears as

$$C_{(7,5,282)}(n) = \begin{cases} 7n + 282, & \text{if } n \equiv 4 \pmod{5}, \\ n \pmod{5}, & \text{if } n \equiv 0 \pmod{5}, \\ \text{HALT}, & \text{else}. \end{cases}$$  \hspace{1cm} (32)

We find that the trajectory and characteristic trajectory of 109 appears as

$$\{109, 1045, 209, 1745, 349, 2725, 545\}, \{1, 0, 1, 0, 1, 0, 0\}.$$  \hspace{1cm} (33)

**Proposition 20.** Fix $\alpha, \beta, k \in \mathbb{Z}_{>0}$ so that $\alpha, \beta$, and $k$ are pairwise coprimes. Let $t \in \{1, \ldots, \beta - 1\}$ satisfying $at + k \equiv 0 \pmod{\beta}$. Let $B \in \{0, 1\}$ such that $B = (\chi'_{(a,b,k)}(n))_{n \leq 0}$. We assume that the trajectory of $n$ is bounded above. Then, there exists some $n'$ contained in the trajectory of $n$ and the smallest $N$ in $\mathbb{Z}_{>0}$ such that $C_{(a,b,k)}^{N}(n') = n'$ if and only if $B$ is a rational 2-adic.

**Proof.** The proof is similar to the proof of Proposition 13. Here, we replace 3 with $\alpha$ and 2 with $\beta$. Since $\alpha$ and $\beta$ are coprimes, then $(\beta^v - \alpha^v)^{-1}$ does not vanish and the quotient $(\alpha^v \beta^v)^{-1}$ again has a denominator that expands with higher powers of $\beta$. Thus, we arrive at the same contradiction. \hfill \square

3.2. Multistate System with No Halting Condition

**Definition 21.** Fix $\alpha, \beta \in \mathbb{Z}_{>0}$ so that $\alpha$ and $\beta$ coprime. Let $\bar{k} = (k_1, \ldots, k_{\beta-1})$ so that for each $1 \leq i \leq \beta - 1$, $k_i \in \mathbb{Z}_{>0}$, $k_i$ is coprime to $\alpha$ and $\beta$, and $k_i \equiv i (\pmod{\beta})$. Let $C_{(a,b,k)}: \mathbb{Z}_{>0} \rightarrow \mathbb{Z}_{>0}$ be defined as

$$C_{(a,b,k)}(n) = \begin{cases} n + k_i, & \text{if } an + k_i \equiv 0 \pmod{\beta}, \\ \frac{n}{\beta}, & \text{if } n \equiv 0 \pmod{\beta}. \end{cases}$$  \hspace{1cm} (34)

Let $C_{(a,b,k)}(n) = n$. Furthermore, for $s \geq 0$, we denote function composition as $C_{(a,b,k)}^{s+1}(n) = C_{(a,b,k)}^s \circ C_{(a,b,k)}(n)$.

**Definition 22.** Fix $\alpha, \beta \in \mathbb{Z}_{>0}$ so that $\alpha$ and $\beta$ are coprimes. Let $\bar{k} = (k_1, \ldots, k_{\beta-1})$ so that for each $1 \leq i \leq \beta - 1$, $k_i \in \mathbb{Z}_{>0}$, $k_i$ is coprime to $\alpha$ and $\beta$, and $k_i \equiv i (\pmod{\beta})$. Let $\chi_{(a,b,k)}: \mathbb{Z}_{>0} \rightarrow \{0, 1, 2, \ldots, \beta - 1\}$ be defined as

$$\chi_{(a,b,k)}(n) = \begin{cases} i, & \text{if } -\alpha \times C_{(a,b,k)}(n) \equiv i (\pmod{\beta}), \\ 0, & \text{if } C_{(a,b,k)}(n) \equiv 0 (\pmod{\beta}). \end{cases}$$  \hspace{1cm} (35)

Let $\chi_{(a,b,k)}^0(n) \equiv n (\pmod{\beta})$. Furthermore, for $s \geq 0$, we denote function composition as $\chi_{(a,b,k)}^{s+1}(n) = \chi_{(a,b,k)}^s \circ \chi_{(a,b,k)}(n)$.

