#### Abstract

This paper is devoted to develop a new 8-node higher-order hybrid stress element (QH8) for free vibration and buckling analysis based on the Mindlin/Reissner plate theory. In particular, a simple explicit expression of a refine method with an adjustable constant is introduced to improve the accuracy of the analysis. A combined mass matrix for natural frequency analysis and a combined geometric stiffness matrix for buckling analysis are obtained using the refined method. It is noted that numerical examples are presented to show the validity and efficiency of the present element for free vibration and buckling analysis of plates. Furthermore, satisfactory accuracy for thin and moderately thick plates is obtained and it is free from shear locking for thin plate analysis and can pass the nonzero shear stress patch test.

## 1. Introduction

It is well-known that the finite element method for free vibration and buckling analysis of plates is highly significant in civil, mechanical, and aerospace engineering applications. The patch test [1], which can be used to examine the convergence of the element and construct a convergence element, has been seen as a criterion for assessing the convergence of the finite element for a long time.

The potential energy function of Mindlin plate element contains the displacements and the first-order derivatives of the displacements. According to the $C^{0}$ continuity condition, it is quite easy to establish interpolation functions of deflection and rotation. Historically, the displacement-based approach was the first attempt in the formulation of effective Mindlin plate bending elements [2]. However, as we all know, the original displacement element tends to cause the shearlocking phenomenon which induces overstiffness as the plate becomes progressively thinner for low-order interpolation polynomials in the Mindlin elements. During this time, the convergence characteristics of the Mindlin plate elements were performed by means of numerical computation of pure
bending and pure torsion [3, 4]. In order to avoid shear locking, various numerical techniques and effective modifications have been proposed and tested, such as the reduced integration and selective reduced integration schemes proposed by Zienkiewicz et al. [5], Pugh et al. [6], and Hughes et al. [7]; assumed natural strain method introduced by Hughes and Tezduyar [8]. It is acknowledged that the methods of reduced integration and selective integration are efficient approaches to prevent the appearance of the shear-locking phenomenon. However, it is found that such elements often exhibit extra zero-energy modes and also produce oscillatory results for some problems. Moreover, these solutions are not applicable to very thin plate; the thickness/span ratio of the plate is about restricted to $10^{-6}$.

Later, Belytschko et al. [9] proposed the stabilization procedure to remove the zero-energy modes by perturbing the stiffness. In addition, several efficient 9-DOF triangular elements based on the discrete Kirchhoff constraint and the equilibrium conditions were developed by Batoz et al. [10, 11]. These elements can eliminate locking phenomenon and converge towards the discrete Kirchhoff plate bending elements when the thickness of the plate is very thin. On the other
hand, no element is free of shear locking in theory. Bathe et al. [12] introduced the MITC element and proposed strain energy patch test function to evaluate the convergence. Based on Timoshenko beam function, Soh et al. [13] proposed a triangular 9-DOF plate bending element which can be employed to analyze very thin plate (the thickness/span ratio of the plate is about $10^{-11}$ ). Soon, Soh et al. [14] introduced a quadrilateral 12-DOF plate bending element. At this time, the progressively thinner plate which has the thickness/span ratio $10^{-20}$ can be calculated. Wanji and Cheung [15] proposed the zero shear stress patch test functions. It is apparent that this patch test is more rigorous than the patch test using numerical computation of pure bending and pure torsion of a smallscale plate. Then, elements such as RDKQM [15], RDKTM [16], AC-MQ4 [17], and QC-P4 [18] that can pass the above patch test functions were proposed, indicating that the shearlocking problem is solved. All these elements can be used to solve the extremely thin plate problem (the thickness/span ratio of the plate can reach to $10^{-30}$ ). In other words, these elements can accurately converge to thin plate finite element solution.

Chen proposed the enhanced patch test [19] and presented the zero shear deformation patch test and nonzero constant shear deformation test functions of Mindlin plate [20]. Current patch test for Mindlin plate only satisfies the zero shear deformation condition. The patch test of nonzero constant shear for Mindlin plate problem cannot be performed. The convergence test should be performed during the process of developing finite element method. Only passing the rigorous nonzero constant shear stress patch test, the convergence can be completely guaranteed. The programs of this commercial software have no proof of convergence. The enhanced patch test is stronger than the original test; the original constant stress patch test is just a special case of it. This paper is devoted to establish Mindlin plate element which can pass the strict constant shear patch test.

Different from the classical Timoshenko beam function, Jelenić and Papa [21] proposed a new arbitrary-order Timoshenko beam function in 2011. So far, it is the only function which can be used to construct the functions of nonzero constant shear patch test for thick beam element. Since beam function can be regarded as a function on the boundary, the adopted hybrid stress method just requires the boundary function rather compared to the domain function. Because this beam function is arbitrary order, thus it has high enough order to perform the nonzero constant shear stress patch test. Since a complete cubic polynomial for the element function to pass the constant shear stress patch test is required, it was used to develop the higher-order hybrid stress triangular Mindlin plate bending element named TH6 [22] and quadrilateral Mindlin plate bending element named QH8 [23]. The results of static analysis have proved that the TH6 element and QH8 element can pass the rigorous nonzero constant shear stress patch test and its accuracy is quite high. Only passing the rigorous nonzero constant shear stress patch test, the convergence can be completely guaranteed.

The purpose of this paper is to develop an 8-node Mindlin plate bending finite element for free vibration analysis and buckling analysis within an assumed stress formulation,
whose main feature is that passing the rigorous nonzero constant shear stress enhanced patch test. To achieve this objective, the following steps have been taken. The first step concerns the choice of the variational framework with the adoption of complementary energy principle. Then boundary displacement interpolation function is established based on the new arbitrary-order Timoshenko beam function. Since the choice of the stress approximation is a crucial issue in developing reliable hybrid finite element, selecting a suitable stress approximation which satisfies the plate equilibrium equations is not trivial. In order to improve the performance of the constructed element, a refined mass matrix for calculation of the natural frequency and a refined geometric stiffness matrix for buckling analysis are developed by using refined element method [24-26].

## 2. A Brief Introduction of the Higher-Order Hybrid Stress Quadrilateral Mindlin Plate Bending Element

2.1. Fundamental Equations of Mindlin Plate. Consider a plate referred to as a Cartesian coordinate frame ( $o, x, y, z$ ), with the origin $o$ on the mid-surface $\Omega$ and the $z$-axis in the thickness direction, $-h / 2 \leq z \leq h / 2$, where $h$ is the plate thickness. Let $\partial \Omega$ be the boundary of $\Omega$. The ReissnerMindlin theory, that is, the first-order shear deformable theory, is employed. Thus it is assumed that

$$
\begin{align*}
& u(x, y, z)=z \theta_{y} \\
& v(x, y, z)=-z \theta_{x}  \tag{1}\\
& w(x, y, z)=w(x, y)
\end{align*}
$$

where $u, v, w$ are displacements along the $x$-, $y$-, and $z$-axes, respectively, $\theta_{x}, \theta_{y}$ are the rotations of the transverse normal about the $x$ - and $y$-axes, and $w$ is the transverse displacement field.

