Received 30 January 2024; Accepted 30 January 2024; Published 31 January 2024

Copyright © 2024 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant). Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: Music Segmentation Algorithm Based on Self-Adaptive Update of Confidence Measure

Journal of Mathematics

Received 23 January 2024; Accepted 23 January 2024; Published 24 January 2024

Copyright © 2024 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity. We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: Evaluation Algorithm of Ecological Energy-Saving Effect of Green Buildings Based on Gray Correlation Degree

Journal of Mathematics

Received 23 January 2024; Accepted 23 January 2024; Published 24 January 2024

Copyright © 2024 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: Text Knowledge Acquisition Method of Collaborative Product Design Based on Genetic Algorithm

Journal of Mathematics

Received 19 December 2023; Accepted 19 December 2023; Published 20 December 2023

Copyright © 2023 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: Early Warning System for Penalty Constrained Financial Risks of Enterprises under Diversified Investment

Journal of Mathematics

Received 31 October 2023; Accepted 31 October 2023; Published 1 November 2023

Copyright © 2023 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: A Survey of Multimedia-Assisted English Classroom Teaching Based on Statistical Analysis

Journal of Mathematics

Received 21 November 2022; Accepted 21 November 2022; Published 5 January 2023

Copyright © 2023 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

Journal of Mathematics has retracted the article titled "A Survey of Multimedia-Assisted English Classroom Teaching Based on Statistical Analysis" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

Retracted: Preorder of Factors Affecting Oil Prices: Fuzzy PROMETHEE Approach

Journal of Mathematics

Received 19 December 2023; Accepted 19 December 2023; Published 20 December 2023

Copyright © 2023 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Oil is a highly demanded worldwide product as oil prices can have a major economic and social impact. There are many factors affecting oil prices, but little is known about which factor mostly influenced oil prices. To understand what caused the fluctuation of oil prices, the investigation leading up to the identification of the factors must be constructed. Thus, this paper attempts to explore the factors that might have contributed to oil prices and analyze them using the fuzzy preference ranking organization method for enrichment evaluation (PROMETHEE) method. In particular, the objective of this study is to rank the influential factors affecting oil prices with the consideration of a few criteria. The fuzzy PROMETHEE model comprises four criteria and five factors with respect to criteria. In computation, the evaluations are treated as triangular fuzzy numbers in which the uncertainty in data is dealt with amicably. This approach combines the advantages of transformation equation and nonarithmetic mean of the defuzzification method that transforms triangular fuzzy numbers into crisp numbers. The results indicate that "supply and demand" is the most influential factor in determining oil prices. Comparative analysis and future research directions are also discussed at the end of this paper.

1. Introduction

One of the most critical issues in the economic development of a country is global oil prices. The price of oil indirectly affects the cost of living of most people, since it is so directly attached to petrol costs. This implies that if global oil prices rise, so the price of petrol is rising as well, and this will affect people's daily life. Oil prices are inconceivably sensitive, changing rapidly considering news cycles, arrangement changes, and fluctuation in the world's business, manufacturing industries, and economic development sectors. For example, as oil prices go up, all the petrochemicalrelated industries such as plastic, rubber, paints, dyes, textile solvent, and so on will be affected directly [1]. It has been suggested that global oil price stands out among the most important floating prices in the world [2]. Oil prices are considered floating prices as there are many factors that can be attached to them. Oil prices changes are most likely to lead to inflation, and it is more intense when oil prices are on the rise. As indicated by the concept of supply and demand, the oil price should increase with increasing demand or decreasing supply [3]. Therefore, the oil price is not a straightforward issue as there are many other factors that concurrently attached to it. There is no quick-fix solution when it comes to finding the most influential factors that affect oil prices. Moreover, it shows that oil prices have a nonlinearly impact on inflation risk and other economic variables [4]. The presence of nonlinearity in the relationship between oil prices and their impacts and also factors that affect oil prices might influence the way oil prices are investigated.

1.1. Related Works. To further explore the issue of fluctuation and nonlinearity of oil prices, Kaufmann et al. [5] conducted a study that used a statistical model to assess casual relationships between factors to influence oil prices and monthly oil prices. A linear relationship could be a reasonable estimation under ordinary conditions. However, under extreme events, oil price may shift the market balance among supply and demand towards different types of markets in which prices are much more sensitive that will contain a small sample bias. Dees et al. [6] also show that a nonlinear effect of oil producers' country's capacity and condition in future markets are the factors of the oil price increase. The researchers developed a model to estimate the real average price of US crude oil. They expect the regression coefficient associated to be negative. However, there are a few weaknesses in the regression models that should be pointed out. Results from the econometric regression-based analysis are highly sensitive. Small changes in the data set and the model designs can give a huge impact on the outcomes [7]. Zakaria et al. [8] discussed further the nonlinearity of oil prices. They measured the influence of the world oil prices on inflation rates in South Asian countries using the value at risk, cointegration, and nonlinearity analysis. The results tell that cointegration holds among oil prices and inflation. Nonlinear causality tests stipulated that oil price causes inflation. A similar approach was also employed by Oloko et al. [9] who concluded that the monetary policy of oil-importing countries appears to accommodate oil price shocks. In a correlational study, Wu and Wang [10] examined the relationship between oil prices and corporate investment, conditional on market conditions. They discovered that oil prices are negatively correlated with corporate investment expenditure. However, they also found out that if market conditions are favorable, then corporate investment expenditure increases as oil prices rise.

As to depart from regression- and correlation-based analysis where data employed in studies are very much sensitive, Wang et al. [11] used a different approach. They used an extensive variety of generalized Maclaurin symmetric mean (MSM) aggregation operators that multicriteria decision-making (MCDM) issues were solved. The criteria in MCDM problems were enhanced by considering weights to reflect the importance of the criteria. They provide a practical example and conduct a comparison analysis between the proposed method and other existing methods in order to verify the proposed method and demonstrate its validity. They also successfully applied the proposed methods to a real-life MCDM problem. Very recently, in application research to biodiesel feedstock, Anwar [12] conducted research on defining the best possible biodiesel feedstock using various MCDM processes. Four MCDM processes, namely the preference ranking organization method for enrichment evaluation (PROMETHEE) graphical analysis for interactive assistance [13, 14],

weighted sum method [15, 16], weighted product method [17], and technique for order preference by similarity to the ideal solution [18], were implemented for this investigation.

However, there are two pertinent matters that are normally attached to most of the MCDM methods. The matters are about their parametrization and its uncertainty. In fact, the feasibility of MCDM is directly connected to the importance and quality of the chosen parameters. One of the MCDM methods related to parametrization is the PROM-ETHEE. Unlike most of the MCDM method such as the analytic hierarchy process (AHP) that handle preference directly from decision-makers' opinions, the PROMETHEE method heavily relies on the chosen parameters, which are normally known as preference functions. Preference function and pairwise comparison of alternatives and differences between two alternatives are the main advantages of PROMETHE that the final output is the partial preorder (partial ranking) and total preorder (complete ranking). Because of these advantages, the PROMETHEE method has specific application in decision-making and generally is utilized far and wide in a wide assortment of decision scenarios, in fields such as business, administrative establishment, health care, transportation, and education. The second matter is about uncertainty. As to deal with uncertainty in information, the fuzzy PROMETHEE was proposed. There is a fuzzy concept to the PROMETHEE method when dealing with uncertain and subjective information. The fuzzy set theory and the ranking technique were incorporated into the fuzzy PROMETHEE method. According to Brans and Mareschal [19], the fundamental advantage of this technique is the ease of use. Linguistic evaluations and the thought of fuzziness are the two notions that are germane to decision-making problem.

1.2. Motivation. A search of literature found that most of the researchers tend to conduct research using PROMETHEE rather than fuzzy PROMETHEE because the fuzzy PROM-ETHEE method is associated with the theory of fuzzy sets [20]. Another reason could be associated with heavy calculation in fuzzy PROMETHEE besides no readily available software to assist computation. However, in recent years, there has been an increasing interest in applications of fuzzy PROMETHEE not only as a single model but also integrated with other fuzzybased decision-making models. For example, fuzzy PROM-ETHEE has been integrated with AHP in group decisionmaking [21]. Recent research also unveiled several new extensions of fuzzy PROMETHEEE such as m-polar fuzzy PROMETHEE [21], bipolar fuzzy PROMETHEE [22], and q-rung orthopair fuzzy PROMETHEE [23]. In application to health sciences, Maisaini et al. [24] conducted a study to break down the most common therapeutic techniques for lung cancer. In their venture, the fuzzy PROMETHEE method was utilized to investigate the therapeutic techniques that are dependent on six factors. The results demonstrated that the surgery among other techniques showed an incredible act on lung cancer treatment depending on the criteria, importance, and weights chosen. In addition, fuzzy PROMETHEE also has been integrated.

Fuzzy PROMETHEE also shows that one can easily adjust the method by including more criteria and change their significance and weight relying upon the application. Afful-Dadzie et al. [25] had proposed a two-phase framework of a decision-making methods and sensitivity analysis to show how aid recipient countries can be assessed to heighten transparency, reasonableness, esteem for cash, and manageability of such guide programs. Utilizing the OECD set for subjective criteria for assessing aid programs, a numerical model precharacterized by linguistic terms parameterized by triangular fuzzy numbers was given to assess aid programs. Fuzzy PROMETHEE was utilized in the first phase to assess and rank aid recipients pursued by a comparative analysis with other fuzzy-based decision-making methods. The result demonstrates a framework that can be utilized in assessing the aid effectiveness of recipient countries. Very recently, Ziemba [26] applied the fuzzy PROMETHEE combined with the Monte Carlo method and elements of the stochastic multicriteria acceptability analysis method. They applied their proposed method for assessing vehicles under uncertain conditions. The approach allowed us to identify almost unambiguously the electric vehicle that is likely to gain the highest acceptance. As a result of the conducted research, it was found that the approaches to uncertainty based on fuzzy sets, outranking relations, and stochastic analysis complement each other, allowing the decision-maker to conduct a wider analysis of the imprecision of the obtained solution.

1.3. Innovative Contribution. Turning now to the fluctuations and nonlinearity of oil prices where understanding the importance of causal factors that affect oil prices is the main aim of this paper. The fuzzy PROMETHEE is used as a selection tool with the end goal is to identify the most influential factors that affect oil prices. The contributions of this paper are fourfold: (1) we propose to use a transformation equation in the computational steps of fuzzy PROMETHEE where information that is given in triangular fuzzy numbers is transformed into left-right fuzzy numbers. This transformation is meant to ease the computational burden and also to avoid the loss of information during the implementation. (2) We propose to introduce a nonarithmetic mean of defuzzification where a constant is used as a multiplying factor to the mid-values of the left-right triangular fuzzy numbers. This would enhance the dominance of mid-values of left-right triangular fuzzy numbers. (3) We propose partial preorder and total preorder of factors that affect oil prices. (4) We propose a comparative analysis of net value flows to validate the results obtained using the proposed method. These four contributions are embedded in the proposed fuzzy PROMETHEE where the partial preorder and total preorder of factors can indicate the most influential factors that affect global oil prices.

1.4. Framework of the Paper. The rest of this paper is organized as follows. Section 2 briefly revisits the definitions of linguistic variables, triangular fuzzy numbers, and their algebraic operations. Section 3 presents the methodology of the research, which includes the evaluation model. In Section 4, computational procedures and results for the case study of factors affecting oil prices are described. Section 5 provides the comparative results of the final ranking and net flows. Finally, Section 6 concludes.

2. Preliminary

In a similar way to MCDM methods, there is a fuzzy expansion of the PROMETHEE method when dealing with uncertain and subjective information. Fuzzy PROMETHEE has similarly observed enhancements in several variations such as PROMETHEE I, II, III, IV, V, and VI. The fuzzy PROMETHEE method has been used in solving numerous decision-making problems where the task of ranking alternatives and concurrently considering fuzzy information, fuzzy preferences, and fuzzy weights is indeed very challenging. This is partly due to interval data that would increase the complexity of computation. According to Brans and Mareschal [27], the fundamental advantage of this technique is ease of use in implementation because most of the decision-making problems can be solved by incorporating linguistic evaluations and the thought of fuzziness. Later, we revisit several notions related to fuzzy MCDM that will be used in the subsequent text.

2.1. Linguistic Variable [28]. Linguistic variables are used for system input and output and are represented by words or sentences instead of the number investigated by Zadeh [29, 30]. In explaining this, take the example of the linguistic variable "temperature." Let *T* be a set of linguistic variable "temperatures" where $T = \{\text{very cold, cold, moderate, warm, very hot}\}$. The members of set *T* are called linguistic terms where gradations of *T* are defined. These linguistic terms are normally translated into triangular fuzzy numbers.

2.2. Triangular Fuzzy Numbers [31]. The triangular fuzzy number, $\mu_A(x)$, is defined by its lower limit *a*, its upper limit *b*, and the modal value *m* so that a < m < b. It is written in the form of function A(x) as follows:

$$A(x) = \begin{cases} 0, & x \le a, \\ (x-a)/(m-a), & x \in (a,m), \\ (b-x)/(b-m), & x \in (b,m), \\ 1, & x \ge 0. \end{cases}$$
(1)

In this function, interval a to m is increasing function, and interval m to b is decreasing function.

For x < a or x > b, x does not belong to the set. For $[x \le a \le b]$, the membership degree is indicated by membership function between 0 and 1.

These fuzzy numbers and their basic arithmetic operations are widely used in the fuzzy MCDM method.

2.3. Basic Operations of Triangular Fuzzy Numbers [32]. Let A = (a, b, c) and B = (d, e, f) be two triangular numbers, then the basic arithmetic operations for addition,

subtraction, multiplication, division, and scalar multiplication are defined as follows:

$$A(+)B = (a, b, c)(+)(d, e, f) = (a + d, b + e, c + f),$$

$$A(-)B = (a, b, c)(-)(d, e, f) = (a - f, b - e, c - d),$$

$$A(\times)B = (a, b, c)(\times)(d, e, f) = (ad, be, cf),$$

$$A(\div)B = (a, b, c)(\div)(d, e, f) = \left(\frac{a}{f}, \frac{b}{e}, \frac{c}{d}\right),$$

$$nA = (na, nb, nc).$$
(2)

2.4. Preference Function [27]. Let $P_j(a, b) = F_j[d_j(a, b)]$ is a preference function of PROMEHEE, where $P_j(a, b)$ signify the function of the difference between the evaluations of alternative *a* with respect to alternative *b* on each criterion into a degree ranging from 0 to 1. The smaller number of functions indicates the indifference of the decision-maker. Conversely, closer to 1 indicates greater preference. If $P_j(a, b)$ the usual criteria function, then the indifference only occurs when f(a) = f(b). The function of f(x) is given as follows:

$$p(x) = \begin{cases} 0, & \text{for } x \le 0, \\ 1, & \text{for } x > 0. \end{cases}$$
(3)

The above notions are used directly during the implementation of computational procedures of the fuzzy PROMETHEE. The output of computational procedures are partial ranking and complete ranking of factors affecting oil prices.

3. Methodology

The methodology is a process used to collect information and data, which regularly includes interviews, data collection, and computational models. The purpose of this section is to have a discussion of the methodology used so that the objective of this study is met. This section begins by describing the type of data collection via experts, factors, and criteria that affect oil prices, followed by computational procedures of the fuzzy PROMETHEE method.

3.1. Experts and Linguistic Variable. In this research, data are collected via personal communication with a group of three experts. All experts have vast experiences in the oil and gas industry in which their details are summarized in Table 1.

In personal communication, experts are requested to provide a rating of five factors that affect oil prices with respect to four criteria of oil prices using the linguistic variable shown in Table 2.

The experts are also requested to provide a level of importance of each criterion using the linguistic variable of "importance." This linguistic variable and its respective triangular fuzzy numbers are shown in Table 3. 3.2. Factors and Criteria. Five factors a_1, a_2, a_3, a_4 , and a_5 that represent supply, demand, report (OPEC, target pricing, and investment), political event and crises, and access markets, respectively, are the factors chosen in this study. Descriptions of factors are given in Table 4.

Through personal communication, the experts (E_1, E_2, E_3) are requested to rank and evaluate the factors that affect oil prices with respect to four criteria. In this study, criteria are defined as a benchmark in determining oil prices. Benchmark crude or marker crude is raw petroleum that fills in as a source of the reference price for purchasers and dealers of raw petroleum. Benchmarks are utilized in light of the fact that there are various assortments and grades of unrefined petroleum. The benchmark makes it simpler for dealers, investors, experts, and others to decide the prices of multitudes of grades of unrefined petroleum [1]. In this study, the criteria are O_1 (West Texas Intermediate, WTI), O_2 (Brent), O_3 (OPEC Reference Basket), and O_4 (Western Canadian Select, WCS). Descriptions of the criteria are presented in Table 5.

Evaluation of the criteria and the factors become the input data or information for computation using the fuzzy PROMETHEE. The output of the computations are partial ranking and complete ranking. Information processing is implemented using the fuzzy PROMETHEE where information of the input data are given in triangular fuzzy numbers. Detailed computational procedures are given as follows.

3.3. Computational Procedures of Fuzzy PROMETHEE Method. In most fuzzy MCDM frameworks, identifying alternatives, criteria, linguistic variables, and experts are required. In the following, we propose the computational procedures for the generic fuzzy PROMETHEE, which later can be used in the case of oil prices. These computational procedures are adopted from Abdullah et al. [41] where the steps of PROMETHEE with crisp numbers are the main designs. Several innovations are made in the proposed fuzzy PROMETHEE compared to the PROMETHEE [41]. Apart from the substitution of crisp numbers with triangular fuzzy numbers, the proposed fuzzy PROMETHEE method also includes a transformation process where triangular fuzzy numbers are transformed into left-right triangular fuzzy numbers. This transformation is needed as left-right fuzzy numbers can easily fit with the Yager index that will be employed in the subsequent step. Instead of using the arithmetic mean in defuzzification, this proposed method introduced coefficient 3 to the mid-value of left-right triangular fuzzy numbers. This will propel the dominance of the mid-value of left-right triangular fuzzy numbers without ignoring their left width and right width. Another innovation is the sequence of obtaining partial preorder and total preorder. In the proposed method, the partial preorder is obtained just before the step of transformation and defuzzification where this decision is made based on the values of triangular fuzzy numbers of inflows and outflows. This sequence is contrasting with the regular PROMETHEE where partial preorder and total preorder happen one after

Unimportant		(0.00, 0.00, 0.25)
Little important		(0.00, 0.25, 0.50)
Moderately important		(0.25, 0.50, 0.75)
Important		(0.50, 0.75, 1.00)
Very important		(0.75, 1.00, 1.00)

	TABLE 4: Descriptions of factors.
Factors	Descriptions
<i>a</i> ₁ (supply)	The Organization of Petroleum Exporting Countries (OPEC) has been colossal on the world's exchanging floors, with its oil-producing member nations cooperating to decide prices by boosting or decreasing oil production. OPEC as of now controls 40% of the world's oil production; in this way, they still have a significant impact on the oil market [33]. Therefore, supply is one of the factors affecting oil prices.
<i>a</i> ₂ (demand)	Solid monetary development and modern generation will in general lift the demand for oil as reflected in changing demand patterns by non-OECD countries, which have grown quickly as of late. As indicated by the concept of supply and demand, the oil price should increase with increasing demand or decreasing supply [3].
<i>a</i> ₃ (report)	Report on creation figures, spare capacity, target pricing, and investments can be a critical factor in the setting of oil prices [34].
a_4 (political events and crises)	War, natural disasters, political change, and new government pioneers are on the whole factors impacting crude oil pricing [35].
<i>a</i> ₅ (access markets)	The futures market of oil plays a role in influencing the spot price of oil [36]. An oil futures contract is a binding agreement that gives the privilege to buy oil by the barrel at a predefined price on a predefined date later on. Under a prospects contract, both the purchaser and the merchant are committed to satisfying their side of the

exchange	on	the	predetermined date.	

	TABLE 5: Description of criteria.
Criteria	Descriptions
O ₁ (West Texas intermediate, WTI)	WTI, otherwise called Texas light sweet, is a grade of crude oil used as a benchmark in oil pricing [37]. This grade is portrayed as medium crude oil in light of its generally low thickness and sweet because of its low sulphur content
O ₂ (Brent)	Brent is also an important benchmark for crude oil pricing [38]. Brent contains around 0.37% of sulphur classifying it as sweet crude, yet not as sweet as WTI. Brent is reasonable for the production of petrol and middle distillates. Historically, price differences between Brent and other index crudes have been founded on physical contrasts in crude oil specifications and short-term variations in supply and demand.
<i>O</i> ₃ (OPEC Reference Basket)	Besides WTI and Brent, the OPEC Reference Basket is also a benchmark for oil pricing [39]. The OPEC Basket is a weighted average of prices for petroleum blends produces by OPEC members. It is utilized as an imperative benchmark for crude oil prices. OPEC has frequently endeavored to keep the price of the OPEC basket between upper and lower limits, by increasing and decreasing production. This makes the measure essential for market analysts.
<i>O</i> ₄ (Western Canadian Select, WCS)	WCS is one of North America's biggest overwhelming crude oil streams. It is an alternative to the Canadian oil and gas industry, and individual firms' equity prices react to oil price fluctuations [40]. It is an overwhelming mixed crude oil, made for the most part of bitumen mixes with sweet synthetic and condensate diluents and 25 existing streams of both ordinary and flighty. WCS is the benchmark for emerging heavy, high TAN (acidic).

the other. The flowchart of the proposed method is shown in Figure 1.

The proposed nine-step computational procedures are as follows:

Step 1. Define factors, criteria, and experts.

Suppose in a decision-making problem, we have m alternatives, k criteria, and n experts.

Step 2. Define linguistic variables and linguistic terms in triangular fuzzy numbers.

Define the criteria weight of each criterion corresponding to the linguistic term. The w_j represents the weight of criterion based on linguistic terms assigned by experts. The weight of the criterion is expressed in triangular fuzzy numbers.

Step 3. Aggregate the evaluation.

The weights of the criteria and the ratings of factors are aggregated using the basic proportion equation as follows:

$$\widetilde{w}_{jk} = \frac{\widetilde{w}_j}{\widetilde{w}_k} \left(0 \le \widetilde{w}_{jk} \le 1 \right), \widetilde{w}_k = \max\left(\widetilde{w}_j\right) (k, j = 1, 2, \dots, n).$$
(4)

Step 4. Construct preference function.

The preference function $\tilde{P}_{j}(m, n)$ represents the experts' preference between pairs of factors. The preference function $\tilde{P}_{i}(a, b)$ for a criterion can be defined as follows:

$$\widetilde{P}_{j}(a,b) = \begin{cases} 0, & \widetilde{x_{aj}} \le \widetilde{x}_{bj}, \\ \widetilde{x}_{aj} - \widetilde{x}_{bj}, & \widetilde{x_{aj}} > \widetilde{x}_{bj}, \end{cases} \text{ where } j = 1, 2, \dots, k.$$
(5)

Step 5. Compute the multifactor preference index.

Multicriteria preference index is used to choose the rate in outranking relation.

$$\widetilde{\pi}(a,b) = \frac{\sum_{j=1}^{k} \left[\widetilde{w_j} \widetilde{p}_j(a,b) \right]}{\sum_{j=1}^{k} \widetilde{w_j}},$$
(6)

where $\widetilde{w_i}$ denotes the important weight of the factor.

If $\tilde{\pi}(a, b) \approx 0$, it implies a weak preference of *a* over *b*. If $\tilde{\pi}(a, b) \approx 1$, it implies a strong preference of *a* over *b*.

Step 6. Compute the positive and negative outranking flows for partial preorder.

For PROMETHEE I (partial ranking), the ranking of factors is made by calculating the positive and negative outranking flows as follows:

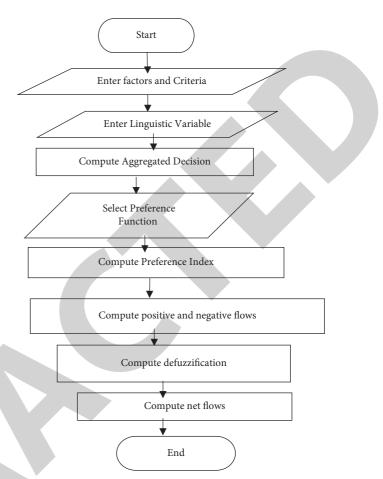

FIGURE 1: Flowchart of fuzzy PROMETHEE.

Positive outranking :
$$\tilde{\varphi}^+(m) = \frac{1}{n-1} \sum_{m \neq l} \tilde{\pi}(m, l),$$
 (7)

$$fm, l \in A,$$

Negative outranking :
$$\tilde{\varphi}^{-}(m) = \frac{1}{n-1} \sum_{m \neq l} \tilde{\pi}(l, m),$$
(8)
 $\forall m, l \in A.$

where m and n denote the number of factors and experts, respectively.

Step 7. Transform triangular fuzzy numbers.

The triangular number (L, M, R) needs to transform into the form (M, a, b)

where
$$a = M - L$$
 and $b = R - M$. (9)

It is necessary to represent fuzzy numbers in form of left-right.

Step 8. Defuzzify.

The defuzzification method used in this study is the Yager index method. The average of left-right and middle of triangular fuzzy numbers is the defuzzification value. The defuzzification equation is

$$(M, a, b) = \frac{3M - a + b}{3}.$$
 (10)

Step 9. Establish total preorder

The complete or full ranking of factors is established based on the value of net flows. Negative net flows subtracted from positive net flows will give net flows.

Net flow:
$$\tilde{\varphi}(m) = \varphi^+(m) - \tilde{\varphi}^-(m), \quad \forall m \in A.$$
 (11)

The above computational procedures are implemented in the case of factors affecting oil prices. Detailed computations and results are given in the following section.

4. Computations and Results

Information about the evaluation becomes the input data for implementing the computation. All this information is given in triangular fuzzy numbers, and the execution of the computation is made according to the proposed computational procedures.

Evaluation of criteria given by experts is summarized in Table 6.

Aggregation of weight of criterion from experts is computed using equation (4).

$$\begin{split} \tilde{w}_{1} &= \frac{1}{3} \left((0.50, 0.75, 1.00) \oplus (0.50, 0.75, 1.00) \oplus (0.25, 0.50, 0.75) \right) \\ &= (0.42, 0.67, 0.92), \\ \tilde{w}_{2} &= \frac{1}{3} \left((0.25, 0.50, 0.75) \oplus (0.75, 1.00, 1.00) \oplus (0.50, 0.75, 1.00) \right) \\ &= (0.5, 0.75, 0.92), \\ \tilde{w}_{3} &= \frac{1}{3} \left((0.25, 0.50, 0.75) \oplus (0.25, 0.50, 0.75) \oplus (0.75, 1.00, 1.00) \right) \\ &= (0.42, 0.67, 0.83), \\ \tilde{w}_{4} &= \frac{1}{3} \left((0.50, 0.75, 1.00) \oplus (0.75, 1.00, 1.00) \oplus (0.25, 0.50, 0.75) \right) \\ &= (0.5, 0.75, 0.92). \end{split}$$
(12)

Equation (12) shows the weights represent aggregated weights for oil benchmarks (criteria) O_i (i = 1, 2, 3, 4), respectively.

Table 7 shows the ratings of the factors with respect to criteria.

The above ratings are aggregated using equation (4) to obtain aggregated rating for each criterion. For example,

$$\begin{split} \widetilde{x}_{11} &= \frac{1}{3} \left[(0.25, 0.50, 0.75) \oplus (0.75, 1.00, 1.00) \oplus (0.25, 0.50, 0.75) \right] \\ &= (0.42, 0.67, 0.83), \\ \widetilde{x}_{12} &= \frac{1}{3} \left[(0.25, 0.50, 0.75) \oplus (0.75, 1.00, 1.00) \oplus (0.25, 0.50, 0.75) \right] \\ &= (0.42, 0.67, 0.83), \\ \widetilde{x}_{13} &= \frac{1}{3} \left[(0.25, 0.50, 0.75) \oplus (0.50, 0.75, 1.00) \oplus (0.00, 0.25, 0.50) \right] \\ &= (0.25, 0.5, 0.75), \\ \widetilde{x}_{13} &= \frac{1}{3} \left[(0.25, 0.50, 0.75) \oplus (0.50, 0.75, 1.00) \oplus (0.25, 0.50, 0.75) \right] \\ &= (0.33, 0.58, 0.83), \\ \widetilde{x}_{13} &= \frac{1}{3} \left[(0.25, 0.50, 0.75) \oplus (0.50, 0.75, 1.00) \oplus (0.00, 0.25, 0.50) \right] \\ &= (0.33, 0.58, 0.83), \\ \end{aligned}$$

Oil benchmark	E_1	E_2	E_3
<i>O</i> ₁	(0.50, 0.75, 1.00)	(0.50, 0.75, 1.00)	(0.25, 0.50, 0.75)
O ₂	(0.25, 0.50, 0.75)	(0.75, 1.00, 1.00)	(0.50, 0.75, 1.00)
O_3	(0.25, 0.50, 0.75)	(0.25, 0.50, 0.75)	(0.75, 1.00, 1.00)
O_4	(0.50, 0.75, 1.00)	(0.75, 1.00, 1.00)	(0.25, 0.50, 0.75)

Equation (13) shows part of the aggregated ratings for criteria. These results are summarized in Table 8.

This study uses the usual function (type 1) as a preference function (see equation (5)). For example,

$$\begin{split} \widetilde{p}_1(a_1, a_2) &= (0.42 - 0.83, 0.67 - 0.67, 0.83 - 0.42) = (-0.42, 0, 0.42), \\ \widetilde{p}_1(a_1, a_3) &= (0.42 - 0.75, 0.67 - 0.50, 0.83 - 0.25) = (-0.33, 0.17, 0.58), \\ \widetilde{p}_1(a_1, a_4) &= (0.42 - 0.75, 0.67 - 0.58, 0.83 - 0.33) = (-0.42, 0.08, 0.50), \\ \widetilde{p}_1(a_1, a_5) &= (0.42 - 0.75, 0.67 - 0.50, 0.83 - 0.25) = (-0.33, 0.17, 0.58), \\ \widetilde{p}_1(a_3, a_1) &= (0.25 - 0.83, 0.50 - 0.67, 0.75 - 0.42) = (-0.58, -0.17, 0.33). \end{split}$$

The initial part of the preference functions is shown in equation (14). Tables 9–13 show the fuzzy preference function of a_1, a_2, a_3, a_4, a_5 , respectively.

The next step is calculating the multifactor preference index using equation (6).

For example,

$$\begin{aligned} \pi\bigl(a_1,a_2\bigr) &= \frac{\sum[\left[(-0.42,0,0.42)*(0.42,0.67,0.92)\right]\right]}{\left[(0.42,0.67,0.92)\right]},\\ &= \frac{(-0.1764,0,-0.3864)}{(0.42,0.67,0.92)}. \end{aligned}$$

TABLE 12: Fuzzy preference function, \dot{H}	$\bar{p}_{i}(a_{4},a_{i}).$
--	-----------------------------

Parts of the preference index values are shown in equation (15). It is summarized in Table 14.

(-0.42, 0.08, 0.58)

In the following, the positive outflows and negative outflows of each factor (PROMETHEE I partial ranking) can be determined using equations (7) and (8). Table 15 shows the positive outflows and negative outflows of factors.

In fuzzy PROMETHEE I, the partial preorders of factors of $a_1P^{(I)}b_2$ are $a_1P^{(I)}a_2$, $a_1P^{(I)}a_3$, $a_1P^{(I)}a_4$, $a_1P^{(I)}a_5$, $a_2P^{(I)}a_3$, $a_2P^{(I)}a_5$, $a_3P^{(I)}a_5$, $a_4P^{(I)}a_2$, $a_4P^{(I)}a_3$, and $a_4P^{(I)}a_5$. The partial preorders of factors are shown in Figure 2.

It can be seen that the dominant factor is a_1 as this factor influences four other factors. However, PROMETHEE I could not tell the complete outranking of factors. The next analysis is PROMETHEE II where complete outranking can be obtained.

(-0.50, 0, 0.50)

Normalization equation (see equation (9)) is used to transform the triangular fuzzy numbers into left-right fuzzy numbers.

For example,

$$\phi^{+}(a_{i}):$$

$$a_{1}: (0.0242, 0.3333, 2.0336) \longrightarrow (0.3333, (0.3333 - 0.0242), (2.0336 - 0.333))$$

$$= (0.3333, 0.3091, 1.7003),$$

$$a_{2}: (-1.4570, 0.5664, 2.31922) \longrightarrow (0.56634, (0.5664 - (-1.4570))), (2.31922 - 0.5664)$$

$$= (0.5664, 2.0234, 17528).$$
(16)

Two examples of left-right fuzzy numbers are shown in equation (16). Table 16 summarizes all flows written in form of left-right fuzzy numbers.

The Yager index method is used as the defuzzification method in this study (see equation (10)). Table 17 presents the defuzzified value of flows.

Net flows (PROMETHEE II) of the factors are calculated using equation (11). The complete ranking is obtained by arranging net flows in descending order. Table 18 presents the net flow and complete preference ranking.

The partial preorder of factors as shown in Figure 2 dictates us to draw a complete preorder of factors in fuzzy PROMETHEE II. The complete preorder is

$$a_1 P^{(\text{II})} b_2, a_2 P^{(\text{II})} b_3, a_3 P^{(\text{II})} b_4 \text{ and } a_4 P^{(\text{II})} b_5.$$
 (17)

Equation (17) shows the general complete preorder of five factors. Figure 3 presents the complete order of factors.

As illustrated in Figure 3, the most influential factor affecting oil prices is a_1 (supply) followed by a_2 (demand). The least influential factor affecting oil prices is a_5 (access markets).

The results are undergone further discussion and comparative analysis. The following section discusses the results from a comparative study perspective.

5. Comparative Analysis

It is known that the fuzzy PROMETHEE method is an extension of PROMETHEE in which the evaluation scales in PROMETHEE are substituted with triangular fuzzy numbers. The uses of fuzzy numbers are meant to capture uncertainty in the factors affecting oil prices. Therefore, in this section, a comparative analysis is presented in which the results obtained from fuzzy PROMETHEE are compared to the results obtained from PROMEHEE. The computational implementation of the PROMETHEE method is slightly straightforward as the computation only deals with crisp numbers. All computational procedures in Section 3 are iterated with some modifications in the types of evaluation scales used.

This comparative analysis is presented from two viewpoints. The first outlook is by seeing the respective values of net flows. Figure 4 shows the comparison of fuzzy

TABLE 19: Ranking of Factors under PROMETHEE and fuzzy PROMETHEE.

PROMETHEE and PROMETHEE methods based on their values of net flows.

It can be seen that all factors are consistently shared similar patterns for both methods. However, for the factor of political event and crises, fuzzy PROMEHEE provides negative net flows. On the other hand, the same factor provides positive net flows when the PROMETHEE is implemented. It shows that the fuzzy numbers used in the evaluation can capture wide-ranging values compared to crisp numbers in PROMETHEE. The second viewpoint in this comparative analysis is their final preference ranking. The comparative results of final ranking preference are summarized in Table 19.

It is apparent that the factor a_2 (demand) is ranked in the first position when the crisp scales are employed in evaluation. In contrast, the factor a_1 (supply) is ranked in the first position when triangular fuzzy number scales are employed in evaluation. However, there is a similarity between the two methods. The factor a_5 (access market) shares the weakest performance for both methods.

0.8

The performance of these two methods is further analyzed using a statistical test. From the above analysis, the ranking of factors is obtained from the values of net flows. These values are seemed dissimilar due to the different methods used. However, these values can be hypothesized as having some extent of correlation between the methods. The hypotheses can be written as follows:

- (i) H0: $\rho = 0$
- (ii) H1: *ρ*≠0 where is *ρ* an estimated correlation coefficient

Test statistic $t = r/\sqrt{1-r^2/n-2}$, with df = n-2. Correlation coefficient $r = \sum XY - (\sum X)(\sum Y)$ $/n/\sqrt{(\sum X^2 - (\sum X)^2/n)(\sum Y^2 - (\sum Y)^2/n)}$, where X and Y are net flows of fuzzy PROMETHEE and PROMETHEE, respectively, and n is the number of factors.

From the calculation of the correlation coefficient, it is found that r = 0.4775 and t = 0.9413. With a significant level $\alpha = 0.05$ and t is less than 2.306, this test indicates that there is no correlation between the net flows of PROMETHEE and fuzzy PROMETHEE. From this analysis, we can conclude that these two methods are independent because of the difference in the types of numbers used as input data. It is good to note that fuzzy PROMETHEE uses triangular fuzzy numbers as input data. In contrast, crisp numbers are the input data used in PROMETHEE. This comparison also tells us that the input values are very important in determining the outcome of ranking. In other words, the ranking results obtained from the fuzzy PROMETHEE are sensitive to the input data. Different types of fuzzy numbers used could give different ranking results.

In addition to the comparative analysis between two PROMETHEE-based methods, it is also good to see the analysis between PROMETHEE-based comparative methods with other preference methods. Ziemba [42], for example, conducted a comparative study between fuzzy TOPSIS, fuzzy SAW, and NEAT fuzzy PROMETHEE II in the selection of electric vehicles. The selection problem was solved by these preference methods. The decision problem defined by the preference models gave three different solutions in the form of rankings. The rankings show that the best vehicle was awarded to A11-Volkswagen ID.3 Pro S, regardless of the preference method used. In another comparative analysis, ranking of contractors was conducted using q-ROF TOPSIS, q-ROF VIKOR, and q-ROF PROMETHEE methods [23]. They conclude that all these preference methods are close to the results of their proposed q-ROF PROMETHEE method where the optimal solution is the same for all methods

6. Conclusions

There are many factors that can contribute to global oil prices, and most of these factors are characterized by subjectivity, uncertainty, and variability. Investigation of factors affecting oil prices is therefore must be seen as a multifactor decision analysis, and more importantly, the concept of fuzziness and uncertainty must be embedded. In this paper,

factors affecting oil prices have been investigated using the approach of fuzzy PROMETHEE where triangular fuzzy numbers are employed in expert evaluation. The fuzzy PROMETHEE used in this study is characterized by partial ranking and also complete ranking. The final preference ranking is indeed a modification to the partial ranking of positive outflow values. The final ranking result shows "supply" is the most influential factor in determining oil prices followed by "demand." The current findings add significant knowledge to our understanding of the famous theory in the economic model of the price determination market. It is presumed that in a competitive market, the unit price for a specific cooperative attitude shifts until it settles at a point where the quantity demanded by buyers will equal the quantity supplied by producers. A research finding by Heakal [3] also pointed out that the oil price should increase with increasing demand or decreasing supply. Most researchers, for example [6, 7, 43], also concluded that supply and demand are the most influential factors in oil prices. Contrary to this finding, Chaw et al. [44] found that the "global economic rate" is the most influential factor. However, this research is subjected to some limitations. From the perspective of the evaluation model used, the weight assigned in this study could be improved by employing a more stable method that is germane to fuzzy knowledge such as entropy measures. Other than weight analysis, perhaps aggregation operators and sensitivity tools using PROMETHEE VI could be explored in the future. The latest aggregation methods such as Benforroni mean [45, 46], and Choquet integral [47] are among the potential candidates that could be explored as a future research direction. In future investigations, it might be possible to use different MCDM methods such as rough ELECTRE II [48] and D-TOPSIS [49], in which these methods can be applied to investigate the fluctuation of oil prices.

In order to study the role of tai chi curve algorithm in economic geography and natural ecological management and explore the application value of tai chi curve algorithm and its model, this study discusses the principle of Chinese tai chi diagram, using mathematical model construction method by the previous tai chi map and Pythagoras theorem clever results, produced the tai chi graph *s* curve algorithm, and discusses the application value of tai chi curve algorithm and its model from different angles; this study takes Zhangye geography as an example, which provides an applied research direction for the future scientific research of Chinese economic geography and also provides a clever connection with ecological correlation and nature; finally, it is found that the Taiji graph *s* curve algorithm can calculate the corresponding Yin and Yang values according to the balance point and relative deviation amount of the attribute state, and the results have an extraordinary influence in economic geography, information management system, natural ecology, and other aspects.

1. Introduction

Tai chi is the category of ancient Chinese philosophy used to analyze the movement laws of celestial bodies and to explain the origin of the world.

Since ancient times, tai chi was studied and applied by scholars, said that in early research, it was found that Tai Chi graphics expounded the law of life two, two and three, which is an important graphic expression of yin-yang theory and explained [1]. Chen Shijun (2021) also said that since Zhou Dunyi wrote the Tai Chi diagram in the Song Dynasty, the Tai Chi diagram has a unique significance in the interpretation history of the book of changes. The Tai Chi diagram vividly contains the basic contents of the book of changes, such as Yin and Yang, three talents, four images, five elements, eight trigrams, and nine palaces, reflects the unity of many elements such as image, number, reason, and occupation, and reflects the essence of the book of changes. The "unity" principle exists in the theory and the corresponding quantum field principle [2]. The "correlation principle" emphasizes "mutual exclusion and complementarity," which happens to be the principle of antagonistic unity revealed in "one Yin and one Yang." Chen and Ma studied how to deconstruct the tai chi figure [3] mathematically. Through the inner circle of the unit square, applying the lever balance principle of Archimedes theorem and the core idea of fuzzy mathematics, the s curve of tai chi diagram can be accurately expressed with a primary function. This argument suggests that tai chi maps can be expressed in mathematical language, rather than without standard geometric maps, expressing the basis for tai chi maps reflecting the existence and development of things. In the study of Chen and Wang, taking the classic symbol "Taiji diagram" as an example, this paper analyzes its morphological characteristics and aesthetic artistic conception and explores its expression and design methods in modern architectural landscape design combined with specific cases [4]. Yu elaborated the application of congenital tai chi diagram (Yin-Yang fish diagram) in opera facial makeup from three aspects: the application of tai chi graphics and colors in opera facial makeup, the position of tai chi diagram in facial makeup, and the relationship between tai chi diagram and background color in facial makeup [5].

The form of tai chi mode itself has a good guide to the current economic geography, and the *s* curve of tai chi map runs through the mathematical wisdom based on Pythagoras in ancient Chinese theorem. The intention of this study is to find tai chi Yin and Yang map in fuzzy mathematics to accurately describe the model value in the information management system of economic geography and natural game and to combine tai chi curve algorithm with economic geography, so as to study the influence of tai chi curve algorithm on social and economic development.

2. Mathematical Model of the *s* Curves of Tai Chi Figure

2.1. Quantitative Model of Tai Chi Figure. We establish a right-angle coordinate system to make a unit circle centered on the coordinate origin. The vertical axis represents the relative offset of the state and is set to A, and the two points $N(0, \delta)$; *B* and *B'* are the horizontal lines of the over-*N* point and the two intersections of the circle, respectively. Make the bisector line *OC* over the origin *O* of *AOB*, as shown in Figure 1.

In Figure 1, the coordinates of the relative offset are *N* point, let $\cos \angle AOB = \delta$, when the relative offset of the state is δ . As shown in formulas (1) and (2),

the Yang value is
$$\cos^2 \frac{\angle AOB}{2} = \frac{1+\delta}{2}$$
, (1)
the Yin value is $\sin^2 \frac{\angle AOB}{2} = \frac{1-\delta}{2}$. (2)

Here, the Yin-Yang assignment at this time is also known as the Yin-Yang assignment of point B or B' on the circle O. Notably, the Yang assignment is the square of the relative offset corresponding to the projection OM of the OC on the longitudinal axis. We can obtain a schematic tai chi diagram model under this mathematical model, as shown in Figure 2.

In Figure 2, the coordinates correspond to Figure 1; black block: Yin value; red block: Yang value;

We establish $x = \angle AOB$ and record the Yang function. As shown in formula,

$$P(x) = \frac{1 + \cos x}{2}, \quad x \in (-\infty, +\infty).$$
 (3)

We record the Yin function, as shown in formula:

$$N(x) = \frac{1 - \cos x}{2}, \quad x \in (-\infty, +\infty).$$
(4)

Here, the P(x), N(x) all are periodic functions and periodic at 2π . The Yang and Yin function is shown in Figure 3.

2.2. The Internal Connection between Tai Chi Diagram and the *Pythagorean Theorem*. For the Pythagorean theorem, the mathematical model is shown in formula:

$$a^2 + b^2 = c^2.$$
 (5)

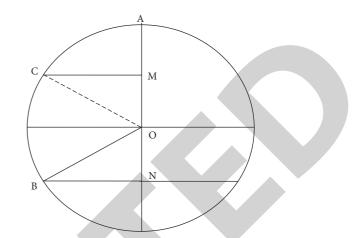

FIGURE 1: Positive value of point B is the line segment 2.

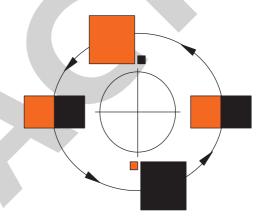

FIGURE 2: Schematic diagram of the tai chi diagram model under the new mathematical model.

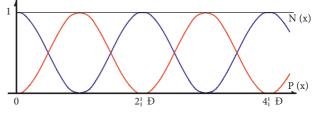

FIGURE 3: Yang function and negative function curves.

Here, *a*, *b*, *c* are the two right and oblique edges of the right triangle, respectively. Starting with the Pythagorean theorem, through the inner cut circle of the unit square, Chen had said that it applies the lever balance principle of Archimedes' theorem and the core idea of fuzzy mathematics; the *s* curve of the tai chi diagram can be accurately expressed with a primary function. The definition of a circle can also be obtained by the Pythagorean theorem; when the oblique edge is a certain length, the set of two right angular edges is the trajectory of the circle. In the end of the Eastern Han Dynasty, Zhao Shuang, a mathematician in China, created "the geometric graph on a circle (Figure 4)" [6], as shown in Figure 4.

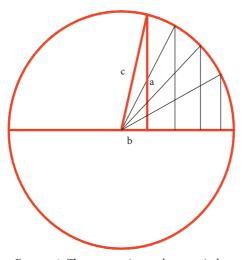

FIGURE 4: The geometric graph on a circle.

In Figure 4, if x and y represent the quotient value of the two right-angle edges' square and oblique edges' square, respectively, and this quotient value is defined as the Yang and Yin values of this triangle, respectively. We can get the relationship between Yang value and Yin value in the right-angle triangle in Figure 5.

In Figure 5, let $x = a^2/c^2$, $y = b^2/c^2$, as shown in formula:

$$x + y = \frac{a^2}{c^2} + \frac{b^2}{c^2} = 1.$$
 (6)

Here, because $a, b \in (0, c)$, so $x, y \in (0, 1)$. With the triangle function, x, y can also be expressed as in the formula:

$$x = \frac{a^2}{c^2} = \frac{c^2 - b^2}{c^2} = \sin^2 \alpha = \frac{1 - \cos 2\alpha}{2} = P(\alpha),$$

$$y = \frac{b^2}{c^2} = \frac{c^2 - a^2}{c^2} = \cos^2 \alpha = \frac{1 + \cos 2\alpha}{2} = N(\alpha).$$
(7)

Here, $\alpha \in (-\infty, +\infty)$; its geometric representation diagram is shown in Figure 6.

In Figure 6, α is the diagonal of *a*. This is perfectly consistent with the Yin-Yang theory and is a perfect combination of algebra and geometry. Connecting the formulas 5 and (6), we can know its essential connotation is that the area of the square corresponding to the oblique edge of the unit right-angle triangle is equal to the sum of the two square areas corresponding to the two right-angle edges. Chen had said that it can be illustrated by the oasis and the area relationship of the desert. Take Zhangye, Gansu Province, China [6], as shown in Figure 7.

In Figure 7, if the total area of Zhangye city is regarded as "1" per unit area, then the sum of oasis and desert area is always equal to "1" (because in the city, the water is an oasis, and the area with no water is a desert, and the sum remains the

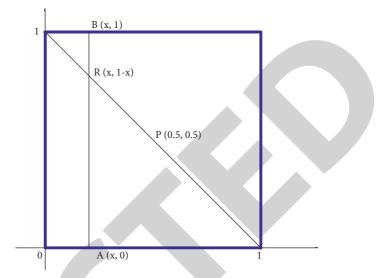

FIGURE 5: Relationship between Yang value and Yin value in the right-angle triangle.

same). When one of the areas increases, the product decreases on the other hand, and vice versa, and the set of this change process is a circular trajectory. As shown in formula (6),

$$y = 1 - x,$$

 $x = 1 - y.$ (8)

Here, therefore, the Yin and Yang function remains in dual equilibrium, entangled each other and superposition, just like quantum entanglement, its total value is fixed to "1." The area of each other is their deviation value, and the sum of the deviation value is fixed to "1." In most areas of Zhangye, it is not an oasis which is not a desert, but out of the "Schrodinger state" of oasis and desert, it is impossible to know which attribute is stronger; oasis and desert are in the x + y = 1, line section, and are in the [0, 1] range. For any set, there can be two completely opposite set discussions on an attribute, and the economic operation state can also be discussed here and divided into two completely opposite concepts of accumulation and consumption. All objective things that exist can be divided into two opposite sets with subjective attitude. However, the real state of affairs is not black or white, but out of the black and white interval, which is also Marx's dialectical "divided in two" of materialism.

2.3. *The Tai Chi Theorem*. For the establishment of the mathematical model of the *s* curve, see Figure 8.

In Figure 8, we establish a circle of diameter 1 with *O* as the center, cross the horizontal circle *O* of crossing *O* points at *A* and *B*, take a single point *P* on *OA*, let a = x, a + b = 1, make *CP* perpendicular to *AB*, connect *AC*, *BC*, and *OC*, and make *PD* perpendicular to *OC*, as shown in Figure 8.

We can get the tai chi theorem:

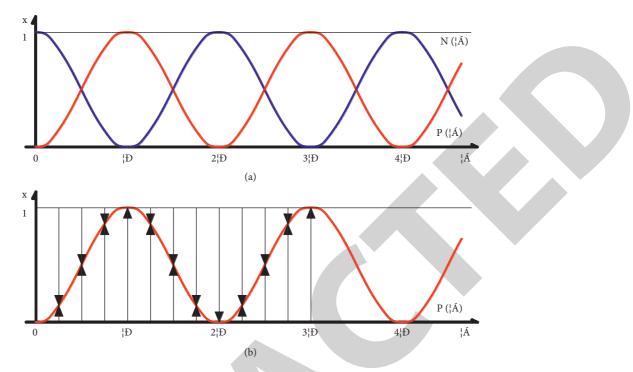

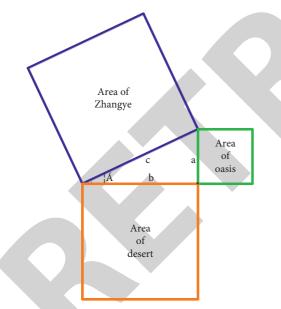

FIGURE 6: Yang and Yin values in the form of the triangle function. (a) Yangzhi and Yinzhi; (b) Yangzhi result.

A A B B

FIGURE 8: Schematic diagram of the tai chi theorem deduction.

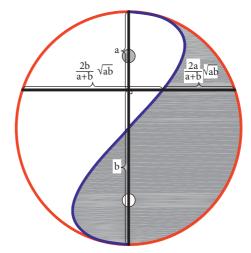

FIGURE 7: Area relationship diagram of Zhangye Oasis Desert.

$$\frac{S}{h} = \frac{OP}{OC} = \frac{b-a}{a+b},$$

$$S = \frac{b-a}{a+b} \cdot \sqrt{ab}.$$
(9)

This can be launched:

$$CD = \frac{h^2}{OC} = \frac{ab}{a+b/2} = \frac{2ab}{a+b} = \frac{2}{(1/a) + (1/b)}.$$
 (10)

FIGURE 9: Mathematical model of the Taiji theorem.

Here, $S = b - a/a + b \cdot \sqrt{ab}$ is the tai chi theorem; its trajectory curve is the China tai chi figure *s* curve. The *s* curve is rotated 90 degrees clockwise, and the tai chi theorem is shown in Figure 9.

3. Application of Tai Chi's Curve Model in Ecological Environment

Natural ecology has been closely related to tai chi since ancient times. Nature has been growing everywhere. The ecological chain also reproduces and breeds according to this law, and the natural environment also plays a game between living beings. When a population's growth rate has exceeded what the environment can accommodate, the natural environment imposes its growth restrictions, such as sudden food reduction, insufficient land resources, and more natural enemies. Ideally, when the growth amount of the population tribe reaches just half the environmental capacity, the biological growth rate is the fastest, and the distribution amount of food and the environment can just be balanced, which is the most favorable growth value conducive to biological survival.

In Table 1, K is the maximum number of populations that can be maintained in a certain space range when the environmental conditions are not damaged; x is the growth rate of the population in this spatial range (all growth rates in the table are compared to the proliferation rate at 1/2 of the environmental capacity).

As shown in Table 1, the environmental capacity is the whole circle, and biological proliferation rate of an environment is the *s* curve. When the biological growth rate rises rapidly and peaks, the curve decreases, indicating that the growth rate of the environment has reached saturation, due to food shortage, spouse shortage, and habitat pressure, the number of the organisms will decline sharply, and the number of resources, natural enemies, and the other factors will inhibit it. When the number drops sharply to a certain range, the amount of biological growth increases again. Let the ambient capacity be the *K* value, and the negative and positive values calculated from the equilibrium value of the relative deviation amount will be the K/2.

If it fails to develop according to its natural laws, the result will flood like the Australian hare, lack of competition from natural enemies, sufficient food, serious damage to the natural environment to limit its growth, and eventually lead to uncontrollable human results.

4. Application of Tai Chi Curve Algorithm in Economic Geography

Taiji curve model can also be applied in economic geography, and its model can generally describe the law of industrial layout and the technical and economic scientific development concept of the research objects. The combination of natural technology, science, and economy separated and integrated in the model is indispensable. The three achieve a wonderful balance in urban planning, human activities, and natural ecology.

TABLE 1: Relationship between the total biomass change and growth rate in an area.

Total biomass	x > K/2	x = K/2	<i>x</i> < <i>K</i> /2	
Biological growth rate in this population	Reduce	Normal growth	Accelerate	
Data source: the study was designed by itself				

Data source: the study was designed by itself.

TABLE 2: The amount use and allocation of urban infrastructure construction and ecological planning between the two cities.

	A city allocated economic use (ten thousand yuan)	<i>B</i> city allocated economic use (ten thousand yuan)
Total state appropriation (ten thousand yuan)	n	n
Urban foundation construction (ten thousand yuan)	a	b
Urban ecological development (ten thousand yuan)	с	d

Data source: the study was designed by itself.

The significance of the model is different between the regions of different scales, and the magic of the *s* curve model diagram is that it can clearly and thoroughly express the correlation of the variables between various complex systems and draw it in the ancient Chinese tai chi figure.

For example, the state allocates n 0.000 yuan to both A and B cities for the development and construction of its cities. A city, because of the urban economic development, is not as developed as B city, so most of the allocated funds are used on urban infrastructure construction, and the remaining small part for urban ecological development; B city is economically developed city, while the natural resources are far inferior to A city, so B city has invested a lot of money in urban ecological planning, the rest is used in urban economic construction. Table 2 is drawn as described above.

In Table 2, n is the amount allocated by the state to the two cities; a is the amount used for urban foundation construction in A city; b is the amount used for urban foundation construction in B city; c is the amount used in A urban ecological development; d is the amount used for urban ecological development of B city:

$$n^2 = a^2 + c^2 = b^2 + d^2.$$
(11)

Here, the formula notes are shown in Table 2. According to Table 2, combined with the tai chi *s* curve model algorithm used, the total national approval fund is set as the circle constructed, and then the funds used in urban ecological development planning and the funds used in urban economic development and construction will be negative and positive values. According to the balance value of the relative deviation value, the funds invested in all parties can be calculated through the *s* curve model. According to the hook theorem, the total value square remains unchanged, the

In recent times, the applications of graph theory in molecular and chemical structure research have far exceeded human expectations and have grown exponentially. In this paper, we have determined the multiplicative Zagreb indices, multiplicative hyper-Zagreb indices, multiplicative universal Zagreb indices, sum and product connectivity of multiplicative indices, multiplicative atom-bond connectivity index, and multiplicative geometric-arithmetic index of a famous crystalline structure, magnesium iodide (MgI₂).

1. Introduction and Preliminary Results

In chemical graph theory, molecules can be modeled as graphs by representing atoms as vertices and atomic bonds as edges [1]. The nervous system can be thought of as a graph, where the neurons (nodes) and the edges (bonds) are between them. The nervous system can be seen as a graph, where the nodes are neurons and the edges are the connections between them.

The representation of a graph can be expressed by numbers, polynomials, and matrices. Graphs have their own characteristics that may be calculated by topological indices, and under graph automorphism, the topology of graphs remains unchanged. Degree-based topological indices are exceptionally important among different classes of indices and take on a vital role in graph theory and in particular in science [2]. Cheminformatics is a brand-new field that combines chemistry, mathematics, and information science. It investigates quantitative structure-activity (QSAR) and structure-property (QSPR) connections, which are used to predict chemical compound biological activities and qualities.

Magnesium iodide (MgI_2) is a chemical compound and has many commercial uses. It is used for manufacture of different organic compounds in large scale due to its cheapness and availability everywhere in the world. Magnesium iodide can be obtained from the reaction of hydroiodic acid with magnesium oxide, magnesium hydroxide, and magnesium carbonate.

$$2HI + MgCO_3 \longrightarrow MgI_2 + H_2O + CO_2$$

$$2HI + MgO \longrightarrow MgI_2 + H_2O$$
 (1)

$$2HI + Mg(OH)_2 \longrightarrow MgI_2 + 2H_2O$$

Every heptagon in MgI_2 is connected to each other in column and row by making three C_4 within each heptagon. We will use "*m*" to represent the number of C_4 rows on the upper side and "*n*" to represent the number of C_4 on the lower side of the heptagon.

m = 1n = 1n = 1n = 2n = 3n = 4n = 5 $FIGURE 1: Graph (<math>\mathfrak{L}_1$) of MgI₂ for m = 2n + 1. m = 1n =

FIGURE 2: Graph (\mathfrak{L}_2) of MgI₂ for m = 2n + 2.

In Figures 1 and 2, there are variables m and n, which are dependent on each other to maintain the structure of magnesium iodide. Magnesium has 2 electrons in its outermost shell, while iodide contains 7 electrons in its valence shell. As a result, to turn out to be stable, magnesium offers its electrons to iodide. To maintain the chemical structure of magnesium iodide, it depends on each other. As a result, the graph was subdivided into even and odd vertices. For the first type, the cardinality of vertices and edges of graph (\mathfrak{L}_1) , as shown in Figure 1, is m = 2n + 1, and for the second type, the cardinality of vertices and edges of graph (\mathfrak{L}_2) , as shown in Figure 2, is m = 2n + 2, where $n \in \mathbb{N}$, respectively.

In this article, " \mathfrak{A} " is considered a structure with a vertex set $V(\mathfrak{A})$ and edge set $E(\mathfrak{A})$, and d(r) is the degree of vertex $r \in V(\mathfrak{A})$.

The "second multiplicative Zagreb index" [4] is defined as

$$II_{2}(\mathfrak{L}) = \prod_{rs \in E(\mathfrak{L})} (d_{r} \times d_{s}), \qquad (2)$$

where (r, s) is any unordered pair of vertices in \mathfrak{L} .

Kulli [5] further described some new and advanced topological indices, and he named them as the "first multiplicative hyper-Zagreb index" and the "second multiplicative hyper-Zagreb index" of a graph " \mathfrak{L} ." The indices are defined as

$$\operatorname{HII}_{1}(\mathfrak{L}) = \prod_{rs \in E(\mathfrak{L})} (d_{r} + d_{s})^{2}, \qquad (3)$$

$$\operatorname{HII}_{2}(\mathfrak{A}) = \prod_{rs \in E(\mathfrak{A})} (d_{r} \times d_{s})^{2}.$$
(4)

The "first multiplicative universal Zagreb index" and the "second multiplicative universal Zagreb index" were introduced by Kulli et al. [6]. These indices are defined as

$$MZ_1^a(\mathfrak{L}) = \prod_{rs \in E(\mathfrak{L})} (d_r + d_s)^a,$$
(5)

$$MZ_2^a(\mathfrak{L}) = \prod_{rs \in E(\mathfrak{L})} (d_r \times d_s)^a,$$
(6)

where $a \in \mathbb{N}$.

The multiplicative sum and product connectivity indices were introduced by Kulli [7], defined as

$$SCII(\mathfrak{Q}) = \prod_{rs \in E(\mathfrak{Q})} \frac{1}{\sqrt{d_r + d_s}},$$
(7)

PCII (
$$\mathfrak{L}$$
) = $\prod_{rs\in E(\mathfrak{L})} \frac{1}{\sqrt{d_r \times d_s}}$ (8)

"Multiplicative atom-bond connectivity index," "multiplicative geometric-arithmetic index," and "multiplicative universal geometric-arithmetic index" for a simple graph \mathfrak{A} were introduced by Kulli [7], and these indices are defined as

ABCII(
$$\mathfrak{L}$$
) = $\prod_{rs \in E(\mathfrak{L})} \sqrt{\frac{d_r + d_s - 2}{d_r \times d_s}}$, (9)

$$\text{GAII}(\mathfrak{L}) = \prod_{rs \in E(\mathfrak{L})} \frac{2\sqrt{d_r \times d_s}}{d_r + d_s},$$
(10)

TABLE 1: Edge subdivision of \mathfrak{L}_1 of MgI₂ based on degree of end vertices of each edge for m = 2n + 1, where $n \in \mathbb{N}$.

(d_r, d_s) where $rs \in E(\mathfrak{L}_1)$	Number of edges
(1, 3)	1
(1, 4)	1
(1, 6)	<i>n</i> + 5
(2, 5)	8
(2, 6)	2 <i>n</i> + 8
(3, 2)	2
(3, 3)	3n
(3, 4)	1
(3, 5)	12
(3, 6)	27n - 13
(4, 2)	2

$$GA^{a}II(\mathfrak{L}) = \left(\prod_{rs \in E(\mathfrak{L})} \frac{2\sqrt{d_{r} \times d_{s}}}{d_{r} + d_{s}}\right)^{a}, \qquad (11)$$

where $a \in \mathbb{N}$.

2. Main Results

Afzal et al. [8] computed the molecular description for magnesium iodide. In this article, we shall discuss the first type and second type of magnesium iodide structure and compute the exact results for topological indices like multiplicative Zagreb indices, multiplicative hyper-Zagreb indices, multiplicative universal Zagreb indices, sum and product connectivity of multiplicative indices, multiplicative atom-bond connectivity index, and multiplicative geometric-arithmetic index for the magnesium iodide structure. For further study of topological indices of various graph families, see [9–14]. For basic definitions and notations, see [15, 16].

2.1. Results for the First Type of Magnesium Iodide Structure. In this section, we compute topological indices such as multiplicative Zagreb indices, multiplicative hyper-Zagreb indices, multiplicative universal Zagreb, sum and product connectivity of multiplicative indices, multiplicative atombond connectivity index, and multiplicative geometric and universal geometric-arithmetic indices for the first type of magnesium iodide structure (Ω_1), as shown in Figure 1.

Theorem 1. Consider the magnesium iodide structure MgI_2 of first type; then, the second multiplicative Zagreb index is equal to

$$II_{2}(\mathfrak{L}) = 13931406950400n(n+5)(2n+8)(27n-13).$$
(12)

Proof. Let \mathfrak{A}_1 be the magnesium iodide structure MgI₂ for $m = 2n + 1, n \in \mathbb{N}$ of first type. In Table 1, there is an edge partition of \mathfrak{A}_1 . From equation (2),

$$II_2(\mathfrak{L}_1) = \prod_{r \in E(\mathfrak{L}_1)} (d_r \times d_s).$$
(13)

By applying edge partition of Table 1,

$$\begin{aligned} \mathrm{II}_{2}\left(\mathfrak{L}_{1}\right) &= 3\left|E_{1}\left(\mathfrak{L}_{1}\right)\right| \times 4\left|E_{2}\left(\mathfrak{L}_{1}\right)\right| \times 6\left|E_{3}\left(\mathfrak{L}_{1}\right)\right| \times 10\left|E_{4}\left(\mathfrak{L}_{1}\right)\right| \times 12\left|E_{5}\left(\mathfrak{L}_{1}\right)\right| \\ &\times 6\left|E_{6}\left(\mathfrak{L}_{1}\right)\right| \times 9\left|E_{7}\left(\mathfrak{L}_{1}\right)\right| \times 12\left|E_{8}\left(\mathfrak{L}_{1}\right)\right| \times 15\left|E_{9}\left(\mathfrak{L}_{1}\right)\right| \times 18\left|E_{10}\left(\mathfrak{L}_{1}\right)\right| \times 8\left|E_{11}\left(\mathfrak{L}_{1}\right)\right| \\ &= 3\left(1\right) \times 4\left(1\right) \times 6\left(n+5\right) \times 10\left(8\right) \times 12\left(2n+8\right) \times 6\left(2\right) \times 9\left(3n\right) \\ &\times 12\left(1\right) \times 15\left(12\right) \times 18\left(27n-13\right) \times 8\left(2\right). \end{aligned}$$
(14)

(15)

We obtain the following by making some calculations: $\Rightarrow II_2(\mathfrak{L}_1) = 13931406950400n(n+5)(2n+8)(27n-13).$ **Theorem 2.** Consider the magnesium iodide structure MgI_2 of first type; then, the first and second multiplicative hyper-Zagreb indices are equal to

$$HII_{1}(\mathfrak{L}_{1}) = 582761278687150080000n(n+5)(2n+8)(27n-13),$$

$$HII_{2}(\mathfrak{L}_{1}) = 168475780918101934080000n(n+5)(2n+8)(27n-13).$$
(16)

Proof. Let \mathfrak{L}_1 be the magnesium iodide structure MgI₂ of first type. In Table 1, there is an edge partition of \mathfrak{L}_1 . From equation (3),

By applying edge partition of Table 1,

 $\operatorname{HII}_{1}(\mathfrak{L}_{1}) = \prod_{rs \in E(\mathfrak{L}_{1})} (d_{r} + d_{s})^{2}.$

(17)

$$HII_{1}(\mathfrak{L}_{1}) = 16[E_{1}(\mathfrak{L}_{1})| \times 25[E_{2}(\mathfrak{L}_{1})| \times 49]E_{3}(\mathfrak{L}_{1})| \times 49]E_{4}(\mathfrak{L}_{1})| \times 64]E_{5}(\mathfrak{L}_{1})| \\ \times 25[E_{6}(\mathfrak{L}_{1})| \times 36[E_{7}(\mathfrak{L}_{1})] \times 49]E_{8}(\mathfrak{L}_{1})| \times 64]E_{9}(\mathfrak{L}_{1})| \\ \times 81|E_{10}(\mathfrak{L}_{1})| \times 36|E_{11}(\mathfrak{L}_{1})| \\ = 16(1) \times 25(1) \times 49(n+5) \times 49(8) \times 64(2n+8) \times 25(2) \\ \times 36(3n) \times 49(1) \times 64(12) \times 81(27n-13) \times 36(2). \\ HII_{2}(\mathfrak{L}_{1}) = 582761278687150080000n(n+5)(2n+8)(27n-13). \\ (19) \\ HII_{2}(\mathfrak{L}_{1}) = 582761278687150080000n(n+5)(2n+8)(27n-13). \\ (19) \\ From equation (4), \\ HII_{2}(\mathfrak{L}_{1}) = 9|E_{1}(\mathfrak{L}_{1})| \times 16|E_{2}(\mathfrak{L}_{1})| \times 36|E_{3}(\mathfrak{L}_{1})| \times 100|E_{4}(\mathfrak{L}_{1})| \times 144|E_{5}(\mathfrak{L}_{1})| \\ \times 36|E_{6}(\mathfrak{L}_{1})| \times 81|E_{7}(\mathfrak{L}_{1})| \times 125|E_{9}(\mathfrak{L}_{1})| \\ \times 324|E_{10}(\mathfrak{L}_{1})| \times 64|E_{11}(\mathfrak{L}_{1})| \\ \times 324|E_{10}(\mathfrak{L}_{1})| \times 36(n+5) \times 100(8) \times 144(2n+8) \times 36(2) \\ (21) \\ = 9(1) \times 16(1) \times 36(n+5) \times 100(8) \times 144(2n+8) \times 36(2) \\ \end{array}$$

 $\times 81(3n) \times 144(1) \times 225(12) \times 324(27n - 13) \times 64(2).$

We obtain the following by making some calculations: $\Rightarrow HII_2(\mathfrak{L}_1) = 168475780918101934080000n(n+5)$ (22)
(2n+8)(27n-13). **Theorem 3.** Consider the magnesium iodide structure MgI_2 of first type; then, the first and second multiplicative universal Zagreb indices are equal to

$$MZ_1^a(\mathfrak{L}_1) = 2^{7+10a} \times 3^{2+4a} \times 5^{2a} \times 7^{3a}n(n+5)(2n+8)(27n-13),$$

$$MZ_2^a(\mathfrak{L}_1) = 2^{7+13a} \times 3^{2+10a} \times 5^{2a} \times n(n+5)(2n+8)(27n-13).$$
(23)

Proof. Let \mathfrak{L}_1 be the magnesium iodide structure MgI₂ of first type. In Table 1, there is an edge partition of \mathfrak{L}_1 . From equation (5),

 $MZ_1^a(\mathfrak{L}_1) = \prod_{rs\in E(\mathfrak{L}_1)} (d_r + d_s)^a.$ (24)

By applying edge partition of Table 1,

$$MZ_{1}^{a}(\mathfrak{L}_{1}) = 4^{a} |E_{1}(\mathfrak{L}_{1})| \times 5^{a} |E_{2}(\mathfrak{L}_{1})| \times 7^{a} |E_{3}(\mathfrak{L}_{1})| \times 7^{a} |E_{4}(\mathfrak{L}_{1})| \times 8^{a} |E_{5}(\mathfrak{L}_{1})| \times 5^{a} |E_{6}(\mathfrak{L}_{1})| \times 6^{a} |E_{7}(\mathfrak{L}_{1})| \times 7^{a} |E_{8}(\mathfrak{L}_{1})| \times 8^{a} |E_{9}(\mathfrak{L}_{1})| \times 9^{a} |E_{10}(\mathfrak{L}_{1})| \times 6^{a} |E_{11}(\mathfrak{L}_{1})| = 4^{a} (1) \times 5^{a} (1) \times 7^{a} (n+5) \times 7^{a} (8) \times 8^{a} (2n+8) \times 5^{a} (2) \times 6^{a} (3n) \times 7^{a} (1) \times 8^{a} (12) \times 9^{a} (27n-13) \times 6^{a} (2).$$

$$(25)$$

We obtain the following by making some calculations:

$$\Rightarrow MZ_1^a(\mathfrak{L}_1) = 2^{7+10a} \times 3^{2+4a} \times 5^{2a} \times 7^{3a}n(n+5)$$

$$(2n+8)(27n-13).$$
(26)

From equation (6),

$$MZ_2^a(\mathfrak{L}_1) = \prod_{rs \in E} (\mathfrak{L}_1) (d_r \times d_s)^a.$$
(27)

By applying edge partition of Table 1,

$$MZ_{1}^{a}(\mathfrak{Q}_{1}) = 3^{a} |E_{1}(\mathfrak{Q}_{1})| \times 4^{a} |E_{2}(\mathfrak{Q}_{1})| \times 6^{a} |E_{3}(\mathfrak{Q}_{1})| \times 10^{a} |E_{4}(\mathfrak{Q}_{1})| \times 12^{a} |E_{5}(\mathfrak{Q}_{1})| \\ \times 6^{a} |E_{6}(\mathfrak{Q}_{1})| \times 9^{a} |E_{7}(\mathfrak{Q}_{1})| \times 12^{a} |E_{8}(\mathfrak{Q}_{1})| \times 15^{a} |E_{9}(\mathfrak{Q}_{1})| \\ \times 18^{a} |E_{10}(\mathfrak{Q}_{1})| \times 8^{a} |E_{11}(\mathfrak{Q}_{1})| \\ = 3^{a}(1) \times 4^{a}(1) \times 6^{a}(n+5) \times 10^{a}(8) \times 12^{a}(2n+8) \times 6^{a}(2) \\ \times 9^{a}(3n) \times 12^{a}(1) \times 15^{a}(12) \times 18^{a}(27n-13) \times 8^{a}(2).$$
(28)

We obtain the following by making some calculations:

$$\Rightarrow MZ_2^a(\mathfrak{L}_1) = 2^{7+13a} \times 3^{2+10a} \times 5^{2a} \times n(n+5)$$
(29)

$$(2n+8)(27n-13).$$

Theorem 4. Consider the magnesium iodide structure MgI_2 of first type; then, the multiplicative sum and product connectivity indices are equal to

SCII
$$(\mathfrak{L}_1) = \frac{4}{35\sqrt{7}}n(n+5)(2n+8)(27n-13),$$

PCII $(\mathfrak{L}_1) = \frac{\sqrt{2}}{135}n(n+5)(2n+8)(27n-13).$
(30)

Proof. Let \mathfrak{L}_1 be the magnesium iodide structure MgI₂ of first type. In Table 1, there is an edge partition of \mathfrak{L}_1 . From equation (7),

$$\mathrm{SCH}(\mathfrak{L}_1) = \prod_{rs \in E(\Upsilon)} \frac{1}{\sqrt{d_r + d_s}}.$$
 (31)

By applying edge partition of Table 1,

 $SCII(\mathfrak{L}_{1}) = \frac{1}{\sqrt{4}} |E_{1}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{5}} |E_{2}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{7}} |E_{3}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{7}} |E_{4}(\mathfrak{L}_{1})|$ $\times \frac{1}{\sqrt{8}} |E_{5}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{5}} |E_{6}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{6}} |E_{7}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{7}} |E_{8}(\mathfrak{L}_{1})|$ $\times \frac{1}{\sqrt{8}} |E_{9}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{9}} |E_{10}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{6}} |E_{11}(\mathfrak{L}_{1})|$ $= \frac{1}{\sqrt{4}} (1) \times \frac{1}{\sqrt{5}} (1) \times \frac{1}{\sqrt{7}} (n+5) \times \frac{1}{\sqrt{7}} (8) \times \frac{1}{\sqrt{8}} (2n+8) \times \frac{1}{\sqrt{5}} (2)$ $\times \frac{1}{\sqrt{6}} (3n) \times \frac{1}{\sqrt{7}} (1) \times \frac{1}{\sqrt{8}} (12) \times \frac{1}{\sqrt{9}} (9) \times \frac{1}{\sqrt{6}} (2).$ (32)

We obtain the following by making some calculations:

From equation (8),

$$\Rightarrow \text{SCII}(\mathfrak{L}_1) = \frac{4}{35\sqrt{7}}n(n+5)(2n+8)(27n-13).$$
(33)

$$PCII(\mathfrak{L}_1) = \prod_{rs \in E(\mathfrak{L}_1)} \frac{1}{\sqrt{d_r \times d_s}}.$$
 (34)

By applying edge partition of Table 1,

$$PCII(\mathfrak{L}_{1}) = \frac{1}{\sqrt{3}} |E_{1}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{4}} |E_{2}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{6}} |E_{3}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{10}} |E_{4}(\mathfrak{L}_{1})|$$

$$\times \frac{1}{\sqrt{12}} |E_{5}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{6}} |E_{6}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{9}} |E_{7}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{12}} |E_{8}(\mathfrak{L}_{1})|$$

$$\times \frac{1}{\sqrt{15}} |E_{9}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{18}} |E_{10}(\mathfrak{L}_{1})| \times \frac{1}{\sqrt{8}} |E_{11}(\mathfrak{L}_{1})|$$

$$= \frac{1}{\sqrt{3}} (1) \times \frac{1}{\sqrt{4}} (1) \times \frac{1}{\sqrt{6}} (n+5) \times \frac{1}{\sqrt{10}} (8) \times \frac{1}{\sqrt{12}} (2n+8) \times \frac{1}{\sqrt{6}} (2)$$

$$\times \frac{1}{\sqrt{9}} (3n) \times \frac{1}{\sqrt{12}} (1) \times \frac{1}{\sqrt{15}} (12) \times \frac{1}{\sqrt{18}} (9) \times \frac{1}{\sqrt{8}} (2).$$
(35)

We obtain the following by making some calculations:

$$\Rightarrow \text{PCII}(\mathfrak{L}_1) = \frac{\sqrt{2}}{135}n(n+5)(2n+8)(27n-13). \tag{36}$$

Theorem 5. Consider the magnesium iodide structure MgI_2 of first type; then, the multiplicative atom-bond connectivity and geometric-arithmetic indices are equal to

ABCII
$$(\mathfrak{L}_1) = \frac{16\sqrt{35}}{3}n(n+5)(2n+8)(27n-13),$$

GAII $(\mathfrak{L}_1) = \frac{442368\sqrt{2}}{1715}n(n+5)(2n+8)(27n-13).$
(37)

Proof. Let \mathfrak{L}_1 be the magnesium iodide structure MgI₂ of first type. In Table 1, there is an edge partition of \mathfrak{L}_1 . From equation (9),

ABCII
$$(\mathfrak{L}_1) = \prod_{rs \in EMgI_2} \sqrt{\frac{d_r + d_s - 2}{d_r \times d_s}}.$$
 (38)

By applying edge partition of Table 1,

$$ABCII(\mathfrak{L}_{1}) = \sqrt{\frac{2}{3}} |E_{1}(\mathfrak{L}_{1})| \times \sqrt{\frac{3}{4}} |E_{2}(\mathfrak{L}_{1})| \times \sqrt{\frac{5}{6}} |E_{3}(\mathfrak{L}_{1})| \times \sqrt{\frac{5}{10}} |E_{4}(\mathfrak{L}_{1})| \\ \times \sqrt{\frac{6}{12}} |E_{5}(\mathfrak{L}_{1})| \times \sqrt{\frac{3}{6}} |E_{6}(\mathfrak{L}_{1})| \times \sqrt{\frac{4}{9}} |E_{7}(\mathfrak{L}_{1})| \times \sqrt{\frac{5}{12}} |E_{8}(\mathfrak{L}_{1})| \\ \times \sqrt{\frac{6}{15}} |E_{9}(\mathfrak{L}_{1})| \times \sqrt{\frac{7}{18}} |E_{10}(\mathfrak{L}_{1})| \times \sqrt{\frac{4}{8}} |E_{11}(\mathfrak{L}_{1})| \\ = \sqrt{\frac{2}{3}} (1) \times \sqrt{\frac{3}{4}} (1) \times \sqrt{\frac{5}{6}} (n+5) \times \sqrt{\frac{5}{10}} (8) \times \sqrt{\frac{6}{12}} (2n+8) \\ \times \sqrt{\frac{3}{6}} (2) \sqrt{\frac{4}{9}} (3n) \times (1) \sqrt{\frac{5}{12}} \times \sqrt{\frac{6}{15}} (12) \times \sqrt{\frac{7}{18}} (27n-13) \times \sqrt{\frac{4}{8}} (2).$$

$$(39)$$

We obtain the following by making some calculations:

From equation (10),

$$\text{GAII}(\mathfrak{L}_1) = \prod_{rs \in E} \left(\mathfrak{L}_1\right) \frac{2\sqrt{d_r \times d_s}}{d_r + d_s}.$$
(41)

$$\Rightarrow \text{ABCII}(\mathfrak{L}_1) = \frac{16\sqrt{35}}{3}n(n+5)(2n+8)(27n-13).$$
(40)

By applying edge partition of Table 1,

$$GAII(\mathfrak{L}_{1}) = \frac{2\sqrt{3}}{4} |E_{1}(\mathfrak{L}_{1})| \times \frac{2\sqrt{4}}{5} |E_{2}(\mathfrak{L}_{1})| \times \frac{2\sqrt{6}}{7} |E_{3}(\mathfrak{L}_{1})| \times \frac{2\sqrt{10}}{7} |E_{4}(\mathfrak{L}_{1})|$$

$$\times \frac{2\sqrt{12}}{8} |E_{5}(\mathfrak{L}_{1})| \times \frac{2\sqrt{6}}{5} |E_{6}(\mathfrak{L}_{1})| \frac{2\sqrt{9}}{6} |E_{7}(\mathfrak{L}_{1})| \times \frac{2\sqrt{12}}{7} |E_{8}(\mathfrak{L}_{1})|$$

$$\times \frac{2\sqrt{15}}{8} |E_{9}(\mathfrak{L}_{1})| \times \frac{2\sqrt{18}}{9} |E_{10}(\mathfrak{L}_{1})| \times \frac{2\sqrt{8}}{6} |E_{11}(\mathfrak{L}_{1})|$$

$$= \frac{2\sqrt{3}}{4} (1) \times \frac{2\sqrt{4}}{5} (1) \times \frac{2\sqrt{6}}{7} (n+5) \times \frac{2\sqrt{10}}{7} (8) \times \frac{2\sqrt{12}}{8} (2n+8)$$

$$\times \frac{2\sqrt{6}}{5} (2) \times \frac{2\sqrt{9}}{6} (3n) \times \frac{2\sqrt{12}}{7} (1) \times \frac{2\sqrt{15}}{8} (12) \times \frac{2\sqrt{18}}{9} (27n-13) \times \frac{2\sqrt{8}}{6} (2).$$

We obtain the following by making some calculations:

$$\Rightarrow \text{GAII}(\mathfrak{L}_1) = \frac{442368\sqrt{2}}{1715}n(n+5)(2n+8)(27n-13).$$
(43)

Theorem 6. Consider the magnesium iodide structure MgI_2 of first type; then, the universal multiplicative geometricarithmetic index is equal to

$$GA^{a}II(\mathfrak{L}_{1}) = 2^{(14+15a/2)} \times 3^{2+a} \times 5^{-a} \times 7^{-3a}n(n+5)$$

$$(2n+8)(27n-13).$$
(44)

Proof. Let \mathfrak{L}_1 be the magnesium iodide structure MgI₂ of first type. In Table 1, there is an edge partition of \mathfrak{L}_1 . From equation (10),

$$GA^{a}II(\mathfrak{L}_{1}) = \prod_{rs\in E(\mathfrak{L}_{1})} \frac{2\sqrt{d_{r}\times d_{s}}^{a}}{d_{r}+d_{s}}.$$
(45)

By applying edge partition of Table 1,

$$GA^{a}II(\mathfrak{L}_{1}) = \left\{\frac{2\sqrt{3}}{4}\right\}^{a}|E_{1}(\mathfrak{L}_{1})| \times \left\{\frac{2\sqrt{4}}{5}\right\}^{a}|E_{2}(\mathfrak{L}_{1})| \times \left\{\frac{2\sqrt{6}}{7}\right\}^{a}|E_{3}(\mathfrak{L}_{1})|$$

$$\times \left\{\frac{2\sqrt{10}}{7}\right\}^{a}|E_{4}(\mathfrak{L}_{1})| \times |E_{5}(\mathfrak{L}_{1})| \left\{\frac{2\sqrt{12}}{8}\right\}^{a} \times \left\{\frac{2\sqrt{6}}{5}\right\}^{a}|E_{6}(\mathfrak{L}_{1})|$$

$$\times \left\{\frac{2\sqrt{9}}{6}\right\}^{a}|E_{7}(\mathfrak{L}_{1})| \times \left\{\frac{2\sqrt{12}}{7}\right\}^{a}|E_{8}(\mathfrak{L}_{1})| \times \left\{\frac{2\sqrt{15}}{8}\right\}^{a}|E_{9}(\mathfrak{L}_{1})|$$

$$\times \left\{\frac{2\sqrt{18}}{9}\right\}^{a}|E_{10}(\mathfrak{L}_{1})| \times \left\{\frac{2\sqrt{8}}{6}\right\}^{a}|E_{11}(\mathfrak{L}_{1})|$$

$$= \left\{\frac{2\sqrt{3}}{4}\right\}^{a}(1) \times \left\{\frac{2\sqrt{4}}{5}(1)\right\}^{a} \times \left\{\frac{2\sqrt{6}}{7}\right\}^{a}(n+5) \times \left\{\frac{2\sqrt{10}}{7}(8)\right\}^{a}$$

$$\times \left\{\frac{2\sqrt{12}}{8}\right\}^{a}(2n+8) \times \left\{\frac{2\sqrt{6}}{5}\right\}^{a}(2) \times \left\{\frac{2\sqrt{9}}{6}\right\}^{a}(3n) \times \left\{\frac{2\sqrt{12}}{7}\right\}^{a}(1)$$

$$\times \left\{\frac{2\sqrt{15}}{8}\right\}^{a}(12) \times \left\{\frac{2\sqrt{18}}{9}\right\}^{a}(27n-13) \times \left\{\frac{2\sqrt{8}}{6}\right\}^{a}(2).$$

(42)

We obtain the following by making some calculations:

$$\Rightarrow GA^{a}II(\mathfrak{L}_{1}) = 2^{(14+15a/2)} \times 3^{2+a} \times 5^{-a} \times 7^{-3a}n(n+5)$$

$$(2n+8)(27n-13).$$
(47)

2.2. Results for the Second Type of Magnesium Iodide Structure. In this section, we compute topological indices such as multiplicative Zagreb indices, multiplicative hyper-Zagreb indices, multiplicative universal Zagreb indices, sum and product connectivity of multiplicative indices, multiplicative atom-bond connectivity index, and multiplicative geometric and universal geometric-arithmetic indices for the second type of magnesium iodide structure.

Theorem 7. Consider the magnesium iodide structure MgI_2 of second type; then, the second multiplicative Zagreb index is equal to

$$II_{2}(\mathfrak{L}_{2}) = 75582720000(n+5)(2n+8)(3n+1)(27n+7).$$
(48)

TABLE 2: Edge subdivision of \mathfrak{L}_2 MgI₂ based on degree of end vertices of each edge for m = 2n + 2, where $n \in \mathbb{N}$.

(d_r, d_s) where $rs \in E(\mathfrak{L}_2)$	Number of edges
(1, 3)	1
(1, 5)	1
(1, 6)	<i>n</i> + 5
(2, 2)	5
(2, 5)	2
(2, 6)	2 <i>n</i> + 8
(3, 2)	6
(3, 3)	3 <i>n</i> + 1
(3, 5)	2
(3, 6)	27 <i>n</i> + 7

Proof. Let \mathfrak{L}_2 be the magnesium iodide structure MgI₂ of second type. In Table 2, there is an edge partition of \mathfrak{L}_2 . From equation (2),

$$II_{2}(\mathfrak{L}_{2}) = \prod_{rs \in E(\mathfrak{L}_{2})} (d_{r} \times d_{s}).$$
(49)

By applying edge partition of Table 2,

$$\begin{aligned} \Pi_{2}(\mathfrak{L}_{2}) &= 3|E_{1}(\mathfrak{L}_{2})| \times 5|E_{2}(\mathfrak{L}_{2})| \times 6|E_{3}(\mathfrak{L}_{2})| \times 4|E_{4}(\mathfrak{L}_{2})| \times 10|E_{5}(\mathfrak{L}_{2})| \\ &\times 12|E_{6}(\mathfrak{L}_{2})| \times 6|E_{7}(\mathfrak{L}_{2})| \times 9|E_{8}(\mathfrak{L}_{2})| \times 15|E_{9}(\mathfrak{L}_{2})| \times 18|E_{10}(\mathfrak{L}_{2})| \\ &= 3(1) \times 5(1) \times 6(n+5) \times 4(5) \times 10(2) \times 12(2n+8) \times 6(6) \\ &\times 9(3n+1) \times 15(2) \times 18(27n+7). \end{aligned}$$
(50)

We obtain the following by making some calculations: $\Rightarrow II_2(\mathfrak{L}_2) = 75582720000 (n+5)(2n+8)(3n+1)(27n+7).$ (51) **Theorem 8.** Consider the magnesium iodide structure MgI_2 of second type; then, the first and second multiplicative hyper-Zagreb indices are equal to

$$HII_{1}(\mathfrak{L}_{2}) = 792872488009728000 (n+5) (2n+8) (3n+1) (27n+7),$$

$$HII_{2}(\mathfrak{L}_{2}) = 4760622968832000000 (n+5) (2n+8) (3n+1) (27n+7).$$
(52)

$$\operatorname{HII}_{1}(\mathfrak{L}_{2}) = \prod_{rs \in E(\mathfrak{L}_{2})} (d_{r} + d_{s})^{2}.$$
 (53)

Proof. Let \mathfrak{L}_2 be the magnesium iodide structure MgI₂ of second type. In Table 2, there is an edge partition of \mathfrak{L}_2 . From equation (3),

By applying edge partition of Table 2,

$$HII_{1}(\mathfrak{L}_{2}) = 16|E_{1}(\mathfrak{L}_{2})| \times 36|E_{2}(\mathfrak{L}_{2})| \times 49|E_{3}(\mathfrak{L}_{2})| \times 16|E_{4}(\mathfrak{L}_{2})| \times 49|E_{5}(\mathfrak{L}_{2})| \times 64|E_{6}(\mathfrak{L}_{2})| \times 25|E_{7}(\mathfrak{L}_{2})| \times 36|E_{8}(\mathfrak{L}_{2})| \times 64|E_{9}(\mathfrak{L}_{2})| \times 81|E_{10}(\mathfrak{L}_{2})| = 16(1) \times 36(1) \times 49(n+5) \times 16(5) \times 49(2) \times 64(2n+8) \times 25(6) \times 36(3n+1) \times 64(2) \times 81(27n+7).$$
(54)

TABLE 3: Comparison among $II_2(\mathfrak{L}_1)$, $HII_1(\mathfrak{L}_1)$, and $HII_2(\mathfrak{L}_1)$ indices of MgI₂ for m = 2n + 1, where $n \in \mathbb{N}$.

Theorem 9. Consider the magnesium iodide structure MgI_2 of second type; then, the first and second multiplicative universal Zagreb indices are equal to

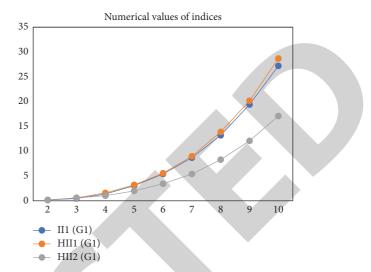

FIGURE 6: Graphical comparison of $II_2(\mathfrak{L}_2)$, $HII_1(\mathfrak{L}_2)$, and $HII_2(\mathfrak{L}_2)$ indices of MgI₂ for m = 2n + 2.

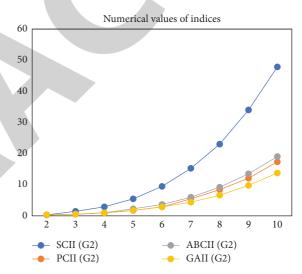

FIGURE 7: Graphical Comparison among SCII(\mathfrak{L}_2), PCII(\mathfrak{L}_2), ABCII(\mathfrak{L}_2), and GAII(\mathfrak{L}_2) indices of MgI₂ for m = 2n + 2.

$$MZ_{1}^{a}(\mathfrak{L}_{2}) = 5^{1+a} \times 7^{2a} \times 24^{1+4a} (n+5) (2n+8) (3n+1) (27n+7),$$

$$MZ_{2}^{a}(\mathfrak{L}_{2}) = 2^{3+8a} \times 3^{1+9a} \times 5^{1+3a} \times (n+5) (2n+8) (3n+1) (27n+7).$$
(59)

Proof. Let \mathfrak{L}_2 be the magnesium iodide structure MgI₂ of second type. In Table 2, there is an edge partition of \mathfrak{L}_2 . From equation (5),

$$MZ_1^a(\mathfrak{L}_2) = \prod_{rs \in E(\mathfrak{L}_2)} (d_r + d_s)^a.$$
(60)

By applying edge partition of Table 2,

$$MZ_{1}^{a}(\mathfrak{L}_{2}) = 4^{a} |E_{1}(\mathfrak{L}_{2})| \times 6^{a} |E_{2}(\mathfrak{L}_{2})| \times 7^{a} |E_{3}(\mathfrak{L}_{2})| \times 4^{a} |E_{4}(\mathfrak{L}_{2})| \times 7^{a} |E_{5}(\mathfrak{L}_{2})| \times 8^{a} |E_{6}(\mathfrak{L}_{2})| \times 5^{a} |E_{7}(\mathfrak{L}_{2})| \times 6^{a} |E_{8}(\mathfrak{L}_{2})| \times 8^{a} |E_{9}(\mathfrak{L}_{2})| \times 9^{a} |E_{10}(\mathfrak{L}_{2})| = 4^{a} (1) \times 6^{a} (1) \times 7^{a} (n+5) \times 4^{a} (5) \times 7^{a} (2) \times 8^{a} (2n+8) \times 5^{a} (6) \times 6^{a} (3n+1) \times 8^{a} (2) \times 9^{a} (27n+7).$$
(61)

We obtain the following by making some calculations:

$$\Rightarrow MZ_1^a(\mathfrak{L}_2) = 5^{1+a} \times 7^{2a} \times 24^{1+4a} (n+5)(2n+8) (3n+1)(27n+7).$$
(62)

From equation (6),

$$MZ_2^a(\mathfrak{L}_2) = \prod_{rs \in E(\mathfrak{L}_2)} (d_r \times d_s)^a.$$
(63)

By applying edge partition of Table 2,

(64)

We obtain the following by making some calculations:

$$\Rightarrow MZ_2^a(\mathfrak{L}_2) = 2^{3+8a} \times 3^{1+9a} \times 5^{1+3a} \times (n+5)(2n+8)$$

$$(3n+1)(27n+7).$$

$$\square$$

Theorem 10. Consider the magnesium iodide structure MgI_2 of second type; then, the multiplicative sum and product connectivity indices are equal to

SCII
$$(\mathfrak{L}_2) = \frac{1}{168\sqrt{5}} (n+5)(2n+8)(3n+1)(27n+7),$$

PCII
$$(\mathfrak{L}_2) = \frac{1}{54\sqrt{15}} (n+5)(2n+8)(3n+1)(27n+7).$$

Proof. Let \mathfrak{L}_2 be the magnesium iodide structure MgI₂ of second type. In Table 2, there is an edge partition of \mathfrak{L}_2 . From equation (7),

$$SCII(\mathfrak{Q}_2) = \prod_{rs \in E(\mathfrak{Q}_2)} \frac{1}{\sqrt{d_r + d_s}}.$$
 (67)

By applying edge partition of Table 2,

$$SCII(\mathfrak{L}_{2}) = \frac{1}{\sqrt{4}} |E_{1}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{6}} |E_{2}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{7}} |E_{3}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{4}} |E_{4}(\mathfrak{L}_{2})| \\ \times \frac{1}{\sqrt{7}} |E_{5}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{8}} |E_{6}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{5}} |E_{7}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{6}} |E_{8}(\mathfrak{L}_{2})| \\ \times \frac{1}{\sqrt{8}} |E_{9}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{9}} |E_{10}(\mathfrak{L}_{2})| \\ = \frac{1}{\sqrt{4}} (1) \times \frac{1}{\sqrt{6}} (1) \times \frac{1}{\sqrt{7}} (n+5) \times \frac{1}{\sqrt{4}} (5) \times \frac{1}{\sqrt{7}} (2) \times \frac{1}{\sqrt{8}} (2n+8) \\ \times \frac{1}{\sqrt{5}} (6) \times \frac{1}{\sqrt{6}} (3n+1) \times \frac{1}{\sqrt{8}} (2) \times \frac{1}{\sqrt{9}} (27n+7). \end{cases}$$
(68)

 $MZ_{2}^{a}(\mathfrak{L}_{2}) = 3^{a} |E_{1}(\mathfrak{L}_{2})| \times 5^{a} |E_{2}(\mathfrak{L}_{2})| \times 6^{a} |E_{3}(\mathfrak{L}_{2})| \times 4^{a} |E_{4}(\mathfrak{L}_{2})|$

(66)

We obtain the following by making some calculations:

$$\Rightarrow \text{SCII}(\mathfrak{L}_2) = \frac{1}{168\sqrt{5}} (n+5)(2n+8)(3n+1)(27n+7).$$
(69)

$$PCII(\mathfrak{L}_2) = \prod_{rs \in E(\mathfrak{L}_2)} \frac{1}{\sqrt{d_r \times d_s}}.$$
 (70)

By applying edge partition of Table 2,

11

(71)

(75)

(77)

$$PCII(\mathfrak{L}_{2}) = \frac{1}{\sqrt{3}} |E_{1}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{5}} |E_{2}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{6}} |E_{3}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{4}} |E_{4}(\mathfrak{L}_{2})|$$
$$\times \frac{1}{\sqrt{10}} |E_{5}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{12}} |E_{6}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{6}} |E_{7}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{9}} |E_{7}(\mathfrak{L}_{2})|$$
$$\times \frac{1}{\sqrt{15}} |E_{9}(\mathfrak{L}_{2})| \times \frac{1}{\sqrt{18}} |E_{10}(\mathfrak{L}_{2})|$$
$$= \frac{1}{\sqrt{3}} (1) \times \frac{1}{\sqrt{5}} (1) \times \frac{1}{\sqrt{6}} (n+5) \times \frac{1}{\sqrt{4}} (5) \times \frac{1}{\sqrt{10}} (2)$$
$$\times \frac{1}{\sqrt{12}} (2n+8) \times \frac{1}{\sqrt{6}} (6) \times \frac{1}{\sqrt{9}} (3n+1) \times \frac{1}{\sqrt{15}} (2) \times \frac{1}{\sqrt{18}} (27n+7).$$

 $ABCII(\mathfrak{L}_2) = \sqrt{\frac{2}{3}} |E_1(\mathfrak{L}_2)| \times \sqrt{\frac{4}{5}} |E_2(\mathfrak{L}_2)| \times \sqrt{\frac{5}{6}} |E_3(\mathfrak{L}_2)| \times \sqrt{\frac{2}{4}} |E_4(\mathfrak{L}_2)|$

 $=\sqrt{\frac{2}{3}}(1)\times\sqrt{\frac{4}{5}}(1)\times\sqrt{\frac{5}{6}}(n+5)\times\sqrt{\frac{2}{4}}(5)\times\sqrt{\frac{5}{10}}(2)$

 $\times \sqrt{\frac{6}{15}} |E_9(\mathfrak{L}_2)| \times \sqrt{\frac{7}{18}} |E_{10}(\mathfrak{L}_2)|$

 $\times \sqrt{\frac{5}{10}} |E_5(\mathfrak{L}_2)| \times \sqrt{\frac{6}{12}} |E_6(\mathfrak{L}_2)| \sqrt{\frac{3}{6}} |E_7(\mathfrak{L}_2)| \times \sqrt{\frac{4}{6}} |E_8(\mathfrak{L}_2)|$

 $\times \sqrt{\frac{6}{12}}(2n+8)\sqrt{\frac{3}{6}}(6) \times (3n+1)\sqrt{\frac{4}{9}} \times \sqrt{\frac{6}{15}}(2) \times \sqrt{\frac{7}{18}}(27n+7).$

From equation (9),

We obtain the following by making some calculations: $\Rightarrow \text{PCII}(\mathfrak{L}_2) = \frac{1}{54\sqrt{15}} (n+5)(2n+8)(3n+1)(27n+7).$ (72) *Proof.* Let \mathfrak{L}_2 be the magnesium iodide structure MgI₂ of second type. In Table 2, there is an edge partition of \mathfrak{L}_2 . From equation (9),

ABCII
$$(\mathfrak{L}_2) = \prod_{rs\in E} \mathfrak{L}_2 \sqrt{\frac{d_r + d_s - 2}{d_r \times d_s}}.$$
 (74)

By applying edge partition of Table 2,

Theorem 11. Consider the magnesium iodide structure MgI_2 of second type; then, the multiplicative atom-bond connectivity index and geometric-arithmetic index are equal to

ABCII
$$(\mathfrak{L}_2) = \frac{8\sqrt{35}}{9} (n+5)(2n+8)(3n+1)(27n+7),$$

GAII $(\mathfrak{L}_2) = \frac{480\sqrt{15}}{49} (n+5)(2n+8)(3n+1)(27n+7).$
(73)

We obtain the following by making some calculations:

$$\Rightarrow ABCII(\mathfrak{L}_2) = \frac{8\sqrt{35}}{9} (n+5)(2n+8)(3n+1)(27n+7).$$

(76)

 $\text{GAII}(\mathfrak{L}_2) = \prod_{rs \in E} (\mathfrak{L}_2) \frac{2\sqrt{d_r \times d_s}}{d_r + d_s}.$

By applying edge partition of Table 2,

$$\begin{aligned} \text{GAII}(\mathfrak{L}_{2}) &= \frac{2\sqrt{3}}{4} |E_{1}(\mathfrak{L}_{2})| \times \frac{2\sqrt{5}}{6} |E_{2}(\mathfrak{L}_{2})| \times \frac{2\sqrt{6}}{7} |E_{3}(\mathfrak{L}_{2})| \times \frac{2\sqrt{4}}{4} |E_{4}(\mathfrak{L}_{2})| \\ &\times \frac{2\sqrt{10}}{7} |E_{5}(\mathfrak{L}_{2})| \times \frac{2\sqrt{12}}{8} |E_{6}(\mathfrak{L}_{2})| \times \frac{2\sqrt{6}}{5} |E_{7}(\mathfrak{L}_{2})| \times \frac{2\sqrt{9}}{6} |E_{8}(\mathfrak{L}_{2})| \\ &\times \frac{2\sqrt{15}}{8} |E_{9}(\mathfrak{L}_{2})| \times \frac{2\sqrt{18}}{9} |E_{10}(\mathfrak{L}_{2})| \\ &= \frac{2\sqrt{3}}{4} (1) \times \frac{2\sqrt{5}}{6} (1) \times \frac{2\sqrt{6}}{7} (n+5) \times \frac{2\sqrt{4}}{4} (5) \times \frac{2\sqrt{10}}{7} (2) \\ &\times \frac{2\sqrt{12}}{8} (2n+8) \frac{2\sqrt{6}}{5} (6) \times \frac{2\sqrt{9}}{6} (3n+1) \times \frac{2\sqrt{15}}{8} (2) \times \frac{2\sqrt{18}}{9} (27n+7). \end{aligned}$$

We obtain the following by making some calculations:

 $\Rightarrow \text{GAII}(\mathfrak{L}_2) = \frac{480\sqrt{15}}{49} (n+5)(2n+8)(3n+1)(27n+7).$ (79)

Theorem 12. Consider the magnesium iodide structure MgI_2 of second type; then, the universal multiplicative geometricarithmetic index is equal to

$$GA^{a}II(\mathfrak{L}_{2}) = 2^{3+2a} \times 7^{-2a} \times 15^{(2+a)/2} (n+5) (2n+8)$$

$$(3n+1) (27n+7).$$
(80)

Proof. Let \mathfrak{L}_2 be the magnesium iodide structure MgI₂ of second type. In Table 2, there is an edge partition of \mathfrak{L}_2 . From equation (10),

$$GA^{a}II(\mathfrak{L}_{2}) = \prod_{rs\in E(\mathfrak{L}_{2})} \frac{2\sqrt{d_{r} \times d_{s}}^{a}}{d_{r} + d_{s}}.$$
(81)

By applying edge partition of Table 2,

$$GA^{a}II(\mathfrak{L}_{2}) = \left(\frac{2\sqrt{3}}{4}\right)^{a} |E_{1}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{5}}{6}\right)^{a} |E_{2}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{6}}{7}\right)^{a} |E_{3}(\mathfrak{L}_{2})| \\ \times \left(\frac{2\sqrt{4}}{4}\right)^{a} |E_{4}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{10}}{7}\right)^{a} |E_{5}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{12}}{8}\right)^{a} |E_{6}(\mathfrak{L}_{2})| \\ \times \left(\frac{2\sqrt{6}}{5}\right)^{a} |E_{7}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{9}}{6}\right)^{a} |E_{8}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{15}}{8}\right)^{a} |E_{9}(\mathfrak{L}_{2})| \times \left(\frac{2\sqrt{18}}{9}\right)^{a} |E_{10}(\mathfrak{L}_{2})| \\ = \left(\frac{2\sqrt{3}}{4}\right)^{a} (1) \times \left(\frac{2\sqrt{5}}{6}\right)^{a} (1) \times \left(\frac{2\sqrt{6}}{7}\right)^{a} (n+5) \times \left(\frac{2\sqrt{4}}{4}\right)^{a} (5) \\ \times \left(\frac{2\sqrt{10}}{7}\right)^{a} (2) \times \left(\frac{2\sqrt{12}}{8}\right)^{a} (2n+8) \left(\frac{2\sqrt{18}}{9}\right)^{a} (27n+7).$$

$$(82)$$

(78)

We obtain the following by making some calculations:

$$\Rightarrow GA^{a}II(\mathfrak{L}_{2}) = 2^{3+2a} \times 7^{-2a} \times 15^{(2+a)/2} (n+5)(2n+8) (3n+1)(27n+7).$$
(83)

3. Numerical and Graphical Comparison

In this section, we compute all the indices numerically and present the result in the following tables.