**Definition 23.** Fix $\alpha, \beta \in \mathbb{Z}_{>0}$ so that $\alpha$ and $\beta$ are coprimes. Let $\bar{k} = (k_1, \ldots, k_{\beta-1})$ so that for each $1 \leq i \leq \beta - 1$, $k_i \in \mathbb{Z}_{>0}$, $k_i$ is coprime to $\alpha$ and $\beta$, and $k_i \equiv i (\pmod{\beta})$. Fix $n \in \mathbb{Z}_{>0}$. Let $\{C_{(a,b,k)}^0(n), C_{(a,b,k)}^1(n), \ldots\}$ denote the trajectory of $n$. Let $\{C_{(a,b,k)}^0(n), C_{(a,b,k)}^1(n), \ldots\}$ denote the trajectory of $n$.

**Definition 24.** Fix $\alpha, \beta \in \mathbb{Z}_{>0}$ so that $\alpha$ and $\beta$ are coprimes. Let $\bar{k} = (k_1, \ldots, k_{\beta-1})$ so that for each $1 \leq i \leq \beta - 1$, $k_i \in \mathbb{Z}_{>0}$, $k_i$ is coprime to $\alpha$ and $\beta$, and $k_i \equiv i (\pmod{\beta})$. Fix $n \in \mathbb{Z}_{>0}$. Let
\[ \{\chi^0_{(a,\beta,\bar{k})}(n), \chi^1_{(a,\beta,\bar{k})}(n), \ldots\} \] denote the characteristic trajectory of \( n \).

Fix \( \beta \in \mathbb{Z}_{\geq 1} \). Let \( \{0, 1, 2, \ldots, \beta - 1\}^{**} \) denote the set of \( \beta \)-adic sequences of infinite length.

**Definition 25.** Fix \( \alpha, \beta \in \mathbb{Z}_{\geq 0} \) so that \( \alpha \) and \( \beta \) are coprimes. Let \( \bar{k} = (k_1, \ldots, k_{\beta - 1}) \) so that for each \( 1 \leq i \leq \beta - 1 \), \( k_i \in \mathbb{Z}_{>0} \), \( k_i \) is coprime to \( \alpha \) and \( \beta \), and \( k_i \equiv i \mod{\beta} \). Fix \( n \in \mathbb{Z}_{>0} \). We say \( B \in \{0, 1, 2, \ldots, \beta - 1\}^{**} \) is associated with the characteristic trajectory of \( n \) if \( B = (\chi^i_{(a,\beta,\bar{k})}(n))_{\geq 0} \).

**Definition 26.** Fix \( \alpha, \beta \in \mathbb{Z}_{>0} \) so that \( \alpha \) and \( \beta \) are coprimes. Let \( \bar{k} = (k_1, \ldots, k_{\beta - 1}) \) so that for each \( 1 \leq i \leq \beta - 1 \), \( k_i \in \mathbb{Z}_{>0} \), \( k_i \) is coprime to \( \alpha \) and \( \beta \), and \( k_i \equiv i \mod{\beta} \). Fix \( n \in \mathbb{Z}_{>0} \). Fix \( n \in \mathbb{Z}_{>0} \) and \( N \in \mathbb{Z}_{>0} \). We suppose further that \( n \) starts an integral loop of length \( N \). Let \( B \in \{0, 1, 2, \ldots, \beta - 1\}^{**} \) such that \( B = (\chi^i_{(a,\beta,\bar{k})}(n))_{\geq 0} \). Let \( \rho \) and \( \nu \) be the count of the number of zeros and nonzero coefficients in a single period of \( B \). Let \( i_j \) be the subindexing of \( i \) so that for all \( 0 \leq j \leq \nu - 1 \), we have \( \chi^i_{(a,\beta,\bar{k})}(n) \equiv 0 \mod{\beta} \). We call \( (i_j)^{**} \) the indexing sequence associated with \( n \).