The geometric equations can be written as follows:

$$
\begin{align*}
& \boldsymbol{\chi}=\mathbf{B}_{b} \boldsymbol{\theta}, \\
& \boldsymbol{\gamma}=\mathbf{B}_{s} w+\widehat{\mathbf{I}} \boldsymbol{\theta} \tag{2}
\end{align*}
$$

where $\boldsymbol{\theta}, \boldsymbol{\chi}$, and $\boldsymbol{\gamma}$ are, respectively, the rotations, the curvatures, and the shear strains:

$$
\begin{align*}
& \boldsymbol{\theta}=\left[\begin{array}{l}
\theta_{x} \\
\theta_{y}
\end{array}\right], \\
& \boldsymbol{\chi}=\left[\begin{array}{l}
\chi_{x} \\
\chi_{y} \\
\chi_{x y}
\end{array}\right],  \tag{3}\\
& \boldsymbol{\gamma}=\left[\begin{array}{l}
\gamma_{x z} \\
\gamma_{y z}
\end{array}\right],
\end{align*}
$$

and operators $\mathbf{B}_{b}, \mathbf{B}_{s}$ and $\widehat{\mathbf{I}}$ are given by the following:

$$
\begin{align*}
\mathbf{B}_{b} & =\left[\begin{array}{cc}
0 & \frac{\partial}{\partial x} \\
\frac{-\partial}{\partial y} & 0 \\
\frac{-\partial}{\partial x} & \frac{\partial}{\partial y}
\end{array}\right] \\
\mathbf{B}_{s} & =\left[\begin{array}{c}
\frac{\partial}{\partial x} \\
\frac{\partial}{\partial y}
\end{array}\right]  \tag{4}\\
\widehat{\mathbf{I}} & =\left[\begin{array}{cc}
0 & 1 \\
-1 & 0
\end{array}\right]
\end{align*}
$$

The equilibrium equations can be obtained from the strain energy in the following form:

$$
\begin{align*}
-\mathbf{B}_{b}^{T} \mathbf{M}+\widehat{\mathbf{I}}^{T} \mathbf{S} & =\mathbf{0}, \\
\mathbf{B}_{s}^{T} \mathbf{S} & =\mathbf{0}, \tag{5}
\end{align*}
$$

where vectors $\mathbf{M}$ and $\mathbf{S}$ are, respectively, the moment and shear resultants:

$$
\begin{align*}
\mathbf{M} & =\left[\begin{array}{l}
M_{x} \\
M_{y} \\
M_{x y}
\end{array}\right],  \tag{6}\\
\mathbf{S} & =\left[\begin{array}{l}
S_{x} \\
S_{y}
\end{array}\right] .
\end{align*}
$$

The boundary forces can be written as follows:

$$
\begin{align*}
& \mathbf{T}=\mathbf{R}\left[\begin{array}{c}
\mathbf{M} \\
\mathbf{S}
\end{array}\right], \\
& \mathbf{R}=\left[\begin{array}{ccccc}
0 & -\sin \alpha & -\cos \alpha & 0 & 0 \\
\cos \alpha & 0 & \sin \alpha & 0 & 0 \\
0 & 0 & 0 & \cos \alpha & \sin \alpha
\end{array}\right], \tag{7}
\end{align*}
$$

where $\alpha$ is the angle between the normal of edge and the local $x$-axis of element.

For a linearly elastic material, the constitutive equations can be written as follows:

$$
\begin{align*}
\mathbf{M} & =\mathrm{D}_{b} \chi,  \tag{8}\\
\mathbf{S} & =\mathrm{D}_{s} \gamma
\end{align*}
$$

where $\mathbf{D}_{b}$ and $\mathbf{D}_{s}$ are the elasticity matrices of bending and transverse shear moduli. In the isotropic case, the elasticity matrices specialize as

$$
\begin{align*}
& \mathbf{D}_{b}=\frac{E h^{3}}{12\left(1-\mu^{2}\right)}\left[\begin{array}{ccc}
1 & \mu & 0 \\
\mu & 1 & 0 \\
0 & 0 & \frac{1-\mu}{2}
\end{array}\right]  \tag{9}\\
& \mathbf{D}_{s}=\kappa G h\left[\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right]
\end{align*}
$$

where $E$ is Young's modulus, $G$ the shear modulus, $\mu$ Poisson's ration, and $\kappa=5 / 6$ a correction factor to account for nonuniform distribution of shear stresses through the thickness.
2.2. Hybrid Stress Formulation. Based on a modified complementary energy principle, the assumed stress hybrid formulation pioneered by Pian [28, 29] can be used to avoid the difficulty of forming the displacement field interpolation functions, in particular, after the work of Malkus and Hughes [30] on the equivalence between reduced integration displacements and mixed/hybrid stress models. This kind of approach based on hybrid stress element method became very useful in recent years [31-36]. A good number of effective elements which are free from shear locking have been developed by authors such as Tong [37], Bathe and Dvorkin [38], Ayad et al. [39], Brasile [40], and Li et al. [22, 23]. The higher-order hybrid stress quadrilateral Mindlin plate bending element QH8 is based on complementary energy principle. The complementary energy principle can be written as

$$
\begin{equation*}
\Pi_{e}=\int_{\Omega_{e}} \frac{1}{2} \boldsymbol{\sigma}^{T} \mathbf{D}^{-1} \boldsymbol{\sigma} d \Omega-\int_{\partial \Omega_{e}} \mathbf{T}^{T} \overline{\mathbf{u}} d S \tag{10}
\end{equation*}
$$

where $\boldsymbol{\sigma}$ is the stress vector, $\mathbf{D}$ is the elasticity matrices, $\mathbf{T}$ is the vector of boundary force, $\overline{\mathbf{u}}=\left[\begin{array}{lll}\widetilde{w} & \widetilde{\theta}_{x} & \widetilde{\theta}_{y}\end{array}\right]^{T}$ is the boundary displacement vector, $\widetilde{w}$ is the transverse displacement, and $\widetilde{\theta}_{x}$, $\widetilde{\theta}_{y}$ are the rotations of the transverse normal about the $x$ - and $y$-axes.

The approximation for stress and boundary displacements can now be incorporated in the functional. The stress field is described in the interior of the element as follows:

$$
\left[\begin{array}{lllll}
M_{x} & M_{y} & M_{x y} & S_{x} & S_{y} \tag{11}
\end{array}\right]^{T}=\mathbf{P} \boldsymbol{\beta}
$$

where $\mathbf{P}$ is matrix of stress interpolation functions and $\boldsymbol{\beta}$ is the unknown stress parameters.

The boundary force $\mathbf{T}$ can be represented as follows:

$$
\begin{equation*}
\mathrm{T}=\mathbf{R P} \boldsymbol{\beta} \tag{12}
\end{equation*}
$$

where $\mathbf{R}$ is the combination of direction cosine for the boundary normal.