- (i) For the comparison of II₂(𝔅₁), HII₁(𝔅₁), and HII₂(𝔅₁) indices of MgI₂ for *m* = 2*n* + 1, where *n* ∈ N, in Table 3, indices for various *n* values have been calculated. One can clearly see that all the indices are increasing in order for increasing values of *n*. Graphical representations of these topological indices are shown in Figure 3 for different values of *n*.
- (ii) For the comparison of SCII(\mathfrak{L}_1), PCII(\mathfrak{L}_1), ABCII(\mathfrak{L}_1), and GAII(\mathfrak{L}_1) indices of MgI₂ for m = 2n + 1, where $n \in \mathbb{N}$, numerically, we computed some indices for different values of *n*. In Table 4, indices for various *n* values have been calculated. One can clearly see that all the indices are increasing in order for increasing values of *n*. Graphical representations of these topological indices are shown in Figure 4 for different values of *n*.
- (iii) For the comparison of $II_2(\mathfrak{L}_2)$, $HII_1(\mathfrak{L}_2)$, and $HII_2(\mathfrak{L}_2)$ indices of MgI_2 for m = 2n + 2, where $n \in \mathbb{N}$, in Table 5, indices for various *n* values have been calculated. One can clearly see that all the indices are increasing in order for increasing values of *n*. Graphical representations of these topological indices are shown in Figure 5 for different values of *n*.
- (iv) For the comparison of SCII(\mathfrak{L}_2), PCII(\mathfrak{L}_2), ABCII(\mathfrak{L}_2), and GAII(\mathfrak{L}_2) indices of MgI₂ for m = 2n + 2, where $n \in \mathbb{N}$, numerically, we computed some indices for different values of *n*. In Table 6, indices for various *n* values have been calculated. One can clearly see that all the indices are increasing in order for increasing values of *n*. Graphical representations of these topological indices are shown in Figure 6 for different values of *n*.

4. Discussion

Since topological indices play a vital role in various fields of science such as software engineering, medication, and pharmaceutical industry, their numerical values and graphical representations are very much important for researchers. Here, we calculate some exact values of multiplicative degree-based indices of a famous crystalline structure, magnesium iodide (MgI₂). Furthermore, we construct Tables 3–6 and Figures 4–7 to estimate the degree-based topological indices for various values of *n*. From tables and figures, we can see that as *n* increases, the degree-based indices of these networks also increase.

5. Conclusion

In this paper, we have constructed the crystalline graph of magnesium iodide with different approaches of graph theory. We subdivided the graph in even and odd vertices. We computed the multiplicative topological indices such as multiplicative Zagreb indices, multiplicative hyper-Zagreb indices, multiplicative universal Zagreb indices, sum and product connectivity of multiplicative indices, multiplicative atom-bond connectivity index, and multiplicative geometric-arithmetic index of MgI_2 structures in this research for the very first time. In addition, we have given general formulation for those indices that may be very beneficial while analyzing the underlying topologies.

In future, we are interested to design some new architectures/networks and then study their topological indices, which will be quite helpful to understand their underlying topologies.

University physical education is an important public basic course in colleges and universities. The traditional teaching is usually within the class time specified in the training program; the teacher teaches the students the basic physical education fundamentals so that the students can master the basic skills of sports, thus improving the students' sports level and physical quality. An improved genetic algorithm is proposed to reduce the problem of slow convergence and partial convergence of the fundamental genetic algorithm for intelligent grouping systems. To ensure the group's stability and variety, the algorithm can rapidly extend the search space by repeatedly rejecting similar individuals. Therefore, this study proposes a new method of intelligent grouping based on the improved genetic algorithm. The new method can overcome the problem of premature convergence of the algorithm more efficiently and easily than the traditional algorithm. A large number of experiments have proved that the proposed algorithm moderate difficulty and reasonable structure.

1. Introduction

Although Massive Open Online Course (MOOC) has been available in China since 2013 and along with the development of these years, many universities have joined the MOOC team, and the online courses have been growing, but through the survey, we can find that most of the online courses in China are mainly focused on computer, foreign language, and some vocational courses, while the MOOC courses on physical education have just begun in China. This means that MOOC is full of opportunities and challenges for the reform of university physical education in China.

Traditional teaching is usually to teach students the basic knowledge of physical education within the class time specified in the training program so that students can master the basic skills of sports to improve their sports level and physical quality. However, such teaching is very limited, and the teacher-student ratio in many colleges and universities is not sufficient, so the choice of programs in physical education classes is very limited, and many students cannot choose the courses they are interested in, and they cannot satisfy the supplementary physical education knowledge and sports skills training outside the curriculum.

MOOC is a combination of modern Internet technology, computer technology, and mobile technology that allows learning to be accessed anytime, anywhere, and quickly. MOOC is an attempt to superimpose the classroom content on top of this modern information, from massive information to cloud information, making the coverage of physical education content infinitely expandable, which is beyond the reach of traditional physical education content. In addition, the openness of MOOC allows students to access other schools, regions, and even other countries' sports courses in addition to their own sports courses, providing a platform for students who want to master different sports. The openness of the MOOC also allows students to have access to other schools, other regions, and even other countries, providing a platform for students who want to master different sports. At the same time, the MOOC can break the limitations of time and space so that students do not lose the opportunity to learn because of the limited number of students who can take courses and can avoid conflicts in taking multiple courses.

The MOOC courses are organized in a cloud learning environment, which allows students to study in different places and different environments at any time, and with access to mobile terminals, students can access MOOC learning opportunities more freely. Students can study anywhere on campus with their mobile phones, and the same account can be used for intermittent learning, making the learning process both humanized and personalized, making it very easy for students to learn.

The integration of sports training and tactics into traditional physical education has greatly enriched the content, especially by incorporating the latest sports events into the teaching of physical education, which can greatly enhance students' interest in sports. In addition, the most important advantage of physical education classes is that they allow students to choose the content that interests them as much as possible, which is a great complement to traditional physical education classes and makes them more diverse [1].

In addition to benefiting students, teachers can also refer to the content and teaching methods of outstanding scholars in MOOC and improve the traditional and outdated teaching methods in their classes to achieve a more interactive and cooperative way of teaching students. In this way, both students' independent online Massive Online Course (MOC) and teachers' teaching reform in physical education classrooms can greatly increase students' interest in physical activity. In addition, MOOC's easy cloud learning environment allows students to enjoy sports anytime and anywhere, replacing "task sports" with "interest sports" and truly achieving happy sports.

In recent years, optimization algorithms have attracted a lot of attention, such as artificial neural networks and genetic algorithms, among others [2]. It provides new ideas for solving complex problems and has been successful in many fields. Intelligent roll-up is a constrained multiobjective optimization problem. Conventional roll formation algorithms suffer from slow convergence, low success rate, and low quality. Automatic generation systems are always an essential research direction in all kinds of computer-aided testing systems. The efficiency and quality of an intelligent paper-forming system are determined by the algorithm. In this study, we focus on the application of genetic algorithms to combinatorial optimization problems.

The genetic algorithm is based on the principle of natural selection, which is the fundamental law of nature as a whole, and the principle of survival of the fittest and elimination of the inferior. The mechanism of natural selection involves the replication of individuals, the selection of individuals, the inheritance and recombination of individuals, and the variation of individual characteristics. Through these processes, selection can work from one generation to the next, allowing the evolution of the organism to develop in a favorable direction. On this basis, species can accumulate and develop from one direction to another, allowing for diversity in organisms. Thus, through natural selection, populations can be diversified and new species can be created.

Genetic algorithms have a significant advantage over other search algorithms because they are simple to implement, fast in target finding, and strong in coding, making them a good stochastic search algorithm with important applications in many fields. The process of implementation and computation of a genetic algorithm is mainly carried out through several important functions specific to the genetic algorithm, and the direction of the computation is achieved by setting the function and using the adjustment of the direction to achieve the final computation result. In order to improve the genetic algorithm and to achieve the initial effect, it is necessary to study and set the parameters of the algorithm; specifically, in this study, the improvement of genetic algorithm is realized by using race selection in factor operation. On this basis, an improved adaptive genetic algorithm selection mechanism is proposed to enable the target population to operate adaptively so that the genetic algorithm can be used in the first step. This allows the genetic algorithm to converge too early in the early stages or inefficiently in the late stages.

In order to avoid the risk of slow and partial convergence of the basic genetic algorithm for intelligent grouping systems, an improved genetic algorithm is proposed. This algorithm can rapidly expand the search space by continuously eliminating similar individuals and ensure the stability and diversity of the clusters. Therefore, this study proposes a new method of intelligent grouping based on the improved genetic algorithm. The new method can overcome the problem of premature convergence of the algorithm more efficiently and easily than the traditional algorithm. It is proved that the proposed algorithm can meet all the requirements of physical education. The algorithm can automatically generate test papers with moderate difficulty and reasonable structure.

The paper organizations are as follows. Section 2 defines the mathematical models. Section 3 discusses the algorithm design and implementation. Section 4 discusses the analysis of experimental results. Section 5 concludes the article.

2. Mathematical Models

The constraints of the intelligent paper system include overall time, paper score, paper difficulty factor, question type ratio, ability level, knowledge point, regional criteria, and the number of generations. From the perspective of extracting the best combination of questions from a large pool of questions, the intelligent paper-grouping problem is a multiconstraint combination optimization problem. Therefore, if each question has n attributes, combining a study with m questions is equivalent to constructing an objective matrix:

$$s = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}.$$
 (1)

In the target matrix, each row represents an attribute of a test question, and there are n attributes in total, i.e., n-dimensional vectors. The total score of the study is a_1 , the difficulty factor is a_2 , the ability level is a_3 , the knowledge is a_4 , the distribution is a_5 , the proportion of questions is a_6 , and the completion time is a_7 . This is a problem of solving the state matrix, and the target transitions are not unique. The target matrix should satisfy the following constraints:

- (1) Total test paper score = $\sum_{i=1}^{m} a_{i1}$ (assigned by physical education, i.e., test paper score constraint)
- (2) Difficulty factor = $\sum_{i=1}^{m} a_{i1}a_{i2}$ /total score (specified by physical education, i.e., the difficulty constraint of the test paper)
- (3) Completion time = $\sum_{i=1}^{m} a_{i7}$ (designated by physical education, i.e., time constraints)
- (4) Proficiency level categories (basic understanding, insight and understanding, skill experience, and free play) and scores are assigned by physical education, also known as proficiency level constraints ∑^m_{i=1} c_ia_{i7} = z_p, where z_p is the p proficiency level of the test score, c_{1i} { 1 . . . a_{i3} = p, 1 . . . a_{i3} ≠ p.
- (5) Distribution = $\sum_{i=1}^{m} a_{i1}a_{i5} / \sum_{i=1}^{m} a_{i1}$ (specified by the physical education curriculum, i.e., distribution constraint); question types, knowledge points, distribution, and other constraints are similar to those mentioned above

3. Algorithm Design and Implementation

In this section, we defined the algorithm design and improvement of genetic operations; the crossover operation selects a single-point crossover, mutation operation, genetic algorithm parameters, coding method, elite protection strategy, and algorithm description.

3.1. Algorithm Design. Genetic algorithm was proposed by J.H. Holland, an American scholar. Genetic algorithm is a computational model that simulates the evolutionary process of living organisms in nature. It is gaining attention because of its advantages, such as simplicity, robustness, global search, and fast convergence, and it is not limited by the constraints of the search space. These advantages make it very suitable for the technical problem of intelligent volume formation. The algorithm establishes an initial population of a specific size before inducing crossover and mutation of individuals with a particular probability, resulting in a structural reorganization of individuals. Then, using a specified evaluation function, a new generation is created by picking the finest individuals for replication. The iterations are repeated until a globally optimal solution is found that satisfies the optimization conditions.

Traditional genetic algorithms suffer from low efficiency and tend to generate immature convergence in the later stages of the algorithm. Therefore, many improvement methods have been tried, including designing different choices, cross-variance operations, changing the algorithm structure, designing adaptive cross-variance probabilities, and combining genetic algorithms with other optimization intelligence algorithms. In this study, we propose a method to solve the problem of automatic paper formation with high reliability and validity by globally optimizing the papers in order to finally form the required papers. The results of the algorithm are very good. The specific method is as follows.

3.1.1. Coding Method. The choice of the encoding method is directly dependent on the characteristics of the problem and is an important factor affecting the performance of the algorithm. Common coding methods include binary coding, decimal coding, and real number coding. Because the constraints of the question database directly affect the speed of accessing the database, the algorithm creates a repository file for each question type in order to quickly select the specified question type and reduce the redundancy problem when automatically grouping papers. As a result, the grouped real number encoding method is chosen by the intelligent paper grouping system. Each question type is coded relative to the real number, each code reflects a question type, and the question grouping codes are separate. We mapped a paper to a chromosome and each question to a gene. The gene value can be directly expressed by the number of question types, e.g., in Java programming (5 multiple choice, 5 fill-in-the-blank, 2 short answer, 2 program reading, and 2 programming); then, the chromosome code can be 23, 45, 90, 67, 22, 11, 69, 112, 9, 37, 78, 54, 23, 35, 11, 23. The initial population of the paper was not generated by a completely random selection method, but was generated randomly based on the proportion of questions, total score, completion time, and absence of redundant knowledge points. This accelerates the convergence of the genetic algorithm and reduces the number of iterations. Since different question types are retrieved from different question tables, the same test string number may appear in the same gene string since they belong to different question types. Therefore, this situation is common and does not affect the automatic grouping. Using the grouped real number encoding method, it is able to overcome the drawbacks of too large search space and excessive encoding length in the previously used binary encoding. Also, it enhances the solving speed by eliminating the decoding time of individuals.

The fitness function, also known as the evaluation function, is a criterion used to distinguish between good and bad individuals in a population-based on an objective function. Genetic algorithms use fitness values to guide the search direction, and the fitness function does not require continuous or differential, or other auxiliary information. We use the following form of the fitness function as

$$F = \frac{1}{\left(1 + \sum_{i=1}^{m} k_i |e_i|\right)},$$
(2)

where e_i corresponds to the *i*th influencing factor of the constraint paper and k_i corresponds to the weighting factor $k_i > 1$ of the error. This fitness function is able to intelligently group the search features of the paper problem. The smaller the error between the individual

paper and the paper constraint is, the closer the individual paper is to the target.

(1) Improvement of genetic operations: selection operation intelligent group roll system selects the fitness proportion method. The fitness proportion method, also known as the roulette wheel method, is the most common and classical selection strategy in genetic algorithms today. The population size is n, the fitness value of individual i is f_i , and the probability of individual i being selected is shown as

$$p_{si} = \frac{f_i}{\sum_{i=1}^n f_i}.$$
(3)

Obviously, the greater the proportion of fitness of an individual, the greater the probability of being selected.

② The crossover operation selects a single-point crossover: for two randomly selected chromosomes, a single-point crossover is used to generate random crossover positions in the same type group. If the number of knowledge points and questions is duplicated, the crossover point is then reselected.

③ Mutation operation: the mutation operation also improves on the traditional single-point mutation, i.e., by restricting the genes at each position of each individual to be disordered according to the assumed mutation probability p_m . With the help of the mutation operation, we are able to obtain the target of the local search.

3.1.2. Genetic Algorithm Parameters. The crossover probability p_c and the variance probability p_m of the genetic algorithm have an important impact on the algorithm performance. If p_c and p_m are too large, the algorithm may become a random search. However, if p_c is too small, it may cause a slower search process. If p_m is too small, then it is difficult to generate a new generation and may also cause the algorithm to mature prematurely and get a local optimal solution. We continuously change the crossover probability and variation probability according to the evolution of the population in order to improve the genetic algorithm's search efficiency, avoid local optimum, and protect outstanding individual papers. The automatic adjustment formula in the automatic paper formation system is as follows:

$$p_{c} = \begin{pmatrix} \frac{0.9(f_{\max} - f)}{f_{\max}}, & f \ge f_{\max}, \\ 0.9, & f < f_{\max}, \\ 0.9, & f < f_{\max}, \\ p_{m} = \begin{pmatrix} \frac{0.3(f_{\max} - f)}{f_{\max}}, & f' \ge f_{\operatorname{avg}}, \\ 0.3, & f' < f_{\operatorname{avg}}, \end{pmatrix}$$
(4)

where p_c denotes crossover probability, p_m denotes variation probability, $f_{\rm max}$ denotes maximum fitness value, $f_{\rm avg}$

denotes average fitness value, f is the greater fitness value of the two crossover individuals, and f is the fitness value of the various individuals. However, for individuals with fitness values lower than the average fitness value, the probability of elimination is relatively high. Therefore, the adaptive p_c and p_m can provide the best crossover probability and variation probability for the individuals of the test paper.

3.1.3. Elite Protection Strategy. After the reproduction, crossover, and mutation operations, the algorithm compares the sufficiency value of the best individual of the new generation with that of the best individual of the previous generation. If it falls, the new generation's poorest individual is replaced by the previous generation's finest individual. This technique protects the best individuals from the effects of reproduction, crossover, and mutation. It is a crucial assurance for the genetic algorithm's convergence.

3.2. Algorithm Description. Parameter settings: maximum number of generations, Max, population size, n, crossover probability, p_c , variance probability, p_m , fitness threshold, M, and input requirements for physical education in an automatic grouping.

In this study, the adaptive selection mechanism and the selection operator are used to calculate the individuals that meet the requirements, to adjust the scale of the competition adaptively, to make timely adjustments according to the variation operation in the process of the competition, to solve the shortcomings of the traditional genetic algorithm of too fast convergence and orientation, and to ensure that the final optimal solution can be obtained in the genetic algorithm. The framework of the algorithm is improved, and the optimal retention strategy is integrated so that the good computational process of the algorithm can be well retained and inherited to ensure that the individuals obtained are in line with the requirements of physical education.

The whole process of the above algorithm can be expressed in the following steps:

Step 1: first, initialize the evolutionary algebra and set it to 0 to start the initialization of the species population Step 2: adaptation calculations were then performed, mainly for the individual

Step 3: if the end condition is not met, the calculated fitness value and the adopted strategy complete the selection step; the crossover in the genetic algorithm is performed, and if the result of the check meets the requirements of the relevant settings of the intelligent group roll, the operation can be performed; if it does not, it returns; after completing the crossover operation, the mutation operation is performed; the selection mutation operation is performed, and the next generation of individuals is successfully obtained through the above operation. If the new individual has a better fitness than all the individuals, the new individual is set as the best individual and the results and values are saved. If not, we proceed to the next step. The process is shown in Figure 1.

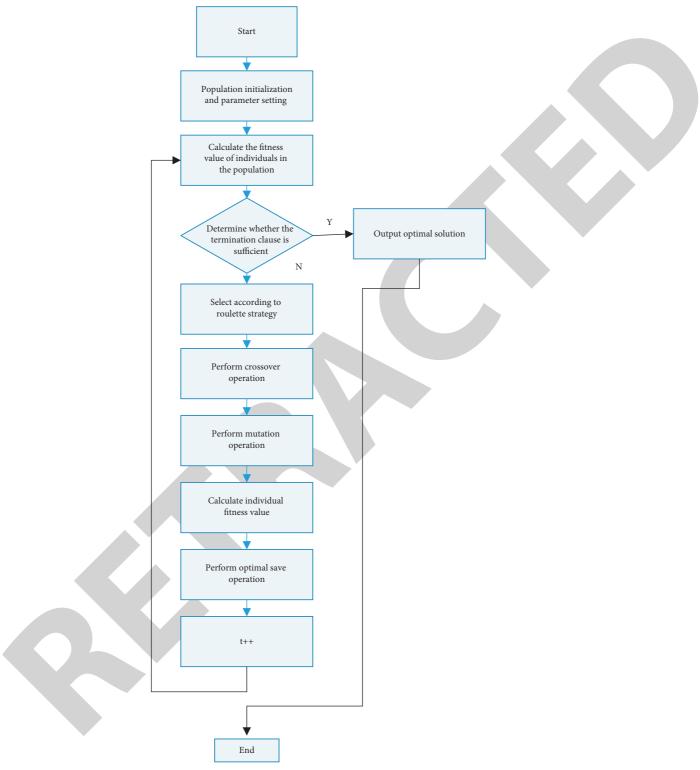

FIGURE 1: Improved genetic algorithm.

4. Analysis of Experimental Results

4.1. Parameter Setting. For the above improved genetic algorithm, the algorithm implementation steps detail each stage of the algorithm and the specific improvement details of each stage, and after the above operations, the improved genetic algorithm can obtain good individuals. In order to verify the effectiveness and efficiency of the improved genetic algorithm, the test bank of the computer course is used as the dataset for testing the algorithm in this section. In the course "Computer Applications Fundamentals," there are 1000 questions in the database with the following properties and contents.

First of all, there are four types of questions in the dataset of the course test bank, namely, single-choice, multiplechoice, judgment, and fill-in-the-blank questions, as shown in Table 1.

Secondly, there are five chapters in the course, as shown in Table 2.

The only requirement for the knowledge points is that they should not be duplicated when assembling the papers. In addition, in practice, the time of the algorithm needs to be as short as possible so that physical education does not have to wait too long for the paper to be formed, and thus, the efficiency of the intelligent paper formation system can be improved. In this study, the error value for generating test papers is set at 5%.

4.2. Algorithm Testing. In the abovementioned test generation table, the IDs, scores, difficulties, chapters, etc., of each question type are listed in detail in the database. The above data can be used to generate the actual scores for each chapter, the actual scores required for teaching, and the scores' set for each difficulty level which is shown in Tables 3 and 4.

The actual scores of the teaching requirement degree are shown in Table 4.

The scores for each difficulty level were set as shown in Table 5.

After the above operation, we can conclude that the improved adaptive genetic algorithm has good algorithm performance and can complete the extraction and distribution of the difficulty of the test questions in the test bank according to the requirements of physical education, so as to complete the requirements of physical education. Therefore, in general, the adaptive genetic algorithm is a better algorithm for paper composition.

4.3. Comparison of Tests before and after Algorithm Improvement. Through the above analysis, it can be seen that the improved genetic algorithm is able to achieve the functional requirements of physical education in the intelligent grouping environment. For the above results, we need to take more rigorous algorithm testing and comparison, through the way of experimental data to effectively compare the improved algorithm with the algorithm before the improvement; here, we mainly take the improved genetic algorithm and the standard genetic algorithm to conduct experiments and analyze the experimental data; the simulation test is shown in Figure 2.

In this study, the standard genetic algorithm before improvement is represented by GA and the improved genetic algorithm is represented by AGA. The effectiveness and performance of the algorithm can be analyzed in the above way, specifically by the evolutionary generation of the algorithm and the convergence performance of the algorithm. From Figure 2, we can see that the evolutionary algebra of the AGA algorithm is significantly lower than that of the GA algorithm when the number of experiments is 1, 2, 4, and 5. As long as the

TABLE 1: Question-type setting.

Question type	Quantity	Score
Single-choice questions	20	2
Multiple-choice questions	10	2
Judgment question	10	2
Completion	10	2

TABLE 2: Score of each chapter.

Chapter	Score
1	10
2	15
3	25 20
4	20
5	30

number of experiments is 3, the evolutionary algebra of the GA algorithm and the evolutionary algebra of the AGA algorithm are comparable.

Then, for the convenience of programming, the functions are set to their global maximum values, and then, the parameters for the algorithm to run are set as shown in Table 6.

The algorithms are run 50 times according to each run parameter in Table 6, and the algorithms are stopped if they reach the termination condition. The average, minimum, and global convergence probabilities of the two algorithms are shown in Table 7.

From Table 7, the average number of generations of convergence of the improved genetic algorithm is 32 and the average number of generations of convergence of the standard genetic algorithm is 57, and the average number of generations of convergence of the improved genetic algorithm is 25 less than that of the standard genetic algorithm. The upgraded genetic algorithms minimum number of generations of convergence is 24, while the regular genetic algorithm's lowest number of generations of convergence is 39. The upgraded genetic algorithm's lowest number of generations of convergence is 15 times lower than the regular genetic algorithms minimum number of generations of convergence. The global convergence probability of both algorithms is 100%.

Figure 3 shows the ratio of the convergence curves of the two algorithms.

Using the above data test set to compare the degree of convergence of the improved genetic algorithm and the standard genetic algorithm, it can be found that the improved genetic algorithm can obtain the optimal solution in terms of fitness and has a clear advantage in terms of the number of generations of evolution and can converge faster; therefore, the improved genetic algorithm has better advantages and further verifies that the algorithm is feasible and effective. Therefore, the improved genetic algorithm has better advantages and further verifies that the algorithm is feasible and effective and has the advantage of operational efficiency of the algorithm. Polya's plausible reasoning methods are crucial not only in discovery of mathematics results, modeling methods, and data processing methods but also in many practical problems' solving. This paper exemplifies how to use Polya's plausible reasoning methods to generalize the popularized notion of 2-connectedness of graphs to a more universal notion of the connected degree of fuzzifying matroids. We introduce the connectedness of fuzzifying matroids, which is generalized from 2-connectedness of graphs, connectedness of matroids, and 2-connectedness of fuzzi graphs. Moreover, the connected degree of fuzzifying matroids is presented by considering the fuzziness degree of connectedness. It is proved that a fuzzifying matroid M is connected, which is equivalent to its connectedness degree Con(M) is the biggest (i.e., Con(M) = 1). This, together with other properties of the connected degree of fuzzifying matroids, demonstrates the rationality of the proposed notion. Finally, we describe the concepts of this paper through some examples.

1. Introduction

Whitney in his fundamental paper [1] defined a matroid as an abstract generalization of a graph and a matrix. One of the great beauties of the subject of the matroid theory is that there are so many equivalent descriptions of a matroid. Bases, circuits, rank function, or closure operator is also sufficient to uniquely determine the matroid besides independent sets [2, 3]. In addition, it is well known that matroids are of great significance in combinatorial optimization and are just the structure that can use the greedy algorithm to find the optimal solution of some problems [4, 5]. Combined with fuzzy set theory [6], some fuzzy concepts of a matroid are given. One is using a family of fuzzy sets instead of that of sets, a Goetschel-Voxman fuzzy matroid was proposed in [7] and was later on widely studied by the various researchers [8-16]. The other is using a mapping from 2^E to [0, 1] rather than a family of sets, a fuzzifying matroid was introduced by Shi, and it can also be determined uniquely by its fuzzifying rank function [17, 18].

Subsequently, some other equivalent descriptions of a fuzzifying matroid were discussed including base-map and circuit-map [19], three kinds of fuzzifying operators [20, 21], fuzzifying nullity [22]. Also, as its applications, a fuzzifying matroid is just the structure of the fuzzifying greedy algorithm for fuzzy optimization problems [23, 24]. Thus, Shi's fuzzification method maintains matroids' features.

We know that there is an important connection between graphs and matroids. A graph (graphs in this paper are always loopless and without isolated vertices and have at least three vertices). G = (V, E) can induce a matroid (E, \mathscr{I}_G) which is called its cycle matroid and denoted by \mathscr{M}_G , where $\mathscr{I}_G = \{A \subseteq E: A \text{ does not contain any cycle of } G\}$. Motivated by analogies in graph theory, the connectedness of a matroid is defined. Here, \mathscr{M}_G is connected, which is equivalent to G is 2-connected; hence, the connectedness for matroids corresponds directly to the idea of 2-connectedness for graphs. It is natural to ask that is there fuzzifying matroid concept that corresponds directly to the idea of connectedness, or 2-connectedness, for fuzzy graphs?

Our main aim is to give a concept of connectedness for fuzzifying matroids, which extends the corresponding notion for fuzzy graphs. We begin by recalling some basic notions and results to be used in this paper. In Section 3, by using Polya's plausible reasoning method, we show the course of discovering the notion of connected degree of fuzzifying matroids. In Section 4, we generalize the concept of 2-connectedness from matroids to fuzzifying matroids, which corresponds directly to the idea 2-connectedness for fuzzy graphs. In Section 5, we consider the fuzziness degree of connectedness for fuzzifying matroids. Using the degree to which a set is a separator, the notion of connected degree for a fuzzifying matroid is introduced. We show that the relationship between the connected degree of a fuzzifying matroid and the connectedness of its corresponding level matroids and investigate the connected degree for the dual of a fuzzifying matroid. We close the section with various examples to illustrate the concepts of this paper.

2. Preliminaries

In this paper, we shall denote by *E* a given finite set and by 2^E the set of all subsets of *E*. Let $\mathscr{A} \subseteq 2^E$ and define Min $\mathscr{A} = \{A \in \mathscr{A} | A \text{ is minimal in } \mathscr{A}\}, \text{ Opp} \mathscr{A} = \{X \subseteq E | X \notin \mathscr{A}\}, \text{ Upp} \mathscr{A} = \{X \subseteq E | \text{there exists } A \in \mathscr{A}, A \subseteq X\}.$

We begin with the definition of a matroid.

Definition 1. (cf. [2, 3]) A matroid \mathcal{M} is a finite set *E* and a collection \mathcal{F} of subsets of *E* (called independent sets) such that (I1)–(I3) are satisfied, denoted by $\mathcal{M} = (E, \mathcal{F})$.

(I1) $\mathcal{J} \neq \emptyset$;

(I2) \mathcal{I} is a descending family;

(I3) For any two elements $A, B \in \mathcal{F}$ with |A| < |B|, one element $e \in B - A$ can be found so that $A \cup \{e\}$ belongs to \mathcal{F} .

It is important (for understanding the notion of fuzzifying matriod in the following Step 5) to notice that a matroid can also be defined equivalently as a finite set *E* and a collection \mathscr{C} of subsets of *E* (called circuits) satisfying three circuit axioms [2]: $(C1) \oslash \notin \mathscr{C}$; $(C2) \mathscr{C}$ is an antichain; (C3) for any two different elements $C_1, C_2 \in \mathscr{C}$ and $e \in C_1 \cap C_2$, one element $C_3 \in \mathscr{C}$ can be found to be included in $(C_1 \cup C_2) - \{e\}$. Specifically, take a matroid (E, \mathscr{F}) (i.e., which means that \mathscr{F} satisfies (I1)–(I3)), then, $\mathscr{C}_{\mathscr{F}} = \text{Min}(\text{Opp}(\mathscr{F}))$ is the family of all circuits for it (i.e., $\mathscr{C}_{\mathscr{F}}$ satisfies (C1)–(C3)); conversely, take a matroid (E, \mathscr{C}) (i.e., \mathscr{C} satisfies (C1)–(C3)), then $\mathscr{I}_{\mathscr{C}} = \text{Opp}(\text{Upp}(\mathscr{C}))$ is the family of all independent sets for it (i.e., $\mathscr{I}_{\mathscr{C}}$ satisfies (I1)–(I3)) and $\mathscr{C} = \mathscr{C}_{\mathscr{I}_{\mathscr{K}}}$.

Moreover, if (E, \mathscr{I}) is a matroid, its rank function $\mathscr{R}_{\mathscr{I}}$ is defined as a mapping from 2^E to the set of natural numbers **N** by $\mathscr{R}_{\mathscr{I}}(A) = \max \{|B|| B \subseteq A, B \in \mathscr{I}\}$ and can uniquely determine the matroid [3].

Next, we present some other notations, notions, and results needed in this paper. As usual, $[0, 1]^E$ denotes the collection of fuzzy subsets on *E*, where a fuzzy subset on *E* is a mapping from *E* to [0, 1]. If $A \in [0, 1]^E$ and $a \in [0, 1]$, we

will often denote the set of $x \in E$ satisfying $A(x) \ge a$ and the set of $x \in E$ satisfying A(x) > a by $A_{[a]}$ and $A_{(a)}$, respectively. Fuzzy natural numbers and their operations have been introduced [17, 22, 23, 25]. An antitone mapping λ from the set of natural numbers N to [0, 1] is called a fuzzy natural number if $\lambda(0) = 1$ and $\wedge \{\lambda(n) | n \in \mathbb{N}\} = 0$. We will use N([0,1]) to denote the collection of fuzzy natural numbers. Let λ, μ be fuzzy natural numbers, their sum, written $\lambda + \mu$ is also a fuzzy natural numbers such that for every $n \in \mathbf{N}$, $(\lambda + \mu)(n) = \bigvee \{\lambda(k) \land \mu(l) | n = k + l\}$, their subtraction is given by $\lambda - \mu = \lor \{\nu \in N([0, 1]) | \nu + \mu \le \lambda\}$. If we regard a natural number *m* as a fuzzy natural number *m* such that m(n) = 1 for $n \le m$ and m(n) = 0 for $n \ge m + 1$, then, we can get following operational properties, for every $a \in [0, 1],$ $(\lambda + \mu)_{[a]} = \lambda_{[a]} + \mu_{[a]}$ and $(\lambda + \mu)_{(a)} = \lambda_{(a)} + \mu_{(a)}.$

In [17, 18], the definition of a fuzzifying matroid on *E* was given.

Definition 2. (cf. [17, 18]) A fuzzifying matroid \mathbb{M} is a finite set *E* and a mapping II from 2^E to [0, 1] (called fuzzy family of independent sets) such that (FI1)–(FI3) are satisfied, written as $\mathbb{M} = (E, II)$. For any two subsets *A*, *B* of *E*,

(FI1) II $(\emptyset) = 1$; (FI2) II $(A) \ge II (B)$ if $A \subseteq B$; (FI3) $\bigvee_{e \in B - A} II (A \cup \{e\}) \ge II (A) \land II (B)$ if |A| < |B|.

For a fuzzifying matroid, the following characterization theorem holds.

Theorem 1 (cf. [17]). If II is a mapping from 2^E to [0, 1], then, (E, II) is a fuzzifying matroid, which is equivalent to each of the following statements.

- (1) $\{(E, II_{[a]})|a \in (0, 1]\}$ is a family of matroids;
- (2) $\{(E, II_{(a)})|a \in [0, 1)\}$ is a family of matroids.

It is also important to notice that a fuzzifying matroid can be defined equivalently as a pair (E, \mathbb{C}) , where \mathbb{C} is a mapping from 2^E to [0, 1] satisfying two axioms [19]: (FC1) for any $a \in (0, 1]$, $\operatorname{Min}(\mathbb{C})_{[a]}$ satisfies circuits axioms (C1)-(C3); (FC2) for any subset C of E, $\mathbb{C}(C) = a \neq 0$ implies $C \in \operatorname{Min}(\mathbb{C}_{[a]})$. In fact, let (E, II) be a fuzziying matroid (i.e., II satisfies (F11)-(F13)), the mapping $\mathbb{C}_{\operatorname{II}}: 2^E \longrightarrow [0, 1]$ defined by for any subset C of E such that $\mathbb{C}_{\operatorname{II}}(C) = 1 - \wedge$ $\{a \in [0, 1)|C \in \mathscr{C}_{\operatorname{II}_{(a)}}\}$, not only is the circuit-map of (E, II) (i.e., $\mathbb{C}_{\operatorname{II}}$ satisfies (FC1)-(FC2)) but also $\operatorname{Min}(\mathbb{C}_{\operatorname{II}})_{[a]} = \mathscr{C}_{\operatorname{II}_{(1-a)}}$ for any $a \in (0, 1]$. Conversely, let (E, \mathbb{C}) be a fuzziying matroid (i.e., \mathbb{C} satisfies (FC1)-(FC2)), the mapping $\operatorname{II}_{\mathbb{C}}: 2^E \longrightarrow [0, 1]$ defined by $\operatorname{II}_{\mathbb{C}}(A) = 1 - \vee \{\mathbb{C}(B)|B\subseteq A\}$ $(\forall A \in 2^E)$ satisfies (F11)-(F13)) and $\mathbb{C} = \mathbb{C}_{\operatorname{II}_{\mathbb{C}}}$.

The fuzzifying rank function was also defined.

Definition 3 (cf. [17, 23]). A mapping \mathbb{R}_{II} from 2^E to $\mathbf{N}([0,1])$ is called fuzzifying rank function of a given fuzzifying matroid (*E*, II), if for any subset *A* of *E* and any natural number *n* such that $\mathbb{R}_{\text{II}}(A)(n) = \vee$ {II (*B*)|*B* \subseteq *A*, |*B*| \geq *n*}.

Theorem 2 (cf. [17, 23]). *The fuzzifying rank function* \mathbb{R}_{II} *for a fuzzifying matroid* (*E*, *II*) *has the properties:*

(1)
$$\mathbb{R}_{II}(A)_{[a]} = \mathscr{R}_{II_{[a]}}(A) (\forall A \in 2^{E}, \forall a \in (0, 1]))$$

(2) $\mathbb{R}_{II}(A)_{(a)} = \mathscr{R}_{II_{(a)}}(A) (\forall A \in 2^{E}, \forall a \in [0, 1]))$

Furthermore, for any fuzziying matroid (*E*, II) (i.e., II satisfies (FI1)–(FI3)), its fuzzifying rank function \mathbb{R}_{II} possesses some features, shown as, for any two subsets *A*, *B* of *E*, (FR1) $\underline{0} \leq \mathbb{R}_{\text{II}}(A) \leq |\underline{A}|$; (FR2) $A \subseteq B$ implies $\mathbb{R}_{\text{II}}(A) \leq \mathbb{R}_{\text{II}}(B)$; (FR3) $\overline{\mathbb{R}}_{\text{II}}(A \cap B) + \mathbb{R}_{\text{II}}(A \cup B) \leq \mathbb{R}_{\text{II}}(A) + \mathbb{R}_{\text{II}}(B)$. Conversely, for a fuzzifying rank function $\mathbb{R}: 2^E \longrightarrow \mathbb{N}([0,1])$ (i.e., \mathbb{R} satisfies (FR1)–(FR3)), the mapping $II_{\mathbb{R}}: 2^E \longrightarrow [0,1]$ defined by $\mathbb{I}_{\mathbb{R}}(A) = \mathbb{R}(A)(|A|)(\forall A \in 2^E)$ satisfies (FI1)–(FI3)) and $\mathbb{R} = \mathbb{R}_{\text{II}_{0}}$.

Definition 4. (cf. [25]) For any fuzzifying matroid $\mathbb{M} = (E, II)$, a new mapping \mathbb{R}_{II} from 2^E to $\mathbb{N}([0, 1])$ is given by for any subset A of E such that $\mathbb{R}_{II}(A) = [|A| + \mathbb{R}_{II}(E - A)] - \mathbb{R}_{II}(E)$. It is proved that \mathbb{R}_{II} satisfies (FR1)–(FR3)), and thus, II ~ satisfies (FI1)–(FI3)), denoted by II^{*}. Hence (E, II^*) is a fuzzifying matroid, which is called the dual of \mathbb{M} , written as \mathbb{M}^* . In addition, the dual of $\mathbb{M}^* = (E, II^*)$ is denoted by $(\mathbb{M}^*)^* = (E, (II^*)^*)$.

Theorem 3. (cf. [25]) Suppose that (E, II) is a fuzzifying matroid, then, $(II^*)^* = II$ is equivalent to each of the following statements:

(1) (II*)_[a] = (II_[a])* for any element a in (0,1],
(2) (II*)_(a) = (II_(a))* for any element a in [0,1).

3. The Course of Discovering the Notion of Connected Degree of Fuzzifying Matroids

We say that a graph is 2-connected if any two distinct edges are contained in a cycle. This notion (actually many others) is easy-to-understand to many students and practitioners. A natural question is that can they discover, starting from such a notion and its relevant results, some innovative things which are interesting, meaningful, or needed for themselves? This paper will exemplify a positive answer. Precisely, it will generalize (by using plausible reasoning method [26]) the notion of 2-connectedness of graphs to a very extended and useful notion (called connected degree of fuzzifying matroids) and present some properties of connected degree of fuzzifying matroids.

We will sketch the course of discovering the notion of the connected degree of fuzzifying matroids which may be of reference value to both our research successors and out-ofthe-box researchers.

Step 1. Find out a characterization 2-connectedness of graphs (from all) start from which the notion described can be generalized: for a graph, written G = (V, E), we call that it is 2-connected if its any two distinct edges are contained in a cycle [2, 3], i.e., for any two different elements e_1, e_2 in E, one element C in \mathcal{C}_G (the set of all cycles of G) can be found to include e_1 and e_2 , simultaneously.

Step 2. Since matroid concept can be regarded as a generalization of graph concept (for a graph *G*, the collection of its cycles is represented as \mathscr{C}_G , which is exactly the family of circuits for the cycle matroid \mathscr{M}_G of *G*, thus, \mathscr{M}_G can also denoted equivalently as (E, \mathscr{C}_G) . So, we can think of *G* as a matroid $\mathscr{M}_G = (E, \mathscr{C}_G)$), it is natural to generalize the notion of 2-connectedness from the class of graphs (written as **G**) to the class of matroids (written as **M**).

Step 3. It is also reasonable saying the special matroid $\mathcal{M}_G = (E, \mathcal{C}_G)$ is connected when G is 2-connected, i.e., for any two different elements e_1, e_2 in E, one element C in \mathcal{C}_G can be found to include e_1 and e_2 simultaneously (see Step 1). Generalization of this can be taken as a definition of connectedness of a matroid (see Step 4).

Step 4. We call that a matroid $\mathcal{M} = (E, \mathcal{C})$ is connected if, for any two different elements e_1, e_2 in E, one element C in \mathcal{C} can be found to include e_1 and e_2 simultaneously [2, 3].

Step 5. As a matroid is a special fuzzifying matroid (for any matroid (E, \mathcal{F}) or (E, \mathcal{C}) , we do not distinguish between (E, \mathcal{F}) and $(E, 1_{\mathcal{F}})$ and between (E, \mathcal{C}) and $(E, 1_{\mathcal{C}})$, where $1_{\mathcal{F}}$ and $1_{\mathcal{C}}$ are characteristic functions of \mathcal{F} and \mathcal{C} , respectively), we naturally extend the notion of connectedness from the class of matroids to that of fuzzifying matroids (written as FM).

Step 6. It is reasonable saying the special fuzzifying matroid $(E, 1_{\mathscr{C}})$ is connected when the corresponding matroid (E, \mathscr{C}) is connected. In other words, for any $\{e_1, e_2\} \subseteq E, \lor \{1_{\mathscr{C}}(C)|e_1, e_2 \in C\} = 1$. Generalization of this can be taken as a definition of connectedness of a fuzzifying matroid (see Step 7).

Step 7. A fuzzifying matroid (E, \mathbb{C}) is called connected (or 2-connected) if for any $\{e_1, e_2\} \subseteq E$, $\lor \{\mathbb{C}(C)|e_1, e_2 \in C \subseteq E\} = 1$ (see the following Theorem 4 for a characterization).

Step 8. Find out a characterization (i.e., the separator characterization) of the connectedness of matroids (from all) start from which the notion described can be generalized: A matroid \mathcal{M} is disconnected if and only if (briefly, iff) a proper subset *A* of *E* can be found to be a separator of \mathcal{M} . Generalization of this can be taken as a definition of connected degree of a fuzzifying matroid (see Step 12).

Step 9. Recall and redescribe the definition of the separator (so that connectedness of a matroid can be generalized to connected degree of a fuzzifying matroid). Suppose that $\mathcal{M} = (E, \mathcal{C})$ is a matroid, a subset A of E is called a separator of \mathcal{M} (in other words, the degree to which A is a separator of \mathcal{M} is equal to 1, denoted by $\operatorname{Sep}(A) = 1$) iff for any $C \in \mathcal{C}$ there must be $C \subseteq A$ or $C \subseteq E - A$, that is, $C \notin \mathcal{C}$ whenever C is a subset of E not included in both A and E - A (i.e., \land $\{[1 - 1_{\mathcal{C}}(C)]|C$ is a subset of E not included in both A and $E - A\} = 1$). Compare the values of $\operatorname{Sep}(A)$ and \land $\{[1 - 1_{\mathcal{C}}(C)]|C$ is a subset of E not included in both A and $E - A\}$, we get $\operatorname{Sep}(A) = \land \{[1 - 1_{\mathcal{C}}(C)]|C$ is a subset of E not included in both A and E - A}. It is natural to generalize the equation from a matroid to a fuzzifying matroid (see Step 10).

Step 10. Given a fuzzifying matroid $\mathbb{M} = (E, \mathbb{C})$ and a subset *A* of *E*, we call that Sep $(A) = \wedge \{[1 - \mathbb{C}(C)] | C \text{ is a subset of } E$ not included in both *A* and $E - A\}$ is the degree to which $A \in 2^E$ is a separator of \mathbb{M} .

Step 11. A matroid \mathcal{M} is disconnected (that is to say the connected degree of \mathcal{M} is equal to 0, denoted by $\operatorname{Con}(\mathcal{M}) = 0$ if a proper subset *A* of *E* can be found to be a separator of \mathcal{M} (i.e., $\land \{1 - \operatorname{Sep}(A) | A \in 2^{E} - \{\emptyset, E\}\} = 0$). Compare the values of $\operatorname{Con}(\mathcal{M})$ and $\{1 - \operatorname{Sep}(A) | A \in 2^{E} - \{\emptyset, E\}\},\$ $\operatorname{Con}(\mathcal{M}) = \wedge$ we get $\{1 - \text{Sep}(A) | A \in 2^E - \{\emptyset, E\}\}$. It is natural to generalize the equality from a matroid to a fuzzifying matroid (see Step 12).

Step 12. Given a fuzzifying matroid $\mathbb{M} = (E, \mathbb{C})$, we call $\operatorname{Con}(\mathbb{M}) = \wedge \{1 - \operatorname{Sep}(A) | A \in 2^{E} - \{\emptyset, E\}\}$ is the connected degree of \mathbb{M} .

4. Characterizations and Rationality of Connectedness of Fuzzifying Matroids

Although a fuzzifying matroid can be defined as both a pair (E, II) and a pair (E, \mathbb{C}) , we find that the circuit-map axioms (FC1)-(FC2) of a fuzzifying matroid is not a natural way to generalize the circuits axioms (C1)–(C3) of a matroid. Hence, in the subsequent discussion, we always suppose that a fuzzifying matroid and a matroid are pairs (E, II) and (E, \mathcal{S}) , respectively.

The following Definition 5, Theorem 4, and Corollary 1 (which characterize the connectedness of fuzzifying matroids, see Step 7 for the definition) show that the connectedness of fuzzifying matroids is in harmony with that of matroids.

Definition 5. Amapping \mathbb{C}_{II} from 2^E to [0, 1] is the circuitmap of a given fuzzifying matroid (E, II) which is said to be connected if for any two elements e_1, e_2 in E such that \vee $\{\mathbb{C}_{\text{II}}(C)|e_1, e_2 \in C \subseteq E\} = 1$.

Theorem 4. A fuzzifying matroid (E, II) is connected, which is equivalent to $(E, II_{(0)})$ is connected.

Proof. If (E, II) is connected, then, for any two elements e_1, e_2 in E, a subset C of E can be found to satisfy $\mathbb{C}_{II}(C) = 1$ and include e_1 and e_2 , and thus $C \in Min(\mathbb{C}_{II})_{[1]} = \mathcal{C}_{II_{(0)}}$ by the property of \mathbb{C}_{II} . This implies that $(E, II_{(0)})$ is connected. Conversely, if $(E, II_{(0)})$ is connected, then, for any two elements e_1, e_2 in E, one element C in $\mathcal{C}_{II_{(0)}}$ can be found to include e_1 and e_2 , and thus $\mathbb{C}_{II}(C) = 1 - \land \{a \in [0, 1) | \mathcal{C} \in \mathcal{C}_{II_{(0)}}\} = 1 - 0 = 1$. Hence, $\lor \mathbb{C}_{II}(C)|e_1, e_2 \in C \subseteq E\} = 1$, which implies that (E, II) is connected.

Notice that, the fuzzifying matroid (*E*, II) induced by a fuzzy family of circuits is introduced [27], it has the following properties, for any two elements *a*, *b* in [0, 1), $a \le b$

implies $\mathscr{C}_{II_{(a)}} \subseteq \mathscr{C}_{II_{(b)}}$. Thus, Theorem 4 deduces the following corollary.

Corollary 1. A fuzzifying matroid (E, II) induced by a fuzzy family of circuits is connected if and only if $(E, II_{(a)})$ is connected $(\forall a \in [0, 1))$.

A fuzzy graph [28] \mathcal{G} is a set of nodes V together with two fuzzy sets σ and μ on V and $V \times V$, respectively, satisfied for any pair of elements x, y of V, $\mu(x, y) \leq \sigma(x) \wedge \sigma(y)$, written as $\mathcal{G} = (V, \sigma, \mu)$. Graph $\mathcal{G} =$ $(V, 1_{\sigma_{(0)}}, 1_{\mu_{(0)}})$ is called the underline graph of \mathscr{G} , and we identify that $1_{\sigma_{(0)}}$ and $1_{\mu_{(0)}}$ are characteristic functions of $\sigma_{(0)}$ and $\mu_{(0)}$, respectively. When σ and μ take no value in (0, 1), \mathcal{G} equals $\underline{\mathcal{G}}$ and so it is a graph, which implies that the class of fuzzy graphs contains that of graphs. Furthermore, the concept of connectedness can be extended from graphs to more general a fuzzy graphs. In one way, a fuzzy graph is 2-connected, which is defined as its underline graph is 2-connected. Actually, each fuzzy graph $\mathscr{G} = (V, \sigma, \mu)$ can induce a fuzzifying matroid which is the set E of edges in \mathscr{G} and a mapping $II_{\mathscr{G}}$ from 2^E to [0,1]defined as for every subset A of E such that $II_{\mathscr{G}}(A) = \vee$ $\{a \in [0,1) | \mu_{(a)} \text{ contains } A \text{ and any cycle of } (V,\mu_{(a)}) \text{ is not } \}$ included in A, called fuzzifying cycle matroid of \mathcal{G} . Therefore, the notion of 2-connectedness for fuzzy graphs can be generalized to that of connectedness for their fuzzifying cycle matroids, and then to that of connectedness for more general fuzzifying matroids (see the following Theorem 5) which means the connectedness of fuzzifying matroids is also in harmony with 2-connectedness of fuzzy graphs.

Lemma 1. $(E, \Pi_{\mathscr{G}})$ and $(E, \mathscr{I}_{\mathscr{G}})$ are the fuzzifying cycle matroid and the cycle matroid, respectively, induced by a fuzzy graph $\mathscr{G} = (V, \sigma, \mu)$ and its underline graph $\underline{\mathscr{G}}$, we have $\mathscr{I}_{\mathscr{G}} = (\Pi_{\mathscr{G}})_{(0)}$.

Proof. $\forall A \in (\Pi_{\mathscr{G}})_{(0)}$, i.e., $\Pi_{\mathscr{G}}(A) > 0$, thus, a number *a* in (0,1) can be found such that $\mu_{(a)}$ contains *A* and any cycle of $(V, \mu_{(a)})$ is not included in *A*. Suppose that *A* contains a cycle of $(V, \mu_{(0)})$, then *A* contains a cycle of $(V, \mu_{(a)})$ since $A \subseteq \mu_{(a)}$. There is a contradiction. Therefore, $\mu_{(0)}$ contains *A* and any cycle of $(V, \mu_{(0)})$ is not included in *A*, i.e., $A \in \mathscr{F}_{\mathscr{G}}$.

 $\forall A \in \mathscr{F}_{\mathscr{G}}$, i.e., $\mu_{(0)}$ contains A and any cycle of $(V, \mu_{(0)})$ is not included in A. We can find a number a in (0,1)satisfying $\mu_{(0)} = \mu_{(a)}$ because the range of μ is a finite set. Hence, $\mu_{(a)}$ also contains A and any cycle of $(V, \mu_{(a)})$ is not also included in A. This implies that $\Pi_{\mathscr{G}}(A) \ge a > 0$, we have $A \in (\Pi_{\mathscr{G}})_{(0)}$.

By Theorem 4 and Lemma 1, we get the fuzzifying cycle matroid $(E, \Pi_{\mathscr{G}})$ is connected iff $(E, (\Pi_{\mathscr{G}})_{(0)})$ is connected iff $(E, \mathscr{I}_{\mathscr{G}})$ is connected iff \mathscr{G} is 2-connected iff \mathscr{G} is 2-connected. Hence, the following theorem holds.

Theorem 5. Fuzzifying cycle matroid $(E, II_{\mathcal{G}})$ induced by a fuzzy graph \mathcal{G} is connected, which is equivalent to \mathcal{G} is 2-connected.

5. Connected Degree of Fuzzifying Matroids

Recall that the connected degree of a fuzzifying matroid is defined by using the notion of the degree to which a set is a separator (see Steps 10 and 12). In this section, we study the connections between the notions of the degree to which a subset is a separator, connected degree, and connectedness of a fuzzifying matroid. We also obtain a generalization of a classical result on separators of matroids (see Theorem 7).

Definition 6. Define the degree to which $A \in 2^E$ is a separator of a given fuzzifying matroid (E, II) as $\text{Sep}(A) = \land \{[1 - \mathbb{C}_{II}(C)] | C \text{ is a subset of } E \text{ not included in both } A \text{ and } E - A\}.$

Theorem 6. The following statements hold, see Definition 6 for this symbol Sep(A).

- (1) If Sep(A) > a, then, A is a separator of $(E, II_{(a)})(a \in [0, 1))$.
- (2) If Sep(A) = a, then, A is not a separator of $(E, II_{(a)})(a \in [0, 1))$.
- (3) If $Sep(A) < a (a \in (0, 1))$, uncertain.
- (4) Sep(A) = 0 if and only if A is not a separator of $(E, II_{(0)})$.

Proof.

- (1) Suppose that A is not a separator of (E, II_(a)), then, one element C ∈ C<sub>II_(a) can be found to be not included in both A and E A; hence, C_{II}(C) ≥ 1 a and then Sep(A) ≤ a by the definitions of C_{II} and Sep(A).
 </sub>
- (2) Suppose that $\operatorname{Sep}(A) = a \in [0, 1)$, i.e., $\land \{1 \mathbb{C}_{\Pi}(C) | C \text{ is a subset of } E \text{ not included in both } A \text{ and } E A\} = a \neq 1$, then, $1 \mathbb{C}_{\Pi}(C) = a \neq 1$ for some subset C of E not included in both A and E A, which implies this subset $C \in \operatorname{Min}(\mathbb{C}_{\Pi})_{[1-a]} = \mathscr{C}_{\Pi_{(a)}}$. In other words, $C \in \mathscr{C}_{\Pi_{(a)}}$ for some subset C of E not included in both A and E A, i.e., A is not a separator of $(E, \Pi_{(a)})$.
- (3) Take a counter example. A finite set $E = \{e_1, e_2, e_3\}$ together with a mapping II from 2^E to [0, 1] defined as II (\emptyset) = II ({ e_1 }) = 1, II ({ e_2 }) = II ({ e_3 }) = (1/2), II $(\{e_1, e_2\}) = II$ $(\{e_1, e_3\}) = II$ $(\{e_2, e_3\}) = II$ $(\{e_1, e_2, e_3\}) = (1/3)$, form a fuzzifying matroid. Then, $\mathscr{C}_{\mathrm{II}_{(2)}} = \emptyset \text{ (if } 0 \le a < (1/3)), \{\{e_1, e_2\}, \{e_1, e_3\}, \{e_2, e_3\}\}$ (if $(1/3) \le a < (1/2)$), {{ e_2 }, { e_3 }} (if $(1/2) \le a < 1$) by the definitions of $\mathrm{II}_{(a)}$ and $\mathscr{C}_{\mathscr{F}}$, and thus by the definition of \mathbb{C}_{II} , $\mathbb{C}_{\text{II}}(C) = 0$ (if $C \in \{\emptyset, \{e_1\}, e_1\}$) $\{e_1, e_2, e_3\}\}), 1/2$ (if $C \in \{\{e_2\}, \{e_3\}\}), 2/3$ (if $C \in \{\{e_1, e_2\}, \{e_1, e_3\}, \{e_2, e_3\}\})$. Let $A = \{e_1\}$, by Definition 6, Sep $(A) = \land \{ [1 - \mathbb{C}_{II}(C)] | C = \{e_1, e_3\}, \}$ $\{e_1, e_2\}, \{e_1, e_2, e_3\}\} = (1 - (2/3)) \land (1 - (2/3)) \land$ (1-0) = (1/3) < 0.4 < 0.5. We can check that A is not a separator of $(E, II_{(0,4)})$ although it is a separator of $(E, II_{(0,5)})$.

(4) If Sep (*A*) = 0, then, *A* is not a separator of $(E, II_{(0)})$ by (2). Conversely, if *A* is not a separator of $(E, II_{(0)})$, then, Sep (*A*) \leq 0 by (1), i.e., Sep (*A*) = 0.

A classical result on separators of matroids: for any subset *A* of *E*, it is a separator of a given matroid (E, \mathcal{F}) , which is equivalent to the rank function $\mathcal{R}_{\mathcal{F}}$ satisfies $\mathcal{R}_{\mathcal{F}}(A) + \mathcal{R}_{\mathcal{F}}(E - A) = \mathcal{R}_{\mathcal{F}}(E)$. Its promotion is as follows:

Theorem 7. The following conditions are equivalent, among them, symbols Sep(A) and \mathbb{R}_{II} refer to Definition 6 and Definition 3, respectively.

- (1) Sep (A) = 1;
 (2) A is a separator of (E, II_(a)) for each a ∈ [0, 1);
 (3) ℝ_{II}(A) + ℝ_{II}(E A) = ℝ_{II}(E);
- (4) A is a separator of $(E, II_{[a]})$ for each $a \in (0, 1]$.

Proof. (1) \Leftrightarrow (2). If Sep(*A*) = 1, then, for each $a \in [0, 1)$, Sep(*A*) > *a*, thus, *A* is a separator of (*E*, II_(*a*)) by Theorem 6 (1). Conversely, if (2) holds, i.e., *A* is a separator of (*E*, II_(*a*)) for each $a \in [0, 1)$. Assume that Sep(*A*) = $b \neq 1$, then, *A* is not a separator of (*E*, II_(*b*)) by Theorem 6 (2), which contradicts (2). Hence, Sep(*A*) = 1.

By Theorem 2 and the property of the addition of fuzzy natural numbers, we have

 $\begin{array}{l} (2) \Leftrightarrow (3). A \text{ is a separator of } (E, \mathrm{II}_{(a)}) \text{ for each } a \in [0, 1) \\ \Leftrightarrow \mathscr{R}_{\mathrm{II}_{(a)}}(A) + \mathscr{R}_{\mathrm{II}_{(a)}}(E - A) = \mathscr{R}_{\mathrm{II}_{(a)}}(E) \text{ for each } a \in [0, 1) \Leftrightarrow \\ \mathbb{R}_{\mathrm{II}}(A)_{(a)} + \mathbb{R}_{\mathrm{II}}(E - A)_{(a)} = \mathbb{R}_{\mathrm{II}}(E)_{(a)} \text{ for each } a \in [0, 1) \Leftrightarrow \\ [\mathbb{R}_{\mathrm{II}}(A) + \mathbb{R}_{\mathrm{II}}(E - A)]_{(a)} = \mathbb{R}_{\mathrm{II}}(E)_{(a)} \text{ for each } a \in [0, 1) \Leftrightarrow \\ a \in [0, 1) \Leftrightarrow \mathbb{R}_{\mathrm{II}}(A) + \mathbb{R}_{\mathrm{II}}(E - A) = \mathbb{R}_{\mathrm{II}}(E). \\ (3) \Leftrightarrow (4). \end{array}$

$$\begin{split} & \mathbb{R}_{II}(A) + \mathbb{R}_{II}(E - A) = \mathbb{R}_{II}(E) \Leftrightarrow [\mathbb{R}_{II}(A) + \mathbb{R}_{II}(E - A)]_{[a]} = \\ & \mathbb{R}_{II}(E)_{[a]} \text{ for each } a \in (0, 1] \Leftrightarrow \mathbb{R}_{II}(A)_{[a]} + \mathbb{R}_{II}(E - A)_{[a]} = \\ & \mathbb{R}_{II}(E)_{[a]} \text{ for each } a \in (0, 1] \Leftrightarrow \mathcal{R}_{II_{[a]}}(A) + \mathcal{R}_{II_{[a]}}(E - A) = \\ & \mathcal{R}_{II_{[a]}}(E) \text{ for each } a \in (0, 1] \Leftrightarrow A \text{ is a separator of } (E, II_{[a]}) \text{ for each } a \in (0, 1]. \end{split}$$

Definition 7. Con $(\mathbb{M}) = \wedge \{1 - \text{Sep}(A) | A \in 2^{E} - \{\emptyset, E\}\}$ is called connected degree of a given fuzzifying matroid $\mathbb{M} = (E, \text{II})$, where Sep(A) is defined in Definition 6.

The connection between the connected degree of a fuzzifying matroid and the degree to which a subset is a separator is described in the following theorem.

Theorem 8. The following statements are true, where symbols Sep(A) and $Con(\mathbb{M})$ are defined in Definition 6 and Definition 7, respectively.

- (1) If $Con(\mathbb{M}) > a$, then $Sep(A) \neq 1 a$ for each nonempty proper subset A of E ($a \in [0, 1)$).
- (2) If $Con(\mathbb{M}) = a$, then Sep(A) = 1 a for some nonempty proper subset A of E ($a \in [0, 1)$).
- (3) If $Con(\mathbb{M}) < a (a \in (0, 1))$, uncertain.
- (4) $Con(\mathbb{M}) = 0$ if and only if Sep(A) = 1 for some nonempty proper subset A of E.

(5) $Con(\mathbb{M}) = 1$ if and only if Sep(A) = 0 for each nonempty proper subset A of E.

Proof

- (1) Suppose that there exists a nonempty proper subset *A* of *E* such that Sep(A) = 1 a, then, $\text{Con}(\mathbb{M}) = \land \{1 \text{Sep}(A) | A \in 2^E \{\emptyset, E\}\} \le a$.
- (2) Suppose that $\operatorname{Con}(\mathbb{M}) = a \in [0, 1)$, i.e., $\land \{1 \operatorname{Sep}(A) | A \in 2^{E} \{\emptyset, E\}\} = a$, then $1 \operatorname{Sep}(A) = a$ for some $A \in 2^{E} \{\emptyset, E\}$, that is, $\operatorname{Sep}(A) = 1 a$ for some nonempty proper subset A of E.
- (3) Consider the fuzzifying matroid \mathbb{M} in [27], it is a set $E = \{e_1, e_2, e_3, e_4, e_5\}$ and a mapping II from 2^E to [0,1] defined as II $(A) = \bigvee \{a \in [0,1) | A \in \mathcal{F}_a\}$. Here, \mathcal{I}_a is constant in [0, 1/3) (resp., [1/3, 1/2), [1/2, 1)), (E, \mathcal{F}_0) , $(E, \mathcal{F}_{1/3})$, and $(E, \mathcal{F}_{1/2})$ are matroids with the families of circuits $\mathcal{C}_0 = \{\{e_1, e_3, e_4\}\},\$ $\mathcal{C}_{1/3} = \{\{e_2, e_3\}, \{e_1, e_2, e_4\}, \{e_1, e_3, e_4\}\},\$ and $\mathscr{C}_{1/2} = \{\{e_2, e_3\}, \{e_2, e_4\}, \{e_2, e_5\}, \{e_3, e_4\}, \{e_3, e_5\},$ $\{e_4, e_5\}$, respectively. Then, by the definition of $\mathbb{C}_{\mathbb{I}}$, $\mathbb{C}_{II}(C) = 1$ (if $C = \{e_1, e_3, e_4\}$), 2/3 (if $C \in \{\{e_2, e_3\}, e_4\}$) $\{e_1, e_2, e_4\}\}), 1/2$ (if $C \in \{\{e_2, e_4\}, \{e_2, e_5\}, \{e_3, e_4\},$ $\{e_3, e_5\}, \{e_4, e_5\}\}$), and 0 (otherwise). Thus, by Definition 6, Sep (A) = 1 (if $C \in \{\emptyset, E\}$), 1/2 (if $C \in \{\{e_5\}, e_5\}$) $\{e_1, e_2, e_3, e_4\}\}), \quad 1/3 \quad (\text{if} \quad C \in \{\{e_2\}, \quad \{e_1, e_3, e_4, e_5\},$ $\{e_2, e_5\}, \{e_1, e_3, e_4\}\}$, and 0 (otherwise). Therefore, by Definition 7, Con(M) = (1/2) < (2/3) < (3/4). For a = (2/3), Sep $(\{e_2\}) = (1/3) = 1 - a$ although $Sep(A) \neq (1/4) = 1 - b$ for b = (3/4) and every nonempty proper subset A of E.
- (4) If Con (M) = 0, then, there exists a nonempty proper subset A of E such that Sep (A) = 1 by (2). Conversely, if Sep (A) = 1 for some nonempty proper subset A of E, then, Con (M) ≤ 0 by (1), i.e., Con (M) = 0.
- (5) $\operatorname{Con}(\mathbb{M}) = 1 \Leftrightarrow \land \qquad \{1 \operatorname{Sep}(A) | A \in 2^{E} \{\emptyset, E\}\} = 1 \Leftrightarrow 1 \operatorname{Sep}(A) = 1$ $(\forall A \in 2^{E} - \{\emptyset, E\}) \Leftrightarrow \operatorname{Sep}(A) = 0, (\forall A \in 2^{E} - \{\emptyset, E\}).$

The following results show that the relationship between connected degree of a fuzzifying matroid and connectedness of its corresponding level matroids. $\hfill \Box$

Theorem 9. The following statements are also true, among them, symbol $Con(\mathbb{M})$ refers to Definition 7, which is the connected degree of a fuzzifying matroid $\mathbb{M} = (E, II)$.

- (1) If $Con(\mathbb{M}) = a \in [0, 1)$, then, $(E, II_{(1-b)})$ is not connected for any b > a. However, the converse is not true.
- (2) If $Con(\mathbb{M}) = 1$ if and only if $(E, II_{(0)})$ is connected.

Proof

(1) Suppose that $b > a = \text{Con}(\mathbb{M})$, by Definition 7, there exists $A \in 2^{E} - \{\emptyset, E\}$ such that 1 - Sep(A) < b, and thus Sep(A) > 1 - b; hence, A is a separator in

 $(E, II_{(1-b)})$ by Theorem 6. This implies that $(E, II_{(1-b)})$ is not a connected matroid.

Consider the fuzzifying matroid $\mathbb{M} = (E, II)$ defined in the proof of Theorem 8 (3). Obviously, three level matroids are all not connected. Take an $a \in [0, 1) - \{1/2\}$; then, $(E, II_{(1-b)})$ is not connected for any b > a, but Con(\mathbb{M}) = $(1/2) \neq a$.

(2) It follows from Theorems 6 (4) and 8 (5).

An immediate consequence of Theorems 5 and 9 is the following Theorem 10 which shows the connections between the connected degree of a fuzzifying matroid and connectedness of a fuzzifying matroid. \Box

Theorem 10. A fuzzifying matroid \mathbb{M} is connected, which is equivalent to its connected degree $Con(\mathbb{M}) = 1$.

The rest of this section discusses the fuzzy analogs of the results: A separator in a matroid is also a separator in its dual, and the connectedness of a matroid is equivalent to that of its dual.

Theorem 11. The symbols \mathbb{M} and \mathbb{M}^* represent a fuzzifying matroid (E, II) and its dual (E, II^{*}), if (II^{*})^{*} = II, then, the following statements hold.

- (1) $Sep^*(A) = Sep(A)$ for each $A \in 2^E$, where Sep(A) and $Sep^*(A)$ are the degrees to which A is a separator of M and M^* .
- (2) $Con(\mathbb{M}^*) = Con(\mathbb{M}).$
- (3) \mathbb{M} is connected, which is equivalent to \mathbb{M}^* is connected.

Proof

- (1) Suppose that Sep (A) = a, then, A is not a separator in $(E, II_{(a)})$ by Theorem 6 (2), so it is not in the dual matroid $(E, (II_{(a)})^*)$, nor in $(E, (II^*)_{(a)})$ by $(II^*)^* =$ II and Theorem 3. By Theorem 6 (1), Sep* $(A) \le a$, i.e., Sep* $(A) \le Sep (A)$. Conversely, Sep $(A) \le Sep^* (A)$ since $(II^*)^* = II$.
- (2) It is an immediate consequence of (1) by the definition of connected degree for fuzzifying matroids.
- (3) It is obvious by Theorem 10 and (2). \Box

Remark 1. The characterization of the disconnectedness for a given fuzzifying matroid $\mathbb{M} = (E, II)$ induced by a fuzzy family of circuits in [27] is as follows: \mathbb{M} is disconnected if and only if there is a nonempty proper subset of *A* such that $\mathbb{R}_{II}(A) + \mathbb{R}_{II}(E - A) = \mathbb{R}_{II}(E)$. From Theorems 7 and 8, it can also be characterized by the connected degree in this paper, \mathbb{M} is disconnected if and only if Con (\mathbb{M}) = 0, that is, \mathbb{M} is connected if and only if Con (\mathbb{M}) = 0. From this, we can see the connected degree introduced in this paper unifies the connectedness in [27].

We now describe the concepts of this paper by various examples.

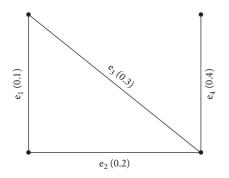

FIGURE 1: The fuzzy graph (V, μ) .

Example 1. A simple class of fuzzifying matroids are fuzzifying uniform matroids. It is a fuzzifying matroid (*E*, II) satisfying for any $A, B \in 2^{E}$, |A| = |B| implies II(A) = II(B) [29].

Consider the example that a fuzzifying uniform matroid \mathbb{M} is a finite set $E = \{e_1, e_2, e_3\}$ and a mapping II from 2^E to [0, 1] defined as II (\emptyset) = 1, II ($\{e_1\}$) = II ($\{e_2\}$) = II ($\{e_3\}$) = 0.5, II ($\{e_1, e_2\}$) = II ($\{e_2, e_3\}$) = II ($\{e_1, e_3\}$) = 0.3, II ($\{e_1, e_2, e_3\}$) = 0.2. So, by the definition of circuit-map, $\mathbb{C}_{II}(C) = 0$ (if $C \in \{\emptyset\}$), 0.5 (if $C \in \{\{e_1\}, \{e_2\}, \{e_3\}\}$), 0.7 (if $C \in \{\{e_1, e_2\}, \{e_1, e_3\}, \{e_2, e_3\}\}$), and 0.8 (if $C \in \{\{e_1, e_2, e_3\}\}$). By Definition 6, we have Sep ($\{e_1\}$) = $\land \{[1 - \mathbb{C}_{\|}(C)]|C = \{e_1, e_2\}, \{e_1, e_3\}, \{e_1, e_2, e_3\}\} = (1 - 0.7) \land (1 - 0.7) \land (1 - 0.8) = 0.2$. Similarly, we also have Sep (A) = 0.2 if $A \in \{\{e_2\}, \{e_3\}, \{e_1, e_2\}, \{e_1, e_3\}, \{e_2, e_3\}\}$. Hence, $Con(\mathbb{M}) = \land \{1 - Sep(A)|A \in 2^E - \{\emptyset, E\}\} = 0.8$.

Example 2. Another simple and more general class of fuzzifying matroids is fuzzifying paving matroids. It is a fuzzifying matroid (*E*, II) satisfying for any $A, B \in 2^{E}$, |A| < |B| implies II (A) \geq II (B) [29].

Consider the fuzzifying matroid $\mathbb{M} = (E, \text{II})$ given in the proof of Theorem 6 (3), which is a fuzzifying paving matroid rather than a fuzzifying uniform matroid. Similarly, we also have Sep(A) = (1/3) if $A = \{e_2\}, \{e_3\}, \{e_1, e_2\}, \{e_2, e_3\}$ or $\{e_1, e_3\}$. Hence, Con(\mathbb{M}) = $\wedge \{1 - \text{Sep}(A) | A \in 2^E - \{\emptyset, E\}\} = 2/3$.

Example 3. Similarly, we can use the examples of fuzzifying acyclic matroids and fuzzifying simple matroids introduced in [29] to illustrate the concepts of this paper, which are omitted here.

Example 4. The very important class of fuzzifying matroids are derived from fuzzy graphs, which have been discussed in Section 4 in detail. In addition, we can also proved that $II_{\mathscr{G}}(A) = \wedge_{x \in A} \mu(x)$ (if A does not contain any cycle), 0 (otherwise). Note that when $\delta(e) \equiv 1$ for any $e \in V$, a fuzzy graph is abbreviated to $\mathscr{G} = (V, \mu)$.

Consider the example that a fuzzifying cycle matroid $(E, \Pi_{\mathcal{G}})$ induced by $\mathcal{G} = (V, \mu)$ in Figure 1, and record it as $\mathbb{M}_{\mathcal{G}}$, where $E = \{e_1, e_2, e_3, e_4\}$ is the edges set in (V, μ) and $\mu(e_1) = 0.1$, $\mu(e_2) = 0.2$, $\mu(e_3) = 0.3$, $\mu(e_4) = 0.4$. Then, $\Pi_{\mathcal{G}}(A) = 0$ (if $A \in \{\{e_1, e_2, e_3\}, \{e_1, e_2, e_3, e_4\}\}$), 0.1 (if $A \in \{\{e_1\}, \{e_1, e_2\}, \{e_1, e_3\}, \{e_1, e_4\}, \{e_1, e_3, e_4\}, \{e_1, e_2, e_4\}\}$), 0.2

(if $A \in \{\{e_2\}, \{e_2, e_3\}, \{e_2, e_4\}, \{e_2, e_3, e_4\}\}$), 0.3 (if $A \in \{\{e_3\}, \{e_3, e_4\}\}$), 0.4 (if $A \in \{\{e_4\}\}$), and 1 (if $A \in \{\emptyset\}$). By the definition of circuit-map, $\mathbb{C}_{\Pi_{\mathscr{C}}}(C) = 1$ (if $C \in \{\{e_1, e_2, e_3\}\}$), 0.9 (if $C \in \{\{e_1\}\}$), 0.8 (if $C \in \{\{e_2\}\}$), 0.7 (if $C \in \{\{e_3\}\}\}$), 0.6 (if $C \in \{\{e_4\}\}\}$), and 0 (otherwise). By Definition 6, Sep $(\{e_1, e_2, e_3\}) = \land \{[1 - \mathbb{C}_{\mathbb{I}_{\mathscr{C}}}(C)]|C = \{e_1, e_4\}, \{e_2, e_4\}, \{e_3, e_4\}, \{e_1, e_2, e_4\}, \{e_1, e_3, e_4\}, \{e_2, e_3, e_4\}, \{e_1, e_2, e_3, e_4\}\} = 1$. Hence, Con $(\mathbb{M}_{\mathscr{C}}) = \land \{1 - \operatorname{Sep}(A)|A \in 2^E - \{\emptyset, E\}\} = 0$.

6. Conclusions

This paper exemplifies an application of Polya's plausible reasoning method (mainly analogous and generalization) in matriod theory, where we obtain some new results on 2connectedness of fuzzifying matroids but just start from the 2-connectedness of graphs (a notion popularized for undergraduate students). We show some properties of connectedness and connected degree of fuzzifying matroids and the reasonability of the definition of connected degree and enrich the theory of fuzzifying matroids. The course of discovering the notion of connected degree of fuzzifying matroids and related results is given clearly and relatively understandably which may be benefiticial to mathematics enthusiasts and researchers in other areas who are interested to discover. There are also some work to be performed further. For example, (1) For the notion of connectedness, a fuzzy graph is either connected or not, we can consider the fuzziness degree of connectedness for a fuzzy graph analogously. (2) We can define and study connected degree of Goetschel-Voxman fuzzy matroids analogously; we can even define and study connected degree of [0, 1]-matroids introduced in [18, 30] (a generalization of Goetschel-Voxman fuzzy matroids) analogously. (3) As we know, as an application of fuzzifying matroids, the fuzzifying greedy algorithm was presented in [23, 24], fuzzifying matroids are precisely the structures for which the very simple and efficient fuzzifying greedy algorithm works. Whether connectedness of fuzzifying matroids could be applied to some fuzzy combinatorial problems, we shall consider this problem in the future. Of course, applications in decision-making problems as in [31-34] should also be considered; (4) We are also extending our work to *m*-polar fuzzifying matroids by imitating reference [15].

Corporate social responsibility based on competitive supply chain pricing has been considered the most efficient strategy of a business globally. In an MCDM challenge, a competent supply chain pricing considerations solutions supplier considers multiple possibly competing for qualitative and quantitative criteria. This study presented a new extended decision-making and FBWM method based on type-2 fuzzy sets TOPSIS for ranking the corporate social responsibility criteria based on competitive supply chain pricing factors. The aim of the ranking is to learn how a company and its supply chain may accomplish joint-optimization of economic, environmental, and social performance by transparently and strategically integrating sustainability into business operations. To verify the efficacy of the suggested strategy, it is compared to a benchmarking model. IT2F VIKOR is the subject of this benchmarking model. The significance weights of the competitive supply chain pricing selection criterion are determined from BWM for both techniques. The results show that the most probable dimension of social responsibility, which may produce competitive supply chain pricing mechanisms based on profitability. Other findings revealed that the elements of competitive supply chain pricing factors in oil companies regarding social responsibility are ranked as follows: customer, product, and competitive supply chain pricing procedures. As a result, maintaining customer values is a major price element in establishing contacts, based on the company's strategic connection with the economy and regional and worldwide partners.

1. Introduction

Corporate sustainability has become a term in today's corporate world. According to statistics, 93 percent of world CEOs feel that maintaining a competitive standard without embracing sustainability is complex [1]. The World Commission on Environment and Development defines corporate sustainability as "meeting the requirements of the existing generation without jeopardizing future generations' ability to satisfy their needs," and this concept demonstrates

how businesses are vulnerable to long-term sustainability if they do not care about the environment [2]. In today's modern world, all firms, particularly oil and gas companies, must have an efficient, sustainable plan since these companies frequently fail to meet the triple bottom of a sustainable plan [3]. The triple bottom line (TBL) of sustainable plans is the total assessment of economic, social, and environmental considerations. The corporate context of this TBL is so critical that today's oil and gas firms cannot operate without one [4]. This TBL notion refers to a situation in which businesses combine their economic objectives with the acceptance of responsibility for their influence on ecosystems and people [5]. Because of the notion that corporate sustainability has become the heart of company success, companies are trying to deploy cutting-edge sustainability strategies [6]. Competitive functions founded on political, social, cultural, and economic development will grow more complicated as the condition of expectations and societal approaches transformation, and this is one of the key challenges confronting businesses, particularly knowledgebased firms [7]. The important aspect here is that an institution or company will be able to engage in and assist stakeholders. It is considered to be a social duty in the context of competitive procedures to maintain the overwhelming interests [8, 9]. Other conventional management supply chain management methodologies that pursued less integration in their processes, on the other hand, do not have the necessary efficacy in today's competitive world since the environmental change, social development, technological development, and increasing cultural contradictions have all decided to bring about comprehensive alterations in this region [10]. The necessity to make the correct decision and select the most suitable among many possibilities in diverse areas, including choosing the perfect manufacturer, distributor, best area to draw more customers, best business alliance in shaping integrations, most efficient pricing process, and so on, are critical issues for making decisions in supply chain management [11, 12]. These judgments cover a wide range of topics, from trivial concerns to serious difficulties. Worries about the influence of business on the environment and society have prompted further study into sustainable supply chain management (SSCM) [13]. This area of study aims to learn how a company and its supply chain may accomplish joint-optimization of economic, environmental, and social performance by integrating sustainability into business operations transparently and strategically. In an MCDM challenge, a competent supply chain pricing consideration solutions supplier considers multiple potentially competing qualitative and quantitative criteria. This study developed an extended decision-making and fuzzy set TOPSIS model based on competitive supply chain pricing factors to rank the corporate social responsibility criteria. By transparently and strategically integrating sustainability into business operations, companies and their supply chains can optimize economic, environmental, and social performance. As a result, the goal of this study is to look at the most efficient operation of competitive supply chain pricing focused on social responsibility dimensions with a case study of oil products from knowledge-based enterprises.

2. Literature Review

2.1. Supply Chain Performance Analysis. Sustainable supply chain management is the systematic integration of essential business operations that allows businesses and their supply networks to achieve economic, environmental, and social objectives [14]. As a result, firms who apply it can meet short-term financial objectives while also proactively dealing

with supply chain activities that have long-term environmental and social implications. Since its products are broadly employed in economic and social activities, the oil sector is critical for long-term sustainability. The use of sustainable supply chain management may help to mitigate the harmful effects of operations. Even though sustainable supply chain management as a discipline has matured, sustainable supply chain management research in the oil sector is still in its infancy [15]. The focus of previous studies on the topic has been on increasing supply chain performance through innovative techniques and open innovation efforts [16-18]. The research also looked at how suppliers may improve by using management frameworks to detect and manage environmental and social risks in their operations [19]. It is also working on a green supply chain management method to assess environmental sustainability in oil refinery operations and assess the environmental impacts of decommissioning offshore oil and gas operational systems [20]. Sharifi et al. examined the influence of artificial intelligence and the digital era on business and energy in the aftermath of the COVID-19 pandemic [21]. Finally, the research focused on the problems of integrating corporate strategy topics in supply chain management and close collaboration between oil companies and suppliers to improve the environmental performance of logistical operations [22]. Many scholars are currently discussing the impact of corporate social responsibility on closed-loop supply chain operations. Panda et al. [23] used consumer surplus as an indicator to measure the degree of corporate social responsibility fulfillment by companies, and they concluded that a company's corporate social responsibility behavior might help improve the overall performance of the corporate social responsibility system. When customers pay differentially for new and remanufactured products [23], Dai et al. [24] studied the impact of corporate social responsibility behavior on price decisions and supply chain coordination in the remanufacturing supply chain. Liu et al. [25] examined the influence of corporate social responsibility choices and the number of green consumers on selecting reverse recycling routes, pricing, and recycling ratios in CLSC. Wang et al. [26] investigated how state subsidies and corporate product contributions influenced closed-loop supply chain recycling and pricing decisions.

2.2. Insight to Social Responsibility. Modak et al. [27] developed four recycling decision models for the closed-loop supply chain based on the manufacturer's corporate social responsibility inputs and looked into the influence of the manufacturer's corporate social responsibility input behavior on the closed-loop supply chain choice of the best recycling channel. Past studies on supply chain coordination focused mainly on contract coordination from economic returns or profit maximization [27]. This has evolved as customers have become more aware of corporate social responsibility [24, 25]. The number of studies on long-term supply chains and supply chain coordination that consider economic and environmental advantages has increased [26, 27]. Corporate social responsibility has a major impact on supply chain operations, with research demonstrating that as the number of corporate social responsibility -sensitive consumers grows, so does the manufacturer's corporate social responsibility level, as well as the manufacturer's and retailer's profitability [25]. Johari and Hosseini-Motlagh [28] found that the recommended corporate social responsibility cost-sharing contract enhances market demand by considerably decreasing selling prices and increasing the degree of corporate social responsibility activities in a competitive context. With the growth in consumer awareness of corporate social responsibility, Wang et al. saw corporate social responsibility investment level competition as a critical component of business competitiveness [29]. They discovered that the manufacturer's profit is convex concerning customers' environmental protection [30]. A socially conscious company might charge a greater price for its goods [31]. Furthermore, corporate social responsibility implications on supply chain operation and coordination exist in various competitive settings and decision-making structures. There are different corporate social responsibility implications in different channel configurations, such as exclusive vs. competitive retailing. Ahmadi et al. discussed how to use object-oriented properties programming to create expert systems for strategic planning [32]. Niu et al. [33] observed that an international vaccine provider would prefer competitive retailing when the global and local vaccines are highly interchangeable. It does not matter if the aim is profit or social responsibility. The supply chain will have various social responsibility techniques in monopoly and duopoly situations. When the conditions for each company's optimal corporate social responsibility efforts, strategic planning preferences, and corporate social responsibility effects in monopoly and duopoly circumstances are considered, Shi et al. [34] discovered that, in the duopoly scenario, the supply chain is more highly likely to be irresponsible and lesser the total corporate social responsibility attempt level. When corporate social responsibility is included, societal welfare in a centralized decision-making scenario is always higher than decentralized [35].

A coordination contract to encourage a company to adopt corporate social responsibility, according to Li et al. [36], can lead to multiple wins for social welfare, customers, and supply chain players. However, once the corporate social responsibility coefficient exceeds a specific level, the disagreement between supply chain participants becomes irreconcilable. As a result, the impact of corporate social responsibility on supply chain operations is a complex issue. The complexity of the impact of social responsibility on supply chain coordination has been a source of worry for educators. Using game theory, scholars investigated the influence of negative social responsibility on the design of supply chain coordination contracts. They observed that in a retailer-led supply chain, a cost-sharing arrangement might increase profit for both parties. In a manufacturer-led collaboration, a profit-sharing model can lead to greater overall returns [37]. From the perspective of the global supply chain, Tian et al. [38] observed that increasing the degree of social responsibility of Chinese suppliers might enhance production demand and the economic advantages of stakeholders. On the other hand, supplier earnings will decline as product greenness increases, but stakeholder profits will increase. Nonetheless, Chinese suppliers' economic earnings

are influenced by their level of social responsibility and the advantages of green production. There is presently a serious lack of collaboration in establishing multinational firms' social responsibility, according to Liu et al. [39]. They created a punishment model that handled supply chain participants' optimal decision-making in centralized and decentralized decision-making procedures. They then looked at the impact of the penalty % on social responsibility input.

2.3. CSR on the Sustainable Supply Chains and Fuzzy TOPSIS Methods. The researchers investigated the construction of resilient supply chains using renewable energy in Lotfi et al. It is suggested that the upper limit for the primary model be less than 10%, which is reasonable for cost estimation of large-scale problems. According to this study, SC should be equipped with RE in order to make them more robust to fluctuations in demand and to serve as an energy resource compatible with the seventh sustainable development agenda (SGD7) [40]. For designing unpredictable mixed resilient-sustainable power logistics, Motlagh et al. developed an innovative technique. In terms of standard deviation and mean value of the overall cost, the results demonstrate that decision-makers can distribute uncertainty budget and safety level efficiently to get more robust solutions using fuzzy-robust techniques [41]. Ahmadi examined how knowledge-based indicators affect economic development and classified and ranked them using logarithmic fuzzy preference programming [42]. Lahri et al. designed an innovative integrated BWM Sustainability supply chain network. This study used the Epsilon-constraint approach coupled with possibility programming, which has been documented sparingly in the literature. Multiple Paretooptimal alternatives can be found by applying the Epsilonconstraint, allowing for a broad range of trade-offs across cost, emission, and ecological equity. When facing an unstable world, the findings help decision-makers [43]. As part of a combination stochastic fuzzy-robust methodology, Sharifi et al. investigated unique resilient-sustainable techniques for the construction of third biofuel networks from neem and eruca sativa. Using three factors, including resilience, social consequences, and cost, and weighing their relative importance, decision-makers can optimize biofuel logistics network architecture. In order to build a healthy supply chain system, Eskandarpour et al. conducted a multidirectional search. In conclusion, the article discusses the influence of greener technologies on supply chain structure from a management perspective [44].

3. Research Methodology

3.1. Social Responsibility. Business executives have voiced a diverse range of views on corporate social responsibility (CSR). In his paper, The Social Responsibility of Business is to Raise Its Earnings, Nobel Prize-winning economist Milton Friedman (1970) clearly stated one perspective on corporate social responsibility [45]. "The business structure that Whole Foods has embraced might symbolize a new kind of capitalism, one that more deliberately works for the

greater good instead of relying only on the "invisible hand" to create beneficial benefits for society, said John Mackey, the founder of Whole Foods" [46]. Regardless of how fundamentally business executives believe about corporate social responsibility, they cannot disregard corporate social responsibility consequences for their organizations. As a result, the purpose of this article is to offer some assistance to businesses looking to evaluate the advantages and costs of corporate social responsibility. These advantages and expenses can help managers judge their firms' corporate social responsibility initiatives. We concentrate on the relationship between accounting and corporate social responsibility since accounting is a critical assessment tool in businesses.

3.2. Corporate Social Responsibility in Oil and Gas. A short assessment of corporate social responsibility in the oil and gas industry immediately connects rising civic expectations and worries about global warming, environmental disasters, dwindling resources, and the impact of transnational corporations on globalization, and perceived expanding power and influence [47]. Consumers and civic organizations increasingly target TNCs to initiate changes by threatening reputational consequences, as skepticism about national governments' desire and capacity to effect change grows. Larger, more focused use of corporate social responsibility techniques, concepts, and ways of reasoning may allow for the detection of broader future dangers and possibilities [48]. Profits, demand, accessibility, market price, and reputation are all at risk. Energy businesses are especially susceptible in this sense. Intangibles such as trust, dependability, validity, continuity, connections, and clarity, as well as tangibles like profitability, investment in staff, communities, and the environment, are critical to their brand and social capital [49]. Organizations confront rising demands and expectations from governments, communities, and consumers as competition for new areas heats up, which are always linked with wider and deeper risks, markets, and energized civil societies. In the oil and gas business, corporate social responsibility (or other similar words such as CR, sustainable development, communities, and our people) has received increased consideration due to altering civic, political, and commercial realities [50]. Transnational initiatives such as the Global Reporting Initiative, the UN Global Compact, and the UK-led Extractive Industries Transparency Initiative (EITI), as well as organizations like the World Business Council for Sustainable Development, the Institute of Business Ethics, and the World Bank Groupfunded CommDev, have been introduced in place of global attempts to control TNCs. Transformation in business behavior is encouraged by such organizations. TNCs have adjusted to shifting attitudes and needs by launching a slew of corporate social responsibility-related activities. Several more oil and gas companies now have codes of ethics, participate in stakeholder dialogue, assist in the construction of schools and hospitals, collaborate with development organizations such as the United Nations Development Programme (UNDP), use nongovernmental organizations

(NGOs) to apply for development programs, and publish financial, social, and environmental performance findings. Various worldwide representative organizations, such as IPIECA and the World Petroleum Council, encourage awareness of ethical and sustainable corporate practices and campaigns highlighting firm community involvement [51].

Despite this, there is broad recognition within the energy industry and representative organizations and increased calls from international pressure groups, civilian populations, and, in some instances, political parties and militias that a more significant focus on social responsibility is necessary. Employees will need more knowledge into how firms engage with communities, governments, and global processes and the repercussions if enterprises are to constructively contribute to more involvement and the adoption of corporate social responsibility -related ways of thinking. Furthermore, despite the more significant expenditure, corporate social responsibility initiatives fail to address many of the issues they are blamed for causing. Corporate social responsibility rules, on the other hand, exacerbate current issues while creating new ones. The issues are exacerbated in regions where oil and gas corporations operate under the so-called absent state theory [52].