**Proposition 27.** Fix \( \alpha, \beta \in \mathbb{Z}_{>0} \) so that \( \alpha \) and \( \beta \) are coprimes. Let \( \bar{k} = (k_1, \ldots, k_{\beta - 1}) \) so that for each \( 1 \leq i \leq \beta - 1 \), \( k_i \in \mathbb{Z}_{>0} \), \( k_i \) is coprime to \( \alpha \) and \( \beta \), and \( k_i \equiv i \mod{\beta} \). Fix \( N \in \mathbb{Z}_{>0} \). Let \( B \in \{0, 1, 2, \ldots, \beta - 1\}^{**} \) such that \( B = (\chi^i_{(a,\beta,\bar{k})}(n))_{\geq 0} \). Let \( \rho \) and \( \nu \) be the count of the number of zero and nonzero coefficients, respectively, in \( B \) for all \( i \) between zero and \( N - 1 \) inclusive. For \( 1 \leq j \leq \nu - 1 \), let \( m_j \) denote the number of zeros between the \((j - 1)th\) and \( jth\) nonzero coefficient. Let \( (i_j)^{**} \) be the indexing sequence associated with \( n \).

1. If \( an \equiv -i \mod{\beta} \), let \( m_0 = 0 \) and \( m_j \) be the remaining zeros after the last nonzero coefficient.
2. If \( n \equiv 0 \mod{\beta} \), let \( m_0 \) be the number of leading zeros. We observe that \( n = B^{m_0} \bar{n} \) for \( \bar{n} \equiv 0 \mod{\beta} \).

Then, \( n \) satisfies the following equality:

\[
C^N_{(a,\beta,\bar{k})}(n) = \frac{\alpha^\nu n + \beta^m \left( \sum_{r=1}^{\nu} \alpha^{\nu - r - 1} k_B^r \beta^{\sum r_i m_i} \right)}{\beta^\rho},
\]

where \( k_B \equiv B^i \mod{\beta} \) for the \( r \)-th nonzero coefficient in a single period of \( B \).

Because Proposition 27 is logically distinct from Proposition 8, it is necessary to restate the proof again.

**Proof.** Let us assume first that \( n \equiv 0 \mod{\beta} \), which implies that \( m_0 = 0 \). Therefore, equation (36) reduces to the form

\[
C^N_{(a,\beta,\bar{k})}(n) = \frac{\alpha^\nu n + \alpha^{\nu - 1} k_B^0 + \sum_{r=1}^{\nu - 1} \alpha^{\nu - r - 1} k_B^r \beta^{\sum r_i m_i}}{\beta^\rho}.
\]

By construction of \( \rho \) and \( \nu \), we make the substitution \( N = \rho + \nu \). We know that \( C^N_{(a,\beta,\bar{k})}(n) \) represents \( N \) compositions of the \( C_{(a,\beta,\bar{k})} \) mapping with starting integer \( n \). Therefore, we can advance the trajectory of \( n \) by one and subtract one step from \( N \) in the following manner:

\[
C^N_{(a,\beta,\bar{k})}(n) = \frac{\alpha^\nu n + \alpha^{\nu - 1} k_B^0 + \sum_{r=1}^{\nu - 1} \alpha^{\nu - r - 1} k_B^r \beta^{\sum r_i m_i}}{\beta^\rho}.
\]

We recall that \( an + k_B^0 \equiv 0 \mod{\beta} \). We can divide by \( \beta \), \( m_1 \) number of times yielding the following expression:

\[
C^N_{(a,\beta,\bar{k})}(n) = C_{(a,\beta,\bar{k})}^{\nu - m_1}(an + k_B^0) = \frac{\alpha^\nu n + k_B^0 \beta^{\nu - m_1} \left( \frac{\alpha n + k_B^0}{\beta^{m_1}} \right)}{\beta^\rho}.
\]

By hypothesis, this expression is again nonzero modulo \( \beta \). Therefore, we can apply the \( C_{(a,\beta,\bar{k})} \) map for one more step.