The boundary displacement field is described by

$$
\overline{\mathbf{u}}=\left[\begin{array}{lll}
\widetilde{w} & \tilde{\theta}_{x} & \widetilde{\theta}_{y} \tag{13}
\end{array}\right]^{T}=\mathbf{L} \mathbf{q}
$$

where $\mathbf{L}$ are interpolation functions and $\mathbf{q}$ is nodal displacement parameters.

Substituting the stress equation (11), boundary force equation (12), and displacement approximations equation (13) into the functional (10),

$$
\begin{equation*}
\Pi_{e}=\frac{1}{2} \boldsymbol{\beta}^{T} \mathbf{H} \boldsymbol{\beta}-\boldsymbol{\beta}^{T} \mathbf{G q}, \tag{14}
\end{equation*}
$$

where

$$
\begin{align*}
& \mathbf{H}=\int_{\Omega_{e}} \mathbf{P}^{T} \mathbf{D}^{-1} \mathbf{P} d \Omega  \tag{15}\\
& \mathbf{G}=\int_{\partial \Omega_{e}}(\mathbf{R P})^{T} \mathbf{L} d S
\end{align*}
$$

The form of (15) is directly amenable to numerical integration (i.e., Gauss quadrature).

Then the internal strain energy can be expressed as follows:

$$
\begin{equation*}
U=\int_{\Omega_{e}} \frac{1}{2} \boldsymbol{\sigma}^{T} \mathbf{D}^{-1} \boldsymbol{\sigma} d \Omega=\frac{1}{2} \boldsymbol{\beta}^{T} \mathbf{H} \boldsymbol{\beta} . \tag{16}
\end{equation*}
$$

By means of $\partial \Pi_{e} / \partial \boldsymbol{\beta}$, we obtained

$$
\begin{equation*}
\mathbf{H} \boldsymbol{\beta}=\mathbf{G q} . \tag{17}
\end{equation*}
$$

Consequently,

$$
\begin{equation*}
\boldsymbol{\beta}=\mathbf{H}^{-1} \mathbf{G q} . \tag{18}
\end{equation*}
$$

Substitution of $\boldsymbol{\beta}$ in (16), the internal strain energy reduces to

$$
\begin{equation*}
U=\frac{1}{2} \mathbf{q}^{T} \mathbf{G}^{T} \mathbf{H}^{-1} \mathbf{G q} . \tag{19}
\end{equation*}
$$

Compared with $U=(1 / 2) \mathbf{q}^{T} \mathbf{K q}$, the element stiffness matrix can be taken as

$$
\begin{equation*}
\mathbf{K}=\mathbf{G}^{T} \mathbf{H}^{-1} \mathbf{G} \tag{20}
\end{equation*}
$$

The solution of the system yields the unknown nodal displacement $\mathbf{q}$. After $\mathbf{q}$ is determined, element stress or internal forces can be recovered by use of (18) and (11). Thus

$$
\begin{equation*}
\sigma=\mathbf{P H}^{-1} \mathbf{G q} . \tag{21}
\end{equation*}
$$

2.3. The Displacement Interpolation Function of QH8 Element. Euler-Bernoulli beam function has been successfully employed in the construction of refined thin plate elements. It is well-known that when constructing Mindlin plate element, both thick and thin plates should be taken into account, and it is necessary to eliminate shear-locking phenomenon. To seek out such element displacement function is definitely very difficult. Note that a closed form solution for both thick and thin beams exists in the form of the Timoshenko beam function, and it is possible to use it to derive more efficient Mindlin plate elements [41]. However, the use of Timoshenko beam function is capable of solving the problem of shear

Figure 1: Eight-node quadrilateral plate element.
locking; it cannot solve the problem of passing the nonzero constant shear patch test. This problem has not resolved for many years. In 2011, Jelenić and Papa [21] presented a new arbitrary-order Timoshenko beam function as follows:

$$
\begin{align*}
& w=\sum_{i=1}^{n} I_{i} w_{i}-\frac{L}{n} \prod_{j=1}^{n} N_{j} \sum_{i=1}^{n}(-1)^{i-1}\binom{n-1}{i-1} \theta_{i}  \tag{22}\\
& \theta=\sum_{i=1}^{n} I_{i} \theta_{i},
\end{align*}
$$

where $L$ is the beam length, $w_{i}$ and $\theta_{i}$ are the values of the displacements and the rotations at the $n$ nodes equidistantly spaced between the beam ends, $I_{i}$ are the standard Lagrange polynomials of order $n-1$, and $N_{j}=x / L$ for $j=1$ and $N_{j}=1-(n-1) /(j-1)(x / L)$ otherwise, in which $x$ is the coordinate along the beam.

An 8-node quadrilateral element was designed as given in Figure 1. If any quadrilateral side is taken as a beam element, take the 1-2 boundary as example and the deflection $\widetilde{w}$ and rotations $\widetilde{\theta}_{x}, \widetilde{\theta}_{y}$ can be derived as follows:

$$
\begin{align*}
\widetilde{w} & =I_{1} w_{1}+I_{2} w_{2}+I_{5} w_{5}-I_{0} L\left(-\theta_{n, 1}+2 \theta_{n, 5}-\theta_{n, 2}\right) \\
& =I_{1} w_{1}+I_{2} w_{2}+I_{5} w_{5}-I_{0}\left[\left(-\theta_{x, 1}+2 \theta_{x, 5}-\theta_{x, 2}\right) b\right. \\
& \left.+\left(-\theta_{y, 1}+2 \theta_{y, 5}-\theta_{y, 2}\right) a\right]  \tag{23}\\
\widetilde{\theta}_{x} & =I_{1} \theta_{x, 1}+I_{2} \theta_{x, 2}+I_{5} \theta_{x, 5} \\
\widetilde{\theta}_{y} & =I_{1} \theta_{y, 1}+I_{2} \theta_{y, 2}+I_{5} \theta_{y, 5},
\end{align*}
$$

where $I_{1}=L_{1}\left(2 L_{1}-1\right), I_{2}=L_{2}\left(2 L_{2}-1\right), I_{5}=4 L_{1} L_{2}, I_{0}=$ $(1 / 3) L_{1} L_{2}\left(L_{2}-L_{1}\right), L_{1}=1-s / L, L_{2}=s / L, L$ is the length of $1-2$ boundary and $s$ is the coordinate along the 1-2 edge.