3.3. Sustainable Supply Chain Management. The sustainable supply chain management approach was examined on two levels: first, as a single idea, regardless of the numerous particular tactics used by oil distribution businesses to promote sustainable supply chain management; and second, as a collection of methods used by oil distribution firms to promote sustainable supply chain management. Second, as particular strategies-green supplier selection, product stewardship, and logistics management [53]. In the administration of a supply chain, oil and gas distribution firms face various economic, environmental, and social issues [54, 55]. As a result, SSCM in the oil sector must deal with many challenges, including pollution impact replacement, elevated energy, material use, and biodiversity conservation [56]. Rather than dealing with each possible issue individually, oil firms opt to follow conventions or use well-established criteria [57]. Codes of conduct, norms, and standards, as well as certification that validates compliance, can be used by oil and gas distribution companies to assess a supplier's environmental or social impact [57, 58]. All of these are elements that can help you improve the efficiency of your supply chain. Since oil and gas distribution companies control their supply chains, they evaluate vendors by establishing minimum requirements and standards. Consequently, suppliers may conduct self-evaluations based on environmental or social criteria, which may be helped by incentives [59].

3.3.1. Product Stewardship Strategy. For example, several facets of sustainability are included in the Product Stewardship approach, reverse logistics, and closed-loop supply chains [60]. Lane and Watson (2012) [61] feel that product stewardship is a swiftly expanding area that is highly relevant in resource conservation and producing a competitive advantage for an organization [36]. According to several scholars, environmental stewardship is becoming a more widely used technique

in relation to material responsibility [62]. From responsible waste management to a stronger focus on resource conservation, the concept of product stewardship has evolved. The interplay between the social and material worlds has changed due to product stewardship methods [63]. Moreover, these activities have contributed to the development of new industrial sectors and collaborations. The main objective of Product Stewardship is to reduce a product's environmental effect throughout its life cycle [64].

3.4. Supply Chain Management Functions. There are a variety of supply chain management functionalities available, each stressing a distinct perspective [65]. Florescu et al. [58] believe that planning and execution are essential to supply chain activities. However, other researchers [66, 67] suggest that sustainable supply chain management requires a broader emphasis on coordination and cooperation. As a result, four supply chain management functions are investigated in this work: planning, execution, coordination, and cooperation. Creating an sustainable supply chain management necessitates a supply chain focus, active participation of supply chain actors, and teamwork. Waste reduction, material recycling, energy conservation [68], and the development of new environmental development techniques [68, 69] are all examples of new environmental methodological approaches.

Moreover, environmental effect data on acquired commodities have been proven to benefit supply chains with adequate planning and coordination. Poor supply chain communication, on the other hand, results in the inadequate transfer of information and has an impact on goal alignment, which is essential to implement environmental sustainability in supply chains [70]. Cooperation among supply chain players affects supply chain sustainability by affecting information transmission and problem-solving among supply chain members [71]. In supply chains, for instance, codes of conduct are employed to establish principles and require communication to reinforce those standards across the network [72]. As a consequence, communication may have a direct influence on the social sustainability performance of the supply chain.

3.5. Integration of Supply Chain Pricing Values. The degree to which a manufacturer collaborates with supply chain partners and as a group handles procedures both inside and outside the business to create competitive advantages is known as supply chain pricing integration [73]. Firms have realized that they must handle the supply chain as a whole system and consider it an integrated function as the necessity of good supply chain management has grown [74]. Stevens (1989) initially examined value integration in terms of the three dimensions listed as follows (see Figure 1):

When a company adopts an integrated strategy, it recognizes that it cannot handle each component of the supply chain as a separate function. However, it must instead comprehend and manage the linkages and interdependencies. This means that sourcing, demand planning, inventory planning, warehousing, logistics, and order

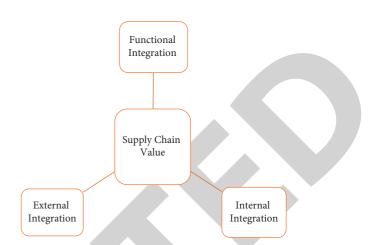

FIGURE 1: A three-dimensional approach to supply chain value integration.

processing must all work simultaneously inside the supply chain organization. The rise of supply chain software solutions that put all of this data together in one place is one indicator of a more integrated approach [75].

Furthermore, many businesses traditionally had these tasks dispersed across many departments with limited chance for interaction. Most big corporations now have an integrated supply chain function with a single management team and shared goals. There are crucial links between marketing, finance, and production and the work done inside the supply chain organization. Marketing has a direct role in forecasting demand and setting consumer expectations for goods and delivery. These should be discussed with the supply chain team so that everyone understands what has to be accomplished. If this is not feasible, modifications may be made and communicated to consumers as soon as possible. Integration with finance is required to ensure that investments are adequately planned, and that inventory is correctly accounted for. Manufacturing is frequently influenced by the supply chain team's decisions and requirements since they rely on enough supplies and must fulfill delivery deadlines to satisfy client promises. This integration functions well when real goals are defined across the companies, a shared perspective of the data (which identifies possibilities for enhanced performance), and clear, frequent communication about possible difficulties and requirements, as with many complicated organizational problems. As a result, all businesses can concentrate on providing value to consumers and fulfilling the company's goal. For instance, Lee and Hang propose the following model (see Figure 2) for supply chain value integration [76]:

3.6. Data Statement. In the qualitative portion, the statistical population comprises 30 university-level professionals and specialists in industrial management who have a skilled and scientific approach to performing scientific research in a related subject. They were chosen using a homogenous sample approach since the participants in this section were expected to understand the study issue theoretically. In addition, research accessible on Iranian websites was utilized

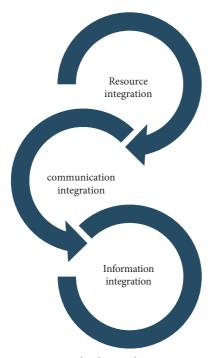

FIGURE 2: Supply chain value integration.

to identify components (functioning of competitive supply chain pricing) and indicators (social responsibility) of the research in this part, based on the meta-synthesis. The interpretative ranking process (IRP) was carried out in the second phase, with 40 managers from knowledge-based firms in the oil industry filling in the matrix checklists depending on the nature of the study.

3.7. Best-Worst Method. For the selection step, the bestworst method (BWM) was developed [30]. The BWM has several distinguishing characteristics, including (i) a highly structured pairwise comparison that yields very continuous and trustworthy findings; (ii) the use of only two vectors rather than a full pairwise comparison matrix. This means that the analyst and decision-maker will have to spend less time gathering data. Surprisingly, because these two vectors are more organized than a whole matrix, less data contributes to improved dependability; (iii) the technique only utilizes integer values, making it more pragmatic than methods requiring fractions.

Step 1: create a list of criteria for making a choice. We examine the criteria $(c_1, c_2, ..., c_n)$ that should be utilized to choose this phase.

Step 2: decide which criteria are the best (most pleasant, most essential) and the worst (least attractive, least essential). In this stage, the decision-maker determines which criteria are the greatest and worst in general. At this point, no comparisons are drawn.

Step 3: utilizing a number between 1 and 9, identify the best criterion's priority above all other criteria. The Best-to-Others vector as a consequence would be: Journal of Mathematics

$$A_{B} = (a_{B1}, a_{B2}, \dots, a_{Bn}),$$
(1)

where a_{Bj} denotes the best criteria B's priority over criterion *j*. $a_{BB} = 1$ is self-evident.

Step 4: utilizing a number between 1 and 9, rank all criteria in order of priority over the worst criterion. The Others-to-Worst vector as a consequence would be:

$$A_{B} = (a_{1W}, a_{2W}, \dots, a_{nW})^{T},$$
(2)

where a_{jW} denotes the criteria j's preference over the worst criterion W. $a_{BB} = 1$ is self-evident.

Step 5: determine the best weights $(w_1^*, w_2^*, \dots, w_n^*)$.

The weight for the criteria that has $w_B/w_j = a_{jw}$ for each pair of w_B/w_j and w_j/w_w is the best. We should develop a solution that minimizes the most remarkable absolute differences $|w_B/w_j - a_{Bj}|$ and $|w_j/w_W - a_{jW}|$ for every *j* to meet these. The next difficulty arises from the nonnegativity and sum condition for the weights:

$$\min \max_{j} \left\{ \left| \frac{w_B}{w_j} - a_{Bj} \right|, \left| \frac{w_j}{w_W} - a_{jW} \right| \right\}, \tag{3}$$

st
$$\sum w_j = 1$$
,
 $w_j \ge 0$. (4)

The following problem can be applied to this one: ξ

$$\min \xi \left| \frac{w_B}{w_j} - a_{Bj} \right| \le \xi \text{ for all } j \left| \frac{w_j}{w_W} - a_{jW} \right| \le \xi \text{ for all } j \sum w_j$$

$$= 1 w_i \ge 0 \quad \text{for all } j.$$
(5)

The optimal weights $(w_1^*, w_2^*, \ldots, w_n^*)$ and ξ^* are computed while solving the problem. The consistency index is then used to determine the consistency ratio (Tables 1 and 2). The larger the $\xi *$, the greater the consistency ratio, and the less trustworthy the comparisons get.

First, FBWM [35] is used to calculate the fuzzy criterion weights in the proposed Integrated Fuzzy Best-Worst-TOPSIS approach. In FBWM, DMs indicate their preferences for criterion comparison using the linguistic characteristics listed in Table 1, then translated into TFNs.

The FBWM's stages are listed below.

Define the Evaluation Criteria and DMs in Step 1. A set of $C = \{c1, c2, ..., cm\}$, (benefit) criteria is established, with the greatest being better for each criterion.

Step 2: determine which criteria are the best and worst. Each DM determines which criterion is the best (most desired) and which is the worst (least desirable) (less desirable).

Step 3: calculate the best criterion's fuzzy preference over all criteria (Best-to-Others (BO) vector). Utilizing the linguistic words in Table 1, each DM decides his or her best criterion's preference over all other criteria, which is then translated to TFNs $\tilde{a}_{ij} j = (1, 2, ..., n)$. It is worth noting that $\tilde{a}_{BB=(1,1,1)}$.

TABLE 1: Consistency index.

aBW	1	2	3	4	5	6	7	8	9
Consistency index	0.00	0.44	1.00	1.63	2.30	3.00	3.73	4.47	5.23

TABLE 2: For the evaluation of criteria, linguistic variables and TFNs are used.

Linguistic variables	Triangular fuzzy numbers (TFNs)
Equally preferred (EP)	(1, 1, 1)
Moderately preferred (MP)	(2/3, 1, 3/2)
Strongly preferred (SP)	(3/2, 2, 5/2)
Very strongly preferred (VSP)	(5/2, 3, 7/2)
Extremely more preferred (EMP)	(7/2, 4, 9/2)

Step 4: Over the Worst criterion (OW) vector, calculate the fuzzy preference of all other criteria. Utilizing the

linguistic words in Table 1, each DM calculates the priority of all other criteria over the worst criterion, which is then translated to TFNs $\tilde{a}_{jw} j = (1, 2, ..., n)$. It is worth noting that $\tilde{a}_{BB=(1,1,1)}$.

Step 5: determine the criteria's optimal fuzzy weights. Problem (7) is addressed for each DM and the ideal fuzzy weight vector $w^- = (w_1^-, w_2^-, \dots, w_m^-)$ and $\xi *$ are found.

Step 6: make sure everything is consistent.

There is a sum of 2n-3 fuzzy reference comparisons (n-2) best-to-others fuzzy comparisons +n-2 others-to-worst fuzzy comparisons +1 best-to-worst fuzzy comparison), which is required to be applied for FBWM. It's worth noting that (fuzzy) BWM only requires 2n-3 comparisons, but (fuzzy) AHP requires (n-1)/2.

In FBWM, optimal fuzzy weights $w^- = (Ij, mj, uj) j = 1$, 2, ..., *n* can be determined as follows [6, 31]:

$$\min \max_{j} \left\{ \left| \frac{\widetilde{w}_{B}}{\widetilde{w}_{j}} - \widetilde{a}_{Bj} \right|, \left| \frac{\widetilde{w}_{j}}{\widetilde{w}_{W}} - \widetilde{a}_{jW} \right| \right\},$$
s.t.
$$\left\{ \sum_{j=1}^{n} R(\widetilde{w}_{j}) = 1,$$

$$l_{j} \leq m_{j} \leq u_{j}, j = 1, 2, \dots, n,$$

$$l_{j} \geq 0, j = 1, 2, \dots, n,$$
(6)

where $\tilde{w}_B = (l_B, m_B, u_B)\tilde{w}_W = (l_W, m_W, u_W)\tilde{a}_{Bj} = (l_{Bj}m_{Bj}, u_{Bj})\tilde{a}_{jW} = (l_{jW_2}m_{jw}, u_{jW})$ The following nonlinearly

constrained optimization problem may be converted to problem (3):

s.t.
$$\begin{cases} \min \tilde{\xi} \\ \left| \frac{\tilde{w}_B}{\tilde{w}_j} - \tilde{a}_{Bj} \right| \le \tilde{\xi}, j = 1, 2, \dots, n \\ \frac{\tilde{w}_j}{\tilde{w}_W} - \tilde{a}_{jW} \mid \le \tilde{\xi}, j = 1, 2, \dots, n \\ \right| \sum_{j=1}^n R(\tilde{w}_j) = 1, \\ l_j \le m_j \le u_j, j = 1, 2, \dots, n, \\ l_j \ge 0, j = 1, 2, \dots, n, \end{cases}$$

(7)

where $\tilde{\xi} = (l^{\xi}, m^{\xi}, u^{\xi})$ taking into account $l^{\xi} < m^{\xi} < u^{\xi}$ presume $\xi * = (k *, k *, k *), K * \leq l^{\xi}$ then problem (6) can be converted to the following problem:

$$\min \tilde{\xi} \\ \left\{ \begin{array}{l} \left| \frac{(l_B, m_B, u_B)}{(l_j, m_j, u_j)} - (l_{Bj}, m_{Bj}, u_{Bj}) \right| \le (k * , k * , k *) \quad j = 1, 2, \dots, n \\ \frac{(l_j, m_j, u_j)}{(l_W, m_W, u_W)} - (l_{jW} m_{jw}, u_{jw}) | \le (k * , k * , k *) \quad j = 1, 2, \dots, n \\ \sum_{j=1}^n R(\tilde{w}_j) = 1 \\ l_j \le m_j \le u_j, j = 1, 2, \dots, n \\ l_j \ge 0, j = 1, 2, \dots, n. \end{array} \right.$$

The optimal fuzzy weights $\tilde{w}_j = (Ij, mj, uj)j = 1$, 2..., *n* and $\tilde{\xi}$ * may be found by solving the preceding issue.

Testing for consistency [34]: to evaluate the consistency of fuzzy pairwise comparisons, the consistency ratio (CR) is utilized.

When $\tilde{a}Bj.\tilde{a}Bj = \tilde{a}BW$, a fuzzy comparison is entirely consistent.

The most excellent possible crisp may be calculated and utilized as a consistency index (CI) for FBWM by calculating equation (8) for various values ($\tilde{a}_{BW} = (l_{BW}, m_{BW}u_{BW})$):

$$\xi^{2} - (1 + 2u_{BW})\xi + (u_{BW}^{2} - u_{BW}) = 0.$$
(9)

Table 2 shows the estimated CI values for various variables.

After that, the consistency ratio (CR) is determined as follows: Closer to zero CR scores indicate great consistency.

3.8. Interval Type-2 Fuzzy Sets TOPSIS (IT2F-TOPSIS). The TOPSIS approach aims to choose the closest alternatives to the positive-ideal solution and furthest away from the negative-ideal solution [77, 78]. IT2F-TOPSIS Pythagorean fuzzy variants of TOPSIS based on fuzzy collections are created as Ak and Gul [74]. Utilizing the benefits of IT2FSs, TOPSIS centered on IT2FSs better represents uncertainty, vagueness, and ambiguity than regular fuzzy TOPSIS [78]. The suggested TOPSIS, which is based on IT2FSs, may be implemented in several ways:

Step 1: suppose that there are S options, with $S = \{s_1, s_2, \ldots, s_n\}$ Furthermore, that there are C criteria, with $C = \{c_1, c_2, \ldots, c_m\}$, and that there are K

decision-makers. $D = \{D1, D2, ..., DK\}$ Each decision-maker took part in our survey and assigned a value to the supplier's performance based on each criterion. Equation (1) may be used to compute the supplier's overall performance value based on each criterion:

$$E_{c} = \left(\tilde{\tilde{c}}_{ij}^{p}\right)_{m \times n} = \begin{cases} c_{1} \\ c_{2} \\ \vdots \\ c_{m} \end{cases} \begin{bmatrix} \tilde{\tilde{c}}_{11}^{p} & \tilde{\tilde{c}}_{12}^{p} & \cdots & \tilde{\tilde{c}}_{1n}^{p} \\ \tilde{\tilde{c}}_{21}^{p} & \tilde{\tilde{c}}_{22}^{p} & \cdots & \tilde{\tilde{c}}_{2n}^{p} \\ \vdots & \vdots & \vdots & \vdots \\ \tilde{\tilde{c}}_{m1}^{p} & \tilde{\tilde{c}}_{m2}^{p} & \cdots & \tilde{\tilde{c}}_{mn}^{p} \end{bmatrix},$$
(10)

where $\tilde{\tilde{c}}_{ij} = (\tilde{\tilde{c}}_{ij}^1 \oplus \tilde{\tilde{c}}_{ij}^2 \oplus \cdots \oplus \tilde{\tilde{c}}_{ij}^k/k)$, $\tilde{\tilde{s}}_{ij}$ is an IT2FS $1 \le i \le m, 1 \le j \le n, 1c \le k$, and k show the number of professionals,

$$\widetilde{\widetilde{c}}_{ij} = \left(a_{i1}^{U}, a_{i2}^{U}, a_{i3}^{U}, a_{i4}^{U}; H_1\left(\widetilde{A}_{i}^{U}\right), H_2\left(\widetilde{A}_{i}^{U}\right)\right), \\
\left(a_{i1}^{L}, a_{i2}^{L}, a_{i3}^{L}, a_{i4}^{L}; H_1\left(\widetilde{A}_{i}^{L}\right), H_2\left(\widetilde{A}_{i}^{L}\right)\right),$$
(11)

and k show the number of professionals,

Step 2: applying the best-worst approach, get the weighting matrix Ws of the criterion,

$$c_{1} \quad c_{2} \quad \cdots \quad c_{m}$$

$$W_{s} = (w_{i}^{s})_{1 \times m} = [w_{1}^{s}, w_{2}^{s}, \cdots, w_{m}^{s}].$$
(12)

Step 3: to produce the weighted decision matrix, multiply the significant weights of the criterion by the

(8)

values in the decision matrix. For each criterion, the weighted decision matrix $\tilde{\tilde{\nu}}$ is written as follows:

$$\widetilde{\widetilde{v}}_{ij} = \widetilde{\widetilde{c}}_{ij} \times w_i, \tag{13}$$

where the weighted trapezoidal interval type-2 fuzzy integers are denoted by $\tilde{\tilde{v}}_{ij}$.

Step 4: determine the IT2FSs' ranking value Rank (\tilde{v}_{ij}) . Ew is a ranking weighted decision matrix that is built. Step 5: identify the positive-ideal solution $x * = (v_1^*, v_2^*, \dots, v_m^*)$ as well as the negative-ideal solution $\overline{x} = (\overline{v}_1, \overline{v}_2, \dots, \overline{v}_m)$, where

$$v_{i}^{*} = \begin{cases} \max_{i \leq j \leq n} \left\{ \operatorname{Rank}\left(\tilde{\tilde{v}}_{ij}\right) \right\}, & iff_{i} \in B, \\ \min_{i \leq j \leq n} \left\{ \operatorname{Rank}\left(\tilde{\tilde{v}}_{ij}\right) \right\}, & iff_{i} \in C, \end{cases}$$

$$v_{i}^{-} = \begin{cases} \min_{i \leq j \leq n} \left\{ \operatorname{Rank}\left(\tilde{\tilde{v}}_{ij}\right) \right\}, & iff_{i} \in B, \\ \max_{i \leq j \leq n} \left\{ \operatorname{Rank}\left(\tilde{\tilde{v}}_{ij}\right) \right\}, & iff_{i} \in C. \end{cases}$$

$$(14)$$

Then, for the green supplier, positive $d * (x_j)$ and negative $d-(x_i)$ ideal solutions are obtained as follows:

$$d^{*}(x_{j}) = \sqrt{\sum_{i \in I} \left(\operatorname{Rank}(\widetilde{\widetilde{v}}_{ij}) - v_{i}^{*} \right)^{2}}, \qquad (16)$$
$$d^{-}(x_{j}) = \sqrt{\sum_{i \in I} \left(\operatorname{Rank}(\widetilde{\widetilde{v}}_{ij}) - v_{i}^{-} \right)^{2}}. \qquad (17)$$

The trapezoidal IT2FS $\tilde{\tilde{A}}_i$'s ranking value $Rank(\tilde{\tilde{A}}_i)$ is formulated as follow:

$$\operatorname{Rank}(\tilde{\tilde{v}}_{i}) = M_{1}(\tilde{v}_{i}^{U}) + M_{1}(\tilde{v}_{i}^{L}) + M_{2}(\tilde{v}_{i}^{U}) + M_{2}(\tilde{v}_{i}^{L}) + M_{3}(\tilde{v}_{i}^{U}) + M_{3}(\tilde{v}_{i}^{L}) - \frac{1}{4} (S_{1}(\tilde{v}_{i}^{U}) + S_{1}(\tilde{v}_{i}^{L}) + S_{2}(\tilde{v}_{i}^{U}) + S_{2}(\tilde{v}_{i}^{L}) + S_{3}(\tilde{v}_{i}^{U}) + S_{3}(\tilde{v}_{i}^{L}) + S_{4}(\tilde{v}_{i}^{U}) + S_{4}(\tilde{v}_{i}^{L})) + H_{1}(\tilde{v}_{i}^{U}) + H_{1}(\tilde{v}_{i}^{L}) + H_{2}(\tilde{v}_{i}^{U}) + H_{2}(\tilde{v}_{i}^{L}),$$
(18)

where $M_p(\tilde{v}_i^j)$ indicates the element's average of v_{ip}^j , and $v_{i(p+1)}^j$, denotes the element's standard deviation of v_{ip}^j and v_{iq}^j and $v_{i(q+1)}^j$'s standard deviations are denoted by $v_{i(p+1)}^i$, and $M_p(\tilde{v}_i^j) = (v_{ip}^j + v_{i(p+1)}^j)/2$, $1 \le p \le 3$,. $S_q(\tilde{v}_i^j) = \sqrt{1/2\sum_{k=q}^{q+1} v_{ik}^j - 1/2\sum_{k=q}^{q+1} v_{ik}^{j^2}}$, $1 \le q \le 3$, $H_p(\tilde{v}_i^j)$ denotes the.

In the trapezoidal membership function \tilde{v}_i^j , $1 \le p \le 3$, $j \in \{U, L\}$, and $1 \le i \le n$., the membership value of the element $v_{i(p+1)}^j$.

Step 6: the $CC(x_j)$ closeness coefficient is then computed.

$$CC(x_{j}) = \frac{d^{-}(x_{j})}{d^{*}(x_{j}) + d^{-}(x_{j})}.$$
 (19)

Step 7: alternatives can be ranked in descending order. The greater the value of $CC(x_j)$, the larger the green supplier's preference.

4. Results

In Iran, fuzzy Best-Worst-TOPSIS assesses and ranks oil corporations based on their social responsibility component. In the research, three managers from oil firms serve as DMs. The environmental dimension is one of the elements being assessed. The social dimension, Economic dimension, Beneficiary dimension, Voluntary dimension, Ethical dimension, and Institutional dimension are based on three elements that influence supply chain price in oil companies: competitors, products, and customers. Table 3 lists the assessment criteria that were established with the assistance of DMs. All of the assessment criteria in Table 3 are advantage criteria (B).

Each DM must first evaluate which parameters are the greatest and worst for him or her. Then, employing the linguistic variables given in Table 2 compares them to other criteria (Tables 4 and 5). All DMs picked C1 as the best criterion, whereas C5 was chosen as the worst criterion.

TABLE 3: Components of social responsibility.

Со	Components	Definitions
B1	Environmental dimension	The environmental component is concerned with the vulnerability of ecological and biophysical systems and their many functions in the event of a hazardous state, which causes damage and degradation. The corporate social responsibility (CSR) trend encourages businesses to go above and beyond legal requirements to contribute to environmental quality. Climate change and greenhouse gas emissions are frequently discussed.
B2	Social dimension	The social dimension of social responsibility differs from the other components. It includes, among other things, the firm's community performance methods as well as dynamic social relationships with stakeholders, such as data supply, performance transparency, and adaptable organizational structures.
B3	Economic dimension	The economic part of corporate social responsibility relates to the distribution of resources to create products and services within the social system. In terms of the economy, social responsibility covers many elements of how companies influence the economy in terms of competition, consumers, employees, community, and environment.
B4	Beneficiary dimension	This dimension is concerned with institutions and organizations' commitment to serving the needs of stakeholders. It is, in fact, a set of management activities that ensure the company's operations have the maximum potential positive influence on society. This viewpoint highlights the importance of CSR's voluntary character.
B5	Voluntary dimension	Business frequently interprets the voluntary character of corporate social responsibility to indicate that, because corporate social responsibility activities are not obligatory, they are always discretionary and so maybe chosen exclusively by the business.
B6	Ethical dimension	While ethics is concerned with what is good and wrong in general, business ethics focuses on benefits for shareholders and stakeholders. On the other hand, social responsibility is concerned with the company's influence on the environment and community. 4th of March 2018
B7	Institutional dimension	Past social responsibility/social performance study has done nothing to address the institutional drivers of social responsibility and its many expressions in terms of social performance in a systematic way. Instead, most of this study has focused on particular areas of the business-society interface, such as the link between social responsibility and economic success and the link between a firm's internal features and its outward social performance.

B7	VSP	MP	VSP

The language preferences of the DMs were translated to TFNs employing the scale in Tables (see Tables 6 and 7). To obtain the fuzzy weights of criteria, Problem (7) was solved for each DM based on Table 8. Table 9 shows the ideal fuzzy criterion weights for each DM and the average fuzzy criteria weights. Average fuzzy weights are used in the F-TOPSIS phase. Equation (8) is used to derive related consistency indicators (ξ) for each DM, as given in Table 9. Because all of the consistency ratios are nearly 0, each DM's criteria comparisons are highly consistent.

DMs assess each alternative according to each criterion in the F-TOPSIS phase, using the linguistic variables in Table 8. Table 10 shows the results of three DMs' evaluations of the competitive supply chain pricing factors based on seven criteria. After linguistic terms are transformed to matching TFNs, the aggregated (average) fuzzy decision matrix is given in Table 11. Once the fuzzy normalized decision matrix is built, as illustrated in Table 12, the fuzzy weighted normalized decision matrix is computed. The distance from a fuzzy positive-ideal solution, the range from a fuzzy negative-ideal solution, and the proximity coefficients are all shown in Table 13. Customers, products, and

competitors are the options rated from best to worst based on the values.

The distance from fuzzy positive-ideal solution, distance from fuzzy negative-ideal solution, and proximity coefficients are computed as shown in Table 13 and Figure 3. Customers, products, and competitors are the options rated from best to worst based on the values.

4.1. The Comparative Analysis. To verify the efficacy of the suggested strategy, it is compared to a benchmarking model. IT2F VIKOR is the subject of this benchmarking model. The significance weights of the Competitive supply chain pricing selection criterion are determined from BWM for both techniques. Both are used to rank Competitive factors in the model's second phase. In our new benchmarking approach, Table 14 provides the final scores and ranking patterns of competitive characteristics. Utilizing our recommended model (combined BWM and IT2F-TOPSIS), once the maximum group utility value (ν) is modified to 0.5 or more than 0.5, the ranking orders of three Competitive factors remain identical, as seen in Table 14. This finding suggests that the suggested technique produces good results and provides appropriate outcomes for competitive factor ranking decision-making. According to the findings of this study, the three variables of competitive supply chain pricing based on customer, supply chain pricing based on products, and supply chain pricing based on competitive have the highest frequency.

5. Discussion

The current situation of the global economy is such that most countries are attempting to acquire a competitive position at the international level. Traditionally competition is a static aspect and success or failure in it as production is dependant. But in today's modern world, competition is a dynamic force, and new product technologies, new market borders, new production methods, and new management ideas contribute to the

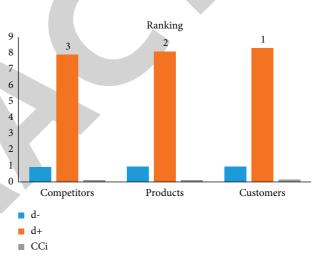

FIGURE 3: Weighted normalized fuzzy decision matrix.

development, alteration, or even extinction of the advantage of national industrial competitiveness. The history of countries such as China and Japan reveals that the only reason for their success is their capacity to exceed the idea of static competitive advantages. The aforementioned nations were able to overcome the restrictions of their resources via scientific and technical advances, expanding the volume of production and growth of foreign commerce. These countries recognized that comparative advantage could be established by increasing skills, capital, and labor, and that structural change could create an environment favorable to economic progress. Today, competitive strategy and its key branches of industry analysis, competitor analysis and strategic positioning are viewed as an acknowledged aspect of management activity. Competitive strategy has offered a comprehensive framework for examining the fundamental determinants of rivalry in industry. As a result, the goal of this study is to look at the most efficient operation of competitive supply chain pricing focused on social responsibility dimensions with a case study of oil products from knowledge-based enterprises.

6. Conclusion and Future Works

With competitive supply chain pricing, corporate social responsibility has become the most efficient business strategy in the globe. Since most firms utilize these performances or acquire information about their businesses to evaluate and choose the best criterion. In an MCDM challenge, a competent Supply Chain Pricing considerations solutions supplier considers multiple possibly competing for qualitative and quantitative criteria. This study presented a new extended decision making and FBWM method based on Type-2 Fuzzy Sets TOPSIS for ranking the corporate social responsibility criteria based on competitive supply chain pricing factors. The aim of the ranking is to learn how a company and its supply chain may accomplish joint-optimization of economic, environmental, and social performance by transparently and strategically integrating sustainability into business operations. The most effective functioning of competitive supply chain pricing in knowledge-based businesses' oil supplies was investigated in this research, which concentrated on social obligation components. Three functions of competitive supply chain pricing and seven propositions connected to the dimensions of social responsibility in knowledge-based businesses in the oil sector were established depending on the research results to meet the first and second research goals. The most plausible dimension of social responsibility in knowledge-based businesses in the oil sector, according to the research, is the environmental dimension in social responsibility, which may produce competitive supply chain pricing mechanisms based on profitability. The environmental factor, which refers to the establishment of professional environment procedures in keeping with the nature of knowledge-based companies based on the production of knowledge-based commodities, shapes corporate social responsibility methods. It keeps them accountable to stakeholders and enhances social perceptions of their performance to more fully integrate the national and domestic economies. Since oil is a vital product in our nation's economy, we focus on development-oriented characteristics in the oil sector and its derivatives. It promotes trust and confidence in firms that utilize such items as primary materials or raw materials, in addition to adhering to environmental standards. It

promotes long-term economic growth and thriving. In other findings; it was revealed that the elements of Competitive Supply Chain Pricing factors in Oil Companies based on social responsibility are ranked as follows: customer, product, and competitive supply chain pricing procedures. As a result, maintaining customer values is a major price element in establishing contacts, as determined by the company's strategic connection with the economy, as well as regional and worldwide partners. In actuality, this price function attempts to persuade clients to use the goods of domestic and Iranian knowledge-based businesses by earning their trust and confidence to create value for their customers. Knowledge-based companies will be able to assess their competitive position in this circumstance strategically, based on value-based competitive supply chain pricing, and plan for likely future scenarios, and sell items to meet customer wants. To gain consumers' trust, the first step to success should involve the significance of professional ethics, in addition to knowledge. In these circumstances, a pricing strategy that focuses on establishing inclusive values for customers may strengthen a company's competitive position and position it at the forefront of strategic connections with energy-using companies. Also, Access to specialists created problems such as prolonging the research process.

6.1. 1- Suggestions for Future Research. Although the model of this research is designed for the energy industry; considering the basic similarities between energy industries such as petrochemicals and refineries, its generalizability can also be examined. It also seems necessary to conduct data-driven research to model the competitive supply chain in NGOs and medium knowledge-based companies.

The topological index is a molecular predictor that is commonly supported in the research of QSAR of pharmaceuticals to numerically quantify their molecular features. Theoretical and statistical study of drug-like compounds improves the drug design and finding work-flow by rationalizing lead detection, instant decision, and mechanism of action comprehension. Using molecular structure characterization and edge segmentation technique, we computed the general temperature topological indices for OTIS networks.

1. Introduction

Mathematical chemistry may be a theoretic science in which artificial structures square measure by the employment of scientific instruments. The artificial diagram hypothesis maybe a part of this field where chart hypothesis devices square measure applied to scientifically demonstrate concoctions. As the graph has vertices that can be pictured by processor nodes and edges represent links between these nodes/processors [1]. The primary application in chemistry was the boiling purpose of the paraffin [1–3].

Topological indices are numerical values that are attributed to a molecular structure. Today, topological indices have been considered by many researchers because they have applications in various sciences, see [4–8].

Aslam et al. [9], obtained new results for OTIS networks by using some of the topological indices. Zahra et al. [3], discussed the swapped networks by using topological indices. In [10], the authors computed some of the topological indices for OTIS networks. Baig et al. [11] discussed some of the DOX and DSL networks by using the topological indices. In [6], the authors obtained some of the new results for anticancer drugs by using the multiplicative topological indices. In [12], the author discussed carbon nanocones and nanotori by using some of the topological indices. Therefore, in this paper, we obtain new results for OTIS networks by using some topological indices.

For a simple graph \mathcal{G} , we denoted the vertex set by $V(\mathcal{G}) = \{x_1, x_2, x_3, \ldots, x_n\}$ and the edge set by $\xi(\mathcal{G}), |\xi(\mathcal{G})| = \varepsilon$. The degree of the vertex $x \in V(\mathcal{G})$ is denoted by ζ_x .

For any graphs \mathcal{G} with *n* vertices, the temperature of a vertex *x* is defined in [13] as

$$\psi(x) = \frac{\zeta_x}{n - \zeta_x}.$$
 (1)

Kulli in [14] defined the following topological indices as

The general first temperature index

$$\psi_1^{\omega}(\mathcal{G}) = \sum_{xy \in \xi(\mathcal{G})} \left(\psi(x) + \psi(y) \right)^{\omega}.$$
 (2)

The general second temperature index

$$\psi_2^{\omega}(\mathcal{G}) = \sum_{xy \in \xi(\mathcal{G})} (\psi(x) \times \psi(y))^{\omega}.$$
 (3)

The general temperature index

$$\psi_{\omega}(\mathscr{G}) = \sum_{xy\in\xi(\mathscr{G})} (\psi(x)^{\omega} + \psi(y)^{\omega}), \tag{4}$$

where $\omega \in R$.

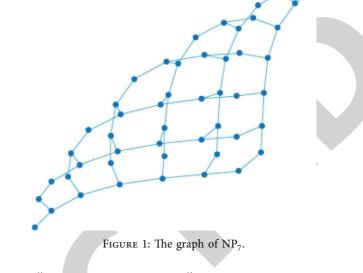

2. Results for NP_n Network

In this section, we compute the exact formulas for the OTIS networks NP_n of some general temperature indices, and we also examine the relationships between these topologies with graphical diagrams.

Let P_n be the path of *n* vertices and NP_n be OTIS (swapped) network with basis network P_n , see Figure 1.

We start by computing the general first temperature index.

Theorem 1. For NP_n network, we have

$$\psi_{1}^{\omega}(NP_{n}) = 2\left(\frac{1}{n^{2}-1} + \frac{3}{n^{2}-3}\right)^{\omega} + 3\left(\frac{4}{n^{2}-2}\right)^{\omega} + (6n-14)\left(\frac{2}{n^{2}-2} + \frac{3}{n^{2}-3}\right)^{\omega} + \left(\frac{3(n-2)(n-3)}{2}\right)\left(\frac{6}{n^{2}-3}\right)^{\omega}.$$
(5)

Proof. The OTIS networks NP_n have n^2 vertices and $3(n^2 - n)/2$, edges. Hence, there are three partitions, $V_{\{1\}} = \{y \in V(\text{NP}_n) | \zeta_y = 1\}, V_{\{2\}} = \{y \in V(\text{NP}_n) | \zeta_y = 2\}$ and $V_{\{3\}} = \{y \in V(\text{NP}_n) | \zeta_y = 3\}$. Hence, we can write that

$$\xi_1 = \left\{ \varepsilon = xy \in \xi(\operatorname{NP}_n) | \zeta_x = 1 \text{ and } \zeta_y = 3 \right\}, \tag{6}$$

$$\xi_2 = \left\{ \varepsilon = xy \in \xi(\operatorname{NP}_n) | \zeta_x = 2 \text{ and } \zeta_y = 2 \right\},$$
(7)

$$\xi_3 = \left\{ \varepsilon = xy \in \xi(\operatorname{NP}_n) | \zeta_x = 2 \text{ and } \zeta_y = 3 \right\},$$
(8)

$$\xi_4 = \left\{ \varepsilon = xy \in \xi(\operatorname{NP}_n) | \zeta_x = 3 \text{ and } \zeta_y = 3 \right\}.$$
(9)

It can be easily seen that $|\xi_1| = 2$, $|\xi_2| = 3$, $|\xi_3| = 6n - 14$ and $|\xi_4| = 3(n-2)(n-3)/2$.

By applying the definitions and Equalities (6)–(9), we can write

$$\psi_{1}^{\omega}(\mathrm{NP}_{n}) = \sum_{xy\in\xi(\mathrm{NP}_{n})} (\psi(x) + \psi(y))^{\omega} + \sum_{xy\in\xi_{2}(\mathrm{NP}_{n})} (\psi(x) + \psi(y))^{\omega} + \sum_{xy\in\xi_{3}(\mathrm{NP}_{n})} (\psi(x) + \psi(y))^{\omega} + \sum_{xy\in\xi_{4}(\mathrm{NP}_{n})} (\psi(x) + \psi(y))^{\omega} + \sum_{xy\in\xi_{4}(\mathrm{NP}_{n})} (\psi(x) + \psi(y))^{\omega} + 2\sum_{xy\in\xi_{4}(\mathrm{NP}_{n})} (\psi(x) + 2\sum_{xy\in\xi_{4}(\mathrm{NP$$

Now, we compute the general second temperature index.

 $\psi_{2}^{\omega}(\mathrm{NP}_{n}) = 2\left(\frac{3}{(n^{2}-1)(n^{2}-3)}\right)^{\omega} + 3\left(\frac{4}{(n^{2}-2)^{2}}\right)^{\omega} + (6n-14)\left(\frac{6}{(n^{2}-2)(n^{2}-3)}\right)^{\omega}$ (11)

$$+\left(\frac{3(n-2)(n-3)}{2}\right)\left(\frac{9}{(n^2-3)^2}\right)^{\omega}.$$

Theorem 2. For NP_n network, we have

Journal of Mathematics

Proof. By applying the definitions and equalities (6)–(9), we have

$$\begin{split} \psi_{2}^{\omega}(\mathrm{NP}_{n}) &= \sum_{xy\in\xi(\mathrm{NP}_{n})} (\psi(x)\times\psi(y))^{\omega} \\ &= \sum_{xy\in\xi_{1}(\mathrm{NP}_{n})} (\psi(x)\times\psi(y))^{\omega} + \sum_{xy\in\xi_{2}(\mathrm{NP}_{n})} (\psi(x)\times\psi(y))^{\omega} + \sum_{xy\in\xi_{3}(\mathrm{NP}_{n})} (\psi(x)\times\psi(y))^{\omega} + \sum_{xy\in\xi_{4}(\mathrm{NP}_{n})} (\psi(x)\times\psi(y))^{\omega} \\ &= 2\Big(\frac{1}{n^{2}-1}\times\frac{3}{n^{2}-3}\Big)^{\omega} + 3\Big(\frac{2}{n^{2}-2}\times\frac{2}{n^{2}-2}\Big)^{\omega} + (6n-14)\Big(\frac{2}{n^{2}-2}\times\frac{3}{n^{2}-3}\Big)^{\omega} + \Big(\frac{3(n-2)(n-3)}{2}\Big)\Big(\frac{3}{n^{2}-3}\times\frac{3}{n^{2}-3}\Big)^{\omega} \\ &= 2\Big(\frac{3}{(n^{2}-1)(n^{2}-3)}\Big)^{\omega} + 3\Big(\frac{4}{(n^{2}-2)^{2}}\Big)^{\omega} + (6n-14)\Big(\frac{6}{(n^{2}-2)(n^{2}-3)}\Big)^{\omega} + \Big(\frac{3(n-2)(n-3)}{2}\Big)\Big(\frac{9}{(n^{2}-3)^{2}}\Big)^{\omega}. \end{split}$$

$$(12)$$

Here, we compute the general temperature index.

Proof. By applying the definitions and Equalities (6)–(9), we can write

Theorem 3. For NP_n network, we have

$$\psi_{\omega}(\mathrm{NP}_{n}) = 3n^{2} \left(\frac{3}{n^{2}-3}\right)^{\omega} + 6n \left(\frac{2}{n^{2}-2}\right)^{\omega} - 9n \left(\frac{3}{n^{2}-3}\right)^{\omega} + 2\left(\frac{1}{n^{2}-1}\right)^{\omega} + 6\left(\frac{3}{n^{2}-3}\right)^{\omega} - 8\left(\frac{2}{n^{2}-2}\right)^{\omega}.$$
(13)

$$\psi_{\omega}(\mathrm{NP}_{n}) = \sum_{xy\in\xi(\mathrm{NP}_{n})} (\psi(x)^{\omega} + \psi(y)^{\omega})$$

$$= \sum_{xy\in\xi_{1}(\mathrm{NP}_{n})} (\psi(x)^{\omega} + \psi(y)^{\omega}) + \sum_{xy\in\xi_{2}(\mathrm{NP}_{n})} (\psi(x)^{\omega} + \psi(y)^{\omega}) + \sum_{xy\in\xi_{3}(\mathrm{NP}_{n})} (\psi(x)^{\omega} + \psi(y)^{\omega})$$

$$+ \sum_{xy\in\xi_{1}(\mathrm{NP}_{n})} (\psi(x)^{\omega} + \psi(y)^{\omega})$$

$$= 2\left(\left(\frac{1}{n^{2}-1}\right)^{\omega} + \left(\frac{3}{n^{2}-3}\right)^{\omega}\right) + 3\left(\left(\frac{2}{n^{2}-2}\right)^{\omega} + \left(\frac{2}{n^{2}-2}\right)^{\omega}\right) + (6n-14)\left(\left(\frac{2}{n^{2}-2}\right)^{\omega} + \left(\frac{3}{n^{2}-3}\right)^{\omega}\right)$$

$$+ \left(\frac{3(n-2)(n-3)}{2}\right)\left(\left(\frac{3}{n^{2}-3}\right)^{\omega} + \left(\frac{3}{n^{2}-3}\right)^{\omega}\right)$$

$$= 3n^{2}\left(\frac{3}{n^{2}-3}\right)^{\omega} + 6n\left(\frac{2}{n^{2}-2}\right)^{\omega} - 9n\left(\frac{3}{n^{2}-3}\right)^{\omega} + 2\left(\frac{1}{n^{2}-1}\right)^{\omega} + 6\left(\frac{3}{n^{2}-3}\right)^{\omega} - 8\left(\frac{2}{n^{2}-2}\right)^{\omega}.$$

 $z \neq x$, see Figure 2.

3. Results for NT_t Network

The OTIS (swapped) network NT_t is derived from the graph Y, which a graph with vertex set $V(NT_Y) = \langle z, x \rangle | z$, $x \in V(Y)$ and edge set $\xi(NT_Y) = \langle z, x_1 \rangle, \langle z, x_2 \rangle z \in V(Y)$,

In this section, we obtaining new results for the OTIS networks NT_t .

 $(x_1, x_2) \in \xi(\mathrm{NT}_{\Upsilon}) \cup (\langle z, x \rangle, \langle z, x, z \rangle) | z, x \in V(\Upsilon))$ and

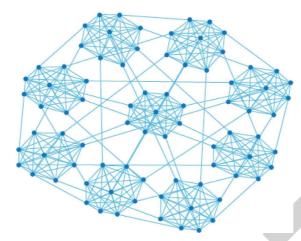

FIGURE 2: The graph NT₇.

Theorem 4. For NT_t network, we have

$$\psi_{1}^{\omega}(\mathrm{NT}_{t}) = nt \left(\frac{t}{(n+2)^{2}-t} + \frac{t+1}{(n+2)^{2}-t-1}\right)^{\omega} + \frac{2^{\omega-1}(t+1)^{\omega} \left(n^{2}(t+1) - n(2t+1)\right)}{\left((n+2)^{2}-t-1\right)^{\omega}}.$$
(15)

Proof. The NT_t has $(n + 2)^2$ vertices and $n^3/2 + 3n^2 + 11n/2 + 3$ edges. Hence, there are two partitions, $V_{\{1\}} =$

 $\begin{cases} y \in V(\mathrm{NT}_t) | \zeta_y = t \end{cases} \ \text{and} \ V_{\{2\}} = \Big\{ y \in V(\mathrm{NP}_n) | \zeta_y = t + 1 \Big\}. \\ \text{Hence, we have the following equalities:} \end{cases}$

$$\xi_1 = \left\{ \varepsilon = xy \in \xi(\mathrm{NT}_t) | \zeta_x = t \text{ and } \zeta_y = t+1 \right\}, \tag{16}$$

$$\xi_2 = \left\{ \varepsilon = xy \in \xi(\mathrm{NT}_t) | \zeta_x = t + 1 \text{ and } \zeta_y = t + 1 \right\}.$$
(17)

It can be easily seen that $|\xi_1| = nt$ and $|\xi_2| = n^2(t+1) - n(2t+1)/2$.

By applying the definitions and equalities (16) and (17), we can write

$$\psi_{1}^{\omega}(\mathrm{NT}_{t}) = \sum_{xy \in \xi(\mathrm{NT}_{t})} (\psi(x) + \psi(y))^{\omega} + \sum_{xy \in \xi_{2}(\mathrm{NT}_{t})} (\psi(x) + \psi(y))^{\omega} \\ = nt \left(\frac{t}{(n+2)^{2}-t} + \frac{t+1}{(n+2)^{2}-t-1} \right)^{\omega} + \left(\frac{n^{2}(t+1)-n(2t+1)}{2} \right) \left(\frac{t+1}{(n+2)^{2}-t-1} + \frac{t+1}{(n+2)^{2}-t-1} \right)^{\omega}$$
(18)
$$= nt \left(\frac{t}{(n+2)^{2}-t} + \frac{t+1}{(n+2)^{2}-t-1} \right)^{\omega} + \left(\frac{n^{2}(t+1)-n(2t+1)}{2} \right) \left(\frac{2(t+1)}{(n+2)^{2}-t-1} \right)^{\omega} \\ = nt \left(\frac{t}{(n+2)^{2}-t} + \frac{t+1}{(n+2)^{2}-t-1} \right)^{\omega} + \frac{2^{\omega-1}(t+1)^{\omega} (n^{2}(t+1)-n(2t+1))}{((n+2)^{2}-t-1)^{\omega}}.$$

Theorem 5. For NT_t network, we have

$$\psi_{2}^{\omega}(\mathrm{NT}_{t}) = nt \left(\frac{t(t+1)}{\left((n+2)^{2}-t\right)\left((n+2)^{2}-t-1\right)}\right)^{\omega} + \left(\frac{n^{2}(t+1)-n(2t+1)}{2}\right) \left(\frac{t+1}{(n+2)^{2}-t-1}\right)^{2\omega}.$$
(19)

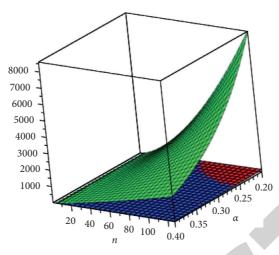

FIGURE 3: Comparison of $\psi_1^{\omega}, \psi_2^{\omega}$, and ψ_{ω} for NP_n.

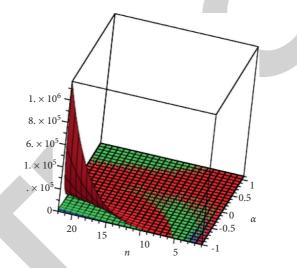

FIGURE 4: Comparison of $\psi_1^{\omega}, \psi_2^{\omega}$ and ψ_{ω} for NT_t.

Proof. By applying the definitions and equalities (16) and (17), we have

$$\psi_{2}^{\omega}(\mathrm{NT}_{t}) = \sum_{xy \in \xi_{1}(\mathrm{NT}_{t})} (\psi(x) \times \psi(y))^{\omega} + \sum_{xy \in \xi_{2}(\mathrm{NT}_{t})} (\psi(x) \times \psi(y))^{\omega} + \sum_{xy \in \xi_{2}(\mathrm{NT}_{t})} (\psi(x) \times \psi(y))^{\omega} = nt \left(\frac{t}{(n+2)^{2}-t} \times \frac{t+1}{(n+2)^{2}-t-1}\right)^{\omega} + \left(\frac{n^{2}(t+1)-n(2t+1)}{2}\right) \left(\frac{t+1}{(n+2)^{2}-t-1} \times \frac{t+1}{(n+2)^{2}-t-1}\right)^{\omega} = nt \left(\frac{t}{(n+2)^{2}-t} \times \frac{t+1}{(n+2)^{2}-t-1}\right)^{\omega} + \left(\frac{n^{2}(t+1)-n(2t+1)}{2}\right) \left(\frac{(t+1)^{2}}{((n+2)^{2}-t-1)^{2}}\right)^{\omega} = nt \left(\frac{t(t+1)}{((n+2)^{2}-t)((n+2)^{2}-t-1)}\right)^{\omega} + \left(\frac{n^{2}(t+1)-n(2t+1)}{2}\right) \left(\frac{t+1}{(n+2)^{2}-t-1}\right)^{2\omega}.$$

Theorem 6. For NT_t network, we have

$$\psi_{\omega}(\mathrm{NT}_{t}) = nt \left(\left(\frac{t}{(n+2)^{2}-t} \right)^{\omega} + \left(\frac{t+1}{(n+2)^{2}-t-1} \right)^{\omega} \right) + \left(n^{2} \left(t+1 \right) - n \left(2t+1 \right) \right) \left(\frac{t+1}{(n+2)^{2}-t-1} \right)^{\omega}.$$
(21)

Proof. By applying the definitions and equalities (16) and (17), we can write

$$\begin{split} \psi_{\omega}(\mathrm{NT}_{t}) &= \sum_{xy \in \xi(\mathrm{NT}_{t})} \left(\psi(x)^{\omega} + \psi(y)^{\omega} \right) \\ &= \sum_{xy \in \xi_{1}(\mathrm{NT}_{t})} \left(\psi(x)^{\omega} + \psi(y)^{\omega} \right) + \sum_{xy \in \xi_{2}(\mathrm{NT}_{t})} \left(\psi(x)^{\omega} + \psi(y)^{\omega} \right) \\ &= nt \left(\left(\frac{t}{(n+2)^{2} - t} \right)^{\omega} + \left(\frac{t+1}{(n+2)^{2} - t-1} \right)^{\omega} \right) + \left(\frac{n^{2}(t+1) - n(2t+1)}{2} \right) \left(\left(\frac{t+1}{(n+2)^{2} - t-1} \right)^{\omega} + \left(\frac{t+1}{(n+2)^{2} - t-1} \right)^{\omega} \right) \\ &= nt \left(\left(\frac{t}{(n+2)^{2} - t} \right)^{\omega} + \left(\frac{t+1}{(n+2)^{2} - t-1} \right)^{\omega} \right) + \left(n^{2}(t+1) - n(2t+1) \right) \left(\frac{t+1}{(n+2)^{2} - t-1} \right)^{\omega} \right) \end{split}$$
(22)

4. Graphical Representation and Discussion

In this paper, we discussed physical properties of some OTIS networks in terms of topological indices. The study of graphs and networks through topological descriptors area unit necessary to grasp their underlying topologies. Hence, in this paper, we computed general topological temperature indices. The graphical representations of general temperature indices of NP_n and NT_t area unit are represented in Figures 3 and 4.

5. Conclusion

In medical science, chemical, medical, biological, and pharmaceutical properties of molecular structure are essential for drug design. These properties can be studied by the topological index calculation. Hence, we have computed general topological indices of some OTIS networks such as NP_n networks and NT_t networks. We obtained the closed formulas of the general first and second temperature indices and the general temperature index for these networks. Our results can help to guess the many physical and chemical properties of networks.

Topological indices are graph invariants that are used to correlate the physicochemical properties of a chemical compound with its (molecular) graph. In this study, we study certain degree-based topological indices such as Randić index, Zagreb indices, multiplicative Zagreb indices, Narumi-Katayama index, atom-bond connectivity index, augmented Zagreb index, geometricarithmetic index, harmonic index, and sum-connectivity index for the bistar graphs and the corona product $K_m o K'_n$, where K'_n represents the complement of complete graph K_n .

1. Introduction

Graph theory techniques [1-4] have applications in chemistry, biology, physics, and computer science. Topological indices are graph invariants that are used to study graph topology. Along with computer networks, graph theory is a powerful tool in other research areas such as coding theory, database management systems, circuit design, secret-sharing schemes, and theoretical chemistry. Cheminformatics is the combination of technology, graph theory, and chemistry. It links organic substances structure and physiochemical properties by using some useful graph invariants and their associated molecular graph. A molecular graph contains sets of points and lines which shows the atoms and covalent bond in the molecule. These points and lines are known as vertices and edges in graph theory, respectively [5]. Theoretical study of underlying chemical structure using useful graph invariants is an appealing area of research in mathematical chemistry due to its practical applications in QSAR/QSPR investigation [6]. Topological indices are used to estimate the physicochemical properties of the chemical compounds. A topological index can be considered as a function that maps a graph to a nonnegative real number [7].

Some degree-based topological indices are Randić index, Zagreb indices, Narumi–Katayama and multiplicative Zagreb indices, atom-bond connectivity index, augmented Zagreb index, geometric-arithmetic index, harmonic index, and sum-connectivity index [8].

Throughout this work, we use standard notations G = (V, E) for graph, V(G) set of vertices, E(G) set of edges, and $d_w(G)$ degree of vertex w in G.

For any simple graph G = (V, E), $w \sim x$ denotes the adjacent vertices w and x in graph G.

Definition 1. Randić index is the most popular topological index among all topological indices and is defined as [9]

Journal of Mathematics

$$R(G) = \sum_{w \sim x} \frac{1}{\sqrt{d_w(G)d_x(G)}}.$$
(1)

Definition 2. The first Zagreb index of a graph G is defined as

$$M_1(G) = \sum_{w \in V(G)} d_w(G)^2.$$
 (2)

The second Zagreb index of a graph G is defined as

$$M_2(G) = \sum_{w \sim x} d_w(G) d_x(G).$$
(3)

The first and second Zagreb index are known as Zagreb indices [10].

Definition 3. The first multiplicative Zagreb index of a graph *G* is defined as

$$\prod_{1} (G) = \prod_{w \in V(G)} d_w(G)^2, \tag{4}$$

with product going overall vertices of a graph G.

The second multiplicative Zagreb index of a graph G is defined as

$$\prod_{2} (G) = \prod_{w \sim x} d_w(G) d_x(G).$$
(5)

The modified first multiplicative Zagreb index of a graph *G* is defined as

$$\prod_{1}^{*} (G) = \prod_{w \sim x} [d_w(G) + d_x(G)].$$
(6)

The first, second, and modified first multiplicative Zagreb indices are known as Narumi-Katayama indices [8, 11].

Definition 4. The atom-bond connectivity index of a graph *G* is defined as [12]

$$ABC(G) = \sum_{w \sim x} \sqrt{\frac{d_w(G) + d_x(G) - 2}{d_w(G)d_x(G)}}.$$
 (7)

Definition 5. The augmented Zagreb index of a graph G is defined as [13]

$$AZI(G) = \sum_{w \sim x} \left[\frac{d_w(G)d_x(G)}{d_w(G) + d_x(G) - 2} \right]^3.$$
 (8)

Definition 6. The geometric-arithmetic index of a graph *G* is defined as [14]

$$GA(G) = \sum_{w \sim x} 2 \left[\frac{\sqrt{d_w(G)d_x(G)}}{d_w(G) + d_x(G)} \right].$$
 (9)

Definition 7. The harmonic index of a graph *G* is defined as [15, 16]

$$H(G) = \sum_{w \sim x} \frac{2}{d_w(G) + d_x(G)}.$$
 (10)

Definition 8. The sum-connectivity index of a graph G is defined as [17, 18]

$$SCI(G) = \sum_{w \sim x} \frac{1}{\sqrt{d_w(G) + d_x(G)}}.$$
 (11)

Randić index was introduced by Milan Randić in 1975 [19]. After that, mathematicians did not pay attention to this index for nearly two decades. However, Pal, Erdos, and Bela Bollobas soon worked on this index and discovered the useful mathematics hidden within it. They published their first paper on this index in 1998. When the mathematical communities realized the value of the Randić index, they started to do research studies and soon a flood of publications on this descriptor were started. Randić also wrote two articles on this descriptor [8].

The work on Randić index encouraged theoretical chemists and mathematicians to discover other topological indices that depend on vertex degree.

During the study of total pi electron energy on molecular structure, some expressions which included the terms of the form

$$M_{1}(G) = \sum_{w} d_{w}(G)^{2},$$

$$M_{2}(G) = \sum_{w \sim x} d_{w}(G)d_{v}(G),$$
(12)

were occurred [8]. In the chemical theory, M_1 and M_2 are called first Zagreb index and second Zagreb index. These two indices were discovered by Trinajestic and Gutman in 1972 [8, 10]. At first, the first Zagreb index was also known as the Gutman index, but Balaban et al. did not want to introduce these descriptors by the names of the discoverers. So, they included M_1 and M_2 in the topological indices after 1982 and named them Zagreb group indices. However, soon, the name Zagreb group indices was changed to Zagreb indices. The second Zagreb index did not get any attention of mathematicians or mathematical chemists and that is why not a single property of M_2 was introduced in [8]. Narumi-Katayama [8] introduced the first product descriptor in 1984 and named it simple topological index. This index is defined as

$$NK(G) = \prod_{w \in V(G)} d_w(G).$$
(13)

This product index was later renamed the Narumi-Katayama index by Tomovic and Gutman. In 2010, Todeshine et al. proposed multiplicative versions of multiplicative Zagreb indices. These two graph invariants are known as the first and second multiplicative Zagreb indices, after Gutman. Eliasi et al. and Iranmanesh and Gutman proposed a multiplicative version of the first Zagreb index. The authors termed it as modified multiplicative Zagreb index, respectively [20]. The first geometric-arithmetic index also known as geometric-arithmetic index is the modified version of the Randić index. This index was proposed by Vukicevic and Furtula in 2009 [6, 8].

The atom-bond connectivity index is another topological index that is similar to the Randić index. This topological descriptor was introduced by Estrada et al. in 1998 [6, 13]. A recent study of this index has caught the attention of some researchers. Furtula et al. [8] introduced the augmented Zagreb index in 2009, a modified version of the atom-bond connectivity index. This descriptor has higher predictive power than the atom-bond connectivity index. Tosovic and Gutman investigated in 2013 that AZI produced nice effects in the formation of heat and also yielded the best results in boiling factors of octane isomers. Furtula et al. investigated the structure sensitivity of twelve topological indices using trees and found that the AZI has the best structure sensitivity [13].

In 1980, Siemion Fajtlowiez introduced another topological index. In 2012, Zhang worked on this index and named it as harmonic index [8]. In sharp construct to other topological indices, no chemical applications of this index were found, but in mathematical chemistry, such research studies are expected very much [8]. In the last few years, this index has attracted the great attention of theoreticians [15, 16].

Bo Zhou and Nenad Trinajstic discovered that the term $d_w d_x$ in the Randić index can be replaced by $d_w + d_x$ and named it sum-connectivity index [8]. This index got the attention of both applied and pure researchers. Some recent work on this index can be found in [21].

There are a number of studies of various topological indices of graphs establishing formulas for computing the indices and also providing upper and lower bounds on the values of such indices. In this study, certain vertex degreebased topological indices are studied. We have determined and computed the closed formulas of these indices for two special families of graphs of diameter three. A graph formed by joining the centers of two-star graphs of order *m* and *n*, i.e., $K_{1,m}$ and $K_{1,n}$ by an edge, is called the bistar graph and is denoted by B(n;m). The corona product $K_m o K'_n$ of two graphs is defined as the graph obtained by taking one copy of K_m of order *m* and *n* copies of K'_n and then joining each vertex of the i^{th} copy of K'_n to the i^{th} vertex of K_m . These graphs are undirected having no loops and multiple edges. These results are novel and significant contributions in graph theory and network science, and they provide a good basis to understand the topology of these graphs and networks (Figures 1 and 2).

2. Topological Indices of Families of Bistar Graphs, i.e., G = B(n; m)

By looking at the earlier results for computing the topological indices for families of bistar graphs, here we introduce new degree-based topological indices to compute their values for these families of graphs.

Theorem 1. The sum-connectivity index of families of bistar graphs B(n;m) is

3

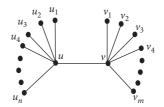

FIGURE 1: A representation of bistar graph *B*(*n*; *m*) of order *m* and *n*.

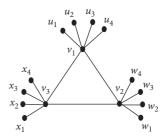

FIGURE 2: A representation of corona product $K_3^{\circ}K_4'$ of two graphs.

$$\frac{n}{\sqrt{n+2}} + \frac{1}{\sqrt{n+m+2}} + \frac{m}{\sqrt{m+2}}.$$
 (14)

Proof. To find the sum-connectivity index of B(n; m), firstly, we select a vertex u on B(n; m) of degree n + 1. There are n vertices u_1, u_2, \ldots, u_n of degree 1 which are adjacent to u. For the vertices u and u_i , where $i = 1, 2, 3, \ldots, n$, the sum is obtained as

$$\sum_{u \sim u_i} \frac{1}{\sqrt{d_u(G) + d_{u_i}(G)}} = \frac{n}{\sqrt{1 + (n+1)}}$$

$$= \frac{n}{\sqrt{n+2}}, \quad i = 1, 2, 3, \dots, n.$$
(15)

Since the degree of u is n + 1, the other vertex which is adjacent to u is v of degree m + 1. For the vertices u and v, we have

$$\frac{1}{\sqrt{d_u(G) + d_v(G)}} = \frac{1}{\sqrt{(n+1) + (m+1)}}$$

$$= \frac{1}{\sqrt{n+m+2}}.$$
(16)

Now, we select a vertex v of degree m + 1 on B(n; m); there are m vertices $v_1, v_2, v_3, \ldots, v_m$ of degree 1 which are adjacent to v. For the vertices v and v_j , the sum is obtained as

$$\sum_{\nu \sim \nu_j} \frac{1}{\sqrt{d_{\nu}(G) + d_{\nu_j(G)}}} = \frac{m}{\sqrt{1 + m + 1}}$$
$$= \frac{m}{\sqrt{m + 2}}, \quad j = 1, 2, 3, \dots, m.$$
(17)

Adding above equations, we have SCI(G) =sum-connectivity index of B(n; m):

$$\frac{n}{\sqrt{n+2}} + \frac{1}{\sqrt{n+m+2}} + \frac{m}{\sqrt{m+2}}.$$
 (18)

Theorem 2. The Zagreb indices of the families of bistar graphs B(n;m) are

$$M_1(G) = (n+1)^2 + (m+1)^2 + n + m,$$

$$M_2(G) = n(n+1) + (n+1)(m+1) + m(m+1).$$
(19)

Proof. To find the first Zagreb index $M_1(G)$ of B(n; m), we select a vertex u on B(n; m) of degree n + 1. For the vertex u, we have

$$\deg(u)^{2} = (n+1)^{2}.$$
 (20)

Since there are *n* vertices $u_1, u_2, u_3, \ldots, u_n$ of B(n; m) of degree 1 which are adjacent to *u*, thus, we have

$$\sum_{u_i} \deg(u_i)^2 = n, \quad i = 1, 2, 3, \dots, n.$$
(21)

As the degree of u is n + 1, the other vertex which is adjacent to u is v of degree m + 1. For the vertex v, we have

$$\deg(v)^{2} = (n+1)^{2}.$$
 (22)

Since the degree of v is m + 1, the other vertices which are adjacent to v are m in numbers of degree 1:

$$\sum_{v_j} \deg(v_j)^2 = m, \quad j = 1, 2, 3, \dots, m.$$
(23)

Adding equations (20) to (23), we have $M_1(G) =$ first Zagreb index of B(n; m):

$$M_1(G) = (n+1)^2 + (m+1)^2 + n + m.$$
(24)

Similarly, $M_2(G)$ = second Zagreb index of B(n; m) is

$$M_2(G) = n.(n+1) + (n+1)(m+1) + m(m+1).$$
 (25)

Theorem 3. The atom-bond connectivity index and augmented Zagreb index of families of bistar graphs B(n;m) are

$$n\sqrt{\frac{n}{n+1}} + \sqrt{\frac{n+m}{(n+1)(m+1)}} + m\sqrt{\frac{m}{m+1}},$$

$$n\left[\frac{n+1}{n}\right]^{3} + \left[\frac{(n+1)(m+1)}{n+m}\right]^{3} + m\left[\frac{m+1}{m}\right]^{3}.$$
(26)

The proof of this Theorem is the same as Theorem 1.

Theorem 4. The geometric-arithmetic index and harmonic index of families of bistar graphs B(n;m) are

$$\frac{2n\sqrt{n+1}}{n+2} + \frac{2\sqrt{(n+1)(m+1)}}{n+m+2} + \frac{2m\sqrt{m+1}}{m+2},$$

$$\frac{2n}{n+2} + \frac{2}{n+m+2} + \frac{2m}{m+2}.$$
(27)

The proof of this theorem is the same as Theorem 1.

Theorem 5. The Narumi–Katayama and multiplicative Zagreb indices of families of bistar graphs B(n;m) are

$$\prod_{1}^{n} (G) = (n+1)^{2} (m+1)^{2},$$

$$\prod_{2}^{n} (G) = (n+1)^{n+1} (m+1)^{m+1},$$

$$\prod_{1}^{*} (G) = (n+2)^{n} (n+m+2) (m+2)^{m}.$$
(28)

Proof. To find the first multiplicative Zagreb index of B(n; m), we select a vertex u on B(n; m) of degree n + 1. For the vertex u, we have

$$\deg(u)^{2} = (n+1)^{2}.$$
 (29)

Since there are *n* vertices $u_1, u_2, u_3, \ldots, u_n$ of B(n; m) of degree 1, thus, we have

$$\prod_{u_i} \deg(u_i)^2 = \deg(u_1)^2 \deg(u_2)^2, \dots, \deg(u_n)^2 = 1.$$
(30)

Similarly, for the vertex v, we have

$$\deg(v)^{2} = (m+1)^{2}.$$
 (31)

Also, for the vertices $v_1, v_2, v_3, \ldots, v_m$ of B(n; m) of degree 1, we have

$$\prod_{\nu_j} \deg(\nu_j)^2 = \deg(\nu_1)^2 \deg(\nu_2)^2, \dots, \deg(\nu_m)^2 = 1.$$
(32)

Multiplying equations (29) to (32), we have $\prod_1 (G) =$ first multiplicative Zagreb index of families of bistar graphs B(n;m):

$$\prod_{1} (G) = (n+1)^{2} (m+1)^{2}.$$
 (33)

Similarly, second multiplicative Zagreb index and modified first multiplicative Zagreb index of families of bistar graphs are

$$\prod_{2} (G) = (n+1)^{n+1} (m+1)^{m+1},$$

$$\prod_{1}^{*} (G) = (n+2)^{n} (n+m+2) (m+2)^{m}.$$
(34)

Example 1. Topological indices of bistar graph B(5; 6) are shown in Table 1.

Journal of Mathematics

$\prod_1 (G)$		1764

3. Topological Indices of Families of Corona Product of Graphs, i.e., $G = K_m \circ \mathbf{K'_n}$

Based on previous results for computing topological indices for families of corona product of graphs, we present new degree-based topological indices to compute their values for these families of graphs.

Theorem 6. The Randić index and sum-connectivity index of families of corona product of graphs $K_m \circ K'_n$ are

$$R(G) = \frac{mn}{\sqrt{m+n-1}} + \frac{m(m-1)}{2(m+n-1)},$$
(35)

$$SCI(G) = \frac{mn}{\sqrt{m+n}} + \frac{m(m-1)}{2\sqrt{2(m+n-1)}}.$$

Proof. To find the Randić index of the family of graphs $K_m \circ K'_n$ obtained by taking the corona product of complete graph K_m of order m and the complement of K_n of order n, firstly, we select a vertex v_1 on $K_m \circ K'_n$ as v_1 is adjacent to m-1 vertices $v_2, v_3, v_4, \ldots, v_m$ and n vertices $u_1, u_2, u_3, \ldots, u_n$. Therefore, the degree of v_1 is m + n - 1.

For the vertices v_1 and u_i , where i = 1, 2, 3, ..., n, the sum is obtained as

$$\sum_{\nu_1 \sim u_i} \frac{1}{\sqrt{\deg_{\nu_1}(G)\deg_{u_i}(G)}} = \frac{n}{\sqrt{m+n-1}}.$$
 (36)

As the graph is symmetric, the same result is obtained for the remaining (m - 1) vertices v_2, v_3, \ldots, v_m . So, combining all the vertices $v_1, v_2, v_3, \ldots, v_m$ equation (36) becomes

$$\sum_{v_{1} \sim u_{i}} \frac{1}{\sqrt{\deg_{v_{1}}(G)\deg_{u_{i}(G)}}} + \sum_{v_{2} \sim w_{i}} \frac{1}{\sqrt{\deg_{v_{2}}(G)\deg_{w_{i}(G)}}} + \dots + \sum_{v_{m} \sim x_{i}} \frac{1}{\sqrt{\deg_{v_{m}}(G)\deg_{x_{i}(G)}}}$$
(37)
$$= \frac{mn}{\sqrt{(m+n-1)}} m \text{ times.}$$

Since v_1 is also adjacent to m-1 vertices $v_2, v_3, v_4, \ldots, v_m$ of degree m + n - 1, for the vertices v_1 and v_j , where $j = 2, 3, 4, \ldots, m$, the sum is obtained as

$$\sum_{\nu_1 \sim \nu_j} \frac{1}{\sqrt{d_{\nu_1}(G)d_{\nu_j}(G)}} = \frac{m-1}{m+n-1}.$$
 (38)

Since K_m is symmetric, the same result is obtained for remaining m - 1 vertices v_2, v_3, \ldots, v_m . Combining the result for all m vertices $v_1, v_2, v_3, \ldots, v_m$, we have

$$= \frac{m-1}{m+n-1} + \frac{m-2}{m+n-1} + \frac{m-3}{m+n-1} + \dots + \frac{m-(m-1)}{m+n-1}$$

$$= \frac{1}{m+n-1} [(m-1) + (m-2) + (m-3) + \dots + (m-(m-1))]$$

$$= \frac{1}{m+n-1} [(m+m+m+,\dots,+m)(m-1) \text{ times} - (1+2+3+,\dots,+m-1)]$$

$$= \frac{1}{m+n-1} \left[m(m-1) - \frac{(m-1)(m-1+1)}{2} \right]$$

$$= \frac{1}{m+n-1} \left[m(m-1) - \frac{m(m-1)}{2} \right]$$

$$= \frac{1}{m+n-1} \left[m(m-1) - \frac{m(m-1)}{2} \right].$$
(39)

Adding equations (37) and (39), we have R(G) = Randićindex of $K_m \circ K'_n$:

$$R(G) = \frac{mn}{\sqrt{m+n-1}} + \frac{m(m-1)}{2(m+n-1)}.$$
 (40)

Similarly, SCI(G) = sum-connectivity index of $K_m \circ K'_n$ is

$$SCI(G) = \frac{mn}{\sqrt{m+n}} + \frac{m(m-1)}{2\sqrt{2(m+n-1)}}.$$
 (41)

Theorem 7. The atom-bond connectivity index and augmented Zagreb index of families of corona product of graphs $K_m \circ K'_n$ are

$$ABC(G) = mn \sqrt{\frac{m+n-2}{m+n-1}} + \frac{m(m-1)}{2(m+n-1)} \sqrt{2m+2n-4},$$

$$AZI(G) = mn \left(\frac{m+n-1}{m+n-2}\right)^{3} + \frac{m(m-1)(m+n-1)^{6}}{2(2m+2n-4)^{3}}.$$
(42)

The proof of this theorem is the same as Theorem 6.

Theorem 8. The geometric-arithmetic index and harmonic index of families of corona product of graphs $K_m \circ K'_n$ are

Journal of Mathematics

(47)

$$GA(G) = \frac{2mn\sqrt{m+n-1}}{m+n} + \frac{m(m-1)(m+n-1)}{2m+2n-2},$$

$$H(G) = \frac{2mn}{m+n} + \frac{m(m-1)}{2m+2n-2}.$$
(43)

The proof of this theorem is the same as Theorem 6.

Theorem 9. The Zagreb indices of families of corona product of graphs $K_m \circ K'_n$ are

$$M_1(G) = mn + m(m + n - 1)^2,$$

$$M_2(G) = mn(m + n - 1) + \frac{m(m - 1)(m + n - 1)^2}{2}.$$
(44)

Proof. For the families of corona product of graphs there are *mn* vertices of degree one and *m* vertices $v_1, v_2, v_3, \ldots, v_m$ of degree m + n - 1, respectively. For the vertices $u_1, u_2, u_3, \ldots, u_n$, we have

$$\sum_{u_i} \deg(u_i)^2 = \deg(u_1)^2 + \deg(u_2)^2 + \dots + \deg(u_n)^2, \quad i = 1, 2, 3, \dots, n$$

$$= (1)^2 + (1)^2, \dots, + (1)^2 n \text{ times} = n.$$
(45)

Since there are *mn* vertices of degree 1, combining the above result for all *mn* vertices, thus, the above equation becomes

$$= n + n + n + \dots + n m \text{ times} = mn.$$
 (46)

Also, for the vertex v_1 , we have

Since the graph is symmetric, the same result is obtained for remaining (m-1) vertices v_2, v_3, \ldots, v_m :

 $\deg(v_1)^2 = (m + n - 1)^2.$

$$\sum_{v_j} \deg(v_j)^2 = \deg(v_1)^2 + \deg(v_2)^2 + \dots + \deg(v_m)^2, \quad j = 1, 2, 3, \dots, m$$

$$= (m+n-1)^2 + (m+n-1)^2 + \dots + (m+n-1)^2 m \text{ times}$$

$$= m(m+n-1)^2.$$
(48)

Adding equations (46) and (48), we have $M_1(G) =$ first Zagreb index of families of corona product of graphs $K_m {}^{\circ}K'_n$:

$$M_1(G) = mn + m(m+n-1)^2.$$
 (49)

Similarly, $M_2(G)$ = second Zagreb index of families of corona product of graphs $K_m^{\circ}K'_n$:

$$M_2(G) = mn(m+n-1) + \frac{m(m-1)(m+n-1)^2}{2}.$$
 (50)

Theorem 10. The Narumi–Katayma and multiplicative Zagreb indices of families of corona product of graphs $K_m \circ K'_n$ are

$$\prod_{1} (G) = (m + n - 1)^{2m},$$

$$\prod_{2} (G) = (m + n - 1)^{m^{2} - m + mn},$$

$$\prod_{1}^{*} (G) = (m + n)^{mn} (2m + 2n - 2)^{m^{2} - m/2}.$$
(51)

Proof. For the families of corona product of graphs, there are *mn* vertices of degree one and *m* vertices $v_1, v_2, v_3, \ldots, v_m$ of degree m + n - 1. For the vertices $u_1, u_2, u_3, \ldots, u_n$, we have

$$\prod_{u_i} \deg(u_i)^2 = \deg(u_1)^2 \deg(u_2)^2, \dots, \deg(u_n)^2, \quad i = 1, 2, 3, \dots, n$$

$$= (1)^2 (1)^2, \dots, (1)^2 n \text{ times} = (1)^n = 1.$$
(52)

Since there are *mn* vertices of degree 1, so the same result is obtained for all *mn* vertices. Thus, the above equation becomes

$$(1)^{mn} = 1.$$
 (53)

Also, for the vertex v_1 , we have

$$\deg(v_1)^2 = (m+n-1)^2.$$
(54)

Since the graph is symmetric the same result is obtained for remaining (m - 1) vertices v_2, v_3, \ldots, v_m . Thus equation (54) becomes

$\prod_{1} (G)$	6,871000000
H(G)	5.875
SCI(G)	9.750
R(G)	8.239
GA(G)	26.314
ABC(G)	23.853
$M_1(G)$	402

$$\prod_{v_j} \deg(v_j)^2 = \deg(v_1)^2 \deg(v_2)^2 \deg(v_3)^2, \dots, \deg(v_m)^2, \quad j = 1, 2, 3, \dots, m$$

$$= (m+n-1)^2 (m+n-1)^2 (m+n-1)^2, \dots, (m+n-1)^2 m \text{ times} = (m+n-1)^{2m}.$$
(55)

Multiplying equations (53) to (55), we have $\prod_1 (G) = \text{first}$ Zagreb index of families of corona product of graphs $K_m \circ K'_n$

$$\prod_{1} (G) = (1). (m+n-1)^{2m} = (m+n-1)^{2m}.$$
 (56)

Similarly, second multiplicative Zagreb index and modified first multiplicative Zagreb index of $K_m^{\circ} K_n^{\prime}$ are

$$\prod_{2}^{*} (G) = (m + n - 1)^{m^{2} - m + mn},$$

$$\prod_{1}^{*} (G) = (m + n)^{mn} (2m + 2n - 2)^{m^{2} - m/2}.$$

$$\Box$$

Example 2. Topological indices of corona product of graphs $K_6 \circ K'_3$ are shown in Table 2.

4. Concluding Remarks

There are several articles published on calculating topological indices for different families of graphs. Some have found applications, but others were devoted to the mathematical side to throw more light on the relationship between these concepts. This study introduces Randić index, Zagreb indices, Narumi-Katayama, and multiplicative Zagreb indices. We further discussed the atom-bond connectivity index, augmented Zagreb index, geometric-arithmetic index, harmonic index, and sum-connectivity index for two particular families of graphs for the first time. We have determined and computed the closed formulas of these families of graphs. We had checked that all vertex degree-based topological indices of families of bistar graphs and corona product of graphs remain the same for all values of m and n. We have also determined the values of some topological indices for B(5; 6) and $K_6^{\circ} K_3'$ graphs, as shown in Tables 1 and 2. This work will give new directions for considering and computing topological indices of several other families of graphs. In the future, we are interested in investigating and calculating some other topological indices of two more special families of graphs whose diameters are greater than three.

After entering the new century, along with the further deepening of global economic and trade cooperation, the industrial division of labor has been newly developed globally, which brings the cooperation among countries in the international logistics chain more and more closely. As the core node linking domestic and foreign water transportation, ports play a very key role in the international logistics chain and have an extremely central position in the national logistics planning. The coordinated development of port economy is an important part of the economic development planning of port cities, and it is also the premise and basis for the comprehensive planning of port logistics infrastructure construction scale, logistics space layout, and port city logistics development direction and function positioning. Therefore, according to the availability of realistic data, this paper establishes a deep neural network prediction model for the collaborative development of ports and uses various port logistics indicators to predict the economic development trend, so as to realize a nonlinear mapping relationship between the level of port economic development and the side of port logistics demand. Meanwhile, the research of this paper will provide theoretical basis and corresponding practical tools for the coordinated development between regional economy and port logistics industry.

1. Introduction

With the renewal of management concept and the deepening of the change of production and manufacturing mode, modern logistics industry is getting more and more attention in the world [1]. Especially after China's accession to WTO, foreign trade has been further enhanced and the prosperity of the market economy has accelerated the rapid development of its distribution industry, which has gradually developed into an important part of the national economy and an economic growth point. In coastal ports and some large central cities, the port economy has even leaped to become a local pillar industry, while a logistics boom has been set off nationwide [2].

The history of port development shows that the port has gradually changed from being a single transportation transit point to a modern logistics service center and it plays an increasingly important role in the economic development of the port city and the region radiated by the port [3]. As a key

node connecting the outside world in a country or region, ports naturally have the advantages of clusters in terms of geographical conditions. In recent years, theoretical research and practical development of port-related industrial clusters have made great progress [4]. The development of port-side industry economy brings great influence on the development of port logistics. At present, the more mature division of port-side industries divides port-side industries into portside core industries, port-side related industries, port-side hinterland industries, and port-side derived industries. The related industries are mainly the logistics creation, storage, processing, and transportation industries directly connected with the port, which is the port logistics industry [5]. There is a close relationship between the port logistics industry and the port economy. The cluster development of the port logistics industry provides a new power engine for the port economy, while the development of the port economy provides a solid foundation for the cluster development of the port logistics industry [6].

With the continuous progress of technology, especially the breakthrough of AI technology, deep learning has been widely used in various fields and industries, promoting industrial innovation and breakthrough development [7]. In the economic and financial fields, people are also increasingly aware of the importance of economic data to the industry, which is an important basis for policy makers and industry practitioners to effectively feel the changes in industrial and economic development. As the volume of economic data increases dramatically and the forms of data become more and more diverse, the approach of deep learning provides a new research idea of finding patterns in big data and learning the potential features behind the data through deep learning models [8]. Therefore, it is of great importance to apply deep learning to the industrial economy.

The purpose of this article is to adapt the port logistics supply to the needs of coordinating with the actual development of the regional economy of the port hinterland and to conduct a prediction study of the port logistics demand from the perspective of port cities' planning of port logistics combined with the economic development of the port. By analyzing the economic influencing factors of port logistics demand, the strong correlation between the level of port economic development and logistics demand is pointed out. According to the availability of realistic data, a deep neural network prediction model of port economic development trend is established to realize a nonlinear mapping relationship between the level of port economic development and port logistics demand. Meanwhile, it is also hoped that this paper can provide a new research direction and a reference for the development of port economy.

Furthermore, Section 2 of this paper proposes a comprehensive review of the related work and literature. It analyzes the port economy and its correlation with hinterland regional economy, drivers of economic growth in ports. This section also presents the steps for the economic development of the ports. In Section 2, the existing methods and the proposed methods are explained. It deeply discusses the RNN, GRU, and LSTM. Furthermore, it proposes the attentional model and a recurrent neural network model on the basis of dual attention mechanism and trend adjustment. Section 4 performs the experiments and analyzes the achieved results. The conclusion of the paper is given in Section 5.

2. Related Work

2.1. Port Economic Analysis. Port economic synergy development analysis refers to the process of correlating the logistics demand of the port and its hinterland with the socioeconomic activities of production and consumption demand [9]. As port logistics activities increasingly penetrate into the whole process of socioeconomic activities such as production, circulation, and consumption, they are closely related to the development of the social economy, especially the port hinterland, and are an important part of the socioeconomic activities of the port and the hinterland. Therefore, there is a close correlation between the synergistic development of port economy and socioeconomic development, and the socio-economic development of port cities and hinterland is the main factor affecting the economic activities of ports [10]. Port economic synergistic development analysis is to understand the demand intensity of port and hinterland socioeconomic activities for the supply of port logistics capacity with the help of qualitative and quantitative analysis tools and to carry out effective demand management. Guiding social investment into the service areas radiated by the port in a purposeful manner will be conducive to rational planning, construction of port logistics infrastructure, and improvement of the supply system of port logistics.

2.2. Analysis of the Correlation between Port Economy and Hinterland Regional Economy. There is an interactive relationship between the port economy and the economic development of the hinterland [11]. The prosperity of the hinterland promotes the demand for port logistics that relies on the hinterland. In turn, the development of the port logistics economy will also promote the development of the hinterland that depends on the port. The development of ports and hinterlands is interdependent and mutually reinforcing. The port not only provides transportation services for the hinterland, but more importantly, it has a strong radiation effect on the hinterland, and there seems to be a natural blood relationship between it and the hinterland region. The hinterland of the port can absorb and gather landward economic energy through the land transportation network, and it can more easily transcend the spatial boundaries of geography through the sea channel and directly participate in the international economic cycle in a large span, absorbing and gathering the factors of productivity in the world. Using the advantages of port transportation, we can vigorously develop import and export trade and processing trade, promote the integration of the hinterland and the world economy, drive the development of the hinterland economy, and make the development of the hinterland economy more vital. While the port promotes the economic development of the hinterland, the development of the hinterland also provides support and guarantee for the development of the port. The hinterland provides financial, trade, consolidation, and distribution services for the port. The development of the hinterland economy constantly makes changes in the types of goods in the port and also makes corresponding changes in the function strategy, service scope, production characteristics, and status role of the port.

2.3. Analysis of the Drivers of Economic Growth in Ports. The total economic volume of the port and hinterland, the regional industrial structure, and the spatial distribution of the port and hinterland economies have a huge impact on the port economy [12]. Port logistics demand is an important driving force for port economic development, and it can be said that the factors affecting port economic development also potentially affect the growth or reduction of port logistics demand [13]. There is an inherent and implicit mapping relationship between the economy and logistics demand. But, this relationship is not a simple linear relationship, because there are many economic factors and each factor may cause a certain degree of impact on logistics demand, so it is difficult

to use a simple and clear model to describe this relationship. However, this intrinsic determining and driving relationship between the regional economy and port logistics demand can be described abstractly by a mathematical expression, as shown in the following:

$$Y = Af(x_1, x_2, x_3, \dots, x_n)$$
(1)

where Y indicates the logistics demand, including logistics demand scale, logistics demand structure, logistics demand main body, etc. $x_1, x_2, x_3, \ldots, x_n$ represent a series of regional economic factors such as total regional economy, industrial structure status, regional economic spatial distribution, etc. From this functional relationship, we can see that the economic influence of port logistics is multifaceted and each economic factor may have an impact on all aspects of logistics demand, while the impact of each economic factor on the growth of logistics demand is not equally important and the focus of the impact on logistics demand is not the same, so this intricate internal linkage determines the multifaceted nonlinear complex mapping relationship between the economy and logistics demand.

2.4. Forecasting Steps for Port Economic Development

2.4.1. Determining the Purpose of Forecasting. Clearly defining the goal of forecasting is the premise of effective forecasting with a clear forecast objective to collect information in a targeted manner; otherwise, it is impossible to determine what to investigate, to whom to investigate, and not to mention how to make forecasts. At the same time, the forecast target is determined as detailed and quantitative as possible, which is conducive to the smooth development of forecasting work.

2.4.2. Analyzing the Factors Influencing the Market Demand of the Logistics System. The analysis of controllable and uncontrollable factors in the system is crucial. For different systems, controllable and uncontrollable factors are different. The same type of system has different controllable and uncontrollable factors depending on its geographical, social, and political environment, and often some factors are controllable in one system while it is uncontrollable in another system. Objective analysis of the main elements of the port logistics system and the main factors affecting market demand is the basis for forecasting.

2.4.3. Determining the Content of the Forecast. Forecasters must recognize the potential impact of different factors on logistics demand and be able to deal with them appropriately. For a particular project, significant components must be identified, analyzed, and combined with appropriate forecasting techniques. The information from the research should be analyzed statistically. The information is analyzed statistically to understand whether the information is complete. Then, the characteristics of the information and data are analyzed, and the sample data are corrected.

2.4.4. Establishing Mathematical Models for Forecasting. In the forecasting of economic systems, the use of quantitative forecasting methods is a necessary means to achieve objective and scientific forecasting. The establishment of forecasting models is not only related to historical data but also to the level of modeling of the forecaster. Both traditional forecasting methods and deep learning-based forecasting methods require a thorough understanding of forecasting theory and forecasting models. The nonlinear nature of the economic system often increases the difficulty of the mathematical model building work, and the determination of the fitting curve is difficult. To overcome the difficulties in building the model, a deep neural network forecasting model is used for forecasting in this paper and the model is modified accordingly.

2.4.5. Calculating the Results and Making Error Analysis Correction. Error analysis is an important part to ensure the prediction accuracy, and the error between the predicted value of the model and the value of the sample data is often used to measure whether the prediction model is good or bad in the prediction process. There are always errors in systematic forecasting, and the errors are caused by various reasons. Some are caused by the model itself, for example, the model always lags the actual value, so the forecast results should be added to the lag amount to make the forecast more accurate. Some errors are caused by changes in the external environment, so we should analyze the future economic and political situation in depth, analyze the future impact factors and give their quantitative values, and use the quantitative values to correct the model's prediction values.

3. Method

3.1. Existing Recurrent Neural Network Models

3.1.1. Recurrent Neural Networks (RNNs). For traditional neural networks, there is no temporal association between inputs, whereas for human thinking, economic forecasting, etc., temporal association is crucial.

But, traditional neural networks and machine learning methods are unable to do this, and recurrent neural networks solve this problem.

The full name of RNN is recurrent neural network [14], which allows information to be passed from one step of the network to the next step of the network, as shown in Figure 1. This chained structure has a natural advantage for data with certain temporal connections, and as you can see from the figure, the output of the current moment can be influenced by all previous moments. If imagined as a reading comprehension problem, this means that the understanding of this text when reading the current position is influenced by the previous fragments and this structure is able to represent this influence.

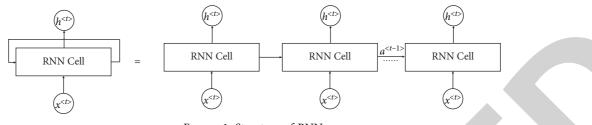

FIGURE 1: Structure of RNN.

Traditional neural networks have several obvious limitations [15]: one is that the input and output of traditional neural networks are too limited, requiring a fixed length of input and a fixed length of output. Second, these models use a fixed number of computational steps, such as the number of layers in traditional neural networks, and third, the learned knowledge of traditional neural networks is not shared. However, recurrent neural networks change this limitation by allowing us to operate on sequences of vectors, with variable-length sequences for both input and output, and a portion of the learned information can be quickly generalized to the entire network. The recurrent neural network scans the data from left to right and the parameters are shared at each time step. The forward propagation algorithm of the recurrent neural network is shown in equation (2). Forward propagation is done from left to right as shown in Figure 2:

$$a^{\langle t \rangle} = g_1 \Big(W_{aa} a^{\langle t-1 \rangle} + W_{ax} x^{\langle t \rangle} + b_a \Big),$$

$$h^{\langle t \rangle} = g_1 \Big(W_{ha} a^{\langle t \rangle} + b_h \Big).$$
(2)

Although recurrent neural networks have good performance for sequential models, there is a big problem with recurrent neural networks, which is the problem of gradient disappearance. To solve this problem, gated recurrent units that change the propagation structure inside the RNN are available.

3.1.2. Gated Circulation Unit (GRU). The purpose of GRU is to solve the problem of gradient disappearance and to allow the model to have long-time memory [16]. The internal structure of the simplified gated neural network is shown in Figure 3, and its formula is shown in equation (4). The GRU introduces a new variable *c*, which means memory cell, to provide the memory capability of the model. The core idea of the GRU is to have an update gate, and the output of the update gate has a value between 0 and 1 due to the use of the sigmoid activation function. But, its probability of being close to 0 or close to 1 is higher, so that Γ_u acts like a gate to decide whether the current input needs to be remembered or not.

$$\widetilde{c}^{\langle t \rangle} = \tanh \left(W_c \left[c^{\langle t-1 \rangle}, x^{\langle t \rangle} + b_c \right] \right),
\Gamma_u = \sigma \left(W_u \left[c^{\langle t-1 \rangle}, x^{\langle t \rangle} \right] + b_u \right),
c^{\langle t \rangle} = \Gamma_u * \widetilde{c}^{\langle t \rangle} + (1 - \Gamma_u) * c^{\langle t-1 \rangle}.$$
(3)

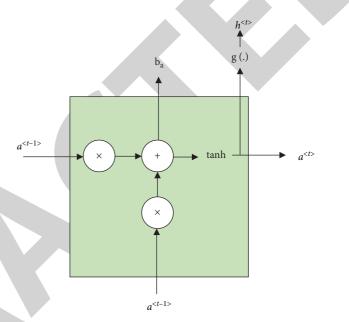

FIGURE 2: Inside structure of RNN.

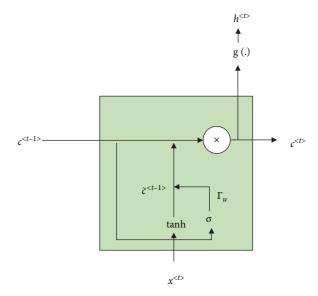

FIGURE 3: Inside structure of simplified GRU.

3.1.3. Long Short-Term Memory Network (LSTM). LSTM is another more common type of recurrent neural networks [17] and a more powerful and general version than GRU. In LSTM, there is still an update gate Γ_u . A new feature of LSTM is that instead of having only one update gate for control, a new gate called forgetting gate is added, denoted by Γ_f and then a new output gate Γ_o . At this point, the update value of the memory cell is changed to $c^{\langle t \rangle} = \Gamma_u * c^{\sim \langle t \rangle} + \Gamma_f * c^{\langle t-1 \rangle}$ and the complete equation of LSTM is shown as follows:

$$\begin{split} \widetilde{c}^{\langle t \rangle} &= \tanh\left(W_c \left[c^{\langle t-1 \rangle}, x^{\langle t \rangle} + b_c\right]\right), \\ \Gamma_u &= \sigma \left(W_u \left[c^{\langle t-1 \rangle}, x^{\langle t \rangle}\right] + b_u\right), \\ \Gamma_f &= \sigma \left(W_f \left[c^{\langle t-1 \rangle}, x^{\langle t \rangle}\right] + b_f\right), \\ \Gamma_o &= \sigma \left(W_o \left[c^{\langle t-1 \rangle}, x^{\langle t \rangle}\right] + b_o\right), \\ c^{\langle t \rangle} &= \Gamma_u * \widetilde{c}^{\langle t \rangle} + \Gamma_f * c^{\langle t-1 \rangle}, \\ a^{\langle t \rangle} &= \Gamma_o * c^{\langle t \rangle}. \end{split}$$
(4)

3.2. Attentional Model

3.2.1. Code-Decoder Architecture. For the encoder-decoder model, it is most common to get a fixed dimensional vector *c* given the input sequence $x = (x^{\langle t \rangle}, \dots, x^{\langle T \rangle})$, as shown in

$$h^{\langle t \rangle} = f(x^{\langle t \rangle}, h^{\langle t-1 \rangle}),$$

$$c = q(\{h^{\langle 1 \rangle}, \dots, h^{\langle T \rangle}\}),$$
(5)

where $h^{\langle t \rangle} \in \mathbb{R}^n$ is the hidden layer output at moment *t*. *c* is obtained from *T* hidden layer outputs by some transformation. Both *f*, *q* denote nonlinear methods, and there are also various choices. For example, *f* can be chosen as the internal structure of RNN or the internal structure of LSTM, and *q* can be chosen directly as the last hidden layer output, or all outputs can be stitched.

The encoder stage is an RNN that reads the input sequence sequentially, and the state of the hidden layer is updated after each reading of the current input. When the input sequence is read at the end, the hidden layer of the RNN finally encodes the whole input sequence as a c-vector. The decoder is another recurrent neural network, and $y^{\langle t \rangle}$ and $h^{\langle t \rangle}$ are determined not only by y^{t-1} but also by the final output *c* of the encoder. Therefore, the hidden layer of the decoder stage at moment *t* is calculated as shown in equation (6) and the conditional distribution probability when the result $y^{\langle t \rangle}$ is obtained in the decoding stage is shown in equation (7). The encoder-decoder model diagram is shown in Figure 4.where *f* and g are the activation functions and the output of the *g* activation function is the probability value.

$$h^{\langle t \rangle} = f(h^{\langle t-1 \rangle}, y^{\langle t-1 \rangle}, c), \quad (6)$$

$$P(y^{\langle t \rangle} | y^{\langle t-1 \rangle}, y^{\langle t-2 \rangle}, \dots, y^{\langle 1 \rangle}, c) = g(h^{\langle t \rangle}, y^{\langle t-1 \rangle}, c), \quad (7)$$

The encoder has to compress the whole input sequence into a c-vector, which means that some part of the information must be missing in the compression process and therefore the accuracy is somewhat affected. To reduce this impact, thus the attention mechanism is introduced [18]. The difference between the attention model and the classical encoder-decoder model is that the encoding stage is not compressed into just a c-vector but generates a sequence of vectors, as shown in Figure 5.

3.3. A Recurrent Neural Network Model Based on Dual Attention Mechanism and Trend Adjustment. The goal of port economic trend forecasting is to forecast future economic trends by means of diverse eigenvalues (influencing factors) and known economic indicators. The formula for port economic forecasting is much like that for autoregressive forecasting, where the input is defined as the entire set of features $\{x_t\}_{t=1}^T = \{x_1, x_2, \dots, x_T\}$ with the corresponding set of economic indicators as $\{y_t\}_{t=1}^T = \{y_1, y_2, \dots, y_T\}$. At time $t, x_t \in \mathbb{R}^n$, where *n* is the dimension of the feature and *T* is the entire time stage. The output of the economic trend forecast is the next Δ values of economic indicators after *T* time stages, which can be expressed as follows: $\{\hat{y}_t\}_{t=T+1}^{T+\Delta} = \{\hat{y}_{T+1}, \hat{y}_{T+2}, \dots, \hat{y}_{T+\Delta}\}$, where Δ is determined by the target of the economic trend forecast, assuming that $\Delta \ll T$ and $\{x_t\}_{t=T+1}^{T+\Delta}$ are unknown factors in the forecast stage.