\[
C^N_{(a,\beta,\bar{k})}(n) = \frac{\alpha^\nu n + k_B^0 \beta^{\nu - m_1} \left( \frac{\alpha n + k_B^0}{\beta^{m_1}} \right)}{\beta^\rho}.
\]
Therefore, we can divide by $m_2$ powers of $\beta$. Following this, we can reduce the expression again

$$C^N_{(\alpha, \rho \beta, 0)} (n) = C^{\rho-m_1-m_2, \nu-r-2}_{(\alpha, \rho \beta, 0)} \circ C^{m_2}_{(\alpha, \rho \beta, 0)} \left( \frac{\alpha n + \beta^m k_{B^1}}{\beta^{m_1 + m_2}} \right) = C^{\rho-m_1-m_2, \nu-r-2}_{(\alpha, \rho \beta, 0)} \left( \frac{\alpha n + \alpha k_{B^1} + \beta^{m_1} k_{B^1}}{\beta^{m_1 + m_2}} \right). \quad (41)$$

We proceed to follow this process inductively until the length of the entire finite subsequence of $B$ is exhausted.

Starting from equation (36), we find by taking $m_0$ steps, we have

$$C^N_{(\alpha, \rho \beta, 0)} (n) = C^{\rho + \nu}_{(\alpha, \rho \beta, 0)} (n) = C^{\rho-m_1, \nu}_{(\alpha, \rho \beta, 0)} \circ C^{m_0}_{(\alpha, \rho \beta, 0)} \left( \frac{n}{\beta^{m_0}} \right). \quad (43)$$

Recalling by hypothesis $n = \beta^{m_0} n$ implies $n/\beta^{m_0} = \tilde{n}$. Substituting this quantity in equation (43) yields

$$C^N_{(\alpha, \rho \beta, 0)} (n) = C^{\rho-m_1+\nu}_{(\alpha, \rho \beta, 0)} \left( \frac{n}{\beta^{m_0}} \right) = C^{\rho-m_1+\nu}_{(\alpha, \rho \beta, 0)} (\tilde{n}). \quad (44)$$

We then consider the previous argument starting with $\tilde{n}$, $p = \rho - m_0$, and $\nu$ unchanged.

On the other hand, we suppose that $n \equiv 0 \pmod{\beta}$. Then, $m_0 > 0$, and by hypothesis, $n = \beta^{m_0} \tilde{n}$ for $\tilde{n} \equiv 0 \pmod{\beta}$. Starting from equation (36), we find by taking $m_0$ steps, we have

$$C^N_{(\alpha, \rho \beta, 0)} (n) = C^{\rho+m_0}_{(\alpha, \rho \beta, 0)} \left( \frac{n}{\beta^{m_0}} \right) = C^{\rho-\nu}_{(\alpha, \rho \beta, 0)} \left( \frac{n}{\beta^{m_0}} \right). \quad (45)$$

Therefore, we find that

$$C^N_{(\alpha, \rho \beta, 0)} (n) = C^{\rho-m_1}_{(\alpha, \rho \beta, 0)} (\tilde{n}) = \frac{\alpha^\nu n + \beta^{m_0} \left( \frac{\alpha^{\nu-1} k_{B^1} + \sum_{r=1}^{\nu-1} \alpha^{\nu-1-r} k_{B^1} \beta^{r} \sum'_{m_j} }{\beta^{m_0}} \right)}{\beta^p}. \quad (46)$$
Example 3. Fix $\alpha = 7$, $\beta = 4$, $k_1 = 1$, $k_2 = 2$, and $k_3 = 3$. The mapping $C_{(7,4,3)}$ appears as

$$C_{(7,4,3)}(n) = \begin{cases} 
7n + 1, & \text{if } n \equiv 1 \pmod{4}, \\
7n + 2, & \text{if } n \equiv 2 \pmod{4}, \\
7n + 3, & \text{if } n \equiv 3 \pmod{4}, \\
n, & \text{if } n \equiv 0 \pmod{4}.
\end{cases}$$

(47)

Under the same hypothesis, we consider the first nine steps of the characteristic trajectory induced by $n = 3713$.

$$\{1, 0, 2, 0, 0, 3, 0, 0, 0\}.$$  
(48)

We verify equation (36) for $C_{(7,4,3)}(3713)$.