The displacement components $\overline{\mathbf{u}}$ along the 1-2 boundary was given as follows:

$$
\overline{\mathbf{u}}_{1-2}=\left[\begin{array}{lll}
\widetilde{w} & \widetilde{\theta}_{x} & \widetilde{\theta}_{y} \tag{24}
\end{array}\right]^{T}=\mathbf{L}_{1-2} \mathbf{q}_{1-2}
$$

where

$$
\begin{align*}
& \mathbf{L}_{1-2} \\
& =\left[\begin{array}{ccccccccc}
I_{1} & I_{0} b & I_{0} a & I_{2} & I_{0} b & I_{0} a & I_{5} & -2 I_{0} b & -2 I_{0} a \\
0 & I_{1} & 0 & 0 & I_{2} & 0 & 0 & I_{5} & 0 \\
0 & 0 & I_{1} & 0 & 0 & I_{2} & 0 & 0 & I_{5}
\end{array}\right] \tag{25}
\end{align*}
$$

and $\mathbf{q}_{1-2}=\left[\begin{array}{lll}\mathbf{q}_{1} & \mathbf{q}_{2} & \mathbf{q}_{5}\end{array}\right]^{T}, \mathbf{q}_{i}=\left[\begin{array}{lll}w_{i} & \theta_{x i} & \theta_{y i}\end{array}\right]^{T}(i=1,2,5)$.
2.4. Assumed Stresses. In this section, a strategy to select the stress approximation in a rational way is presented. In practice, initial polynomials are usually assumed for the stress after which the equilibrium equations are applied to these polynomials yielding relations between the $\beta$ 's and ultimately the final form of $\mathbf{P}$. The number of stress parameters, which is the number of columns in $\mathbf{P}$, must be at least equal to the number of degrees of freedom of the element less the number of degrees of freedom necessary to prevent rigid body motion.

In a series of studies of hybrid element, there is a general consensus on the selection of $\boldsymbol{\beta}$ parameter that is $N(\boldsymbol{\beta}) \geq$ $n_{d}-n_{r}$, while the optimal selection is $N(\boldsymbol{\beta})=n_{d}-n_{r}$, $n_{d}, n_{r}$ being the degrees of freedom of the element and the number of allowed rigid body motions, respectively. The element has 24 DOF; therefore, a stress field with at least 21 parameters is needed to describe the stress field and without spurious zero-energy modes. Numerical results show that the stiffness matrix has spurious zero-energy modes and converges slowly when $N(\boldsymbol{\beta})=21$. The finds that gradually increasing the number of $\left\{\beta_{i}\right\}$ until $N(\boldsymbol{\beta})=28$, there is a proper rank for the stiffness matrix and the absence of spurious zero-energy modes. Moreover, the calculation results are accurate and converged faster. And they are better if the number of $\left\{\beta_{i}\right\}$ reaches $N_{b}=39$ (complete quartic polynomial). Numerical experimentations [23] indicate that this 39-parameter selection of stress field is somewhat more accurate and has no spurious zero-energy modes. For this reason, $39 \beta$ are chosen as the assumed stress field.

The stress field is described in the interior of the element as follows:

$$
\left[\begin{array}{lllll}
M_{x} & M_{y} & M_{x y} & Q_{x} & Q_{y} \tag{26}
\end{array}\right]^{T}=\mathbf{P} \boldsymbol{\beta}
$$

where $\mathbf{P}$ is matrix of stress interpolation functions as shown in Table 1, and $\boldsymbol{\beta}$ is the stress parameters.

From (12), the boundary force $\mathbf{T}$ can be expressed as

$$
\begin{equation*}
\mathrm{T}=\mathbf{R P} \boldsymbol{\beta} \tag{27}
\end{equation*}
$$

Then, along the boundary 1-2, G can be obtained:

$$
\begin{equation*}
\mathbf{G}_{12}=\int_{\partial \Omega(1-2)}(\mathbf{R P})^{T} \mathbf{L}_{1-2} d s \tag{28}
\end{equation*}
$$

Figure 2: Mass lumping at the nodes.

Similarly, along the other boundaries, $\mathbf{G}_{23}, \mathrm{G}_{34}, \mathrm{G}_{41}$ can also be obtained by cyclic permutation.

## 3. The Refined Mass Matrix and Refined Geometric Stiffness Matrix for Vibration and Buckling Analysis of Plates

A refined method has been developed by the authors [24,25], and the method has been applied to develop 12-DOF [15], 9DOF [16], and 5-DOF [49] Mindlin elements and so forth. This method is applied here to formulate QH8-RCV with a mass matrix called refined mass matrix for calculation of the natural frequency and in the same way QH8-R with a refined geometric stiffness matrix for buckling analysis.
3.1. Free Vibration Analysis. It is well-known that the equation of free vibration can be expressed as follows:

$$
\begin{equation*}
\left(\mathbf{K}-\omega^{2} \mathbf{M}\right) \Phi=\mathbf{0} \tag{29}
\end{equation*}
$$

where $\mathbf{K}$ is the global stiffness matrix, $\mathbf{M}$ is the global mass matrix, $\Phi$ is the mode shapes, and $\omega$ is the natural frequencies.

The major complication of the standard eigenvalue problem introduced by the finite element method is the mass matrix M. Two types of the mass matrix are of interest: lumped mass matrix and consistent mass matrix.
3.1.1. The Lumped Mass Matrix. To use the diagonal elements of the consistent mass matrix and form a diagonal matrix by scaling these entries so that the total mass of the element is conserved, the method listed by Hinton et al. [50] produces excellent results. For the cases of eight-node elements, the method leads to the lumping schemes shown in Figure 2. The figures at each node show the proportion of the total mass at that node. For convenience, the total mass has been chosen to be 36. Therefore the following lumped mass matrix will be used to calculate the natural frequencies of plates:

Table 1: Assumed stress function.

| i | $M_{x}$ | $M_{y}$ | $M_{x y}$ | $Q_{x}$ | $Q_{y}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 1 | 0 | 0 | 0 | 0 |
| 2 | 0 | 1 | 0 | 0 | 0 |
| 3 | 0 | 0 | 1 | 0 | 0 |
| 4 | $x$ | 0 | 0 | 1 | 0 |
| 5 | $y$ | 0 | 0 | 0 | 0 |
| 6 | 0 | $x$ | 0 | 0 | 0 |
| 7 | 0 | $y$ | 0 | 0 | 1 |

$$
\mathbf{M}_{\text {lumped }}^{e}=\frac{m_{e}}{36} \operatorname{diag}\left[\begin{array}{llllllllllllllllllllllll}
1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 8 & 0 & 0 & 8 & 0 & 0 & 8 & 0 & 0 & 8 & 0 & 0 \tag{30}
\end{array}\right]
$$

where $m_{e}$ is the element mass.
3.1.2. The Refined Consistent Mass Matrix. In order to improve the accuracy of the natural frequencies, the refined mass matrix has been used in the eigenproblem of the finite element method. We can give herein a new approach for improving the consistent mass matrix which can be obtained from a combination of the element displacement interpolations.