Time series models with features behave differently than traditional autoregressive models for economic trend forecasting because the scalar values we want to predict and in the future are uncharacteristic. Therefore, we model the forecasting of economic indicators with features.

$$\{\widehat{y}_t\}_{t=T+1}^{T+\Delta} = F(\{x_t\}_{t=1}^T, \{y_t\}_{t=1}^T),$$
(8)

where $\{x_t\}_{t=1}^T$ is the feature from time 1 to *T*. $\{y_t\}_{t=1}^T$ is the historical economic information. $\{\hat{y}_t\}_{t=T+1}^{T+\Delta}$ is the value to be predicted. *F* is the mapping method of the nonlinearity to be learned.

For economic forecasting, internal and external characteristics are two different semantic features in terms of time series forecasting. That is, there is a significant difference in the way internal and external features affect economic forecasting. The formula $\{x_t^{int}\}_{t=1}^T$ is used for internal features. External features are represented using $\{x_t^{\text{ext}}\}_{t=1}^T$. Internal characteristics are information about intrinsic attributes that are directly related to the port economy, such as the location of the port and the type of industries surrounding the port. External features are information on attributes external to the external influences, such as the weather conditions of the year and fluctuations in overseas economies. Therefore, a single LSTM encoder structure may lose part of the contextual information due to mapping of all the original features into a uniform space. Therefore, we use two parallel LSTMs to efficiently capture the different ways of feature influence by modeling the internal and external features as two separate subtasks. Accordingly, we extend the problem formulation in equation (8) to the following equation:

$$\{\widehat{y}_t\}_{t=T+1}^{T+\Delta} = F\left(\{x_t^{\text{int}}\}_{t=1}^T, \{x_t^{\text{ext}}\}_{t=1}^T, \{y_t\}_{t=1}^T\right).$$
(9)

The structure of the encoding phase of the recurrent neural network model based on the dual attention mechanism and trend adjustment is shown in Figure 6.

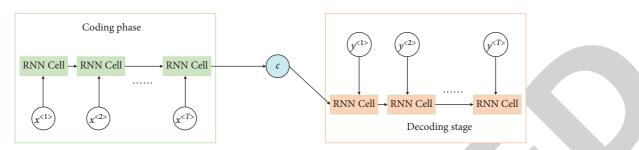

FIGURE 4: Structure of the encoder-decoder model.

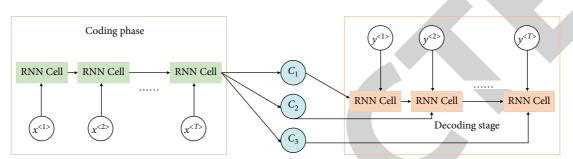

FIGURE 5: Structure of the attention model.

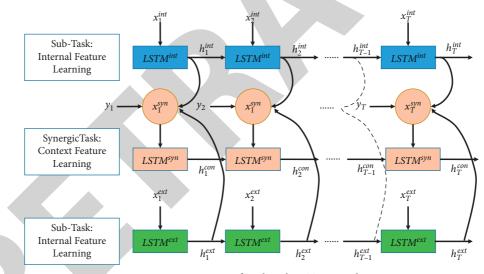

FIGURE 6: Structure of multitask LSTM encoder.

We use $\{h_t^{\text{int}}\}_{t=1}^T$ and $\{h_t^{\text{ext}}\}_{t=1}^T$ to denote the final representation learned from $\{x_t^{\text{int}}\}_{t=1}^T$ internal feature input and $\{x_t^{\text{ext}}\}_{t=1}^T$ external feature input, respectively. Thus, the encoder for multitasking can be expressed as

$$\{h_t^{\text{int}}\} = \text{LSTM}^{\text{int}} (x_t^{\text{int}}, h_{t-1}^{\text{int}}), \{h_t^{\text{ext}}\} = \text{LSTM}^{\text{ext}} (x_t^{\text{ext}}, h_{t-1}^{\text{ext}}),$$
(10)

$$\{h_t^{\text{con}}\} = \text{LSTM}^{\text{syn}} (x_t^{\text{syn}}, h_{t-1}^{\text{con}}).$$

The internal feature-encoded LSTM, the external feature-encoded LSTM, and the joint LSTM encoder are different LSTMs that do not share weights and offsets, but each trip of the LSTM can learn its own weights and offsets.

The decoding stage diagram of the recurrent neural network model with dual attention mechanism and trend adjustment is shown in Figure 7.

The formula for decoding based on the attention mechanism is shown in

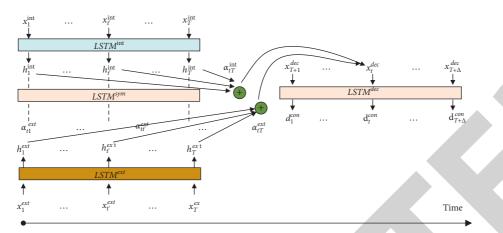

FIGURE 7: Demonstration of attention mechanism for weighted input mapping.

$$\begin{aligned} x_{t}^{\text{dec}} &= W_{\text{dec}} \left[\sum_{t'=1}^{T} \alpha_{tt'}^{\text{int}} h_{t'}^{\text{int}}; \sum_{t'=1}^{T} \alpha_{tt'}^{\text{ext}} h_{t'}^{\text{ext}} \right] + b_{\text{dec}}, \\ e_{tt'}^{\text{int}} &= v_{\text{int}}^{T} \tanh\left(M_{\text{int}} d_{t-1}^{\text{con}} + H_{\text{int}} h_{t'}^{\text{int}}\right), \\ e_{tt'}^{\text{ext}} &= v_{\text{ext}}^{T} \tanh\left(M_{\text{ext}} d_{t-1}^{\text{con}} + H_{\text{ext}} h_{t'}^{\text{ext}}\right), \\ \alpha_{tt'}^{\text{int}} &= \frac{\exp(e_{tt'}^{\text{int}})}{\sum_{s}^{T} \exp(e_{ts}^{\text{int}})}, \\ \alpha_{tt'}^{\text{ext}} &= \frac{\exp(e_{tt'}^{\text{int}})}{\sum_{s}^{T} \exp(e_{ts}^{\text{ext}})}, \end{aligned}$$

where $e_{tt'}^{int}$ and $e_{tt'}^{ext}$ correspond to the correlation scores of the hidden layer output of the internal feature LSTM and the hidden layer output of the external feature LSTM and d_{t-1}^{con} at moment t', respectively. Among them, v_{int}^T , v_{ext}^T , M_{int} , H_{int} , and H_{ext} are the parameters to be learned by the model.

4. Experiments and Results

The port logistics subsystem is divided into input and output indicators, and we have selected container throughput, cargo throughput, length of production quay, and number of production berths as sequential parameters. The regional economic subsystem is divided into total indicators, structural indicators, trade indicators, and investment indicators, as shown in Table 1.

The degree of synergy between port logistics and regional economic system at time t is expressed by Y_t . Here, Y_t is between 0 and 1. The closer the value of Y_t is to 1, the higher the degree of synergy between the regional economic subsystem and the port logistics subsystem. On the contrary, the closer Y_t is to 0, the lower the degree of synergy between the two. It is calculated as shown in

$$C = 2\sqrt{\frac{\left(X_1^t \times X_2^t\right)}{\left(X_1^t + X_2^t\right)^2}},$$

$$F = \frac{\left(X_1^t + X_2^t\right)}{2},$$

$$Y_t = \sqrt{C \times F}.$$
(12)

 X_1^t and X_2^t are the orderliness of the regional economic system and the port logistics system at moment t. The combined level of coordination between the development degree of the port logistics system and the regional economic system is represented by C. The combined level of the port logistics system and the regional economic system at the moment t is expressed by F.

The criteria for classifying the grade of synergy between port logistics and regional economy are shown in Table 2.

This paper is based on publicly available data from a port and the hinterland city where it is located. Using the proposed recurrent neural network model based on the double attention mechanism and trend adjustment, the weights of the sequential covariates of the port logistics system and the hinterland economic system and the orderliness of the sequential covariates are trained. The trend of a port logistics and its hinterland economic orderliness and the integrated synergistic trend are obtained, as shown in Figures 8–10.

The comprehensive synergy degree of port logistics and regional economy is largely on the rise, and when the orderly degree of port logistics develops in the same direction as the orderly degree of regional economy, the comprehensive synergy degree is also on the trend of development. The prediction model presented in this paper is generally consistent with the real data trend.

5. Conclusion

The foundation for logistics planning and construction in port area cities is the port logistics [19]. Therefore, the development trend of port regional economy and its research are practically significant [20]. Thus, in this paper, the analysis was carried out for the characteristics and main contents of port logistics forecasting and economic forecasting of the region where the port is located. This analysis was based on the basic theory of port regional economy and forecasting theory. Hence, we proposed a prediction method based on deep neural network to establish a neural network prediction model that meets the needs of the port regional economy. The results proved the applicability of the model and the feasibility of the method. Because there are many factors influencing the port economy, we have selected a few important indicator factors with focus and the follow-up can be done from improving the network model or adding more indicator factors to study the synergistic development of the port regional economy in depth.

In the present research paper, Chatterjea type contraction is defined and discussed in the framework of quasi-partial b-metric space. Further, some common fixed point results are proved using the notion of interpolation. The results are extended to fixed point theorems for modified Chatterjea type Suzuki contraction using w-admissible maps. The results proved are new and unique supported by application which will enrich the existing literature.

1. Introduction and Preliminaries

In 1922, Banach [1] gave one of the important result called Banach contraction principle and discussed its importance in metric fixed point theory, i.e., let *H* be a self map on a nonempty set *G* and (G, d) be a complete metric space. If there exists a constant $\kappa \in [0, 1)$ such that

$$d(H\sigma, Hv) \le \kappa \ d(\sigma, v), \quad \text{for all } \sigma, v \in G,$$
 (1)

then it possesses a unique fixed point in *G*. Afterwards, many generalizations of Banach contraction principle came in the literature (see [2-4]) In 1968, Kannan [5] removed the continuity property from this principle and defined a new variant.

Theorem 1 (see [5]). Let (G, d) be a complete metric space and a self map $T: G \longrightarrow G$ be a Kannan contraction mapping, i.e.,

$$d(T\sigma, Tv) \le \varrho[d(\sigma, T\sigma) + d(v, Tv)], \tag{2}$$

for all $\sigma, v \in G$, where $\varrho \in [0, 1/2)$. Then, T admits a unique fixed point in G.

In 1972, Chatterjea [6] generalized the contraction mapping on a complete metric space which is stated as follows.

Theorem 2 (see [6]). Let (G, d) be a complete metric space. A self map $T: G \longrightarrow G$ be a Chatterjea type contraction. If

$$d(T\sigma, Tv) \le \varrho[d(\sigma, Tv) + d(v, T\sigma)], \tag{3}$$

for all $\sigma, v \in G$, where $\varrho \in (0, 1/2)$, then T has a unique fixed point.

In 2015, quasi-partial metric space was generalized by Gupta and Gautam [7] to quasi-partial b-metric space. In 2018, Karapinar [8] enriched the concept of interpolation and established a new contraction known as interpolative Kannan-type contractive mapping.

Theorem 3 (see [8]). Let (G, d) be a metric space; a self mapping $T: G \longrightarrow G$ is said to be an interpolative Kannantype contraction map if there exist a constant $\varrho \in (0, 1)$ and $\alpha \in (0, 1)$ such that

$$d(T\sigma, Tv) \le \varrho \left[d(\sigma, T\sigma) \right]^{\alpha} \cdot \left[d(v, Tv) \right]^{1-\alpha}, \quad \text{for all } \sigma, v \in G \setminus Fix(T),$$
(4)

where $Fix(T) = \{z \in G: Tz = z\}.$

Numerous studies have been done on interpolation inequalities in the literature. Many new research papers based on the concept of interpolation came into existence (for example, see [9–11]). Noorwali [12], in the year 2019, extended the Kannan interpolative contraction by proving common fixed point result for two self maps. Several authors [9, 13–25] have contributed immensely to enrich this field.

Definition 1 (see [26]). A quasi-partial metric on a nonempty set G is a function $qp: G \times G \longrightarrow \mathbb{R}^+$ such that for all $\sigma, v, \epsilon \in G$:

(1) $qp(\sigma, \sigma) = qp(\sigma, v) = qp(v, v)$ implies $\sigma = v$ (2) $qp(\sigma, \sigma) \le qp(\sigma, v)$ (3) $qp(\sigma, \sigma) \le qp(v, \sigma)$

(4) $qp(\sigma, v) \leq [qp(\sigma, \epsilon) + qp(\epsilon, v)] - qp(\epsilon, \epsilon)$

The pair (G, qp) is called a quasi-partial metric space.

Definition 2 (see [7]). A quasi-partial b-metric on a nonempty set G is a function $qp_b: G \times G \longrightarrow \mathbb{R}^+$ such that for some real number $s \ge 1$ and all $\sigma, v, \epsilon \in G$:

(1) $qp_b(\sigma, \sigma) = qp_b(\sigma, v) = qp_b(v, v)$ implies $\sigma = v$ (2) $qp_b(\sigma, \sigma) \le qp_b(\sigma, v)$ (3) $qp_b(\sigma, \sigma) \le qp_b(v, \sigma)$ (4) $qp_b(\sigma, v) \le s[qp_b(\sigma, \epsilon) + qp_b(\epsilon, v)] - qp_b(\epsilon, \epsilon)$

The pair (G, qp_b) is called a quasi-partial b-metric space. The number *s* is called the coefficient of (G, qp_b) . Let qp_b be a quasi-partial b-metric on the set *G*. Then,

$$d_{qp_b}(\sigma, v) = qp_b(\sigma, v) + qp_b(v, \sigma) - qp_b(\sigma, \sigma) - qp_b(v, v) \text{ is a b - metric on } G.$$
(5)

Example 1. Let $G = [0, \infty)$ be endowed with metric $qp_b: G \times G \longrightarrow [0, \infty)$ defined by $qp_b(\sigma, v) = \max\{\sigma, v\} + |\sigma - v|$. Dominance of (G, qp_b) for the special case G = [0, 3] is visually checked in Figure 1.

Here, $qp_b(\sigma, \sigma) = qp_b(\sigma, v) = qp_b(v, v) \Rightarrow \sigma = v$ as $\sigma = \max\{\sigma, \sigma\} + |\sigma - \sigma| = v$.

Again, $qp_b(\sigma, \sigma) \le qp_b(\sigma, v)$ as $\max\{\sigma, \sigma\} + |\sigma - \sigma| \le \max\{\sigma, v\} + |\sigma - v|$ and similarly $qp_b(\sigma, \sigma) \le q(v, \sigma)$.

Also,
$$qp_b(\sigma, v) + qp_b(\epsilon, \epsilon) \le qp_b(\sigma, \epsilon) + qp_b(\epsilon, \sigma)$$
.
Let $\sigma, \epsilon, v \in G$. If $\sigma \le v \le \epsilon$, then

$$\max\{\sigma, v\} + |\sigma - v| \le v + |\sigma - \varepsilon| + |\varepsilon - v| \le \max\{\sigma, \varepsilon\} + |\sigma - \varepsilon| + \max\{\varepsilon, v\} + |\varepsilon - v| - \varepsilon.$$
(6)

Thus, (G, qp_b) is a quasi-partial b-metric space.

Lemma 1 (see [23]). Let (G, qp_b) be a quasi-partial b-metric space. Then, the following holds:

(i) If qp_b (σ , v) = 0, then $\sigma = v$ (ii) If $\sigma = v$, then qp_b (σ , v) >rbin0 and qp_b (v, σ) >rbin0

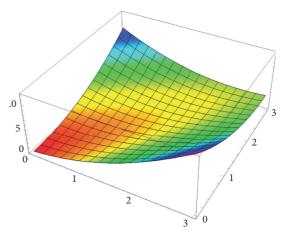

FIGURE 1: The graphical surface represents a 3D view of the function $qp_h(\sigma, v) = \max\{\sigma, v\} + |\sigma - v|$ for [0,3].

Definition 3 (see [7]). Let (G, qp_b) be a quasi-partial b-metric. Then,

- (1) A sequence $\{\sigma_n\} \in G$ converges to $\sigma \in G$ if and only if $qp_b(\sigma, \sigma) = \lim_{n \to \infty} qp_b(\sigma, \sigma_n)$.
- (2) A sequence $\{\sigma_n\} \subset G$ is called a Cauchy sequence if and only if $\lim_{n,m \to \infty} qp_b(\sigma_n, \sigma_m)$ exists.
- (3) A quasi-partial b-metric space (G, qp_b) is said to be complete if every Cauchy sequence {σ_n}⊂G converges with respect to τ_{qpb} to a point σ ∈ G such that

$$qp_b(\sigma,\sigma) = \lim_{n,m\to\infty} qp_b(\sigma_n,\sigma_m). \tag{7}$$

(4) A mapping $f: G \longrightarrow G$ is said to be continuous at $\sigma_0 \in G$ if, for every $\varepsilon > 0$, there exists $\delta > 0$ such that

$$f(B(\sigma_0,\delta)) \in B(f(\sigma_0),\varepsilon).$$
(8)

Lemma 2 (see [18]). Let (G, qp_b) be a quasi-partial b-metric space and $(G, dq p_b)$ be the corresponding b-metric space. Then, $(G, dq p_b)$ is complete if (G, qp_b) is complete.

Definition 4 (see [23]). Let (G, qp_b) be a quasi-partial b-metric space and $H: G \longrightarrow G$ be a given mapping. Then, H is said to be sequentially continuous at $z \in G$ if for each sequence $\{\sigma_n\}$ in G converging to z, we have $H\sigma_n \longrightarrow Hz$, that is, $\lim_{n \longrightarrow \infty} qp_b(H\sigma_n, Hz) = qp_b(Hz, Hz)$. Similarly, let $K: G \longrightarrow G$ be a given mapping. K is said to be sequentially continuous at $z \in G$ if for each sequence $\{\sigma_n\}$ in Gconverging to z, we have $\lim_{n \longrightarrow \infty} qp_b(Kz, K\sigma_n) = qp_b(Kz, Kz)$.

2. Main Results

In this paper, the notion of interpolative Chatterjea type contraction is given in the setting of quasi-partial b-metric space.

Definition 5. Let (G, qp_b) be a complete quasi-partial b-metric space. We say that the self mappings

H, *K*: *G* \longrightarrow *G* are an interpolative Chatterjea contraction if there exists $\varrho \in [0, 1/s), \alpha \in (0, 1), s > 1$ such that

$$qp_b(H\sigma, Kv) \le \varrho \left[\frac{1}{s^2} qp_b(\sigma, Kv)\right]^{\alpha} \left[\frac{1}{s^2} qp_b(v, H\sigma)\right]^{1-\alpha}, \quad (9)$$

for all $\sigma, v \in G$ such that $H\sigma \neq \sigma$ whenever $Kv \neq v$.

Theorem 4. Let (G, qp_b) be a complete quasi-partial *b*-metric space and *H* and *K* be an interpolative Chatterjea type contraction. Then, *K* and *H* posses a common fixed point.

Proof. Let $\sigma_0 \in G$. Define the sequence σ_n by $\sigma_{2n+1} = H\sigma_{2n}$, $\sigma_{2n+2} = K\sigma_{2n+1}$ for all n = 1, 2, ... If there exist $n \in 0, 1, 2, ...$, such that $\sigma_n = \sigma_{n+1} = \sigma_{n+2}$, then σ_n is a common fixed point of *K* and *H*. Suppose that there are no

such three consecutive identical terms in the sequence σ_n and that $\sigma_0 \neq \sigma_1$. Now, using equation (9), we deduce that

$$qp_{b}(\sigma_{2n+1},\sigma_{2n+2}) = qp_{b}(H\sigma_{2n},K\sigma_{2n+1})$$

$$\leq \varrho \Big[\frac{1}{s^{2}}qp_{b}(\sigma_{2n},K\sigma_{2n+1})\Big]^{\alpha} \Big[\frac{1}{s^{2}}qp_{b}(\sigma_{2n+1},H\sigma_{2n})\Big]^{1-\alpha}$$
(10)
$$\leq \varrho \Big[\frac{1}{2}qp_{b}(\sigma_{2n},\sigma_{2n+2})\Big]^{\alpha} \Big[\frac{1}{2}qp_{b}(\sigma_{2n+1},\sigma_{2n+1})\Big]^{1-\alpha}.$$

$$\mathbb{E}\left[\frac{1}{s^2} \mathcal{P}_b(\mathcal{O}_{2n}, \mathcal{O}_{2n+2})\right] \left[\frac{1}{s^2} \mathcal{P}_b(\mathcal{O}_{2n+1}, \mathcal{O}_{2n+1})\right]$$

By using Definition 2,

$$qp_b(\sigma_{2n+1}, \sigma_{2n+1}) \le qp_b(\sigma_{2n+1}, \sigma_{2n+2}).$$
(11)

Therefore,

$$qp_{b}(\sigma_{2n+1},\sigma_{2n+2}) \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(\sigma_{2n},\sigma_{2n+2})\right]^{\alpha} \left[\frac{1}{s^{2}}qp_{b}(\sigma_{2n+1},\sigma_{2n+2})\right]^{1-\alpha},$$

$$[qp_{b}(\sigma_{2n+1},\sigma_{2n+2})]^{\alpha} \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(\sigma_{2n},\sigma_{2n+2})\right]^{\alpha}$$

$$\leq \left[\frac{1}{s^{2}}\left[s\left(qp_{b}(\sigma_{2n},\sigma_{2n+1})+qp_{b}(\sigma_{2n+1},\sigma_{2n+2})-qp_{b}(\sigma_{2n+1},\sigma_{2n+1})\right)\right]\right]^{\alpha},$$

$$[qp_{b}(\sigma_{2n+1},\sigma_{2n+2})]^{\alpha} \leq \varrho \left[\frac{1}{s}\left(qp_{b}(\sigma_{2n},\sigma_{2n+1})+qp_{b}(\sigma_{2n+1},\sigma_{2n+2})\right)\right]^{\alpha}.$$
(12)

Suppose that

$$qp_{b}(\sigma_{2n},\sigma_{2n+1}) \leq qp_{b}(\sigma_{2n+1},\sigma_{2n+2}),$$

$$\frac{1}{s} [qp_{b}(\sigma_{2n},\sigma_{2n+1}) + qp_{b}(\sigma_{2n+1},\sigma_{2n+2})] \leq qp_{b}(\sigma_{2n+1},\sigma_{2n+2}).$$
(13)

By using equation (12),

$$\left[qp_b\left(\sigma_{2n+1},\sigma_{2n+2}\right)\right]^{\alpha} \le \varrho\left[qp_b\left(\sigma_{2n+1},\sigma_{2n+2}\right)\right]^{\alpha},\tag{14}$$

which is a contradiction. Thus, we have

$$qp_{b}(\sigma_{2n+1}, \sigma_{2n+2}) < qp_{b}(\sigma_{2n}, \sigma_{2n+1}), \quad \text{for all } n \ge 1,$$

$$\frac{1}{s} [qp_{b}(\sigma_{2n}, \sigma_{2n+1}) + qp_{b}(\sigma_{2n+1}, \sigma_{2n+2})] \le qp_{b}(\sigma_{2n}, \sigma_{2n+1}).$$
(15)

Using equation (12),

$$[qp_{b}(\sigma_{2n+1},\sigma_{2n+2})]^{\alpha} \leq \varrho [qp_{b}(\sigma_{2n},\sigma_{2n+1})]^{\alpha},$$

$$qp_{b}(\sigma_{2n+1},\sigma_{2n+2}) \leq \varrho^{1/\alpha} qp_{b}(\sigma_{2n},\sigma_{2n+1}),$$

$$qp_{b}(\sigma_{2n+1},\sigma_{2n+2}) \leq \varrho qp_{b}(\sigma_{2n},\sigma_{2n+1}).$$
(16)

Hence,

$$qp_b(\sigma_{2n+1},\sigma_{2n+2}) \le \varrho qp_b(\sigma_{2n},\sigma_{2n+1}) \le \varrho^2 qp_b(\sigma_{2n-1},\sigma_{2n}).$$
(17)

Therefore,

$$qp_b(\sigma_{2n+1},\sigma_{2n+2}) \le \varrho^{2n+1}qp_b(\sigma_0,\sigma_1).$$
 (18)

Similarly,

(21)

$$qp_{b}(\sigma_{2n+1},\sigma_{2n}) = qp_{b}(H\sigma_{2n},K\sigma_{2n-1})$$

$$\leq \varrho \Big[\frac{1}{s^{2}} qp_{b}(\sigma_{2n},K\sigma_{2n-1}) \Big]^{\alpha} \Big[\frac{1}{s^{2}} qp_{b}(\sigma_{2n-1},H\sigma_{2n}) \Big]^{1-\alpha}$$

$$\leq \varrho [qp_{b}(\sigma_{2n},\sigma_{2n})]^{\alpha} \Big[\frac{1}{s^{2}} qp_{b}(\sigma_{2n-1},\sigma_{2n+1}) \Big]^{1-\alpha}$$

$$\leq \varrho [qp_{b}(\sigma_{2n},\sigma_{2n+1})]^{\alpha} \cdot \Big[\frac{1}{s^{2}} qp_{b}(\sigma_{2n-1},\sigma_{2n+1}) \Big]^{1-\alpha}$$

$$\leq \varrho [qp_{b}(\sigma_{2n},\sigma_{2n+1})]^{\alpha} \cdot \Big[\frac{1}{s^{2}} s\{(qp_{b}(\sigma_{2n-1},\sigma_{2n})+qp_{b}(\sigma_{2n},\sigma_{2n+1}))-qp_{b}(\sigma_{2n},\sigma_{2n})\}\Big]^{1-\alpha}$$

$$\leq \varrho [qp_{b}(\sigma_{2n},\sigma_{2n+1})]^{\alpha} \cdot \Big[\frac{1}{s^{2}} sqp_{b}(qp_{b}(\sigma_{2n-1},\sigma_{2n})+qp_{b}(\sigma_{2n},\sigma_{2n+1})) - qp_{b}(\sigma_{2n},\sigma_{2n})\}\Big]^{1-\alpha}$$

$$qp_{b}[(\sigma_{2n},\sigma_{2n+1})]^{1-\alpha} \leq \varrho qp_{b}(\sigma_{2n-1},\sigma_{2n})^{1-\alpha},$$

$$qp_{b}[(\sigma_{2n},\sigma_{2n+1})] \leq \varrho qp_{b}(\sigma_{2n-1},\sigma_{2n}).$$
(19)

Hence,

$$qp_{b}(\sigma_{2n},\sigma_{2n+1}) \leq \varrho q p_{b}(\sigma_{2n-1},\sigma_{2n}) \leq \varrho^{2} q p_{b}(\sigma_{2n-1},\sigma_{2n-2}).$$
(20)

This yields that

 $qp_b(\sigma_{2n},\sigma_{2n+1}) \leq \varrho^{2n}qp_b(\sigma_0,\sigma_1).$

$$qp_b(\sigma_n, \sigma_{n+1}) \le \varrho^n qp_b(\sigma_0, \sigma_1).$$
(22)

To prove sequence $\{\sigma_n\}$ is Cauchy, let $n, k \in N$

$$qp_{b}(\sigma_{n},\sigma_{n+k}) \leq sqp_{b}(\sigma_{n},\sigma_{n+1}) + s^{2}qp_{b}(\sigma_{n+1},\sigma_{n+2}) + \dots + s^{k}qp_{b}(\sigma_{n+k-1},\sigma_{n+k})$$

$$\leq [s\varrho^{n} + s^{2}\varrho^{n+1} + \dots + s^{k}\varrho^{n+k-1}]qp_{b}(\sigma_{0},\sigma_{1})$$

$$\leq s^{k}\sum_{i=n}^{n+k-1} \varrho^{i}qp_{b}(\sigma_{0},\sigma_{1})$$

$$\leq s^{k}\sum_{i=n}^{\infty} \varrho^{i}qp_{b}(\sigma_{0},\sigma_{1}).$$
(23)

From (23),

$$\begin{aligned} qp_{b}\left(\sigma_{n+m},\sigma_{n+m+k}\right) \\ &\leq s^{k}\sum_{i=m}^{\infty}\varrho^{i}qp_{b}\left(\sigma_{n},\sigma_{n+1}\right), \\ &\lim_{m\longrightarrow\infty,n\longrightarrow\infty}qp_{b}\left(\sigma_{n+m},\sigma_{n+m+k}\right) \\ &\leq s^{k}\lim_{m\longrightarrow\infty}\sum_{i=m}^{\infty}\lim_{n\longrightarrow\infty}\varrho^{i}qp_{b}\left(\sigma_{n},\sigma_{n+1}\right) \\ &= 0. \end{aligned}$$

$$(24)$$

Therefore,

$$\lim_{n \to \infty} q p_b(\sigma_n, \sigma_{n+k}) = \lim_{m \to \infty, n \to \infty} q p_b(\sigma_{n+m}, \sigma_{n+m+k}) = 0.$$
(25)

We conclude that $\{\sigma_n\}$ is a Cauchy sequence. Since (G, qp_b) is complete, there exists $z \in G$ such that $\lim_{n \to \infty} \sigma_n = z$. Next, we shall prove that z is a common fixed point of K and H.

$$qp_{b}(Hz, \sigma_{2n+2}) = qp_{b}(Hz, K\sigma_{2n+1})$$

$$\leq \varrho \Big[\frac{1}{s^{2}} qp_{b}(z, k\sigma_{2n+1}) \Big]^{\alpha} \Big[\frac{1}{s^{2}} qp_{b}(\sigma_{2n+1}, Hz) \Big]^{1-\alpha}$$

$$\leq \varrho \big[qp_{b}(z, k\sigma_{2n+1}) \big]^{\alpha}$$

$$[qp_{b}(\sigma_{2n+1}, Hz)]^{1-\alpha}.$$
Letting $n \longrightarrow \infty$, we get $Hz = z$. Similarly,

$$qp_{b}(\sigma_{2n+1}, Kz) = qp_{b}(H\sigma_{2n}, Kz)$$

$$\leq \varrho \Big[\frac{1}{s^{2}} qp_{b}(\sigma_{2n}, Kz) \Big]^{\alpha} \Big[\frac{1}{s^{2}} qp_{b}(z, H\sigma_{2n}) \Big]^{1-\alpha}$$
(26)
$$(26)$$

$$\leq \varrho \left[q p_b \left(\sigma_{2n}, K z \right) \right]^{\alpha} \left[q p_b \left(z, H \sigma_{2n} \right) \right]^{1-\alpha}.$$

Letting $n \longrightarrow \infty$, we get Kz = z. Hence, *K* and *H* attain a common fixed point.

We can justify this result by illustrating it with an example. $\hfill \Box$

Example 2. Let $G = \{0, 1, 2, 3\}$. Define complete quasi-partial b-metric as $qp_b(\sigma, v) = (\sigma - v)^2 + \sigma$, that is:

$\mathbf{qp}_{\mathbf{b}}(\sigma, v)$	0	1	2	3
0	0	1	4	9
1	2	1	2	5
2	6	3	2	3
3	12	7	4	3

We define self mappings *H* and *K* on *G* as *H*: $\begin{pmatrix} 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 0 \end{pmatrix}$, *K*: $\begin{pmatrix} 0 & 1 & 2 & 3 \\ 0 & 0 & 0 & 1 \end{pmatrix}$. Now, consider the value $\alpha = 4/5$ and $\rho = 99/100$.

Case 1. Let $(\sigma, v) = (1, 1)$. Without loss of generality, we have

$$qp_{b}(H\sigma, Kv) \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(\sigma, Kv)\right]^{\alpha} \left[\frac{1}{s^{2}}qp_{b}(v, H\sigma)\right]^{1-\alpha},$$

$$qp_{b}(H1, K1) = 0 \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(1, K1)\right]^{4/5} \left[\frac{1}{s^{2}}qp_{b}(1, H1)\right]^{1-(4/5)}.$$
(28)

Dominance of right-hand side of equation (9) is easily visually checked in Figure 2. Thus, the inequality required in equation (9) holds for $(\sigma, v) = (1, 1)$.

Case 2. Let
$$(\sigma, v) = (0, 0)$$
.
 $qp_b(H\sigma, Kv) \le \varrho \Big[\frac{1}{s^2} qp_b(\sigma, Kv) \Big]^{\alpha} \Big[\frac{1}{s^2} qp_b(v, H\sigma) \Big]^{1-\alpha}$,
 $qp_b(H0, K0) = 0 \le \varrho \Big[\frac{1}{s^2} qp_b(0, K0) \Big]^{4/5} \Big[\frac{1}{s^2} qp_b(0, H0) \Big]^{1-(4/5)}$.
(29)

Dominance of right-hand side of equation (9) is easily visually checked in Figure 3. Thus, the inequality required in equation (9) holds for $(\sigma, v) = (0, 0)$.

Case 3. Let
$$(\sigma, v) = (3, 3)$$
.

$$qp_{b}(H\sigma, Kv) \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(\sigma, Kv)\right]^{m} \left[\frac{1}{s^{2}}qp_{b}(v, H\sigma)\right]^{r},$$

$$qp_{b}(H3, K3) = 1 \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(3, K3)\right]^{4/5} \left[\frac{1}{s^{2}}qp_{b}(3, H3)\right]^{1-(4/5)}.$$
(30)

 $-1-\alpha$

Dominance of right-hand side of equation (9) is easily visually checked in Figure 4. Thus, the inequality required in equation (9) holds for $(\sigma, v) = (3, 3)$.

Therefore, 0 is the common fixed point of H and K in the setting of interpolative Chatterjea type contraction. Many more common fixed points can be obtained in similar manner. Hence, a fixed point exists but is not unique.

Open problem 1. Let (G, qp_b) be a complete quasi-partial b-metric space. Let us consider a family of self mappings K_n : $G \longrightarrow G$, $n \ge 1$, and $s \ge 1$ such that

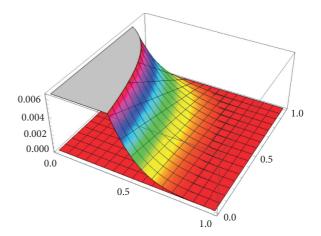

FIGURE 2: 0 is the common fixed point of H and K.

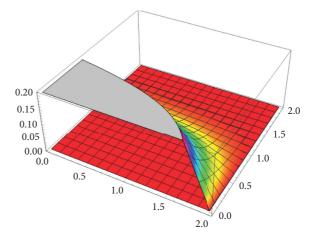

FIGURE 3: 0 is the common fixed point of H and K.

$$qp_b(K_i\sigma, K_jv) \le \varrho_{i,j} \left[\frac{1}{s^2} qp_b(\sigma, K_iv)\right]^{\alpha} \left[\frac{1}{s^2} qp_b(v, K_j\sigma)\right]^{1-\alpha}.$$
(31)

What are the conditions on $\varrho_{i,j}$ and α_i for K_n to have a common fixed point?

3. Modified Chatterjea Type Suzuki Contraction

In our next result, we present the existence of interpolative Chatterjea contraction via Suzuki map. First, let us recall w-admissible map.

Definition 6. Let us consider a self map H defined on G and $w: G \times G \longrightarrow [0, \infty]$ be a map where $G \neq \phi$. H is said to be w-orbital admissible if for all $\sigma \in G$, we have

$$w(\sigma, H\sigma) \ge 1 \longrightarrow w(H\sigma, H^2\sigma) \ge 1.$$
 (32)

R Condition. If $\{\sigma_n\}$ is a sequence in *G* such that $w(\sigma_n, \sigma_{n+1}) \ge 1$ for each *n* and $\sigma_n \longrightarrow \sigma \in G$ as $n \longrightarrow \infty$, then there exists $\{\sigma_{n(k)}\}$ from $\{\sigma_n\}$ such that $w(\sigma_{n(k)}, \sigma) \ge 1$, for each *k*.

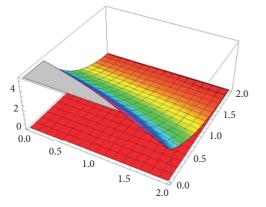

FIGURE 4: 0 is the common fixed point of H and K.

Definition 7. Let (G, qp_b) be a quasi-partial b-metric space. A self map *H* defined on *G* satisfies the C-condition if

$$\frac{1}{2} \left[q p_b(\sigma, H\sigma) \right] \le q p_b(\sigma, v) \Rightarrow q p_b(H\sigma, Hv) \le q p_b(\sigma, v),$$
(33)

for each σ , $v \in G$.

Definition 8 (see [15,22]). Let Ψ be the set of all nondecreasing self mappings ψ on $(0, \infty)$ such that

$$\sum_{n=1}^{\infty} \psi^n(t) < \infty, \quad \text{for each } t > 0.$$
(34)

Notice that for $\psi \in \Psi$, we have $\psi(0) = 0$ and $\psi(t) < t$ for all t > 0.

Definition 9. Let us consider a quasi-partial b-metric space (G, qp_b). A map $H: G \longrightarrow G$ is said to be a w- ψ -interpolative Chatterjea contraction of Suzuki type if there exist ψ and a self-mapping, $w: G \times G \longrightarrow [0, \infty)$ and a real number $\alpha \in [0, 1)$, such that

$$\frac{1}{2} \left[q p_b(\sigma, H v) \right] \le q p_b(\sigma, v) \Rightarrow w(\sigma, v) q p_b(H \sigma, H v) \le \psi \left(\left[q p_b(\sigma, H v) \right]^{\alpha} \left[q p_b(v, H \sigma) \right]^{1-\alpha} \right), \tag{35}$$

for each σ , $v \in G$.

Theorem 5. Let (G, qp_b) be a complete quasi-partial *b*-metric space and $H: G \longrightarrow G$ be a w- ψ -interpolative Chatterjea contraction of Suzuki type. Assume that H is *w*-orbital admissible mapping and $w(\sigma_0, H\sigma_0) \ge 1$ for some $\sigma_0 \in G$. Then, H has a fixed point in G provided that at least one of the following conditions holds:

- (1) (G, qp_b) is w-regular
- (2) H is continuous
- (3) ψH^2 is continuous and $w(\sigma, H\sigma) \ge 1$ where $\sigma \in Fix$ (ψH^2)

Proof. Let us consider an initial point $\sigma_0 \in G$ such that $w(\sigma_0, H\sigma_0) \geq 1$ and now construct a sequence $\{\sigma_n\}$ by using $H^n(\sigma_0) = \sigma_n$ for each positive integer *n*. If $\sigma_{n_0} = \sigma_{n_{0+1}}$ for some $n_0 \in N$, we get $\sigma_{n_0} = H\sigma_{n_0}$ that means we get σ_{n_0} is a fixed point of *H*. Then, we can assume that $\sigma_n \neq \sigma_{n+1}$ for each positive integer *n*. As *H* is *w*-orbital admissible, we have the condition $w(\sigma_0, H\sigma_0) = w(\sigma_0, \sigma_1) \geq 1$ implies that $w(\sigma_1, H\sigma_1) = w(\sigma_1, \sigma_2) \geq 1$. In continuation, we have

$$w(\sigma_n, \sigma_{n+1}) \ge 1. \tag{36}$$

Hence, choosing $\sigma = \sigma_{n-1}$ and $\epsilon = H\sigma_{n-1}$ in (54), we get

$$\frac{1}{2}qp_b(\sigma,\epsilon) = \frac{1}{2}qp_b(\sigma_{n-1},H\sigma_{n-1}) = \frac{1}{2}qp_b(\sigma_{n-1},\sigma_n) \le qp_b(\sigma_{n-1},\sigma_n),$$
(37)

which implies

$$qp_{b}(\sigma_{n},\sigma_{n+1}) \leq w(\sigma_{n-1},\sigma_{n})qp_{b}(H\sigma_{n-1},H\sigma_{n})$$

$$\leq \psi([qp_{b}(\sigma_{n-1},H\sigma_{n})]^{\alpha}.[qp_{b}(\sigma_{n},H\sigma_{n-1})]^{1-\alpha})$$

$$= \psi([qp_{b}(\sigma_{n-1},\sigma_{n+1})]^{\alpha}.[qp_{b}(\sigma_{n},\sigma_{n})]^{1-\alpha})$$

$$< [qp_{b}(\sigma_{n-1},\sigma_{n})]^{\alpha}.[qp_{b}(\sigma_{n},\sigma_{n+1})]^{1-\alpha}.$$
(38)

Hence, it follows that

$$\left[qp_b\left(\sigma_n,\sigma_{n+1}\right)\right]^{\alpha} < \left[qp_b\left(\sigma_{n-1},\sigma_n\right)\right]^{\alpha},\tag{39}$$

or equivalently

$$qp_b(\sigma_n, \sigma_{n+1}) < qp_b(\sigma_{n-1}, \sigma_n). \tag{40}$$

Thus, it follows that the sequence $\{qp_b(\sigma_{n-1}, \sigma_n)\}$ is a nonincreasing sequence of positive terms and $\lim_{n\longrightarrow\infty}qp_b(\sigma_{n-1}, \sigma_n)=1$. From the above equations and the nondecreasing nature of function ψ , we obtain

$$qp_b(\sigma_n, \sigma_{n+1}) \le \psi(qp_b(\sigma_{n-1}, \sigma_n)) \le \psi^2(qp_b(\sigma_{n-2}, \sigma_{n-1})) \le \dots \le \psi^n(qp_b(\sigma_0, \sigma_1)).$$

$$(41)$$

Now, applying triangular inequality, for all $j \ge 1$, we get

$$qp_{b}(\sigma_{n},\sigma_{n+j}) \leq \left[sqp_{b}(\sigma_{n},\sigma_{n+1}) + s^{2}qp_{b}(\sigma_{n+1},\sigma_{n+2}) + \dots + s^{j}qp_{b}(\sigma_{n+j-1},\sigma_{n+j})\right]$$

$$\leq \left[s\psi^{n}qp_{b}(\sigma_{0},\sigma_{1}) + s^{2}\psi^{n+1}qp_{b}(\sigma_{0},\sigma_{1}) + \dots + s^{j}\psi^{n+j-1}qp_{b}(\sigma_{0},\sigma_{1})\right]$$

$$= \sum_{m=n,r=1}^{n+j-1} s^{r}\psi^{m}(qp_{b}(\sigma_{0},\sigma_{1}))$$

$$= P_{n+j-1} - P_{n-1},$$
(42)

where $P_k = s^k \sum_{m=0}^k \psi^m (qp_b(\sigma_0, \sigma_1))$. However, the series $\sum_{m=0}^{\infty} \psi^m (qp_b(\sigma_0, \sigma_1))$ is convergent, so there exists a positive real number *P* such that $\lim_{k \to \infty} P_k = P$. Letting *n* and $j \to \infty$ in the above inequality, we get

$$qp_b(\sigma_n, \sigma_{n+j}) \longrightarrow 0. \tag{43}$$

Therefore, $\{\sigma_n\}$ is a Cauchy sequence, and using the completeness property of qp_b space, it follows that there exists $w \in G$ such that

$$\lim_{n \to \infty} \sigma_n = w, \tag{44}$$

and we claim that w is the fixed point of H.

In case that the assumption (1) holds, we have $w(\sigma_n, t) \ge 1$ and we claim that

$$\frac{1}{2}qp_{b}(\sigma_{n},H\sigma_{n}) \leq qp_{b}(\sigma_{n},w),$$
or
$$\frac{1}{2}qp_{b}(H\sigma_{n},H(H\sigma_{n})) \leq qp_{b}(H\sigma_{n},w),$$
(45)

for every $n \in N$. Suppose

$$\frac{1}{2}qp_{b}(\sigma_{n},H\sigma_{n}) > qp_{b}(\sigma_{n},w),$$

$$\frac{1}{2}qp_{b}(H\sigma_{n},H(H\sigma_{n})) > qp_{b}(H\sigma_{n},w).$$
(46)

By triangular inequality in qp_b space, we have

 $qp_{b}(\sigma_{n},\sigma_{n+1}) = qp_{b}(\sigma_{n},H\sigma_{n}) + qp_{b}(w,w) \leq qp_{b}(\sigma_{n},w) + qp_{b}(w,H\sigma_{n})$ $<\frac{1}{2}qp_{b}(\sigma_{n},H\sigma_{n}) + \frac{1}{2}qp_{b}(H\sigma_{n},H(H\sigma_{n}))$ $= \frac{1}{2}qp_{b}(\sigma_{n},\sigma_{n+1}) + \frac{1}{2}qp_{b}(\sigma_{n+1},\sigma_{n+2})$ $\leq \frac{1}{2}qp_{b}(\sigma_{n},\sigma_{n+1}) + \frac{1}{2}qp_{b}(\sigma_{n},\sigma_{n+1})$ $= qp_{b}(\sigma_{n},\sigma_{n+1}),$ (47)

which is a contradiction. Therefore, for every $n \in N$, either

$$\frac{1}{2}qp_{b}(\sigma_{n},H\sigma_{n}) \leq qp_{b}(\sigma_{n},w),$$
or
$$\frac{1}{2}qp_{b}(H\sigma_{n},H(H\sigma_{n})) \leq qp_{b}(H\sigma_{n},w),$$
(48)

holds. If the first condition holds, we obtain

$$qp_{b}(\sigma_{n+1}, Hw) \leq w(\sigma_{n}, w)qp_{b}(H\sigma_{n}, Hw)$$

$$\leq \psi [qp_{b}(\sigma_{n}, H\sigma_{n})]^{\alpha} [qp_{b}(w, Hw)]^{1-\alpha}$$

$$= \psi [qp_{b}(\sigma_{n}, H\sigma_{n+1})]^{\alpha} [qp_{b}(w, Hw)]^{1-\alpha}$$

$$< [qp_{b}(\sigma_{n}, H\sigma_{n+1})]^{\alpha} [qp_{b}(w, Hw)]^{1-\alpha}.$$
(49)

If the second condition holds, we get

$$qp_{b}(\sigma_{n+2}, Hw) \leq w(\sigma_{n+1}, w)qp_{b}(H^{2}\sigma_{n}, Hw)$$

$$\leq \psi [qp_{b}(H\sigma_{n}, H^{2}\sigma_{n})]^{\alpha} [qp_{b}(w, Hw)]^{1-\alpha}$$

$$= \psi [qp_{b}(\sigma_{n+1}, \sigma_{n+2})]^{\alpha} [qp_{b}(w, Hw)]^{1-\alpha}$$

$$< [qp_{b}(\sigma_{n+1}, \sigma_{n+2})]^{\alpha} [qp_{b}(w, Hw)]^{1-\alpha}.$$
(50)

Therefore, letting $n \rightarrow \infty$, we get that $qp_b(w, Hw) = 0$, that is, w = Hw.

In case that assumption (2) holds, that is, the mapping H is continuous, we get

$$Hw = \lim_{n \to \infty} H\sigma_n = \lim_{n \to \infty} H\sigma_{n+1} = w.$$
(51)

If the last assumption (3) holds, we have $\psi H^2 w = \psi \lim_{n \to \infty} H^2 \sigma_n = \psi \lim_{n \to \infty} \sigma_{n+2} = \psi w$ and we show that, Hw = w. Suppose on the contrary, that $Hw \neq w$ since

$$\frac{1}{2}qp_b(Hw,\psi H^2w) = \frac{1}{2}qp_b(Hw,\psi w) \le qp_b(Hw,\psi w).$$
(52)

By (54), we get

$$\begin{aligned} qp_{b}(w,Hw) &\leq w(Hw,w)qp_{b}(H^{2}w,Hw) \\ &\leq \psi \left[qp_{b}(Hw,H^{2}w) \right]^{\alpha} \left[qp_{b}(w,Hw) \right]^{1-\alpha} \\ &= \psi \left[qp_{b}(\sigma_{n+1},\sigma_{n+2}) \right]^{\alpha} \left[qp_{b}(w,Hw) \right]^{1-\alpha} \\ &< \left[qp_{b}(Hw,w) \right]^{\alpha} \left[qp_{b}(w,Hw) \right]^{1-\alpha} \\ &= qp_{b}(w,Hw), \end{aligned}$$
(53)

which is a contradiction. So, w = Hw, i.e., w is the fixed point of the mapping H.

4. Application

In this section, we have discussed the existence of the solution for the nonlinear matrix equation by using interpolative Chatterjea mapping in the notion of quasi-partial b-metric space. Consider a nonlinear matrix equation as

$$\sigma = Q + \sum_{i=1}^{n} M_i^* H(\sigma) M_i, \tag{54}$$

$$Q = \sigma - M_1^* H(\sigma) M_1 - \ldots - M_n^* H(\sigma) M_n,$$
(55)

where $\mathscr{H}(n)$ denotes the set of $n \times n$ Hermitian matrices and p(n) denotes the set of $n \times n$ positive definite matrices. Here, $p(n) \subseteq \mathscr{H}(n)$, $Q \in p(n)$, and M_i is $n \times n$ matrices. Let us suppose a continuous order preserving map $H: p(n) \longrightarrow p(n)$ with H(0) = 0.

Define a trace norm $\|.\|_{tr}$ on the set (*n*) that is a complete quasi-partial b-metric space and partially ordered with partial ordering \prec , where $\sigma \prec v \Rightarrow v \prec \sigma$.

Lemma 3. If σ , $v \ge 0$ are $n \times n$ matrices, then

$$0 \le tr(\sigma, v) \le \|v\| |tr(\sigma)|. \tag{56}$$

Lemma 4. If $\sigma, v \prec I_n$, then

$$\|\sigma\| < 1. \tag{57}$$

Theorem 6. Let a nonlinear matrix equation (54) and suppose the following conditions hold:

(1) There exists $Q \in p(n)$ with

$$Q = Q + \sum_{i=1}^{n} M_i^* H(Q) M_i.$$
 (58)

(2) For all
$$\sigma, v \in p(n)$$
,

$$\sigma \le v \Longrightarrow \sum_{i=1}^{n} M_i^* H(\sigma) M_i \le \sum_{i=1}^{n} M_i^* H(v) M_i.$$
(59)

(3) There exists $\varrho \in (0, 1/2s)$ for which $\sum_{i=1}^{n} M_i^* M_i < \varrho I_n$ and $\sum_{i=1}^{n} M_i^* H(Q) M_i > 0$ such that

$$\sigma \le v \Longrightarrow \sum_{i=1}^{n} M_i^* H(\sigma) M_i \le \sum_{i=1}^{n} M_i^* H(v) M_i.$$
(60)

(4) There exists $\sigma, v \in p(n)$ and $\varrho \in (0, 1/2s)$ such that

$$\|H\sigma - Hv\|_{tr} \le \left[\frac{1}{s^2}\|\sigma - Hv\|_{tr}\right]^{\alpha} \left[\frac{1}{s^2}\|v - Hv\|_{tr}\right]^{1-\alpha}.$$
 (61)

Then, equation (54) owns a solution in $p(n) \subseteq \mathcal{H}(n)$.

Proof. Consider a quasi-partial b-metric $qp_b: p(n) \times p(n) \longrightarrow \mathbb{R}^+$ as

$$qp_b(\sigma, v) = \|\sigma - v\|_{tr} + \|\sigma\|_{tr}.$$
 (62)

Define a continuous map $H: p(n) \longrightarrow p(n)$ as

$$H(\sigma) = Q + \sum_{i=1}^{n} M_i^* H(\sigma) M_i, \tag{63}$$

for all $\sigma \in p(n)$. Then, the solution of the matrix equation (54) is the fixed point of the map *H*.

On taking, $\sigma, v \in p(n)$ with $\sigma \prec v$, then $H(\sigma) \prec H(v)$. Thus, for $qp_b(\sigma, v) > 0$. Now, (1) \longrightarrow (4) of Theorem 6 yields the following:

$$\begin{split} qp_{b}(H\sigma, Hv) &= \|H\sigma - Hv\|_{tr} = \|H\sigma - Hv\|_{1} \\ &= \|H\sigma - Hv\| + \|H\sigma\| \\ &= \|\sum_{i=1}^{n} M_{i}^{*}H(\sigma)M_{i} - \sum_{i=1}^{n} M_{i}^{*}H(v)M_{i}\| + \|Q + \sum_{i=1}^{n} M_{i}^{*}H(\sigma)M_{i}\|, \end{split}$$
(64)

$$\begin{aligned} qp_{b}(\sigma, v) &= \|\sigma - v\|_{tr} \Rightarrow \|\sigma - v\|_{1} \\ &= \|\sigma - v\| + \|\sigma\|, \\ qp_{b}(\sigma, Hv) &= \|\sigma - Hv\|_{tr} \Rightarrow \|\sigma - Hv\|_{1} \\ &= \|\sigma - Hv\| + \|\sigma\|, \\ &= \|\sigma - Hv\| + \|\sigma\|, \\ &= \|\sigma - Q - \sum_{i=1}^{n} M_{i}^{*}H(v)M_{i}\| + \|\sigma\|, \\ \end{aligned}$$
(65)

$$\begin{aligned} qp_{b}(v, H\sigma) &= \|v - H\sigma\|_{tr} \Rightarrow \|v - H\sigma\| \\ &= \|v - H\sigma\| + \|v\| \\ &= \|\sigma - Q - \sum_{i=1}^{n} M_{i}^{*}H(\sigma)M_{i}\| + \|v\|. \end{aligned}$$
(66)

From equation (64) \longrightarrow (66) and (61), we have

i=1

$$\begin{aligned} \left\| \sum_{i=1}^{n} M_{i}^{*} M_{i} \left(H\left(\sigma\right) - H\left(v\right) \right) \right\| + \left\| Q + \sum_{i=1}^{n} M_{i}^{*} H\left(\sigma\right) M_{i} \right\| \\ \leq \varrho \left[\frac{1}{s^{2}} \left\| \sigma - Q - \sum_{i=1}^{n} M_{i}^{*} H\left(v\right) M_{i} \right\| + \left\| \sigma \right\| \right]^{\alpha} \left[\frac{1}{s^{2}} \left\| \sigma - Q - \sum_{i=1}^{n} M_{i}^{*} H\left(\sigma\right) M_{i} \right\| + \left\| v \right\| \right]^{1-\alpha}. \end{aligned}$$

$$\tag{67}$$

We deduce that

$$\|H\sigma - Hv\| \le \varrho \left[\frac{1}{s^2} \|\sigma - Hv\|_1\right]^{\alpha} \left[\frac{1}{s^2} \|v - Hv\|\right]^{1-\alpha}.$$
 (68)

Thus,

$$qp_{b}(H\sigma,Hv) \leq \varrho \left[\frac{1}{s^{2}}qp_{b}(\sigma,Hv)\right]^{\alpha} \left[\frac{1}{s^{2}}qp_{b}(v,H\sigma)\right]^{1-\alpha}.$$
(69)

Since $\sum_{i=1}^{n} M_i^* H(Q) M_i > 0, \quad \text{we} \quad \text{conclude}$ that $Q \le H(Q)$. Thus, by using Theorem 4, H owns a fixed point in *p*(*n*). \Box

5. Conclusion

The significant contribution of this manuscript is to provide the existence of common fixed points that are nonunique for interpolative Chatterjea contraction mappings in the realm of quasi-partial b-metric space. Further, we have given examples to show that the new results are applicable. In metric fixed point theory, interpolative contraction is a generalization of Kannan-type contraction. Additionally, these proposed contractions can be generalized in other well-known spaces and can give new fixed point results. The uniqueness property of obtained fixed points for these mappings and their application in the study of nonlinear integral equations will be an interesting concept for subsequent work.

Complex software systems that support organizations are updated regularly, which can erode system architectures. Moreover, documentation is rarely synchronized with the changes to the software system. This creates a slew of issues for future software maintenance. To this goal, information extraction tools use exact approaches to extract entities and their corresponding relationships from source code. Such exact approaches extract all features, including those that are less prominent and may not be significant for modularization. In order to resolve the issue, this work proposes an enhanced approximate information extraction approach, namely, fact extractor system for Java applications (FESJA) that aims to automate software modularization using a fact extraction system. The proposed FESJA technique extracts all the entities along with their corresponding more dominant formal and informal relationships from a Java source code. Results demonstrate the improved performance of FESJA, by extracting 74 (classes), 43 (interfaces), and 31 (enumeration), in comparison with eminent information extraction techniques.

1. Introduction

Software systems are essential in our daily lives, businesses, and governmental organizations, and they require an updated software system to meet their functional and nonfunctional requirements. Client requests or changes in the system's environment may cause changes in requirements [1-3]. Changes deteriorate the architecture of software systems, making it difficult to maintain them. In such situations, the software system must be designed in such a way that the negative effects of modifications to the software system are kept to a minimum. Updated documentation is

required for updated software. If the documentation is outdated, the software systems need to be retired or replaced.

Reverse engineering is the first step in re-engineering, and it involves understanding the system and acquiring the necessary information for software system maintenance [4, 5]. Information can be extracted from a software system through documentation, compiled code, development team members, and source code [6]. The most reliable source of information for restoring software architecture has been observed to be source code. The reason is the most recent version of the software, and this source code will be built and eventually run, the information gathered from it is the most reliable. Information extracting from the source code of a software system, on the other hand, is a challenging task since no developer can fully know the code of a large and complex system. As a result, we need tools to automatically extract information from source code, which will help in the recovery of software architecture and the comprehension of software systems [7]. The understanding and recovery of architecture are crucial for software maintenance and evolution.

The first step in modularizing a software system is to analyze it since source code is the primary source of information for extracting artifacts. The need for a software modularization technique that transforms low-level artifacts (source code) into abstract views (high-level) [1, 5]. Two approaches can be utilized for code analysis: an exact approach and an approximate one. The exact approach utilized the parser to analyze the whole source code, whilst the approximate approach utilized it to extract the specified parts of the information. We propose a methodology for evaluating Java source code in order to discover entities and their relationships in a Java software system in this paper. The selection of an object-oriented system since it is a more realistic approach to software development. Object-oriented software systems developed in the 1990s are now legacy systems with an unstable structure due to changes made to them [5, 7]. Their documentation is either non-existent or obsolete. A comprehensive understanding of these software systems is necessary for future updates and maintenance.

The proposed system is named "Fact Extractor System for Java Application," or FESJA, which gives an approximate approach to automatic Java application software modularization. Entities such as classes, interfaces, and enumerations and their relationships (formal and informal) can be extracted using the tool. We utilized FESJA to extract formal relationships from classes in several Java software systems; interfaces and informal relationships are 74 and 43, respectively. We have extracted 31 relationships to analyze, which are divided into seven categories: folder-based, implements-based, composition-based, file-based, generality based, and router-based relationships. To the list of contributions, the following items could be added:

- (1) A framework for extraction of relationships
- (2) Introduction of enumeration is an entity
- (3) Introduction of additional formal and informal relationships

The organization of the paper is composed of the following sections. Section 2 focuses on related work. The source code entities and relationships are described in Section 3. The research methodology for the fact extraction system is described in Section 4. Section 5 discusses the experimental setup. Section 6 presents the results. Section 7 contains the outcome of the experiment as well as a discussion.

2. Related Work

In the literature, several fact extractor systems for extracting features from source code have been proposed. To

modularize software systems, Raimond and Lovesum [8] followed Anquetil and Lethbridge employed formal and informal features. They used files, routines, classes, and processes as entities. User-defined data types, procedure calls, file inclusion, macro use, and global variables are some of the formal features mentioned. Identifiers and comments are examples of nonformal features. They focused on how to modularize structured language software systems using hierarchical clustering algorithms. They came to the conclusion that identifiers provide good design results that the file has a good expert comparison, and those comments have a good expert comparison, but that bad design results and routine calls perform poorly. The authors in [9-12] proposed a method for improving the accuracy of autonomous software architecture reconstruction. The method uses a combination of graph clustering and partitioning. They considered classes as distinct entities and created eleven relationships between them. The following relationships were discovered: inheritance, implements an interface, members (A has at least one member of type B), method parameter (A has at least one method with a parameter of type B), local variable (A has a local variable of type B in a method), returned type (A has a method that returns type B), field access (A directly accesses at least one field of type B), static method call (A calls a static method of B), object instantiation (an object of type B is instant (inside A a cast to B is done). Their focus was on object-oriented systems (java).

Hussain et al. [13] adopted an agglomerative approach for clustering of structured software systems. They considered functions as entities. They took advantage of formal features like entity calling functions, global variables that entities refer to, and user-defined types that entities can access. Aghdasifam et al. [14] carried out work of software modularization using agglomerative hierarchical clustering algorithms. They targeted the structured system. They used functions as an entity. In their work, they utilized use global variables, user-specified data types, and function calls. Based on the results of the experiments, they determined that the type of feature outperforms the global and call features. Zahoor et al. [15] presented a tool called the WAFE tool (Web Application Fact Extractor) which extract features from web application. Similarly, a similar work presented by [16, 17], automate extraction dependency between web component and database resources in java web applications. The Web Page contains classes. The WAFE tool extracted the following information: a class called from a web page, a class function called from a web page, web page form submits on another web page or the same web page, web page link to another web page, web page redirect to another web page, and web page folder or directory. Custom Code Files are included in Web Pages, and Custom Code File functions are called by Web Pages. Web Pages' classes are derived from these classes. Classes derived from Web Page classes, as well as functions of classes derived from Web page classes.

Shah et al. [1] followed Abdul Qudus Abbasi's research work carried out a detailed study about features between entities. They developed a Fact Extractor that could extract twenty-six features from the source code of object-oriented systems to extract the features. Classes, structs, unions, files, folders, global functions, global variables, and macros were all considered entities by them. Class to class relationships based on inheritance, class to class relationships based on containment, class to class relationships based on genericity, class to class relationships based on member access, class to class relationships based on source files and folders, class to class relationships based on a friend, class to global functions or data relationships or macro, and global function to global function are among relationships extracted by fact extractor. An experimental evaluation of relationships for the modularization of object-oriented software systems was reported by Thakur et al. [18]. Using Abbasi's Fact Extractor [13], they retrieved the twenty-six features. Direct and indirect relationships were the two types of relationships. They also found that indirect relationships give better modularization results than direct relationships based on the experimental data

Aljarah et al. [19] improved on the work of Tzerpos and Andritso, who developed the LIMBO algorithm for software architecture recovery. They combined structural and nonstructural features to determine the usefulness of nonstructural features to the reverse engineering process. Developers' names, directory paths, lines of code, and times of the last update were among the nonstructural features they examined at. The experiments revealed that directory structure and ownership information, but not lines of code, are important factors in software clustering. They also concluded that weighing schemes are useful in breaking down software systems.

Krishnan preferred Koschke's Ph.D. thesis [20] to introduce a classification of component recovery techniques. They used several features for architectural component recovery of structured systems. The features are function calls, set (subprogram sets the value of a global variable), use (subprogram uses the value of object T), take-address-of (subprogram takes the address of object T), function parameter (subprogram has a formal parameter of user-defined data type), return (subprogram returns a value of userdefined type), local-obj-of-type (subprogram has a local object of user-defined type), actual-parameter of (object is an actual parameter in a call to subprogram), of type (S is of type T, where S is an object and T is user-defined type), same-expression (S and T occur in the same expression where S and T are objects) and part-type (S is a part type of T where both S and T are user-defined types).

Richner and Ducasse proposed an environment for generating high-level views of object-oriented systems from both static and dynamic information, and Alshuqayran et al. [21] followed suit. For modularization of a software system, they used composition, inheritance, invocation (method of sender invokes received method on one of the candidates), access (an attribute of class 1 is accessed by the method of class 2), and method (a class defines a method that belongs to another class) as well as dynamic features.

Aljarah et al. [19] proposed MULICsoft, a software clustering algorithm. For the modularization of software systems, they exploited both static and dynamic features. Source files are the objects to be clustered. Procedure calls and variable references are static features, but dynamic features on a software system are the results of profiling the system's execution, indicating how many times each file called procedures in other files during the run time. In 2003, Trifu [22] proposed a technique that combines clustering with pattern-matching, to automatically recover subsystem decompositions. For the clustering process, they used inheritance, association, aggregation, call, and access features. They also proposed a method for assigning weights to these relationships.

Rathee and Chhabra [23] used a combination of static and dynamic features to modularize java software systems. They used inheritance, implementation, containment, calls to methods, and access to variables and assignment relationships along with dynamic features for the software modularization process. Eski and Buzluca [24] presented a comprehensive comparative study of six software clustering algorithms. They developed a lightweight C/C++ source code extractor called CTSX. CTSX is built on CTags and CScope. CTSX uses CTags to extract program entities (functions, variables, and data types) and CScope to retrieve features (function calls).

Teymourian et al. [25] presented an approach for the evaluation of dynamic clustering. They used both static and dynamic features for the modularization process. For feature extraction, they used the CPPX fact extractor system. From the experimental results, they concluded that static features perform better than dynamic features. Rafi et al. [26] introduced a systematic study to categorize the critical challenges associated with best practices of software implementation for organizations and Akbar et al. [27] discussed the challenges associated with successful execution of outsource software development. Using a combined algorithm, Alanazi [28] focused on clustering software systems. Functions were considered as entities in their study, and the following features were used: function call (functions called by an entity), global variables (global variables referred to by an entity), and user-defined types (user-defined types accessed by an entity). Tjortjis [29] proposed a method for mining association rules from code in order to capture program structure and achieve a better understanding of the system. To classify code chunks as entities, they used the following characteristics: Code blocks, variables, and data types are all entitled.

Yadav et al. [30] proposed an approach for analyzing Java code. They analyzed programs and built tables using a Java code analyzer. They also used a clustering engine, which works with such tables and finds relationships between code elements. They considered files, packages, classes, methods, and parameters as entities. The relationships they used in their study include entities ID, entities Name, imported packages, inheritance, implements relationship, arguments, return value, modifier, parameter type, and parameter used.

Rathee and Chhabra [6, 23] followed Tonella presented an approach of using concept analysis for module reconstruction. Accesses to global variables, dynamic location accesses, the presence of a user-defined structured type in the signature, and the presence of a user-defined structured type in the return type are the relationships he used for module reconstruction.

3. Source Code Entities and Relationship

This section focused on entity and relationship relationships in source code. These source code entities and relationships have been created based on Java source code entities and relationships.

3.1. Entities in Java Source Code. Entities are the smallest significant elements at the architectural level [20]. They are part of the clustering process and become members of clusters during the automated software clustering and modularization process [1]. The proposed "FESJA" extracted three types of entities, these types are classes, interfaces, and enumerations.

A class and an interface can be an entity in objectoriented systems, it has been used widely in software architecture reconstruction and recovery [1, 4]. The approach used by [9] helps to create basic, fully automated tools that can help detect the core classes of a software system based on its code. The study done by [22] used a Model-Driven Engineering technique to provide support for Micro Service Architecture Recovery (MiSAR). In their work, they described an empirical study that uses manual analysis on eight microservice-based open-source projects to identify the core elements of the approach. The research helps software developers and maintainers in taking steps at the design level to create maintainable object-oriented software with classes [22, 23, 31]. "An enum type is a form of data that allows a variable to be a set of specified constants." Enums are java reference types, much as classes. We can add methods, variables, and constructors to an enum in the same way that we would in a regular Java class of Java beat version issued in 2013.

3.2. Relationships. Similarities between entities are always calculated during the modularization process based on their connections. It establishes links between the application's entities. However, the first step is to analyze feature extraction; afterward when, we applied clustering to group entities with similar features or attributes [15]. The relationship types extracted by the proposed fact extractor system, a java-based system, have been identified. Static, dynamic, informal, direct, and indirect relationships are examples of these types of relationships.

4. The Research Methodology of Fact Extraction System

The proposed methodology uses low-level artifacts (source code) to build high-level (abstract views) of the software system in the form of a Java-based Fact Extractor System. Extraction of features is the first stage in modularization, and FESJA has utilized an API named *java.util.regex* to search for necessary parts (approximated approach). Regular expressions were utilized to match patterns in this

Java API. FESJA has extracted three categories of entities, as follows:

$\bclass[\s][\s]*[_[a-z[A-Z]]][\w]*[\s]\[\s][\s][\s]]$

The regular expression above can be used to extract a class myClass{, class myClass {, class myClass<.

$\line \line \lin$

For the extraction of interfaces, the below regular expression is used.

The regular expression above, for example, can retrieve interface myInt {, interface myInt{, interface myInt<.

$\benum[\s][\s]^{[a-z[A-Z]]][\w]^{*}$

The enumerations are extracted using a regular expression.

The regular expression above, for example, can extract the enum myEnum.

The Process of fact extraction in FESJA starts with some data being uploaded, folders being extracted, and folder names that are alike being removed. After the extraction process of FESJA, the system check whether the source folder (src) exists or not. The process will end if there is no src folder. The same entity names are removed if the src file exists. Figure 1 shows the whole process of the fact extraction system, whereas Figure 2 shows entities with relationships.

5. Experimental Setup

The experiments are conducted using data sets to evaluate the relationships. These datasets are being designed and implemented using java (object-oriented methodology). JFree Chart (an open-source library for graphs and charts), JUnit (an open-source java unit testing framework), and Weka (an open-source java testing framework) compensate our dataset (Machine learning algorithm for data mining tasks). All these datasets are taken from Github and the source (https://www.grepcode.com). Entities identified by the FESJA tool in the above systems are shown below in Tables 1–4

5.1. Comparative Analysis of Intradataset. This study explores the results of multiple versions of the same data set.

5.1.1. *iText*. The statistics of the iText software system are shown in Tables 5–9. It has been concluded from the statistics that:

- (i) Class is the most important entity in the iText software system, and enumerations are not utilized at all
- (ii) Folder-based relationships, composition-based relationships, and access-based relationships are the most common relations for classes
- (iii) In comparison to file-based and access-based relationships, folder-based relationships occur frequently in interfaces

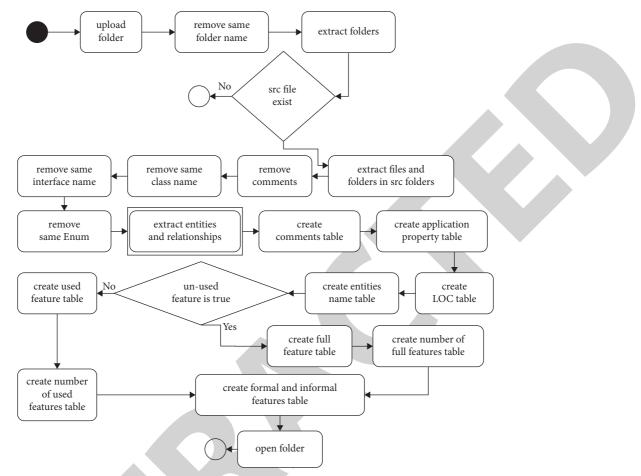

FIGURE 1: Process of fact extraction.

- (iv) Generic or outer implement relationships are not used in the iText software system
- (v) Figures 3 and 4 illustrate those formal relationships in iText are based on formal relationships of classes, while formal relationships of interfaces contribute to just 3% of formal relationships

Figures 3–7 providegraphical representations of iText software system statistics.

5.1.2. JFreeChart. Tables 10–14 summarizes statistics of the JFreeChart software system. From the statistics, it has been observed that.

- (i) Like iText the most dominant entity in the JFree-Chart software system is class while enumerations are not used at all.
- (ii) The dominant relationships for classes are folderbased relationships, composition-based relationships, and access-based relationships while implements-based relationships and inheritance-based relationships have also good frequency.
- (iii) For interfaces the used relationships are folderbased, file-based, extend based and access-based

relationships while other relationships are infrequent. Also, among used relationships, folder-based relationships have the highest frequency.

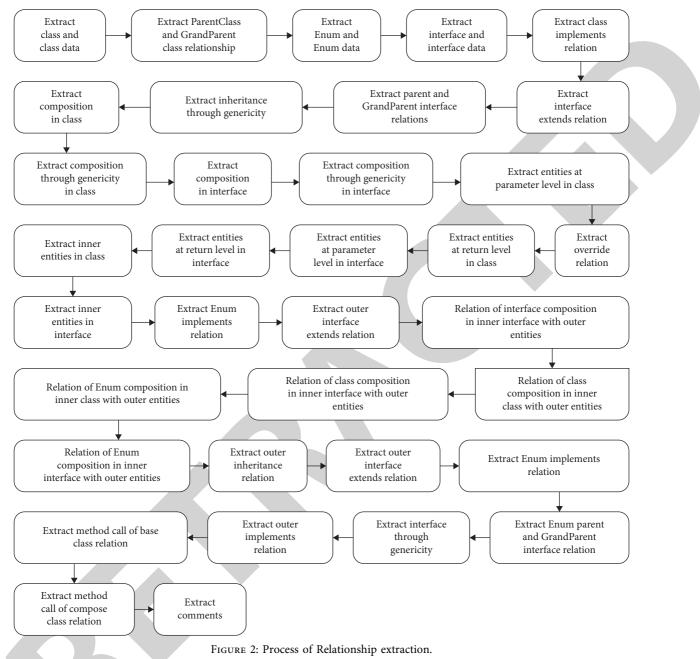

- (iv) Same as iText generics-based relationships and outer implements-based relationships are not used in the JFreeChart software system.
- (v) By comparing Figures 8 and 9 it can be calculated that in JFreeChart 92% of formal relationships are based on formal relationships of classes while 8% of formal relationships are based on formal relationships of interfaces.

Figures 8-12 provides a graphical representation of statistics of the JFreeChart software system.

Due to the absence of enumerations, no relationships for enumeration exist in the JFreeChart software system.

5.1.3. JUnit. Tables 15–20 summarizes the statistics of a JUnit software system. From the statistics, it has been observed that.

 (i) In the JUnit software system enumerations are introduced in all versions except JUnit 4.8 but have a very low frequency of occurrence.

relationships have the highest frequency of occurrence.

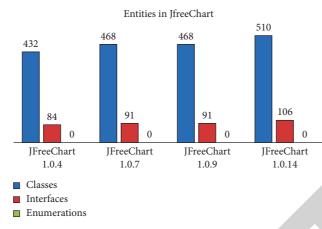

- (iv) Generics bases relationships have been introduced for classes and interfaces.
- (v) The used relationships in enumerations are folderbased, file-based, and access relationships while composition-based relationships are only used in JUnit 4.11. Among them, the dominant relationship is folder-based relation.
- (vi) By comparing Figures 13 and 14 it can be calculated that in JUnit 89% of formal relationships are based on formal relationships of classes while 10% of formal relationships are based on formal

relationships of interfaces. Similarly, formal relationships in JUnit 4.9, JUnit 4.10, and JUnit 4.11 are based on 0.57%, 0.55%, and 0.92% of formal relationships of enumerations respectively.

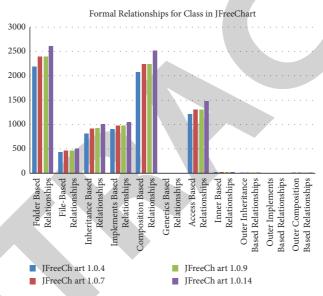

Figures 15–18 provide a graphical representation of statistics of a Junit software system.

5.1.4. Weka. Table 21–26 summarizes the statistics of the Weka software system. From the statistics, it has been observed that.

 (i) In the Weka software system the dominant entity is class while enumerations have a low frequency of occurrence.

Outer composition relationships	0	0	0	0

- (ii) For classes composition-based relationships are the most dominant relationships. Other relationships having a good frequency of occurrence are folderbased and access-based relationships.
- (iii) Folder-based relationships, file-based relationships, and access-based relationships have a high frequency of occurrence in interfaces while other relationships are either have a very low frequency of

occurrence or not used at all. Among used relationships, folder-based relationships have the highest frequency.

- (iv) Generics-based relationships are used in classes and interfaces but have very low usage.
- (v) Like JUnit the used relationships in enumerations are folder-based, file-based, access relationships, and composition-based relationships. Among them,

Formal relationships for enumeration	Junit 4.8	Junit 4.9	Junit 4.10	Junit 4.11

relationships are based on formal relationships of interfaces and, 1% of formal relationships are based on formal relationships of enumerations.

Figures 19-24 provide a graphical representation of statistics of the Weka software system.

6. Discussion and Analysis

The above Tables 5–26, we have provided the result and analysis of datasets that we have used to conduct our experiment. Different tables and graphs are provided for result analysis, and it can be concluded that the most dominant entity is class, informal relationships have higher occurrence

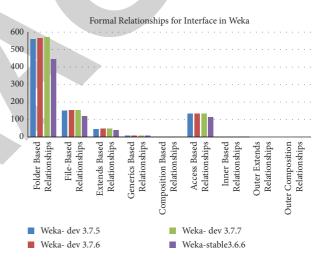

FIGURE 23: Count of formal relationships for interface in weka.

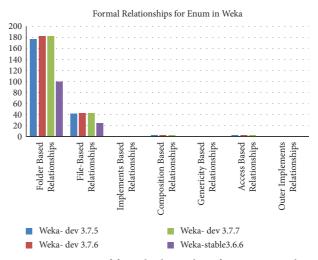

FIGURE 24: Count of formal relationships for enum in weka.

than formal relationships, and formal relationships are mostly based on formal relationships for classes. We provided a framework for the extraction of entities and relationships that exist t in a Java software system. Our Fact Extractor can extract three types of entities which are classes, interface, and enumerations. The fact extractor can be used to extract both formal and informal relationships. For classes, interfaces, and enumerations, the total number of formal relationships retrieved is 74, 43, and 31, respectively. Similarly, the fact extractor extracted a total of 73 informal relationships.

7. Conclusion

Fact Extractor System for Java Applications (FESJA) is an automatic software modularization tool, used to extract entities and relationships from java source code. The entities extracted by the fact extractor system are classes, interfaces, and enumerations. The Fact Extractor can extract both formal and informal relationships. The formal relationships are categorized into three parts which are formal relationships for classes, formal relationships for interfaces, and formal relationships for enumerations. For evaluation of relationships, we performed our experiment on four systems (dataset). The systems are iText, JFreeChart, Junit, and Weka software systems. We have provided different graphs and tables for analysis of results and presented our observations which can help researchers to carry out tasks related to software modularization process, software architecture recovery, and software clustering.

Lately, the music therapy is being used widely around the world. Henceforth, this study focuses on the analysis of the music's effect on fetal heart rate (FHR) curve. To this end, we treated people with music therapy and carried out the experiment. Firstly, 118 people with 32–40 weeks of gestational age who were expecting to give birth were invited to participate in the experiment. There was one control group and three experimental groups: 27 people were in the control group, 32 people were in the experimental group that listened to music for the first 10 minutes and did not listen to music for the second 10 minutes, 29 people were in the experimental group that did not listen to music for the first 10 minutes and listened to music for the second 10 minutes, and 30 people were in the experimental group that listened to music for all 20 minutes. In this paper, a convolutional neural network (CNN) based data processing model for fetal heart rate curves is proposed to improve the accuracy of fetal status assessment. First, the model method divides the high-dimensional one-dimensional fetal heart rate (FHR) records into 10 segments and then the characteristics of the FHR are extracted using a feature extraction method based on basic statistics. These features are regarded as input of support vector machine (SVM) and multilayer perceptron (MLP) for classification. According to the experimental results, the classification accuracies of SVM and MLP are 85.98% and 93.24%, respectively.

1. Introduction

At present, fetal monitoring mainly focuses on counting, fetal heart auscultation, and amniotic fluid pattern observation, but these methods have some limitations because the extracted information is very complex. However, since the 1960s, the large-scale development of electronic systems has made the extraction of fetal information feasible and reliable [1–3].

At present, a method called EMF is used [4, 5], which can monitor fetal information in real time and continuously and is also the most widely used method at present. With the development of artificial intelligence and the emergence of a large number of intelligent algorithms such as deep learning, we can monitor the fetus more accurately [6, 7].

Along with the study and analysis of fetal heart rate curves, numerous people have gone on to study what kind of treatments affect the data related to the characteristics of fetal heart rate curves, and music therapy is one of these tools. The discipline of music therapy was introduced to China as an emerging discipline in the late intersectional era. Although the development of music therapy in China is still in its infancy, concerned medical practitioners and researchers have been pushing its development. The crosscutting discipline was born in the United States in 1940 as a combination of music, medicine, and psychology. It was introduced to China in the late 1980s. Although the development of music therapy in China is still in its infancy, relevant medical practitioners and researchers have been promoting its development. Numerous related literature has seen the use of music therapy for psychotherapy, presurgical anxiety, postsurgical pain management and maternity treatment, and even cancer treatment. Music therapy is a form of treatment that employs the relevant properties of music to transform the patient's mind and body during the treatment process [8, 9], which is shown in Figure 1.

In this paper, the analysis of the music's effect on the FHR curve is carried out. In order to conceive the required target, we treated people with music therapy by some experiments. Section 2 of this paper debates on the topic of music therapy which is based on neural network. The MLP and SVM are also discussed in Section 2. Furthermore, the experimental subjects and methods are discussed in Section 3. And finally, the conclusion is given in Section 4.

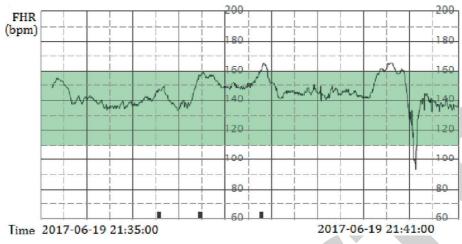

FIGURE 1: The relevant properties of music and treatment process.

2. Neural Network-Based Music Therapy

In this paper, we use a multilayer perceptron and a support vector machine to classify the features of the data, which are extracted by a statistical-based approach. These two methods are mainly used to compare the experimental results with CNNs without feature extraction. The basic concepts of multilayer perceptron and support vector machine are introduced below.

2.1. Multilayer Perceptron. The neural networks are the ability to find dependencies between different inputs. The criteria for classification of fetal heart rate curves are fixed, while physicians consider a combination of features and ratios during fetal heart rate assessment. Therefore, in order to monitor the fetus more accurately, we need to classify the extracted data, determine its weight relationship, and then train the extracted data. In the neural network, in order to improve the accuracy of the neural network, we can appropriately increase the training of the neural network, so that we cannot add too many parameters to maintain the training model. However, the disadvantage of this network is to select different parameters for different models.

This paper is a multilayer perceptron-based multiclassification algorithm, which is also often referred to as a feed-forward neural network. The multilayer perceptron has one or more implicit layers between the input and output layers, where each layer contains multiple neurons interconnected with each other by weights, which is shown in Figure 2.

For parameter initialization, a random initialization strategy is used in this paper. This method can easily avoid the dilemma of local minima. The activation function of this paper is ReLU (Rectified Liner Units), which can well solve the gradient calculation problem brought by the sigmoid activation function and can avoid the gradient disappearance problem now. The multilayer perceptron in this paper is trained using back propagation. In this paper, we use stochastic gradient descent for training and back propagation for gradient computation. The cost function used in the multilayer perceptron is the cross-entropy cost function.

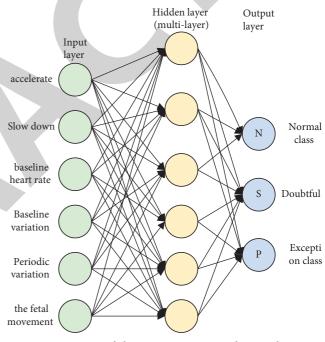

FIGURE 2: Multilayer perceptron neural network.

When the error is bigger, the gradients are greater, and the parameter W is altered faster, resulting in a faster training speed. As a result, the cross-entropy cost function's training impact is generally superior to the quadratic function's training effect.

Algorithm 1 is the basic step used by the multilayer perceptron for classification.

2.2. Support Vector Machines. Support vector machine (SVM) refers to a series of machine learning algorithms originally developed in the early 1990s by Vapnik and colleagues at AT&T. The basis of this class is essentially the Support Vector Algorithm, which is an extension of the Generalized Portrait algorithm, which was developed by Vapnik in the Soviet Union in 1963. In short, SVM classifiers are binary or discriminative models that distinguish between

Input: training set

Output: accuracy

- (1) Network initialization: randomly initialize all connection rights and thresholds in the network in the range (0, 1), given the learning rate and excitation function.
- (2) repeat
- (3) for all (x, y) do
- (4) First calculate the output of the hidden layer based on the weights and thresholds and calculate the output of the current sample;
- (5) Based on the output of the implicit layer from the previous step, the connection weights and thresholds are performed to calculate the predicted output of the BP, and the gradient term of the neurons in the output layer is calculated;
- (6) Calculate the network prediction error based on the network prediction output and the desired output; calculate the gradient term of the hidden layer neurons;
- (7) Update connection weights based on network prediction errors; update connection weights with threshold values;
- (8) end for
- (9) until the stop condition is reached;
- (10) Calculation accuracy (Softmax);

ALGORITHM 1: MLP classifier,

two types of data and thus classify them. The most basic idea in learning classification is to divide the plane, which in this paper is to find a division hyperplane in the data representation space corresponding to the fetal heart rate dataset. In this paper, we use SVC (Support Vector Classification), which is a nonlinear kernel called Radial Basis Function (RBF). If the original space is finite dimensional, i.e., has a finite number of attributes, then there must exist a highdimensional feature space to make the samples separable. Therefore, the method is applicable to the fetal heart rate dataset.

In the experiment, some of the obtained characteristics are fed into MLP and SVC, and the classification performance is calculated from the following:

$$\operatorname{accuracy} = \frac{\operatorname{prediction}}{\operatorname{actual}} \times 100\%. \tag{1}$$

2.3. Classification Results Based on MLP and SVC. First, in our experiments, we utilize the MLP algorithm. The classification accuracy is significantly improved with the number of hidden layers from 1 to 200, and the instruction instance and testing time are as well significantly increased. Furthermore, the classification accuracy is not significantly improved with more than 200 hidden layers. We adjusted the hidden layers to 150 layers to maximize efficiency and ensure accuracy, taking into consideration the training and testing duration. Iteration is the procedure of repeating of every experimental step. The numeral of iterations for the experimental guidance was 200, and increasing the quantity of iterations had little effect on the classification accuracy. Identity, logistic, tanh, and ReLU are some of the perception employed in the trials. The results of ReLU are better. Given the huge exploratory data set, the weight optimization technique used in this paper is Kingma Diederik's gradient descent optimization technique, which is more accurate than quasi-optimization methodologies in the quasi-Newton algorithm family. The training data is initially set to 0.0001.

Figure 3 depicts the experimental results. When the training dataset is too short, the consistency decreases. As the size of the training data set increases, the accuracy rate slowly increases and stabilizes.

In the SVC algorithm, we classify the data extracted from the fetus. The function of parameter *C* is to regularize the parameters. If the parameter *C* becomes larger, it means that the final variable is close to 0, which means that the result error will be larger and larger. If the parameter *C* becomes smaller, it means that the error prone of the system is better, as shown in Figure 4. According to the training results, we can know that SVC algorithm has better accuracy. In this experiment, we found that when C=1, the experimental effect is the best.

3. Experimental Subjects and Methods

In this section, the experiments are carried out to validate the proposed methods. In this regard, we first proceed with the general information and then experimental methods are described.

3.1. General Information. One hundred and eighteen people at 32–40 weeks who were on birth control from December 01, 2016, to January 31, 2017, were selected. The participating pregnant volunteers were divided into the following four groups, i.e., three experimental groups and a control group:

- (i) *Normal group*: 27 people were in the normal group (no music therapy)
- (ii) *Experimental group 1:* people listened to music for the first ten minutes and not for the second ten minutes (n = 32).
- (iii) *Experimental group 2:* people who did not listen to music for the first ten minutes and listened to music for the second ten minutes (n = 29)
- (iv) *Experimental group 3:* people who received music therapy for all twenty minutes (n = 30)

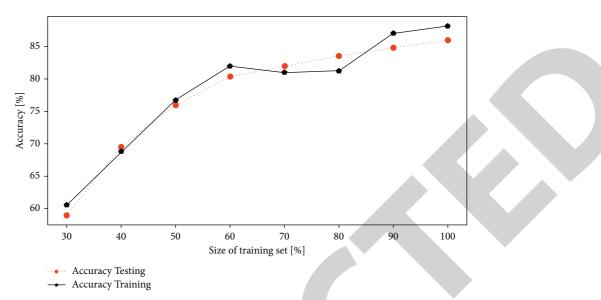

FIGURE 3: Relationship between dataset size and MLP classification accuracy.

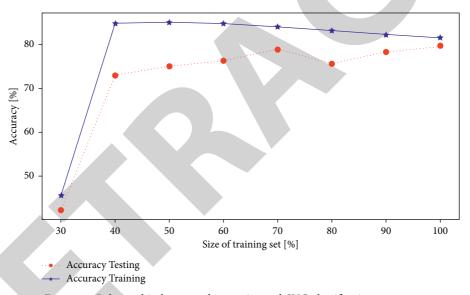

FIGURE 4: Relationship between dataset size and SVC classification accuracy.

In this paper, the data of the four groups were analyzed by ANOVA between groups, and the differences were not statistically significant (P > 0.05) for the demographic attributes of the four groups of people. The details are shown in Table 1.

3.2. Experimental Method. The pregnant volunteers came to the laboratory 2 hours after lunch and lay flat on the bed in a quiet room under the guidance of the relevant staff. After resting for half an hour, the experiment was started simultaneously on four groups of people. At the beginning of the experiment, accelerations and decelerations, baseline fetal heart rate, amplitude variation, cycle variation, fetal movement, and contractions were observed and recorded for 20 minutes without music. After measurement and recording in a quiet environment, this paper provides music therapy to the experimental group on the basis of conventional care. According to the literature of music therapy, the metronome was selected as bass tune and slow rhythm with more than 60 and less than 80 beats, and the soft music with certain relaxation effect, the experimental music in this paper was mainly fetal music, and other soft music was supplemented. And the people in the normal group had the same experimental environment as the experimental group except that there was no music therapy. After one consecutive week, the characteristic indexes of fetal heart rate curve, such as acceleration, deceleration, fetal heart baseline, amplitude variation, cycle variation, fetal movement, and contraction, were measured in the experimenter.

Therefore, we evaluate different algorithms in different networks. In particular, the aggregation layer in this study is at the tSNE position of the last two layers (conv4 3 and conv5 3), and the last convolution layer (fc7) integrates all

Index	Normal group	Experimental group 1	Experimental group 2	Experimental group 3	F P

FIGURE 5: Subsampled conv and fc features from a collection of data are embedded in tSNE: (a) conv5 3 and (b) fc7.

TABLE 2: Reliability of various hybrid models in various algorithms.

	Basic facts	Correct	Miss
Early fusion	0.8543	0.7522	0.8568
Intermediate fusion	0.8752	0.7358	0.8812
Late fusion	0.9331	0.8324	0.8879

the features of image conv and fc, as shown in Figure 5. For each scenario, the suggested aggregating layer is trained before the block of layers. Thus, for conv4, the loss is indicated by conv4 1, and for fc7, the loss is indicated by fc7. The outcome is denoted in Figure 5 which clearly verifies that aggregating the last evolutionary layer (conv5 3) produces the best performance. The performance of fc6 characteristics is similar to that of fc7.

There are only two reasons for this. One is that we add pooling in the full connection layer, but this method will compress the extracted information prematurely and affect the accuracy. Second, in the characteristic information of fc7, we compared the characteristic values from different information and added the comparison values. Although these characteristic values are very similar (Figure 5(b)), since we added conv5 in the later stage, the signal capture ability of the network is increased, and the captured information is more complex (Figure 5(a)), as shown in Section 3.1.

As can be seen from Table 2, under different algorithm conditions, the later fusion algorithm has the highest accuracy.

4. Conclusions

In this paper, a convolutional neural network-based data processing model for fetal heart rate curves is proposed to enhance fetal condition meeting the criteria. First, the model separates the high-dimensional one-dimensional FHR recordings into 10 sections and then extracts the FHR characteristics using a feature extraction technique related to basic statistics. These characteristics are then fed into support vector machine (SVM) and multilayer perceptron (MLP) classification algorithms. According to the experimental results, the classification accuracies of SVM and MLP are 85.98% and 93.24%, respectively.

Recently, the Internet financial market has developed rapidly both at home and abroad. Simultaneously, its study has also become the focus of academic circles. The financial markets have higher liquidity and volatility as compared to traditional financial markets. In view of the Internet financial market dynamic (volume and daily trading), it is proposed based on a deep neural network for fusion level time series prediction model. First, the proposed model processes the input of characteristic variables of multiple series (market macrodynamic series and multiseed series) and uses an attention mechanism to fuse the input variables in two dimensions of time and sequence feature. Second, the model also designs an optimization function based on the stability constraints of the prediction sequence, so that the model has better robustness. Finally, a large number of experiments are carried out on real large-scale data sets, and the results fully prove the effectiveness and robustness of the proposed model in the dynamic prediction of the Internet financial market.

1. Introduction

Financial forecast is the prediction, estimation, and judgment of the financial activity process and its changing trend. The essence of financial forecasting is a special financial analysis method, which is related to the future as well as uncertainty [1]. The whole forecasting process is a scientific analysis process of financial activities. The analysis process is mainly based on the actual data and past experience, uses scientific methods and means to simulate the past financial development process, and obtains the change trend of the future development process. Preconceived judgments and inferences are made about the impact of financial activities to reduce uncertainty about the future [2]. At present, financial forecasting is highly valued in academic circles, financial circles, and people's daily life. News and information on financial forecasts related to stocks, futures, and exchange rates can be found everywhere on the Internet, Television (TV) media, and newspapers. But financial activities are particularly complex and subject to many uncertainties, making it difficult to grasp future trends [3]. With regard to the current economic situation and the vigorous development of the market economy, the government must timely understand the actual situation of national economic development and financial market changes and grasp more accurate financial information.

From the 1950s to the present, information science and technology and computer network development by leaps and bounds, big data increasingly rich. People used to predict financial market prices on the basis of economics and finance, but now, they use a variety of interdisciplinary combination models to predict financial markets, which makes financial market forecasting become a unique field of financial research [4]. The research content and purpose of this article can be described: USES certain method to maximize the extraction of financial time series contains rules and information; according to the existing financial time series, information reflected to robust hybrid forecasting model is established, and by using the model to predict financial time series trend of short-term operation, as a reference of market investors' investment decisions [5].

The prediction process of the financial time series includes the following steps: data preparation, algorithm definition, self-training and learning, prediction evaluation, and optimization. The data preparation stage is mainly data acquisition, data feature selection, data denoising, time series segmentation, clustering to provide data sets for selflearning, training, prediction, evaluation, and optimization [6]. The algorithm definition stage includes determining the prediction model and calculation method. The self-training learning stage includes selecting training learning algorithm, implementing training learning process, and adjusting training learning parameters. The prediction evaluation and optimization stage includes defining feedback indicators and optimizing the model according to the prediction results [7]. The basic framework of the financial time series forecasting process is shown in Figure 1.

Most traditional financial time series prediction algorithms take the sequence of target variables as the main research object. Among them, representative technologies include the autoregressive model [8], vector autoregressive model [9, 10]. With deep learning technology development, recurrent neural network (RNN) is widely used in the sequence problem and shows a better learning ability than traditional linear model [11]; especially in the financial market dynamic prediction problem, deep learning model has good nonlinear mapping ability and strong generalization ability, thus better able to model the variable characteristics of financial markets, nonlinear associations, and time series dependencies. Among various deep neural network models, long short-term memory (LSTM) effectively solves the problem of long sequence dependence by introducing gate structure and retaining the long-term information that needs to be remembered in sequence features [12]. In addition, with the help of the powerful heterogeneous data processing ability of the neural network, some scholars designed fusion based on the structure of long- and short-term neural network. The prediction model is based on composite variable features [13]. Recent studies have found that the introduction of attention mechanism [14] into the sequence prediction problem can more effectively and quickly screen out the information that is more critical to the current task, thus further enhancing the prediction ability of the model. However, the traditional attention mechanism is mainly designed from the time dimension and cannot distinguish the different effects of multivariable time series.

Aiming at the dynamic sequence of the Internet financial market (including daily trading volume and daily trading times), this paper designs a prediction model based on longand short-term memory neural network structure. The dynamic macromodel of the overall market sequence integrates the dynamic sequence of each submarket and combines two attention mechanisms in terms of the time dimension and sequence characteristics. Due to the time dependence of modeling characteristics and the comprehensive influence of sequence input, the model is based on the sequence stability constraint optimization function so that the model has good robustness. The experimental results verified on the largescale data of real Internet financial platforms fully demonstrate the effectiveness of the method designed in this paper in predicting the dynamics of the Internet financial market. In section two of this paper, we presented some of the related

works to our research topic. In section three, we explained the neural networks and attention mechanism in much detail. In section four, the prediction model has been presented. In section five, we carried out experiments using the real data sets and analyzed their results to verify the working and efficiency of our method. In section six, the conclusion to the research is written.

2. Related Work

In financial scenarios, market information changes dynamically over time. Therefore, time series-based analysis and prediction are the focus of research in this field. This section first introduces the traditional time series prediction method, then introduces the deep learning model and attention mechanism in sequence problems related to research, and finally discusses the latest research work of sequence prediction in financial scenarios.

2.1. Traditional Time Series Prediction Method. According to the output results of the model, the traditional classical models are classified. The prediction models can be divided into random sequence model and deterministic sequence model. The traditional time series model generally needs strict mathematical principles. As the support of the model, it needs to be subject to more stringent constraints in order to use the extrapolation principle to predict future changes.

Deterministic model: In many practical application problems, the change of time series is obtained by the superposition or coupling of many factors, such as seasonal change, trend factor, periodic change, and irregularity. In order to eliminate the influence of irregular factors on time series prediction, scholars have carried out relevant research. In this kind of prediction model, the decomposition method [15], moving average method [16], and seasonal coefficient method [16] are often used to construct the time series analysis model.