Proposition 28. Fix $\alpha, \beta \in \mathbb{Z}_{>0}$ so that $\alpha$ and $\beta$ are coprimes. Let $k = (k_1, \ldots, k_{\beta-1})$ so that for each $1 \leq i \leq \beta - 1$, $k_i \in \mathbb{Z}_{>0}$, $k_i$ is coprime to $\alpha$ and $\beta$, and $k_i \equiv i \pmod{\beta}$. Fix $N \in \mathbb{Z}_{>0}$. Let $B \in \{0, 1, 2, \ldots, \beta - 1\}$ such that $B = (\chi^i_{(\alpha, \beta, k)}(n))_{i=0}$. We suppose that $N$ is the smallest positive integer such that $C_{(\alpha, \beta, k)}^N(n) = n$. Let $\rho$ and $\nu$ be the count of the number of zeros and ones, respectively, in $B$ for all $i$ between $0$ and $N$ inclusive. For $1 \leq j \leq \nu - 1$, let $m_j$ denote the number of zeros between the $(j - 1)$th and $j$th nonzero coefficient. Let $(i)_{j=0}^{\nu-1}$ be the indexing sequence associated with $n$.

1. If $a_n \equiv -i \pmod{\beta}$, let $m_i = 0$ and $m_{i+1}$ be the remaining zeros after the last nonzero coefficient.

2. If $n \equiv 0 \pmod{\beta}$, let $m_i$ be the number of leading zeros. We observe that $n = \beta^{m_i}n$ for $\bar{n} \equiv 0 \pmod{\beta}$. So, we obtain $m_1, \ldots, m_{\nu-1}$ by (1) and $\bar{n}$.

Then, $n$ satisfies the following equality:

$$n = \beta^{m_i} \left( \sum_{j=0}^{\nu-1} \frac{\alpha^{-1} k_{B_j} + \sum_{r=1}^{\nu} \alpha^{-1} \rho \sum_{j=1}^{\nu} \beta \sum_{j=1}^{\nu} m_j}{\beta^\nu - \alpha} \right).$$

(50)

Proof. Equation (50) can be derived from equation (36) by setting $C_{(\alpha, \beta, k)}^N(n) = n$.

Example 4. Fix $\alpha = 5$ and $\beta = 3$. We consider the integral loop induced by $k_1 = 19558$, $k_2 = 39116$, and $n = 358$. The mapping $C_{(5,3,3)}$ appears as

$$C_{(5,3,3)}(n) = \begin{cases} 
5n + 19558, & \text{if } n \equiv 1 \pmod{3}, \\
5n + 39116, & \text{if } n \equiv 2 \pmod{3}, \\
n, & \text{if } n \equiv 0 \pmod{3}.
\end{cases}$$

(51)

We find that the trajectory and characteristic trajectory of 358 appear as

$$\{358, 21348, 7116, 2372, 50976, 16992, 5664, 1888, 28998, 9666, 3222, 1074\},$$

$$\{1, 0, 0, 2, 0, 0, 0, 1, 0, 0, 0, 0\}.$$  
(52)
We suppose first that \( \bar{\beta}/\alpha > 1 \). Following from equation (55), we distribute the first term, yielding the following:

\[
x_0 = \left( \frac{\beta'}{\alpha'} \right)^n \left( x_n - \left( \frac{\sigma}{\beta' - \alpha'} \right) \right) + \frac{\sigma}{\beta' - \alpha'}.
\]  

(57)

Then, there exists an \( N \) such that for all \( n > N \),

\( x_n = \sigma/\bar{\beta} - \alpha' \). We find a new \( x_N \), which maybe different from \( x_0 \) such that \( x_N \) generates an integral loop coinciding with the original rational loop.