As for free vibration analysis, 8 -node shape function is used to interpolate the displacement function components $w$, $\theta_{x}, \theta_{y}$ as

$$
\begin{align*}
& w=\sum_{i=1}^{8} N_{i} w_{i} \\
& \theta_{x}=\sum_{i=1}^{8} N_{i} \theta_{x i}  \tag{31}\\
& \theta_{y}=\sum_{i=1}^{8} N_{i} \theta_{y i}
\end{align*}
$$

where

$$
\begin{align*}
& N_{i}=\frac{1}{4}\left(1+\xi_{i} \xi\right)\left(1+\eta_{i} \eta\right)\left(\xi_{i} \xi+\eta_{i} \eta-1\right), \\
& \quad i=1,2,3,4 \\
& N_{i}=\frac{1}{2}\left(1-\xi^{2}\right)\left(1+\eta_{i} \eta\right), \quad i=5,7  \tag{32}\\
& N_{i}=\frac{1}{2}\left(1-\eta^{2}\right)\left(1+\xi_{i} \xi\right), \quad i=6,8 .
\end{align*}
$$

Another 4-node shape functions are used to interpolate the deflection part of displacement function as

$$
\begin{equation*}
w_{b}=\sum_{i=1}^{4} \bar{N}_{i} w_{i} \tag{33}
\end{equation*}
$$

where

$$
\begin{equation*}
\bar{N}_{i}=\frac{1}{4}\left(1+\xi_{i} \xi\right)\left(1+\eta_{i} \eta\right), \quad i=1,2,3,4 . \tag{34}
\end{equation*}
$$

So the new deflection function part $w^{*}$ can be described as

$$
\begin{equation*}
w^{*}=w+\alpha\left(w-w_{b}\right) \tag{35}
\end{equation*}
$$

where $\alpha$ is an adjustable constant which is used to improve the accuracy of the vibration analysis.

Based on (31), (33), and (35), the shape function of refined consistent mass matrix is of the following form:

$$
\left[\begin{array}{lll}
w^{*} & \theta_{x} & \theta_{y}
\end{array}\right]^{T}=\left[\begin{array}{lll}
w+\alpha\left(w-w_{b}\right) & \theta_{x} & \theta_{y} \tag{36}
\end{array}\right]^{T}=\mathbf{N q}
$$

and the element consistent mass matrix $\mathbf{M}_{c}^{e}$ can be expressed as

$$
\begin{equation*}
\mathbf{M}_{c}^{e}=\iint_{\Omega} \mathbf{N}^{T} \mathbf{m} \mathbf{N} d x d y \tag{37}
\end{equation*}
$$

where $\mathbf{m}$ is the matrix containing the mass density of the material $\rho$ and thickness $t$ as follows:

$$
\mathbf{m}=\rho\left(\begin{array}{ccc}
t & 0 & 0  \tag{38}\\
0 & \frac{t^{3}}{12} & 0 \\
0 & 0 & \frac{t^{3}}{12}
\end{array}\right)
$$

3.2. Buckling Analysis Problem and Refined Geometric Stiffness Matrix. Consider a plate under an initial stress which may induce instability. Similar to the free vibration problem of plate, the equation of stability analysis can be expressed as

$$
\begin{equation*}
\left(\mathbf{K}-\lambda \mathbf{K}_{G}\right) \Phi=0 \tag{39}
\end{equation*}
$$

where $\mathbf{K}$ is the global stiffness matrix, $\mathbf{K}_{G}$ is the geometric stiffness matrix of the whole structure, $\lambda$ is the critical load, and $\Phi$ is the mode shape of buckling. The element geometric stiffness matrix $\mathbf{K}_{G}^{e}$ can be written as

$$
\begin{equation*}
\mathbf{K}_{G}^{e}=\mathbf{K}_{G 1}^{e}+\mathbf{K}_{G 2}^{e}+\mathbf{K}_{G 3}^{e}, \tag{40}
\end{equation*}
$$

where the terms of (40) are

$$
\mathbf{K}_{G 1}^{e}=t \int_{\Omega_{e}}\left[\begin{array}{ll}
\frac{\partial w}{\partial x} & \frac{\partial w}{\partial y}
\end{array}\right]\left(\sigma^{0}\right)^{T}\left[\begin{array}{l}
\frac{\partial w}{\partial x} \\
\frac{\partial w}{\partial y}
\end{array}\right] d x d y
$$

$$
\mathbf{K}_{G 2}^{e}=\frac{t^{3}}{12} \int_{\Omega_{e}}\left[\begin{array}{ll}
\frac{\partial \theta_{x}}{\partial x} & \frac{\partial \theta_{x}}{\partial y}
\end{array}\right]\left(\sigma^{0}\right)^{T}\left[\begin{array}{c}
\frac{\partial \theta_{x}}{\partial x}  \tag{41}\\
\frac{\partial \theta_{x}}{\partial y}
\end{array}\right] d x d y
$$

$$
\mathbf{K}_{G 3}^{e}=\frac{t^{3}}{12} \int_{\Omega_{e}}\left[\begin{array}{ll}
\frac{\partial \theta_{y}}{\partial x} & \frac{\partial \theta_{y}}{\partial y}
\end{array}\right]\left(\sigma^{0}\right)^{T}\left[\begin{array}{c}
\frac{\partial \theta_{y}}{\partial x} \\
\frac{\partial \theta_{y}}{\partial y}
\end{array}\right] d x d y
$$

Figure 3: Constant stress patch test.
and vector $\sigma^{0}=\left[\begin{array}{cc}\sigma_{x}^{0} & \tau_{x y}^{0} \\ \tau_{x y}^{0} & \sigma_{y}^{0}\end{array}\right]$ stands for the initial stress of plate, $\sigma_{x}^{0}, \sigma_{y}^{0}$ are unit tractions in the direction of $x$ and $y$, and $\tau_{x y}^{0}$ is the unit shear stress.

Similarly, we can obtain the refined geometric stiffness matrix from the following relation:

$$
\begin{align*}
\left\{\begin{array}{l}
\frac{\partial \bar{w}}{\partial x} \\
\frac{\partial \bar{w}}{\partial y}
\end{array}\right\}= & \left\{\begin{array}{l}
\frac{\partial w}{\partial x} \\
\frac{\partial w}{\partial y}
\end{array}\right\}+\alpha_{0}\left(\left\{\begin{array}{l}
\frac{\partial w}{\partial x} \\
\frac{\partial w}{\partial y}
\end{array}\right\}-\left\{\begin{array}{c}
\theta_{y} \\
-\theta_{x}
\end{array}\right\}\right) \\
& +\alpha_{0}\left(\left\{\begin{array}{l}
\frac{\partial w}{\partial x} \\
\frac{\partial w}{\partial y}
\end{array}\right\}-\left\{\begin{array}{c}
\frac{\partial w_{b}}{\partial x} \\
\frac{\partial w_{b}}{\partial y}
\end{array}\right\}\right) \tag{42}
\end{align*}
$$

where $\alpha_{0}$ is an adjustable constant used to improve the accuracy of the stability analysis, the displacement interpolation functions $w, \theta_{x}, \theta_{y}$ are the same as 8 -node shape function (31), and $w_{b}$ is in terms of (33).