Random model: Scholars in the field of statistics study time series by using random theory and find that irregular changes in time series caused by the joint action of many random factors are not completely chaotic but have certain regularity. Inspired by this phenomenon, the design of prediction models based on stochastic theory has attracted the attention of many scholars. Such models are generally based on the following procedures: First, the distribution of time series data to determine some reasonable conditions is observed and then used deductive reasoning to get a theoretical model describing the time series. If the theoretical model meets the characteristics of actual data, the actual model will be established and then used for time series analysis and prediction. Representative models of this kind include auto-regressive-moving average (ARMA) [17], auto-regressive integrated moving average (ARIMA) [18], auto-regressive conditional heteroskedasticity (ARCH) [19].

2.2. Time Series Prediction Method Based on Deep Learning. Deep neural network can obtain better representation capability than traditional methods through nonlinear

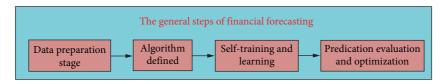

FIGURE 1: The general steps of financial forecasting.

variation of high-dimensional features. In time series prediction, the most widely used deep learning model is a cyclic neural network (RNN) [11] and long- and short-term memory neural network [12]. Cyclic neural network deals with the before and after dependence in time series data by introducing a cyclic mechanism. On the basis of RNN, LSTM introduces a "gate" structure to screen the antecedent information and selectively forget the unimportant information, so as to solve the difficulty of gradient disappearing in long sequence problems of RNN and further strengthen the dependence of long-distance information in learning time series.

2.3. Time Series Prediction Method Based on Attention Mechanism. Attention mechanism is an optimization method based on deep learning framework [20]. At present, attention mechanism has been well applied in natural language processing, computer vision, speech recognition, and other fields. Because the accuracy index of the attention model has increased significantly, many researchers have been exploring how to apply it to scenes that need more optimization details. The attention model refers to the mechanism of human visual attention. That is, when human beings obtain information, they will give priority to important information or some information they need at present.

3. Neural Network and Attention Mechanism

This section first introduces the structure and principle of long- and short-term memory neural network model and then analyzes the design and construction of attention mechanism in sequence prediction for the extraction of important information in time series.

3.1. LSTM Neural Network. Based on the classical recurrent neural network RNN, the LSTM network can selectively forget nonimportant information and strengthen the prior important information by adding a nonlinear "gate" structure inside network neurons. Therefore, LSTM avoids the inevitable gradient disappearance problem when RNN trains on long sequences. Specifically, the gate structure of LSTM is defined as follows:

$$i_{t} = \delta \Big(W_{i} x_{t} + W_{hi} h_{t-1} + W_{ci} c_{t-1} + b_{i} \Big),$$

$$f_{t} = \delta \Big(W_{f} x_{t} + W_{hf} h_{t-1} + W_{cf} c_{t-1} + \hat{b}_{f} \Big),$$

$$c_{t} = f_{t} c_{t-1} + i_{t} \tanh \Big(W_{c} x_{t} + W_{hc} h_{t-1} + \hat{b}_{c} \Big),$$

$$o_{t} = \delta \Big(W_{o} x_{t} + W_{ho} h_{t-1} + W_{co} c_{t} + \hat{b}_{o} \Big),$$

$$h_{t} = o_{t} \tanh (c_{t}),$$
(1)

~ \

where i_t , f_t , c_t , o_t , and h_t represent the hidden state of input gate, forgetting gate, memory module, output gate, and neuron, respectively. The forgetting gate and input gate structure of LSTM effectively propagates gradients by selectively preserving historical information, avoiding the problem of gradient disappearance caused by long-time sequence information. LSTM solves the problem that RNN cannot effectively learn the long-distance information dependency in time series, so it has been well applied in many time series modeling problems. The network structure of LSTM is shown in Figure 2.

3.2. Attentional Mechanism. The attention mechanism in the timing problem is mostly based on the encoder-decoder process of the deep loop network. The learning model is divided into two modules. The first is an encoder composed of a single or multilayer RNN, and the input sequence is input into the encoder according to the time relationship, which is used to learn the before and after dependencies of known sequences and the current state representation. The hidden state at the last moment is obtained and retained, which is called vector C, which retains the dynamic information of the input sequence and the current state of the sequence. Then, a decoder is also composed of neural network units with similar structure, and the encoding vector E is converted into timing sequence information with predicted length T'. The input of each moment *j* is the vector obtained by the mapping vector E with the target value sequence $(y_1, y_2, \dots, y_{i-1})$. The output value of moment *j* is the predicted value of the corresponding moment, and its mathematical expression is

$$E = F(x_1, x_2, \dots, x_T),$$

$$y_j = G(E, y_1, y_2, \dots, y_{j-1}).$$
(2)

In the traditional codec model, the context vector *E* used at each moment of decoding is fixed, and this construction does not incorporate the different principles of information concerned at different moments into the model. Researchers have further explored this problem by introducing the attention mechanism in image recognition into the sequence problem. By combining the attention mechanism with the codec structure, a sequential attention mechanism method is proposed, which is as follows:

$$E_{j} = F(x_{1}, x_{2}, \dots, x_{T}, h, h_{j-1}),$$

$$y_{j} = G(E_{i}, y_{1}, y_{2}, \dots, y_{j-1}),$$
(3)

where *F* represents the process of combining the attention mechanism with the encoder, \dot{h}_{j-1} is the implicit state of the

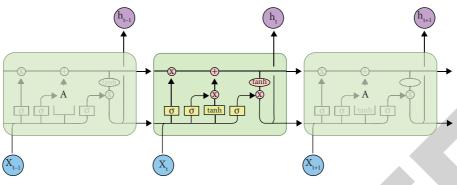

FIGURE 2: The network structure of LSTM.

previous step of the decoder, and h is the implicit state set of the encoder. Different from the traditional codec model, for each prediction moment j, the encoder gets a dynamic context vector E that pays attention to different information, so that the decoding process can pay more attention to the historical information that is more important to the prediction content of the current time.

4. Prediction Model

On the basis of the above introduction of long- and shortterm memory neural network and attention mechanism, this section presents the specific content of the integrated multitime series market dynamic prediction model proposed in this paper in detail. Let's start with the model. The framework is then introduced in detail from three aspects: multisequence input, attention mechanism design, and optimization function.

4.1. Model Framework. In this section, an attention network model based on multiple time series (MALSTM) is designed and implemented by analyzing the dynamic characteristics of the financial market. The arrows in Figure 3 represent the corresponding vectors of input and output in each module. Structures such as LSTM and full-connection layer are represented by marked rectangular boxes, and the state matrix of the hidden layer is represented by rounded rectangles. Specifically, the model first proposes an input module based on multiple time series and then designs the attention mechanism from two dimensions of time and feature. Finally, an optimization function based on the stability constraint of the prediction sequence is designed to make the prediction results more robust.

4.2. Multisequence Input. The traditional time series prediction method only considers the change of the target variable time series and does not consider the interaction of other feature sequences at the same time. However, in the dynamic analysis of the Internet financial market, its market dynamics will be affected by a number of different subcategories of market dynamics. Therefore, this paper modeled the overall macrodynamics of the market and the subsequences of multiple market categories at the same time and established multiple time series inputs.

$$x_t = [x_t^1, x_t^2, \dots, x_t^n],$$
 (4)

where x_t represents the overall input of the model at time t, and x_t^c represents the input data of the c – th subclass sequence at the current time. For example, x_t^1 represents the observed trading volume of the platform at time t. x_t^i represents the volume of transactions in a particular category (such as technology or robust items). Next, the model uses a single-layer LSTM to model the dynamic evolution process of multi-input time series. Specifically, for each time step, there are

$$h_t, c_t = \text{LSTM}(h_{t-1}, c_{t-1}), \tag{5}$$

where h_t and c_t , respectively, represent the market hidden state and memory state of the current moment t. Therefore, the dynamic representation h_t of the current multisequence can be obtained through LSTM.

4.3. Attention Mechanism Design. After multisequence LSTM input modeling, the dynamic state h_t of the market at every moment and the memory state c_t of multisequence input can be obtained. Considering that the macrodynamic modeling of the financial market requires important information in the sequential time series, the model needs to learn the key role of information at a different time for longterm change prediction. At the same time, considering the composition of the macromarket, the model should be able to automatically mine the subclass sequence that has the greatest influence on the overall macroseries prediction and further enhance the ability to forecast the market dynamics. Therefore, this paper designs two attention mechanisms from time dimension and multisequence feature dimension, respectively, to model the important influencing factors of market dynamics.

First, the attention mechanism based on the historical state of the market is constructed in the time dimension by referring to the design idea of the traditional codec model; that is, the attention degree of the hidden state at different moments is different. According to the processing process of the LSTM input module in Section 4.1, the output matrix $h = [h_1, h_1, \ldots, h_T]$ model composed of hidden layer state at each moment can be obtained, and h is further taken as the output of the encoder. Each column vector h in matrix h_t represents the market state at moment t, and it is taken as the

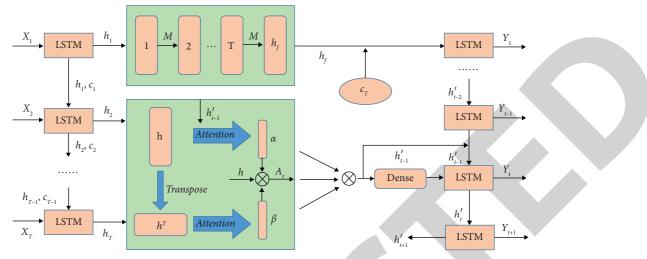

FIGURE 3: Structure diagram of multitime series attention network model.

input of the attention mechanism. Then, through formula (6), the importance of the current moment state to the prediction state y_i is calculated as follows:

$$e_{tj} = V_a^{\top} \tanh\left(W_a h'_{j-1} + U_a h_t\right),$$

$$a_{tj} = \operatorname{softmax}(e_{tj}),$$
(6)

 \dot{h}_{j-1} is decoder on one phase of the hidden states, and h_t is market status at encoder time t. W_a , U_a , and V_a^{\top} state of the encoder and decoder are hidden states attention mechanism parameter matrix, and e_{tj} represents the market state of the encoder in time t for the influence degree of the current state output prediction time j finally by softmax function, normalization of e_{tj} operation, so as to obtain the weight factor of market state at each historical moment to the current forecast, that is, the attention value in the time dimension.

In addition, considering that the macromarket dynamics are affected by the temporal changes of multiple subclasses, this paper proposes another attention mechanism based on multisequence feature dimensions. Different from the time dimension, the multisequence dimension attention mechanism needs to consider the influence of the historical coding state of each sequence on the complete macrodynamics of the market. By calculating the influence of the current sequence state on the macromarket dynamics according to all states of each sequence in the encoder sequence, the specific process is as follows:

$$e'_{k} = V^{T}_{\beta} \tanh(U_{\beta}h^{T}_{k}),$$

$$\beta_{k} = \operatorname{softmax}(e'_{k}),$$
(7)

where h_k^T represents the historical hidden state of the *k*-th subsequence, U_β and V_β^T are the parameter matrices of the attention mechanism, and β_k is the weight factor of the influence of the current sequence on the macromarket. Considering that the decoder needs to integrate the attention mechanism of time and feature dimension at the same time, a linear joint method of attention weight is designed in this

paper to obtain the total weight factor E_j of the market prediction of time *j* by historical sequence.

$$E_{j} = \sum_{t=1}^{j} a_{tj} \sum_{k=1}^{n} \beta_{k} h_{t}.$$
 (8)

Finally, LSTM combined with attention factor E_j can be used to form the decoder part of the model, so that the predicted value y_j at time *j* can be gradually obtained as follows:

$$y'_{j} = \text{LSTM}(E_{i}, h'_{j-1}, c'_{j-1}).$$
 (9)

When j = 1, $y'_1 = \text{LSTM}(E_1, h'_f, c'_T)$. Where (h'_f, c'_T) is the coded output of the historical sequence, and h'_f is the macromarket, hidden state c'_T represents the last memory state of a historical sequence.

4.4. Optimization Function Design. From the macrolevel, compared with specific financial products, the dynamic change of the financial market tends to be gentle due to the relative balance between total demand and total supply [21]. Therefore, the representation of macromarket should also tend to be stable and gentle change. In this study, a linear evolution constraint process is proposed for the representation of the output of the macromarket of the model; that is, the conditional distribution of equation (10) is adopted to satisfy the linear stationary constraint in the macrodynamic coding process of the model.

$$h_t | h_{t-1} \sim N(Mh_{t-1}, \Sigma),$$
 (10)

where *M* is the state transition matrix, whose value is optimized during model training, and Σ is the covariance matrix. It can be seen that the hidden state of the macromarket is no longer directly generated by LSTM but evolved from the final state of the market. The evolution mode is as follows:

$$h_f = M h_T, \tag{11}$$

where h_f represents the hidden state of macromarket, and h_T represents the last time step state of historical information. In order to further satisfy the stable characteristics of the macromarket dynamics, we design an optimization objective based on the linear evolution process of historical hidden states, which is used to constrain the representation of the macromarket to satisfy the linear stable characteristics in the learning process of the model. The specific optimization objective is to minimize L, and its mathematical expression is

$$L_p = \sum_{t=1}^{T-1} h_{t+1} - Mh_{t2}^2 + h_p - Mh_{T2}^2.$$
 (12)

The ultimate purpose of the model is to predict the future market state at T time by learning the historical sequence information. Therefore, accuracy is the most important optimization objective. The model selects root mean square error (RMSE), which is the most common in time series prediction at present, as shown in formula (13).

$$L_n = \sqrt{\frac{1}{T'} \sum_{j=1}^{T'} (y'_j - y_j)^2}.$$
 (13)

In order to prevent over-fitting caused by model training, the optimization objective of the equilibrium model with adjustable parameter λ in terms of its smoothness and accuracy is introduced. The final optimization function is

$$L = \min \sum_{i=1}^{N} (L_n + \lambda L_p).$$
(14)

Specifically, the model uses the RMSPROP algorithm [22] with an initial learning rate of 0.0001 to optimize model parameters until the model converges. This section proposes a decoding time model and designs a new attention structure starting with the feature dimensions to be considered and the importance of different features. Then, the model is analyzed from the macro level. Specifically, the dynamic change of the financial market is restricted by the relative balance of high total demand and total supply because the prediction process constraint is realized by driving the needle slip linear constraint function. These two improvements are the most important innovations of this model.

5. Experiments and Results

This section verifies the effectiveness of the designed model in macrodynamic prediction of the Internet financial market by constructing experiments on real data sets.

5.1. The Experimental Data. The experimental data in this paper are all from the Prosper platform, which is the second-largest Internet P2P lending platform in the world. The experiment collected a total of 1622 days of investment records of the lender recorded on the platform from April 1, 2006, to May 25, 2011. In the experiment, all data samples

were divided into training sets and test sets according to the ratio of 4:1; that is, 1297 days' transaction data were used for model training, and 325 days' transaction data were used for testing. Specifically, the daily trading volume and the number of transactions are mainly used as the research objects in the experiment. The six (risk order from high to low is "HR," "E," "D," "C," "B," and "A") dynamic sequences of the projects with different risk ratings are extracted, and the subclass sequence of the macromarket is used as the input of the model, and the historical sequence and target sequence of each sample are constructed according to the sliding window method.

In view of the incompleteness and inconsistency of the platform for collecting real data, this paper introduces the preprocessing of training set and test set, which are as follows: (1) firstly, the linear interpolation method is used to deal with the shortcomings of data set values. Linear interpolation is adopted because a missing value cannot be simply deleted in the time series problem, which will lead to the fracture of the time series index; (2) after the standardization of the original time series data, the values of time series variables with different credit ratings vary greatly. The influence of numerical series on model training and prediction results will have great interference, and direct input to the model will lead to the weight deviation of model experiment. Therefore, the data normalization method is used to map all time series variables to the [0,1] interval:

$$X^* = \frac{X - X_{\min}}{X_{\max} - X_{\min}},\tag{15}$$

where X is the original data of the sequence variable, X_{max} and X_{min} are the maximum and minimum values of the original sequence variable respectively, and X^* is the value normalized by the data, whose value range is [0, 1].

5.2. The Experimental Setup. In the experiment, the MALSTM model and all comparison methods proposed in this paper are implemented based on Python 3.5 and Tensorflow1.2.1. In all models involving LSTM structure, the number of neurons is set to 200, the dropout is 0.5, and batch size is set to 8. All the methods and programs in this paper run in the Linux environment with two 2.20GH2 Intel Xeon E5-2650 V4 CPU and four Tesla K80 GPU.

In order to compare and verify the effect of the model proposed in this paper, four methods are selected and designed as the comparative experiment, which are as follows:

- ARIMA is a classical traditional time series prediction model. The input is a single time series, which only includes the total amount of the platform or the total number of loans.
- (2) LSTM model of single sequence infusion. In the cyclic network model, LSTM is used to construct encoders and decoders, and the input of each time step only includes the total amount of platform or total number of transactions per day.
- (3) LSTM model with multisequence input (denoted as LSTM-M), which uses LSTM to construct encoders

Method	Days									
Method	1	2	3	4	5	6	7	8	9	10
ARIMA	0.064	0.063	0.064	0.064	0.065	0.065	0.066	0.067	0.068	0.070
LSTM	0.062	0.063	0.064	0.064	0.065	0.066	0.067	0.068	0.070	0.072
MLSTM	0.062	0.063	0.063	0.063	0.064	0.064	0.065	0.065	0.066	0.067
MLSTM-t	0.059	0.059	0.060	0.061	0.061	0.062	0.062	0.063	0.063	0.064
MALSTM	0.059	0.059	0.060	0.060	0.061	0.061	0.062	0.061	0.062	0.062
MALSTM-L	0.058	0.058	0.059	0.059	0.059	0.060	0.058	0.060	0.060	0.061

and decoders. Referring to the multisequence input mechanism in this paper, the input of each time step includes not only the total amount or total transaction volume of the current platform every day but also the total amount or total transaction volume of projects with different risk levels every day. The input of each time step includes not only the total amount of money or total transactions of the current platform every day but also the total amount of money or total transactions of projects with different risk levels every day.

- (4) Multisequence attention mechanism model (MALSTM-T). On the basis of LSTM-M model, the attention mechanism in time latitude is added.
- (5) Multisequence attention mechanism model (MALSTM), namely, the attention model based on multisequence input proposed in this paper. MALSTM uses only RMSE as an optimization goal in training.
- (6) The model of stationary optimization objective (MALSTM-L) is added. The linear stationary constraint proposed in this paper to the MALSTM model to optimize the model is added, and the complete optimization function designed in this paper is used.

5.3. Experimental Results and Analysis. In this paper, the total loan amount and total loan number of the platform are forecasted and compared. When the number of fixed historical days is 10, the prediction is made. The test days were adjusted from 1 to 10 to observe the performance of different models, as shown in Tables 1 and 2.

Tables 1 and 2, respectively, show the RMSE and MAE values of the total transaction amount of the platform predicted by the four algorithms in the prediction days from 1 to 10 days. It can be clearly observed from the table that the model proposed in this paper (MALSTM and MALSTM-L) is significantly superior to other comparison models. Among them, in terms of RMSE index, MALSTM and MALSTM-L proposed in this paper have achieved a maximum improvement of 2.04% and 4.18%, respectively, compared with the classical attention architecture MALSTM-T and have achieved an improvement of 4.45%–6.72% and 6.04%–8.67% compared with other models without the use of attention mechanism.

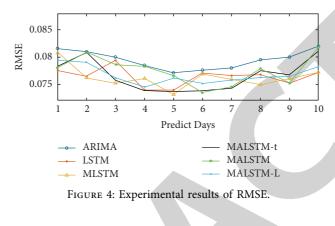

Meanwhile, in MAE index, compared with the classical attention architecture MALSTM-T, MALSTM and MALSTM-1 achieved a maximum improvement of 1.78% and 4.33%, respectively. Compared with other models without attention mechanism, MALSTM and MALSTM-1 achieved an improvement of 4.26%-8.96% and 5.82%-11.06%, respectively. These results illustrate the multi-input proposed in this paper. These results demonstrate the effectiveness and advancement of the multi-input attention deep network model proposed in this paper. At the same time, by comparing the two models proposed in this paper, it can be found that compared with MALSTM, the RMSE index, and Mae index of MALSTM-1 increase by 2.02% and 2.52%, which shows the rationality and effectiveness of the stability constraints based on the model and proves that the dynamic changes of the market tend to be stable.

Furthermore, through the horizontal analysis of the prediction results according to the time dimension, it can be found that the prediction effect of the traditional LSTM and MLSTM models decreases significantly as the prediction time goes by. For example, the accuracy of the prediction results of the two models on the 10th day decreases 14.51% and 7.21%, respectively, under the RMSE index compared with the first day. It can be seen that the multisequence input model is significantly better than the model that directly inputs the target single sequence, which proves that the relationship between multiple sequences can effectively assist the macrodynamic modeling of the market, improves the accuracy of the model for long-term forecasting results. At the same time, for MALSTM and MALSTM-L models, the long-term prediction results are only reduced by 5.41% and 4.80% under the RMSE index, which indicates that the model proposed in this paper can well model the long-term fluctuations of the macrodynamics of the financial market and also indicates the effectiveness of the stability constraint in the macroprediction of the market, which further proves the robustness of the proposed model in financial macromarket forecasting. Figures 4 and 5 show the RMSE and MAE values of the total number of transactions on the platform predicted by the four algorithms in the period from 1 to 10 days.

From Figures 4 and 5, it is clear that the MALSTM-L proposed in this paper has the largest stationarity constraint. The results further demonstrate the importance of the multisequence proposed in this paper for the prediction of macromarket dynamics and also prove the effectiveness of the multisequence attentional

mechanism and the advance of the model designed in this paper. The results in Tables 3 and 4 show the RMSE and MAE results of the market counts prediction in the next ten days.

The results show that the accuracy of the sequence prediction model increases first and then decreases with the passage of prediction time. Moreover, by comparing the variation trend of the prediction errors of the four methods, it can be found that the error of the MALSTM-L model has the smallest variation range over time, which further verifies the robustness of the model proposed in this paper in macromarket prediction and demonstrates the effectiveness of the introduced market stability constraint. In addition, in comparison, because the sequence of transaction number is less stable than that of the transaction amount, MAISTML has some cases weaker than MALSTM in the results of Tables 3 and 4. And the graphs of the results are shown in Figures 6 and 7.

6. Conclusion

Internet is the macrodynamic prediction of financial markets, and the author of this paper, first, introduces the time series of dynamic characteristics of the Internet financial markets and the prediction problem of the research background and reviews the traditional time series prediction method, based on the deep learning method and attention mechanism, and on the current temporal prediction, research has carried on the brief introduction of the financial markets. In view of the characteristics of strong liquidity and high volatility of the Internet financial market, this paper proposes a prediction model based on deep neural network fusion hierarchical multitime series learning. First, the model can process the input of multiple sequence feature variables (macrodynamic series and multiseed series) and fuse the input variables in time and sequence feature by using the attention mechanism. Second, the model designs an optimization function based on the stability constraint of the prediction sequence, which makes the model prediction have better robustness. Finally, a large number of experiments are carried out on a real large Internet financial data set. The experimental results show that the neural network time series learning prediction model based on multilevel fusion depth proposed in this paper has achieved the best prediction performance, which fully proves the effectiveness and robustness of the model in the macrodynamic prediction of the Internet financial market.

In this paper, the macrodynamic prediction of the Internet financial market is explored, and the influence of multisequence input on market dynamics is modeled. Meanwhile, the stability of the market macrodynamic is utilized to improve the accuracy of time series prediction, providing a new research idea for time series prediction. Future research can be carried out from two aspects: (1) to further explore the influence of subsequences on macrodynamics and the interaction between subsequences; (2) to explore the influence of external information, such as news media texts, on the prediction of market macrodynamics.

The purpose of this study is to introduce a new T-X family lifetime distribution known as exponentiated exponential-inverse Weibull, and we refer to this distribution as EE-IW. The new model's basic mathematical characteristics are studied. The maximum likelihood (ML) estimator (MLE) approach is used to estimate the parameters. A Monte Carlo simulation is done to examine the behavior of the estimators. Finally, a real-world dataset is utilized to show the utility of the proposed model in many industries and to compare it to well-known distributions.

1. Introduction

In statistical theory, improvement of classical distribution becomes a common practice. Probability distributions are used to model the phenomenon of natural life, but in many situations, there is a need to propose a new model for the better exploration of the data. The recent development in distribution theory stresses on new approaches for introducing new models. The new approaches depend on modifying the baseline by adding one or more parameters, to generalize the existing family. The aim of these is to provide more flexibility or to obtain better fits to the model compared with related distributions.

Barreto-Souza et al. [1] discussed the beta generalized exponential (BGE) model, Khan [2] investigated the beta inverse Weibull (BIW) model, Kundu and Howlader [3] studied Bayesian inference of the inverse Weibull (IW) model under type II censored schemes. Gusmao [4] discussed the generalized IW (GIW) distribution, modified IW distribution has been studied by Khan and King [5], Hanook et al. [6] introduced beta IW distribution, Abbas et al. [7] studied the Topp–Leone IW distribution. Elbatal and Muhammed [8] proposed Exponentiated generalized inverse Weibull distribution, and Elbatal et al. [9] introduced the beta generalized IW geometric model. Alkarni et al. [10] studied the half logistic IW. Nadarajah [11] studied the exponentiated exponential (EE) model, and also, Alzaghal et al. [12] defined a new family named "exponentiated T-X distribution". Some of its characteristics and specific instances are examined, and obtained on *t* is a nonnegative continuous random variable (RVr) *T* specified as $[0, \infty)$.

In this study, we used the T-X family approach to obtain the EE-IW model. The newly suggested model is formed by combining two models known as the T-X family. The RVr Tis the generator of the EE model and IW model. The primary goal of this study is to propose and determine the statistical features of a novel distribution (EE-IW). The hazard function and its many shapes allow it to suit various datasets.

The remainder of the paper is arranged as described in the following. Section 2 introduces the new model (EE-IW) distribution with some important different characteristics such as the probability density function (pdf), the cumulative function (cdf), the hazard function, and graphs of different values for parameters. The r^{th} moment is discussed in Section 3. The MLE estimators are introduced in Section 4. A simulation study is introduced in Section 5. A real dataset is applied in Section 6. Finally, Section 7 concludes this study.

2. The EE-IW Model

In this section, we propose the EE-IW distribution, and we derive density, cumulative, reliability, and hazard functions of the new distribution.

Let r(t) be the pdf of RVr *T*, then the exponential model of *t* is

$$r(t) = \beta e^{(-\beta t)}; \quad \beta, t > 0.$$
⁽¹⁾

The cdf and pdf of the RVr X of the IW model are

$$g(x) = \alpha x^{-\alpha - 1} e^{-x^{-\alpha}}; \quad x > 0, \ \alpha > 0,$$
(2)

$$G(x) = e^{-x^{-\alpha}}; \quad x > 0, \; \alpha > 0.$$
 (3)

Using the formula in Alzaghal et al. [12], we define the cdf for the EE-IW model for an RVr *X* as

$$f(x) = c\beta g(x) [G(x)]^{(c-1)} (1 - G^{c}(x))^{\beta-1}.$$
 (4)

Inserting (2) and (3) in (4), we get the pdf EE-IW as

$$f(x) = c\alpha\beta x^{-\alpha-1} (e^{-cx^{-\alpha}}) [1 - (e^{-cx^{-\alpha}})]^{\beta-1}; \quad x > 0, \ c > 0, \ \alpha > 0,$$
(5)

where *c*, α , and β are the shape parameters.

We can expand the above pdf given in (5) using the binomial expansion as follows:

$$f(x) = c\alpha\beta \sum_{i=0}^{\infty} (-1)^{i} {\binom{\beta-1}{i}} x^{r-(\alpha+1)} e^{-c(i+1)x^{-\alpha}}.$$
 (6)

The corresponding cdf for the EE-IW model given in (5) is

$$F(x) = 1 - \left[1 - \left(e^{-cx^{-\alpha}}\right)\right]^{\beta}; \quad \beta, \alpha, c, x > 0.$$
 (7)

The corresponding reliability of the EE-IW model has the following form:

$$R(x) = \left[1 - \left(e^{-cx^{-\alpha}}\right)\right]^{\beta}; \quad \beta, \alpha, c, x > 0.$$
(8)

The corresponding hazard function of the EE-IW model has the following form:

$$h(x) = \frac{c\alpha\beta x^{-\alpha-1} \left(-e^{-cx^{-\alpha}}\right) \left[1 - \left(e^{-cx^{-\alpha}}\right)\right]^{\beta-1}}{\left[1 - \left(e^{-cx^{-\alpha}}\right)\right]^{\beta}}.$$
 (9)

2.1. The Submodels of the EE-IW Distribution. In this section, some special cases of the proposed model are given. Table 1 introduces a brief list of the submodels.

From Table 1, it can be noticed that the EE-IW reduces to the exponentiated IW (E-IW) model when $\beta = 1$. For $\beta = c = 1$, it becomes the standard IW exponentiated (SIWE) model. For $\beta = \alpha = 1$, it reduces to the exponentiated standard inverted exponential (ESIE) distribution. For $\alpha = -1$, it becomes the EE model. For c = 1, we get the exponentiated Frechet (EF) distribution. Figures 1–4 illustrate the plots of the pdf, cdf, hazard, and reliability functions, respectively.

Figure 1 shows various shapes of the pdf for various values of the parameters, such as unimodal right-skewed.

Figure 2 shows the cdf curves for various values of some selected parameters.

Figure 3 shows the h(x) curves of the EE-IW model with various values of the shape parameters, and as the shape parameter increases, the h(x) first increase and then decrease.

Figure 4 shows the R(x) curves for different values of the parameters for distribution, and as the shape parameter increases, the R(x) decreases.

3. Basic Properties

This section investigated some important basic properties of the EE-IW model.

3.1. The Noncentral Moment. The r^{th} moment about zero of the EE-IW model is provided by

$$\mu_r' = E(X^r) = A_r \Gamma\left(1 - \frac{r}{\alpha}\right), \frac{r}{\alpha} < 1, \tag{10}$$

where

$$A_{r} = \left\{ c\beta \sum_{i=0}^{\infty} (-1)^{i} \frac{\binom{\beta - 1}{i}}{\left[c\left(i+1\right)\right]^{1 - r/\alpha}} \right\}, \quad r = 0, 1, \dots.$$
(11)

Let r = 1 in equation (10), we get the expected value or the first moment:

$$\mu'_{1} = \mu = E(X) = A_{1}\Gamma\left(1 - \frac{1}{\alpha}\right).$$
 (12)

For r = 2 in equation (10), we get the second moment:

$$\mu'_{2} = E(X^{2}) = A_{2} \Gamma(1 - \frac{2}{\alpha}).$$
 (13)

For r = 3 in equation (10), we get the third moment:

$$\mu_3' = E\left(X^3\right) = A_3 \Gamma\left(1 - \frac{3}{\alpha}\right). \tag{14}$$

For r = 4 in equation (10), we get the fourth moment:

$$\mu_4' = E\left(X^4\right) = A_4 \Gamma\left(1 - \frac{4}{\alpha}\right). \tag{15}$$

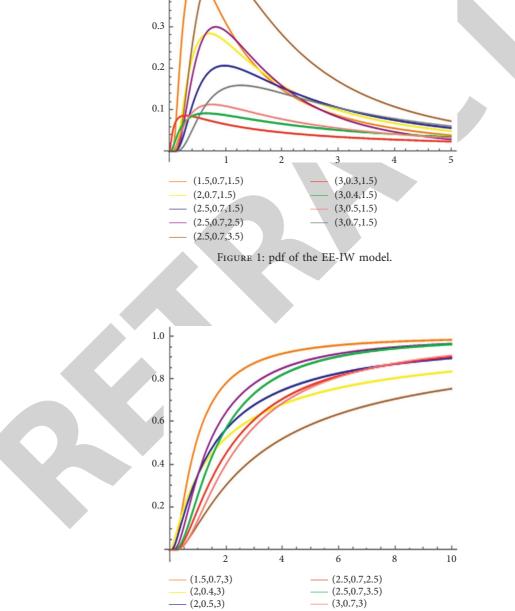

The variance of the EE-IW distribution is obtained by using both equations (12) and (13) as follows:

$$\sigma^{2} = \operatorname{Var}(X) = A_{2} \cdot \Gamma\left(1 - \frac{2}{\alpha}\right) - \left\{A_{1} \Gamma\left(1 - \frac{1}{\alpha}\right)\right\}^{2}, \alpha > 0.$$
(16)

We can define the coefficient of variation of EE-IW distribution by using both equations (12) and (13):

0.4

(2,0.7,3) - (2.5,0.7,1.5) FIGURE 2: cdf of the EE-IW model.

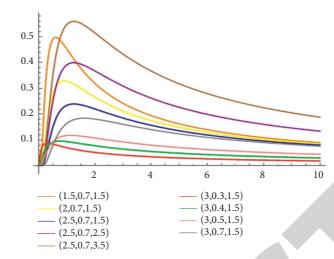

FIGURE 3: h(x) of the EE-IW model.

$$CVar = \frac{\sqrt{A_2 \Gamma (2 - 1/\alpha) - \{A_1 \Gamma (1 - 1/\alpha)\}^2}}{A_1 \Gamma (1 - 1/\alpha)}.$$
 (17)

The skewness for EE-IW is γ_3 which can be obtained by referring to the moments by using equations (12)–(14) as

$$\gamma_{3} = \frac{A_{3}\Gamma(1-3/\alpha) - 3A_{1}A_{2}\Gamma(1-1/\alpha)\Gamma(1-2/\alpha) + 2\left[A_{1}^{3}\Gamma(1-1/\alpha)^{3}\right]}{\left\{A_{2}\Gamma(1-2/\alpha) - \left\{A_{1}\Gamma(1-1/\alpha)\right\}^{2}\right\}^{3/2}}, \alpha > 0.$$
(18)

The kurtosis for EE-IW is γ_4 which can be obtained by referring to the moments by using equations (12)–(15) as follows:

$$\gamma_{4} = \frac{A_{4}\Gamma(1-4/\alpha) - 4A_{3}A_{1}\Gamma(1-3/\alpha)\Gamma(1-1/\alpha) + 6A_{1}^{2}A_{2}\Gamma(1-1/\alpha)^{2}\Gamma(1-2/\alpha) - 3\left[A_{1}^{4}\Gamma(1-1/\alpha)^{4}\right]}{\left\{A_{2}\Gamma(1-2/\alpha) - \left\{A_{1}\Gamma(1-1/\alpha)\right\}^{2}\right\}^{2}}, \alpha > 0.$$
(19)

Figure 5 shows the *mean*, *variance*, *skewness*, *and kurtosis* curves of the EE-IW model with c = 2 and for various values of α and β .

3.2. The Quantile Function. The quantile function of the EE-IW model is computed by using (7) as

$$x_q = MD = \left\{\frac{-1}{c}\ln\left\{1 - [1 - q]^{1/\beta}\right\}\right\}^{-1/\alpha}$$
 (20)

For q = 0.5 in (20), we calculate the median (MD) of the EE-IW model as

$$x_q = \text{MD} = \left\{ \frac{-1}{c} \ln \left\{ 1 - \left[1 - 0.5 \right]^{1/\beta} \right\} \right\}^{-1/\alpha}.$$
 (21)

The mode (MO) of the EE-IW model is derived by taking the first derivative of equation (5) and solving it as

$$f'(x) = c\alpha\beta x^{-\alpha-1} \left(-e^{-cx^{-\alpha}}\right) \left[1 - \left(e^{-cx^{-\alpha}}\right)\right]^{\beta-1}; x > 0, c > 0, \alpha > 0.$$
(22)

The MO for EE-IW is derived by putting equation (22) equal to 0 and solving it numerically.

Table 2 displays some outcomes for various mean values, MD, MO, standard deviation (SD), γ_3 , and γ_4 .

Table 2 shows the measures of central tendency, SD, γ_4 , and γ_3 of parameters *c*, α , and β for selected values. The statistical properties of the newly derived model were obtained numerically using Mathematica 11.2. Hence, to obtain the mean, MD, MO, SD, γ_4 , and γ_3 , we noticed the following remarks.

When the values α and β are constant for various values of *c*, the mean, MD, MO, and SD will be increased, but γ_4 and γ_3 are decreasing.

When the values c and β are constant for various values of α , the mean, MD, MO, and SD will be decreased, but γ_4 and γ_3 are increasing.

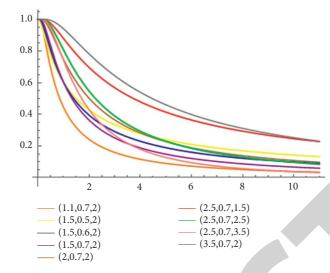

FIGURE 4: $\mathbf{R}(\mathbf{x})$ of the EE-IW model.

When the values c and α are constant for various values of β , the mean, MD, MO, and SD will be decreased, but γ_4 and γ_3 are decreasing.

4. The Maximum Likelihood Estimators

In this section, the MLE of the unknown parameters is introduced.

Let $X_1, X_2, X_3, ..., X_n$ be a random sample from the EE-IW model which has parameters c, α , and β . The likelihood function (LLF) is $L(\theta|x) = \prod_{i=1}^n f(x_i)$ where f(.) is reported in (5) and $\underline{\theta} = (c, \alpha, \beta)$. By calculating the logarithm of LLF, we have the following:

$$l = n \ln c + n \ln \alpha + n \ln \beta - (\alpha + 1) \sum_{i=1}^{n} \ln x_i - c \sum_{i=1}^{n} x_i^{-\alpha} + (\beta - 1) \sum_{i=1}^{n} \ln \left[1 - \left(e^{-cx_i^{-\alpha}} \right) \right].$$
(23)

Differentiate (23) in regard to c, α , and β and correspondingly we have

$$l_j = \frac{\partial \ln L}{\partial \theta_j} = \frac{1}{L} \frac{\partial L}{\partial \theta_j}, \quad j = 1, 2, 3.$$
(24)

From (23), we have

$$I_{1} = \frac{\partial l}{\partial c} = \frac{n}{c} - \sum_{i=1}^{n} x_{i}^{-\alpha} + (\beta - 1) \sum_{i=1}^{n} x_{i}^{-\alpha} \left\{ \frac{x_{i}^{-\alpha} \left(e^{-cx_{i}^{-\alpha}} \right)}{\left[1 - \left(e^{-cx_{i}^{-\alpha}} \right) \right]} \right\},$$
(25)

$$l_3 = \frac{\partial l}{\partial \beta} = \frac{n}{\beta} + \ln\left[1 - \left(e^{-cx_i^{-\alpha}}\right)\right]. \tag{27}$$

By setting the previous two equations (24) and (25) equal to 0 and solving them simultaneously yield the MLEs (\hat{c} , $\hat{\alpha}$) of parameters (c, α).

The MLE of the parameter β , $\hat{\beta}_{MLE}$, can be computed by using (26) as

$$\widehat{\beta}_{MLE} = \frac{-n}{\sum_{i=1}^{n} \ln\left[1 - \left(e^{-\widehat{c}x_{i}-\widehat{\alpha}}\right)\right]}.$$
(28)

We computed the asymptotic variance-covariance (VC) matrix by $I_{ij}(\underline{\theta})$, which includes the VC of estimations while

ignoring the expectation of the second partial derivative (SPD) $I_{ij}(\underline{\theta}) = E(-\partial^2 \ln \ln L/\partial \theta_i \partial j)$.

The SPD of the parameters for the EE-IW model is

$$\frac{\partial^{2}l}{\partial c^{2}} = \frac{-1}{c^{2}} - \frac{(\beta - 1)(x^{-\alpha})^{2}(e^{-cx^{-\alpha}})}{[1 - (e^{-cx^{-\alpha}})]^{2}} - \frac{(\beta - 1)(x^{-\alpha})^{2}(e^{-cx^{-\alpha}})^{2}}{[1 - (e^{-cx^{-\alpha}})]^{2}},$$

$$\frac{\partial^{2}l}{\partial a^{2}} = \frac{-1}{a^{2}} - cx^{-\alpha}(\ln x)^{2} + \frac{c(\beta - 1)x^{-\alpha}(\ln x)^{2}(e^{-cx^{-\alpha}})}{[1 - (e^{-cx^{-\alpha}})]} - \frac{c^{2}(\beta - 1)(x^{-\alpha})^{2}(\ln x)^{2}(e^{-cx^{-\alpha}})}{[1 - (e^{-cx^{-\alpha}})]^{2}},$$

$$\frac{\partial^{2}l}{\partial \beta c^{2}} = \frac{-1}{\beta^{2}},$$

$$\frac{\partial^{2}l}{\partial \beta c} = \frac{\partial^{2}l}{\partial c \partial \beta} = \frac{x^{-\alpha}(e^{-cx^{-\alpha}})}{[1 - (e^{-cx^{-\alpha}})]},$$

$$\frac{\partial^{2}l}{\partial \beta \partial \alpha} = \frac{\partial^{2}l}{\partial \alpha \partial \beta} = -\frac{cx^{-\alpha}(\ln x)(e^{-cx^{-\alpha}})}{[1 - (e^{-cx^{-\alpha}})]},$$

$$\frac{\partial^{2}l}{\partial \alpha \partial c} = x^{-\alpha}(\ln x) - \frac{(\beta - 1)x^{-\alpha}(\ln x)(e^{-cx^{-\alpha}})}{[1 - (e^{-cx^{-\alpha}})]} - \frac{c(\beta - 1)(x^{-\alpha})^{2}(\ln x)(e^{-cx^{-\alpha}})^{2}}{[1 - (e^{-cx^{-\alpha}})]^{2}}.$$
(29)

5. Simulation Outcomes

To demonstrate the theoretical outcomes of the estimated issue, simulation experiments were conducted using Mathematica 11.2 software. 1000 random samples of size n = 20, 40, 60, 80, and 100 were generated from the EE-IW model. The initial value is chosen as $c = 0.8, \alpha = 0.2, \beta = 0.5$. The accuracy of the produced parameter estimators has been evaluated in terms of their estimate for the parameters, bias (B) and mean square error (MSEr), where

$$B = \frac{\sum_{i=0}^{1000} \widehat{\theta}}{1000}, \text{ MSEr} = \frac{\sum_{i=0}^{1000} (\widehat{\theta} - \theta)^2}{1000}.$$
 (30)

The B and MSEr of the estimators for the parameters for each sample size are computed.

Table 3 shows the values of B and the MSEr for the non-Bayesian estimators when parameters \hat{c} , $\hat{\alpha}$, and $\hat{\beta}$ are unknown based on complete samples, using different sample sizes *n*.

Table 4 shows the values of B and MSEr for the non-Bayesian estimators for the parameter \hat{c} when α and β are known based on complete samples, using different sample sizes *n*.

Table 5 shows the values of B and MSEr for the non-Bayesian estimators for the parameter $\hat{\alpha}$ when *c* and β are known based on complete samples, using different sample sizes *n*.

Table 6 shows the values of B and MSEr for the non-Bayesian estimators for the parameter $\hat{\beta}$ when *c* and α are known based on complete samples, using different sample sizes *n*.

From Table 3 The values of B and the MSEr for the non-Bayesian estimators for the parameters \hat{c} are evaluated when α and β is known based on complete samples, using different sample size *n*. we note that

- (1) The biases of the estimates decrease as the *n* increases
- (2) The MSErs of the estimates decrease as the sample size increases

From Tables 4-6, we note that

- (1) The Bs and the MSErs of the estimates decrease as the *n* increases
- (2) As the sample size increases, the MSErs approaches zero

6. Modelling to Real Data

In this section, we choose different distributions of the same family and approximately from the EE-IW distribution such as exponentiated Weibull (EW) [16], EE Bur XII [17], EE [15], and exponentiated Frechet (EF) [14], and it is considered an application to three datasets. In order to choose the best model, we calculate some information criterion (IC), Akaike IC (AIC), corrected AIC (CAIC), and Bayesian IC (BIC) for all competing and subdistribution. We compute the MLEs for the EW, EE Bur XII, EE, and EF models.

6.1. First Dataset. The following dataset is presented by Almetwally [18]. The data came from a 32-day COVID-19 dataset from Saudi Arabia. The data are as follows: 0.0557, 0.0559, 0.0617, 0.0649, 0.0683, 0.0709, 0.0711, 0.0736, 0.0737, 0.0739, 0.0741, 0.0743, 0.0776, 0.0782, 0.0804, 0.0808, 0.0815, 0.0818, 0.0819, 0.0840, 0.0850, 0.0864, 0.0867, 0.0869, 0.0901, 0.0904, 0.0907, 0.0914, 0.0943, 0.0946, 0.1009, 0.1134.

Table 7 clearly shows that the EE-IW distribution fits better than the EE Bur XII, EF, EE, and EW models for this

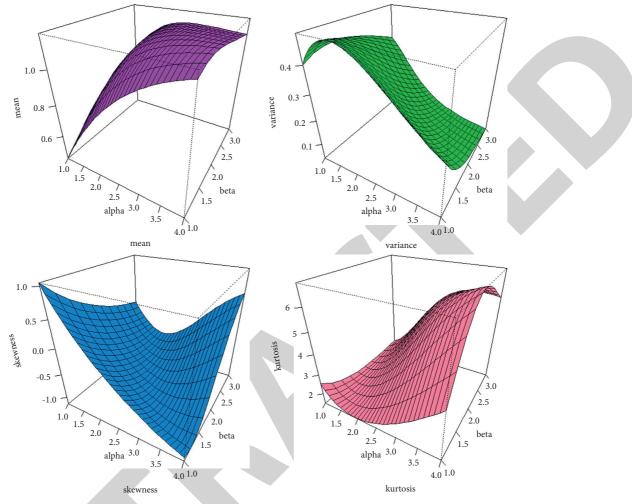

FIGURE 5: 3D plots of moments.

dataset. Also, Figure 6 illustrates the fitted empirical pdf for the dataset. Figure 6 shows that the EE-IW distribution is the best-fitting model among all the models tested, and they back up the results.

6.2. Second Dataset. The following dataset is presented by Nichols [19]. The data resulted from breaking stress of carbon fibers (in Gba). The data are as follows: 3.7, 3.11, 4.42, 3.28, 3.75, 2.96, 3.39, 3.31, 3.15, 2.81, 1.41, 2.76, 3.19, 1.59, 2.17, 3.51, 1.84, 1.61, 1.57, 1.89, 2.74, 3.27, 2.41, 3.09, 2.43,

2.53, 2.81, 3.31, 2.35, 2.77, 2.68, 4.91, 1.57, 2.00, 1.17, 2.17, 0.39, 2.79, 1.08, 2.88, 2.73, 2.87, 3.19, 1.87, 2.95, 2.67, 4.20, 2.85, 2.55, 2.17, 2.97, 3.68, 0.81, 1.22, 5.08, 1.69, 3.68, 4.70, 2.03, 2.82, 2.50, 1.47, 3.22, 3.15, 2.97, 2.93, 3.33, 2.56, 2.59, 2.83, 1.36, 1.84, 5.56, 1.12, 2.48, 1.25, 2.48, 2.03, 1.61, 2.05, 3.60, 3.11, 1.69, 4.90, 3.39, 3.22, 2.55, 3.56, 2.38, 1.92, 0.98, 1.59, 1.73, 1.71, 1.18, 4.38, 0.85, 1.80, 2.12, 3.65.

Table 8 clearly shows that the EE-IW distribution fits better than the EE Bur XII, EF, EE, and EW models for this dataset. Also, Figure 7 illustrates the fitted empirical pdf for

Retraction

Retracted: A Survey of Multimedia-Assisted English Classroom Teaching Based on Statistical Analysis

Journal of Mathematics

Received 21 November 2022; Accepted 21 November 2022; Published 5 January 2023

Copyright © 2023 Journal of Mathematics. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

Journal of Mathematics has retracted the article titled "A Survey of Multimedia-Assisted English Classroom Teaching Based on Statistical Analysis" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

With the promotion of information technology and education reform, multimedia classroom teaching, which has distinctive teaching characteristics, rich teaching resources, and vivid teaching forms, has been widely used in different classrooms, especially in English classrooms. However, there are still some problems in the application of multimedia-assisted instruction, and much work so far has focused more on language input (vocabulary, listening, and reading) of multimedia-assisted instruction, but there is limited empirical research on output (especially writing) of it. Therefore, from the perspective of statistical analysis, this empirical study investigates the effectiveness of multimedia-assisted English classroom teaching from the detailed aspects like preferred teaching activity, understanding key and difficult points, and overall performance and then formulates a multimedia writing teaching model in order to improve students' writing performance. The result shows that multimedia teaching does have superior advantages and the model enhances students' interest and scores in writing.

1. Introduction

The 21st century is an information age, and information technology makes the knowledge grow with an unprecedented trend, and the cycle of updating is also shorter and shorter [1]. Therefore, education, which is regarded as the significant means of knowledge dissemination, demands teachers to update knowledge faster and make students master the knowledge with higher efficiency. As there are some disadvantages associated with traditional method of teaching, the Chinese education system started thinking to reform their education policies. Therefore, under the premise of education reform and the change of teachers' teaching ideas, the traditional teaching methods are gradually changing to modern teaching methods [2]. Teachers realize that transferring a large amount of scientific knowledge and information to students quickly and effectively in a limited time has been the most important concern they face, even till today. With the development of information science and technology, the development of multimedia technology represented by computer has penetrated the field of education. The introduction of multimedia has

brought a new teaching mode for the diversity of classroom teaching. It not only broadens students' access to information and expands students' horizons but also enriches classroom activities and greatly improves students' interest in learning [3]. Moreover, multimedia-assisted teaching provides guidance, practice, and skill training for students' language learning, which acts as an indispensable auxiliary teaching tool.

Although multimedia has many advantages in classroom teaching, it is still in the process of practical application, and we have had problems of one kind or another. Due to the lack of hardware and software, teachers' own concepts and skills are backward, which is considered as one of the major problems associated with using multimedia in classroom teaching. Due to teachers lack of related theory, multimediaassisted foreign language teaching is still in its infancy [4]. In addition, at the beginning of exploration, the implementation of multimedia-assisted English classroom teaching is found as imperfect; henceforth, teachers are not satisfied with the application of multimedia in class.

This empirical study aims at the problems of multimedia in today's English classroom. A teaching experiment with college students as its participants will be conducted between an experimental group and a control group, and the effectiveness of multimedia-assisted English classroom teaching will be investigated and evaluated from different perspectives, and then a multimedia writing teaching model will be formulated in order to improve students' writing performance and develop other English skills, so that language learners will benefit more comprehensively from multimedia teaching and thus enhance the effective use of multimedia technology in English classroom.

The organizational structure of this paper is as follows. Section 1 mainly introduces the research background, research purpose, research significance, and the structure of this paper. The related work is discussed in Section 2. Section 3 analyses the characteristics and application mode of multimedia-assisted instruction. Based on the statistical analysis, Section 4 analyses the effectiveness of multimediaassisted English classroom teaching. Section 5 illustrates the multimedia-assisted writing model and its effect, and Section 6 summarizes the whole paper.

2. Related Work

In recent years, there are many kinds of progress in the research of multimedia-assisted instruction. Many EFL research studies suggest that integration of multimedia can activate learning atmosphere, provide plenty of information, enhance motivation and interaction, and promote teaching and learning efficiency of language skills.

It is worth affirming that multimedia-assisted English teaching has activated our classroom, which is really helpful to English learning [5]. Multimedia-assisted college English teaching has changed the traditional classroom teaching mode which is based on teacher teaching [6]. With the rapid development of information technology and network resources, the emergence of foreign language learning tools like CD-ROM, courseware, and various Apps makes it possible for students to study independently on a single machine, and they can arrange their own learning according to their own time, which is not limited by class time and place, so that students can develop personalized learning and autonomous learning.

The combination of various kinds of media information can be realized by computers, which have the characteristics of high efficiency and interactivity. Multimedia can provide learners with a real language learning environment and multisensory input in learning. Besides, it can accommodate more diverse teaching information and train students' listening, speaking, reading, and writing skills in one class at the same time. It also enables teachers to extract teaching resources from all over the world at any time in classroom, which saves teachers' time and energy to collect information, and students can quickly obtain the latest knowledge and resources, thus improving classroom efficiency.

Multimedia teaching can realize the direct interaction between teachers, students, and computers without waiting. The process becomes more convenient, and feedback can be obtained immediately through multimedia, which can cultivate students to be active learners, rather than as passive absorbers of information [7], while in class, teachers can freely choose multimedia teaching resources that are consistent with the teaching objectives and can adjust the teaching pace and content of the class at any time according to the feedback of students. This kind of efficient interaction can stimulate students' interest in learning.

The design standard of multimedia-assisted college English teaching courseware and the transformation of classroom teaching mode point out a clear way for teachers to correctly use multimedia-assisted English teaching. For example, some universities combine traditional teaching methods with multimedia teaching methods and create a network of "online learning + face-to-face tutoring", which stimulates students' interest in English learning and improves students' learning efficiency [8]. Moreover, multimedia-assisted English vocabulary teaching courseware also stimulates students' interest in English vocabulary learning and enhances the quality of vocabulary teaching [9]. In addition, research shows the display of multimedia glosses can reduce students' cognitive load and result in better performance in reading comprehension and vocabulary learning [10]. Relevant scholars believe that the combination of multimedia and English teaching can maximize the advantages of multimedia in image, sound, and animation, stimulate students' learning enthusiasm, and explore the auxiliary role of multimedia technology in teaching listening skills [11]. EFL learners' communicative competence can also get developed through the use of multimedia-assisted language instruction [12]. By watching, summarizing, and discussing YouTube online English learning resources, language learners can improve their writing fluency [13]. Also, practice has proved that the application of task-based multimedia-assisted translation teaching has significant advantages [14].

However, there is also a considerable amount of literature that discusses the challenges faced using multimedia in classroom teaching. The significant challenges include technical problems, accessibility of computers, sharing computer resources among teachers, student-teacher ratio in technological setting, outdated teaching practices, lack of advanced computer skills like designing graphics, adding animations, inserting cartoons, etc., lack of adding emotive values to the lecture, and lack of interaction between teachers and students [15, 16]. Some teachers lack adequate understanding of multimedia teaching, and they use PowerPoint presentations as an alternative to traditional way of teaching. Here, teachers copy textbook content to the slides with little explanation and expandation to the key points, which leads to knowledge overlapping and inefficiency. It was also found that student's role in such cases is passive [15, 17]. Teachers play the dominant role, and the development of students' creativity and critical thinking skills is restricted. These problems lead to serious educational issues where students slowly began to rely on computers or multimedia instead of teachers. Too much use of multimedia in classrooms distracts the attention of students as well. It was found that when using too many videos and images, students easily get distracted and lose their attention as well as presence of mind. The background effects can easily affect

the psychology of the students, and hence it will be not easy for them to choose to concentrate on the teaching content or on the videos [15, 16].

Multimedia-assisted teaching should be guided by advanced teaching theories. Nowadays, many related theories can be referred and applied, such as constructivist learning theory, Mayer's multimedia learning theory which provides an informative set of principles that can be used to create effective instructional message design, Paivio's dual coding theory, Baddeley's working memory model, and Sweller's cognitive load theory [18]. According to multimedia learning theory, teachers should use multiple simultaneous techniques such as combining narration and visuals in the presentation. Using multiple tools and techniques to deliver information will help the learners to relate themselves with the content. In fact, multimedia learning theory will help the teachers to communicate effectively with the learners. Several theories have discussed the effectiveness of using multimedia theory in classroom teaching, and one of the major contributions predominantly focuses on the use of various types of multimedia while teaching that attracts the attention of the learners and eventually impacts the effectiveness of learning [19].

To sum up, the advantages of multimedia-assisted language teaching outweigh its disadvantages, and the benefits of multimedia-assisted English teaching should be brought into full play, and problems occurred during teaching practice need to be solved. As many research studies have focused on language input (vocabulary, listening, and reading) of multimedia-assisted instruction, but limited empirical research on output (especially writing) of it, this study first investigates the effectiveness of multimedia teaching mode and then formulates a multimedia-assisted writing teaching model that aims to improve students' writing performance and develop with other language skills. The solution of writing issues will enable students to benefit more comprehensively from multimedia teaching and to further improve the advantages of multimedia teaching.

3. Multimedia-Assisted Instruction

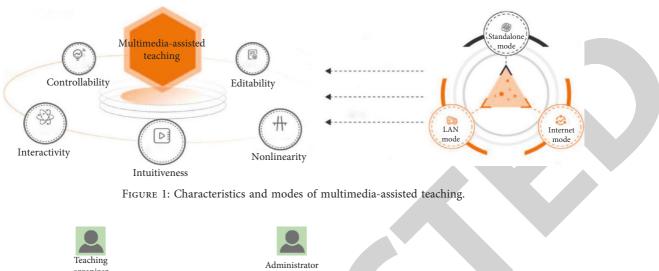

The so-called multimedia-assisted teaching is to combine graphics, images, sound, text, animation, and other media organically through computers, video display platforms, projectors, and other equipment to show the teaching content to the students in an intuitive, vivid and beautiful way, so as to enhance teaching effectiveness [20]. Because multimedia teaching is mainly composed of computer and video media, with the development of computer technology and integration technology, multimedia teaching mainly refers to computer integrated multimedia teaching, that is, using computer to gather a variety of media to realize the combination of various media. In the teaching process, teachers follow the teaching plan which is made according to the teaching objects, objectives, and content, select the appropriate teaching media, directly display the teaching content, and interact with students in real time, to achieve the effectiveness of multimedia display and real-time explanation. The composition of multimedia determines that multimedia has the following characteristics in teaching: intuition, interaction, integration, controllability, nonlinearity, and editability. Also, multimedia teaching can be roughly divided into three categories: teaching mode based on a single machine; teaching mode based on LAN; and teaching mode based on the Internet (Figure 1).

3.1. Multimedia Teaching System. Multimedia teaching system has access to massive technology, and each has powerful functions. For example, display technology, where the technology investment cost and energy consumption are relatively low, can get high-definition pictures and images, to provide users with accurate port connection [21]. Users can easily get connected, and the connection does not need to be verified, so they can log in at any time. Software technology can make complex software be used in a wide range, and its use repeatability is relatively strong. Wireless technology, such as broadband CDMA technology and infrared technology, can provide efficient broadband to users. In addition, we must mention virtual reality, which is based on a kind of virtual space, to realize the continuous expansion of the picture, giving people a sense of immersive experience, and it has been proved to be very effective in terms of ease of learning [22]. In fact, it has already been used in language learning and welcomed by users. Media application platform gives users a broad space, and it promotes the continuous development of science and technology and integration of industry technology, making the technology market become prosperous [23]. With the improvement of technology, people enjoy telemedicine, active image, high-definition television, distance teaching, interactive voice, and other services. The powerful functions enrich people's lives as well as education field.

Multimedia teaching system combines these technologies together. Usually, the main hardware of multimedia integrated classroom is composed of a computer, a video display platform, a projector, an electric screen, and a variety of playback equipment (such as video recorder, VCD or DVD player, power amplifier, etc.), which is controlled by console and computer, so as to form a scientific, coordinated, and efficient teaching demonstration system (as shown in Figure 2).

3.2. Multimedia Teaching Mode. At present, the application of multimedia technology in college English teaching mainly focuses on using online platforms and their resources. Compared with traditional classroom's "chalk + blackboard" environment, multimedia integrated classroom enables teachers prepare and display teaching content in time, helping students fully understand the corresponding teaching objectives, key and difficult points, and teaching process and saving valuable classroom time. In addition, teachers can also provide students with more information input and more opportunities to practice, so as to improve the efficiency of teaching.

Based on related theories and previous research findings, this experiment integrates and balances the teaching of five English language skills (listening, speaking, reading, writing,

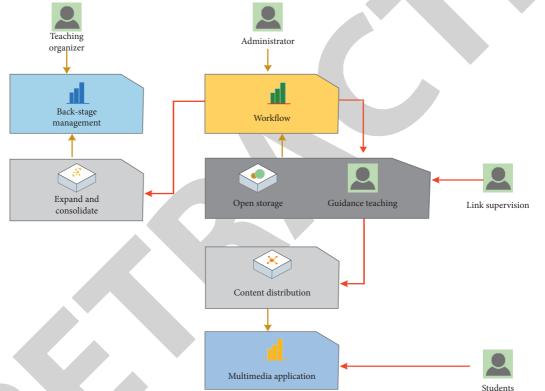

FIGURE 2: Multimedia teaching system.

and translating) and tries to make full use of multimediaassisted teaching. Figure 3 shows a general multimedia teaching mode used in this teaching experiment. From the figure, it can be inferred that the database mainly includes teaching content in the form of audio, video, pictures, PPT, texts, and so on, interactive platform, digital library, and online dictionary. Teachers and students use equipment such as laptops, mobile phones, and classroom terminal to access the data transferred through the Internet, intranet, or mobile network. Then, teaching and learning interactionrelated activities include lecturing, individual and group learning, students' presentation, etc. In this way, multimedia is used in classroom teaching, and each part of the multimedia plays a crucial role in applying the multimedia technology in and beyond classrooms as proposed in Figure 3.

Under the guidance of constructivist learning theory, college integrated English course should be student-centered in order to achieve certain teaching objectives. Teachers, as the organizers of teaching, should actively create learning situations for students that are conducive to activating their original knowledge and experience, provide corresponding counselling and practice opportunities, organize and participate in the cooperation and interactive learning among students, and evaluate the learning effect in time, so as to improve teaching [2]. As the main body of meaning construction, students should give full play to their subjective initiative, actively participate in the whole process of classroom learning with the help of teachers, complete the corresponding tasks of learning activities, carry out self-test, consolidate and improve the construction of knowledge, and improve the learning effect and efficiency [24]. Also, the

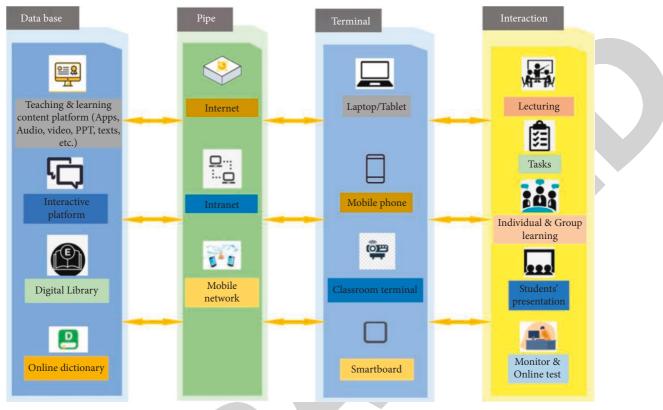

FIGURE 3: Multimedia teaching mode.

multimedia comprehensive classroom runs through the whole process of teaching experiment. The important role of multimedia-assisted instruction is mainly reflected in the clearer display and presentation of a large number of background information and language exercises, which is convenient for students to build and consolidate their knowledge and improve the efficiency of learning.

4. Evaluation of Multimedia-Assisted English Teaching

The participants of the teaching experiment were 90 firstyear undergraduates of non-English majors from a western Chinese university, who were selected and divided into two groups (45 students for each) according to their English scores of National College Entrance Examination and Pretest. Chinese was their L1 and English was their foreign language. Participants in both experimental group (multimedia methods) and control group (traditional mode, where textbooks, cards, pictures, and PowerPoint slides are often used) have the similar English proficiency (intermediate level). The experiment was conducted over a period of one academic year, and each lesson (90 minutes) was given twice per week and all participants from the two classes were taught by the same English teacher with the same textbook New Progressive College English (Books 1 and 2). In this study, the performance of two groups of participants was measured after the experiment, and questionnaire survey and examination results were employed to collect information to measure the effectiveness of multimedia-assisted

English teaching. Participants' subjective and objective evaluation is shown below.

4.1. Students' Feedback on Multimedia-Assisted English Teaching. At the end of the first semester, the author conducted a questionnaire survey of students' feedback on multimedia-assisted English teaching, and it covers many aspects which serve as the evaluation of the teaching mode. The questionnaire consists of two parts: the first part consists of 20 multiple-choice questions, each of which has five options of 5-point Likert scale. The second part is question and answer, which is open-ended and consists of five subquestions.

4.1.1. Learning Interest and Efficiency. It can be seen from Figure 4(a) that 8.7% (2% very inconsistent and 6.7% inconsistent) students think that multimedia-assisted teaching does not enhance their interest in English learning; 13% of the students think that the multimedia plays a general role in raising their interest in learning, while 45% of the students consider that their interest in learning English has been improved, and 33.3% of the students believe that they have become passionate about learning English. As it can be seen from Figure 4(b), 10.9% (2% very inconsistent and 8.9% inconsistent) of the students think that multimedia-assisted teaching does not improve their English learning efficiency; 18% of the students think it sometimes improve their learning efficiency, while 42.2% of the students believe they have greater English learning efficiency, and 28.9% of the

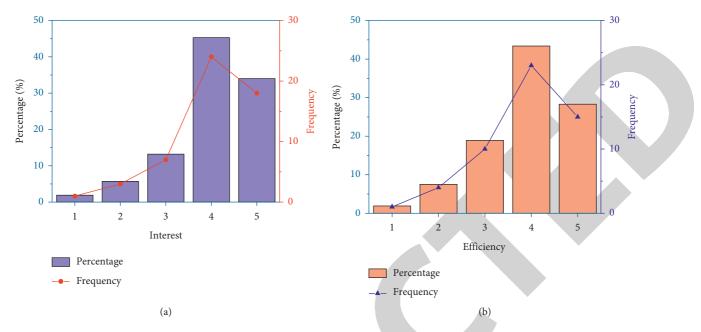

FIGURE 4: Percentage of learning interest and efficiency after multimedia-assisted teaching. (a) Interest. (b) Efficiency.

students think that their English learning efficiency has been advanced to a large extent.

4.1.2. Understanding Key Points and Having Positive *Thinking.* It can be seen from Figure 5(a) that only 4% (2% very inconsistent and 2% inconsistent) think that multimedia-assisted teaching does not help them understand key and difficult points in English learning; 15.5% of the students think that the multimedia mode can sometimes help their understanding; 45% of the students believe it helps them better grasp the key knowledge, and 35.5% of the students think that their understanding of key and difficult points has been greatly improved. It can be seen from Figure 5(b) that 6.5% of the students think that multimedia-assisted teaching does not inspire their positive thinking in English learning, and the students who think it sometimes inspires their positive thinking occupy 11.1%. However, 49% of the students believe that the teaching mode generally stimulates their thinking, and 33.3% of the students think that their positive thinking in English learning has been fully inspired.

4.1.3. Preferred Teaching Activity. The questionnaire related to this part has options ranging from Strongly Agree, Agree, Uncertain, Disagree to Strongly Disagree, and when it comes to answer the question: "Which is your favorite teaching activity?" The result shows that "open-ended task" gets the highest rank.

Open-end tasks generally have a wide range of appropriate responses, take longer time to complete, evaluate the knowledge and skills of the learners, include problemsolving strategies, allow learners to think critically, and demonstrate higher levels of understanding by providing opportunities. It also engages learners to discuss their opinions and ideas in a creative manner. Multimedia learning provides seamless opportunities for students to perform the open-ended tasks in their own original and unique manner using different multimedia technologies.

It can be seen from the survey results in Figure 6 that the vast majority of students believe that the implementation of open-ended tasks in multimedia environment has many merits. A total of 71.1% of the students think that the implementation of open-ended tasks expands their vocabulary. 75.5% say it improves reading ability, and 57.8% think it also enlarges their reading scope. In the process of preparing their works, students collect raw materials by browsing foreign websites and English books to enrich their ideas and expressions, thus virtually increasing the amount of vocabulary and reading range. The results show that 82.2% and 73.3% of the students think their expressing enthusiasm and learning enthusiasm have been stimulated, respectively, as the tasks enhance their self-confidence, while 20% and 17.8% of the students are uncertain about their reading scope and spoken English proficiency, respectively, which may be due to the reason that many students' reading range is limited by the text topic of the textbook, and some students just read aloud the prepared manuscripts, which cannot be seen as effective face-to-face communication. Meanwhile, some students' pronunciation is not accurate and their vocabulary is limited, which may cause listeners to lose interests.

4.1.4. Autonomous Learning. The questionnaire also examines whether multimedia teaching promotes learners' autonomous learning ability. Autonomy is an ability responsible for one's own learning. When learners have the ability of autonomous learning, it means that learners themselves can determine the learning objectives, contents, materials and methods, time, place, and progress of learning and evaluate learning. The questionnaire designs

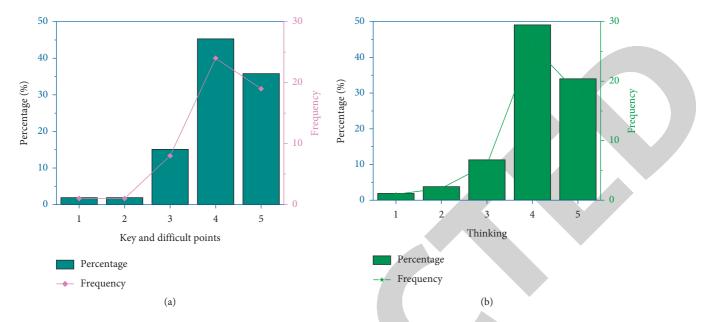

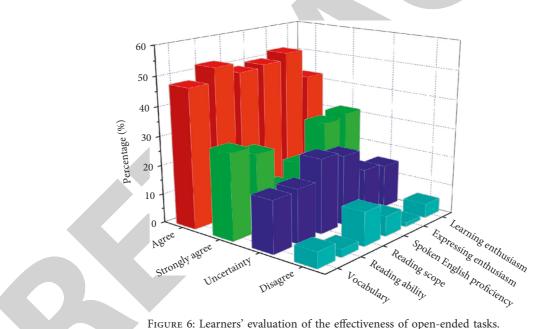

FIGURE 5: Percentage of understanding key and difficult points and having positive thinking after multimedia-assisted teaching. (a) Key and difficult points. (b) Thinking.

TIGURE 0. Learners evaluation of the effectiveness of open-ended tas

questions from the perspectives of learning attitude, learning contents, materials and methods, and reflection on learning process.

According to the relevant statistics in Figure 7, 75.6% of the students like to participate in open activities. 80% of the students think that they have freedom to choose learning materials and 71.1% think they can process the selected materials and learn in their own way. 77.8% of the students believe that multimedia teaching enhances their study ability. In the process of completing tasks, students have a certain decision-making power and can selectively absorb and reconstruct information in their own way. Overall, most students think that multimedia teaching can promote the development of autonomous learning ability. However, 25.3% of the students are uncertain about whether to reflect and modify their works, and 12% of them do not agree to reflect and modify their works. It can be seen that students fail to realize the importance of reflection in promoting autonomous learning. In the answer of open-ended questions, students generally say that due to busy homework and limited time, they cannot keep improving their works all the time. Some students think that they have spent a lot of time and energy to prepare the activity before class. Once the unit teaching is over, they will not have the motivation to modify it, so they ignore the continuous learning in the reflection stage.

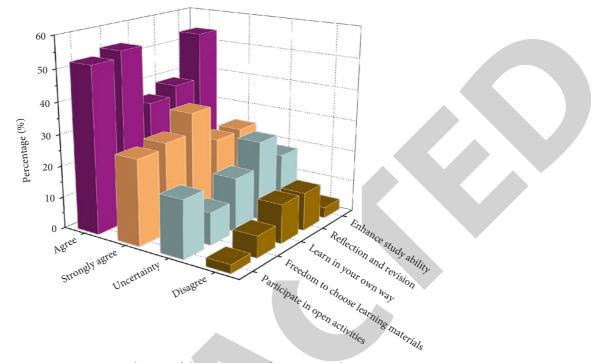

FIGURE 7: Evaluation of the promotion of autonomous learning.

4.2. Students' Performance after Multimedia-Assisted English Teaching. In order to compare the performance differences between traditional teaching and multimediaassisted teaching, this paper examines the final examination results of 90 freshmen at the end of the first semester. The final exam is adapted from a past exam paper of CET-4 (College English Test-Band 4, a large-scale English exam in China) and is divided into five parts: listening, vocabulary and grammar, reading, writing, and translation.

The distribution of students' scores in traditional teaching environment is wide and scattered, while the distribution of that in multimedia teaching environment is relatively concentrated. After obtaining the candidates' scores, the paper makes a comparison of various achievements, as shown in Figure 8.

From Figure 8, it can be inferred that multimediaassisted English teaching mode has significant advantages, among which the average difference of listening and reading is the largest (2.5 and 2, respectively). From the average of the total score, the difference between the two is 6.6. Although the average total score of traditional teaching is lower than that of multimedia-assisted English teaching mode, there is no significant difference between the items of writing and translation, which may be due to many possible reasons, including L1 influence in the process of EFL writing, limited time, inappropriate teaching model, and so forth. How to improve the effect of multimedia teaching in writing and translation is a problem that needs to be focused. As writing is considered to have a close relationship with students' academic performance and research, a new experimental writing teaching model was sketched and conducted in the second semester.

5. Modified Writing Teaching Model and Its Effect

Compared with traditional writing teaching, where the teacher often provides writing samples to students, assigns writing tasks, and checks them, the multimedia-assisted writing teaching model focused more on providing learning resources and using online writing correction websites and the teacher to help students correct their writing errors in the first semester. However, much work can be done to make full use of multimedia-assisted instruction to improve writing performance.

5.1. Modified Writing Teaching Model. Multimedia and multimodal have similar definitions. While "multimedia" is used more frequently in public/industry contexts and it emphasizes the production of a deliverable text, "multimodal" is preferred in the field of composition and rhetoric, and it focuses on design and process [25]. Multimodal composing is influenced by social semiotics and uses a variety of social symbols and multiple modes to express meaning, including but not limited to text mode, visual mode, audio mode, body mode, and space mode. Researchers like G. Kress, T. Van Leeuwen, and the New London Group all believe that all texts are expressed or embodied by linguistic, visual, or spatial modes. In other words, in order to express meaning, the authors usually use multiple modal resources to design and demonstrate their way of thinking [26-28]. In today's intelligent and digital age, text-centric communication has been replaced by image-centric and other modal-centric methods. This means that although language is regarded as the primary channel of

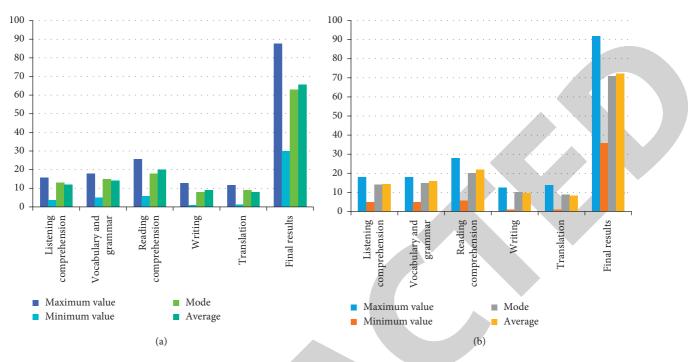

FIGURE 8: Comparison of English test results. (a) Traditional teaching. (b) Multimedia-assisted teaching.

communication, other modes such as body language, images, and sound can also express important meanings [29]. In this sense, the authors can use multiple modal resources when creating texts and express meaning or communicate with readers through multiple modal resources. Multimodal text creation is an extension of traditional writing, and it also enables writing to develop in a more diversified and multimodal direction.

Therefore, based on multimodal composing theory and findings of the teaching experiment in the first semester, like students' preference on open-ended tasks, their expressing enthusiasm and understanding of key and difficult points have been improved in multimedia environment, and a revised writing teaching model (Figure 9(b)) was constructed, which added discussion section before writing and summary writing section after learning each text. Other major differences lie in a clear closed-learning loop, multiple modification, and teacher guiding practice which aims at improving students' writing accuracy instead of too much reliance on students' autonomous learning. The model was hoped to better satisfy students' learning need, suit their major, and improve their writing performance.

5.2. Students' Performance after Multimedia-Assisted EFL Writing. According to questionnaire survey, 75.6% students think teacher guiding practice, especially imitating sentence patterns, is their favorite writing activity, for it gives them a sense of security that at least one-third or a half of the sentence is correct, which indicates that they value accuracy. For instance, after watching the video clips and reading the novel *Pride and Prejudice* written by Jane Austen, students chose the first sentence of the novel as a good sentence pattern—"It is a

truth universally acknowledged that a single man in possession of a good fortune must be in want of a wife" [30]. Then, the teacher guides students to imitate the sentence pattern to write their own sentences relating to the writing topic—How to conserve water? Here are the examples of students' writing: "It is a truth universally acknowledged that dry areas must be in want of water" and "It is a truth universally acknowledged that desalination of seawater is very expensive." They are more than happy to have the ability to use the same sentence patterns in various contexts properly.

Furthermore, 82% of students like multimodal writing and believe that it arouses their interest in writing for it helps learners relate themselves with the writing content and integrates English learning, their major, creativity, online resources, autonomous learning, and so forth in a whole package. Students use various software programs (some related to their majors) to design pictures, headings, and instructions, take notes on a cognitive map, type in text, check their writing, and record and send their voices narrating what they had written. Figure 10 shows students' multimodal writing examples in response to the writing task—design a useful machine that helps to protect the environment.

In addition, all the writings of the final examination of the second semester were evaluated by two teachers within two rounds with the four scoring criteria of IELTS: response to the task, grammatical range and accuracy, lexical resource, and coherence and cohesion. From the average writing score, the difference between the two is 1 (total of 9 points), which showed a relatively significant improvement in their writing within multimedia-assisted model. Also, the students reported that they would like to continue using this teaching method in future.

Journal of Mathematics

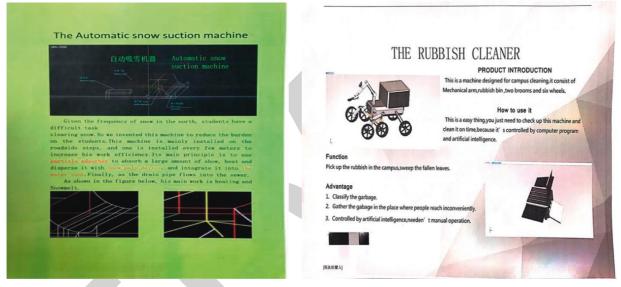

FIGURE 10: Students' writing examples (majored in Mechanical Design).

6. Conclusion

This paper evaluates multimedia-assisted English teaching from different aspects, and it proves that multimedia-assisted language learning provides authentic learning resources, cultivates learner motivation, complements traditional curriculum, and increases better learning outcomes. Furthermore, it is also found that multimedia teaching can significantly improve students' listening and reading ability, which makes the total English score of multimedia teaching group obviously higher than that of traditional teaching group. However, there is no significant difference between multimedia teaching and traditional teaching methods in writing and translation after one semester's experiment, but the study continues to adjust and apply a new writing teaching model in the second semester, which later shows that it better enhances students interest in writing and further improves the advantages of multimedia teaching. Due to time limitations, the study only involved overall writing scores rather than detailed comparison of vocabulary, sentence length, type of errors, etc. between the two groups of writing, which may

be examined in detail in the future. Multimedia classroom teaching is a complex teaching process. The development and evaluation of all aspects of multimedia classroom teaching needs long-term research and practice. We should clearly realize that no matter how advanced multimedia technology is and how helpful it is to English teaching, it is only a teaching aid. To achieve real success in English classroom teaching, we must give full play to teachers' leading role and students' subjectivity. It is believed that through our efforts, multimedia-assisted English teaching will promote the steady development of English teaching towards a better direction.

In view of the core process data such as temperature and humidity of the tea product packaging process and the automatic control operation parameters of the production line, this paper designs a smart tea product packaging 5G Internet of Things gateway system, which realizes the 5G Internet of Things onsite monitoring and remote monitoring of the tea product packaging production line equipment. The design and implementation of the 5G Internet of Things gateway system are divided into three aspects, namely, 5G Internet of Things gateway configuration design, data communication protocol conversion. First, the 5G Internet of Things gateway configuration is to design the relevant control information of the tea processing production line equipment and complete the configuration storage of the PLC controller; secondly, the data communication protocol conversion is to pass the Modbus/TCP OPC standard to transfer the collected 5G Internet of Things. The sensor data undergoes unified standardized conversion, and then the standardized converted data is sent to the database and server using the MQTT protocol; the data processing of the 5G Internet of Things gateway system is the design of the internal data of the 5G Internet of Things gateway. Finally, the test was carried out and the results were obtained, which proved that the designed 5G Internet of Things gateway system is useable, reliable, has good stability and scalability, and provides an important solution for the construction of smart tea product packaging in the industry. The tea product packaging system based on 5G Internet of Things technology compiles electronic production management files for tea garden production, tea picking, tea processing, tea packaging and other links in accordance with the requirements of the national agricultural product quality and safety related systems and industry standards, and has become the traceability of tea quality The recorded important production management information provides important information support for the traceability of the whole process of tea.

1. Introduction

In recent years, 5G Internet of Things technology has been widely used in agriculture, and its advantages such as advancement and intelligence have played an important role in promoting agricultural modernization [1]. In the construction of the tea quality traceability system, 5G Internet of Things technologies such as sensors, RFID, QR codes, and wireless sensor networks are integrated and applied to tea planting, processing, storage, packaging, sales and other links to realize intelligent traceability information collection

and processing can effectively improve the credibility and efficiency of traceability, which greatly promotes the quality of famous and high-quality tea in tea enterprises, and is of great significance to the expansion of the brand influence of tea enterprises [2–4]. Smart tea product packaging is the intelligent development direction of the tea processing industry and an important part of the Industry 4.0 smart factory. At present, most tea product packaging is still based on the construction of automated production lines, using the PC-PLC system, that is, using the PC in the control room of the tea product packaging to realize the PLC control system and the collection and storage of sensor data through configuration software And monitoring has not realized the true 5G Internet of Things and cloud data storage and computing services [5–7].

The packaging process of tea products is very demanding on the environment. The existing tea product packaging factories are generally PC-PLC systems, which collect and upload real-time data through PLC chips or other types of chips, and store them in the local area network, which is not convenient for the staff to understand the tea. The product packaging environment can be viewed in real time and remotely monitored. Therefore, the application of 5G Internet of Things systems to tea product packaging will also become a trend in our research. As a bridge between sensing devices and traditional network transmission, 5G Internet of Things gateways play a very important role in 5G Internet of Things systems [8]. The 5G Internet of Things gateway for smart tea product packaging obtains sensor data such as temperature and humidity and control data such as forward rotation and reverse rotation in the tea product packaging equipment, and then uploads them to the local database and network server. At the same time, the 5G Internet of Things gateway can monitor various data on the packaging of smart tea products and play a key role in the subscription and publishing process. This is of great significance for improving the quality of tea, the total amount of processing, reducing the cost of tea production, and building a smart tea processing plant [9].

This article introduces 5G Internet of Things technology to agriculture, realizes the integration of 5G Internet of Things technology and agricultural technology, and specifically applies it to agricultural production, operation, management and services, thus forming the 5G Internet of Things for agriculture. It uses various sensors, sensor networks, and the Internet to collect and transmit agricultural production, processing, and circulation information, and then uses a back-end software platform to process massive agricultural information, so as to realize the entire process of agricultural production monitoring and scientific management, thereby achieving intensive agricultural production, goals of high quality, high yield, ecology and safety. Based on the assessment of the current platform design approaches, a simulation platform was constructed. The platform utilises an event scheduling system to realize the operation of the complete simulation process, and has the features of high simulation accuracy. At the same time, the platform employs script configuration files and text output files, which can accomplish easy creation of simulation scenarios and quick verification of simulation results, and has the benefits of excellent scalability and high repeatability. The agricultural product quality traceability system uses 5G Internet of Things technology to collect real-time information data about agricultural product planting, processing, warehousing, packaging and other environments and transmits it to the Internet traceability information management platform through the network. Massive data transmission and sharing are available for consumers, enterprises, and consumers. The government provides support for product traceability.

2. Related Work

The 5G Internet of Things uses RFID, various sensors, 5S technology (remote sensing technology, global positioning system, geographic information system, expert system, decision support system) and other sensing devices to connect objects with the Internet and process the collected data Analysis to achieve a high degree of integration of things and things, people and things, in order to achieve the purpose of precise management and real-time control [10].

Ding [11] takes Nongken tea as the research object, conducts research on the quality traceability system of tea, and applies 5G Internet of Things technology to tea growth, tea product packaging and tea sales. Users can query product information through the terminal. Based on the perception layer, transmission layer, and control layer of the 5G Internet of Things system, Vu [12] realized the traceability, planting, environment, tea processing and sales management monitoring of the tea platform, and explored and analyzed the network protocols, Issues such as interactive interfaces. Nasrallah [13] takes Anhui tea as the research object, using 5G Internet of Things, wireless communication and big data technologies to design a unified platform based on SOA architecture to achieve comprehensive monitoring and management of tea, effectively improving the production level of related companies and marketing capabilities. Aiming at the problems of the 5G Internet of Things gateway system not reaching the unified standard and the easy construction of the wireless sensor network, communicates through multiple remote communication modes such as GPRS, Wi Fi, and Ethernet, and uses the python integrated Sqlite3 as the embedded database. Indrawan [14] lowered network maintenance costs by using FPGAs to simulate and evaluate the frame format conversion and address mapping between Ethernet and FC in order to establish a smooth connection and protocol conversion between FC and Gigabit Ethernet. Wan [15] extends the multi-network information architecture using software-defined approaches. Hierarchical 5G Internet of Things software-defined controllers in the feedback intermediate device can not only reduce link congestion, realize the scheduling of various business flows, but also improve the current network operating conditions and algorithm performance to achieve full optimization of the network's performance. Additionally, two distributed energy management research and development systems that are suited for smart city scenarios have been developed. The platform has a wide range of use, supports a large scale of network business, and can realize resource sharing and complete the interaction between heterogeneous Internet of Things devices.

Some scholars have integrated 5G Internet of Things technologies such as RFID, sensors, ZigBee wireless sensor network, GPS, distributed data storage and processing based on cloud computing, data mining and knowledge discovery, artificial intelligence, through the breeding and transportation of pigs. The collection, storage, processing and application of all information from slaughter, processing to sales can provide consumers, corporate customers and the government with product tracking, information query, departmental supervision, industry early warning and other services [16]. At the same time, it implements refined management of agricultural products and livestock products from the source of production to the consumer market, records the quality and safety information of growers and farmers throughout the process, provides effective agricultural product quality and safety supervision and management mechanisms and methods for the agricultural and animal husbandry departments, and provides a variety of traceability information inquiries to facilitate consumers' inquiries. With the help of RFID technology, the researcher has carried out the development of information transmission carrier, information recording and exchange equipment, as well as the construction of information exchange and transmission platform, and has developed and established the traceability code, traceability carrier, and traceability equipment "Trinity" of agricultural product quality and safety traceability system. They introduced a differential algorithm to solve the minimum life cycle, so that the routing node selects the cluster with the longest life cycle to communicate, and through GAThe PSO method uses cluster nodes to identify the best route. Due to its role as part of the 5G Internet of Things, a 5G Internet of Things gateway takes on a role of merging perception networks and communication networks, allowing for smooth connections between the perception layer and network layer [17, 18]. An effective security system must be built for 5G Internet of Things gateways, which must have comprehensive access capabilities for detecting networks and nodes as well as extensive administration capabilities. Increasing user privacy is simply one aspect of the widening reach of information perception, which is closely linked to environmental monitoring, production, and life safety. The above improvements aimed at energy consumption have made ZigBee wireless communication technology a big step forward. For today's society where resources are scarce and green development is emphasized, it has high research value [19, 20].

3. Collection of Inheritance Characteristics and Design Model Construction of Tea Product Packaging Art Form Based on 5G Internet of Things Technology

3.1. 5G Internet of Things Technology Level Nesting. The 5G Internet of Things technology is an important part of the information age, and is a carrier of information based on the Internet and traditional communication networks. With the rapid development of sensor technology, communication technology, "Internet +" information technology, and the perfect integration of Internet of Things technology, it is applied to tea product packaging to strengthen the

information management, control and lean production process in the tea product packaging process. A high-efficiency and high-quality smart tea product packaging has been established, and its structure is shown in Figure 1.

The 5G Internet of Things gateway transfers the collected data information through the MQTT proxy message, realizes the conversion of Modbus to MQTT protocol, and transmits the data of the wireless sensor network to the server on the Internet, so that users can monitor the unified format of different device modules. The human-computer interaction equipment provides a simple and efficient human-machine interface. By obtaining data from the server and transmitting the user's operating instructions to the server, the user's real-time and remote query and operation functions are realized.

$$p(x(1), x(2), \dots, x(n)) = \prod_{i=1}^{n} p\{x(n) | x(n-i+1)\},$$

$$C = \frac{2 * (p(x) * p(n))^{1/2}}{(p(x) + p(n))}.$$
(1)

The tea product packaging tea machine equipment is equipped with a mechanical sensing layer that is made up of sensor equipment and PLC modules. The tea machine's environmental sensor data must be classified and sent to the higher 5G Internet of Things gateway system before it can be used. The sensor is in charge of gathering the information. The PLC module is in charge of translating data into the standards needed by 5G Internet of Things gateways, and it makes use of multi-threaded data processing to assure data transmission consistency and dependability.

$$f(x) = x(i) + \frac{x(i) * x(j)}{x(i) + x(j)},$$

$$U(x) = (I - C)^{-1} * C^{T}$$
(2)

$$-\sum_{i=1}^{n} p(x) * C(i) \sum_{i=1}^{n} p(x) * Z(i).$$

The sensor network information includes the network topology information of the sensor node, the energy information of the node, etc., which is convenient for making judgments on the status of the sensor network. At the same time, it can also introduce rapid network diagnosis according to the actual deployment in the future to provide users with instruction. Specific application information is the information captured by various sensors installed on nodes according to specific application fields, such as soil temperature and pH value in precision agriculture.

$$Z(x, y) = \begin{bmatrix} x(i) \\ x(j) \end{bmatrix} \begin{bmatrix} \frac{\exp(x(i) + x(j))}{y(i) + y(j) + y(k)} & 1 \\ \\ \\ -1 & -\frac{\exp(x(i) + x(j))}{y(i) + y(j) + y(k)} \end{bmatrix}.$$
(3)

Journal of Mathematics

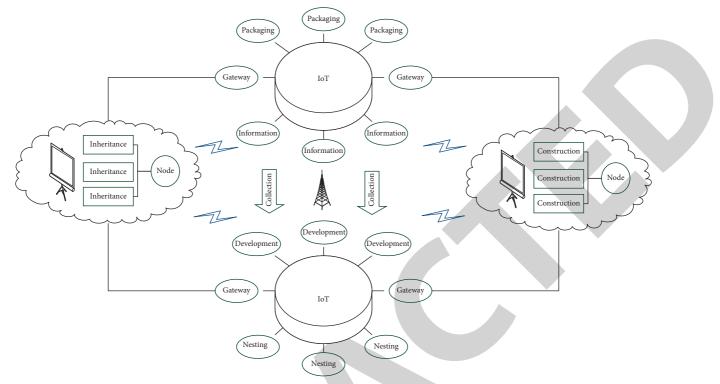

FIGURE 1: Hierarchical structure of 5G Internet of Things technology.

The 5G Internet of Things gateway communication layer is responsible for collecting the data transmitted by the sensor terminal, and converting the wired and wireless transmission signals into unified computer binary data according to the MQTT protocol, which is composed of DCS field workstations or 5G Internet of Things gateways. The data resource layer reads and stores the collected data. Different servers correspond to different data. Data storage is realized through programs and data query and call are realized through user commands.

3.2. Tea Product Packaging Process. Smart tea product packaging is the intelligentization of the whole process, integrating sensor technology, industrial wireless sensors, long-distance wireless communication technology, international open field bus, information fusion and intelligent processing technology into all links of production, according to the existing factory. The specific conditions and actual needs of the complex industrial site are intelligently processed for data information collection, real-time monitoring, tea product quality tracking and tracing, equipment operation and maintenance and diagnosis. The essence of the tea quality traceability system is the recording and transmission system of tea information, including the tea quality traceability system, data centers (national, local, and enterprise), system specifications, and work team composition, covering all aspects of tea production, processing, and marketing, thus forming a highly reliable traceability system. The software of the smart tea garden collection management system belongs to the top application layer of the 5G Internet of Things structure model. Data presentation, storage, and

administration are all handled by this layer, which is a combination of the 5G Internet of Things and consumer and industrial demands. Scalability, complexity of development, workload, and visual page aesthetics of the software system are all influenced by the software framework and development methodology. The smart tea garden collection management system's software architecture is intended to satisfy as many of the aforementioned needs as feasible. It plays a role by correctly identifying, truthfully recording and effectively transmitting information throughout the entire process of tea planting, processing, and sales, so as to solve the problem of tea quality and safety.

Figure 2 is the convergence curve of the features of the Internet of Things. Tea packaging is mainly divided into small bag packaging and gift box packaging. Small bags of tea are commonly found in hotels and hotels, and gift box packaging of tea is usually directly facing consumers. In the case of tea packaged in small bags, the hygienic quality problems of the packaging bags may occur; in the process of packaging tea products, quality problems such as unqualified packaging materials or improper use of oxygen scavengers and preservatives may occur. Therefore, it is necessary to set up packaging information collection points to record tea packaging information. With the implementation of an electronic file tracking system, it is feasible to minimise the mixing of goods between batches; separate storage facilities for raw materials and finished tea are established, stacked in operating areas, and processed products are united and kept in a single location. Different network connection techniques should be used in the development of the enterprise local area network in accordance with the various needs for the collection of information in tea growing, processing,

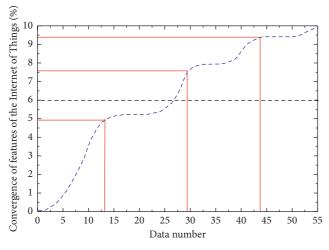

FIGURE 2: Convergence curve of Internet of Things features.

storage, packaging, and sales, for example. As part of the traceability database server's wireless network is connected to the tea garden's temperature sensors and PH sensors; the factory's RFID tag readers, QR code printers, and other equipment are connected to the traceability database server via the factory's wired or wireless network.

3.3. Information Feature Collection. The working method adopted in the Internet of Things is to wait for commands, and the difference between the PLC and the Internet of Things is the working method of cyclic scanning. The CPU of the PLC starts with the first command to collect sensor data, collects data, and returns to the first command after encountering the terminator, continuously looping, and continuously real-time collecting information is transmitted to the upper layer. If there is no termination instruction and jump instruction, the program is executed in order. The server application layer includes a multi-function server in the cloud that provides users with human-computer interaction functions and a data server that stores the entire 5G Internet of Things system. The function server performs the data calling function, reads the sensor data from the 5G Internet of Things gateway, and displays it in the humancomputer interaction device used by the user. At the same time, it also packages and encapsulates the user's operation instructions to the 5G Internet of Things gateway system. The data server stores various data required for the normal operation of the 5G Internet of Things system, including part of the configuration information, user data, and device data of the 5G Internet of Things gateway. The user management layer is for different people and has different authority settings, so the data information obtained is also different. Figure 3 is the distribution of the characteristic indicators of the Internet of Things information.

PLC is the abbreviation of Programmable Logic Controller. It is a kind of programmable memory. It is widely used in electromechanical automatic control systems and assembly line automatic control systems in various fields. PLC is mainly composed of user program memory, central processing unit (CPU), power supply, I/O module, system program memory and communication interface. PLC has a series of advanced functions, such as PID control, highspeed counting, terminal counting and so on. Each server will only process part of the data, and the processing efficiency will be greatly improved. Column-oriented means that the data in the database is stored in a column, and the data of a column is stored as a part. Compared with JSX, it is more natural and easy to understand in reading and writing. Compared with Angular, the API and documentation provided by Vue are more flexible and comprehensive. Learn-to-use costs are decreased, and the application's speed improves. Benefits like two-way data binding, componentization, support for the integration of numerous UI frameworks, and simplicity of use provided by Vue are exactly what this software system requires in terms of easy expansion, simple development, and visually appealing pages. Vue. To summarise, we've decided to work with Vue as our front-end framework of choice. The row-oriented database will query each row of data if you query certain fields of the real data. It is an alternative technique to use columns. The efficiency of queries will be considerably increased since just the columns that are required will be queried. With the continuous updating and upgrading of products, various functions and processing speed have been greatly improved.

3.4. Design Model Factor Fusion. When the Internet of Things network is established by the coordinator, it first becomes the cluster head of the first cluster. After the first cluster is established, the depth of the router is calculated. The 5G Internet of Things gateway node of the first cluster will gain. The node with the most even and connected child nodes is selected as the cluster head of the next cluster, and finally the node with the odd depth and the terminal node are divided into the cluster where the parent node is located. The ISO/OSI model has 7 layers, namely the physical layer, data link layer, network layer, transport layer, session layer, presentation layer and application layer. ModBus is a protocol for text transmission at the application layer of the seventh layer of the model, including three message types: ASCII, RTU, and TCP. The powerful functional modules of PLC give it the advantages of good stability, strong antiinterference ability, high compatibility, wide expansion ability, and simple operation of programming software, making PLC unique in engineering applications. Smart tea product packaging uses PLC to collect data. First, the calculation speed is fast, which can reflect the changes in the tea-making environment in a timely manner; the second is the storage capacity is relatively large, and developers can write various programs according to their own needs.

Sensors are connected to one other through wireless communication to establish a network system that transmits data gathered by the sensors to a fusion processing application system. Figure 4 depicts a framework for integrating design model factors. Wireless sensor network technology combines wireless communication, embedded system technology, sensor technology, and distributed information processing to provide real-time monitoring of monitored

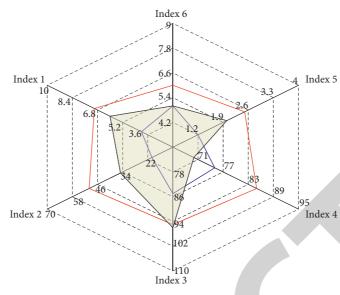

FIGURE 3: The distribution of Internet of Things information characteristic indicators.