If conversely we suppose \( \bar{\beta}/\alpha < 1 \), then we simply reverse equation (55) to solve for \( x_n \) in terms of \( x_0 \):  

\[
x_n = \left( \frac{\alpha''}{\beta''} \right)^n \left( x_0 - \left( \frac{\sigma}{\beta'' - \alpha''} \right) \right) + \frac{\sigma}{\beta'' - \alpha''}.
\]  

(58)

Suppose first that \( x_0 = \sigma/\bar{\beta} - \alpha' \), then it follows that \( x_1 = \sigma/\bar{\beta} - \alpha' \). This equality is true for all \( x \), and thus, we have an integral loop. So, we assume instead that \( x_0 \neq \sigma/\bar{\beta} \). Then, we can write equation (56) in the form of a ratio exhibited in equation:

\[
\begin{align*}
x_n - \sigma/\bar{\beta} - \alpha' &= \left( \frac{\alpha''}{\beta''} \right)^n, \\
x_0 - \sigma/\bar{\beta} - \alpha' &= \left( \frac{\alpha''}{\beta''} \right)^n.
\end{align*}
\]  

(59)

However, we recall that \( x_0 \) and \( \sigma/\bar{\beta} - \alpha' \) are both fixed values. Thus, the left hand side has a fixed denominator. However, as the right hand side is the quotient of two coprime integers, the denominator expands with irreducible powers of two. If \( x_n \) is a trajectory of integers, then there would be some index \( N \) of which the denominator on the right hand side would be larger than the left hand side. This would be a contradiction. Finally, as \( \bar{\nu} = \ln(\bar{\beta})/\ln(\alpha)\bar{\rho} \), as a irrational ratio cannot be expressed with a finite \( \beta \)-adic sequence. Thus, we have shown that no rational cycle apart from an integral loop exists for any \( C_{(a,b,\bar{\beta})} \) mapping. 

**Example 5.** Fix \( \alpha = 5, \beta = 3, k_1 = 1, \) and \( k_2 = 155 \). The mapping \( C_{(5,3,\bar{\beta})} \) appears as

\[
C_{(5,3,\bar{\beta})} (n) = \begin{cases} 
5n + 1, & \text{ if } n \equiv 1 \pmod{3}, \\
5n + 155, & \text{ if } n \equiv 2 \pmod{3}, \\
n/3 & \text{ if } n \equiv 0 \pmod{3}.
\end{cases}
\]  

(60)

We find that the trajectory and characteristic trajectory starting at \( n = 25 \) appears as

\[
\{25, 126, 42, 14, 225, 75, \ldots\},
\]

\[
\{1, 0, 0, 2, 0, 0, \ldots\}.
\]  

(61)

That is to say, 25 starts an integral loop which induces a rational 3-adic sequence. Let us attempt to construct a trajectory, different from the integral loop starting at 25, based on the 3-adic sequence \( \{1, 0, 0, 2, 0, 0, \ldots\} \). We will proceed inductively by considering the smallest starting
integer corresponding to $s$ repetitions of the finite sequence (see Table 1) $\{1, 0, 0, 2, 0, 0, 0\}$.

We find that the sequence of starting integers $\{n_s\}_{s \geq 1}$ diverges. We conclude that the only trajectory corresponding to the rational 3-adic sequence $\{1, 0, 0, 2, 0, 0, 0, \ldots\}$ for all iterations is the integral loop starting at $n = 25$.

### 4. Conclusion

We have shown that the characteristic trajectory of a starting integer is eventually periodic if and only if the trajectory eventually enters an integral loop. This is not a new idea, but the proof presented here is new. The proof contained in Corollary 2.1a [7] employs a direct proof comparing parity vectors (characteristic trajectories). That proof would also apply to any two state system with halting condition (see Section 3.1). In that case, the nonzero symbol $t$ is replaced with one. The proof contained in Proposition 4 [8] demonstrates that if a characteristic trajectory is terminally periodic, then it represents a 2-adic number. The proof here does not require detailed knowledge of the 2-adics. Apart from the previous two proofs, this new proof demonstrates the claim is 2-adic invariant. In this way, we have presented a generalization of a known result.