Based on (42), we only modify the interpolation function $w$ and geometric stiffness matrix part $\mathbf{K}_{G 1}^{e}$ as

$$
\overline{\mathbf{K}}_{G 1}^{e}=t \int_{\Omega_{e}}\left[\begin{array}{ll}
\frac{\partial \bar{w}}{\partial x} & \frac{\partial \bar{w}}{\partial y}
\end{array}\right]\left(\sigma^{0}\right)^{T}\left[\begin{array}{l}
\frac{\partial \bar{w}}{\partial x}  \tag{43}\\
\frac{\partial \bar{w}}{\partial y}
\end{array}\right] d x d y
$$

The refined geometric stiffness matrix can be written as

$$
\begin{equation*}
\overline{\mathbf{K}}_{G}^{e}=\overline{\mathbf{K}}_{G 1}^{e}+\mathbf{K}_{G 2}^{e}+\mathbf{K}_{G 3}^{e} . \tag{44}
\end{equation*}
$$

## 4. Numerical Examples

To investigate the accuracy and reliability of the proposed QH8 element for free vibration analysis and buckling analysis, several numerical examples with different geometry and boundary condition are calculated in this section. For convenience, the boundaries of plates are denoted as follows: clamped supported (C), hard-type simply supported (S), softtype simply supported ( $\mathrm{S}^{*}$ ), and free ( F ), so a boundary condition can be written as CCCC, SSSS, CFFF, SCSC, SFSF, and so on for a rectangular plate. For example, the symbol, SFCF, represents simply supported edge along $x=0$, a free edge along $y=0$, a clamped edge along $x=a$, and a free edge along $y=b$.
4.1. Patch Test: Consistency Assessment. Consistency of the developed elements is tested for the constant strain and stress states on the patch example with five elements, covering a rectangular domain of a plate as shown in Figure 3. The size of the domain is $0.24 \times 0.12$. The mechanical properties of the plate are chosen as $E=10^{3}, \mu=0.25, \kappa=5 / 6$.

For zero shear deformation patch test, the test function [20,23] can be written as follows:

$$
\begin{align*}
w & =a_{0}+a_{1} x+a_{2} y+a_{3} x^{2}+a_{4} x y+a_{5} y^{2} \\
\theta_{x} & =a_{2}+a_{4} x+2 a_{5} y  \tag{45}\\
\theta_{y} & =-a_{1}-2 a_{3} x-a_{4} y .
\end{align*}
$$

For nonzero shear deformation patch test, the test function can be expressed as follows:

$$
\begin{align*}
w= & a_{0}+a_{1} x+a_{2} y+a_{3} x^{2}+a_{4} x y+a_{5} y^{2}+a_{6} x^{3} \\
& +a_{7} x^{2} y+a_{8} x y^{2}+a_{9} y^{3} \\
\theta_{x}= & \frac{h^{2}}{3 k(1-\mu)}\left(a_{7}+3 a_{9}\right)+a_{2}+a_{4} x+2 a_{5} y+a_{7} x^{2} \\
& +2 a_{8} x y+3 a_{9} y^{2}  \tag{46}\\
\theta_{y}= & -\frac{h^{2}}{3 k(1-\mu)}\left(3 a_{6}+a_{8}\right)-a_{1}-2 a_{3} x-a_{4} y \\
& -3 a_{6} x^{2}-2 a_{7} x y-a_{8} y^{2}
\end{align*}
$$

where $a_{i},(i=0, \ldots, 9)$ are arbitrary constants. In the present paper, we assume that $a_{i}=i+1$.

The mesh of patch test is presented in Figure 3. The displacements at the nodes on the boundaries are imposed according to (45) and (46), given the displacements and rotations at the boundary nodes (8 displacements and 16 rotations), while all the internal nodal displacements and rotations are to be calculated by the finite element solution procedure.

Test results show that the element QH8-39 $\beta$ passes both the constant bending with zero shear stresses $S_{x}, S_{y}$ (Table 2) and the strict patch test with nonzero constant shear stresses $S_{x}, S_{y}$ (Table 3). No matter the inner element edges are straight or curved, and no matter the shapes of the elements are convex or concave, the exact results of the displacements and stresses at inner node obtained using the present QH8$39 \beta$ element agree well with the test functions. This demonstrates that the new element passes the strict constant stress patch test, thus ensuring solution convergence.
4.2. Free Vibration Analysis. In this section, we examine the efficiency and the applicability of the 8 -node quadrilateral hybrid stress element in analyzing natural frequencies of plates. The proposed 8 -node quadrilateral hybrid stress elements with lumped mass matrix (30) and refined consistent mass matrix (37) in vibration analysis are denoted by QH8LV and QH8-RCV, respectively.

The effects of various slenderness ratios, skew angles, and boundary conditions on the frequencies are also discussed. Unless other stated, the following material parameters are used throughout the paper: Young's modulus $E=2.0 \times 10^{11}$, Poisson's ratio $\mu=0.3$, the mass density of the material $\rho=8000$, and the shear correction factor $\kappa=5 / 6$ is taken if not specified otherwise.

In the numerical calculation, the dimensionless solutions of natural frequencies with a multiplier $\pi^{2} / b^{2} \sqrt{D / \rho}$ are obtained. $b$ is the width of the edge, $D=E t^{3} / 12\left(1-\mu^{2}\right)$. Unless otherwise specified, the actual computations are done using dimensionless units.
4.2.1. Square Plate. For the hybrid stress element with the lumped mass matrix (QH8-LV) and refined mass matrix (QH8-RCV), the fundamental natural frequencies or free vibration problems of a square plate with different meshes and different boundary conditions are calculated.

The parameter $\alpha$ in (36) for the present element QH8RCV (8-node hybrid element with refined mass matrix) is determined by comparison using numerical examples. A square plate (the length of the plate $a$ and the width of the plate $b: a / b=1$ ) is divided into mesh of $16 \times 16$ elements. The thickness-to-width aspect ratios $t / b=0.001,0.1$, boundary conditions SSSS, CCCC, and $\alpha=-1,-0.5,-0.25,-0.08,0$ are
chosen. The results of six lowest modes are given in Tables 4-7 and Figure 4, in which the exact solutions can be found in [27]. We advise $\alpha=-0.08$ of the present $\mathrm{QH} 8-\operatorname{RCV}(\alpha)$ for following numerical examples.

The convergence of frequencies results of thin and thick square plates with SSSS and CCCC boundary conditions for QH8-RCV(-0.08) and QH8-LV are shown in Table 8 and Figure 5. The square plate is discretized by $N \times N$ uniform meshes with $N=4,8,16$. The results agree well with [27] when $N=8,16$.

Then, natural frequencies analyses are further carried on the thin $(t / b=0.001)$ and thick $(t / b=0.1)$ square plate with the meshes of $16 \times 16$ elements and various boundary conditions such as SSFF, SFSF, SCSC, CFFF, CCFF, and CFCF. The results are summarized in Table 9 and agree well with [27]. The six lowest modes of clamped and simply supported (CCCC, SSSS) thin square plate obtained by the QH8-RCV are also investigated and plotted in Figure 6.