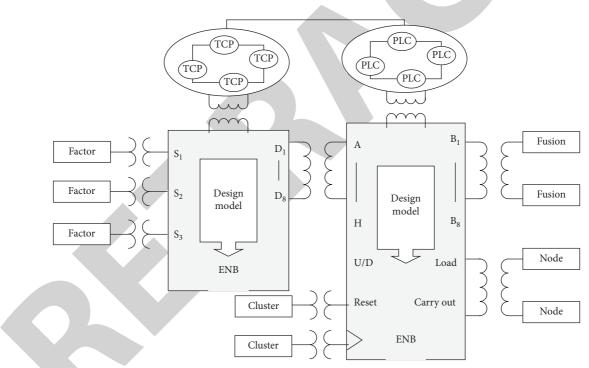

FIGURE 4: Design model factor fusion framework.

items in the coverage area. The Internet of Things is used in the food safety and quality monitoring system to track the production, processing, distribution, and consumption of agricultural goods, resulting in a chain of agricultural product safety and quality monitoring that spans the whole industry. To assure the safety of agricultural goods on the market, the whole process is open and accessible. A distributed database that employs key-value pairs instead of relational tables stores data in a nonrelational format. Nonrelational databases do not need to go through the analysis of the SQL layer to read and write data, and have high read and write performance; based on key-value pair storage, the data is not coupled and easy to expand; the format is flexible, and the data can be stored in the database in multiple forms, as opposed to relational items. There are not many restricted format requirements for the type databases. Compared with relational databases, nonrelational databases are more efficient in reading and writing large amounts of data.

4. Application and Analysis of Collection and Design Model Inheritance Characteristics of Tea Product Packaging Art Form Based on 5G Internet of Things Technology

4.1. 5G Internet of Things Data Screening. The number of 5G Internet of Things base stations is set to 16, the transmission power is set to 24 dBm, and the fixed coordinates are evenly distributed in the simulation area. During the simulation, the number of terminals gradually increased from 3200 to 3200, and the transmit power was set to 20 dBm. At the same time, in order to ensure that the number of access terminals for each base station in the two platforms is the same, and to ensure that the location distribution of the terminals in each base station is roughly the same, we divide the number of terminals into 16 groups in each simulation, and each group of terminals adopts a uniform distribution method. They are respectively distributed in the coverage area centered on each base station. Non-real-time services report the operation of the network by sending fixed-length short packets to the system periodically and at a low rate, which are used for remote status monitoring and automatic control; real-time services are composed of fixed bytes. First, the base station transmits the collected information to it. The concentrator is then transferred by the concentrator and sent to the terminal equipment, and then the current system situation is reflected to the monitoring system by means of information feedback.

Figure 5 is a comparison of the transmission power convergence of Internet of Things base stations. The transmission accuracy rate of OPC to MQTT is distributed between 98% and 99%, which fails to reach 100%. This is a short-term data lag problem caused by the use of half-duplex communication in the data protocol conversion. In addition, there are also data in multi-threaded communication. It is necessary to employ buffer stack technology to increase transmission success rates because of this overflow. Interpolation processing should be done using one of three methods: adjacent-point interpolation, linear interpolation, or spline interpolation. Because it provides the smoothest results, spline interpolation is often utilised in processing applications. Interpolation for the sine wave's terminal is used in all four interpolation techniques. First 64 data points may be utilised for FFT transformation if you do not add a significant content rate for each harmonic (usually, the total content rate of each harmonic of a channel is 20 percent). Some simple amplitude processing is done before FFT transformation. After some processing, the result of FFT transformation can get up to 32 harmonics. The content rate meets the requirements of the 2nd to 19th harmonics in the statute and is compared with the standard table in the experiment, and the error does not exceed 0.2%.

4.2. Product Form Feature Collection Simulation. The simulation in this article uses NS.2 Simulation platform, this simulation platform comes with the protocol modules of the

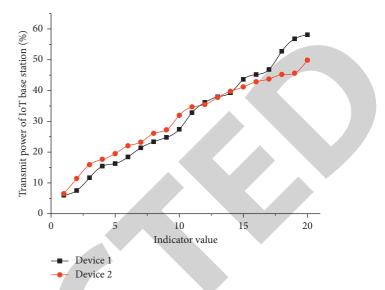

FIGURE 5: Comparison of transmission power integration of Internet of Things base stations.

media access layer and the physical layer defined by IEEE 802.15.4, and only the protocol module of the network layer algorithm needs to be written during simulation. We use AWK to process and analyze the results of the simulation, and then draw the graphs. In this paper, the ZBR algorithm and the improved ZBR algorithm are simulated and compared in different scenarios with the number of nodes ranging from 10 to 100. The data is the average value of 20 runs. During the simulation, the nodes are randomly distributed, and 8 data streams are randomly concurrent. The speed is 0.5 packets/s. In order to achieve the design goals of the above traceability system, the tea quality traceability system adopts a hybrid mode combining B/S architecture and C/S architecture. The internal information collection and processing of tea product packaging companies mainly adopt C/S architecture design, and each information collection accesses the local traceability database server through the client system; the consumer information query adopts the B/S architecture design, and each user accesses the traceability database that has been audited by the Ministry of Agriculture through the Web page.

In order to verify the usability and rationality of the smart tea product packaging 5G Internet of Things gateway system, this chapter conducts operational tests on the 5G Internet of Things gateway, including module operation test, system operation test and performance test, and analyzes the test results. Figure 6 is the distribution of the amount of information in the Internet of Things database. The test environment consists of a PLC embedded control system, a Windows host operating system, a Mosquitto proxy server, a Web server, a MySQL database, and so on and so forth. The human-computer interface device may be used to query and operate the smart tea product packaging server when the system is operating and testing. Analysis is done on the three metrics of average delay, remaining energy and packet delivery rate once the simulation experiment is completed. To limit the quantity of communication, the clustering method

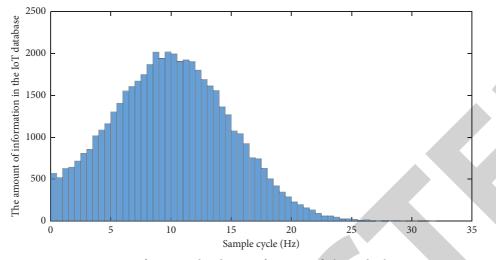

FIGURE 6: Information distribution of Internet of Things database.

uses a data fusion process, which lowers the time delay between data transfers. From the picture, it is clear that the revised algorithm's latency has been decreased by 12.4% when compared to that of its predecessor. An energy percentage is a metric for determining how much of the network's original energy remains after it has been exhausted. It is able to accurately monitor the algorithm's energy consumption. The higher the remaining energy percentage is, the better the energy saving effect is. It can be seen that the remaining energy ratio of the improved algorithm is higher than that of the improved money algorithm. As the number of nodes increases, the percentage of remaining energy decreases, and as time goes by, the decrease is more gentle. This is also in line with the actual situation. The unnecessary forwarding of RREQ packets reduces the overall energy consumption of the network.

4.3. Example Application and Analysis. The system is responsible for the collection of tea garden production environmental information data, and then collects the data through the ZigBee-based wireless sensor network for summary, and finally transmits the information data to the remote control center through the 3G/4G wireless communication network and the Internet. The server side of the control center realizes the monitoring and management of the production process and data analysis and decisionmaking through application software. The number of transmitters gradually increased from 5 to 200, and they were distributed in the simulation area in a random manner. The listening signal range of each terminal is set to 550 m, the receiving signal range is set to 220 m, and the MAC layer selects the CSMA protocol as the access layer protocol standard. The parameters of the simulation configuration mainly include the following categories: simulation area, simulation time, simulation service type, terminal attribute value, wireless channel propagation model, etc. An increase in packet loss rates and a drop in throughput may be seen when using event scheduling to process data packets in a network with increasing numbers of terminals, according to

experimental studies. There is zero packet loss when there are just a few terminals using the channel, since the channel is generally inactive while only a few devices are using it. A higher throughput is achieved as a result of increased channel use as more terminals contact the channel to deliver data packets. Data from the Internet of Things database is shown in Figure 7 at a glance.

Power allocation is a core component of wireless resource management. Under the condition of ensuring the respective communication quality requirements of the terminal, this technology reduces the impact on other users by reducing its transmission power value and improves the system capacity. This technology sets different reuse factors in different areas of the cell, divides the total resources into multiple frequency bands according to the total amount of system resources and the setting of simulation scenarios, and divides the coverage area of each cell from the inside to the outside. Multiple circular areas allow users in different circles to use frequency bands alternately, so as to reduce interference at the edge of the cell, improve the fairness of each user in the cell, and improve the experience of edge users. When the channel is saturated, if you continue to increase the number of terminals, the channel collision will intensify, and the packet loss rate will increase and approach 1. At the same time, multiple terminals will collide with each other, resulting in a sudden decrease in the total number of packets sent by the system and a decrease in throughput. After comparison, the trend of the packet loss rate and throughput measured by the two platforms with the number of terminals is roughly the same as that of NS2. Therefore, the event scheduling method designed by the platform is basically accurate and can be used for simulation of common scenarios.

Figure 8 is a comparison of the data latency of the Internet of Things database channel. The packet delivery rate is a key indicator for detecting network transmission performance. It can reflect the stability and reliability of the network. The packet delivery rate is the ratio of the number of data packets received to the number of data packets sent, which is directly proportional to network performance. The

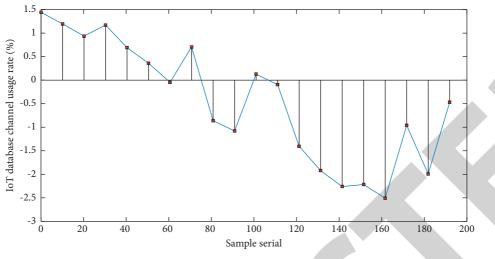

FIGURE 7: Channel utilization rate of Internet of Things database.

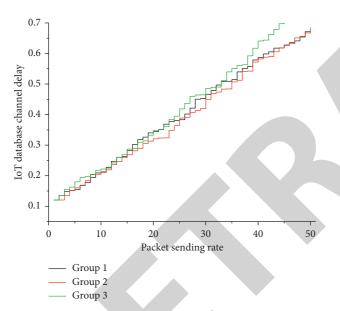

FIGURE 8: Comparison of data latency of Internet of Things database channel.

MQTT client mqtt-client-NW09wrg calls the publish interface to publish a message to the Mosquitto server. The message subject is test and the size is 62 bytes. The Mosquitto server temporarily caches the message locally on the server and publishes the response. When the client receives the response, it will do it again Initiate a request to release the message to the Mosquitto server, and finally the server returns a response that the message was successfully published and deletes the local cache. The 5G Internet of Things gateway system transmits data to the server, and manages the equipment through the entire 5G Internet of Things front-end system, which can display terminal sensor data in real time, and perform certain analysis, processing and visualization. For the different functional interfaces of the front-end system, when the 5G Internet of Things gateway system is running normally, the interface can receive and display the local and overall information and status of the tea

product packaging, and can also perform reverse command operations. And through the running test graph, we can roughly understand that the network I/O read and write speed is 4.8 M/s when data is written from MySQL to HDFS cluster on different servers. The writing speed of HDFS is 9.5 M/s, and the files of HDFS are stored on the disk, and the writing speed of the disk is 9.5 M/s–19 M/s. It can be seen that the packet delivery rate of the improved algorithm is higher than that of the previous algorithm. Because the improved algorithm discards unnecessary RREQ control packets, the packet delivery rate is higher and the network transmission performance is better.

5. Conclusion

This paper arranges Internet of Things sensors in the packaging process of tea products, collects environmental data related to the growth of tea, visualizes it in the software system, alarms the environment that is not conducive to the growth of tea, and uniformly manages the agricultural operations of tea farmers. On this basis, the energy consumption of the sensor and the overall performance of the system are optimized. First, according to the principles and requirements of the tea quality traceability system and the production practice of it and its affiliated tea product packaging enterprises, nine technical steps for the traceability of the tea quality traceability system are designed. Then, based on the agricultural product quality traceability system of the Ministry of Agriculture, the introduction of 5G Internet of Things technologies such as sensors, RFID, QR codes, and wireless sensor networks, the overall framework of a tea quality traceability system based on the 5G Internet of Things was constructed, and user information and coding management were designed. Tea plantation production and information collection, tea processing and information collection, quality monitoring management, tea sales management, data collection, information query and system maintenance and other eight system function modules and related databases, develop a special website and user query terminal, users through the user The terminal queries the

Based on the poor quality of engineering cost teaching, this paper puts forward the application method of in-depth learning in engineering cost teaching evaluation. This study aims to construct the engineering cost teaching evaluation system, optimize the engineering cost teaching evaluation algorithm combined with the in-depth learning method, standardize the evaluation index of the engineering cost teaching system, and realize the research goal of engineering cost teaching evaluation. Finally, the experiment proves that the application effect of in-depth learning in engineering cost teaching evaluation is obviously better, which can better guide the quality of engineering cost teaching.

1. Introduction

The focus of in-depth learning research returns to people themselves, advocates studying learning in real school and classroom situations, and emphasizes the "problem-driven" educational science research paradigm [1]. The project cost teaching activity mode is very compatible with the development of the "five education concurrently" education system for the growth of students' core literacy and the direction of educational assessment in the new age. The direction and baton of classroom teaching improvement is classroom teaching evaluation [2]. The current classroom teaching evaluation of engineering cost teaching in China is mainly to "evaluate teaching by teaching," and the teacher's "teaching" behavior is the main index to evaluate the teaching effect. The classroom teaching of engineering cost teaching urgently needs to construct a classroom teaching evaluation system of "evaluating teaching by learning," evaluate classroom teaching by students' behavior of "learning," and promote students' "effective development." Under this background, the application of in-depth learning in engineering cost teaching evaluation is studied [3].

2. Application of Deep Learning in Engineering Cost Teaching Evaluation

2.1. Construction of Project Cost Teaching Evaluation System. Guided by the deep learning theory and combined with many years of practical experience in classroom teaching design of engineering cost teaching, this paper summarizes the characteristics of teaching design based on deep learning in the intelligent era, as shown in Figure 1.

The engineering cost teaching evaluation index method is based on engineering cost teaching and geared at nurturing students' in-depth understanding. It is used to assess whether engineering cost teaching can reach the engineering cost teaching objective system. Teachers must master not only professional knowledge, but also information technology knowledge, integrate new teaching techniques at the appropriate moment, and achieve successful teaching, according to the TPACK knowledge framework [4]. Students may eventually attain high-order thinking via shallow learning, according to the deep learning paradigm. Therefore, in the project cost teaching, based on the in-depth learning theory and the TPACK knowledge framework, the

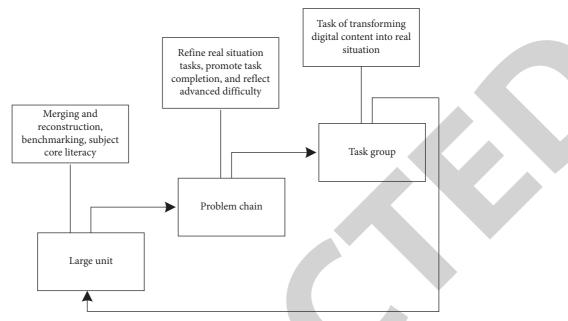

FIGURE 1: Characteristics of a classroom teaching design based on deep learning.

constituent elements of the project cost teaching evaluation index system are determined (as shown in Figure 2), and the teachers' wisdom teaching is integrated with the students' in-depth learning, so as to promote the development of students' high-level thinking ability and in-depth learning ability.

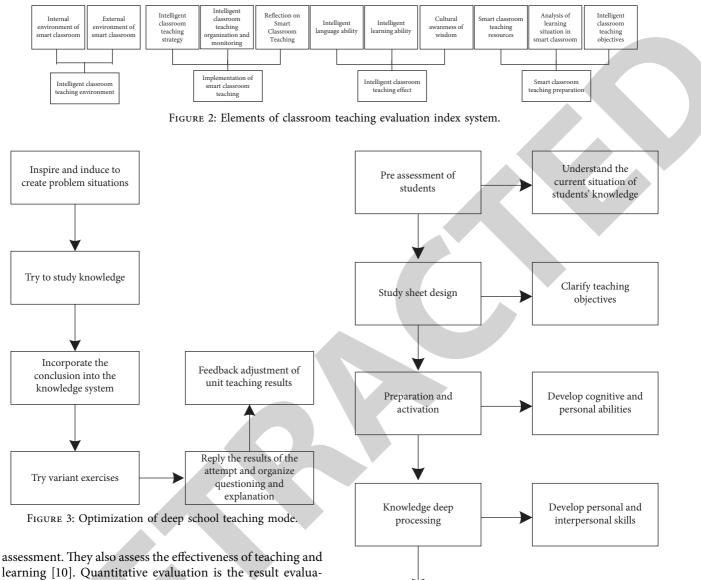

In order to guide students to better carry out in-depth learning, we need to select teaching methods that focus on students and fully mobilize their initiative [5]. The most common are heuristic, deep learning, collaborative inquiry, and task-driven. In the teaching process of engineering cost, teachers take students' learning characteristics and the nature of teaching tasks into account, actively mobilize students' initiatives, open inspire students' high-level thinking, and then promote the improvement of in-depth learning levels.

According to the in-depth learning route and goal of project cost teaching, shown in Figures 3 and 4, the design of the engineering cost evaluation index is carried out from two dimensions: qualitative evaluation and quantitative evaluation, which are combined with the ideas of "emphasizing process" and "paying equal attention to both qualitative and quantitative" in the classroom teaching evaluation of indepth learning. The following framework shown in Figure 5 is built based on the idea of in-depth learning and instructional design, as well as the major features of classroom teaching design based on in-depth learning in the intelligent age.

The teaching goal of engineering cost is not only the starting point and destination of teaching but also the basis of teaching evaluation. The determination of unit objectives needs to be combined with the core literacy of the discipline [6]. In the framework of instructional design based on indepth learning, the determination of unit objectives needs to be guided by the core literacy of the discipline, based on the needs, cognitive development law, and learning status of learners, and the core concepts and contents of the discipline as an important carrier [7]. Teachers help students master discipline ideas and methods by guiding them to carry out autonomous learning, cooperative learning, and inquiry learning, cultivate students' critical thinking, transfer and application ability and problem-solving ability.

2.2. Teaching Evaluation Algorithm of Deep Learning of Engineering Cost. Project cost teaching evaluation refers to a series of activities to judge the value of teaching activities, learners' state, and teaching effects according to certain teaching objectives. It plays a feedback role in the whole learning process and provides important support for how to improve and improve the teaching system [8]. This study uses the method of intelligent evaluation to evaluate the quality of teaching and learning. In the intelligent evaluation, we rely on the intelligent teaching tools to collect the data of students' learning process or learning results in class to realize the comprehensive evaluation of students. Big data provides an important supporting role for the teaching evaluation of engineering costs [9]. We use the big data generated in the learning process to deeply evaluate the learning effects of students with the help of external factor progress analysis. The in-depth learning evaluation relies on the engineering cost teaching tool classroom to realize the diversification of evaluation subjects, multidimensional evaluation contents, and diversified evaluation methods, as shown in Figure 6.

The project cost is minimized by using a variety of data sources, and modular analysis technology is used to provide visual analysis findings, as shown in Figure 7. Teacher assessment used to be done by instructors. Teachers are the assessment topic of students in wisdom evaluation. Students are evaluated both as the object and as the topic of the

learning [10]. Quantitative evaluation is the result evaluation, which evaluates the final effect of students' learning after a semester of complete teaching activities. The evaluation is mainly to evaluate the students' mastery of the course content and teaching effectiveness through the final examination results [11]. Therefore, the final test is taken as the primary evaluation index of quantitative evaluation, and the degree of knowledge mastery is taken as the secondary evaluation index of quantitative evaluation.

The differences between deep learning and shallow learning are compared and analyzed from the aspects of learning motivation, learning objectives, knowledge system, and transfer ability, as shown in Table 1.

The perceptron inputs the features x_1, x_2, \ldots, x_n into the calculation unit p, and the weighted is K. Then, the sum is

sum =
$$p \sum K(a_1 + a_2 + \dots + a_n).$$
 (1)

Then, the result is input into the activation function f, and the output R is the result of the perceptron.

$$t = R - f(\text{sum}). \tag{2}$$

Evaluate learners

The activation function of perceptron *Q* usually adopts the nonlinear function, such as sigmoid function and tanh function:

sigmoid
$$(x, y) = \frac{1}{Q + e^{-x}} - t,$$
 (3)

$$\tanh(x) = \frac{e^{x} - e^{-x}}{e^{x} + e^{-x}} - \text{sigmoid}(x, y), \tag{4}$$

Pay attention to both

qualitative and

quantitative

where *e* is the data index of teaching information. If the assignment matrix is $C = (c_1, c_2, ..., c_n)$, then the comprehensive score of each index is

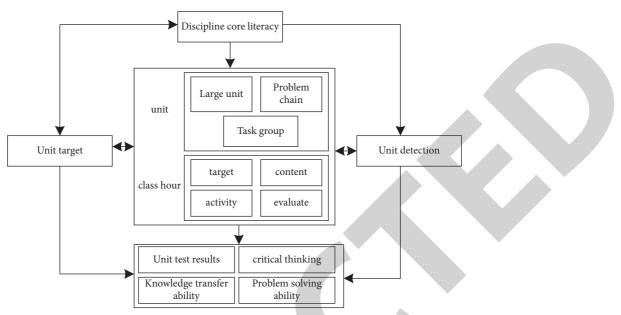

FIGURE 5: Classroom teaching design framework based on deep learning.

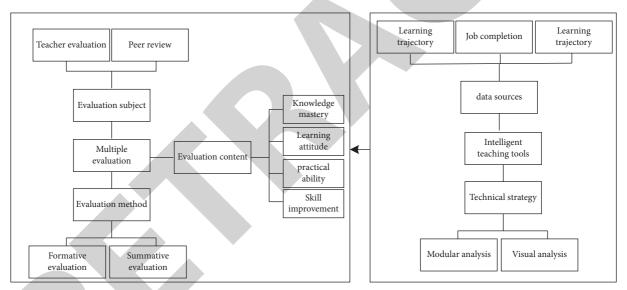

FIGURE 6: Teaching evaluation steps of deep learning of project cost.

$$S = Q_i \cdot C - \tanh(x) \begin{pmatrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{pmatrix}.$$
 (5)

Because the weights of all indicators are the same, the final comprehensive evaluation score \overline{X} is the average of the comprehensive scores of each indicator; i.e.,

$$A = \overline{X} + \frac{1}{e} \sum_{n=1}^{i=1} S - \tanh(x).$$
(6)

According to weight vector W and comprehensive evaluation matrix $R = (r_{ij})mn$, the fuzzy comprehensive evaluation set of the evaluation object B is calculated:

$$B = W \cdot R - A\left(\overline{X} + \frac{1}{e}\right). \tag{7}$$

The geometric average of all elements of the judgment matrix a_{ij} is calculated, such as the formula

$$\overline{w_i} = \sqrt[n]{\prod_{n=1}^{j} a_{ij} + B - A.}$$
(8)

The above geometric average is normalized, and the specific formula is as follows:

$$w_i = \frac{\overline{w_i}}{(A+B)\sum_n^i \overline{w_i}}.$$
(9)

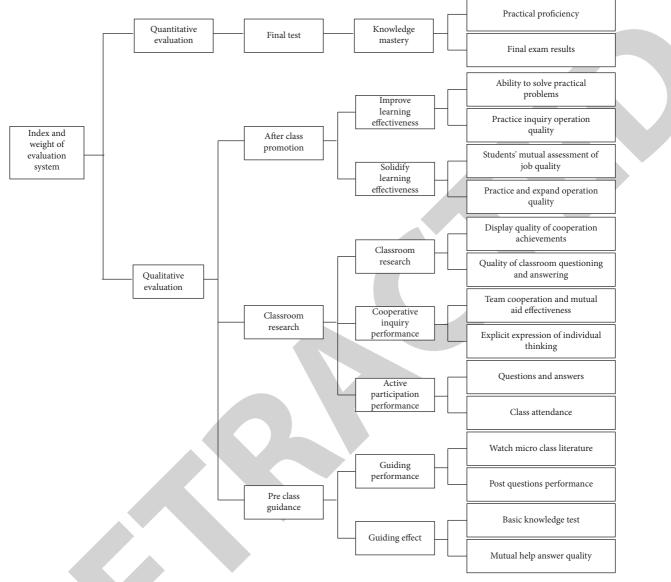

FIGURE 7: Teaching evaluation index system of deep learning of project cost.

The key points of project cost evaluation shown in Table 2 are to evaluate teachers' teaching with learning science as the basic concept, effectively promoting students' learning as the basic value pursuit, and students' learning behavior as the basic index:

According to the constructed evaluation index system of engineering cost teaching, the index system of engineering cost teaching is tested to verify the effectiveness and operability of the index system. The evaluation index system is mainly applied to engineering cost teaching [12]. It examines the hardware environment of engineering cost teaching, instructors' teaching preparation, implementation process, teaching impact, teaching interaction among teachers and students, students' learning process, and other features to see whether they adhere to engineering cost teaching. The engineering cost teaching evaluation index method requires a great deal of practice and examination. Three engineering cost instruction courses were chosen for assessment in this

research [13]. Before the evaluation, a five-person evaluation team including educational technology experts, college English teaching experts, and intelligent teaching experts should be established. Before the implementation of the evaluation, the team members were familiar with the engineering cost teaching process, as well as the relevant theories such as intelligent teaching, TPACK knowledge framework, in-depth learning, and English subject literacy, so as to fully understand the construction of the engineering cost teaching evaluation index system and the connotation of each index element to form a standardized evaluation standard [14]. Each evaluator will record the observed contents in detail according to each element of the index system and rate each index throughout the assessment process. The real scores of each index element are totaled by SPSS 21.0 when the evaluation is completed, the scores of each evaluator are sorted out, and the findings are eventually summarized [15].

Comparison items	Deep learning	Shallow learning
Learning motivation	Learners' internal knowledge needs	It mainly comes from the external pressure of non-self- demand
Learning objectives	Focus on learners' ability to understand, transfer, apply, and solve problems, mainly the development of high-order thinking ability	Focus on the acquisition of learners' basic knowledge and skills, mainly the development of low-level thinking ability
Learning style	Meaning construction, memory, and learning based on understanding	Do not use mechanical learning with simple knowledge
Learning environment	Learning resources are very rich and diverse	Learning resources are relatively single
Learning effectiveness	High effect, but low efficiency	High efficiency, but the effect is poor
Knowledge system	New and old knowledge practice, meaningful learning as the goal, deep processing knowledge, etc.	A simple concept that is simple, and easy to understand
Focus	Pay attention to the internal relationship between core knowledge and seek a breakthrough point to solve problems	Basic knowledge of focusing on simple problems
Migration ability	Flexible use of knowledge	Mechanical learning cannot effectively transfer to the solution of practical problems
Evaluation method	Process evaluation and qualitative evaluation	Summative evaluation and quantitative evaluation
Learning attitude	Positive emotional state	Negative emotional state

TABLE 1: Comparison between deep learning and shallow learning.

TABLE 2: Key points of classroom teaching evaluation based on learning science.

Evaluation content	Evaluating indicator	Focus
Instructional design	The design of teaching objectives conforms to the law of students' cognition	Existing knowledge
U	The design of teaching activities reflects students' independent construction	Active learning
	Create a knowledge center environment and build a learning support	Forward support understanding
Teaching process	Highlight the systematicness of knowledge and promote understanding and application Creating deep learning situations to promote high-level thinking Pay attention to learning transfer and promote "five education and mutual education"	Core concept Metacognition Migration ability
Teaching effectiveness	Clear problem representation can effectively promote learning generation Grasp the essence of discipline and effectively form learning strategies Achieve smooth extraction and effectively enhance cognitive ability	Target Mode Effect

2.3. Realization of Teaching Evaluation of Project Cost. Deep learning theory attaches importance to the long-term development of learners, encourages learners to promote their own understanding and construction of knowledge through dialogue and cooperation based on their personal learning characteristics, and finally integrate all kinds of information, solve practical problems, and enhance creativity [16]. In fact, all this ultimately points to the learners' own learning level, requiring their learning process to have depth and breadth, so as to finally realize in-depth learning. In the teaching process, it is necessary to shape the creative teaching situation. Simultaneously, it is necessary to design teaching objectives with high-level thinking, deliver instruction around complex, cooperative, and challenging deep learning tasks, and emphasize objective, comprehensive evaluation methods that point to the process and developmental high-level for indepth learning evaluation [17]. According to the five teaching links of the traditional scaffolding teaching model, and based on the analysis of the characteristics of deep learning, guided

by the deep learning theory, combined with the abovementioned scaffolding teaching principles for deep learning and the types and functions of learning scaffolding, this study systematizes and deepens the core elements of scaffolding teaching model [18]. A scaffolding teaching model for college students' in-depth learning is constructed to guide the specific curriculum teaching design and implementation, as shown in Figures 8 and 9.

Teachers design and develop preview resources and release preview tasks to inspire students' in-depth learning [19]. Students individually preview, remember, and grasp the content, complete exam questions, apply what they have learned, discuss, and communicate to evaluate difficulties, as indicated in Figure 5, in order to gain knowledge and master skills and improve in-depth learning [20]. The discussion and communication link might be a conversation on a specific subject defined by the instructor, or students can talk freely about the difficulties they faced in advance, depending on the teaching material, in order to encourage students' in-depth learning.

Journal of Mathematics

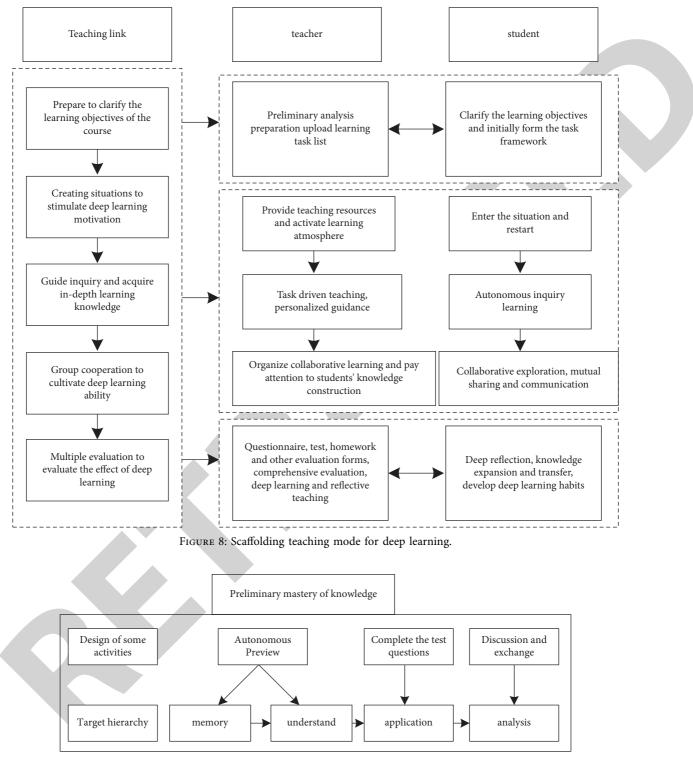

FIGURE 9: The level of deep learning objectives in the preview stage.

Based on reflection, the essence of deep learning is to cultivate learners' reflective consciousness and ability and actively carry out reflective activities in the process of deep learning [21]. Model construction is to add reflective factors to the general process model of deep learning to make it run through the whole learning process, as shown in Figure 10. The important stage is the learning preparation stage. This stage requires students to creatively guide and plan the next learning activities on the basis of reflecting on their original knowledge and experience and create a real situation to stimulate students' high learning investment [22] using self-assessment form and other methods to promote students' reflection before learning. The main stage is the key

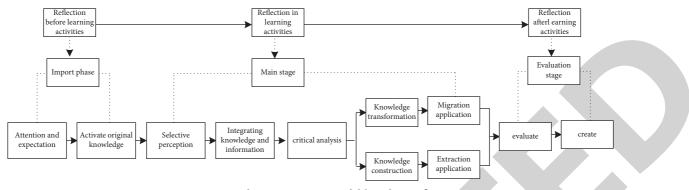

FIGURE 10: Deep learning process model based on reflection.

stage of learning [23]. This stage requires students to reflect on the learning process in real-time, find and solve problems, and ensure the smooth progress of learning. In order to achieve in-depth learning, students need to add in-depth knowledge, and the key link is to construct and transform knowledge [24]. This study, when combined with the analysis, creates a preliminary action plan for classroom assessment that points to deep learning. The action path is based on three pieces of evidence: the deep learning occurrence route, the essential content of classroom assessment to facilitate learning, and the notion of deep learning classroom evaluation. These three proofs are listed above. Now, we will look at how they play a part in path creation. First, the deep learning occurrence road is the foundation of the classroom assessment action path leading to deep learning. When it comes to classroom assessment that leads to deep learning, evaluation should not be done separately, but rather as part of the teaching and learning process. Classroom assessment can only be effective if it is integrated into the whole educational environment. In other words, there are few opportunities for in-depth study. As a result, depicting it as the central axis of the whole action path and boosting learning classroom assessment is the first step in fostering in-depth learning. Teaching and learning should always be accompanied by and conducted via evaluation. To put it another way, the assessment of boosting deep learning should go along deep learning path. Therefore, the evaluation should be drawn as an external driving circle closely surrounding deep learning. Third, classroom evaluation at different stages faces different "missions," such as diagnosing learning situations, determining objectives, collecting evidence, adjusting teaching, promoting understanding, and reflective learning. In order to have a clear direction and problem-solving direction in operation, it is necessary to distinguish between each classroom evaluation form. Therefore, the evaluation is given different names according to the stage and functional differences, i.e., comprehensive diagnosis, classroom pretest, and formative evaluation. In a comprehensive view, the action path can fit the classroom evaluation concept, pointing to deep learning. The integrated in-depth learning route and classroom evaluation are an inseparable whole, in which goal, learning, teaching, and evaluation form an integration, which reflects the concept of consistency. The path emphasizes the formative evaluation

of real-time and dynamic interaction in class, which reflects the concept of "paying attention to the sharing between teachers and students." Designing learning day standards and learning content is the starting part of the action path; that is, we should first design the task according to the goal, which reflects the concept of "paying attention to task guidance." In the process of promoting (dotted arrow) deep learning, classroom evaluation circulates with the cycle of deep learning, which reflects the concept of "cycle."

As shown in Figure 11, the classroom evaluation action path pointing to deep learning is mainly composed of two teaching circles: the outer ring and the inner ring. The inner ring is the deep learning generation circle integrating "goal learning teaching evaluation," and the outer ring is the classroom evaluation promotion circle composed of different evaluation types, so as to improve the quality of teaching evaluation and promote teaching effect.

3. Data Analysis and Processing of Experimental Results

Data analysis, teaching implementation, homework statistics, teaching administration, and other tasks are included in the experimental detection platform of the teaching environment. Many teaching aids supporting virtual teaching environments are classified, examined, and compared, as indicated in the table, based on the teaching demands of this study course. Based on the analysis, the intelligent teaching tool classroom shown in Table 3 is selected as the support of the virtual teaching environment.

By externalizing students' internal knowledge structures through graphics, we can directly observe the changes of students' knowledge structures. It is proposed to use deep learning to evaluate students' deep learning. It judges whether students have deep learning according to the changes of structure, content, and connections of concept map drawn by students before and after learning.

This study compares the characteristics of deep teaching and shallow teaching across the dimensions of teaching concept, teaching objectives, knowledge system, teaching methods, students' investment, thinking level, teaching evaluation, teaching reflection, and teaching results, as shown in Tables 4 and 5.

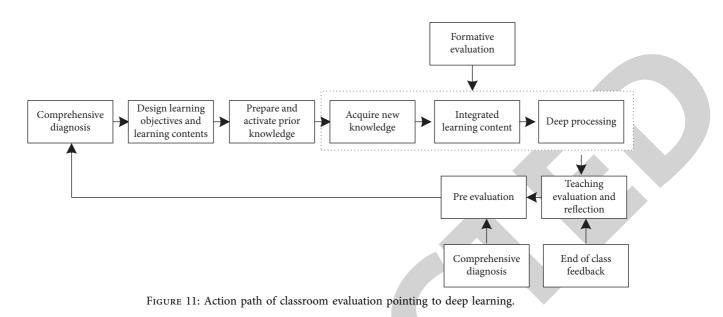

TABLE 3: Summary of teaching tools.

Learning platform name	Platform introduction	Function introduction
Rain class	Intelligent teaching tool jointly developed by online and university online education office	Implement question and answer interaction, student difficulty feedback, and teaching data statistics
China university	Online education, undertake the national high-quality open	Curriculum construction, teaching management,
MOOC	courses of the Ministry of Education and provide MPPC courses	and data statistics
Superstar learning link	Pan Asia mobile app	Curriculum construction, teaching management, and class group chat
Pan Asian network	Curriculum construction and daily teaching	Curriculum construction, teaching management, and data statistics
Wisdom tree	Can complete cross school course selection	Curriculum construction, online learning, and class management

TABLE	4:	Evaluation	n indexes	s of	deep	learning	and	shallow	learning.
					avep			0114110 11	

	Deep learning	Shallow learning	Not learning
Definition	The link between old and new concepts	New concepts replace or simply add new concepts	There is no conceptual change
Content	The concept map reflects the old and new concepts	The concept map reflects a large number of new concepts	The concept map does not present new concepts
Contact	The relationship between new concepts and old knowledge in the concept map	The concept map has not changed significantly	There are no new connections in the concept map
Structure	Obviously, the organization, connection, and richness have been qualitatively improved	There is no significant change in the overall type, richness, and interpretability of the concept map	There is no change in the structure of the concept map

Take the classes with almost no difference in usual performance as the control. Take class A, which offers the course of modern educational technology, as the experimental class and class B as the control class. Experimental class A uses the "3 + 1" intelligent teaching mode designed in this paper to verify the teaching effect of this mode. Control class B still adopts the traditional teaching method to study the theory course and experiment course. After the semester course, class A and class B with basically the same initial conditions are compared and analyzed, and the examination and test are conducted from two dimensions: test papers and micro class works. The same test paper is designed for

examination. Teachers grade the micro class video works made by students at the end of the semester. The comparison results are shown in Table 6.

The results show that class A and class B have basically the same initial conditions. Class A adopts the engineering cost teaching mode based on in-depth learning for teaching practice. At the end of the course, there will be an obvious gap between the two classes. Class A has a higher excellent rate than class B in terms of test paper scores and micro class works, and the highest and lowest scores are higher than class B. First, this research examines the final assessments of students in the experimental and control groups in order to

TABLE 5: Comparis	an hateraan	doom too ahima	and challour	taaahima

		-
	Depth teaching	Shallow teaching
Teaching concept	Student center	Teacher center
Teaching objectives	From easy to difficult hierarchical expression	Focus on basic knowledge and skills
Knowledge system Teaching method	Emphasize the connection between old and new knowledge Proper selection of teaching methods	Knowledge points are isolated and scattered The method is single and inflexible
Student involvement	Active participation and high investment	Passive participation and low investment
Thinking level	Higher order thinking	Low order thinking
Teaching evaluation	Diversified ways and pay attention to students' multiple intelligences	The evaluation method is single, mostly performance evaluation
Teaching reflection	Be able to adjust the teaching state according to reflection	Reflection is simple and not systematic
Teaching results	High quality, pay attention to the sustainable development of students	

TABLE 6: Results	comparison	of class A/B.
------------------	------------	---------------

Class Number of people		Test paper	Micro class works				
Class	Number of people	Excellent rate (%)	Pass rate (%)	Highest score	Lowest score	Excellent rate (%)	Pass rate (%)
Class A	103	46.35	86.35	100	55	56.32	87.65
Class B	102	31.23	71.31	95	42	28.96	45.32

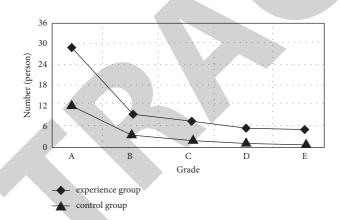

FIGURE 12: Statistics of final test scores of experimental group and control group.

compare the teaching impacts of regular classroom teaching and scaffolding teaching for in-depth learning. The test will last 120 minutes and have a maximum score of 100. Students' scores are classified into five categories according to administrative methods for evaluating the academic accomplishments of undergraduates in a university: A, B, C, D, and D. The test questions of the experimental group and the control group are completely consistent, and they are all computer operation questions, including the learning points of six chapters of the teaching material. The test questions cover a wide range and highlight the key and difficult points. It is mainly a comprehensive investigation of the mastery and application ability of students' knowledge, so as to reflect the students' in-depth learning. Statistics and comparative analysis of the final test scores of the two classes are shown in Figure 12.

It can be seen that the scaffolding teaching model for indepth learning in this study helps students in grades B, C, and below to move forward to grade A. In order to better grasp the changes of students' in-depth learning status in the course, the "College Students' in-depth learning evaluation scale" was distributed to 27 students in the experimental class before and after the teaching experiment. Students filled it out truthfully according to their actual learning situation and made use of SPSS software. The pretest and post test data after the questionnaire are collected for an independent sample *t*-test to compare the mean. The results are shown in Table 7.

It can be seen that the promotion of deep learning motivation is relatively fast after the implementation of scaffolding teaching. In addition, there are significant differences in these four dimensions, and their p values are 000 < 0.01. It indicates that there is a significant difference in the in-depth learning level between the experimental class before and after the curriculum implementation. It fully reflects that the scaffolding teaching mode for in-depth learning has significantly improved the in-depth learning level of the students in the experimental group, especially in the dimension of in-depth learning motivation, which is more inclined to actively collect learning materials for

Dimension	Up/down	N	Mean value	Standard-deviation	T value	p value
Deep learning motivation	Up Down	28	3.3025 3.5896	0.8954 0.8689	22.6582	0.000**

TABLE 7: Independent sample *t*-test results of students' deep learning status.

autonomous learning than before, showing that the students' learning consciousness and initiative are significantly enhanced.

4. Conclusion

Along with the goal and route of deep learning, this paper constructs the evaluation system of deep learning teaching, designs three-level evaluation indexes from the two dimensions of qualitative evaluation and quantitative evaluation, and determines the corresponding weights. The evaluation system runs through the whole process of a preclass, classroom, after-class, and final examination, comprehensively reflects teachers' teaching preparation, teaching organization, and management ability, and comprehensively examines students' autonomous learning, individual thinking, problem-solving and inquiry, and innovation ability. At the same time, according to the evaluation system, this paper makes an empirical study on the effectiveness of in-depth learning classroom practice teaching. The research shows that most students are satisfied with the teaching mode and their autonomous learning ability, and their final grades have been greatly improved, but there are also some problems. Therefore, the author believes that the construction of a teaching evaluation system is a long-term, interactive, and continuous improvement process. In the future, the flipped learning practice teaching process, according to the basis and characteristics of students, cooperate with other teaching strategies and means to constantly improve the evaluation system in order to comprehensively improve students' autonomous learning, application skills, and lifelong learning abilities and improve the teaching quality of engineering cost teaching.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the implementation of the strategic policy of rejuvenating the country through science and education, many innovative and practical teaching concepts and teaching models have been comprehensively developed. This breaks the backward teaching mode of traditional teaching activities. With the development of science and technology and Internet technology, deep learning is widely used in the field of education. Music teachers in colleges and universities constantly update their teaching methods and comprehensively use a variety of methods to carry out in-depth teaching in the classroom, and strive to stimulate students' learning Interest and enthusiasm, and comprehensively enhance students' music aesthetic ability. This article uses decision tree algorithms, support vector machines, Bayesian theory, and random forest four different classification techniques to evaluate the student curriculum evaluation dataset. Classification experiment: through the analysis of the experimental results, the performance of the four classifier models was compared, and the data showed the difference in accuracy, precision, recall, and F1 value of the four classifiers. At the same time, each of the classifier models was analyzed. This article verifies the effectiveness of machine learning models in curriculum evaluation and higher education mining, the importance of evaluation features.

1. Introduction

Art and science technology have never been separated. As Li Zhengdao said, "Science and art are inseparable, just like the two sides of a coin [1-5]." Music as a form of art is naturally inseparable from science [6]. With the advent of the Internet era, higher education institutions continue to improve their own informatization teaching level, resulting in a large amount of data related to the teaching process [7]. How to use this information to improve the quality of teaching and scientific research services in universities and the level of management decision-making has become the biggest challenge facing universities. The use of machine learning technology can effectively analyze and extract hidden information in large datasets, that is, discovering patterns and knowledge in large amounts of data and predicting results or behaviors. In recent years, the application of machine learning in higher education has become increasingly popular, involving the optimization of educational resource

allocation, predicting student academic performance, academic planning, and enhancing the future development of alumni. It has also given birth to the birth of new educational research fields [8-12]. Excavating in-depth information from educational entities such as students, teachers, teaching assistants, alumni, and education administrators can help colleges and universities allocate various teaching resources and organize educational activities more effectively, and more effectively improve students' satisfaction with courses, to enhance the learning effect of students and increase the enrollment rate of majors [13]. One of the common problems in higher education is to evaluate the performance of teachers in the curriculum. Students are the only source of information for the learning process and the only person who can evaluate the quality, effectiveness and satisfaction of course content, teaching methods, teaching materials, and assignments. Student evaluation is mainly used to improve the quality of course teaching and, at the same time, as the basis for teaching assessment of teaching staff. Most colleges

and universities still use student evaluation as an effective measure of teaching evaluation. Music as an artistic form of expression contains very rich emotions. In the process of teaching in universities in my country at this stage, relevant education departments pay more attention to the teaching of music as a subject. With the continuous improvement of my country's social economy, culture, and people's pursuit of spiritual civilization, the requirements of college music majors have become increasingly demanding. In order to meet people's growing spiritual needs, music teachers in colleges and universities, in the process of organizing teaching, should contact the reality of life, aiming at students' hobbies and diversified classroom teaching to fully mobilize students' learning enthusiasm.

Currently, the main focus of machine learning research in the education field is to explore the learning environment and web-based teaching systems, and improve student performance. There are a few applications of information mining for student evaluation. This article studies the potential of data mining in the teacher performance measurement standards perceived by students and chooses decision tree algorithm (DS), support vector machine (SVM), naive Bayes (NB), and random forest (RF), the four commonly used machine learning classifiers, which model the dataset of students' online evaluation of course information and compare the performance indicators of various classification techniques. Section 2 of our study reviews the related works and the literature. In Section 3, the methodology of our work is described along with the description of proposed techniques. Moreover, the study also proposes the experimental section, that is, Section 3, which carries out tests and verifies the strength and working of the proposed techniques through the results of tests. In Section 5, the conclusion of the study is given.

2. Literature Review

In order to further advance the reform of music education in colleges and universities, promote the development of music education, and strengthen the management system of music education, many countries are constantly studying the basic theories and practical applications of music teaching evaluation in colleges and universities, so that it can better achieve the teaching goals service. In some of these countries, the research on the evaluation of music teaching is earlier, and the theory is relatively mature, with a certain degree of operability. Among them, the United States and Japan have conducted in-depth research on the evaluation of music education [14–18].

Overview of foreign music teaching evaluation. The American music teaching evaluation mainly includes the music test movement, the goal model of curriculum design, the taxonomy of educational goals, and the achievement responsibility system movement. In the early 20th century, American school music education mainly consisted of music tests. Music tests were used to collect objective data on the development characteristics and achievements of students in music, as well as music courses and evaluation effects in music education, so that music teaching could be measured

based on measurement. These objective materials come to evaluate the results and process of music education in the past, and to revise and improve new goals, processes, courses, and teaching. The tools used are musical aptitude test (such as "Westshore Musical Abilities Measurement") and musical achievement test (such as "Beach Music Test"). In the 1940s and 1950s, the evaluation committee led by Professor Taylor, based on the "eight-year study," proposed that teaching evaluation should focus on describing the consistency between educational results and educational goals. Therefore, a goal-centered evaluation model was established. Based on the "eight-year study," the Evaluation Committee of China proposed that teaching evaluation should focus on describing the consistency between educational results and educational goals. Therefore, a goalcentered evaluation model was established. In the 1960s and 1970s, the performance accountability movement was popular in the United States. Boyer and Radoqi proposed in their book "Musical Experience Measurement and Evaluation" that the service functions of music education program evaluation may have the following types: responsibility system; teaching effect; teacher effect; classroom effect; subject knowledge taught and so on. The abovementioned theoretical and practical research has established important value standards for the development of an evaluation index system for teaching effects. Educational evaluation is developed from educational measurement [19, 20].

Overview of Music Teaching Evaluation in my country. Educational measurement can be traced back to various tests in the 19th century. The initial germination of education evaluation in my country originated from the ancient imperial examination system. It is considered to be the earliest comprehensive examination in the world. Some people call it the "civilian examination." The purpose of the examination is to become an official. People flew up and down overnight. Due to various reasons, the research on educational testing, measurement, and evaluation in my country has not been developed since the last century. After the founding of the People's Republic of China, my country's education evaluation has gradually developed. Since the 1950s, my country has been following the Soviet Union's music education evaluation model. It shows the phenomena of "compulsion" (ignoring the development of the main body), "rigidity" (ignoring development vitality), "one-sided" (ignoring overall development), and "separation" (ignoring the integration of evaluation and development) of evaluation. Music teaching evaluation emphasizes the purpose of "evaluation," and "selection" pays attention to serving the society through the management function of evaluation and talent selection but ignores the aesthetic education function and development function of evaluation. Evaluation emphasizes the guidance of external objectives but ignores the objectivity of the needs of the evaluation object and cannot focus on stimulating the internal motivation of the evaluation object, so as to promote the positive development of the subject of the evaluation object, and most of the evaluation objects are in a passive position. The evaluation is to use standardized examination or paper and pencil test as the only means to evaluate students. Teaching evaluation often only pays attention to the level of scores and ignores them. The objectivity of the evaluation object is based on the degree of effort: too much attention is paid to the evaluation result and the meaning of the evaluation process itself is ignored; teaching evaluation is a partial and nonholistic objective evaluation. For example, the school considers students' progress to higher education (advanced to higher art colleges) and awards in various competitions at all levels that students participate in as important indicators for evaluating music teachers' teaching performance. The school organizes relevant personnel to attend classes in the classroom and scores according to a predesigned scale, and then calculates the total score uniformly to determine the pros and cons of the class. This kind of evaluation work is carried out in some parts of the chain. Therefore, they are not scientific enough or comprehensive enough for teaching evaluation. The abovementioned various teaching evaluations affect a series of operation sequences and judgment methods, which make the functional structure of evaluation deviate from the track of quality education, and thus, the content and methods of music teaching cannot be truly reformed. At present, the evaluation of music teaching in my country mainly presents the following basic characteristics:

- (i) Evaluation content-excessive reliance on subject knowledge (a static knowledge), especially knowledge in textbooks: teachers rely on participating in textbooks to strengthen the knowledge and knowledge of textbooks. Analysis and practice of skills. Ignore the evaluation and analysis of students' emotions and attitudes, the internalization and integration of knowledge and skills.
- (ii) Evaluation subject-teachers are the mainstay, ignoring evaluations at the same level and evaluations from different sources, for example, parent evaluation, student evaluation, manager evaluation, and multiple evaluation. Although some students selfevaluate, in general, students are still in a negative position to be evaluated.
- (iii) Evaluation results—Most of the evaluation results pay attention to the final results, pay more attention to horizontal comparison, and emphasize the conclusion of summary evaluation, while ignoring the progress of each stage and the scientific process of the result feedback. Therefore, teaching evaluation has not achieved good results.
- (iv) Evaluation index—single: the status quo places more emphasis on commonality and general trends, ignoring the differences and uniqueness between individuals.
- (v) Evaluation method—monotonous: pay more attention to "quantification" and ignore "qualitative" evaluation. Because the formulation of reliability and validity is a description of quantification, it is difficult to describe a person's overall characteristics as a result of quantification, and "qualitative"

evaluation focuses on the process and can promote the development of the individual.

- (vi) Evaluation methods—traditional paper and pen methods are mostly used, and there is a lack of techniques and methods that reflect the latest evaluation ideas.
- (vii) Evaluation implementation process: the current evaluation implementation process is closed, static, and lacking in flexibility and dynamics. The evaluation process should be dynamic, allowing multiple evaluations.

In recent years, with the rapid growth of knowledge, the original knowledge structure can no longer meet the needs of the development of the times. Music teaching has shifted from focusing on skills to focusing on cultivating students' emotions, attitudes, and values. Music teaching evaluation has shifted from summative evaluation to formative evaluation; from partial evaluation to overall and comprehensive evaluation; from passive waiting for evaluation to active participation in evaluation development. In terms of evaluation theory, it emphasizes the evaluation of comprehensive qualities such as the ability to solve practical problems, innovative ability, practical or practical ability, good psychological quality and scientific spirit, and positive learning mood. Evaluation is no longer for selection and screening, but for the growth and progress of students. Evaluation is no longer "selecting children suitable for education" but "creating education suitable for children." Evaluation should be expressed in terms of motivation and integration functions. To evaluate a teacher's teaching is to enable the teacher to understand his own development direction in his evaluation and self-evaluation, so as to use the power of evaluation to integrate his/her teaching abilities and gain lessons in class [21, 22]. Better, complete the teaching work better. With the continuous deepening of reform and opening up and the introduction of advanced foreign education and teaching methods, art education, especially music education, as an important part of quality education, has received more and more attention. In recent years, the evaluation of music teaching has developed rapidly. In the process of music teaching evaluation, people expect a more scientific and feasible way to make an objective and feasible evaluation of teaching quality; hope that through evaluation, it will help teachers and students diagnose problems in the teaching and learning process and improve teaching strategies. We should make clear the direction of our efforts. It is hoped that through evaluation, communicating the existing problems, improving teaching strategies, and exchanging information, teachers can continuously improve education and teaching methods and improve teaching ability and level. We hope to promote the continuous development of students' personality through evaluation. And we hope to adjust the school management strategy and improve the overall level of school education and teaching through evaluation.

3. Method

Machine learning is a discipline that studies how to use machines to simulate human learning activities. It is the study of machines to recognize existing knowledge, acquire new knowledge and new skills, continuously improve performance, and achieve self-improvement. The initial research purpose of machine learning is to make computer systems have human learning capabilities in order to realize artificial intelligence. It has mainly experienced three processes: the enthusiastic period (from the mid-1950s to the mid-1960s), the calm period (from the mid-1960s to the mid-1970s), and the revival period (from the mid-1970s to the mid-1980s). Among them, the successful holding of the first machine learning international academic exchange seminar at Carnegie Mellon University in 1980 marked the rise of machine learning research all over the world. Nowadays, with the continuous development of computer technology, human beings have collected and accumulated a large amount of data in various fields, such as search engines, geological prospecting, speech and handwriting recognition, information security, robot application, securities market analysis, and other fields. However, how to analyze the potential laws from these massive data has become a common demand in almost all fields. This is why machine learning technology has received increasing attention. At present, machine learning has become another important research field of artificial intelligence applications after expert systems (subject to the bottleneck problem of knowledge acquisition), and it has become one of the most active and promising fields in computer science. Currently, the widely used machine learning methods mainly include decision trees, SVM, Bayesian theory, and RFs.

Decision tree algorithm is one of the most classic machine learning algorithms. It is an algorithm that classifies and learns data through a top-down, well-organized process. The purpose of the decision tree algorithm is to recursively divide the observations into mutually exclusive subgroups until there are no more differences in the given statistics. Among the statistics used to find the classification attributes of tree nodes, information gain, gain ratio, and Gini index are the most commonly used. Usually, iterative dichotomy (ID3) uses information gain, C4.5 and C5.0 use gain ratio, and classification and regression tree (CART) uses Gini index. The support vector machine tries to find a hyperplane to separate the classes, minimize the classification error, and maximize the margins. SVM is a good classification and regression technique proposed by Vatnik of Bell Laboratories, AT&T. Through calculating the probability of an object belonging to a certain category, the Bayesian classifier classifies the samples. The theoretical basis of its classification is Bayes' theorem. According to the Bayesian formula, the posterior probability of an object is calculated according to the prior probability, and the class with the largest posterior probability is selected as the class to which the object belongs. In other words, the Bayesian classifier is an optimization in the sense of the minimum error rate. Random forest is a type of ensemble learning, which is an algorithm that integrates the classification effects of multiple

decision trees. It consists of multiple base classifiers, and each base classifier is a decision tree. Each decision tree acts as a separate classifier, independently performing learning and classification prediction. These predictions are finally integrated to obtain a total prediction that is better than all the individual classifiers. There are many performance indicators for evaluating the classification model based on the correctness of the model classification decision. Suppose that in a binary classification task, the value of the class variable can be assumed to be positive (P) and negative (N). The classification of actual positive cases (P) correctly marked as positive cases is named true cases (TP), and the classifiers where actual positive cases are incorrectly marked as negative cases are false-negative cases (FN). In a similar manner, actual negative examples (N) that are correctly marked as negative examples are regarded as true-negative examples (TN), and actual negative examples that are incorrectly marked as positive examples are regarded as false-positive examples (FP).

4. Experiment and Result Analysis

Data collection and characterization. We selected the student evaluation data of a university in recent two years and randomly selected 3150 scoring data, of which the number of positive samples is 1769 and the number of negative samples is 1183. Each of scoring data has 37 variables, which come from students' online scoring, involving classroom preparation, classroom performance, course implementation, case organization, homework correction, teacher attitudes, and course network construction. The range of values is from 1 to 5. The numbers on the scale from 1 to 5 point to "strongly disagree," "disagree," "neutral," "agree," and "strongly agree"; or "never," "rarely," "sometimes," "often," and "always." The last variable is a binary variable, which is the student's overall evaluation information of the teacher, where 1 means "unsatisfied" and 2 means "satisfied." This variable serves as the class label of the data sample. Divide all samples into training set and test set. In order to ensure the balance of positive and negative samples, 70% of them were randomly selected from the positive and negative sample sets, totaling 2205 as the training set. The positive samples were 1377, the negative samples were 828, and the remaining 945 were used as the test set. The number of positive samples was 590, and the number of negative samples is 355.

This article generates four classification models. Its performance is evaluated by the precision rate, recall rate, F1 value, and accuracy rate of the test data. In the decision tree algorithm, the gain ratio is used as the measurement index, and multipath partitioning is adopted, and the minimum value of each subinstance is set to 2. The confusion matrix of DS classification is shown in Table 1.

In the parameter selection of the support vector machine classifier, a polynomial function is used as the kernel function. The confusion matrix of SVM classification is shown in Table 2.

Naive Bayes parameter selection. Since the sample feature value is a discrete value in the range of 1–5, we choose the naive Bayesian polynomial NB with polynomial distribution a priori, and the prior probability is calculated from

Journal of Mathematics

the training set sample. The confusion matrix of the NB classification results is shown in Table 3.

When the random forest classifier is used for classification learning, in order to prevent the occurrence of overfitting or underfitting, the number of base classifiers is selected as 10. Since the number of dataset samples selected in this article is not large, the decision tree is not limited depth. The classification results of confusion matrix of RF are shown in Table 4.

Finally, use the evaluation index to compare the performance of the applied classifiers. It also can be seen from Table 4 that the classifier gives similar results in the test dataset. When comparing the model performances, it is found that all the methods used in this article can effectively classify the "satisfied" and "unsatisfied" teacher performances, which are shown in Figures 1–3.

The accuracy of all classifier models is at least 89%. The random forest classifier has the best performance, followed by SVM, and NB has the worst performance. The results of accuracy rate F1 and recall rate once again show that random forest is the best classifier. There are some differences in the results of other classifiers. It can be said that all classifiers can better predict the results of students' evaluation of teachers. However, according to the given performance index, random forest is the best among all the selected classifiers.

Then, analyze the evaluation indicators used in student evaluation, and dig out the importance of each evaluation indicator under each classifier. The management department can improve the evaluation and assessment indicators according to the importance of the indicators and formulate the assessment mechanism more scientifically. Among the four methods used, three methods, decision tree, support vector machine, and random forest, are selected for eigenvalue importance analysis.

For decision tree classification algorithms, information gain (IG) is used to calculate feature importance for the decision tree. For each feature a, calculate the "information gain" obtained by dividing the sample set D with the attribute a. The larger the information gain, the more important the attribute.

Actual value	Predictive value		
Actual value	Positive example	Counter example	Total

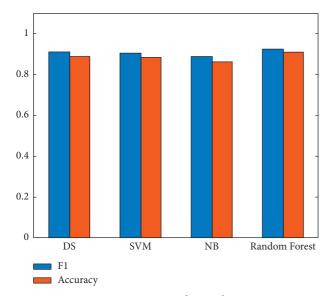

FIGURE 3: Comparison of F1 and accuracy.

$$\operatorname{Gain}(D, a) = \operatorname{Ent}(D) - \sum_{\nu=1}^{V} \frac{|D^{\nu}|}{D} \operatorname{Ent}(D^{\nu}), \qquad (1)$$

where Ent(D) is the information entropy of D:

$$\operatorname{Ent}(D) = -\sum_{k=1}^{|y|} p_k \log_2 p_k,$$
(2)

where p_k (k = 1, 2, ..., |y|) represents the proportion of the k sample in this set D. In the decision tree classifier, the first three important variables are V23: "This class has helped me increase my knowledge and interest in the subject," V13: "The teacher is very enthusiastic about this subject," and V5: "The teacher is very enthusiastic about the subject." The knowledge of the company is well mastered. The importance of features in support vector machines is usually considered the absolute value of the feature coefficient, that is, the weight corresponding to the independent variable. For the dataset used in this article, the three most important variables of SVM are V25: "Teacher's rating (homework/examination) is fair," V23: "This course helped me increase my knowledge and interest in the subject," and V22: "I need to spend a lot of time preparing homework/exams." In the random forest algorithm, the feature importance is calculated by dividing the sum of the Gini coefficients of each feature classification by the Gini coefficient of the total feature. First, calculate the importance of each feature based on a single tree, explore the contribution rate of each feature to each tree, and then take the average. The three most important variables for calculating RF are V22: "The homework/ exam fully tests the knowledge taught", V17: "The course materials (textbooks, handouts, cases, etc.) are perfect," and V23: "This course helps me Increased knowledge and interest in the subject."

5. Conclusion

In this article, we classified the online course evaluation data through machine learning methods and analyzed the importance of characteristics of student evaluation. The different dimensions of college courses and teacher effectiveness are measured by the online course evaluation. It has been proved by the experiments that the machine learning method accurately classifies teachers' "satisfaction" and "dissatisfaction." In this article, we used different classification techniques, which include decision tree algorithms (DS), support vector machines (SVM), Bayesian theory, and random forest (RF) methods. The results showed that performance indicators of all the mentioned techniques were around 90%. Among them, students' personal interests and knowledge gained are the main basis for students to evaluate courses. These results can be used to improve the establishment and improvement of online evaluation indicators, so as to set more reasonable and scientific evaluation indicators.

On daily life datasets, data mining techniques are proposed, especially the effectiveness of DS, SVM, NB, and RF in higher education data mining. This can help teachers carry out reasonable teaching reforms and experiments based on the analysis results in a timely manner and improve their own teaching ability. The analysis result of the feature importance of the classifier shows that there are many possible improvements in the design of the measurement indicators used in the teacher performance evaluation, and it provides a certain reference for the management department to improve the evaluation indicators.

Generally speaking, in the process of teaching work, ordinary colleges and universities reform the teaching evaluation system of musicology, which can carry out the teaching work of musicology in a scientific and regular manner, and integrate the main tasks of musicology teaching in colleges and universities. Completed smoothly, so in the process of organizing classroom teaching activities, music teachers should respect the students' personalities, make reasonable references to the teaching evaluation system, and give full play to the students' learning enthusiasm, so that through classroom teaching activities, every student can obtain a certain amount of music knowledge. In this way, a large number of music talents in line with social development can be cultivated and the progress of music education can be promoted.

Aiming at the problems of poor classification effect, low accuracy, and long time in the current automatic classification methods of music genres, an automatic classification method of music genres based on deep belief network and sparse representation is proposed. The music signal is preprocessed by framing, pre-emphasis, and windowing, and the characteristic parameters of the music signal are extracted by Mel frequency cepstrum coefficient analysis. The restricted Boltzmann machine is trained layer by layer to obtain the connection weights between layers of the depth belief network model. According to the output classification, the connection weights in the model are fine-tuned by using the error back-propagation algorithm. Based on the deep belief network model after fine-tuning training, the structure of the music genre classification network model is designed. Combined with the classification algorithm of sparse representation, for the training samples of sparse representation music genre, the sparse solution is obtained by using the minimum norm, the sparse representation of test vector is calculated, the category of training samples is judged, and the automatic classification of music genre is realized. The experimental results show that the music genre automatic classification effect of the proposed method is better, the classification accuracy rate is higher, and the classification time can be effectively shortened.

1. Introduction

Music is an art that can effectively show human emotions. At the same time, music is a note composed of a specific rhythm, melody, or musical instrument according to certain rules [1-3]. Rock music, jazz, classical music, and other music genres are examples of diverse style tracks comprised of unique beats, timbres, and other aspects exhibited in music works. With the fast development of network and multimedia technologies, people's primary method of listening to music has shifted to digital music, which has fueled people's need for music appreciation to some level [4-6]. Most online music websites' major categorization and retrieval elements are now based on the music genre. Simultaneously, the music genre has evolved into one of the categorization features used in the administration and storage of digital music databases. The pace of database updating is sluggish when dealing with a large volume of music data information. The effectiveness of manual

labelling in the early days of music information retrieval could not satisfy the real demands of contemporary management. Therefore, it is of great significance to study the automatic classification of music genres.

At present, scholars in related fields have studied the classification of music genres and achieved some theoretical results. Reference [7] proposed a music type classification method based on Brazilian lyrics using the BLSTM network. With the help of genre labels, songs, albums, and artists are organized into groups with common similarities. Support vector machine, random forest, and two-way short- and long-term memory networks are used to classify music types, combined with different word embedding techniques. This method is effective. Reference [8] proposed a music genre classification method based on deep learning. Machine learning technology is used to classify music types. The residual learning process, combined with peak and average pool, provides more statistical information for higher-level neural networks. This method has significant classification

performance. However, the above methods still have the problems of low classification accuracy, long time, and poor effect.

An automated music genre categorization technique based on deep belief networks and sparse representation is suggested to address the aforementioned issues. Framing, pre-emphasis, and windowing are used to preprocess the music signal, and Mel frequency cepstrum coefficient analysis is used to extract the signal's distinctive properties. A music genre classification network model is built based on the deep belief network and integrated with the sparse representation classification technique to achieve autonomous music genre categorization. This method has a good effect and high accuracy in music genre classification and can effectively shorten the classification time.

2. Deep Belief Network and Sparse Representation

2.1. Deep Belief Network

2.1.1. Restricted Boltzmann Machine. Restricted Boltzmann machine (RBM) belongs to a randomly generated neural network based on the probability distribution characteristics of the learning input data set [9–11]. It can be seen that the layer $q = \{q_1, q_2, \ldots, q_n\}$ and the hidden layer $w = \{w_1, w_2, \ldots, w_m\}$ together constitute an RBM, in which the neurons in each level have no connection. Use $q_i \in \{0, 1\}, w_j \in \{0, 1\}$ to describe the value of the binary random unit. The data features are mainly described by neurons in the visible layer, and the features of hidden layer neurons are used for feature extraction. The RBM network structure is shown in Figure 1.

The RBM energy function is defined as the following formula:

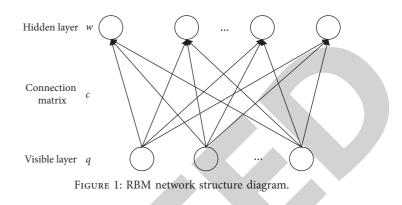

$$E(q, w; \alpha) = -q^{T}Ww - z^{T}q - x^{T}w$$

= $-\sum_{i=1}^{n} b_{i}q_{i} - \sum_{j=1}^{m} z_{j}w_{j} - \sum_{i=1}^{n} \sum_{j=1}^{m} q_{j}c_{ij}w_{j}.$ (1)

In formula (1), $\alpha = \{a, b, w\}$ is a real parameter, q_i and w_j are used to describe the states of the *i* and *j* neurons in the RBM layers, z_j is the bias of q_i , b_i is the bias of w_j , c_{ij} is the weight between the states of q_i and w_j neurons, and *n*, *m* is its corresponding node. According to formula (1), the joint probability distribution $P(q, w; \alpha)$ of (q, w) can be obtained as the following formula:

$$P(q, w; \alpha) = \frac{1}{V(\alpha)} \exp\left(-E(q, w; \alpha)\right).$$
(2)

In formula (2), $V(\alpha)$ is a normalized function. When both q and w are known, formulas (3) and (4) are used to express the activation probability of neurons in the two layers of RBM:

$$P\left(w_{j} = \frac{1}{q}\right) = \text{sigmoid}\left(b_{j} + \sum_{i} q_{i}c_{ij}\right), \quad (3)$$

$$P\left(q_{i} = \frac{1}{w}\right) = \text{sigmoid}\left(z_{i} + \sum_{j} c_{ij}w_{j}\right).$$
(4)

In formulas (3) and (4), sigmoid = $1/1 + e^{-x}$ is the activation function. When the training data set *K* is given, the likelihood function is maximized to express the RBM target as shown in the following formula:

$$H_{\alpha,K} = \sum_{n=1}^{o} \log P(q^n).$$
⁽⁵⁾

In formula (5), δ is the number of training set data. The essence of RBM is to map the original data to different feature spaces to retain the key feature information of the data and obtain a better low-dimensional representation. According to this idea, an idea of optimizing RBM training in this paper is to replace the objective function formula (5) of RBM equally. If the output of each RBM is converted according to formula (6), the output of its hidden layer can be inversely converted and then compared with the original data. The errors of the two can be used as the standard to judge the learning effect of the current RBM network, so as to learn the key features of the data faster.

$$T = (G_{y}J + \kappa)J^{T} + \theta.$$
(6)

In formula (6), G_y is the original data set, J is the weight of RBM, J^T is the transposed matrix of J, κ is the bias of the visible layer, and θ is the bias of the hidden layer. The difference between the new data obtained by formula (6) and the original data is calculated, and the mean square error MSE is used as the objective function of RBM, and then, the optimization algorithm is used for evaluation.

2.1.2. Deep Belief Network. Deep belief network (DBN) is one of unsupervised learning algorithms [12–14]. It is composed of RBM, so there is no connection in the same layer. The relationship between the two layers of RBM is represented by a joint probability distribution. Journal of Mathematics

$$P(q, w^{1}, w^{2}, ..., w^{l}) = P(q|w^{1})P(w^{1}|w^{2}),$$

..., $P(w^{l-2}|w^{l-1})P(w^{l-1}, w^{l}).$ (7)

In formula (7), l is the number of hidden layers of DBN. DBN is a hybrid model composed of two parts. The structure of the DBN model is shown in Figure 2.

As shown in Figure 2, the undirected graph model of the top two layers forms associative memory, and the other layers are directed graph models. In practice, they are stacked restricted Boltzmann machines. They are Boltzmann machine layers stacked layer by layer, two adjacent to each other. However, the training in the DBN model has direction. DBN training method can be simply summarized into two parts: first, RBM is trained layer by layer to obtain better initial parameter values, and then, the network is optimized. The specific steps are as follows:

The original input is set to $s^{(i)}$, $d^{(i)}$ is used to describe the reconstructed input, and batch gradient descent tuning is used for *n* samples of a given training set $\{(s^{(1)}, d^{(1)}), \ldots, (s^{(i)}, d^{(i)})\}$ [15, 16]. The sample size loss function can be expressed as follows:

$$C(R, \nu) = \left[\frac{1}{n}\sum_{i=1}^{n} C(R, \nu; s^{(i)}, d^{(i)})\right] + \frac{\lambda}{2}\sum_{l=1}^{m_{i}}\sum_{i=1}^{s_{i}}\sum_{j=1}^{s_{i}} \left(M_{ij}^{(l)}\right)^{2}$$
$$= \left[\frac{1}{n}\sum_{i=1}^{n} \left(\frac{1}{2}\left\|h_{R,\nu}(s^{(i)}) - s^{(i)}\right\|\right) + \frac{\lambda}{2}\sum_{l=1}^{m_{i}-1}\sum_{i=1}^{s_{i}}\sum_{j=1}^{s_{i}} \left(M_{ij}^{(l)}\right)^{2}\right].$$
(8)

In formula (8), $M_{ij}^{(l)}$ is used to describe the weight coefficient between the *i* and *j* nodes in the *l* and *l* + 1 layers, $v_i^{(l)}$ is used to describe the *i* node offset in the *l* layer, and $h_{R,\nu}(s^{(i)})$ is used to describe the result after $s^{(i)}$ reconstruction. The difference between the original input and the current input after reconstruction is calculated, that is, the mean square error term. In order to avoid overfitting, the weight coefficient is greatly reduced, that is, the regularization term. The above two items are balanced by λ . $C(R, \nu)$ is used to describe the correctness of the convex function. In order to obtain the global optimal solution, the gradient descent method is used to realize it [17, 18]. In order to optimize the loss function, the mean square error is reconstructed to minimize it, and the partial derivative of $C(R, \nu)$ is found as follows:

$$\frac{\partial C(R,\nu)}{\partial M_{ij}^{(l)}} = \left[\frac{1}{n}\sum_{i=1}^{n}\frac{\partial C(R,\nu;s^{(i)},d^{(i)})}{\partial M_{ij}^{(l)}}\right] + \lambda M_{ij}^{(l)},\qquad(9)$$

$$\frac{\partial C(R,\nu)}{\partial \nu_i^{(l)}} = \frac{1}{n} \sum_{i=1}^n \frac{\partial C(R,\nu;s^{(i)},d^{(i)})}{\partial \nu_i^{(l)}}.$$
(10)

DBN has good flexibility; that is, it is easy to expand to other networks or combine with other models. A typical example of DBN expansion is the convolution depth belief network.

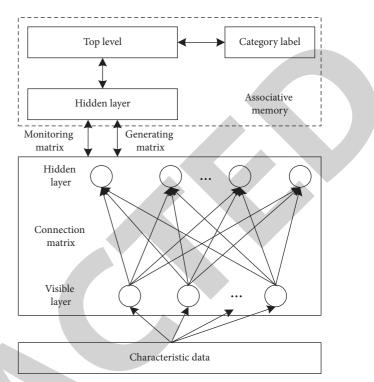

FIGURE 2: DBN model structure diagram.

2.2. Sparse Representation

2.2.1. Sparse Representation Method. If there are G type training samples, and there are sufficient numbers in any category, the *i* training sample data and number are denoted by $B_i = [b_{i,1}, b_{i,2}, \ldots, b_{i,n_i}] \in \mathbb{R}^{m \times n_i}$ and *m*, respectively, and the feature set dimension is denoted by n_i . Then, its space is composed of n_i column vectors, and the linear combination is expressed as follows:

$$y = \chi_{i,1}b_{i,1} + \chi_{i,2}b_{i,2} + \dots + \chi_{i,n_i}b_{i,n_i}.$$
 (11)

In formula (11), $\chi_{i,n_i} \in R$ is described as the linear coefficient to be solved. Therefore, a complete vector matrix *U* is defined, which is represented by training samples of *G* categories, and the vector matrix is represented by test samples of different categories that can be written as follows:

$$U = [U_1, U_2, \dots, U_G] = [b_{1,1}, b_{1,2}, \dots, b_{G,n_G}] \in \mathbb{R}^{m \times n_i}.$$
 (12)

At this time, for the test sample y from the i category, the space formed by the training matrix U can be rewritten as follows:

$$y = Up_0 \in \mathbb{R}^m. \tag{13}$$

In formula (13), $p_0 = [0, \dots, 0, \chi_{i,1}, \chi_{i,2}, \dots, \chi_{i,n_i}, 0, \dots, 0]^T \in R$ is the coefficient vector.

2.2.2. Seeking Sparse Solution. When m > n, the reconstructed training matrix space has a unique solution. However, under normal circumstances, when $m \le n$, the reconstructed training matrix space has infinite solutions. As a result, the nonzero vectors contained in the coefficient

vector obtained by reconstructing the training matrix space are reduced, which can be converted to

$$p_0 = \arg\min \|p\|_0 \text{ subject to } \text{Up} = y.$$
(14)

In formula (14), $\|\cdot\|_0$ is described as l^0 norm. However, formula (14) has an NP problem, which is difficult to solve. Therefore, solving the NP problem by minimizing the problem [19, 20] is expressed as follows:

$$p_1 = \arg\min \|p\|_1 \text{ subject to Up} = y.$$
(15)

In formula (15), $\|\cdot\|_1$ represents the l^1 norm, and \hat{p}_1 is the approximate solution of p.

3. Automatic Classification Method of Music Genre

Music genre is a traditional means of categorising the attribution of musical works, and it is commonly separated into categories based on historical context, geography, origin, religion, musical instruments, emotional topics, performance styles, and so on. Western music dominates the music genres. Western music encompasses a wide range of musical styles. Classical, blues, rock, pop, metal, jazz, country, hip-hop, and other music genres are widespread [21-25]. This research proposes a deep belief network and sparse representation-based automated music genre categorization approach. A music genre categorization network model is created by preprocessing music signals, extracting music signal characteristic parameters, pretraining, and finetuning the DBN model. The sparse representation of the test vector is calculated, the category of the training samples is assessed, and the automated classification of music genres on this basis is achieved, in combination with the sparse representation classification method. The automatic classification process of music genres based on a deep belief network and sparse representation is shown in Figure 3.

3.1. Preprocessing Music Signal. Usually, before classifying music genres, music signals need to be preprocessed, which is mainly divided into three steps: framing, preemphasis, and windowing. The music signal preprocessing process is shown in Figure 4.

(1) Framing: For signal processing, framing is generally performed. The purpose of framing is to facilitate the extraction of features, and framing can also reduce the dimensionality of the feature matrix. When framing, you need to select the appropriate frame length and frame width. The following relationship among the sampling period T = 1/f, window width *L*, and frequency *F* can be expressed as:

$$F = \frac{1}{LT}.$$
 (16)

It can be seen from formula (16) that when T is constant, the frequency F is determined by the change of the window width L, which is inversely proportional. At this time, the frequency resolution

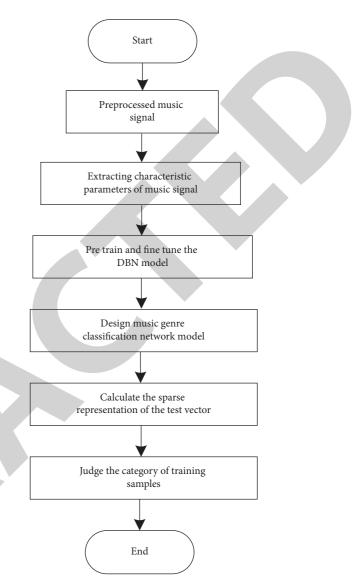

FIGURE 3: Flow chart of automatic classification of music genres based on deep belief network and sparse representation.

is improved, but the time resolution is reduced. Increasing the window width will result in a decrease in frequency resolution and an increase in time resolution, resulting in a contradiction between window width and frequency resolution. For this reason, an appropriate window length should be selected according to different needs. If the window width becomes larger, the appropriate window width is selected according to different needs. When selecting the length, we should also consider that it is suitable for computer operation. The computer operation is based on binary, so the selected length should also be an integer multiple of 2 as far as possible.

(2) Pre-emphasis: When classifying music genres, because glottic excitation directly affects the average power spectrum of music signals, it is difficult to obtain the spectrum. Therefore, pre-emphasis

FIGURE 4: Flow chart of preprocessing music signal.

processing of music signals is required. In this paper, the first-order digital filter is used to pre-emphasis the music signal. The formula is as follows:

$$H(z) = 1 - az^{-1}.$$
 (17)

In formula (17), a is the pre-emphasis factor, which is generally taken as a decimal number close to 1. Assuming that the sample value of the music genre signal at time n is x(n), the result after pre-emphasis is as follows:

$$y(n) = x(n) - ax(n-1).$$
 (18)

(3) Windowing: It is for framing service. Framing itself means adding a window function. However, due to the truncation effect of the frame during framing, it is necessary to select a good window function. The good slope at both ends of the window shall be reduced as slowly as possible to avoid drastic changes. The frame division is realized by the method of movable finite-length window weighting; that is, the music signal with window is expressed as follows:

$$s_{\omega}(n) = s(n) \times \omega(n).$$
(19)

Digital processing of music signal using rectangular window and Hamming window is expressed as follows:

Rectangular window:

$$\omega(n) = \begin{cases} 1, & 0 \le n \le n-1, \\ 0, & \text{otherwise.} \end{cases}$$
(20)

Hamming window:

$$\omega(n) = \begin{cases} 0.54 - 0.46 \cos\left(\frac{2\pi n}{(M-1)}\right), & 0 \le n \le M-1, \\ 0, & n = \text{else.} \end{cases}$$
(21)

In formula (21), M is expressed as the frame length. The comparison of relevant indexes of the rectangular window and Hamming window function is shown in Table 1.

As can be seen from Table 1, for the main lobe width, the rectangular window is smaller than the Hamming window. However, the outer band attenuation of the rectangular window also decreases. Although the rectangular window has a good smoothing performance, its high-frequency component has a certain loss and loses the detail component. According to the above analysis, the Hamming window function has good performance.

3.2. Extracting Characteristic Parameters of Music Signal. The process of precisely describing a music signal using a set of parameters is known as music signal feature parameter extraction. To some degree, the performance of music genre categorization is determined by the selection of music characteristics. The accuracy and speed of music genre categorization may be improved by using good music signal properties.

Through the examination of the results of hearing trials, Mel frequency cepstral coefficient (MFCC) analysis, it is thought that its voice qualities are excellent [26, 27]. The linear spectrum is first mapped to the Mel nonlinear spectrum based on auditory perception and then turned into a cepstrum, taking into consideration the features of human hearing. According to the work of *Stevens* and *Volkman*, there is the following conversion relationship:

$$f_{\rm mel} = 2595 \times \log_{10} \left(1 + \frac{f}{700} \right).$$
 (22)

In formula (22), f_{mel} is used to describe the perceived frequency, which is in Mel, and f is used to describe the actual frequency, in Hz. The music signal is preprocessed by the first-order FIR high-pass filter to the MFCC music signal. The goal is to compensate for the spectrum. Next, the preprocessed signal is divided into multiple overlapping frames, and each frame is multiplied by the Hamming window to reduce the ringing effect. The FFT operation is performed on each frame, and the corresponding frequency spectrum is obtained corresponding to the frame of the Hamming window. After the discrete cosine transform (DCT) processes the logarithm of Y(b), the parameters for obtaining MFCC are expressed as follows:

MFCC(
$$\gamma$$
) = $\sum_{b=0}^{Z-1} \ln(1 + E(b)) \cos\left(\gamma \frac{\pi}{Z} (b + 0.5)\right)$, (23)

$$E(b) = \sum_{k=0}^{O-1} |X_a(k)|^2 H_b(k), 0 \le b \le Z.$$
(24)

In formula (23), *Z* is the total number of filters, and γ is the length of the MFCC feature vector. The function of offset 1 in MFCC is to get positive energy for any value. Finally, the MFCC feature vector is expressed as follows:

$$X_{\text{MFCC}} = [\text{MFCC}(0), \text{MFCC}(1), \dots, \text{MFCC}(\gamma - 1)]^{T}.$$
 (25)

3.3. Design of Music Genre Classification Network Model. The DBN model structure is formed by stacking RBMs. The feature dimension of the input sample is set to the number of visible units, and the number of hidden layer units needs to

TABLE 1: Comparison of relevant indexes of rectangular window and Hamming window function.

Sidelobe peak (dB)	Main lobe width	Minimum stopband attenuation (dB)
-14	4Π/M	-23
-15	8П/M	-51
	-14	-14 4Π/M

be given in advance. For the visible layer and the hidden layer, *c* is used to describe the connection matrix, and κ and θ are used to describe the bias vector. The implementation steps of the fast contrast divergence learning method are as follows:

- (1) Initialization: $q_1 = x_0$ is used to describe the initial state of the visible layer, and *c*, κ , and θ is used as random small values.
- (2) Cycle all $q^{(t)}, t = \{1, 2, 3, \dots, T\}$:

Find the conditional probability distribution $P(q, w; \alpha)$, and select $q \in \{0, 1\}$ from it Find the conditional probability distribution $P(w', q; \alpha)$, and select $w' \in \{0, 1\}$ from it Find the conditional probability distribution $P(q', w'; \alpha)$, and select $q' \in \{0, 1\}$ from it.

(3) Parameter update:

$$c(t+1) = c(t) + \vartheta (P(q, w; \alpha)w - P(q', w'; \alpha)w')$$

$$\kappa(t+1) = \kappa(t) + \vartheta (w' - w)$$
(26)

$$\theta(t+1) = \theta(t) + \vartheta (P(q, w; \alpha) - P(q', w'; \alpha)).$$

This article is based on the DBN model training implemented by the Theano library written in Python. The training of the DBN model includes two stages. The first step is the pretraining stage. The RBM is trained layer by layer from the DBN input layer to the output layer to obtain the DBN model layer and layer. The connection weight among each neural unit in the hidden layer is independent and obtained through *Gibbs* sampling. In the second step, in the fine-tuning stage, DBN uses the error back-propagation algorithm to fine-tune the connection weights in the model according to the output classification and sets the objective function as the maximum likelihood function to optimize the whole model. According to the RBM network structure [28–30], this paper designs the music genre classification network model structure as shown in Figure 5.

3.4. Classification Algorithm Based on Sparse Representation. Under the music genre classification network model structure, for the test sample y, the sparse representation \hat{p}_1 of the test vector can be calculated through formulas (13) and (15). The nonzero coefficients in the estimation should be related to the atoms belonging to a certain class *i* in *U*. Based on these nonzero coefficients, we can quickly judge which class the test sample belongs to [31, 32]. However, due to the existence of factors such as noise and model errors, there will be a small number of cases where \hat{p}_1 is not zero in the projection coefficient. In order to distinguish the categories where y exists, a new vector $\delta_i(\hat{p}_1) = [0, \dots, 0, \chi_{i,1}]$,

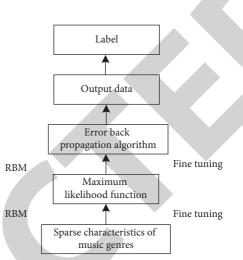

FIGURE 5: Structure diagram of music genre classification network model.

 $\chi_{i,2}, \ldots, \chi_{i,n}, 0, \ldots, 0]^T$, $i = 1, 2, \ldots, G$ is constructed, whose nonzero elements are only \hat{p}_1 related components. If $\hat{y}_i = U\delta_i(\hat{p}_1)$, and there is a small distance from y, then \hat{y}_i belongs to this category has a higher probability. The calculation formula is as follows:

$$\iota_{i}(y) = \left\| y - U\delta_{i}(\hat{p}_{1}) \right\|_{2}, \quad i = 1, 2, \dots, G.$$
(27)

So the method of judging which category *y* belongs to is as follows:

$$identity(y) = \arg\min_{i}\mu_{i}(y).$$
(28)

Through the above steps, the automatic classification of music genres is realized.

4. Experimental Analysis

ļ

4.1. Experimental Environment and Data Set. The MATLAB 2016a programming software is utilised as an experimental platform, and a deep belief network based on the Theano library of Python language is developed to validate the efficiency of the automated categorization technique of music genres based on deep belief networks and sparse representation. Too much sample data will take up a lot of processing time while updating each level in the deep belief network. The sample database is separated into tiny batches of data packets in preparation to boost computing performance, and then, the batch learning approach is utilised. The fine-tuning learning rate is set to 0.1, while the pretraining learning rate is set to 0.01, in this study, and tests and verifications are carried out using the GTZAN data set, which contains 1000 audio files. There are ten different sorts of music genres included in these 1000 files, each having 100 samples. MPCC is utilised to extract the distinctive characteristics of a music signal in this experiment [33, 34]. The frame length is 512, and the number of frames is 2133. The sampling frequency is 48000 Hz, the sample bits are 16, the frame length is 512, and the number of frames is 2133 [33, 34]. In the stage of extracting Mel frequency cepstrum coefficient, 12 dimensional Mel filter is used, and its frequency index is shown in Table 2.

The classification algorithm is based on the combination of a deep belief network and sparse representation. The methods of reference [7] and the methods of reference [8] are compared with the proposed methods to verify the effectiveness of the proposed methods.

4.2. Evaluation Indicators for Automatic Classification of Music Genres. The automatic classification evaluation indexes of music genres used in this paper are classification accuracy, recall, F1 value, confusion matrix, and classification time. The above classification evaluation indexes are used to evaluate the performance of the proposed method. The classification accuracy is expressed as the ratio of the number of correct samples to the total number of music genre samples. The calculation formula is expressed as follows:

$$P_r = \frac{F_y}{F_s} \times 100\%.$$
 (29)

In formula (29), F_y is the number of correctly classified samples, and F_s is the number of classified samples. The classification recall rate is expressed as the ratio of the number of correct samples classified to the total number of music genre samples. The higher the classification recall rate, the higher the classification accuracy of the method. The calculation formula is expressed as follows:

$$R_e = \frac{F_y}{F_z} \times 100\%. \tag{30}$$

In formula (30), F_z is the population size of the sample. The F1 value represents the harmonic mean of the accuracy rate and the recall rate. The closer the F1 value is to 1, the higher the classification accuracy of the method. The calculation formula is expressed as follows:

$$F1 = \frac{2\left(P_r \times R_e\right)}{\left(P_r + R_e\right)}.$$
(31)

4.3. Effect of Automatic Classification of Music Genres. In order to verify the effect of automatic music genre classification, the confusion matrix is used to represent the effect of automatic music genre classification. Rock, metal, country, classical, and blues music genre samples are selected, the proposed method to evaluate the classification performance of the trained music genre classification network model is used, and the automatic classification effect of the proposed method is obtained as shown in Figure 6.

Figure 6 shows that rock, blues, and classical music all have high classification effects, with confusion matrices of 0.98, 0.96, and 0.95, respectively, although metal and country

TABLE 2: Frequency index of Mel filter.

Number	Frequency range (Hz)	Center frequency (Hz)
1	[0, 76)	24
2	[24, 135)	76
3	[76, 213)	135
4	[135, 305)	213
5	[213, 368)	305
6	[305, 468)	368
7	[368, 543)	468
8	[468, 659)	543
9	[543, 768)	659

12	[905, 1154)	1023

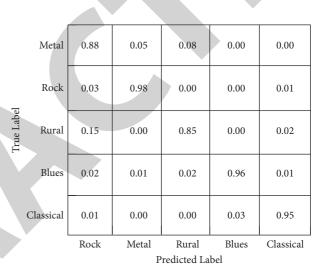

FIGURE 6: Automatic classification effect of music genre of the proposed method.

music had less misclassification, with confusion matrices of 0.88 and 0.85, respectively. Because certain country music may be used to accompany country dancing, and some related metal music is incorrectly labelled as country music, country music can easily be misclassified as metal music. There are also some differences between metal and rock music, maybe due to the fact that they all pay attention to rhythm and share commonalities. However, the suggested technique can successfully accomplish the automated classification of five music genres, according to the above study, and the automatic classification impact of music genres is superior.

4.4. Accuracy of Automatic Classification of Music Genres. In order to verify the classification accuracy of the proposed method, 1000 music genre samples are selected, and the methods of reference [7] and the methods of reference [8] and the proposed method are used for automatic classification of music genres, respectively. According to formula (29), the accuracy of automatic classification of music genres by different methods is calculated, and the comparison results are shown in Figure 7.

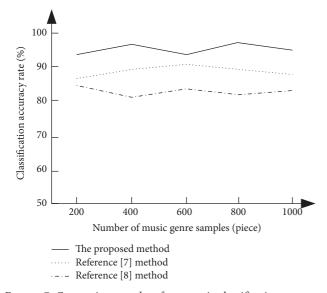

FIGURE 7: Comparison results of automatic classification accuracy of music genres by different methods.

It can be seen from Figure 7 that under the number of 1000 music genre samples, the average accuracy of automatic music genre classification of the methods of reference [7] is 88%, the average accuracy of automatic music genre classification of the methods of reference [8] method is 82%, and the average accuracy of automatic music genre classification of the proposed method is as high as 95%. It can be seen that compared with the methods of reference [7] and the methods of reference [8], the proposed method has higher accuracy in automatic classification of music genres and can effectively improve the accuracy of automatic classification of music genres.

On this basis, the accuracy comparison results of automatic classification of music genres by different methods are calculated according to formula (30), as shown in Figure 8.

As can be seen from Figure 8, under the number of 1000 music genre samples, the average recall rate of automatic music genre classification of the methods of reference [7] is 85%, the average accuracy rate of automatic music genre classification of the methods of reference [8] is 78%, and the average accuracy rate of automatic music genre classification of the proposed method is as high as 97%. Therefore, compared with the methods of reference [7] and the methods of reference [8], the proposed method has a higher recall rate of automatic music genre classification, indicating that the automatic music genre classification accuracy of the proposed method is higher.

On this basis, F1 values of automatic music genre classification of different methods are calculated according to formula (31), and the comparison results are shown in Figure 9.

The average music genre automatic classification F1 value of the methods of reference [7] is 0.74, the average music genre automatic classification F1 value of the methods of reference [8] method is 0.6, and the average music genre automatic classification F1 value of the proposed method is

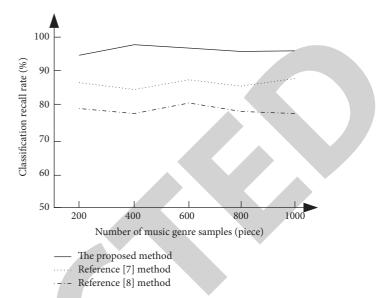

FIGURE 8: Comparison results of recall rates of automatic classification of music genres by different methods.

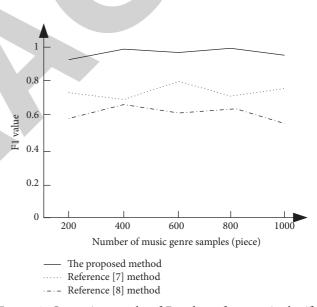

FIGURE 9: Comparison results of F1 values of automatic classification of music genres by different methods.

0.98, as shown in Figure 9. As a result, when compared to the approaches of references [7, 8], the suggested method's F1 value is closer to 1, suggesting that the proposed method's accuracy is greater.

Finally, the suggested technique has a high accuracy and recall rate for automated music genre classification, and the F1 value is near to 1, demonstrating that the proposed method may significantly increase automatic music genre classification accuracy.

4.5. Automatic Classification Time of Music Genres. On this basis, the automatic classification time of the proposed method is further verified. The methods of reference [7], the methods of reference [34], and the proposed method are

Music genre samples (piece)	The proposed method (s)	The methods of reference [7] (s)	The methods of reference [8] (s)
200	5.8	8.3	10.2
400	8.2	12.7	15.1
600	10.9	15.9	18.6
800	13.6	18.4	22.9
1000	15.8	22.6	25.8

TABLE 3: Comparison results of different methods of music genre automatic classification time.

used for the automatic classification of music genres, respectively. The comparison results of automatic classification time of music genres of different methods are shown in Table 3.

According to the data in Table 3, the automated categorization time of music genres of various approaches grows as the number of music genre samples increases. The automatic classification time of music genre of the methods of reference [27] is 22.6 s, the automatic classification time of music genre of the methods of reference [8] is 25.8, and the automatic classification time of music genre of the proposed method is only 15.8 s when the number of music genre samples is 1000. It can be noticed that the suggested method's automated categorization time of music genres is shorter than the approaches of reference [27, 28].

5. Conclusion

The automatic music genre classification method based on deep belief network and sparse representation proposed in this paper gives full play to the advantages of deep belief network and effectively realizes the automatic music genre classification combined with the sparse representation method. It has a good classification effect and high accuracy and can effectively shorten the time of automatic classification of music genres. However, in the process of automatic classification of music genres, this paper ignores the fuzziness of music genres. Therefore, in the next research, we can consider reasonably analyzing the music theory components of music genres and propose a direct end-to-end audio spectrum classification method to further improve the accuracy of music genre classification.

Recent advances in data analysis and processing methods can improve the ability of computational applications to perform complex steps of different tasks. With the progress of information and communication technologies (ICT), Blockchain-based complex data processing for transaction analysis and smart contract agreement has become a new research area in the fields of mathematics and computation. Stability of financial sector based on the ICT is a core component for growing the economics of medium and small enterprises. This stability brings the innovation to businesses productivity, while the management of information takes more prospective for improving the efficiency and more ways for innovating the business of products. In this study, we use the autoregressive distribution lag (ARDL) model with Blockchain-based complex data processing approach to emphasize the role of ICT in the field of trade credit maintainability. Actually, the ICT connects the industries in the entire world and makes business sectors that use its technologies be more advanced. Based on the ARDL model conducted on the records gathered from 2000 to 2019, the analysis concludes that the ICT-based complex data processing is a critical component of trade credit. The statistics of ICT are chosen based on the economy penetrations through the Internet and mobile phones. The causality exposed between the trade credit and ICT is bidirectional in nature. Also, it is found that the usage of mobile phones has a substantial influence on the business sectors, as a substantial amount of trading and business transactions are conducted over the phone. Therefore, the primary concern is the association between the Blockchain and trade credit, which is thoroughly discussed in this work. The trade credit improves the stability of financial sector and the Blockchain supports its maintainability by the role of ICT. The results of the study can help the business stakeholders and investors to estimate the marketing for future useful execution.