TABLE 7: The six lowest nondimensional frequency parameters of a SSSS thick square plate $(t / L=0.1)$.

| Element ( $\alpha$ ) | Mode sequence number |  |  |  |  |  |

Figure 4: Error of six lowest nondimensional frequency parameters.
4.2.2. Free Vibration of Circular Plate. Free vibration of a circular plate (Figure 7) of $R=5$ with the clamped boundary is then studied in this subsection. The material parameters of the circular plate are given as follows: the density mass $\rho=8000$, Young's modulus $E=2.0 \times 10^{11}$, and Poisson's ratio $\mu=0.3$.

60 proposed elements and 205 nodes as shown in Figure 7, Mesh A, are used to discretize the whole plate for S8R of Abaqus, QH8-RCV(-0.08) and QH8-LV, while the compared solutions given by other elements employ even finer meshes. The frequencies given by MIN3 and NS+ESFEM [51] employ a mesh of 394 elements and 222 nodes; the solutions of NS-DSG and ES-FEM+DSG3 employ a much finer mesh of 848 elements and 460 nodes and ANS4 [52] using 432 quadrilateral plate elements (or 864 triangular elements).

The first ten modes of thin $(t / 2 R=0.01)$ and thick $(t / 2 R=0.1)$ circular plates are shown in Tables 10 and 11,
respectively. Figure 8 plots the results obtained from different methods. It is observed that the QH8-RCV and QH8-LV are good competitors to ANS4 and exact solutions [42, 43] and is more accurate than MIN3, ES-FEM+DSG3, and NS+ESFEM.

First six lowest modes of this clamped circular obtained from QH8-RCV using the mesh of Figure 7 Mesh B are shown in Figure 9, which exactly describes the real physical modes of the circular plate.
4.2.3. Free Vibration of Triangular Plates. QH8-RCV ( $\alpha=$ -0.08 ) and QH8-LV are then applied in the free vibration analyses of a cantilever triangular plate (CFF) with various shape geometries just as shown in Figure 10(a). The material parameters of the triangular plate are given as follows: the density mass $\rho=8000$, Young's modulus $E=2.0 \times 10^{11}$, and Poisson's ratio $\mu=0.3$. The plate is discretized by the meshes as shown in Figure 10 for QH8. The convergence study of

FIGure 5: Convergence of six lowest nondimensional frequency parameters $(t / h=0.001,0.1$, and SSSS, CCCC).
nondimensional frequency parameter $\bar{\omega}=\omega L^{2} \sqrt{\rho t / D} / \pi^{2}$ for thin $(t / L=0.001)$ and thick $(t / L=0.2)$ triangular plates against different skew angles $\alpha=0^{\circ}, 15^{\circ}, 30^{\circ}, 45^{\circ}$, and $60^{\circ}$ is undertaken and shown in Tables 12 and 13, respectively. The first four nondimensional frequency parameters for the thin and thick triangular plates are plotted in Figures 11 and 12.

The NS+ES-FEM [51] with the mesh of 170 triangular elements and 108 nodes and DSG3, MIN3, and ES-FEM+DSG3 are also used for comparison. The reference solution was obtained by the ANS method [52] using a mesh of 796 triangular elements. For thick triangular plate, QH8-RCV's performance is the best, but QH8-LV provides worse result when the angle becomes larger for the third and fourth modes in Figure 12, because of the mesh with small number of elements ( $45^{\circ}, 26$ elements and $60^{\circ}, 28$ elements) in some degree. For the thin triangular plate, QH8-LV is better than DSG3 and MIN3 and competes well with NS+ES-FEM and Rayleigh-Ritz [53]. QH8-RCV's performance is still the best and a strong competitor of Rayleigh-Ritz. Six lowest modes of
cantilever triangular plates (CFF) obtained from QH8-RCV are illustrated in Figure 13.
4.3. Critical Load of Buckling. In the following tests, we perform a series of plate buckling analyses to assess the convergence characteristics and accuracy of the developed QH8 element in predicting a critical buckling load. The results are presented in terms of a nondimensional buckling load intensity factor.

$$
\begin{equation*}
K_{b}=\frac{\lambda b^{2}}{\left(\pi^{2} D\right)} \tag{47}
\end{equation*}
$$

with $b$ being the edge width of the plate that is used throughout the paper and $D=E t^{3} / 12\left(1-\mu^{2}\right)$.
4.3.1. Rectangular Plates Subjected to an In-Plane Compressive Load. The parameter $\alpha_{0}$ in (42) for the present element

(b) Thick circular plate $(t / 2 R=0.1)$

Figure 8: Ten lowest parameterized natural frequencies of a clamped circular plate.

Figure 9: Shape of the six lowest modes of a clamped thick circular plate obtained from QH8-RCV $(t / 2 R=0.1)$.

QH8-R (8-node hybrid element with refined geometric stiffness matrix) is determined by comparison using numerical examples. A square plate $(a / b=1)$ compressed in one direction or two perpendicular directions are divided into different meshes $2 \times 2,4 \times 4,6 \times 6,8 \times 8,12 \times 12,16 \times$ 16. Thickness-to-width aspect ratios $t / b=0.01,0.1, \alpha_{0}=$ $-1,-0.75,-0.5,-0.3,-0.17,0$, and boundary conditions SSSS, CCCC are chosen. The computational results of the critical load are given in Tables 14 and 15 and Figure 14, in which the exact solutions can be found in [44-46]. After
analysis of numerical examples, the present 8-node hybrid stress element QH8-R $\left(\alpha_{0}\right)$ has higher accuracy when $-0.4 \leq$ $\alpha_{0} \leq-0.1$, and we advise $\alpha_{0}=-0.17$ for following numerical examples.

A shear-locking phenomenon is firmly involved when using thick plate theories to analyze thin plates. The present QH8 element is free of shear-locking in static calculation. A square plate is considered for this purpose and all other related parameters are taken exactly the same as above. Various boundaries such as SSSS, SFSC, SFSS, and SFSF

Table 12: The lowest six parameterized natural frequencies of triangular plates with $t / L=0.001$.

nodes) and MK, Shear-MK use a regular pattern of $21 \times 21$ elements ( 441 nodes). A shear correction factor $\kappa=\pi^{2} / 12$ is used here for a proper comparison.

Through the achieved results shown in Table 16 and Figure 15, the shear-locking phenomenon, on the one side, is found very clearly because of losing the accuracy significantly when the standard MK is applied to deal with thin plates, that is, $t / b=0.001,0.05$, but conversely matches well with thick plates, that is, $t / b=0.1,0.2$. Higher buckling loads by the standard MK are obtained because the plates may exhibit highly stiffer behavior. On the other hand, a good agreement and free of shear-locking are found when the Shear-MK, S8R, and the present QH8-R are used.

The results of uniaxial buckling loads $\left(\sigma_{y}{ }^{0}\right)$ along the $y$ axis and the biaxial in-plane compression load ( $\sigma_{x}{ }^{0}=\sigma_{y}{ }^{0}$ ) are shown in Tables 17 and 18 and Figures 16 and 17 associated
with five different densities of regular elements such as $2 \times 2$ ( 21 nodes), $4 \times 4$ ( 65 nodes), $6 \times 6$ ( 133 nodes), $8 \times 8$ ( 225 nodes), and $10 \times 10$ ( 341 nodes).

We also consider simply supported plates (SSSS) with various thickness-to-width ratios, $t / b=0.05,0.1,0.2$, and length-to-width ratios, $a / b=0.5,1.0,1.5,2.0,2.5$.

Table 19 and Figure 18 show the buckling factors using the element $\mathrm{QH} 8-\mathrm{R}$ with regular mesh of $9 \times 9$ rectangular elements (280 nodes) when $a / b=1.0$. The QH8-R results are also compared to the DSG3 and ES-DSG3 [47] (mesh of $16 \times 16$ elements and 289 nodes), S8R (mesh of $9 \times 9$ elements and 280 nodes), mesh-free method [48], and the pb-2 Ritz [46]. It is seen that the QH8-R exhibits a good agreement with the $\mathrm{pb}-2$ Ritz method, and S8R is not suitable for plate $t / b$ $=0.2$. Figure 19 also depicts the uniaxial buckling modes of simply supported rectangular plates with thickness-to- width

FIGURE 15: Normalized uniaxial buckling load factors along the $x$-axis $\left(\sigma_{x}{ }^{0}\right)$ versus the thickness-span aspect ratio $t / b=0.001,0.05,0.1,0.2$ with various boundaries.
ratios $t / b=0.01$ and various length-to-width ratios, $a / b=1.0$, 1.5, 2.0, 2.5.
4.3.2. Compression Buckling Behavior of Skew Plates. The buckling problem of skew plate has also been considered by Kitipornchai et al. [46] and Wang et al. [56] using the pb-2 Ritz method. Skew plates, as shown in Figure 20, with skew angle, $\theta$, thickness-to-width ratio, $t / b$, and different combinations of edge support conditions, are examined. The plate is modelled with $6 \times 6,9 \times 9$ and $16 \times 16$ distributed particles for QH8-R $\left(\alpha_{0}=-0.17\right)$ element.

Numerical results for thick plates with thickness-to-width ratios, $t / b=0.05,0.1$, skew angles, $\alpha=0^{\circ}, 15^{\circ}, 30^{\circ}, 45^{\circ}$, and various boundary conditions of $S^{*} S^{*} S^{*} S^{*}$, CCCC, CFCF, and $S^{*}$ FS* F , are compared with those of mesh-free method [48] (with $17 \times 17$ distributed particles) and Kitipornchai et al. [46] in Table 20. S*, C, and F denote soft-type simply supported, clamped, and free boundary conditions, respectively. Based
on the favorable comparisons observed in Table 8, it can be concluded that the plate buckling load intensity factors are well approximated by the QH8-R ( $\alpha_{0}=-0.17$ ) element.
4.3.3. A Square Plate with a Hole Subjected to Different InPlane Loads. Lastly we consider a hard-type simply supported (SSSS) and clamped (CCCC) square plate with a hole. For the purpose of the comparison, the material parameters are taken the same as in the above example but the length $a=b=10$ and the thickness $t=1$ are employed instead. The irregularly scattered pattern of 84 elements and 308 nodes shown in Figure 21 is used. The plate is subjected to three different in-plane load cases, namely, an uniaxial compressive load in $x$-direction, $\sigma_{x}^{0}$, pure shear load, and biaxial compressive loads in $x$ and $y$ directions, where $\sigma_{x}{ }^{0}=$ $\sigma_{y}{ }^{0}$, respectively.

The results of the normalized buckling load factor calculated for those loads with different boundary conditions

Figure 16: Normalized axial buckling load factors along the $y$-axis $\left(\sigma_{y}{ }^{0}\right)$ versus the thickness-span aspect ratio $t / b=0.001,0.05,0.1,0.2$ with various boundaries.
are shown in Table 21. The results agree very well with those computed by the EFG [57] involving both the thirdorder shear deformation plate theory (TSDT) and the FSDT. And the Shear-MK [55] with 400 nodes is also used for comparison. Additionally, it is also interesting to view the buckling modes of the problem and, thus, Figure 22 presents the first buckling modes under the three types of buckling loads for four different boundary conditions.

## 5. Conclusions

The higher-order hybrid stress quadrilateral Mindlin plate element QH8 for solving free vibration and buckling analysis problems is formulated in this paper. Due to numerical results given above, some concluding remarks can be drawn as follows.

The QH8 element is an efficiency method for solving the free vibration problems and buckling analysis of plate due to its high accuracy. It is free of shear locking and can pass both the constant bending with zero shear stresses and the strict
patch test with nonzero constant shear stresses, no matter the element edges are straight or curved and no matter the shapes of the elements are convex or concave.

The refined nonconforming element method is a very efficient method, which can be used to improve the accuracy of nonconforming elements. It has been used to construct the QH8 element successfully. With the refined mass matrix and refined geometric stiffness matrix, the accuracy of vibration and stability analysis has been improved just by changing the value of $\alpha$ and $\alpha_{0}$, and it really works.

From the numerical results, the present plate element has performed well in most situations. It is shown that the present plate element is applicable to either thin or thick situations with enough accuracy.

## Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Note. $6 \times 6,9 \times 9,16 \times 16$ : the meshes for element QH8-R $(-0.17)$.

Table 21: The uniaxial, biaxial, and pure shear buckling load factor for a square plate with a circular hole and different boundary conditions.

| Buckling load | Boundary | EFG (FSDT) | EFG (TSDT) | Shear-MK | HQ8-R |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Uniaxial | CCCC | 7.995 | 8.097 | 8.0777 | 8.0543 |
|  | SSSS | 1.986 | 1.969 | 1.9544 | 2.0580 |
| Biaxial | CCCC | 4.781 | 4.860 | 4.9878 | 4.8477 |
|  | SSSS | 1.032 | 1.021 | 1.0511 | 1.0696 |
|  | CCCC | 12.669 | 13.357 | 13.5252 | 12.6976 |
|  | SSSS | 7.867 | 7.873 | 8.1544 | 7.8971 |

Figure 21: Square plate with a circular hole and the distributions (308 nodes, 84 elements).

FIgure 22: The first uniaxial, biaxial, and pear shear buckling modes of the plate with a circular hole associated with different boundaries as SSSS, CCCC (thickness $t=1.0$ ).

## Acknowledgments

The work in this paper was supported by the National Natural Sciences Foundations of China (no. 11702242 and no. 11572204), Youth Foundation of Hebei Educational Committee (QN2017151), and Foundations of Yanshan University (no. 15LGB020, no. 16LGB015, no. B922, and no. B981). Those grants are gratefully acknowledged.