1. Introduction

Graph-based data analysis (GDA) concept is theoretically applicable in the computer science (CS) field for several practical applications. Blockchain-based complex data processing in information and communication technology (ICT) such as graph-based smart contract based agreement modelling, computing resource allocation, and users' interactions and transaction analysis has become popular in recent years. In most parts of the world, trade credit is significant short-term funding for SME's businesses [1, 2]. In the United States, most businesses offer their products and services based on trade credit. The trade credit is considered a major source of short-term funding in many businesses. The biggest consumers of trade credit are the nonfinancial firms as these firms are mostly facing a lack of financing. For young and emerging businesses, it is a regular source of capital [3]. The use of trade credit is so extended even after other financial banking systems [2, 4–7]. Since traders alone are often unable to find and connect with the banking sector, they are unable to take bank loans. Companies depend more on trade credit for external financing due to the same nature of business between all trading parties.

Trade credit is important for small investors, and since it is the second-largest financing mechanism, the importance of trade credit is also globally recognized [8]. There have been several sorts of explanations proposed for the trade credit. As per the financial perspective, firms can obtain resources at a lower budget due to trade credit as compared to high financing costs [9, 10]. Trade credit is a short-term investment that is more profitable than marketable securities [9]. The operational motive of trade credit is that it provides smooth demands and eliminates cash volatility in the payments among firms [11]. The financial motive is that large and financially stable firms offer trade credit to smaller firms to meet their financing requirements. Large firms always have an advantage while dealing with trade credit to secure sales and build long-term relationships with small firms.

Due to the Internet, the entire planet has evolved into a global community. Developed as well as developing countries are interconnected globally. Globalization identifies the merger of multiple economies and countries for economic growth and prosperity [12]. Since the beginning of the 21st century, the concept of globalization has entered into a new millennium. Both developed and developing countries are facing certain kinds of challenges related to the equilibrium between the economy and globalization. As the phrase that "the world is getting smaller" signifies the junction of transport and communication as well as the foreign trade of commodities and services, including the procurement and distribution of commodities and services [13], globalization focuses on market liberalization and economies of scale for the growth of countries around the world which foster the resource sector globally. Many developing countries get benefits from globalization, such as improved technology, the worldwide flow of advanced machinery and equipment, and improved trade operations. The natural resources, state, political stability, and cultural exchange of countries also increase economic growth and globalization [12].

Information and communication technology (ICT) has always brought innovation, improves efficiency, and enhances the ability to share knowledge and skills leading to the change in overall trading and business units around the world. ICT is considered as the two poles of a single rod which are attached as it is required for sustainable economic growth in the society and also to resolve many environmental issues [14]. Now, as the world is interconnected, the ICT has also impacted every phase of life, like education, cultural aspects, business networks, infrastructures, and transportations [15]. No doubt, the use of ICT has increased as time passed by. The report generated by the worldwide telecom unit (ITU) has likewise proposed that more clients of the Internet are in the year 2015 which are 3.2 billion, when contrasted with earlier years around 400 million [16]. ICT has a major role in the growth of economy and stability of societies in both developed and developing countries [17].

ICT is a becoming a reason to globally connect numerous devices. It is feasible to connect smart devices and carry on the transactions without discriminating that the user is virtually connected. There are various frameworks that support reliable and effective communications with tangible accuracy. Due to similar significance, the platform of ICT has raised the development of small and medium industries and their interconnectedness with the rest of the world. The ICT is helpful for future planning of the world economy and in information society to strengthen labor forces [18]. Various forecasting, predictions, and long-term financial planning are done by computer-aided techniques and devices. Nepal scored first in the area with ICT score of 40, followed by Bangladesh with ICT score of 39, Sri Lanka with ICT score of 32, India with ICT score of 28, and Pakistan with ICT score of 23, according to the Global Competitiveness Index [19]. Because of the above social and technological aspects, as well as the importance of information and communication technology (ICT), which is below the national average for small and medium business units, the study highlights the need for further research into ways to contribute to economic development through trade credit in South Asian countries.

It is a common observation that the financial demand also grows as the firm grows in size because it plays an integral part in the elaboration and growth of economy [20, 21]. The trade credit provides the necessary infrastructure including skills and expertise in trading around the world which encourages the efficient use of the country's resources around the globe. This paper adds to prior work in several ways. First, it is the first study to focus on the relationship between economic growth, information and communication technology, and trade credit. Second, the autoregressive distributive lag (ARDL) model is utilized to control the interactions between the stated variables in longrun behavior. To determine the results' robustness, the bound test is used [22].

The remaining part of the article provides an overview of the trade credit that affects the economic structure of Pakistan. The literature review section provides the previous findings of the literature. The model specification, data source, and econometric strategies are discussed in model construction; next, the empirical analysis of the research is explained. The conclusion discusses the findings and concludes the implications, and, finally, limitations and future research direction provide suggestions for future work.

1.1. Overview of Trade Credit in Pakistan. Technology has now removed the concept of boundaries and limitations. The broad term global village is very well known in this regard. Due to globalization, the distances are reduced, and new business horizons are opened. The effect of ICT and globalization on trade credit is an aspect of scholarly discussion. Because of ICT, the lands have changed into new buildings and industries and there is a shift in infrastructure as observed from past decades. Due to the upgradation of infrastructure, the investor's and small business unit's strategies are also changed. Technology like smartphones has reformed the trading mechanisms at the fingertips. Trade credit is beneficial for many reasons. The most important reason is one owner business type which occupies the biggest portion of the private sector of Pakistan. Also, trade credit is time-saving and beneficial for new business entities in a competitive environment [23]. Trade credit increases the profitability of firms [24].

Particularly keeping the focus on underdeveloped countries, to improve the economic stability and growth in the country, the Pakistan government is making efforts in the power sector to fulfill the energy needs of the country. This again involves smart technology on the core end. The government has also jointly worked on different projects to bring innovations for technology productions. One of the projects is the China-Pakistan Economic Corridor (CPEC) in which the main idea is to open the western China trade through rails, roads, and gas pipelines from Kashgar to Gwadar ports of the country [25]. This is not only a road that connects regions together but also a future pathway to progress. The regional connectivity includes utility and regulation of energy hubs, logistic refinements, high level trading, the regional promotion, various domains like tourism, maintenance of peace, and prosperity, diverse investment schemes, and industrial boosting. There are indirect chances of improvement in education, internal infrastructure like medical, human resource development, basic human needs development and support, social diversity and collaboration, and so forth. China is investing about \$46 billion in the energy sector and the development of the transportation infrastructure in Pakistan [26]. This joint venture may bring revolutionary progress in financial gains as well as technology refinements around the country.

The use of information and communication has been widely spread over the past few years. Not only is ICT as important as the human heart but also it adds a significant part in growth, education, health, and the way of living of the population [27]. Ultimately, ICT is bringing enormous productive results in trade credit which is beneficial for the SME. In today's emerging markets, ICT plays two types of roles: inputs and outputs. As input, ICT reduces the coordination cost in markets and results in inefficient trading and, as output, ICT becomes a source for public services like education and health sector and provides e-services in many departments [28]. It means the future is broad and progressive where finance is equally supported by technology.

One of the best reasons for trade credit based infrastructure is that it is facilitating for SMEs. This ensures the sustainability of any small organization, which is continuously making efforts to grow gradually. This strategy is based on the phenomena that there are no financial reservoirs, no fixed assets, and no regular income. The system is entirely relying on trade credit where the goods are sold under fixed terms and the turnout is returned to the company. This system needs worthy and trust building system where the producer organizer hands over the product to the seller organizer for a tangible duration under fixed term returns. This facilitates the load of small organization to involve services at minimum to no cost and the product is launched to the market as soon it is completely manufactured. The consumer later gets the profit which is the ultimate target of the business. So, the scheme is ideally applicable to both entities.

2. Literature Review

The literature is reviewed under three subdivisions. The first and most important subdivision has revealed reviews that deal with the qualities of ICT in accelerating economic growth. Next, the second subdivision highlights the findings on trade credit and the growth of the economy. The third subdivision discloses findings on the topics connected with significance of ICT and trade credit.

The existing literature has enlightened the association between ICT and economic growth. Because of ICT, there expanded the decisions for individuals, simple way to deal with the information and skill, and that actions that are important and agreeable to make life more agreeable [29, 30]. The use of electronic facilities including health, education, and services to bring access to these facilities makes economic development in the societies. E-health benefits raise the health standards of the individual and improve outcomes, help in cost reduction, and extend services [31, 32]. Therefore, ICT brings positive changes in human capabilities which are necessary for the prosperity of the economy [15]. The importance of economic growth is related to economic efficiency [33].

The second component of the study focuses on the association between trade credit and economic growth. Several studies have highlighted the importance of trade credit in developing countries [34]. The rapid increase in the demand for industrialization and urbanization is moving the economy to find out easy and fast ways of financing; trade credit is the most effective way of financing [35]. The macroeconomic conditions have a positive effect on trade credit usage and many researchers highlighted its importance [36, 37]. The world's largest retailer, Walmart, is the biggest user of trade credit and prefers it over a bank loan [38, 39]. The trade credit is also considered as a key source for new and young firms because supplier firms have more information about buyer firms [40]. It also provides a source of short-term financing to financially constrained firms [41]. As per [42], globalization leads to long-term economic efficiency; therefore it has a substantial influence on economic growth.

The third component of the literature concentrated on the association between ICT and trade credit as the main characteristic of global industrial growth. As demonstrated earlier that the entire planet has evolved into a global community because every firm is connected through technology, all the trading is interconnected through reliable Internet connections. Even online businesses are expanding worldwide. Huge financial transactions can be processed in the nick of time [29]. ICT has effects on international trading, urbanization, and advanced technology [43]. Trade credit supports industry-level growth having less developed financial access in the country; also, it results in financial gains for both buyer firms and supplier firms [44, 45]. Because of the increase in sales or market share, facilitating financial transactions by reducing restrictions and easy-going policies for payment, supplier firms can benefit from generating additional revenue [5]. Global trading can be seen flawlessly in the widespread pandemic. Due to the spread of Coronavirus disease (COVID-19), where life is threatened, the small industries are most affected in developing countries [46]. In this critical time, trade credit is the most effective and useful way of financing throughout the world. This sort of business can be channeled from any part of the world and is interconnected with the rest of the world through technological advancements.

Despite these valuable contributions, there are many areas to be further discussed. For example, trade credit and its importance for small and medium enterprises (SMEs) are highlighted [34]. The risk factor associated with trade credit is discussed but the ICT factor is not considered [34]. To fill this gap in the research, the existing body of knowledge adds to the existing information of economics by observing the ICT, trade credit, and their effects on the economic growth of Pakistan.

3. Construction of the Model and Econometric Strategy

4

In this section, the construction of the model and econometric strategy and the data sources are stated, for the empirical implication of the above literature. Specifically, the main objective of this study is to establish the role of ICT and trade credit in the economic growth of Pakistan. The trade credit approach is ideally applicable for the underdeveloped countries where there are less financial assets and the services can be the alternatives. Countries like Pakistan, India, Bangladesh, Ghana, and so forth are the best examples for this model. Larger business units like leather, minerals and mining, textile, chemical, and mechanical units, and similar industries which produce the consumable products on regular basis are some common examples in Pakistan which regulate trade credit support. The financial support is never foreseen in this area; also the reasons like natural disasters, political instability, corruption, unemployment, and similar reasons raised uncertainty. In this concern, the trade credit is not less than a blessing for the survival and even the improvement of the SME. As is usual in most of the econometric studies, all variables were transformed into logarithms. The logarithmic transformation also eliminates the possibility of heteroscedasticity.

3.1. Equations.

$$LogTC_{t} = \beta_{0} + \beta_{1t}LogICT_{t} + \beta_{2t}LogGDP_{t}$$

$$+ \beta_{3t}LogGLOB + \varepsilon_{t},$$
(1)

where TC is the trade credit index, GDP is the measure of growth of economy, GLOB is short for globalization, ICT is the information and telecommunication technology index, and ε is the residual error, where t stands for the years. Considering obvious motive for the selected variables, ICT in international trading yields industrialization and urbanization, thus enhancing the trade credit in the country. Trade credit not only enhances economic development and stability but also boosts social development by the interaction of SME investors in the country. Cross-border trade benefits the manufacturing sector; so, it is helpful to influence the economic growth in the country. Different types of econometric techniques are used and applied to observe long-run and short-run relationships among variables (Engle and Granger) [47]. The appropriate technique is the ARDL approach as is applied and suitable for a mostly small set of data to check the cointegration association. Also, the bond test method of ARDL is used as a simple linear transformation for simultaneous use of the long and short run. The correct lag should be calculated before applying the ARDL technique. The procedure for performing bound testing on the variable of interest is as follows:

$$\Delta LogTC = \beta_0 TC + \sum_{k=1}^n \beta_{1k} \Delta LogTC_{(t-k)} + \sum_{k=0}^n \beta_{2k} \Delta LogICT_{(t-k)} + \sum_{k=0}^n \beta_{3k} \Delta LogGDP_{(t-k)}$$

$$+ \sum_{K=0}^N \beta_{4k} \Delta LogGLOB_{(t-k)} + \lambda_1 TC\Delta LogTC_{(t-1)} + \lambda_2 TC\Delta LogICT_{(t-1)} + \lambda_3 TC\Delta LogGDP_{(t-1)}$$

$$+ \lambda_4 TC\Delta LogGLOB_{(t-1)} + \varepsilon_{1t},$$

$$(2)$$

where Δ indicates primary variance, λ expresses the long-run measurements, θ represents the dynamics of small path, and ε denotes the error. Meanwhile the null assumption explains that there does not exist cointegration, besides the substitute hypothesis.

3.2. Model Estimation. F-statistics are used to test cointegration in the ARDL approach. The decision is based on the upper and lower bounds [48]. If the *F*-statistics are more than the upper value, the null hypothesis is refused, and if the *F*-statistics fall somewhere between the upper and lower

boundaries, the result will be inconclusive. The next process after cointegration is to examine the paths term. The model's stability is verified using several tests such as ARCH, LM, and Ramsey tests.

The Granger causality test is the most extensively used test for time and panel data. The analysis was used to decide whether variables can also be used to predict other variables. According to Engle and Granger [47], there is a cause-andeffect link between the variables. The test is used to determine which way trade credit, information and communication technology, and economic growth are causally related. This causality is helpful for policy suggestions. The Granger causality model is expressed in matrix equation as follows:

$$\begin{bmatrix} \text{Log}TC\\ \text{Log}ICT\\ \text{Log}GDP\\ \text{Log}GLOB \end{bmatrix} = \begin{bmatrix} \beta_{1}\\ \beta_{2}\\ \beta_{3}\\ \beta_{4} \end{bmatrix} = \begin{bmatrix} \beta_{11k}\beta_{12k}\beta_{13k}\beta_{13k}\beta_{14k}\beta_{15k}\beta_{16k}\\ \beta_{21k}\beta_{22k}\beta_{23k}\beta_{24k}\beta_{25k}\beta_{26k}\\ \beta_{31k}\beta_{32k}\beta_{33k}\beta_{34k}\beta_{35k}\beta_{36k}\\ \beta_{41k}\beta_{42k}\beta_{43k}\beta_{44k}\beta_{45k}\beta_{46k} \end{bmatrix}$$

$$= \begin{bmatrix} \text{Log}TC_{it}\\ \text{Log}ICT_{it}\\ \text{Log}GDP_{it}\\ \text{Log}GLOB_{it} \end{bmatrix} \begin{bmatrix} n_{1}\\ n_{2}\\ n_{3}\\ n_{4} \end{bmatrix} = ect_{it-1} + \begin{bmatrix} \varepsilon_{1t}\\ \varepsilon_{2t}\\ \varepsilon_{3t}\\ \varepsilon_{4t} \end{bmatrix}.$$

$$(3)$$

 $\mathrm{EC}_{\mathrm{t-1}}$ indicates that the long-run causality exists among variables and specifies that the pathway is the first difference of the short-run causal relationship that ICT has a contributing connection with trade credit, and trade credit has an association with ICT, respectively. As a result, bidirectional causation develops between the two variables. For the study, time-series data covering the years 2000 to 2019 was employed. Data on trade credit is taken from nonfinancial enterprises' financial statements in Pakistan; ICT is calculated by mobile phone and Internet penetration rates and GDP.

4. Results of Empirical Research

The first and most critical step in any study is to ensure that the data is stationary. This is accomplished through the use of the unit root. Firstly, in a time-series evaluation, stationarity of the data should be evaluated. All variables are assumed to be stationary in a standard regression analysis. As previously stated, nonstationarity in general causes erroneous regression. The ARDL approach, for example, is not applicable to any integrated variable of order 2. NG-Perron unit root, as shown in Table 1, confirms the level of stationarity, and the results show that the ARDL is suitable for analysis.

Because the standard unit root test fails to detect structural fractures, the Zivot-Andrews (ZA) test is appropriate for research. The results of the structural break test are shown. The outcomes revealed that at level the series is not stationary. The series, however, became stationary when the first difference was taken. Table 2 indicates the statistical analysis of the yearly data; findings are generated by the ZA test. Here, the variations can be seen through variables and probability results. Following that, an alternate method known as bound testing is developed, which is based on an autoregressive distributed lag model. It is not necessary for the variables to be integrated in the same sequence. Furthermore, as compared to Johansen cointegration, which requires a high sample size, it is deemed a more appropriate method when the sample size is small. Because it is based on a single equation, it is simple to implement and interpret.

The bond testing is performed for analysis, a suitable length of the lags is selected, and the next *F*-statistics are checked to see the long-run behavior of variables. The bond testing approach is recommended by the first order of integration to monitor the cointegration. The following table shows the outcomes of the bond analysis and several other diagnostic methods for the model, the results of which explain that the *F*-statistics are larger as compared to the upper bond of the 1%, 5%, and 10% levels of significance, which results in rejecting the null hypothesis. Also, the results assure that the variables are cointegrated at the long-run relationship among trade credit and other variables.

Now, the discussion is on the most significant portion of the research, that is, the analysis of the results of long-run estimation. To estimate the long and short runs, the autoregressive distributed lag (ARDL) model is used. The outcomes of the long run and short run are estimated in the table below. However, the most significant parameter in Table 3 is the decision column. The logistic diagnostic methods using *F*-value and Lag order indicate that the conclusion is constructive or destructive. The statistical values are represented involving trade infrastructure.

As the consequences mentioned in Table 4, the figure of the coefficient is -0.0264 which suggests a negatively strong association with trade credit. The negative association is because of the small size of the market that deals globally with trade credit and thus there are decreased exports. ICT is always an opportunity, especially for the business of the developing countries, so that the technology brings rigorous actions for imports and exports policy by the country. Trade credit is globally recognized and is very effective for business investors to deal internationally around the globe. The results of economic growth, as stated in Table 4, have a considerable beneficial impact on trade credit as a 1% rise in growth brings trade credit to increase by 0.0543%. Trade credit helps to endorse the utilization of new and innovative products, services, and technology and thereby increases economic growth in the country. The positive association yields that trade credit brings economic growth to the country. Pakistan, as a country with a developing economy, has more focus on economic growth which is the backbone of the country.

So, the government of Pakistan should take precautionary measures and develop policies to check and maintain the economic stability by industrial sector, innovative products, and utilization of advanced instruments, machinery, and updated technology; this has an immediate impact on the monetary benefits of a country. These policies are helpful for the economy and these resources are utilized in the long term.

TABLE 4: Projected outcomes of long versus short trends.

Note: "*," "***,", and "***" indicate the significance at 1%, 5%, and 10%, respectively.

The statistics of the coefficient of resources available globally are 0.0365, indicating a 1% rise in the figures of global means, and spread the practice of trade credit by 0.0365%. The evaluation of the study recommends that globalization is the main provider to the attraction of foreign investment in the country. The trade credit could be

recognized as if the management or the officials will take measures concerning the proper utilization of technology, as also presented in Table 5.

The use of assets has a tremendous effect on credit because Pakistan is bestowed with many natural resources. These resources are abundantly available in the country. However, the economy of Pakistan can flourish when manufacturing units are abundant to utilize these resources and deal internationally to expand their trades. Also, the policy mechanism of the country is not so effective for decision-makers and a poor mechanism to handle these natural resources destroys them. These problems can be minimized if the government of Pakistan takes measures to deal with and utilize these resources and trade credit is suitable for this investment. The government takes initiatives, and the foreign investors can deal with trade credit to mutually benefit from the technological progress in the country.

The study also emphasizes autocorrelation and heteroscedasticity by applying analytical methods like ARCH, LM, and Ramsey tests. The results show that there is no autocorrelation or heteroscedasticity, as seen in Table 4. The ARDL approach is used to track long-term outcomes, although causation direction is not clear. The interconnection analysis is used to explore the interconnected relationship.

As shown in Table 5, the VECM Granger test is used to prove that the variables have a long-term relationship.

Table 5 explains the results which show that the causal long-run relationship between trade credit and globalization is established. Bidirectional causality is found between these two variables. The economic growth is also observed to be

bidirectional. VECM test confirms that there exists a longrun relationship among the selected variables, as also shown in the above table.

5. Blockchain Technology as a Case Study in Trade Credit

Blockchain is an electronic shared, immutable ledger, which is distributed in a business network that facilitates the process of tracking and recording transactions and assets. Blockchain technology records and tracks different information of trade credit for SMEs. It includes variables like amount, time, and data and the unique digital signature for security. One of the distinct features of the Blockchain technology is its reliability. The structure is maintained concretely by allocating every block a unique number. The number of blocks is allocated unique numbers representing a series. Then, the blocks are connected in such a way that every block is connected to the next block. The data is further secure where it requires the hash sum of the entire connected blocks to maintain its security. Other unique features of Blockchain sustainability and integrity are decentralization, cryptography, and consensus, which were least identified previously, especially in obsolete systems. The ICT is applicable in the form of Blockchain so that the financial transactions can be operational flawlessly and effectively. For financial concerns, each Blockchain contains the dealings such that every new transaction is saved to the ledger of every participant. All the trade credit information is saved in a distributed database which is managed by multiple participants called Distributed Ledger Technology (DLT). DLT is a database that is accessible by multiple users from multiple locations, so the data are managed on various memory locations using identical copy; the users can access it using various platforms.

(i) Smart contract concept by Blockchain in trade credit: Blockchain enables the concept of smart contract in trade credit. Smart contracts are decentralized contracts with the consensus of trading parities having transparent immutable proof algorithmic exclusions. A smart contract is a series of digital documents and agreements which includes transactions detail and term and conditions promised by trading parties. The immutable nature program protocol of smart contract allows the execution process and automation of contracts terms and conditions. The smart contract does not need the third parties, for example, banks, to play an intermediary role and parties can directly collaborate to minimize the cost and time. The smart contract can drastically reduce the cost of resources required, documentation, information gathering, and processing, negotiating, and drafting of contracts, monitoring, transparency, reliable communication, secure payment, and digital cryptographic agreement signatures.

Smart contracts advance the increase in the trust up to a higher level by providing a secured distributed database, enhance transparency in trade transactions, reduce the risks and frauds, increase data reliability, and facilitate the exchange of payments and automatic executions without human mistakes or intermediary involvement. The information is highly secure in leisure systems. This is one of the important requirements for online systems. The privacy preservation is solely under the decision of the organization; the components which indicate the progress or revenue generations can be displayed while keeping the company credentials hidden. The system is maintained in a distributed manner; leisure system works on privilege-based authentication; therefore, it is not possible to easily drain the protected information. Thus, Blockchain provides smart contracts technology system that will reshape the traditional trade credit, very appropriate for small-to-large international trade activities.

5.1. Traditional Trade-Credit Limitations: A Space for Blockchain Technology. Traditional manual trade credit has some limitations as follows:

- (i) Manual process involves a lot of paper documentation by the issuing banks (the importer and exporter's banks) to process the contracts, exchange the documents, analyze discrepancies, and so forth, which is subjected to human error and takes time and cost.
- (ii) Invoice factoring is requested by exporters who present their payment invoices to several banks; thus, it increased the risk profile.
- (iii) delayed timeline and delayed payment, the paperbased traditional trade credit involves multiple financial procedures and intermediaries to execute the agreements, contracts, and payment. Several days are taken to issue, confirm, and execute payments.
- (iv) Multiple communication channels that exposed banks and business parties to miscommunication and fraud are involved.

- (v) Duplication in documentation can result in mistakes or processing the same transaction twice or more.
- (vi) Tampering and less security of the financial record as the documentation can be used by unauthorized access. As a result, a record could be illegally duplicated, updated, manipulated, or falsified.
- (vii) Illegal financial record tempering is of a high frequency.

5.2. Blockchain Reshaping the Traditional Trade Credit. Blockchain technology has some potential advantages that could help trade credit in many ways:

- (i) From paper to bytes: Banks are trying to use technology to digitalize the documentary tradecredit process, but, still, most of the transactions are paper-based but this time with a better and advanced technology of Blockchain and smart contracts promising to enable easier, faster, efficient, and secure digital transactions and digital documentation.
- (ii) Efficiency: Smart contracts make the trade credit more efficient by providing fast, digitalized information with no intermediary platform and extra communication channels. The smart systems are efficient for data processing. The other considerable factor involves storage speed. Smart contracts speed the trade finance cycle. Transactions that took months can be reduced to days and days can be reduced to hours. As the terms of the contract are digitally signed, the Blockchain in real-time status is updated, which reduces the time as well as the headcounts which are required to monitor the delivery.
- (iii) Traceability: Blockchain facilitates the importers and exporters that can easily trace the information, transactions, goods, and assets. The Blockchain title specifies transparency into the location as well as the ownership of the goods. All the execution processes are traceable between the trading parties.
- (iv) Transparency: The distributed ledger ensures the transparency of all information and transactions to improve the trust among the trading parties. Blockchain invoices provide a real-time and transparent view with time stamped.
- (v) This helps to reduce tempering risk and offers more advanced option for financing trade.
- (vi) Auditability: Blockchain ensures high auditability by storing record sequentially and indefinitely avoiding extra activities for the auditing. A clear and better verification of transactions, goods, and assets is provided with a reduction of compliance costs. This minimizes fraudulent activities.
- (vii) Security: Each transaction has a unique identity and independently cryptographic verification. Encryption and programmed cryptography

protect the transmission of data between different trading companies and thus highly privatize the data to ensure their authenticity.

- (viii) Documents real-time review: Financial documents which are linked and accessible via Blockchain are properly reviewed.
- (ix) Automated settlement of accounts and reduction of transaction fees: All those contract terms which are executed through the smart contract eliminate the requirement for financial banks or institutions to charge additional transaction fees.
- (x) Autonomy is ensured by Blockchain, as smart contracts remove the intermediate parties or any reliance on banks.
- (xi) Costs and fees are reduced, by improved efficiency to save time and removing intermediate third parties to save the extra cost.
- (xii) Bogus transactions, fraud, accidental financial transference, and online credit threats can be avoided.
- (xiii) E-commerce transactions are highly applicable particularly during the COVID-19 pandemic; exponential rise of financial flows can be protected by the end to the endpoint of the security system, which is ensured by Blockchain.

6. A Blockchain-Based Complex Data Processing for Trade Credit: A Framework Design

Different SMEs are actively trying to participate in economic progress. The bottlenecks mentioned in the above section are critically important. The association of these SMEs can be technically connected using the Blockchain method. The Blockchain model is represented in Figure 1. It indicates that various SMEs can be connected. It means the financial block of components which either participate in financial completion or are involved in the initialization of financial transactions, particularly for trade credits; they are connected in the block-by-block architecture.

Financial Blockchain enables the transaction recording on the distributed ledger for multiple users from multiple locations. This can connect the SMEs and financial firms in a way where the transactions are maintained with associations. The data is stored in the form of blocks and every block has encrypted time-stamped transactions. These blocks are chained or connected chronologically, thereby creating a long chain or Blockchain technology.

DLT reshapes the traditional trade credit and digital documentation flow transparently among banks, imports and exports, trading companies, and other business communities. All the transactions are secured by unique cryptographic signatures with a timestamp that is immutably recorded on the blockchain. Business partners with the right permission can access the shared information for complete transparency, which helps to tackle the fraud issue and increase trust.

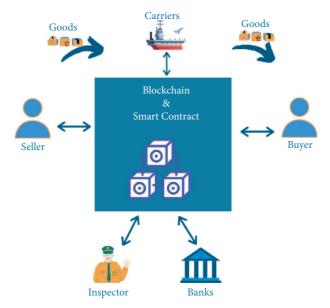

FIGURE 1: Trade credit consolidation through Blockchain model.

7. Conclusion

The investment in trade credit is an important aspect that becomes an important part of the balance sheet of the firms. The trade credit exists as the firm allows the buyer firms to delay payment of the amount and relaxes the policies for them. Therefore, customer firms take advantage of these investments and increase their profitability. Thus, this study is an important contribution towards trade credit, ICT, and globalization, which bring economic growth and stability to the country.

This research is an attempt to support Pakistan to maintain the trade credit relationship with ICT, globalization, and economic growth for 2000–2019. ARDL cointegration methodology is applicable to monitor the long-run relationship between the variables. Also, the VECM Granger causality test is applied to conclude both the long-run and short-run directions of the applied variables. Lastly, several other diagnostic methods are also applied, including ARCH, LM, and Ramsey tests. Globalization has an encouraging influence on trade as it expands with globalization and the economy is also flourishing. ICT has also a positive influence on trade credit if these technological resources are properly utilized.

Managing trade credit is an essential perspective for small industries. Efficient and productive trade credit enhances the productivity and efficiency of the firms. The trade credit policy implementation is of high importance for profitability. Offering trade credit is a significant factor for the life of the small business in particular, where trade credit is above the long-term assets of the company. Trade credit is also considered to be an important element of the management policy of the firms. Therefore, it alleviates the information asymmetry regarding the quality of the goods before paying for the product. Trade credit is for commercial purposes to increase the sales of the goods and to increase the worth of the business. The results of the study also recommend that the government of Pakistan should be aware of ICT, globalization, and particularly small business units which have a direct effect on the exports of the country. Also, formal quality should be certified by reforms of policies that will enhance globalization and bring trade to the country. Improved legal systems, control over corruption, quality of information transferred by officials, and supervision of the financial and nonfinancial institutions could also support the country to improve globalization and trade credit in the country.

Therefore, this study also required a thorough, complete rearrangement of policies by the officials of the country, built on the development and executions of social, economic, ethical, and political actions. No doubt, this century is one of technology. Therefore, ICT has an encouraging influence on trade credit because mobile and Internet resources are the biggest asset for the country and policymakers must spotlight the appropriate utilization of technologies as these are not utilized optimally.

The exports of natural coal, gas, salt, and other minerals are an edge to the trade credit investors. Economic growth is also positive and significant to trade credit. As investment in research and development is required for any nation, which brings economic growth and stability. Pakistan is facing many sorts of challenges in development and growth. The shortage of electricity is because of the energy deficiency faced by the country. The deficiency of electric supply is an outcome of mismanagement and mechanism and control from the government. The state should concentrate on and implement policies on this vital scenario and must approve some strategies which restore the available resources of the country. Having an abundance of energy resources is always an advantage for poverty alleviation and enhancing human development. The productive use of these natural resources brings the quality of life. The legitimate usage of innovation diminishes the advancement of wellbeing and training areas to prosper and brings the quality of services at the doorsteps.

Policymakers should also concentrate on these Internet usages when state security issues are involved. Global trade along with the rest of the world opens a new horizon for growth and innovations. An increase in the international business hub leads to economic growth and stability. The government of Pakistan should also take measures to facilitate and benefit from the trade credit, which encourages the entry of foreign investors to deal with the local markets and increases the efficiency of the business hub. Overall, results show that trade credit is essential, and incorporating routine credit management for a firm's profitability is an essential factor for technology. Therefore, trade credit is an important strategy for financials and planning management to encourage the business. Also, the effects on trade credit help the investors to forecast the economic condition of the country. This work essentially clears the varying results in the literature concerning the association between ICT, globalization, the growth of the economy, and trade credit.

At present, the digital image watermarking algorithm has not embedded the synchronization signal in the image, resulting in the poor performance of the embedded image in terms of, for example, imperceptibility, anti-attack ability, and robustness. Therefore, a digital image watermarking algorithm based on scrambling and singular value decomposition is proposed. The digital watermark is preprocessed by dimensionality reduction and encryption; the digital image is processed in sections and embedded in the synchronization signal. The digital watermark image is embedded in the digital image watermark by using the low-frequency energy ratio technology of sound channel. The watermark image extraction step is designed to extract the watermark image. The transmittance of the degraded image is calculated, the transmittance is refined by relying on the soft matting algorithm and guiding filter, the image contrast in the image frequency domain is enhanced, and the results are mapped to the appropriate visual range to optimize the visual brightness of the image. Finally, according to the uniqueness of singular value matrix, the distributed characteristics of image matrix data are described, the visual effect is enhanced, and the research of digital image watermarking algorithm is completed. The experimental results show that the algorithm can extract the watermark information completely, the image contrast and singular value have been significantly improved, and the algorithm has better anti-attack performance.

1. Introduction

With the rapid development of network technology and digital multimedia technology, digital photos, paintings, voice, text, video, and other products have been very common [1]. However, with the development of digital technology and networking [2], fast, accurate, and cheap digital transmission means bring opportunities to countless businesses but also pose new challenges, including infringement, piracy, and arbitrary tampering with digital products (such as electronic publications, audio, video, animation, and image products). This leads to the problems of digital information security and digital product copyright protection. Digital image watermarking technology came into being in this environment [3]. It is regarded as the last line of defense of information security and has attracted extensive attention from all walks of life. Among digital image watermarking techniques, digital image watermarking considering scrambling and singular value

decomposition is the core one. Digital image refers to the display image in two-dimensional digital form, which always takes digital unit as pixel representation structure, which can better describe the mathematical relationship between real image and virtual image [4]. Digital image watermarking algorithm is a process of hiding secret information into the host image to prevent the repeatability of original data and maintain authenticity, subtitle, and copyright control [5, 6].

At present, mankind has entered the digital information age. Through digital media, we can spread and obtain network information such as audio and video, which has greatly enriched people's lives and improved the transmission efficiency of information. Some scholars put forward relevant research. Reference [7] proposed a sparse domain lossless digital image watermarking algorithm based on k-singular value decomposition algorithm and introduced a robust lossless sparse domain watermarking algorithm combined with discrete cosine transform (DCT), which hides secret information into important sparse elements of the host image. In order to improve the security of the original image, the secret information is first transformed by a discrete cosine transform. These DCT coefficients with some regularization parameters will be inserted into the selected important sparse coefficients. In the extraction stage, the sparse domain orthogonal matching pursuit algorithm is used to extract secret information from important sparse coefficients. Finally, the inverse discrete cosine transform is used to extract secret information without losing any information.

Reference [8] proposed a robust logo watermarking algorithm based on the maximum wavelet transform. Digital image watermarking is used to protect the copyright of digital images. A new blind logo image watermarking technology for RGB images is proposed. This technology makes use of the error correction ability of the human visual system. It embeds two different watermarks in the wavelet/multiwavelet domain. The two watermarks are embedded in different subbands and are orthogonal for different purposes. One is a high-capacity multibit watermark for embedding the logo, and the other is a watermark for detecting and reversing geometric attacks. Both watermarks are embedded using the spread spectrum method, based on pseudorandom noise sequence and unique key. By embedding a watermark into the modulus maxima coefficients of the wavelet transform, the robustness to geometric attacks such as rotation, scaling, and translation is realized. Although the above methods have made some progress, with the development of digital technology, security problems of digital information have been caused, such as copyright infringement, illegal copying of software or documents, and wanton tampering with digital information. Due to the visual quality conditions of digital images, there will be obvious loss of watermark pixels in the spatial domain environment. In order to solve these problems, based on the above research, a digital image watermarking algorithm based on scrambling and singular value decomposition is proposed.

The following is a summary of the research: Section 1 contains the introduction. Section 2 discusses the research on digital image watermarking algorithm. Section 3 discusses the visual effect enhancement of the digital image watermarking algorithm under scrambling and singular value decomposition. Section 4 discusses the experimental analysis with tables. Finally, the conclusion brings the paper to an end in Section 5.

2. Research on Digital Image Watermarking Algorithm

The suggested approach preserves the watermarked image's invisibility and quality. The developed algorithm is a blind watermarking technique that meets invisibility and robustness requirements. A watermark is embedded in the middle-frequency coefficient block of three DWT levels to accomplish watermarking.

2.1. Preprocessing Digital Image Watermarking. In order to make the digital image watermark random before

embedding audio and robust in the process of processing, dimensionality reduction and encryption preprocessing are carried out for the digital image watermark [9]. Select one frame image in the digital image sequence, and obtain three high-frequency bands and one low-frequency band along with the horizontal and vertical directions. The structure is shown in Figure 1.

In Figure 1, the high-frequency part in the horizontal direction and the low-frequency part in the vertical-horizontal direction of the image are represented as BB1; the low-frequency part in the horizontal direction and the high-frequency part in the vertical direction are represented as CC1; and when both the horizontal direction and the vertical direction are high-frequency parts, they are represented as DD1. AA1 retains the main features of the image to be detected, and the other three high-frequency bands maintain the edge details. Assuming that the selected digital image watermark with the size of $S_1 \times S_2$ is S, the pixel amplitude s of the digital image watermark is

$$S = \{ s(x, y), \quad 0 \le x < S_1, 0 \le y < S_2 \}, \tag{1}$$

where s(x, y) represents the pixel amplitude of the digital image watermark at position (x, y). According to (1), the digital image watermark is preprocessed [10], and the processing process is as follows:

Step 1. Dimensionality reduction. Since digital image signal belongs to one-dimensional signal, dimensionality reduction is carried out for digital image signal [11], and it is transformed into a one-dimensional sequence. Then, the one-dimensional sequence V of digital image watermark image after dimensionality reduction is

$$R = \{r(n) \times s(x, y), \quad n = x \times S_2 + y, n \in S_1 \times S_2\}, \qquad (2)$$

where *n* represents the length of the digital image and r(n) represents the sequence of digital image watermark when the length of the digital image is *n*.

Step 2. Watermark image encryption. The digital image watermark sequence obtained by scrambling formula (2) needs to use logistic chaotic mapping to generate the binary chaotic sequence. The processing formula is as follows:

$$E = f(n) \times e(n) \oplus l(n), \tag{3}$$

where *E* represents the scrambled digital image watermark signal, f(n) represents the scrambled digital image watermark signal when the digital image length is n, \oplus represents the algorithm, e(n) represents the one-dimensional sequence of digital image watermark, and l(n) represents the binary chaotic sequence. According to the encrypted digital image watermark image obtained by (3), the digital image watermark is encrypted by using the sensitivity of chaotic sequence to the initial value, and the watermark spectrum has high balance and security [12].

When embedding the visibility watermark in the digital image, in most cases, the visibility watermark should maintain a clear and visible existence state, which is very easy to be found by the human eye. However, since it cannot

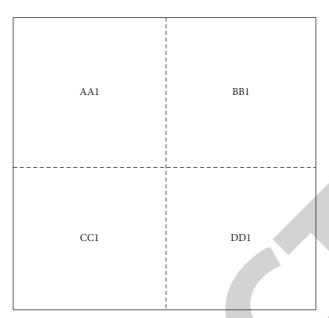

FIGURE 1: Video image structure decomposed by wavelet transform.

affect the original detail characteristics of the digital image, the impact on the quality of the digital image should be kept as small as possible, so as not to be too prominent and attract the attention of the human eye. It can be seen that digital image watermarking does not need to be completely confidential, but it must have a certain representative significance. Based on this, all watermarks in the digital image are counted, and then the embedded synchronous signal processing is implemented for the segmented original image, until the standard information deviation in each block space environment and the real-time display strength of the watermark node are calculated and the research of digital image watermarking algorithm is completed.

2.2. Embedded Synchronization Signal. In this study, the digital image watermarking algorithm is studied. The digital image is segmented, and the length of each signal is the same, which is n. A synchronization signal is hidden in each digital image and embedded in the time domain [13]. At this time, it is also necessary to control the number of synchronization codes to avoid the contradiction between transparency and robustness of the algorithm and reduce the amount of search calculation of the algorithm.

Therefore, it is assumed that the synchronization signal embedded in the time domain is $\{a_n\}$ and $\{a_n\} \in \{-1, 1\}$, where *n* represents an appropriate threshold and takes an odd number. A total of *k* digital images are segmented this time, and there are *B* sampling points in each digital image A(k). When the synchronization signal b(i) is embedded in B1, the sampling point *B* is the B_1 bit of the sampling point, where *i* represents the *i* audio data. Then, the digital image X(u) embedded in the synchronization signal is

$$X(u) = \begin{cases} x(u), & \mod\left[\frac{x(u)}{B}, 2\right] = a(n), \\ x(u) + \frac{m}{2}, & \mod\left[\frac{x(u)}{B}, 2\right] \neq a(n). \end{cases}$$
(4)

In (4), m represents a positive integer, [Brackets value] represents an integer operation, and mod represents the factorial of a positive integer.

According to (4), the synchronization signal is embedded in the digital image. At this time, the watermark can be embedded in the digital image according to the synchronization signal.

2.3. Embedding Digital Image Watermark with Low-Frequency Energy Ratio of Sound Channel. After the digital image watermark image is preprocessed, the synchronization signal is embedded in the digital image. At this time, the digital image watermark can be embedded in the digital image by using the channel low-frequency energy ratio technology [14]. The embedding process is as follows:

(i) Step 1: Frame processing embeds the original image signal into the sync signal. The digital image signal of the embedded synchronization signal obtained according to formula (4) is $X = \{x(u), 0 \le u \le n\}$, and $x(u) \in \{0, 1, 2, ..., (2^p - 1)\}$ is the amplitude of the *u* audio data. If the original audio is divided into several lengths, its length is determined by the original image signal and the amount of watermark information to be embedded, that is,

$$X = \left\{ X(q), \quad 0 \le q \le \frac{l}{N} \right\}.$$
(5)

- (i) In (5), N represents the amount of data contained in each frame signal and *l/n* represents the number of data segments divided into the whole audio segment.
- (ii) Step 2: Select the embedded frame. According to the segmentation processing steps when embedding the synchronization signal, segment the digital image, mark each segment of the signal, and calculate the audio energy D_{ν} calculation formula of each frame:

$$\begin{cases} D_1 = \sum_{i=0}^{l'=1} x^2(n), \\ D_v = \sum_{i=0}^{n'=1} x^2 [(a-1) \times n']. \end{cases}$$
(6)

- (i) In (6), *F* represents the total number of frames of the image signal and D_{ν} represents the audio energy of the ν frame. According to (6), calculate the energy of all audio frames and arrange them in descending order. Considering the robustness and imperceptibility of the watermark, the audio frame with large energy is selected and embedded in the digital image. Only 1 bit is embedded in the watermark information of each image signal.
- (ii) Step 3: Calculate the average value W of the selected embedded frame. When W < 0, the inverse signal of the embedded frame signal needs to be taken, and then the inverse transform is carried out. When W > 0, the complex cepstrum of each frame image signal can be calculated. Therefore, assuming that the f audio data frame of the *i* frame is $X_f(i)$, the complex cepstrum C_f^i of the image signal of each frame is

$$C_{f}^{i} = C_{\text{cceps}}\left(X_{f}\left(i\right)\right), \left(1 \le f \le \frac{l}{N}, \quad 1 \le i \le N\right).$$
(7)

- (i) In (7), C_{cceps} represents the number of additional delay samples when the f frame image signal is subjected to complex cepstrum transformation and returns to the audio frame $X_f(i)$.
- (ii) Step 4: Calculate the low-frequency energy of the channel. Assuming that the complex cepstrum coefficient of the *j* scale factor is C_j, the low-frequency energy E_j of the *j* scale factor is

$$E_j = \sum_{j=S_{\text{starti}}}^{E_{\text{endi}}} C_f^i.$$
(8)

- (i) In (8), *E*_{endi} represents the end of the *j* scale factor band index and *S*_{starti} represents the beginning of the *j* scale factor band index.
- (ii) Step 5: Quantify the low-frequency energy of the channel. Assuming that the quantization step of channel low-frequency energy is q, the measured channel low-frequency energy E_j is

$$E_{j}' = \left[round\left(\frac{E_{j}}{2q} - \frac{p}{2}\right) \right] \times 2q + pq.$$
(9)

- (i) In (9), *roun d* represents rounding, and *p* represents the number of bits used for each data.
- (ii) Step 6: Adjust the complex cepstrum coefficient C_f^i of each frame image signal, and perform inverse cepstrum transform $X_f^{'i}$; then,

$$C_{f}^{'i} = C_{f}^{i} + \alpha,$$

$$X_{f}^{'i} = \text{icceps}\left(C_{f}^{'i}, d(f)\right).$$
(10)

- (i) In (10), *icceps* represents the inverse transform function, α represents the change of the mean value of the complex cepstrum coefficient after quantization, and C'_f represents the *i* complex cepstrum coefficient of the *f* frame.
- (ii) Step 7: Repeat steps 3 to 6 until all watermark information is embedded in the whole digital image signal; that is, the watermark embedding is completed.

2.4. Extracting Digital Image Watermark. According to the digital image watermark embedding process designed in Section 2.3, the digital image watermark is extracted. The watermark image extraction is the calculation link of the design of the new digital image watermark algorithm. With the support of scrambling and singular value decomposition, the actual position of the image information node in the spatial domain environment can be determined, and then through function processing, realize the conversion from clear watermark to fuzzy watermark. In a complete digital image, due to the influence of spatial domain change conditions, the watermark node is basically always in a changing state. In this case, some pixels may be covered by interfering noise, resulting in the continuous decline of the execution ability of the watermark node. To solve this problem, after the visible watermark processing is completed, the position of individual pixel noise should be limited to realize the watermark extraction processing. The extraction process is shown in Figure 2.

According to the watermark extraction process shown in Figure 2, in the watermark embedding process, the frame division process is used to split watermarked image signal into frames and complex cepstral transform and calculate the mean value of complex cepstrum coefficient of each frame image signal. Therefore, assuming that the selected digital image is $X' = \{X'(k), 1 \le k \le z\}$, where z represents the number of frames embedded with the digital image watermark, the watermark sequence W_f before inverse scrambling is

$$W_{f} = \begin{cases} 1, & \text{if } \mod(m'_{f}, 2) = 1, \\ 0, & \text{if } \mod(m'_{f}, 2) = 0. \end{cases}$$
(11)

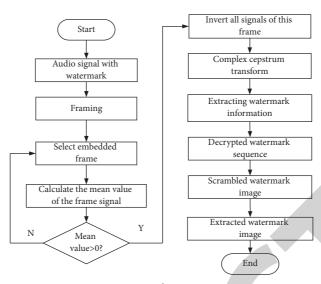

FIGURE 2: Watermark extraction process.

In (11), mlf represents the mean value of the complex cepstrum coefficient of each frame of image signal. Let k_0 represent the pixel extraction coefficient at the initial stage of spatial domain watermark embedding and k_n represent the pixel extraction coefficient at the end of spatial domain watermark embedding. The extraction expression at the watermark node can be defined as

$$Y_U = \frac{1}{A} \sum_{k_0}^{\kappa_n} |K \times z_{\max} - K' \times z_{\min}|.$$
(12)

In (12), K and K' represent two different discrete Fourier function transformation conditions, and z_{\min} and z_{\max} represent the minimum and maximum amount of watermark information data in digital image spatial domain, respectively. According to logistic chaotic map, binary chaotic sequence is generated, and the watermark sequence before inverse scrambling is decrypted to obtain one-dimensional sequence; the dimension of one-dimensional sequence is raised to obtain two-dimensional image. The dimension raising process is the inverse process of dimension reduction in watermark image preprocessing, so as to extract digital image watermark.

3. Visual Effect Enhancement of Digital Image Watermarking Algorithm under Scrambling and Singular Value Decomposition

3.1. Digital Image Transmittance Estimation. In the digital image, if the transmittance and atmospheric spectrum can be obtained from the image, the blurred area in the digital image can be restored to normal Z. There are three unknown parameters in the operation formula (13) of digital image, which is an ill-conditioned equation. Some a priori conditions need to be used to operate the ill-conditioned equation. A priori dark color system can solve this problem very well.

$$C_E(x) = Z(x)m(x) + A_z(1 - m(x)).$$
(13)

In (13), $C_E(x)$ represents the reflected light intensity of the scene point collected by the observation point, Z(x)represents the pixel in the image, m(x) represents the transmittance of the light area, and A_z represents the atmospheric luminosity.

If the atmospheric light is homogeneous, (13) is satisfied for all channels in the RGB color space. It is proposed that the atmospheric light is known, and it is further proposed that the transmittance is normally bright in local areas. Assuming the transmittance equation $\tilde{m}(x)$ of this region, calculate the dark primary color for (13), and the equation is as follows:

$$U_{ty} = \tilde{m}(x) \min_{y \in \Omega(x)} \frac{Z^{c}(y)}{A^{c}} + (1 - \tilde{m}(x)).$$
(14)

In (14), $Z^c(y)$ represents the pixel ordinate in the image, A^c represents the local window centered on the abscissa and ordinate, and $\Omega(x)$ represents a color channel in the RGB color space of the image Z. With (14), the dark primary color calculation of the digital image is reduced to tend to 0.

In fact, there are no particles in the atmospheric light in the normal image. When viewing distant objects, the image is still a digital image. Therefore, in this paper, a small number of degraded areas are reserved in a certain area of the ordinary image. By integrating a constant parameter $\omega \in [0, 1]$, the rough transmittance calculation formula is

$$\widetilde{m}(x) = 1 - \omega \min_{y \in \Omega(x)} \left(\frac{Z^c(y)}{A^c} \right).$$
(15)

In fact, the transmittance is not always the same in a region. For example, when the depth of field protrudes, the transmittance will change.

3.2. Fine Processing of Digital Image Transmittance. Directly processing the blurred area in the digital image through rough transmittance will lead to obvious halo in the background of the image. In order to remove the halo effect, the transmittance is refined by soft matting algorithm and guided filter.

3.2.1. Soft Matting Algorithm. The soft matting formula is as follows:

$$I_{o} = \alpha_{1} \times Q_{1} + (1 - \alpha_{1})B_{n}.$$
 (16)

In (16), Q_1 represents the foreground, B_n represents the background, a_1 represents the image, and I_0 represents the image fused by the foreground and the background. Through the above calculation, it is found that the transmittance distribution is affected by the corresponding soft matting formula. To refine the transmittance, the soft matting algorithm can obtain better-refined transmittance.

3.2.2. Guided Filter. The guided filter is an edge-preserving smoothing filter, which has a good effect on smoothing filtering and edge-preserving. If the output degraded image formula q_1 , the guidance diagram formula I_i , and the input digital image formula p_1 are proposed, there is a linear correlation between the output image and the guidance diagram in the local window w_{k1} . The guidance filter equation is as follows:

$$D_q = (a_{k1}I_i + b_{k1}) + (q_1 \times p_1 \times w_{k1}).$$
(17)

In (17), a_{k1} and b_{k1} are linear constant coefficients of local window w_{k1} . By calculating the linear constant coefficient, the difference between the input images is minimized, and it is proved that the edge of the guide image and the output image can be consistent. Since the guided filter can only be calculated by matrix point multiplication and mean filtering, it can be optimized through the integral image algorithm, so that the guided filter is only associated with the image size N and is not associated with the window size. Then, the time complexity of the guided filter is O(N). Relying on the guided filter can effectively improve the calculation efficiency of the soft matting algorithm.

3.3. Digital Image Visual Effect Enhancement

3.3.1. Frequency Domain Enhancement. In digital images, the movement of pixel gray value will be represented by frequency. Frequency description is a spatial frequency that changes with the change of coordinates. For the characteristics of lines, noise, and edges, such as lakes, rivers, or roads with large differences, there are large spatial frequencies. The frequency domain is a stable structure with large gray value change frequency and large area in a short pixel size.

Frequency enhancement is to calculate the Fourier transform coefficient in the frequency domain of the digital image and then change it back to the initial spatial domain to obtain the image with enhanced details. Frequency domain enhancement is an indirect processing method. Firstly, the digital image is processed by Fourier transform, and the frequency domain of the image is filtered. Finally, the lowfrequency part of the image is transformed into a more stable region. Specifically, it has the characteristics of high pass, low pass, and homomorphic filtering and band stop in the frequency domain.

Frequency domain enhancement has three processes, namely:

- (1) Transferring the digital image in the spatial domain to the frequency domain.
- (2) Enhancing the image in the frequency domain [4].
- (3) Returning the enhanced image in the frequency domain to the spatial domain.

If the convolution of linear bit invariant operator h(x, y)and function f(x, y) is g(x, y), that is, $f(x, y) = h(x, y) \otimes g(x, y)$, then it exists in the frequency domain by virtue of the convolution theorem:

$$G(u, v) = H(u, v)F(u, v).$$
 (18)

In (18), G(u, v), H(u, v), F(u, v) represent the Boyle transformation of G(x, y), H(x, y), F(x, y), respectively, and H(u, v) can be described as a transfer function through the linear coefficient theory.

f(x, y) is the set input image, and H(u, v) needs to be determined. After determining H(u, v), g(x, y) with required characteristics can be obtained after calculating G(u, v) by

$$g(x, y) = T^{-1}[H(u, v)F(u, v)].$$
(19)

In (19), T^{-1} represents the required time transpose. With the above calculation, the frequency domain of the digital image can be enhanced, so as to improve the contrast details in the image.

3.3.2. Brightness Intensity Component Enhancement. The pixel brightness intensity on both sides of the inner edge of the digital image is quite different from that at the center of the image. Therefore, if you want to enhance the image, you need to compare the pixels in the image one by one, and the brightness intensity value is regarded as the external stimulus. Then, the pixel set close to the space and with the same intensity can be expressed as synchronous ignition, and vice versa. This can be expressed in image visual enhancement: synchronous ignition means that there is the same brightness intensity between pixels, and the image area can be smoothed through brightness. Asynchronous ignition means that pixels produce different brightness intensities. Relying on the same and different ignition, we can improve the brightness gradient between image areas, so as to highlight the edge of the digital image, so as to improve the image brightness intensity distribution and make the image have a more obvious hierarchy.

Because the brightness range of the digital image is small, the image contrast decreases. If human visual characteristics are added to the image contrast enhancement algorithm, the contrast enhancement effect can be effectively improved. This is because the brightness perceived by the human visual system has a logarithmic relationship with the brightness that can be obtained by the personnel, so the image contrast within the personnel's visual range can be greatly improved. In digital image, due to the effect of hard limiting function, the output digital image will be transformed into binary image. In order to enable the output mapping function to effectively enhance the brightness of the image, the brightness intensity of the image is mapped within a suitable visual range by using the logarithmic mapping function according to the human visual characteristics. The calculation formula is as follows:

$$Y_{ij}(n) = 1nI_{\max} - \frac{\Delta t}{\tau_{\theta}} (n-1).$$
(20)

In (20), I_{max} represents the intensity value of the brightest pixel in the initial image; *n* represents the ignition time n = 1, 2, 3; $\Delta t/\tau_{\theta}(n-1)$ represents the attenuation step of the dynamic threshold function in the image at the (n-1) ignition time; and $Y_{ij}(n)$ represents the perceived output at the ignition time, that is, the brightness intensity of the enhanced digital image.

3.3.3. Singular Value Decomposition. Digital image can be represented as a matrix composed of multiple nonnegative scalars. This matrix has the unique characteristic of singular value, which can describe the distribution characteristics of matrix data. It is very stable to describe the image by singular value, and it also has the characteristics of transpose, image invariance, translation, and rotation. It can effectively describe the algebraic features in the image. Therefore, the purpose of enhancing the image can be achieved by enhancing the singular value of the image matrix.

The singular value of the matrix can be obtained by singular value decomposition. The definition of singular value decomposition is as follows: *A* is proposed to represent $m \times n$ real matrix, and rank(A) = r; then, there are *m* order West matrix *U* and *E* order West matrix *V*, so that

$$A = USV^{H} \times U \sum V^{H}, U * U^{H}.$$
 (21)

In (21), V^H represents all r nonzero singular values of A; each column of U and V is the eigenvector of $A * A^H$ or $A^H * A$, respectively; and S represents the decomposed singular value matrix.

After singular value decomposition, the set information and texture of the image will appear in the matrix U, V, and the energy information of the image will be concentrated in the singular value. The singular value of the image matrix is enhanced by incorporating a certain amount of Gaussian noise into the image. The general process is as follows:

- The preprocessed image f (x, y) is subjected to singular value decomposition to obtain the matrix U, S, V.
- (2) The Gaussian noise is superimposed into the preprocessed image, and the noisy image is decomposed by singular value decomposition to obtain matrix U_n, S_n, V_n.
- (3) The image enhanced by singular value decomposition is $g(x, y) = US_n V^H$; $g(x, y) = US_n V^H$.

(4) The image f(x, y) is modified by the adaptive histogram averaging method to obtain the final visual effect enhanced image, so as to complete the research on the digital image watermarking algorithm based on scrambling and singular value decomposition.

4. Experimental Analysis

With the support of scrambling and singular value decomposition, the effect and feasibility of the designed digital image watermarking algorithm are verified. Therefore, a simulation experiment is designed for verification. The MATLAB programming parameters required for the specific experiment are shown in Table 1.

Set the digital image watermark embedding intensity coefficient as 0.1 according to the parameters in Table 1, and draw the waveform of the original image signal and the watermark image signal embedded by the digital image watermark algorithm based on scrambling and singular value decomposition. The experimental results are shown in Figure 3.

According to Figure 3, after introducing the digital image watermarking algorithm based on scrambling and singular value decomposition studied in this paper, there is almost no difference between the waveform of the watermarked image signal and the original signal. It can be seen that there is no obvious difference between them in the process of watermark inspection and testing. According to the above analysis, when the image is not attacked, the watermark information can be completely extracted.

The normalized correlation coefficient (NC) mainly describes the robustness of the watermark. The main factors affecting the robustness of the watermark are various attacks. Select the original image as the test object, and count the normalized correlation coefficient values of the three video watermarking algorithms after various attacks. Suppose that the sampling point of the audio is o, the total length of the audio is L, the original carrier audio is X, and the embedded watermark audio is X'; then, the normalized correlation coefficient calculation formula S of watermark audio is

$$S = 10 \log_{10} \frac{\sum_{0=1}^{L} X^{2}(i)}{\sum_{0=1}^{L} [X(i) - X'(i)]^{2}}.$$
 (22)

Calculate the normalized correlation coefficient results according to (13), as shown in Table 2.

As can be seen from Table 2, compared with the algorithms in [7] and [8], the normalized correlation coefficient of the algorithm in this paper is larger, indicating that the detected watermark is more similar to the original watermark, and the watermark has strong robustness and can resist various attacks. This is mainly because the algorithm in this paper considers scrambling and singular value decomposition, and the watermark is more robust.

In order to further prove the practicability of the proposed method, six digital images are extracted from the image database, and the singular values and contrast increments of the six digital images before and after enhancement are compared. The results are shown in Table 3.

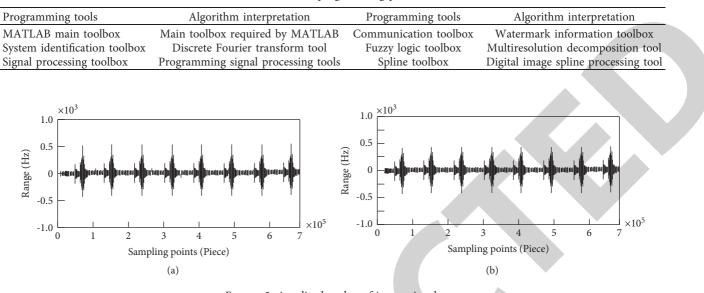

FIGURE 3: Amplitude value of image signal.

TABLE 2: Comparison	results of normaliz	ed correlation	coefficients of	different a	algorithms.

Aggressive behavior	Paper algorithm	Reference [7] algorithm	Reference [8] algorithm
Noise	0.972	0.825	0.937
Frame loss	0.963	0.867	0.920
Shear	0.946	0.838	0.902
Tampering	0.955	0.857	0.910
Compression	0.955	0.822	0.910

It can be seen from Table 3 that the image contrast and singular value have been significantly improved after enhancement using the algorithm in this paper. This is because the proposed method will describe the image by singular value, and because of the characteristics of singular value, the improvement of singular value can also drive the improvement of image visual effect.

From the five audio digital images selected in this experiment, the popular audio is selected as the experimental object. Through the correlation coefficient, the resistance of the three groups of algorithms to attacks is verified. The closer the correlation coefficient of the algorithm to 1, the higher the similarity between the extracted watermark information and the original watermark, and the better the anti-attack ability of the algorithm. Therefore, assuming that the original watermark is w, the extracted watermark is w, the pixel at a certain position of the watermark is (i, j), and the number of pixels of the watermark is m * n, the correlation coefficient C of the algorithm is calculated as follows:

$$C(w,w') = \frac{\sum_{i=1}^{m} \sum_{j=1}^{n} w(i,j)w(i,j)}{\sqrt{\sum_{i=1}^{m} \sum_{j=1}^{n} w^{2}(i,j)}\sqrt{\sum_{i=1}^{m} \sum_{j=1}^{n} w^{2}(i,j)}}$$
(23)

MATLAB software is selected to attack the three algorithms selected in this experiment. Formula (23) is used to calculate the correlation coefficients of the three algorithms and verify the resistance of the three algorithms to attacks, and the experimental results are shown in Table 4.

TABLE 3: Contrast and entropy increment of images before and after enhancement.

Image ↓	Initial digital image		Enhanced digital image	
	Singular value	Contrast ratio	Singular value	Contrast ratio
1	5.55	1.07	5.97	1.24
2	5.43	1.11	5.69	1.22
3	5.35	1.14	5.93	1.24
4	6.80	1.13	7.39	1.27
5	6.81	1.10	7.42	1.27
6	6.90	1.15	7.53	1.28

It can be seen from Table 4 that under the attack of the attack mode set in this experiment, there is a gap of 0.17 and 0.16 between the correlation coefficient of the algorithm in [7] and the algorithm in [8] and the non-attack, respectively, indicating that the similarity between the watermark information extracted by the two groups of algorithms and the original watermark is low, and the anti-attack performance is poor when attacked. Under the attack of the attack mode set in this experiment, there is only a gap of 0.02 between the correlation coefficient and the non-attack. It can be seen that the digital image watermarking algorithm based on scrambling and singular value decomposition in this research has high similarity between the extracted watermark information and the original watermark and has better anti-attack ability when attacked.

TABLE 4: Test results of resistance to attack.

5. Conclusion and Prospect

5.1. Conclusion.

- (1) After introducing the digital image watermarking algorithm based on scrambling and singular value decomposition, there is almost no difference between the waveform of the watermarked image signal and the original signal. When the image is not attacked, the watermark information can be extracted completely.
- (2) The watermark detected by this algorithm is more similar to the original watermark. The watermark has strong robustness and can resist various attacks.
- (3) After using this algorithm for enhancement, the image contrast and singular value have been significantly improved.
- (4) The digital image watermarking algorithm based on scrambling and singular value decomposition in this study has high similarity between the extracted watermark information and the original watermark and has better anti-attack ability when attacked.

5.2. Prospect. Digital image watermarking algorithm has been fully studied and developed. In the future research work, digital image watermarking technology needs to be deeply studied in the following aspects:

- (1) Research on the robustness, security, and anti-attack ability of the existing digital watermarking algorithms, combined with the digital signal processing technology, will be conducted to find out the relationship between them, so as to find the digital image watermarking technology with better performance.
- (2) Digital watermarking technology based on biometrics can also embed some human characteristics, such as fingerprint, palm print, and other information in the image as copyright authentication, so it may become the focus of research in the future.
- (3) At present, other digital image watermarking technologies can be used as a research direction of digital image watermarking algorithm in the future, such as digital watermarking technology based on graphics, vector graphics, and animation; watermark

embedding algorithm based on triangular patch geometry; audio watermarking algorithm; and video watermarking algorithm.

In order to overcome the problems of poor clustering effect and large error of text knowledge acquisition in traditional text knowledge acquisition methods, a new text knowledge acquisition method of collaborative product design based on genetic algorithm is proposed in this paper. The definition of collaborative product design text knowledge clustering is given. According to the operation process of the genetic algorithm, the chromosomes of clustered text are constructed and encoded and the initial population is obtained. The fitness function of clustering is constructed by the DB index evaluation method; the selection, crossover, and mutation operators in the genetic algorithm are determined; and the objective function of collaborative product design text knowledge clustering is constructed. After the text knowledge clustering is completed, the text knowledge data of collaborative product design are obtained in an all-around way by using the method of rough set and neural network. The experimental results show that compared with the traditional text knowledge acquisition methods, the clustering effect of the proposed method is better and the text knowledge error is reduced up to 0.02.

1. Introduction

The product design process is an important stage of the whole product development. Modern product design is becoming more and more complex. It is difficult for a single unit to have a design team with a professional configuration. Many product design units adopt the networked collaborative product design method to unite product designers scattered in local alliances to jointly complete product design [1]. In the process of collaborative product design, knowledge exchange and sharing are important to guarantee successful product design. At present, most of the commonly used knowledge acquisition methods are that product designers obtain the knowledge they need from the product design knowledge base of each unit through a query. It requires collaborative product designers to have a deep understanding of the product design knowledge base of cooperative units [2-4]. With the continuous increase of product design knowledge, the query takes longer and longer, and it is even difficult to find the knowledge that meets the requirements of product design, which affects the efficiency of product design. Therefore, the traditional query method has been difficult to meet the requirements of networked product collaborative design.

In the process of collaborative product design, multidisciplinary design teams in distributed, remote, and dynamic environments involve many complex interactive tasks [5]. The practice results show that the sharing and reuse of design knowledge can reduce unnecessary repeated labor and shorten the product development cycle. In particular, the variant design of products can reuse the design experience and design knowledge accumulated by the design unit, so as to solve a large number of problems in many fields encountered in design [6]. Therefore, it is very important to study an effective text knowledge acquisition method for collaborative product design.

Reference [7] proposes a text knowledge acquisition method based on multigranularity. Multigranularity

cognitive ability is a common strategy for human beings to analyze complex data. As one of the complex data types, multisource data make data analysis complex because of its many data sources. Inspired by the idea of multigranularity, based on multisource information system and pessimistic decision-making strategy, the definition of multisource partition reduction set is proposed. The relationship between the multisource partition reduction set and partition reduction set is discussed, and the corresponding discrimination method of attribute characteristics is given. Finally, for a multisource decision information system, based on an optimistic decision strategy, multisource decision rules are proposed. Based on the multigranularity model, the multisource data analysis method proposed from a new perspective further enriches the method of knowledge acquisition. Reference [8] proposes a text knowledge acquisition method based on a fuzzy hyper network. Combined with the relevant knowledge of fuzzy rough set theory and hyper network, the fuzzy hyper network model adopts fuzzy equivalent relationship to replace the clear equivalent relationship in hyper network and improves the generation and evolution of hyperedges on this basis. According to the distribution of samples, the sample set is divided into three regions, namely positive domain, boundary domain, and negative domain. Samples in different regions generate super edges in different ways. According to the classification effect, the super edge set is also divided into three regions, and the super edges in different regions are replaced accordingly, so as to complete the acquisition of text knowledge. Reference [9] proposes a text knowledge acquisition method based on word meaning disambiguation of knowledge map, uses TF-IDF model to obtain the set of text feature words, uses the word meaning sequence relationship expressed by knowledge map to determine the unique semantics of polysemy in a specific semantic environment, completes the vectorial representation of text at the level of word meaning concept, and realizes text knowledge acquisition.

Based on the above research results, in order to further improve the clustering and acquisition effect of collaborative product design text knowledge, a collaborative product design text knowledge acquisition method based on a genetic algorithm is proposed. A genetic algorithm is used to optimize the text knowledge clustering algorithm to improve the effectiveness of clustering, so as to obtain more effective collaborative product design text knowledge.

The research is organized as follows: the introduction and literature review are presented in Section 1. Section 2 analyzes the text knowledge acquisition of collaborative product design based on genetic algorithm. Section 3 discusses the experimental verification of the proposed concepts. Finally, in Section 4, the research work is concluded.

2. Text Knowledge Acquisition of Collaborative Product Design Based on Genetic Algorithm

In this section, we described the text knowledge clustering of collaborative product design based on genetic algorithm and collaborative product design text knowledge acquisition with detail. 2.1. Text Knowledge Clustering of Collaborative Product Design Based on Genetic Algorithm. Collaborative product design text knowledge clustering is a fully automatic process of grouping knowledge text sets. It is a typical unsupervised machine learning process. The goal of knowledge text clustering is to find a set of such classes. The similarity between classes is as small as possible, and the similarity within classes is as large as possible [10–13]. As an unsupervised machine learning method, clustering does not need a training process and manual labeling of collaborative product design text knowledge in advance. Therefore, clustering technology is very flexible and has a high automatic processing ability. At present, it has become an important means to effectively organize, summarize, and navigate collaborative product design text knowledge.

In order to improve the effect of text knowledge clustering in collaborative product design, a genetic algorithm is used to optimize a k-means algorithm for text knowledge clustering. The specific process is as follows.

Collaborative product design text knowledge clustering is based on the famous clustering hypothesis: the similarity of similar text knowledge is large, while the similarity of different text knowledge is small [14]. Text knowledge clustering is to divide the text knowledge set into several clusters without any predictive information. It is required that the similarity of text knowledge content in the same cluster should be as large as possible, and the similarity of objects between different clusters should be as small as possible.

Definition 1. Collaborative product design text knowledge clustering is to divide a given text knowledge set $F = \{f_1, f_2, \ldots, f_m\}$ to obtain a class set $V = \{v_1, v_2, \ldots, v_l\}$, where $v_k \in F(k = 1, 2, \ldots, l)$, making $\forall f_o(f_o \in F)$, $\exists v_l(v_l \in V)$, and $f_o \in v_l$, and minimizing the cost function g(V).

The grouping in clustering is also called a cluster. The definition of a cluster is as follows: (1) the set of similar objects, and the objects in different clusters are not similar; (2) the distance between two objects in the cluster is less than the distance between any object in the cluster and any object outside the cluster.

Clustering is similar to classification in that it groups data. However, different from classification, the input set of clustering analysis is a group of unidentified records. Therefore, this is an unsupervised learning process; that is, the clustering algorithm does not need supervision and does not need to provide training data. It tends to the natural division of data. A classification algorithm is a supervised learning process, which needs to train the labeled data set.

Genetic algorithm is similar to natural evolution. It finds a good chromosome to solve the problem by acting on the genes on the chromosome. Similar to nature, the genetic algorithm knows nothing about the problem itself. All it needs is to evaluate each chromosome generated by the algorithm and select chromosomes based on fitness value so that the chromosomes with good adaptability have more reproductive opportunities. In a genetic algorithm, several numerical codes of the problem are generated randomly, that is, chromosomes, to form the initial population; A numerical evaluation is given to each individual through the fitness function, the chromosomes with low fitness are eliminated, and the individuals with high fitness are selected to participate in the genetic operation. The individual set after genetic operation forms the next generation of the new population, the next round of evolution of the new species.

The biggest difference between a genetic algorithm and a traditional algorithm is that the calculation does not terminate automatically. The termination conditions are often artificially limiting the evolutionary algebra or setting the termination conditions by controlling the consistency of evolutionary results.

The genetic algorithm differs from other search methods in that

- The encoded variable value is utilized instead of the variable itself when employing the genetic algorithm to search
- (2) The search method for a genetic algorithm is to iterate from one set of points to the next set of points and to iterate from one point to another, unlike most other search algorithms, but search by population
- (3) Rather than using a deterministic operation process, the genetic algorithm employs a random operation process
- (4) The qualities of the search space (such as connectedness, convexity) are unimportant to the genetic algorithm, which only requires the value of each point of the objective function and no additional auxiliary information

2.1.1. Chromosome Construction and Coding of Clustering Problems. According to the objective function K(I, W) of collaborative product design text knowledge clustering, the ultimate goal of collaborative product design text knowledge clustering is to obtain l partition matrices I of sample set Cand the prototype matrix W of clustering, and I and W are related. The partition matrix I can also be encoded, and the prototype matrix W can also be encoded.

Let M samples be divided into l classes. $M = (s_1, s_2, \ldots, s_m)$ represents the chromosome structure of the genetic algorithm, s is an 1 * N-dimensional row vector, s_o represents the o-th gene, but $s_o \in \{1, 2, \ldots, l\}, i = 1, 2, \ldots, M$. When $s_o = v$, it means that the o-th sample belongs to class v. Generally, standard genetic operations can be used to support this expression. Therefore, for any scheme that divides the sample M into lclusters, it is its corresponding coding matrix:

$$I = (\mu_{ok})l * M, \mu_{ok} = \begin{cases} 1, & \text{if } o \in k, \\ 0, & \text{else.} \end{cases}$$
(1)

2.1.2. Initial Population. The initial population required by the genetic algorithm should have diversity. Therefore, when operating a genetic algorithm, first determine the population

size M and then randomly generate M random numbers. According to the *o*-th random number l_o , a chromosome with length l_o is generated. The chromosome represents the centroid set containing l_o genes, and each gene in the chromosome represents an initial cluster center. In this way, the initial population with the population size of M and different chromosome lengths is obtained.

2.1.3. Fitness Function. The genetic algorithm basically does not use external information in the process of evolutionary search, and only takes the fitness function as the basis for optimization. The fitness function in the genetic algorithm is used to evaluate the fitness of individuals and distinguish the advantages and disadvantages of individuals in the population. The higher the fitness, the greater the probability of being inherited, and the better the clustering effect [15]. Therefore, the selection of fitness function is very important, which directly affects the convergence speed of the genetic algorithm and the ability to find the optimal solution. DB index evaluation method is adopted.

The DB evaluation method is described as follows:

$$D_{i} = \frac{1}{N_{i}} \sum_{G \in C_{i}} |G - H_{i}|, H_{i} = \frac{1}{N_{i}} \sum_{G \in C_{i}} G.$$
 (2)

Here, H_i represents the center of the set, $|G - H_i|$ represents the distance from the collaborative product design text knowledge vector P to the center H_i , and D_i represents the average cohesion of the cluster set.

$$f_{ij} = \left| H_i - H_j \right|. \tag{3}$$

Here, f_{ij} represents the distance between two clustering centers.

$$S_{i} = \max\left\{\frac{d_{i} + d_{j}}{f_{ij}}\right\} i \neq j,$$

$$DB = \frac{1}{Z} \sum_{i=1}^{Z} S_{i}.$$
(4)

Because the smaller the DB is, the better the clustering effect is, the reciprocal 1/DB of the DB can be used as the fitness function, that is:

$$F = \frac{1}{DB}.$$
 (5)

From the above calculation, it can be seen that the smaller the DB, the greater the fitness value F, and the greater the probability of individual inheritance; the smaller the DB, the better the clustering effect. Therefore, it shows that the fitness value F is directly proportional to the clustering effect.

2.1.4. Genetic Operator. The main task of genetic operation is to operate the individuals of the population according to their degree of adaptation to the environment, so as to realize the evolutionary process of survival of the fittest. From the perspective of optimization search, genetic operations can optimize

the problem from generation to generation, constantly approaching the optimal solution.

The genetic algorithm includes three basic operators: selection, crossover, and mutation.

- (1) Selection Operator. In the process of biological evolution, species with strong adaptability to the living environment will have more opportunities to inherit to the next generation; the probability of inheritance to the next generation is relatively small. The selection operation in genetic algorithm embodies the principle of "survival of the fittest": the higher the fitness, the higher the probability of participating in offspring reproduction [16-18]. A selection operation is a genetic operation used to determine how to select which individuals from a parental population to inherit to a descendant population. It is based on the evaluation of individual fitness: individuals with higher fitness have a higher probability of genes being inherited into the offspring population; in individuals with low fitness, the probability of genes being inherited into the offspring population is small.
- (2) Crossover Operator. Crossover operation, also known as recombination, is the most important genetic operation in genetic algorithm. The crossover operation can not only maintain the excellent characteristics of the parent population to a certain extent but also make the algorithm explore the new gene space, so as to maintain the individual diversity in the new population. Crossover operation in genetic algorithm means that two paired individuals exchange some genes with each other in some way, so as to form two new individuals. The crossover operation is carried out according to a certain probability (called crossover probability). Crossover operation is an important feature that distinguishes genetic algorithm from other evolutionary operations. It plays a key role in genetic algorithm and is the main method to generate new individuals. The crossover operator simulates the mutation of natural organisms and embodies the idea of information exchange. The higher the crossover probability, the faster the convergence to the global optimal solution, but it may also lead to premature convergence; the crossover probability is too low, which may cause the search to stagnate, generally 0.4-0.9.
- (3) Mutation Operator. Mutation operation is to imitate the variation link in the process of biological inheritance and evolution. It refers to replacing the gene value of some gene positions in the individual chromosome coding string with other alleles of the gene position, so as to form a new individual. Variation takes place with a very small probability (called variation probability). It is a random algorithm, and combined with selection and crossover operators, it can avoid the loss of some information caused by selection and crossover operations and ensure the

effectiveness of genetic algorithm. Mutation is an auxiliary method to generate new individuals, but it is also an essential step of genetic algorithm, because it determines the local search ability of genetic algorithm. Mutation operation and crossover operation cooperate with each other to complete the global search and local search of the search space so that the genetic algorithm can complete the optimization process of the optimization problem with good search performance. It can increase the diversity of groups. If the mutation probability is too large, the genetic algorithm may degenerate into a random search. If the mutation probability is too small, it may not be able to produce new genes. Generally, it is 0.001–0.1.

2.1.5. Construction of Clustering Objective Function. In this study, the problem of clustering analysis of collaborative product design text knowledge is described from a mathematical point of view. Let $C = \{C_1, C_2, \ldots, C_m\}$ be the whole of *m* objects to be clustered. Each C_k ($k = 1, \ldots, m$) objects in *C* are often described by a finite number of attributes S_o ($o = 1, \ldots, n$). Each attribute value depicts a feature of C_k , which can be expressed as $C_k = [c_{k,1}, c_{k,2}, \ldots, c_{k,n}]$, and $C_k = [c_{k,1}, c_{k,2}, \ldots, c_{k,n}]$ is the feature vector of C_k . Cluster analysis is to analyze the similarity of multicorresponding eigenvectors of *m* objects in all *C* objects, divide C_1, C_2, \ldots, C_m into multiple disjoint subsets V_1, V_2, \ldots, V_l according to the distance relationship between each object, and meet the following conditions:

$$V_{1} \cup V_{2} \cup \dots \cup V_{k} = C,$$

$$V_{o} \cap V_{k} = \Phi,$$

$$V_{o} \neq \Phi,$$

$$V_{o} \neq C,$$

$$1 \le o \ne k \le l.$$
(6)

The membership relationship of m samples C_o to the subset can be expressed as follows:

$$\mu_{\nu_i}(C_k) = \mu_{ok} = \begin{cases} 1, & C_k \in V_o, \\ 0, & C_k \notin V_o. \end{cases}$$
(7)

The membership function must meet $\mu_{ok} \in Rl$; that is, each sample can only belong to a certain class, and each subclass is required to be nonempty. For *l* partition space Q_l of *C*, there are

$$\begin{cases} Q_{l} = \left\{ I \in T^{lm}I = [\mu_{ok}]_{l \times m}; \mu_{ok} \in \{0, 1\} \\ \sum_{o=1}^{l} \mu_{ok} = 1, \forall k; 0 < \sum_{k=1}^{n} \mu_{ok} < n, \forall 0 \right\}. \end{cases}$$
(8)

Let $T = \{T_1, T_2, ..., T_l\}$ represent *l* clustering models, and then, the objective function of clustering analysis can be expressed as follows:

$$\begin{cases} K_1(I,W) = \sum_{o=1}^l \left(\sum_{C_k \in V_o} (f_{ok})^2 \right), \\ \text{s.t.} \quad I \in Q_l. \end{cases}$$
(9)

Here, $f_{ok} = f(C_k, W_o)$ represents the dissimilarity measure between sample C_k and prototype V_o of W_o in the *o*-th type V_o , and $K_1(I, W)$ represents the sum of squares of errors between various samples and their prototypes. Using μ_{ok} , $K_1(I, W)$ can also be expressed as follows:

$$\begin{cases} K_1(I, W) = \sum_{k=1}^{m} \sum_{o=1}^{l} \mu_{ok} (f_{ok})^2, \\ \text{s.t.} \quad I \in Q_l, \end{cases}$$
(10)

where $K_1(I, W)$ is also called clustering objective function. The clustering criterion is to find the best group pair (I, W) so that when the constraint $\mu_{ok} \in Q_l$ is satisfied, $K_1(I, W)$ is the minimum, that is, min $\{K_1(I, W)\}$.

By solving the objective function of clustering, the clustering results of collaborative product design text knowledge can be obtained for subsequent text knowledge acquisition.

The process of collaborative product design text knowledge clustering based on genetic algorithm is shown in Figure 1.

2.2. Collaborative Product Design Text Knowledge Acquisition. Based on the above clustering results of collaborative product design text knowledge, text knowledge is obtained according to rough set theory.

Rough set theory gives the dependency relationship between conditional attribute set and decision attributes; that is, the mapping relationship between input data and output data can be obtained by decision table simplification.

The text knowledge acquisition methods proposed in this study can be divided into the following steps: using self-organizing mapping (SOM) neural network method, based on the above clustering text data, the data are discretized, and the data interval is divided; rough set theory is used to extract rules to determine the input text data. According to the maximum matching rule, the optimal rule is selected to obtain the rough set evidence distribution; the evidence distribution is obtained according to the output results of the neural network, and the text data fusion results are obtained by Murphy average method combined with decision rules [19, 20].

The self-organizing mapping network is used to realize the discretization of clustering text knowledge data. There is a SOM network corresponding to each attribute a_i , which is composed of subnet. The single-attribute data are one-dimensional change, and the two-dimensional rough set decision table is obtained after network training. In order to prevent excessive discretization of the decision table, the initial number of neurons in the output layer is set to 2. The dependency among attributes in the data information system is obtained by rough set theory. The basic results of the neural network are shown in Figure 2.

The rough membership function of the relative set X of attribute values under relationship U is expressed as

$$\sigma_X^U(\alpha) = \frac{\left| X \cap [\alpha]_U \right|}{[\alpha]_U}.$$
 (11)

Here, $|\cdot|$ represents the number of elements in the set, and α represents the attribute value. It can be seen from the

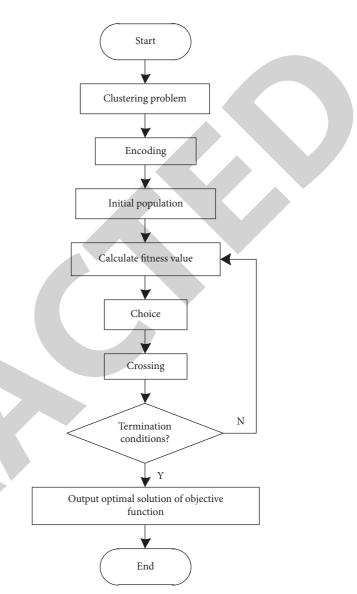

FIGURE 1: Collaborative product design text knowledge clustering process.

above formula that the greater the value of $\sigma_X^U(\alpha)$, the higher the possibility of obtaining the *X* set according to the attribute value α . Using rough set theory, i Q (condition) $\longrightarrow h$ (decision) rules are extracted from the original data of discrete collaborative product design text knowledge. The *n*-th rule U^i in the description rules is as follows.

If $f(x, q_1) = t_1^i, \dots, f(x, q_n) = t_n^i$, then exist $f(x, q_1) = r_1^i, \dots, f(r, p_r) = r_n^i$.

The matching degree of a set of input *IN* and the *i*-th rule is described as follows:

$$B_i = \frac{\sum_{i=1}^n IN(k)}{n}, \quad i = 1, 2, \dots, n.$$
(12)

Here, IN(k) represents the input mode function. Formula (12) represents the matching degree between the input pattern and the rule. The rules are obtained from the text knowledge data of collaborative product design, and the reliability of each rule is different. The rough membership

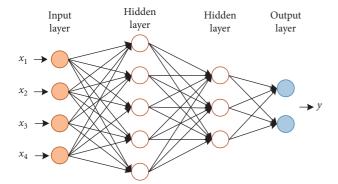

FIGURE 2: Structure of the neural network.

function is used to describe the reliability of the rules, and the applicability is obtained combined with the matching degree [21].

The applicability of rule i corresponding to input in is described as

$$\eta_i = \max\{\eta_X^{qj}(t_1^i)r_i(1), \eta_X^{qj}(t_2^i)r_i(2), \eta_X^{qj}(t_n^i)r_i(n)\}.$$
 (13)

The evidence P_{RS} is obtained by rough set theory analysis, and the weight value ω is obtained by extracting rules and processing the input. According to the principle of maximum matching degree, appropriate rules are selected. It is assumed that the subscript set of rules is $\vartheta = \{e_1, e_2, \ldots, e_n\}$, the corresponding decision expression is $\{Le_1, Le_2, \ldots, Le_n\}$, and the applicability is $\{\varepsilon e_1, \varepsilon e_2, \ldots, \varepsilon e_n\}$. Assuming that the output of the neural network is $y = [Y_1, Y_2, \ldots, Y_n]$, the output $\lambda_i = [\gamma_1, \gamma_2, \ldots, \gamma_n]^T$ of the collaborative product design text knowledge acquisition function is solved according to the Murphy average method; then,

$$\lambda_{i} = \frac{\left(P_{RS}(i) + P_{NN}(i)/2\right)^{2}}{\sum_{i=1}^{n} \left(P_{RS}(i) + P_{NN}(i)/2\right)^{2}}, \quad i = 1, 2, \dots, n.$$
(14)

Here, P_{NN} represents collaborative product design text knowledge data input into neural network to obtain evidence. According to the decision rules of text knowledge acquisition, the text data output decision category is obtained as follows:

$$w_n = \begin{cases} \text{ture, } \lambda_i = \max(\gamma_1, \gamma_2, \dots, \gamma_n) \\ \text{false, else} \end{cases}.$$
 (15)

The K-means clustering is optimized by genetic algorithm, the collaborative product design text knowledge is clustered, and the rough set combined with neural network method is used to obtain the collaborative product design text knowledge data in an all-round way [22].

3. Experimental Verification

In order to verify the practical application effect of the proposed collaborative product design text knowledge acquisition method based on genetic algorithm, simulation and comparative verification experiments are carried out.

3.1. Experimental Data. The experimental research data come from the developed collaborative product design project, which is jointly completed by 100 people. Therefore, it has high requirements for the acquisition frequency and speed of text knowledge, which meets the requirements of experimental verification. The structure of the collaborative product synchronous design pattern is shown in Figure 3.

Due to the large scale of the project, the amount of collaborative product design text knowledge data generated is large, with a total of 100 GB. And because the text knowledge data generated in the design process may be used, there is no need to preprocess the experimental data.

3.2. Experimental Environment Deployment. The experimental environment parameters are shown in Table 1.

3.3. Analysis of Experimental Results. The experimental verification scheme is as follows: taking the clustering performance, clustering time, algorithm convergence, and text knowledge acquisition error as the experimental comparison indexes, the text knowledge acquisition method based on genetic algorithm proposed in this paper is compared with the multigranularity method proposed in reference [7] and the method based on fuzzy hyper network proposed in reference [8].

3.3.1. Clustering Performance Judgment. The commonly used indicators for judging clustering performance are accuracy, recall, and F1 test value. Accuracy (PR) represents the correctness of clustering, that is, the proportion of texts in the document that really meet the search intention. It is defined as follows:

$$\Pr_i = \frac{TP_i}{TP_i + FP_i}.$$
(16)

Recall (Re) represents the integrity of clustering, that is, the ratio of all texts that meet the search intention to the retrieved text. It is defined as follows:

$$\operatorname{Re}_{i} = \frac{TP_{i}}{TP_{i} + FN_{i}}.$$
(17)

Here, FP_i represents the number of text incorrectly assigned to a certain cluster and belonging to other clusters, TP_i represents the number of text correctly assigned to a certain cluster, and FN_i represents the number of text belonging to a certain cluster and assigned to other clusters.

Accuracy and recall reflect two different aspects of clustering quality, which must be considered comprehensively. In some cases, some new evaluation indexes, F1 test value, will be used, which is defined as follows:

$$F1 = \frac{\Pr \times \operatorname{Re} \times 2}{\Pr + \operatorname{Re}}.$$
 (18)

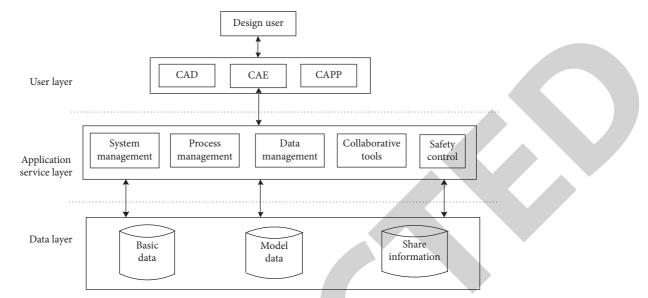

FIGURE 3: Structure of the collaborative product synchronous design pattern.

TABLE 1: Experimental environment parameters.

Parameter name	Parameter index
Equipment model	Dell OptiPlex
Operating system	Windows 10
CPU	Inter(R) core(TM) i5
Memory	16 GB
Network environment	300 GB

It can be seen from the above formula that the larger the F1 value, the better the clustering effect.

The clustering performance comparison results of the three methods are shown in Table 2.

It can be seen from the experimental results in Table 2 that the F1 values of the proposed genetic algorithm are higher than the two comparison methods, so it shows that the clustering effect of this method is better than that of the traditional method.

3.3.2. Clustering Time. In order to more fully verify the performance of the proposed method, considering the acquisition time of the overall text knowledge, clustering time is the key index. Therefore, the clustering time of the proposed method is verified, and the proposed method is compared with two traditional methods. The comparison results of clustering time of the three methods are shown in Figure 4.

By observing the clustering time comparison results shown in Figure 4, it can be seen that under multiple experiments, the proposed method based on genetic algorithm has a shorter clustering time, the maximum clustering time is no more than 1 min, the maximum clustering time based on multigranularity method is 2.5 min, and the clustering time based on fuzzy hyper network method is even 5.8 min. Therefore, it shows that the text knowledge clustering form optimized by genetic algorithm can effectively shorten the clustering time. 3.3.3. Convergence of Clustering Algorithm. The convergence of clustering algorithm has a key impact on the clustering results of collaborative product design text knowledge. Therefore, taking the convergence of clustering algorithm as the experimental comparison index, the convergence of this clustering algorithm is compared with the multigranularity method proposed in reference [7] and the fuzzy hypernetwork method proposed in reference [8]. The convergence comparison results of clustering algorithms in the three methods are shown in Figure 5.

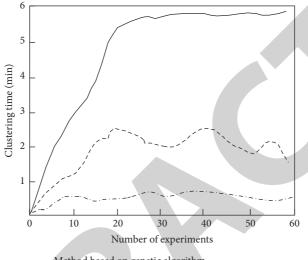

From the convergence comparison results shown in Figure 5, it can be seen that the convergence speed based on fuzzy hyper network method is faster (20 iterations), but it is earlier than a larger objective function value, while the convergence speed based on multigranularity method is slower (45 iterations). Only the method based on genetic algorithm proposed in this paper converges to a minimum value under the requirement of convergence speed (33 iterations). Therefore, it shows that the convergence performance of the proposed method is good.

3.3.4. Collaborative Product Design Text Knowledge Acquisition Error. In the process of collaborative product design, once the text knowledge acquisition error is large, it will affect the final design result of the product. Therefore, the accuracy of text data acquisition in collaborative product design is required. Therefore, it is necessary to verify the text acquisition error of collaborative product design based on text method. The comparison results of collaborative product design text knowledge acquisition errors are shown in Figure 6.

From the comparison results of text knowledge acquisition errors shown in Figure 6, compared with the two comparison methods, the collaborative product design text knowledge acquisition error of this method is the smallest, and the error of this method does not change greatly with the increase of the number of experiments.

Test group	Amount of text knowledge data (GB)	F1 value			
		Method based on genetic algorithm	Method based on multigranularity	Method based on fuzzy hyper network	
1	20	0.890	0.652	0.637	
2	20	0.902	0.686	0.554	
3	20	0.939	0.737	0.611	
4	20	0.868	0.584	0.617	
5	20	0.895	0.687	0.560

This article is concerned with a class of contractions in the framework of a fuzzy metric space endowed with a graph. The main results obtained not only broaden but also generalize a number of relevant results in the literature. Particularly, we get some results for cyclic contractions in fuzzy metric spaces. We also consider an integral equation.

1. Introduction

In recent years, fixed-point theory has become a tantalizing field of research in nonlinear analysis due to its wide range of applications in computer sciences, game theory, physics, economics, and various other fields. It has become a tool to find solutions for nonlinear equations such as differential equations, integrodifferential equations, and matrix equations [1, 2]. After the fundamental Banach's theorem [3] in 1922, a huge amount of literature appeared for the investigation of fixed points of self-operators. Among those results, two aspects must be considered: underlying geometric structure on which self-operator is defined and an appropriate contraction condition on operator.

The investigation of existence of a fixed point of selfmappings on a metric space (\mathcal{N}, d) equipped with a partial ordering was originated by the works of Ran and Reurings [4]. By replacing a partial order with a graph, Jachymski [5] studied some prolific results about the existence of a fixed point involving the graph concept. Later on, several researchers conducted further studies in this area by relaxing the contractive condition and analyzing the connectivity condition of a graph. For more details, see [6-8].

On the other hand, Kramosil and Michalek [9] gave the concept of a fuzzy metric space. Afterward Grabiec [10] extended the Banach contraction principle (BCP) to fuzzy metric spaces in the sense of Kramosil and Michalek. Many authors undertook further advancements in this direction by generalizing the contraction inequalities and by providing the underlying space with rich geometric structure to make the results more viable. In this context, recently a number of authors contributed new and exciting developments in fixed-point theory using fuzzy metric spaces; see [9–18] and the references included therein. For some very recent studies on the topic, we refer the reader to [19–21].

In particular, Altun [11] proved some useful results about the existence of fixed points of fuzzy order κ -contractive mappings with the setting of non-Archimedean fuzzy metric spaces. The work of Jachymski motivated us to introduce the notion of fuzzy order κ_G -contractive mappings and study related fixed-point results in the context of a fuzzy metric space equipped with a graph. Our introduced notion unifies the concept of Altun and Mihet, and Jachymski. By a successful application of our main result, we also ensure the existence of a solution for an integral equation.

2. Preliminaries

In this section, we recall some basic notions and results which are used in the sequel. Throughout this article, we use J = [0, 1].

Definition 1 (see [9]). A binary operation $\theta: J \times J \longrightarrow J$ is a continuous *t*-norm if, for all $u, v, w, z \in J$, it satisfies the following conditions:

- (1) θ is continuous,
- (2) $(u\theta v)\theta w = u\theta(v\theta w)$ and $u\theta v = v\theta u$,
- (3) $u\theta 1 = u$,
- (4) $w \ge u$ and $z \ge v$ imply that $w\theta z \ge u\theta v$.

If there exists a strictly increasing sequence $\{v_n\} \in (0, 1)$ such that $v_n \theta v_n = v_n$ for all $n \in \mathbb{N}$, then the continuous *t*-norm θ is known as Hadzic type.

Definition 2 (see [9]). Let \mathcal{N} be an arbitrary set, let $\Gamma: \mathcal{N} \times \mathcal{N} \times [0, \infty) \longrightarrow J$ be a fuzzy set, and let θ be a continuous *t*-norm. $(\mathcal{N}, \Gamma, \theta)$ is said to be a fuzzy metric space if, for all $\alpha, \beta, \gamma \in \mathcal{N}$ and $\iota, \lambda > 0$, the following conditions hold:

- (1) $[(FM_1)] \Gamma(\alpha, \beta, 0) = 0,$
- (2) $[(FM_2)] \Gamma(\alpha, \beta, \iota) = 1$ if and only if $\alpha = \beta$,
- (3) $[(FM_3)] \Gamma(\alpha, \beta, \iota) = \Gamma(\beta, \alpha, \iota),$
- (4) $[(FM_4)] \Gamma(\alpha, \beta, \iota) \theta \Gamma(\alpha, \gamma, \lambda) \leq \Gamma(\alpha, \gamma, \iota + \lambda),$
- (5) $[(FM_5)] \Gamma(\alpha, \beta, \cdot): [0, \infty) \longrightarrow J$ is left continuous.

Remark 1 (see [11]). If we take the inequality (NA) rather than (FM_4) of Definition 2,

$$\Gamma(\alpha, \beta, \iota)\theta\Gamma(\alpha, \gamma, \lambda) \leq \Gamma(\alpha, \gamma, \max\{\iota, \lambda\}),$$

for all $\alpha, \beta, \gamma \in \mathcal{N}$ and $\iota, \lambda > 0$, (NA), (1)

then we call $(\mathcal{N}, \Gamma, \theta)$ a non-Archimedean fuzzy metric space. It is worthwhile to note that every non-Archimedean fuzzy metric space is a fuzzy metric space. From now on, we denote a fuzzy metric space simply by \mathcal{N} .

Definition 3 (see [9, 11]). A sequence $\{\alpha_n\}$ in \mathcal{N} is called

- (i) Cauchy if $\lim_{n \to \infty} \Gamma(\alpha_n, \alpha_{n+p}, \iota) = 1$ for each $\iota > 0$ and p > 0;
- (ii) convergent to $\alpha \in \mathcal{N}$ if $\Gamma_{n \longrightarrow \infty}(\alpha_n, \alpha, \iota) = 1$ for all $\iota > 0$;
- (iii) *M*-Cauchy if for each $\varepsilon \in (0, 1)$ and $\iota > 0$ there is a natural number n_0 such that $\Gamma(\alpha_n, \alpha_m, \iota) > 1 \varepsilon$ for all $m, n > n_0$;
- (iv) *G*-Cauchy if $\lim_{n \to \infty} \Gamma(\alpha_n, \alpha_{n+1}, \iota) = 1$, for all $\iota > 0$.

 \mathcal{N} is called complete if every Cauchy sequence is convergent. Additionally, it is called *M*-complete if every *M*-Cauchy sequence is convergent and *G*-complete if every G-Cauchy sequence is convergent.

In the following, we take into account the main results of [11]. A self-map \mathcal{T} on an ordered set (\mathcal{N}, \prec) is named nondecreasing (nonincreasing) w.r.t \prec if $\alpha \prec \beta$ implies $\mathcal{T}\alpha \prec \mathcal{T}\beta(\mathcal{T}\alpha \geq \mathcal{T}\beta)$.

Definition 4 (see [11]). Let (\mathcal{N}, \prec) be a partially order set and let $(\mathcal{N}, \Gamma, \theta)$ be a fuzzy metric space. Let $\kappa: J \longrightarrow J$ be a function. $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ is called a fuzzy order κ -contractive mapping if the following holds:

$$\alpha, \beta \in \mathcal{N}, \alpha \prec \beta \Longrightarrow \Gamma(\mathcal{T}\alpha, \mathcal{T}\beta, \iota) \ge \kappa(\Gamma(\alpha, \beta, \iota)), \quad \text{for all } \iota > 0.$$
(2)

Theorem 1 (see [11], Theorem 2.3). Let $(\mathcal{N}, \Gamma, \theta)$ be an *M*-complete non-Archimedean fuzzy metric space with the *t*-norm θ of Hadzic type, in which \mathcal{N} is a set with the partial order \prec . Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function. Assume that

- (i) \mathcal{T} is nondecreasing;
- (ii) either for every nondecreasing sequence {α_n} in N with α_n → α ∈ N implies α_n ≺ α for all n or T is continuous;
- (iii) there exists $\alpha_0 \in \mathcal{N}$ such that $\alpha_0 \prec \mathcal{T}\alpha_0$ and $\lim_{n \to \infty} \kappa^n (\Gamma(\alpha_0, \mathcal{T}\alpha_0, \iota)) = 1$ for each $\iota > 0$.

Then there is $\omega \in \mathcal{N}$ such that $\mathcal{T}\omega = \omega$.

Theorem 2 (see [11], Theorem 2.4). Let $(\mathcal{N}, \Gamma, \theta)$ be an *M*-complete non-Archimedean fuzzy metric space with the *t*-norm θ of Hadzic type in which \mathcal{N} is a set with the partial order \prec . Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous mapping such that $\kappa(\iota) > \iota$ for all $\iota \in (0, 1)$. Assume that

- (i) \mathcal{T} is nondecreasing;
- (ii) either for every nondecreasing sequence {α_n} in N with α_n → α ∈ N implies α_n ≺ α for all n or T is continuous;
- (iii) there is $\alpha_0 \in \mathcal{N}$ such that $\alpha_0 \prec \mathcal{T}\alpha_0$, $\Gamma(\alpha_0, \mathcal{T}\alpha_0, \iota) > 0$ for all $\iota > 0$.

Then there exists $\omega \in \mathcal{N}$ such that $\mathcal{T}\omega = \omega$.

Following [5], we include basic notions about graph which are used throughout this paper. Let $(\mathcal{N}, \Gamma, \theta)$ be a fuzzy metric space. The diagonal of $\mathcal{N} \times \mathcal{N}$ is represented by Δ . Consider a directed graph *G* such that its diagonal is a subset of E(G) and V(G) is equal to the whole set \mathcal{N} . We assume that *G* does not have any edges which are parallel and describe *G* with the pair (V(G), E(G)). By G^{-1} , we mean the converse of graph *G* and it is defined as

$$E(G^{-1}) = \{(\alpha, \beta) \in \mathcal{N} \times \mathcal{N} : (\beta, \alpha) \in E(G)\}.$$
 (3)

The undirected graph is denoted by \tilde{G} and it is obtained by neglecting the direction of edges. $E(\tilde{G})$ is given as

$$E(\tilde{G}) = E(G^{-1}) \cup E(G).$$
(4)

If V' is a subset of V(G), E' is a subset of E(G) and, for any edge $(\alpha, \beta) \in E', \alpha, \beta \in V$; then (V', E') is called a subgraph of *G*. The sequence $\{\alpha_j\}_{j=0}^p$ of (p+1) vertices, such that

$$\alpha = \alpha_0, \alpha_p = \beta \text{ and } (\alpha_{j-1}, \alpha_j) \in E(G),$$

where $j \in \{1, 2, \dots, p\},$ (5)

is called the path of length p between two vertices α and β in G, where p is a nonnegative integer. If between any two vertices there is always a path, then we call G a connected graph. G is said to be weakly connected if \tilde{G} is connected. Let α be a vertex in G and let E(G) be symmetric; then the set of vertices and edges that are comprised in certain path starting at α is known as component of G which contains α ; it is a subgraph of G and is denoted by G_{α} . The set of all edges in G_{α} is denoted by $E(G_{\alpha})$ and $V(G_{\alpha}) = [\alpha]_G$. It is worthwhile to indicate that G_{α} is connected. Here, $[\alpha]_G$ is the equivalence class of R and the relation R on vertices of V is defined as

$$\beta R\gamma$$
, if there is a path amidst β and γ in G. (6)

Let $\{\alpha_n\}$ be any sequence in \mathcal{N} . If for $\{\alpha_n\}$ with $\alpha_n \longrightarrow \alpha$ and $(\alpha_n, \alpha_{n+1}) \in E(G)$ for $n \in \mathbb{N}$ implies that there exists a subsequence $\{\alpha_{n_k}\}$ of $\{\alpha_n\}$ such that $(\alpha_{n_k}, \alpha) \in E(G)$ for $k \in \mathbb{N}$, then G is called (C)-graph.

3. Main Results

From now on, we denote a fuzzy metric space endowed with a graph *G* simply by \mathcal{N} .

Definition 5. A mapping $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ is called fuzzy order κ_G -contractive if, for all $\alpha, \beta \in \mathcal{N}$, we have

$$(\alpha, \beta) \in E(G) \text{ implies } (\mathcal{T}\alpha, \mathcal{T}\beta) \in E(G),$$
 (7)

$$\Gamma(\mathcal{F}\alpha, \mathcal{F}\beta, \iota) \ge \kappa(\Gamma(\alpha, \beta, \iota)),$$

for all $\iota > 0$ whenever $(\alpha, \beta) \in E(G),$ (8)

where $\kappa: J \longrightarrow J$ is a continuous and nondecreasing function.

Example 1. Suppose that *G* is any graph such that $V(G) = \mathcal{N}$. Define $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ by $\mathcal{T}\alpha = u$ for all $\alpha \in \mathcal{N}$, where *u* is any constant; then \mathcal{T} is a fuzzy order κ_G -contractive mapping.

Example 2. Let G_0 be a graph such that $E(G_0)$: = $\mathcal{N} \times \mathcal{N}$. Then any fuzzy order κ_G -contractive mapping is a fuzzy order κ_{G_0} -contractive mapping.

Definition 6. Two sequences $\{\alpha_n\}$ and $\{\beta_n\}$ in \mathcal{N} are said to be equivalent if $\lim_{n \to \infty} \Gamma(\alpha_n, \beta_n, \iota) = 1$ for all $\iota > 0$. In addition, $\{\alpha_n\}$ and $\{\beta_n\}$ are called Cauchy equivalent if each of them is Cauchy.

Lemma 1. Let $\{\alpha_n\}$ and $\{\beta_n\}$ be equivalent sequences in \mathcal{N} . Then the following hold:

(i) if α_n → α, then β_n → α and its converse holds;
(ii) if {α_n} is a Cauchy sequence, then {β_n} is also a Cauchy sequence and vice versa.

Proof. By using condition (FM_4) of Definitions 2 and 3, one can easily invoke the conclusions.

Proposition 1. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ_G -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function. Then the following hold:

- (i) *T* is both a fuzzy order κ_G contractive mapping and a fuzzy order κ_{G⁻¹}-contractive mapping,
- (ii) $[\alpha_0]_{\widetilde{G}}$ is \mathcal{T} -invariant, and $\mathcal{T}|_{[\alpha_0]_{\widetilde{G}}}$ is a fuzzy order $\kappa_{\widetilde{G}_a}$ -contractive mapping provided that $\alpha_0 \in \mathcal{N}$ is such that $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{G}}$.

Proof. (i) It could be proved easily by taking into account (FM_3) of Definition 3. (ii) Let $\alpha \in [\alpha_0]_{\widetilde{G}}^-$. Then there exists a path between α and α_0 ; that is, there exists a sequence $\{z_j\}_{j=0}^p$ of (p+1) vertices such that $\alpha = z_0, z_p = \alpha_0$ and $(z_{j-1}, z_j) \in E(G)$, for j = 1, 2, ..., p. Since \mathcal{T} is fuzzy order κ_G -contractive, one writes $(\mathcal{T}z_{j-1}, \mathcal{T}z_j) \in E(G)$ for $j \in \{1, 2, ..., p\}$. Thus $\mathcal{T}\alpha \in [\mathcal{T}\alpha_0]_{\widetilde{G}}^- = [\alpha_0]_{\widetilde{G}}^-$. Now, suppose that $(\alpha, \beta) \in E(\widetilde{G}_{\alpha_0})$. Since \mathcal{T} is fuzzy order κ_G -contractive, we have $(\mathcal{T}\alpha, \mathcal{T}\beta) \in E(G)$. But $[\alpha_0]_{\widetilde{G}}^-$ is \mathcal{T} -invariant, which implies that $(\mathcal{T}\alpha, \mathcal{T}\beta) \in E(\widetilde{G}_{\alpha_0})$. As \widetilde{G}_{α_0} is a subgraph of G, we have

$$\Gamma(\mathcal{F}\alpha,\mathcal{F}\beta,\iota) \ge \kappa(\Gamma(\alpha,\beta,\iota)),$$

for all $\iota > 0$ whenever $(\alpha,\beta) \in E(\widetilde{G}_{\alpha_0}).$

$$(9)$$

Lemma 2. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ_G -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function. Assume that, for $\alpha \in \mathcal{N}$ and $\beta \in [\alpha]_{\widetilde{C}}$, we have

$$\lim_{\to\infty} \kappa^n \left(\Gamma(z_{j-1}, z_j, \iota) \right) = 1, \quad \text{for all } \iota > 0, \tag{10}$$

where $\{z_j\}_{j=0}^p$ is any path between α and β . Then $\{\mathcal{T}^n\alpha\}$ and $\{\mathcal{T}^n\beta\}$ are equivalent.

Proof. Let $\alpha \in \mathcal{N}$ and $\beta \in [\alpha]_{\widetilde{G}}$; then a path $\alpha = \alpha_0, \alpha_1, \ldots, \alpha_p = \beta$ exists between α and β with $(\alpha_{j-1}, \alpha_j) \in E(\widetilde{G})$ for $j \in \{1, 2, \ldots, p\}$. From Proposition 1, \mathcal{T} is a fuzzy order $\kappa_{\widetilde{G}}$ -contractive mapping. So, for all $n \in \mathbb{N}$ and $j \in \{1, 2, \ldots, p\}$, we obtain

$$\Gamma\left(\mathcal{T}^{n}\alpha_{j-1}, \mathcal{T}^{n}\alpha_{j}, \iota\right) \ge \kappa\left(\Gamma\left(\mathcal{T}^{n-1}\alpha_{j-1}, \mathcal{T}^{n-1}\alpha_{j}, \iota\right)\right),$$

for all $\iota > 0,$ (11)

whenever $(\mathcal{T}^n \alpha_{j-1}, \mathcal{T}^n \alpha_j) \in E(\tilde{G})$. Now, for all $n \in \mathbb{N}$ and $j \in \{1, 2, \dots, p\}$, we obtain

$$\Gamma\left(\mathcal{F}^{n}\alpha_{j-1},\mathcal{F}^{n}\alpha_{j},\iota\right) \geq \kappa\left(\Gamma\left(\mathcal{F}^{n-1}\alpha_{j-1},\mathcal{F}^{n-1}\alpha_{j},\iota\right)\right)$$

$$\geq \cdots \geq \kappa^{n}\left(\Gamma\left(\alpha_{j-1},\alpha_{j},\iota\right)\right).$$
(12)

It yields that $\{\mathcal{T}^n \alpha_j\}_{j=0}^p$ is a path in \tilde{G} from $\mathcal{T}^n \alpha$ to $\mathcal{T}^n \beta$. Thus,

$$\Gamma\left(\mathcal{T}^{n}\alpha,\mathcal{T}^{n}\beta,\iota\right) \geq \Gamma\left(\mathcal{T}^{n}\alpha_{0},\mathcal{T}^{n}\alpha_{1},\frac{\iota}{p}\right)\theta^{\left(p \text{ times}\right)}\theta\Gamma\left(\mathcal{T}^{n}\alpha_{p-1},\mathcal{T}^{n}\alpha_{p},\frac{\iota}{p}\right)$$

$$\geq \kappa^{n}\left(\Gamma\left(\alpha_{0},\alpha_{1},\frac{\iota}{p}\right)\right)\theta^{\left(p \text{ times}\right)}\theta\kappa^{n}\left(\Gamma\left(\alpha_{p-1},\alpha_{p},\frac{\iota}{p}\right)\right).$$
(13)

By letting $n \longrightarrow \infty$, we conclude $\lim_{n \longrightarrow \infty} \Gamma(\mathcal{T}^n \alpha, \mathcal{T}^n \beta, \iota) = 1.$

Proposition 2. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ_G -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function. Assume that, for $\alpha_0 \in \mathcal{N}$, we have $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{C}}$ and

$$\lim_{n \to \infty} \kappa^n \left(\Gamma \left(z_{j-1}, z_j, \iota \right) \right) = 1, \quad \text{for all } \iota > 0, \tag{14}$$

where $\{z_j\}_{j=0}^p$ is any path between α_0 and $\mathcal{T}\alpha_0$. Suppose that, for any sequence $\{\mathcal{T}^n\alpha_0\}$ in \mathcal{N} with $\mathcal{T}^n\alpha_0 \in [\alpha_0]_{\widetilde{G}}, n \ge 1$ and $\Gamma(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0, \iota) \longrightarrow 1$, there is $n_0 \in \mathbb{N}$ satisfying $(\mathcal{T}^m\alpha_0, \mathcal{T}^n\alpha_0) \in E(G)$ for each $m, n \ge n_0$.

Then $\{\mathcal{T}^n\alpha_0\}$ is an M-Cauchy sequence in \mathcal{N} .

Proof. Since $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{G}}$, from Proposition 1, it follows that $\mathcal{T}^n \alpha_0 \in [\alpha_0]_{\widetilde{G}}$ for all $n \ge 1$. Now, we suppose that $\{\beta_j\}_{j=0}^p$ is a

path connecting α_0 and $\mathcal{T}\alpha_0$. Using the similar reasoning like in the proof of Lemma 2, we have

$$\lim_{n \to \infty} \Gamma(\mathcal{T}^n \alpha_0, \mathcal{T}^{n+1} \alpha_0, \iota) = 1, \quad \text{for all } n \in \mathbb{N}.$$
(15)

Now, we show that $\{\mathcal{T}^n\alpha_0\}$ is an *M*-Cauchy sequence. Suppose on the contrary that $\{\mathcal{T}^n\alpha_0\}$ is not an *M*-Cauchy sequence; then there exist $\varepsilon \in (0, 1)$ and two subsequences $\{\mathcal{T}^{m(k)}\alpha_0\}$ and $\{\mathcal{T}^{n(k)}\alpha_0\}$ of $\{\mathcal{T}^n\alpha_0\}$ with n(k) > m(k) > k such that

$$\Gamma\left(\mathscr{T}^{m(k)}\alpha_{0},\mathscr{T}^{n(k)}\alpha_{0},\iota\right) \leq 1-\varepsilon.$$
(16)

Let, for each k, m(k) be the least integer exceeding n(k) satisfying (16), but

$$\Gamma\left(\mathcal{T}^{m(k)-1}\alpha_0, \mathcal{T}^{n(k)}\alpha_0, \iota\right) > 1 - \varepsilon.$$
(17)

Now, for each $k \in \mathbb{N}$, we obtain

$$1 - \varepsilon \ge \Gamma\left(\mathcal{T}^{m(k)}\alpha_{0}, \mathcal{T}^{n(k)}\alpha_{0}, \iota\right) \ge \Gamma\left(\mathcal{T}^{m(k)-1}\alpha_{0}, \mathcal{T}^{n(k)}\alpha_{0}, \frac{\iota}{2}\right) \theta \Gamma\left(\mathcal{T}^{m(k)-1}\alpha_{0}, \mathcal{T}^{m(k)}\alpha_{0}, \frac{\iota}{2}\right)$$

$$> (1 - \varepsilon) \theta \Gamma\left(\mathcal{T}^{m(k)-1}\alpha_{0}, \mathcal{T}^{m(k)}\alpha_{0}, \frac{\iota}{2}\right).$$
(18)

By taking $k \longrightarrow \infty$ and using (15), we obtain

$$\lim_{k \to \infty} \Gamma\left(\mathcal{T}^{m(k)} \alpha_0, \mathcal{T}^{n(k)} \alpha_0, \iota\right) = 1 - \varepsilon.$$
(19)

Since $\lim_{n\to\infty} \Gamma(\mathcal{T}^n \alpha_0, \mathcal{T}^{n+1} \alpha_0, \iota) = 1$, for all $n \in \mathbb{N}$ and $\iota \ge 0$, by condition (i), there exists a positive integer n_0 such that $(\mathcal{T}^m \alpha_0, \mathcal{T}^n \alpha_0) \in E(G)$ for each $m, n \in \mathbb{N}$ with $m, n > n_0$. Now, by using triangular inequality for all $k \ge n_0$, we obtain

$$\Gamma\left(\mathcal{F}^{m(k)}\alpha_{0},\mathcal{F}^{n(k)}\alpha_{0},\iota\right) \geq \Gamma\left(\mathcal{F}^{m(k)}\alpha_{0},\mathcal{F}^{m(k)+1}\alpha_{0},\frac{\iota}{3}\right)\theta\Gamma\left(\mathcal{F}^{m(k)+1}\alpha_{0},\mathcal{F}^{n(k)+1}\alpha_{0},\frac{\iota}{3}\right)$$

$$=\Gamma\left(\mathcal{F}^{n(k)+1}\alpha_{0},\mathcal{F}^{n(k)+1}\alpha_{0},\frac{\iota}{3}\right)\theta\kappa\left(\Gamma\left(\mathcal{F}^{m(k)}\alpha_{0},\mathcal{F}^{n(k)}\alpha_{0},\frac{\iota}{3}\right)\right)$$

$$=\theta\Gamma\left(\mathcal{F}^{n(k)+1}\alpha_{0},\mathcal{F}^{n(k)}\alpha_{0},\frac{\iota}{3}\right).$$
(20)

On letting $k \longrightarrow \infty$ and by using (15) and (19), we acquire

$$1 - \varepsilon \ge 1\theta\kappa(1 - \varepsilon)\theta = \kappa(1 - \varepsilon) > 1 - \varepsilon.$$
(21)

Hence,
$$\{\mathcal{T}^n \alpha_0\}$$
 is an *M*-Cauchy sequence in \mathcal{N} .

Remark 2. It is important to note that assertion of Proposition 2 still holds if we replace the condition $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{G}}$ with $(\alpha_0, \mathcal{T}\alpha_0) \in E(G)$. In that case, condition (i) is also replaced by the following: "for any sequence $\{\mathcal{T}^n\alpha_0\}$ in \mathcal{N} with $(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0) \in E(G)$ and $\Gamma(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0, \iota) \longrightarrow 1$, there exists $n_0 \in \mathbb{N}$ such that $(\mathcal{T}^m\alpha_0, \mathcal{T}^n\alpha_0) \in E(G)$ for all $m, n \geq n_0$."

Below we extend the definitions of (H_f) - and (C_f) -graphs to the setting of fuzzy metric spaces.

Definition 7. Suppose that $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}, \beta \in \mathcal{N}$, and the sequence $\{\mathcal{T}^n\beta\}$ in \mathcal{N} is such that $\mathcal{T}^n\beta \longrightarrow \alpha \in \mathcal{N}$.

- (i) If there exists a subsequence {𝔅^{nk}β} of {𝔅ⁿβ} such that (𝔅^{nk}β, α) ∈ 𝔅(𝔅) for all k≥ p ∈ ℕ, then 𝔅 is called a (𝔅_f)-graph.
- (ii) A graph *G* is called an (H_f) -graph if $\mathcal{T}^n \beta \in [\alpha]_{\widetilde{G}}$ for $n \ge 1$; then $r(\mathcal{T}^n \beta, \alpha, \iota) \longrightarrow 1$ (as $n \longrightarrow \infty$), where $r(\mathcal{T}^n \beta, \alpha, \iota) = \Gamma(z_0, z_1, \iota/p) \theta^{(p-\text{times})} \theta \Gamma(z_{p-1}, z_p, \iota/p)$ and $\{z_j\}_{j=0}^p$ is a path from $\mathcal{T}^n \beta$ to α .

It is evident that every (C)-graph is a (C_f) -graph for the identity mapping I, but the other side is not always true. Similarly, every (H)-graph is an (H_f) -graph for the identity mapping I, but the other side is not always true (see [8], Examples 2.4 and 2.5).

Lemma 3. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be fuzzy order κ_G -contractive, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function. Then, for any $\alpha \in \mathcal{N}$ and $\beta \in [\alpha]_{\widetilde{G}}$ and for each $n \in \mathbb{N}$, there is $r_n(\alpha, \beta, \iota) \in J$ such that

$$\Gamma\left(\mathcal{T}^{n}\alpha,\mathcal{T}^{n}\beta,\iota\right) \geq r_{n}\left(\alpha,\beta,\iota\right).$$
(22)

Furthermore, if $\lim_{n \to \infty} \kappa^n (\Gamma(z_{j-1}, z_j, \iota)) = 1$ for all $\iota > 0$, where $\{z_j\}_{i=1}^p$ is any path between α and β , then

$$\lim_{n \to \infty} \Gamma(\mathcal{T}^{n} \alpha, \mathcal{T}^{n} \beta, \iota) = \lim_{n \to \infty} r_{n}(\alpha, \beta, \iota) = 1.$$
(23)

Proof. Let $\alpha \in \mathcal{N}$ and $\beta \in [\alpha]_{\widetilde{G}}$; then there exists a path $\alpha = \alpha_0, \alpha_1, \ldots, \alpha_p = \beta$ between α and β with $(\alpha_{j-1}, \alpha_j) \in E(\widetilde{G})$ for $j \in \{1, 2, \ldots, p\}$. From Proposition 1 for all $\iota > 0$, we have

$$\Gamma\left(\mathcal{T}^{n}\alpha_{j-1},\mathcal{T}^{n}\alpha_{j},\iota\right) \geq \kappa\left(\Gamma\left(\mathcal{T}^{n-1}\alpha_{j-1},\mathcal{T}^{n-1}\alpha_{j},\iota\right)\right).$$
(24)

Since \mathcal{T} is a fuzzy order $\kappa_{\widetilde{G}}$ contraction such that $(\mathcal{T}^n \alpha_{j-1}, \mathcal{T}^n \alpha_j) \in E(\widetilde{G})$ for each natural number *n* and *j* varies from 1 to *p*, for a positive integer *n* and $j \in \{1, 2, ..., p\}$, we have

$$\Gamma\left(\mathscr{T}^{n}\alpha_{j-1}, \mathscr{T}^{n}\alpha_{j}, \iota\right) \ge \kappa\left(\Gamma\left(\mathscr{T}^{n-1}\alpha_{j-1}, \mathscr{T}^{n-1}\alpha_{j}, \iota\right)\right)$$

$$\ge \cdots \ge \kappa^{n}\left(\Gamma\left(\alpha_{j-1}, \alpha_{j}, \iota\right)\right).$$
(25)

Note that $\{\mathcal{T}^n\alpha_j\}_{j=0}^p$ is a path in \tilde{G} from $\mathcal{T}^n\alpha$ to $\mathcal{T}^n\beta$. Thus,

$$\Gamma\left(\mathcal{T}^{n}\alpha,\mathcal{T}^{n}\beta,\iota\right) \geq \Gamma\left(\mathcal{T}^{n}\alpha_{0},\mathcal{T}^{n}\alpha_{1},\frac{\iota}{p}\right)\theta^{\left(p\,\text{times}\right)}\theta\Gamma\left(\mathcal{T}^{n}\alpha_{p-1},\mathcal{T}^{n}\alpha_{p},\frac{\iota}{p}\right)$$

$$\geq \kappa^{n}\left(\Gamma\left(\alpha_{0},\alpha_{1},\frac{\iota}{p}\right)\right)\theta^{\left(p\,\text{times}\right)}\theta\kappa^{n}\left(\Gamma\left(\alpha_{p-1},\alpha_{p},\frac{\iota}{p}\right)\right).$$
(26)

It suffices to set

$$r_n(\alpha,\beta,\iota) = \kappa^n \left(\Gamma\left(\alpha_0,\alpha_1,\frac{\iota}{p}\right) \right) \theta \kappa^n \left(\Gamma\left(\alpha_1,\alpha_2,\frac{\iota}{p}\right) \right) \theta^{(p \text{ times})} \theta \kappa^n \left(\Gamma\left(\alpha_{p-1},\alpha_p,\frac{t}{p}\right) \right).$$
(27)

On letting $n \longrightarrow \infty$, we obtain

$$\lim_{n \to \infty} \Gamma\left(\mathcal{T}^{n} \alpha, \mathcal{T}^{n} \beta, \iota\right) = \lim_{n \to \infty} r_{n}\left(\alpha, \beta, \iota\right) = 1.$$
(28)

Now, we proceed to establish our first main result. From now on, \mathcal{N} represents an M-complete fuzzy metric space endowed with a graph G.

Theorem 3. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ_G -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function. Assume that, for a given $\alpha_0 \in \mathcal{N}$, $(\alpha_0, \mathcal{T}\alpha_0) \in E(G)$ and

$$\lim_{n \to \infty} \kappa^n \left(\Gamma\left(\alpha_0, \mathcal{T}\alpha_0, \iota\right) \right) = 1, \quad \text{for all } \iota > 0.$$
 (29)

Moreover, if

- (i) G is a (C_f) -graph,
- (ii) for any sequence $\{\mathcal{T}^n\alpha_0\}$ in \mathcal{N} with $(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0) \in E(G), n \ge 1$ and $\Gamma(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0, n) \longrightarrow 1$, then there is a natural number n_0 so that $(\mathcal{T}^m\alpha_0, \mathcal{T}^n\alpha_0) \in E(G)$ for every $m, n \ge n_0$.

Then there is $\omega \in [\alpha_0]_{\widetilde{G}}$ in such a way that $\mathcal{T}\omega = \omega$. In addition, if, for every $\beta \in [\alpha_0]_{\widetilde{G}}$, we have

$$\lim_{n \to \infty} \kappa^n \left(\Gamma(z_{j-1}, z_j, \iota) \right) = 1, \quad \text{for all } \iota > 0, \tag{30}$$

where $\{z_j\}_{j=0}^p$ is any path between α and β , then $\mathcal{T}|_{[\alpha_0]_{\widetilde{G}}}$ is a Picard operator.

Proof. Let $(\alpha_0, \mathcal{T}\alpha_0) \in E(G)$; then $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{G}}$. From Proposition 2, we infer that $\{\mathcal{T}^n\alpha_0\}$ is an *M*-Cauchy sequence. Since \mathcal{N} is an *M*-complete space, there exists $\omega \in \mathcal{N}$ such that $\mathcal{T}^n\alpha_0 \longrightarrow \omega$. Since *G* is a (C_f) -graph, there are $\{\mathcal{T}^{n_k}\alpha_0\}$, a subsequence of $\{\mathcal{T}^n\alpha_0\}$, and a positive integer *q* in such a way that $(\mathcal{T}^{n_k}\alpha_0, \omega) \in E(G)$ for every positive integer *k* and $q \leq k$. Thus, for all $p \leq k$, we obtain

$$\Gamma(\mathscr{T}\omega,\omega,\iota) \ge \Gamma\left(\mathscr{T}\omega,\mathscr{T}^{n_{k}+1}\alpha_{0},\frac{\iota}{2}\right)\theta\Gamma\left(\mathscr{T}^{n_{k}}\alpha_{0},\omega,\frac{\iota}{2}\right)$$

$$\ge \kappa\left(\Gamma\left(\omega,\mathscr{T}^{n_{k}}\alpha_{0},\frac{\iota}{2}\right)\right)\theta\Gamma\left(\mathscr{T}^{n_{k}}\alpha_{0},\omega,\frac{\iota}{2}\right).$$
(31)

Using the continuity of κ and taking $n \longrightarrow \infty$, one gets

$$\Gamma(\mathcal{T}\omega,\omega,\iota) = 1. \tag{32}$$

This infers that $\mathcal{T}\omega = \omega$. We observe that $\{\alpha_0, \mathcal{T}\alpha_0, \dots, \mathcal{T}^{n_1}\alpha_0, \dots, \mathcal{T}^p\alpha_0, \omega\}$ is a path between α_0 and ω in \tilde{G} . Thus, $\omega \in [\alpha_0]_{\tilde{G}}$. Now, take a random element $\beta \in [\alpha_0]_{\tilde{G}}$ and, using Lemma 2, we obtain

$$\lim_{n \to \infty} \Gamma(\mathcal{T}^n \beta, \mathcal{T}^n \alpha_0, \iota) = 1.$$
(33)

Thus, $\lim_{n\to\infty} \mathcal{T}^n \beta = \omega$. To ensure the uniqueness, we argue by contradiction. Suppose that ω and π are two distinct fixed points of \mathcal{T} in $[\alpha_0]_{\widetilde{C}}$, so

$$\Gamma(\omega, \pi, \iota) = \Gamma\left(\mathcal{T}^{n}\omega, \mathcal{T}^{n}\pi, \iota\right) \ge \Gamma\left(\mathcal{T}^{n}\omega, \mathcal{T}^{n}\alpha_{0}, \frac{\iota}{2}\right)$$

$$\theta\Gamma\left(\mathcal{T}^{n}\alpha_{0}, \mathcal{T}^{n}\pi, \frac{\iota}{2}\right).$$
(34)

On letting
$$n \longrightarrow \infty$$
, we obtain $\omega = \pi$.

Remark 3. Observe that, in Theorem 3, \mathcal{T} is a Picard operator on \mathcal{N} if the underlying graph *G* is weakly connected such that $[\alpha_0]_{\widetilde{G}} = \mathcal{N}$.

By analyzing condition on graph *G* and imposing a strict condition on κ , we have the following variant.

Theorem 4. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ_G -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous, nondecreasing function such that $\kappa(\iota) > \iota$ for all $\iota \in (0, 1)$. Assume that for $\alpha_0 \in \mathcal{N}$ and $\beta \in [\alpha_0]_{\widetilde{G}}$ we get

$$\lim_{n \to \infty} \kappa^n \left(\Gamma \left(z_{j-1}, z_j, \iota \right) \right) = 1, \quad \text{for all } \iota > 0, \tag{35}$$

where $\{z_j\}_{j=0}^p$ is any path between α_0 and β . Moreover, if (i) G is an (H_f) -graph,

(*ii*) for any sequence $\{\mathcal{T}^n\alpha_0\}$ in \mathcal{N} with $(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0) \in E(G), n \ge 1$ and $\Gamma(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0, \iota) \longrightarrow 1$, then there is $n_0 \in \mathcal{N}$ in such a way

that
$$(\mathcal{T}^m \alpha_0, \mathcal{T}^n \alpha_0) \in E(G), \forall m, n \ge n$$

(iii) G is weakly connected.

Then \mathcal{T} is a Picard operator.

Proof. Assume that $\alpha_0 \in \mathcal{N}$ and condition (iii) holds. Then $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{G}}$; that is, there is a path between α_0 and $\mathcal{T}\alpha_0$ in \widetilde{G} . Take into account Proposition 2; we infer that the sequence $\{\mathcal{T}^n\alpha_0\}$ is an *M*-Cauchy sequence. Since \mathcal{N} is an *M*-complete fuzzy metric space, there exists $\omega \in \mathcal{N}$ such that $\mathcal{T}^n\alpha_0 \longrightarrow \omega$. Since condition (iii) holds, we have, for each natural number n, $\mathcal{T}^n\alpha_0 \in [\omega]_{\widetilde{G}}$. Then there exists a path $\{z_j^n\}_{j=0}^{p_n}$ of finite length p_n between $\mathcal{T}^n\alpha_0$ and ω with $z_0^n = \mathcal{T}^n\alpha_0, z_{p_n}^n = \omega$. Using the conditions that \mathcal{T} is a κ_G -contractive mapping and $\kappa(\iota) > \iota$, we obtain

$$\Gamma(\omega, \mathcal{T}\omega, \iota) \geq \Gamma\left(\omega, \mathcal{T}^{n+1}\alpha_{0}, \frac{\iota}{2}\right) \theta \Gamma\left(\mathcal{T}^{n+1}\alpha_{0}, \mathcal{T}\omega, \frac{\iota}{2}\right)$$

$$\geq \Gamma\left(\omega, \mathcal{T}^{n+1}\alpha_{0}, \frac{\iota}{2}\right) \theta \left[\Gamma\left(\mathcal{T}z_{0}^{n}, \mathcal{T}z_{1}^{n}, \frac{\iota}{2l_{n}}\right) \theta^{\left(\mathcal{P}_{n} \operatorname{times}\right)} \theta \Gamma\left(\mathcal{T}z_{j-1}^{n}, \mathcal{T}z_{j}^{n}, \frac{\iota}{2l_{n}}\right)\right]$$

$$\geq \Gamma\left(\omega, \mathcal{T}^{n+1}\alpha_{0}, \frac{\iota}{2}\right) \theta \left[\kappa\left(\Gamma\left(z_{0}^{n}, z_{1}^{n}, \frac{\iota}{2l_{n}}\right)\right) \theta^{\left(\mathcal{P}_{n} \operatorname{times}\right)} \theta \kappa\left(\Gamma\left(z_{j-1}^{n}, z_{j}^{n}, \frac{\iota}{2l_{n}}\right)\right)\right)\right]$$

$$= \Gamma\left(\omega, \mathcal{T}^{n+1}\alpha_{0}, \frac{\iota}{2}\right) \theta r\left(\mathcal{T}^{n}\alpha_{0}, \omega, \iota\right).$$
(36)

By letting $n \longrightarrow \infty$ and using condition (i), we get $\Gamma(\omega, \mathcal{T}^{n+1}\alpha_0, \iota/2)\theta r(\mathcal{T}^n\alpha_0, \omega, \iota) \longrightarrow 1$. Hence, we have

 $\Gamma(\omega, \mathcal{T}\omega, \iota) = 1$. Thus, $\omega = \mathcal{T}\omega$. Now, let β be a random element of $[\alpha_0]_{\widetilde{C}}$; then Lemma 2 implies

$$\lim_{n \to \infty} \Gamma(\mathcal{T}^n \beta, \mathcal{T}^n \alpha_0, \iota) = 1.$$
(37)

Thus, $\lim_{n\to\infty} \mathcal{T}^n \beta = \omega$. Now, for uniqueness, suppose that $\omega \neq \pi$ are two fixed points of \mathcal{T} in $[\alpha_0]_{\widetilde{C}}$; we have

$$\Gamma(\omega, \pi, \iota) = \Gamma\left(\mathcal{T}^{n}\omega, \mathcal{T}^{n}\pi, \iota\right) \ge \Gamma\left(\mathcal{T}^{n}\omega, \mathcal{T}^{n}\alpha_{0}, \frac{\iota}{2}\right)$$

$$\theta\Gamma\left(\mathcal{T}^{n}\alpha_{0}, \mathcal{T}^{n}\pi, \frac{\iota}{2}\right).$$
(38)

On letting $n \longrightarrow \infty$, we obtain $\omega = \pi$.

Definition 8. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$. If, for all $\alpha, \beta \in \mathcal{N}$ and some sequence $\{p_j\}_{j \in \mathbb{N}}$ of a positive integer, $\mathcal{T}^{p_j} \alpha \longrightarrow \beta$ implies $\mathcal{T}(\mathcal{T}^{p_j} \alpha) \longrightarrow \mathcal{T}\beta$ as $j \longrightarrow \infty$, then \mathcal{T} is called orbitally continuous. If, for each $\alpha, \beta \in \mathcal{N}$ and some sequence $\{p_j\}_{j \in \mathbb{N}}$ of a positive integer $\mathcal{T}^{p_j} \alpha \longrightarrow \beta$ and $(\mathcal{T}^{p_j} \alpha, \mathcal{T}^{p_j+1} \alpha) \in E(G)$ for each positive integer n implies $\mathcal{T}(\mathcal{T}^{p_j} \alpha) \longrightarrow \mathcal{T}\beta$, then \mathcal{T} is known as orbitally *G*-continuous.

Theorem 5. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ_G -contractive mapping, where $\kappa: J \longrightarrow J$ is a continuous and nondecreasing function. Assume that, for given $\alpha_0 \in \mathcal{N}$,

$$(\alpha_0, \mathcal{T}\alpha_0) \in E(G) \text{ and } \lim_{n \to \infty} \kappa^n (\Gamma(\alpha_0, \mathcal{T}\alpha_0, \iota)) = 1,$$

for all $\iota > 0.$ (39)

Moreover, if

- (i) \mathcal{T} is orbitally G-continuous or \mathcal{T} is orbitally continuous,
- (ii) for any sequence $\{\mathcal{T}^n\alpha_0\}$ in \mathcal{N} with $(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0) \in E(G), n \ge 1$ and $\Gamma(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0, l) \longrightarrow 1$, there is $n_0 \in \mathbb{N}$ in such a way that $(\mathcal{T}^m\alpha_0, \mathcal{T}^n\alpha_0) \in E(G), \forall m, n \ge n_0.$

Then there is an element ω in $[\alpha_0]_{\widetilde{G}}$ such that $\mathscr{T}\omega = \omega$. In addition, if, for every $\beta \in [\alpha_0]_{\widetilde{G}}$, we have

$$\lim_{n \to \infty} \kappa^n \left(\Gamma \left(z_{j-1}, z_j, \iota \right) \right) = 1, \quad \text{for all } \iota > 0, \tag{40}$$

where $\{z_j\}_{j=0}^p$ is any path between α and β , then $\mathcal{T}|_{[\alpha_0]_{\widetilde{G}}}$ is a Picard operator.

Proof. Since $(\alpha_0, \mathcal{T}\alpha_0) \in E(G)$, we have $\mathcal{T}\alpha_0 \in [\alpha_0]_{\widetilde{G}}$. From Proposition 2, $\{\mathcal{T}^n\alpha_0\}$ is an *M*-Cauchy sequence. Since \mathcal{N} is an *M*-complete fuzzy metric space, there exists $\omega \in \mathcal{N}$ such that $\mathcal{T}^n\alpha_0 \longrightarrow \omega$. As $(\mathcal{T}^n\alpha_0, \mathcal{T}^{n+1}\alpha_0) \in E(G)$, for all $n \ge 1$, and \mathcal{T} is orbitally *G*-continuous, we obtain $\mathcal{T}\mathcal{T}^n\alpha_0 \longrightarrow \mathcal{T}\omega$. Hence, $\mathcal{T}\omega = \omega$. Let $\beta \in [\alpha_0]_{\widetilde{G}}$ be arbitrary, so Lemma 3 yields $\mathcal{T}^n\beta \longrightarrow \omega$. Uniqueness can be easily followed.

Now, we include another result when the underlying fuzzy metric space is endowed with a partial order. \Box

Corollary 1. Let (\mathcal{N}, \prec) be a partially ordered set and let $(\mathcal{N}, \Gamma, \theta)$ be an *M*-complete fuzzy metric space. Let $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ be a fuzzy order κ -contractive mapping, where

 $\kappa: J \longrightarrow J$ is a continuous and nondecreasing function. Assume that

- (i) \mathcal{T} is nondecreasing (or nonincreasing),
- (ii) either for every nondecreasing (nonincreasing) sequence {α_n} in N with α_n → α ∈ N implies α_n ≺ α (or α_n≽α) for all n or T is continuous, and
- (iii) there exists $\alpha_0 \in \mathcal{N}$ such that $\alpha_0 \prec \mathcal{T}\alpha_0$ ($\alpha_0 \succ \mathcal{T}\alpha_0$) and $\lim_{n \to \infty} \kappa^n (\Gamma(\alpha_0, \mathcal{T}\alpha_0, \iota)) = 1$ for each $\iota > 0$.

Then \mathcal{T} has a fixed point.

Proof. Define G by $V(G) = \mathcal{N}$ and $E(G) = \{(\alpha, \beta) \in \mathcal{N} \times \mathcal{N} : \beta \prec \alpha\}.$

Since \mathcal{T} is nondecreasing, we have that (7) is satisfied and (8) holds in the light of condition (2). Thus, \mathcal{T} is a κ_G -contractive mapping. Also, note that condition (ii) implies that G is a (C_f) -graph. Thus, taking into account Theorem 3, we invoke the result.

Remark 4. Note that Corollary 1 extends/generalizes ([22], Theorem 2.3) to non-Archimedean *M*-complete fuzzy metric spaces.

Example 3. Let $\mathcal{N} = (0, \infty)$ be equipped with a fuzzy metric $\Gamma(\alpha, \beta, \iota) = (\min\{\alpha, \beta\}/\max\{\alpha, \beta\})$ so that $\alpha\theta\beta = \alpha\beta$. Then $(\mathcal{N}, \Gamma, \theta)$ is an *M*-complete fuzzy metric space (see [23]). Define $\mathcal{T}: \mathcal{N} \longrightarrow \mathcal{N}$ by

$$\mathcal{T}\alpha = \begin{cases} 2\alpha, & 0 < \alpha < 1, \\ \frac{\alpha+5}{3}, & 1 \le \alpha \le 4, \\ 2\alpha-5, & \alpha > 4. \end{cases}$$
(41)

Let *G* be a graph in such a way that $V(G) = \mathcal{N}$ and $E(G) = \Delta \cup \{(\alpha, \beta): \alpha, \beta \in [1, 4], \alpha \leq \beta\}$. Condition (7) is trivial. We show that \mathcal{T} is fuzzy order κ_G -contractive with $\kappa(u) = \sqrt{u}$. Indeed, let $\alpha, \beta \in \mathcal{N}$ with $(\alpha, \beta) \in E(G)$. Now, if $\alpha \leq \beta$, then

$$\Gamma(\mathcal{T}\alpha,\mathcal{T}\beta,\iota) = 1 \ge \kappa(1) = \kappa(\Gamma(\alpha,\beta,\iota)).$$
(42)

If $\alpha, \beta \in [1, 4]$ with $\alpha \leq \beta$, then

$$\Gamma(\mathcal{T}\alpha, \mathcal{T}\beta, \iota) = \frac{\min\{(\alpha+5)/3, (\beta+5)/3\}}{\max\{(\alpha+5)/3, (\beta+5)/3\}}$$

$$= \frac{\alpha+5}{\beta+5} \ge \sqrt{\frac{\alpha}{\beta}} = \kappa(\Gamma(\alpha, \beta, \iota)).$$
(43)

Therefore, \mathcal{T} is a fuzzy order κ_G -contractive mapping with $\kappa(u) = \sqrt{u}$. Moreover, for $\alpha_0 = 1$, $(\alpha_0, \mathcal{T}\alpha_0) \in E(G)$. Hence, all the conditions of Theorem 3 are satisfied and \mathcal{T} has a fixed point.

4. Application

In [24], the following definition was initiated: let \mathcal{N} be a nonempty set and let $\{G_j\}_{j=1}^k$ be nonempty closed subsets of

 \mathcal{N} , where *n* is any positive integer. Then, $D = \bigcup_{j=1}^{k} G_j$ is called a cyclic representation of \mathcal{N} with respect to the mapping $\mathcal{T}: D \longrightarrow D$ if

$$\mathcal{T}(G_1) \in G_2, \dots, \mathcal{T}(G_{m-1}) \in G_m, \mathcal{T}(G_m) \in G_1.$$
(44)

Then \mathcal{T} is called a cyclic operator.

Theorem 6. Let $(\mathcal{N}, \Gamma, \theta)$ be an *M*-complete fuzzy metric space. Let $\{G_j\}_{j=1}^k$ be nonempty closed subsets of \mathcal{N} , $D = \bigcup_{j=1}^k G_j$, and $\mathcal{T}: D \longrightarrow D$. Further, suppose the following:

- (i) $\bigcup_{j=1}^{k} G_j$ is a cyclic representation of D with respect to \mathcal{T} .
- (ii) There exists κ: J → J, where κ is a continuous and nondecreasing function such that, for α ∈ G_j, β ∈ G_{j+1}, we have

$$\Gamma(\mathcal{T}\alpha,\mathcal{T}\beta,\iota) \ge \kappa(\Gamma(\alpha,\beta,\iota)), \quad \forall \iota > 0.$$
(45)

(iii) Let $\alpha_0 \in D$; for a sequence $\{\mathcal{T}^n \alpha_0\}$ in D with $\Gamma(\mathcal{T}^n \alpha_0, \mathcal{T}^{n+1} \alpha_0, \iota) \longrightarrow 1$, there are a natural number n_0 and some $j \in \{1, 2, \ldots, k\}$ such that $\mathcal{T}^m \alpha_0 \in G_j, \mathcal{T}^n \alpha_0 \in G_{j+1}$, for all $m, n \ge n_0$ and

$$\lim_{n \to \infty} \kappa^n \left(\Gamma \left(\alpha_0, \mathcal{T} \alpha_0, \iota \right) \right) = 1, \quad \forall \iota > 0.$$
(46)

Then \mathcal{T} has a fixed point $w \in \bigcap_{i=1}^{k} G_i$ and $\mathcal{T}^n \alpha_0 \longrightarrow w$.

Proof. Since $\{G_j\}_{j=1}^k$ are closed subsets, one can assert that (D, Γ, θ) is an *M*-complete fuzzy metric space. Let *G* be a graph such that

$$V(G) = D \text{ and } E(G) = \Delta \cup \left\{ (\alpha, \beta) \in D \times D : \alpha \in G_j, \beta \in G_{j+1}; j = 1, 2, \dots, k \right\}.$$

$$(47)$$

As $D = \bigcup_{j=1}^{k} G_j$ is a cyclic representation of D with respect to \mathcal{T} , it follows that \mathcal{T} preserves edges. Also, observe that, in light of inequality (45), \mathcal{T} is a κ_G -contractive mapping. Now, for a sequence $\{\mathcal{T}^n \alpha_0\}$ in D, we have $(\mathcal{T}^n \alpha_0, \mathcal{T}^{n+1} \alpha_0) \in E(G), \forall n \ge 1$ and if $\Gamma(\mathcal{T}^n \alpha_0, \mathcal{T}^{n+1} \alpha_0, i) \longrightarrow 1$, then, from condition (iii), there is $n_0 \in \mathbb{N}$ such that $(\mathcal{T}^m \alpha_0, \mathcal{T}^n \alpha_0) \in E(G)$ for all $m, n \ge n_0$. Let $\mathcal{T}^n \alpha \longrightarrow w$ in D be such that $(\mathcal{T}^n \alpha, \mathcal{T}^{n+1} \alpha) \in E(G)$ for all $n \ge 1$; then, from (44) in every G_j , the sequence $\{\mathcal{T}^n \alpha\}$ has infinitely many terms; thus we have a subsequence of $\{\mathcal{T}^n \alpha\}$ which converges to w in each G_j . As G_j 's are all closed subsets, we get $w \in \bigcap_{j=1}^k G_j$. Thus, there exists a subsequence $\{\mathcal{T}^{n_r} \alpha\}$ in some G_j , $j \in \{1, 2, \ldots, k\}$, such that $(\mathcal{T}^{n_r} \alpha, w) \in E(G)$ for $r \ge 1$, which shows that G is a weakly connected (C_f) -graph. Taking into account Theorem 3, we invoke the conclusion.

Now, we present an application of our result to find a solution of an integral equation. Consider the below integral equation:

$$\alpha(r) = \int_0^r K(r, s, \alpha(s)) ds + g(r), \quad \forall r \in [0, I] \text{ where } I > 0.$$
(48)

Let $\mathcal{N} = C([0, I])$ be the set of all real valued continuous functions defined on [0, I]. Then (\mathcal{N}, d) is a complete metric space endowed with the metric

$$d(\alpha,\beta) = \sup_{r \in [0,I]} |\alpha(r) - \beta(r)| \quad \alpha,\beta \in \mathcal{N}.$$
(49)

For $a\theta b = ab$ for all $a, b \in J$, define a fuzzy metric by

$$\Gamma(\alpha,\beta,\iota) = \frac{\iota}{\iota + d(\alpha,\beta)}, \quad \text{for all } \alpha,\beta \in \mathcal{N} \text{ and } \iota > 0.$$
(50)

Then $(\mathcal{N}, \Gamma, \theta)$ is an *M*-complete fuzzy metric space.

In the following, we discuss the existence of the solution for the integral equation (48). $\hfill \Box$

Theorem 7. Let \mathcal{N} be the set of all real valued continuous functions defined on [0, I]. Let $\mathcal{T} \colon \mathcal{N} \longrightarrow \mathcal{N}$ be the integral operator given by

$$\mathcal{T}\alpha(r) = \int_0^r K(r, s, \alpha(s)) ds + g(r), \quad \forall r \in [0, I] \text{ and } g \in \mathcal{N},$$
(51)

where $K: [0, I] \times [0, I] \times \mathbb{R} \longrightarrow \mathbb{R}$ is continuous. Assume that

(i) there exist a nondecreasing, continuous function $\kappa: J \longrightarrow J$ and a continuous function $\mathcal{T}: [0, I] \times [0, I] \longrightarrow \mathbb{R}^+$ such that

$$|K(r, s, \alpha(s)) - K(r, s, \beta(s))| \le f(r, s)\kappa(|\alpha(s) - \beta(s)|), \quad (52)$$

for each $r, s \in [0, I]$ and $\alpha(r) \leq \beta(r)$ for all $r \in [0, 1]$;

(*ii*) $K(r, s, .): \mathbb{R} \longrightarrow \mathbb{R}$ is nondecreasing for each $r, s \in [0, I];$

(*iii*) $\sup_{r \in [0,I]} \int_{0}^{r} f(r,s) ds \le 1;$

- (iv) there exists $\alpha_0 \in \mathcal{N}$ such that $\alpha_0(r) \leq \int_0^r K(r, s, \alpha_0(s)) ds + g(r)$ for all $r \in [0, I]$;
- (v) for any sequence $\{\alpha_n\}$ in \mathcal{N} with $\Gamma(\alpha_n, \alpha_{n+1}, \iota) \longrightarrow 1$ there exists $n_0 \in \mathbb{N}$ such that $\alpha_m(\iota) \leq \alpha_n(\iota)$ for all $m, n \in \mathbb{N}, m, n \geq n_0$.

Then the integral equation (48) has a unique solution in the set $\{\alpha \in \mathcal{N} : \alpha(r) \le \alpha_0(r), \text{ or } \alpha(r) \ge \alpha_0(r) \text{ for all } r \in [0, I]\}.$

Proof. Let *G* be a graph such that $V(G) = \mathcal{N}$ and $E(G) = \{(\alpha, \beta) \in \mathcal{N} \times \mathcal{N} : \alpha(r) \le \beta(r) \text{ for all } r \in [0, I]\}$. It follows from (ii) that *T* is nondecreasing and thus preserves edges. Also, for every nondecreasing sequence $\{\alpha_n\} \subset \mathcal{N}$ which converges to $\omega \in \mathcal{N}$, it implies $\alpha_n(r) \le \omega(r)$ for every

 $r \in [0, I]$, which shows that *G* is a (C_f) -graph. Now, for all $\alpha, \beta \in \mathcal{N}$, we obtain

$$\begin{aligned} |\mathcal{T}\alpha(r) - \mathcal{T}\beta(r)| &\leq \int_{0}^{r} |K(r, s, \alpha(s)) - K(r, s, \beta(s))| \mathrm{d}s \\ &\leq \int_{0}^{r} f(r, s) |\alpha(s) - \beta(s)| \mathrm{d}s \\ &\leq \kappa(|\alpha(s) - \beta(s)|) \int_{0}^{r} f(r, s) \mathrm{d}s. \end{aligned}$$

$$(53)$$

Hence, $d(\mathcal{T}\alpha, \mathcal{T}\beta) \leq \kappa(d(\alpha, \beta))$. Thus,

$$\frac{\iota}{\iota + d\left(\mathcal{T}\alpha, \mathcal{T}\beta\right)} \ge \kappa\left(d\left(\alpha, \beta\right)\right) \ge \kappa\left(\frac{\iota}{t + d\left(\alpha, \beta\right)}\right). \tag{54}$$

It follows that

$$\Gamma(\mathcal{T}\alpha,\mathcal{T}\beta,\iota) \ge \kappa(\Gamma(\alpha,\beta,\iota)).$$
(55)

From (iv), we have $(\alpha_0, \mathcal{T}\alpha_0) \in E(G)$ and the conclusion follows from Theorem 3. Moreover, the solution lies in $[\alpha_0]_{\widetilde{G}} = \{\alpha \in \mathcal{N}: \alpha(r) \le \alpha_0, \text{ or } \alpha(r) \ge \alpha_0 \text{ for all } r \in [0, I]\}.$

With the development of Internet technology, multimedia information resources are increasing rapidly. Faced with the massive resources in the multimedia music library, it is extremely difficult for people to find the target music that meets their needs. How to realize computer analysis and perceive users' needs for music resources has become the goal of the future development of humancomputer interaction capabilities. Content-based music information retrieval applications are mainly embodied in the automatic classification and recognition of music. Traditional feedforward neural networks are prone to lose local information when extracting singing voice features. For this reason, on the basis of fully considering the impact of information persistence in the network propagation process, this paper proposes an enhanced two-stage super-resolution reconstruction residual network which can effectively integrate the learned features of each layer while increasing the depth of the network. The first stage of reconstruction is to complete the hierarchical learning of singing voice features through dense residual units to improve the integration of information. The second stage of reconstruction is mainly to perform residual relearning on the high-frequency information of the singing voice learned in the first stage to reduce the reconstruction error. In the middle of these two stages, the model introduces feature scaling and expansion convolution to achieve the dual purpose of reducing information redundancy and increasing the receptive field of the convolution kernel. A monophonic singing voice separation based on the high-resolution neural network is proposed. Because the high-resolution network has parallel subnetworks with different resolutions, it also has original resolution representations and multiple low-resolution representations, avoiding information loss caused by serial network downsampling effects and repeating multiple feature fusions to generate new semantic representations, allowing for the learning of comprehensive, high-precision, and highly abstract features. In this article, a high-resolution neural network is utilized to model the time spectrogram in order to correctly estimate the real value of the anticipated time-amplitude spectrograms. Experiments on the dataset MIR-1K show that compared with the current leading SH-4Stack model, the method in this paper has improved SDR, SIR, and SAR indicators for measuring the separation performance, confirming the effectiveness of the algorithm in this paper.

1. Introduction

Multimedia technology changes with each passing day, constantly enriching people's daily lives and work. As an important part of multimedia technology, audio technology affects people's lives all the time. Since human civilization, music has been an important part of people's spiritual culture [1]. It is a special language for people to place spiritual ideals, express their thoughts and feelings, and achieve mutual exchanges. It is also the crystallization of the human's great wisdom. The creation, expression, understanding, and appreciation of music are the most basic spiritual activities of mankind [2]. In the advancement of human civilization, music has inherited a rich culture and history. It has always been an indispensable part of human life for thousands of years. Its meaning, form of existence, and mode of transmission are in a new era. Driven by technology, there will be new interpretations [3]. With the vigorous promotion of network technology, the amount of online music data is increasing day by day, and the demand for analysis, retrieval, and processing of music information has become increasingly prominent [4]. As one of the hotspots in the field of signal and information processing, music separation is an important part of music technology research [5].

It is common for one singer to sing many different songs in singer search and song search, and one song has been sung by many singers. The separation of singing voice can improve the accuracy of singer identification [6]. Because in music information retrieval, the effect of direct retrieval is often unsatisfactory. If it can be separated, the retrieval efficiency will be greatly improved without mutual interference, and many complex multitone music processing can be avoided. Technology simplifies the problem even more. Similarly, during music information analysis (preprocessing, pitch, melody extraction, etc.), the mutual interference between music and singing also leads to inaccurate information analysis [7]. A good separation system will bring great convenience to this. In automatic lyrics recognition, it is usually required to input a single singing voice, which is not in line with reality. Because the singing voice has background music, such a requirement can be achieved. Correcting lyrics for singing voices is a critical and tedious step for applications such as karaoke. Automatic lyrics correction will bring great convenience, but automatic lyrics correction task becomes difficult when background music exists.

The auditory characteristics of the singer's voice signal are described in detail, which is also an important part of the system, and the analysis and calculation methods of each auditory characteristic are introduced. The super-resolution reconstruction model based on the deep residual network is one of the research trends in the past two years. This article first introduces the basic principles of the deep residual network and analyzes the advantages and disadvantages of the existing super-resolution model based on the residual network. After analyzing and inspired by densely connected networks, this paper combines the advantages of deep residual networks and densely connected networks to propose an enhanced two-stage reconstruction residual network and introduces two deep learning features. The suggested twostage residual deep convolutional neural network technique is subjected to comparative experimentation and analysis in this study. The experimental environment, data preparation, and singing voice separation evaluation indicators were first introduced; second, experimental schemes based on the high-resolution network separation of songs, phase optimization algorithms, spectrum amplitude constraints, and data expansion were designed; finally, the separation performance of each algorithm was compared and analyzed.

2. Related Work

In theory, deep learning belongs to the category of machine learning [8]. Machine learning completes the learning of the model by selecting appropriate features. The result depends on the choice of features. However, manually selecting features is very time consuming and labor intensive, and requires a lot of prior knowledge. Therefore, the introduction of deep learning has greatly promoted the development of machine learning, among which the most widely used are visual problems, speech recognition, and text processing [9]. The application effect of deep learning in computer vision is remarkable. In addition to common classification problems, the accuracy of tasks such as face recognition, object detection, and singing voice super-resolution has also been greatly improved [10].

Convolutional neural network (CNN) is a common deep learning architecture inspired by biological natural visual cognitive mechanisms. Researchers found that their unique network structure can effectively reduce the complexity of the feedback neural network when studying neurons used for local sensitivity and direction selection in the cat brain cortex and then proposed CNN [11]. The new recognition machine proposed by related scholars is the first realization of the convolutional neural network. Later, more scientific researchers improved the network [12, 13]. Researchers established the modern structure of CNN [14]. They designed a multilayer artificial neural network, named "LeNet-5," which can classify handwritten digits. Like other neural networks, LeNet-5 can also be trained using the back propagation (BP) algorithm. CNN can obtain the effective feature representation of the original singing voice, which enables CNN to recognize the rules of vision directly from the original pixels [15]. However, due to the lack of largescale training data at that time and the computing power of the computer that could not keep up, LeNet-5 was not ideal for handling complex problems.

Based on the research on the perception mechanism of the human auditory system, related scholars proposed the concept of "synchronization string" [16, 17]. They used the Gammatone filter bank to simulate the structure of the human cochlea to process mixed sounds and then obtained a series of time-frequency units. The degree of correlation between adjacent parts classifies the synchronization string to which the sound signal belongs, and analyzes the mixed sound step by step in time sequence. Researchers have proposed a new CASA system, the "blackboard" model, based on the physiological and psychological characteristics of the human auditory system, using many different criteria to extract and recombine sound signals [18]. This model's organization and processing method of sound signals is a breakthrough innovation for CASA research, which can better realize the simulation of the human auditory system. Relevant researchers reported a neural network-based CASA system that detailed how the same sound source signal is separated into a sound stream based on several sound separation triggers [19]. A schema-driven phoneme repair model has been created by related researchers. This method can restore a sound signal by processing it via an imprecise speech recognition model and restoring the associated masking material. Related scholars have studied a model that uses harmonic characteristics to separate sounds, designs a filter according to the pitch frequency to simply and roughly separates each sound source, and then performs targeted enhancement and compression on the separated sound to highlight the target voice. Researchers proposed a speech separation algorithm based on sound localization and auditory masking effect, using binaural effect as the main sound separation clue, and combined with an ideal binary masking algorithm to separate mixed sounds [20].

3. Analysis of the Auditory Characteristics of Singing Voice Signals

3.1. Pretreatment

3.1.1. Sampling. They are all digital music, with a certain sampling frequency and encoding mechanism, whether they are songs on the Internet or CDs. However, the encoding technique and sample frequency of music have a significant impact on the processing of music data in the experiment. As a result, before framing, the music signal's sampling frequency and encoding technique must be unified. In most applications, digital music does not require a too-high sampling rate, and a too-high sampling rate will increase the complexity of the calculation. In this paper, the music signal is uniformly converted into a WAV format, which is convenient for analysis and processing in the MATLAB environment. For the sampling frequency, the unified standard 22050 Hz in the MIR research field is adopted, which also improves the execution efficiency of the algorithm. The test music signal (44.1 kHz) can be downsampled without losing the basic music recognition characteristics, and the recognition effect is less.

3.1.2. Framing. According to this characteristic, considering the time continuity and short-term stability of the music signal, the music signal needs to be framed after sampling. The length of the frame will directly affect the feature extraction and recognition results. Suppose the sampling period is T = 1/f, there is the following relationship between the window length N and the frequency Δf :

$$\Delta f = \left(NT_s\right)^{-1}.\tag{1}$$

When the sampling period T_s is constant, the frequency resolution Δf is inversely proportional to the frame length N. When N increases, Δf will decrease.

3.1.3. Preemphasis. Normally, hardware or software can be used for preemphasis. This article uses software preemphasis in the MATLAB environment. The transfer function used is

$$H(z) = 1 - (1 - a)z^{-1}.$$
 (2)

Among them, a is called the preemphasis coefficient.

3.1.4. Add Windows. The purpose of windowing is to divide the speech signal into frames, and the frame length is denoted as N. For each frame, the time window function ω (*n*) is multiplied with the original speech signal *s* (*n*). This frame contains the speech signal sequence of N points in the sample, and N is the window length. Generally, there are two commonly used window functions in the windowing process.

The rectangular window function is

$$w(n) = \begin{cases} 0, & n \in [0, N-1], \\ 1, & \text{others.} \end{cases}$$
(3)

The Hamming window function is

$$w_{H}(n) = \begin{cases} 1, & \text{others,} \\ 0.42 - 0.38 \sin\left(2\pi \frac{n-1}{N}\right), & n \in [0, N-1]. \end{cases}$$
(4)

It can be seen from the above two formulas that the length of the window function N is used to calculate the amplitude of the signal. When the window length is extremely large, the window function is approximately equivalent to a narrow low-pass filter, and the length of N is equal to several pitch periods. During this period of time, the short-term information of the signal changes very slowly, and the details of the waveform are often ignored. Conversely, if N is extremely small, this value may be equivalent to or even less than a gene period for a pitch period, and the short-term energy change of the signal will fluctuate according to the change of the signal waveform. If N is too small, the bandwidth of the filter will become wider, and smooth short-term information cannot be obtained. Therefore, the length of the window function should be selected appropriately. It is generally believed that 1 to 7 pitch periods can fully reflect the change characteristics that should be in a speech frame. But the pitch period varies widely for different people, so the choice of N is more difficult. Generally, when the sampling frequency is 10 kHz, the window length is most appropriate to choose from 100 to 200 points, that is, the duration of 15 mins to 30 mins.

3.2. Mel Cepstral Coefficient. Mel frequency cepstral coefficient (MFCC) is a cepstral coefficient based on Mel frequency. To obtain the frequency spectrum of the signal, the discrete Fourier transform is first used to calculate the short-time Fourier transform; second, the obtained logarithmic energy spectrum is filtered with M Mel triangular filter banks; finally, the output vector is subjected to the discrete cosine transform DCT, with the first N coefficients taken. The discrete cosine transform; that is, the cepstral coefficients are obtained.

The reason why MFCC reflects the auditory characteristics of the human ear is that the Mel filter simulates the cochlea model of the human ear. According to the cochlea function, the cochlea's filtering function is similar to the function of the Mel filter, which mainly presents a relationship on a logarithmic scale. It is basically linear below the lower 1000 Hz, and the frequency greater than 1000 Hz is shown as a logarithmic relationship; that is, the human ear recognizes low-frequency sounds more easily than highfrequency sounds. The Mel frequency of the Mel frequency filter bank similar to the cochlear model is expressed as follows:

$$f_{\rm mel} = 2400 \cdot \log\left(\frac{f}{300+1}\right).$$
 (5)

The output formula of the Mel filter is

Journal of Mathematics

$$H_{m}(k) = \begin{cases} 1, & k \ge f(m+1), \\ \frac{k-f(m+1)}{f(m+1) - f(m-1)}, & f(m) < k < f(m+1), \\ \frac{f(m-1) - (k-1)}{f(m) - f(m-1)}, & f(m-1) < k < f(m), \\ 0, & k \le f(m-1). \end{cases}$$
(6)

Among them, M represents the number of channels of the filter and f(m) represents the center frequency. The definition of f(m) is

$$f(m) = NF_{S}^{-1}F_{mel}^{-1}[F_{mel}(f_{1})] - m\frac{F_{mel}(f_{h})}{M-1} - F_{mel}(f_{l}).$$
(7)

Among them, f_h and f_l represent the highest and lowest frequencies, N represents the frame length, and FS represents the sampling frequency.

3.3. Mel Transformation of Linear Prediction Coefficients. The Mel frequency is a simulation of the frequency characteristics of the human cochlea, in which the Mel filter plays a decisive role in this simulation performance. Therefore, linear prediction Mel-frequency cepstral coefficient (LPMCC) is based on linear prediction cepstral coefficient (LPCC), improving its Mel frequency and achieving better results in recognition. LPCC is often used as a characteristic parameter of speech recognition. It has a good performance in speaker recognition. Therefore, LPCC is improved to enhance its performance. Next, the theoretical model of LPCC is introduced.

We assume that the p-order linear prediction coefficient of the speech signal is calculated. We use the first p samples of the speech signal to predict the current speech sample, so the p-order linear prediction value is obtained. The specific description is that the first p samples are linearly combined to predict the voice signal sample value at the next moment, and the prediction standard is that the error is minimized. That is, the predicted value of s(n) is

$$\hat{s}(n) = \prod_{i=0}^{p-1} a_i \cdot s(n-i-1),$$
 (8)

where s(n) is constructed with {ak}, which fits the data in the sense of least mean square. {ak} is the coefficient of p-order linear prediction. The forecast error is

$$e(n) = s(n) - \prod_{i=0}^{p-1} a_{i-1} s(n-i-1).$$
(9)

We perform z-transformation on the above formula to obtain the transfer function of the prediction error sequence:

$$A(z) = 1 - \sum_{i=0}^{p-1} a_{i-1} z^{-k+1}.$$
 (10)

According to the definition of p-order linear prediction, the sum of squares E of all prediction errors of the speech frame is

$$E = \prod_{n=p-1}^{N} \left[s(n-1) - \prod_{i=0}^{p-1} a_{i-1} s_{n-i-1} \right].$$
(11)

4. Deep Convolutional Neural Network Model Based on Two-Stage Residuals

This section will give a detailed introduction to the information of each part of the two-stage progressive reconstruction residual network. Figure 1 shows the overall framework of the network. The low-resolution singing voice to be reconstructed is preprocessed by the feature extraction layer, and then the extracted features are transported to the first reconstruction stage. The pseudo-high frequency is obtained through the local residual learning of each dense residual unit. The main work of the second reconstruction stage is to integrate the original singing voice and real highfrequency information to achieve global residual learning and finally output a high-resolution singing voice. The techniques of feature scaling and expansion convolution are also included between the two reconstruction phases to complete the conversion of pseudo-high-frequency information to actual high-frequency information, making the singing voice's high-frequency component richer and more delicate.

4.1. The First Stage of Reconstruction. In general, the first stage of the model is based on the local residual learning of multiple dense residual units to obtain the initial high-frequency information of the singing voice required for the reconstruction process because they have to be processed subsequently. So, it is called pseudo-high-frequency information.

The model obtains the original features of the singing voice through the feature extraction layer. The feature extraction layer is composed of two convolutional layers, and the structure of each convolutional layer is the same as that of each layer in the dense residual unit. The first layer takes low-resolution singing voices as input, and the output features will be used in two parts. One is as the input of the next layer, and the other is to provide the global residual learning module. The second layer of the feature extraction layer receives the output of the previous layer and then performs a nonlinear mapping on the features, and the obtained output directly participates in the local residual learning process corresponding to each dense residual unit. The following formula can express the abstraction layer:

$$Y_0 = F_0 \left[F^{-1} \left(x - 1 \right) \right]. \tag{12}$$

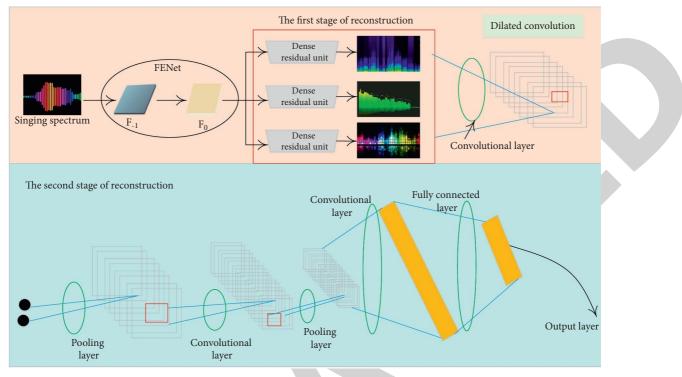

FIGURE 1: Two-stage super-resolution residual network framework diagram.

Here, x is the input low-resolution singing voice, F^{-1} represents the first layer of the feature extraction layer, and F_0 is the second layer. Then, based on the local residual learning of each dense residual unit, the characteristic is that the input of each dense residual unit is Y_0 , which ensures that the learned singing residuals are structurally consistent with the original singing voices.

Considering that in the traditional network, information will inevitably lose a part of it through the forward transmission of each layer, ensuring the invariance of information in the process of dissemination and maintaining the robustness of information memory is the focus of this article. This article uses the cyclic unit of a memory block as the main component of the dense residual learning unit. The cyclic unit is made up of 6 residual building blocks (RBBs). The learning process of the *d*th residual block of the *r*th dense residual unit can be expressed as

$$Y_{d,r} = F(Y_{d,r-1}) - |Y_{d,r-1}|.$$
(13)

 $Y_{d, r-1}$ and $Y_{d, r}$ are the input and output of this block, respectively, and \mathcal{F} is the residual function. In particular, \mathcal{F} contains two convolutional layers, each of which undergoes a preactivated BN-ReLU nonlinear mapping and then performs a 3×3 convolution operation:

$$F(Y_{d,r-1}) = W_{m,r} \cdot \tau \left[\tau (Y_{d,r-1}) W_{m,r}^2 \right].$$
(14)

 $W_{m, r1}$ and $W_{m, r}$ are the weights of the first and second layers, respectively, and ? is the BN-ReLU operation. For the sake of simplicity, the offsets in all formulas in the text are omitted.

The dense residual unit will comprehensively consider the hierarchical characteristics of each RBB when abstracting the features. Through this dense connection operation, the network will minimize the loss of information after the information passes through each layer. However, this also leads to a problem of a large amount of calculation. For example, suppose now that the output of each block has G feature maps, so the output of each unit will have 6.G feature maps. If the number of G is large, for example, G = 64, then the number of feature maps of the final output G is 384, which requires a high amount of calculation for hardware. Therefore, the model in this article considers the use of information filters, which can reduce the dimension of Y_d and achieve the purpose of information fusion. The followingdescribes the specific implementation process of information filters.

In a dense residual unit, the information filter filters the output results of the current dense residual unit Yd so that it can not only reduce the corresponding calculation amount but also meet the reconstruction requirements, thus making the learning process simple. ETRN uses a 1×1 convolutional layer to act as an information filter.

4.2. Dilated Convolution. The comparison between dilated convolution and traditional convolution is shown in Figure 2. After the completion of the first stage of reconstruction, the 6 dense residual units will generate 6 different levels of pseudo-high-frequency information, and then the pseudo-high frequency corresponding to the previous unit is added element-by-element to form the dense residual unit. Relearning the residuals is the second stage of

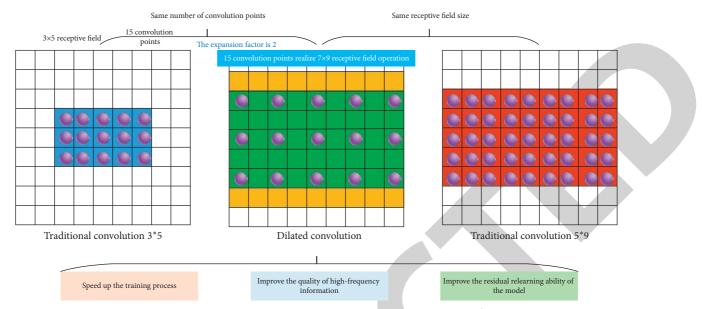

FIGURE 2: Comparison of dilated convolution and traditional convolution.

reconstruction. After two different levels of pseudo-high frequency singing voice features are directly added, the model uses expanded convolution to process the fused data.

In traditional convolution, a 3×5 receptive field requires 15 convolution points to participate in the calculation. After changing to dilated convolution, when the dilation factor is 2, the same 15 convolution points can achieve a 7×9 receptive field operation. The expanded convolution has a larger receptive field with the same amount of calculation, expands the global field of view of the convolution kernel, and the size and number of feature maps remain unchanged. For super-resolution reconstruction, the receptive field means how many contextual pixels can be extracted from the high-frequency information of the singing voice, so in the second stage of reconstruction to obtain real high-frequency information, using dilated convolution has three advantages: (1) in the process of converting pseudo-high-frequency information into real high-frequency information, the training process is speeded up while keeping the number of parameters unchanged; (2) the receptive field is increased, and the self-similarity of the singing voice structure is used to improve the high-frequency information quality; and (3) the redundancy of singing residual information learned between adjacent dense residual units is diluted, and the residual relearning ability of the model is improved.

4.3. The Second Stage of Reconstruction. The second stage of reconstruction can be subdivided into three processes. First, the pseudo-high-frequency features learned by each dense residual unit are gathered to form a pseudo-high-frequency feature set. After ordering, the dth feature and the d—1st feature are directly added, and the expansion convolution is performed. Then, the true high-frequency characteristics corresponding to the dense residual unit of d are obtained:

$$H_{d} = \varphi \Big(H_{d+1,\sim} \Big) - 2\varphi \Big(H_{d,\sim} \Big) + \varphi \Big(H_{d-1,\sim} \Big). \tag{15}$$

As shown in Figure 3, a feature scaling operation is added after each pseudo-high frequency feature, and there is a scaling factor equal to 0.1, and then it is added to the latter one. The reason for this is that, on the one hand, each dense residual unit is stacked by multiple convolutional layers. This high-level abstract representation of features makes the training process extremely prone to numerical instability. This operation is added after each residual block in the deep residual network to solve this problem. On the other hand, the scaling factor can change the weight of each level of pseudo-high frequency feature participating in the expansion convolution operation, and the value of the feature is changed. In this way, the features can be made to meet the statistical distribution characteristics of the residuals of the singing voice as much as possible, thereby avoiding repeated learning of the same or similar information between two adjacent features.

4.4. Objective Function Construction. This paper chooses the mean square error as the objective optimization function of model training. During training, the objective function is continuously reduced. When the model converges, the optimal value of the network parameters can be found through this iterative optimization method. The high-frequency information generated by each dense residual unit can be regarded as a certain order residual between the final reconstructed super-resolution singing voice and low-resolution singing voice. Therefore, the intermediate prediction singing voice output by each dense residual unit can be formulated as

$$I_d = H_d - X + H_{d-1}.$$
 (16)

For the two-stage super-resolution residual network proposed in this paper, 6 dense residual units will output 6 intermediate predictions in the first stage. Therefore, 6

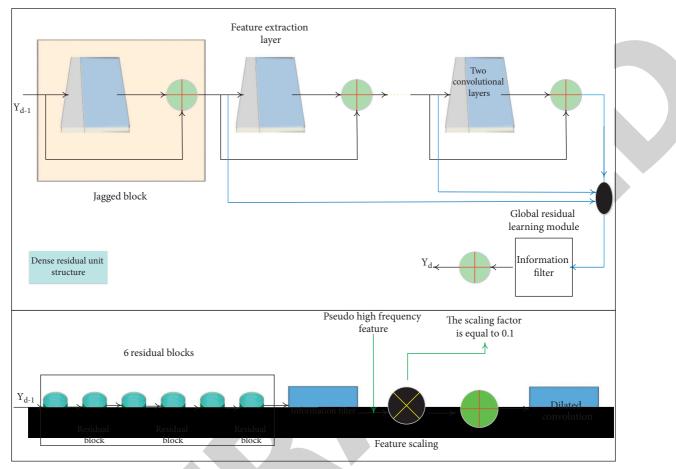

FIGURE 3: Residual relearning based on dense residual unit.

objective functions need to be optimized, and the loss function corresponding to each unit is

$$L_D(\Theta) = \prod_{i=0}^{N-1} \frac{2}{N} \cdot \left(Y_i - I_{d,i}\right)^2.$$
 (17)

? is the set of parameters to be learned in the d dense residual unit. In the second stage, the errors between the final output predicted singing voice and the real high-resolution singing voice are calculated by

$$L_{\sum}(\theta) = \prod_{i=0}^{N-1} \frac{2}{N} (Y_{i-1} - I_{i+1})^2.$$
(18)

? is a collection of parameters to be learned in the entire network. The objective optimization function of the entire network should be the sum of $\mathcal{L}d(\Theta)$ corresponding to each unit and $\mathcal{L}\Sigma(\Theta)$ corresponding to the final reconstructed singing voice, so

$$L(\Theta) = \alpha L \sum_{\Delta} (\Theta) - \beta L_D(\Theta).$$
(19)

Among them, α and β are the trade-off factors, which are used to prevent the value of the two types of objective functions.

5. Experiment and Result Analysis

5.1. Experimental Plan Design. An experiment of monophonic singing based on the high-resolution network is carried out to validate the high accuracy of the spectrogram when the high-resolution network separates the accompaniment/singing voice.

The audio sampling rate is set to 8 kHz, the frame length is set to 1024, the frame shift is set to 256, the network learning rate is set to 0.0001, and iterations are set to 30,000. The original audio sampling rate is 16 kHz, thus setting the sampling rate to 8 kHz. The sample rate is lowered, and the quantity of computation is considerably reduced on the premise of not impacting the separation effect. The learning rate and the number of iterations are reasonable parameters chosen from a variety of options and various tests.

The training set songs are transformed into the frequency domain, and the time spectrogram is input as a highresolution network. After the above-mentioned network structure, the predicted mask is obtained, and finally, the time spectrogram is restored from the mask. The pure singing voice and pure accompaniment corresponding to the song are used in the loss function to measure the difference between the predicted result and the true pure time-spectrogram. A high-resolution network is continuously iterated and trained for singing voice separation. For the 825 original song audios in the test set, the time spectrogram is obtained through STFT transformation, which is input as a high-resolution network, and the time spectrogram of the accompaniment and singing voice is obtained through network prediction and integration. Finally, combined with the phase reconstruction of the original song, the accompaniment and singing signals in the test song are obtained.

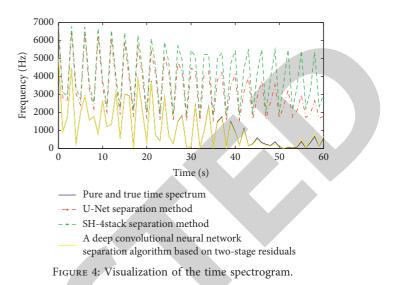

5.2. Visualization of the Time Spectrogram. We randomly select a song to be separated, yifen_5_02.wav, and use the U-Net separation method, SH-4stack separation method, and a deep convolutional neural network based on two-stage residuals to predict the corresponding accompaniment and singing time spectrogram of the song. We visualize the time spectrogram, compare the gap with the real pure singing voice, and evaluate the separation quality of each method. Figure 4 shows the true and pure time spectrogram and the time spectrogram separated by each method. The upper layer shows the accompaniment time spectrogram. The lower level shows the frequency spectrum of singing.

Compared with the pure accompaniment, it can be seen that the three separation methods can basically predict a more accurate time spectrogram; the specific analysis of the accompaniment in the yellow box reveals that the SH-4stack and U-Net methods contain "nonaccompaniment" parts. There are errors, and the deep convolutional neural network based on the two-stage residual is relatively closer to the pure accompaniment, and the separation accuracy is improved.

In the overall comparison of the frequency spectrum of the singing voice, the prediction accuracy of these algorithms is relatively high for places with large amplitudes and obvious changes, which are close to the original pure signal. Observing the content of the yellow box, for some places with small amplitude, it is found that after the SH-4stack and U-Net methods are separated, the prediction is not accurate enough, and the difference between the original spectrogram is large, and the accuracy is relatively low. The deep convolutional neural network method performs better than the above algorithms in small and subtle areas, can predict results that are closer to the pure spectrogram, can better capture learning, and predict high accuracy and is close to the true value.

5.3. Separation Quality Assessment. Figures 5 and 6 compare the separation performance of the four methods on the dataset MIR-1K and measure each method by evaluating the global normalized signal deviation ratio GNSDR, the global signal interference ratio GSIR, and the global signal artifact ratio GSAR.

Figure 5 evaluates the overall separation performance of the accompaniment. It can be seen that the three indicators of the deep convolutional neural network algorithm based on the two-stage residual have improved compared with other algorithms. The overall separation performance of the GNSDR evaluation algorithm and the deep convolutional neural network algorithm based on

the two-stage residual error is 0.43 dB higher than the good performance SH-4stack. Compared with the good performance SH-4stack, the algorithm improves by 0.79 dB; for the GSAR evaluation signal artifact ratio, the deep convolutional neural network algorithm based on the two-stage residual error improves by 0.59 dB compared with the good performance SH-4stack. This shows that the deep convolutional neural network algorithm based on the two-stage residuals can better eliminate the interference from the singing voice in the accompaniment, the artifacts in the accompaniment signal are small, and the separation performance is good.

The total separation performance of singing voices is evaluated in Figure 6. It can also be noted that, when compared to other algorithms, the three indicators of the deep convolutional neural network method based on the two-stage residual have improved. For the GNSDR index, the deep convolutional neural network algorithm based on two-stage residual error outperforms the SH-4stack by 0.82 dB; for the GSIR index, the deep convolutional neural network algorithm based on two-stage residual error outperforms the good SH-4stack by 1.22 dB; for the GSAR index, the deep convolutional neural network algorithm based on two-stage residuals outperforms the good SH-4stack. This demonstrates that the two-stage residual-based deep convolutional neural network technique can also distinguish high-quality singing vocals.

By comparing the three indicators of accompaniment and singing, the algorithm in this paper has improved the amplitude compared with other algorithms and found that the singing voice has improved more. This is because the high-resolution network can improve the accuracy of the singing voice, and compared with the rich singing voice, the improvement of the singing voice resolution is more obvious on the single-structured singing voice. Compared with accompaniment, singing voice has monotonous spectrum components and a single structure. The high-resolution network can greatly improve the amplitude accuracy.

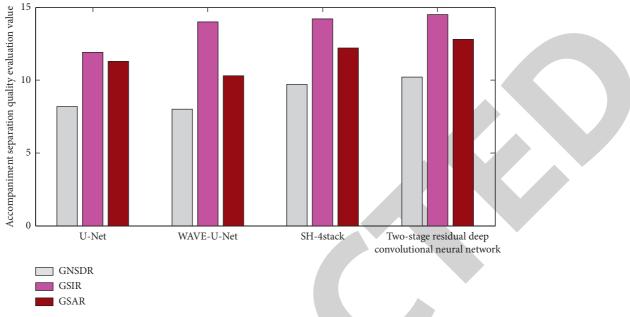

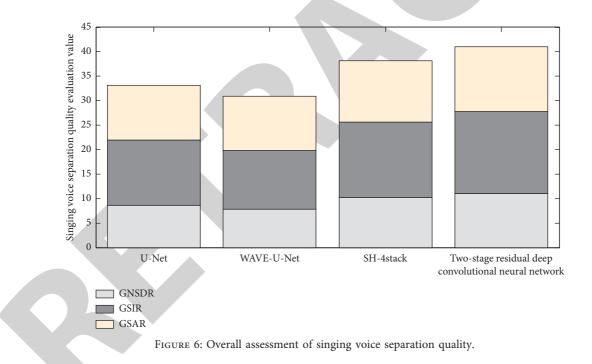

FIGURE 5: Overall assessment of the quality of accompaniment separation.

5.4. Time-Domain Waveform Comparison. The time-domain waveform of the singing voice following the song yifen 5 02 is shown in Figures 7 and 8. The time-domain waveform of the pure singing voice is separated by a deep convolutional neural network based on the two-stage residual error, and wav is separated by a deep convolutional neural network based on the two-stage residual error. It is observed that the outline of the separated accompaniment singing waveform curve is very close to the waveform of the original pure signal, especially where the curve changes are very similar, and there is only a slight gap between the pure signal and the pure signal in some subtle places. It is confirmed that the

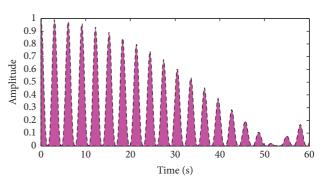

FIGURE 7: Time-domain waveform of pure singing.

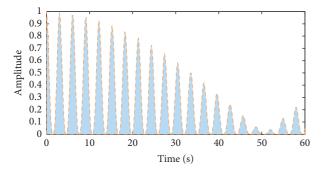

FIGURE 8: Time-domain waveform of singing voice after separation.

separated signal is very close to the original pure signal, and the separation accuracy is relatively high.

6. Conclusion

In the preprocessing stage of the music signal, the unified standard 22050 Hz, which was uniformly adopted by the international MIR conference, was adopted as the music sampling frequency, and through framing, windowing, and preemphasis processing, preparations were made for the subsequent stages of feature extraction. In the stage of extracting human auditory features, we consider and extract as many feature parameters as possible, remove some infrequently used or poorly effective features, and leave only the parameters that represent human auditory features. This paper proposes a deep but concise two-stage super-resolution reconstruction network based on residual learning. In this model, the reconstruction is divided into two stages, and the different levels of high-frequency information of the singing voice are learned progressively. The first stage of reconstruction is based on the BN-ReLU-weight convolutional layer, and a new dense residual unit is constructed to learn the hierarchical features of the singing voice of the training set of different scales. The pseudo-high-frequency information is obtained by the local residual learning method and used as the input of the next reconstruction stage. The second stage of reconstruction uses the output of the previous stage for relearning based on the residuals between units instead of directly using it for reconstruction. Between these two stages, PSGAN introduces feature scaling and expansion convolution technology to reduce the information redundancy between high-frequency information of each order and greatly improve the detection effect. Finally, the global residual learning is completed based on the structural information. A deep convolutional neural network algorithm based on two-stage residuals of high-resolution neural network is proposed. For singing voice separation in the frequency domain, the focus of the research is to ensure that the separated accompaniment/singing time spectrogram is infinitely close to the true and pure time spectrogram. In this paper, using deep learning technology, starting from the frequency domain model, treating the time spectrogram as a singing voice, using the parallel structure of the high-resolution network and the characteristics of multiple fusion of features, it is proposed to apply the highresolution neural network. The time spectrogram of the monosong to be separated is separated through a trained high-resolution network to obtain a high-precision accompaniment and singing time spectrogram, and finally, the time-domain signal is reconstructed.

In response to the shortcomings of the traditional methods for evaluating the mental health status of college students in terms of computational complexity and low accuracy, a method for evaluating the mental health status of college students based on data reduction and support vector machines was proposed. A model experiment containing internal and external personality tendency classification, anxiety, and depression dichotomy was designed using logistic regression analysis, information entropy, and SVM algorithm to construct the feature dimensions of the network behavior data, combined with the labeled data of mental state to derive the sample data set for model experiments. In the experimental process, to reflect the difference in the effect of different models, various types of mathematical models were constructed for horizontal comparison; at the same time, to reflect the influence of the parameters of the same type of model, different combinations of parameters were constructed using a grid search algorithm to vertically compare the difference in the effect. The average accuracy of the dichotomous model for anxiety and depression in the sample of 1433 students was 0.80 or higher. The experiments show that the method of predicting students' psychological status through their online behavioral data is feasible, and the mathematical classification model can be used to grasp students' psychological status in real time and to warn students with abnormal psychological status, thus helping school counselors to intervene and prevent them promptly.

1. Introduction

With the increasing competition in society, college students are facing multiple pressures in employment, life, study, and emotion, which lead to the frequent occurrence of college students' mental health problems and directly affect the stability of campus life and learning environment; therefore, it is of great practical significance and theoretical value to evaluate the mental health of college students [1]. At present, the methods for evaluating the mental health status of college students are mainly based on traditional machine learning algorithms, such as decision trees (DT) and feedforward neural networks (BPNN), which have the disadvantages of great computational effort and low accuracy rate [2]. The university campus life is a critical period for students' rapid psychological development and maturity and is a key step in the formation of healthy psychology; school educators and parents should pay attention to the guidance and education of students during this period to help them shape healthy psychology. Unsatisfactory schooling has a number of detrimental repercussions on pupils' psyche, as well as their subsequent incapacity to integrate effectively into social life. The goal of this research is to gather information regarding students' psychological well-being without putting them under undue stress so that psychologists can perform their jobs more effectively. This paper investigates the relationship between students' psychology and data and builds the feature vector associated with psychology using behavioral data, including mining students' social relationship characteristics using behavioral data and proving the scientificity of the method using students' social sensitivity data, constructing regularity correlation index features using the theory of information entropy and penalty factor, and measuring students' social sensitivity data.

In today's era of big data, students, as the majority of the campus population, produce the most data, the most

valuable of which is data records of students' online behavior, which are generated by students of their own volition, can reflect differences between students to the greatest extent, and have laid a solid data foundation for this topic's research [4]. The traditional psychological method of data collection is based on the concept of random sampling, and its analysis method is based on hypothesis testing, both of which have drawbacks that affect the accuracy of the results, whereas big data psychology uses the full volume and full data analysis method, which completely squeezes the value contained in the data and greatly improves the accuracy of the experimental results. In this paper, based on the online behavioral data generated by school college students on the Internet and the basic attribute data of students, combined with the content of the MBTI assessment scale, PHQ-9 depression screening scale, and GAD-7 anxiety screening scale, the correlation between students' behavioral data and their psychological states is explored, and the data mining method is used to construct the models of internal and external personality tendency classification, depression state classification, and anxiety classification [5]. The data mining method is used to construct a classification model for personality internal and external tendencies, depression, and anxiety, to predict the psychological state of students based on their behavioral data at school, to warn students with psychological abnormalities, and to assist psychologists in better psychological intervention.

With the digitization of colleges and universities, the degree of information technology in each college and university is getting higher and higher, and everything is gradually being data-driven. Every instantaneous behavior of students on campus is transformed into a data record, and these data records lay the foundation for the study of this topic. The psychological research approach based on big data technology has its significant superiority compared with traditional psychological research. Furthermore, the big data research approach analyzes all data from the entire dataset, avoiding the sampling error that may arise from the traditional research method of sampling samples from the entire dataset, then generalizing to the entire dataset, collecting data directly from the real environment, and avoiding the experimental error caused by the traditional research method of overcontrolling the experimental conditions, which results in the generation of behaviors that are not representative of the real environment. In terms of the efficiency and scale of data processing, it can relieve the pressure of traditional research methods that require a lot of time and workforce; in terms of time validity, it can instantaneously collect, analyze, and predict real-time psychological states, avoiding the bias of analysis results caused by the lag of data collection of traditional research methods. This paper analyzes the correlation and degree of correlation between students' behaviors and their psychological states based on the behavioral data and scale data generated by students at school, constructs the features associated with students' psychological states by combining students' static attributes, and builds a prediction model of students' psychological states through machine learning methods. The goal is to forecast students' present psychological states by

collecting real-time data on their school behavior, to warn students with aberrant psychological states, and to aid campus psychology professors and specialists in intervening with kids who may have psychological issues.

2. Current Status of Research

Based on summarizing previous studies, a model based on robust multitask learning was established using the Big Five personality assessment scale as an indicator to achieve accurate classification prediction of personality variables of active Weibo users [6]. As for the research on the prediction of students' depression, Barenholtz et al. established a regression model to analyze the severity of students' depression by using the number of posts, likes, and likes for others as the characteristic dimensions of students' microblog comments in a week, and the results showed that people with heavy depression had a higher number of dynamic posts, but a lower number of likes for others [7]. In a study on student suicide risk prediction, Kumari et al. used keywords extracted from text data published by microblog users for data analysis and used MLP models to achieve a predictive assessment of suicide risk based on microblog text data [8]. However, one of the obvious drawbacks of these studies is that they only focus on users who have social network accounts, such as Sina Weibo, and not every student uses Sina Weibo; in fact, according to the survey, the average number of active users of Sina Weibo is only 4 to 5 [9]. There are no studies that show a psychological difference between Weibo users and non-Twitter users. Therefore, data from social networks such as Weibo are not sufficient to predict the psychology of all school students. The higher the psychological indicator of gratitude, the lower the value of the corresponding indicator of depression [10]. The cross-sectional study demonstrated that the quality of sleep of college students is related to their depression level, the quality of sleep and depression level can interact with each other, and long-term poor sleep quality significantly increases the occurrence of depression. A study of a sample of more than 2,000 individuals through a mediated moderation model verified that peer friendships influence the psychological aspects of depression in students and that friendship support negatively predicts depression. However, these aspects of the study only made psychological causal explanations and did not do so to the extent of predicting psychological states [11].

Anomaly detection techniques aim to automatically identify those observations in a large set that are valuable or whose behavior is different from the expected one. Anomaly detection is one of the important applications in data mining technology and has specific applications in many practical production's lives, such as credit card fraud, industrial damage detection, and image detection. Through in-depth research, scholars at home and abroad have proposed many anomaly detection algorithms with high feasibility, which has laid a solid foundation for further research on anomaly detection [12]. Nevertheless, the basic mathematical models are still very useful and have eventually been adapted to many computational scenarios. Current research tools are divided into nonparametric and parametric approaches: the nonparametric approach does not require the assumption of knowledge of any parameters and uses nonparametric techniques to estimate the density of the distribution, for example, histograms and Parzen window estimation; the parametric approach requires the assumption that normal data are generated based on parametric distributions, and it requires these parameters from training samples, for example, outlier detection methods based on normal distributions [13]. Neural networks, which may be classified into single-classification neural networks and multiclassification neural networks [14], are an important field of nonlinear modeling approaches. Multiclassification neural networks, such as multilayer perceptron, neural tree, and others, use data from multiple classifications to train the model and then input test data into the model, which the network interprets as normal or abnormal; single-classification neural networks, such as Replicator Neural Networks (RNNs), use a function (like a step function) to transform the sample into N discrete variables for sample clustering.

The mental health status data of college students collected according to the conventional model assessment guidelines and the symptom self-assessment scale SCL-90 are high-dimensional datasets, so there are drawbacks of huge computation and redundant correlations between data features when conducting mental health assessment of college students. With the extensive research of popular learning algorithms, this method has been widely applied to image retrieval, text classification, face recognition, and plant leaf recognition as data feature extraction and dimensionality reduction. A mental health assessment approach based on a local linear embedding algorithm (LLE) and support vector machine (SVM) is presented to increase the accuracy of college students' mental health status evaluation. LLE-SVM may successfully increase the accuracy rate of college students' mental health status assessment when compared to SVM, BPNN, and DT.

3. SVM Analysis of Multidimensional State Data Reduction and Evaluation of College Students' Mental Health

3.1. SVM Multidimensional State Data Reduction Evaluation Design. The evaluation of the college students' mental health status is essentially a nonlinear classification problem. Since the characteristics of everyone's mental state data are multidimensional and these characteristics involve many nonlinear factors and have the characteristics of multilevel, multivariable, nonlinear, and strong coupling, it is difficult to describe quantitatively by traditional mathematical models or methods [15]. To improve the accuracy of the evaluation of the mental health status of college students, it is very necessary to establish a more scientific and reasonable evaluation model of the mental health status of college students. In this study, nine dimensions of psychoticism, paranoia, hostility, terror, anxiety, depression, obsessivecompulsive symptoms, interpersonal sensitivity, and somatization were used as input vectors of the LLE-SVM model, and the mental health status of college students was

divided into healthy, mildly unhealthy, and unhealthy as output vectors of the LLE-SVM model to establish the evaluation model of college student's mental health status based on LLE-SVM. The evaluation model is shown in Figure 1.

In this study, the data of nine dimensions, including psychoticism, paranoia, hostility, terror, anxiety, depression, obsessive-compulsive symptoms, interpersonal sensitivity, and somatization, were used as the input vectors of the LLE-SVM model, and the mental health status of college students was divided into healthy, mildly unhealthy, and unhealthy as the output vectors of the LLE-SVM model to establish a mental health status evaluation model of college students based on the LLE-SVM. The process of the evaluation algorithm based on LLE and SVM can be described in detail [16]. The data of mental health characteristics of college students were collected: SCL-90 was issued to collect the data of mental health characteristics of college students, which included nine dimensions of psychoticism, paranoia, hostility, terror, anxiety, depression, obsessive-compulsive symptoms, interpersonal sensitivity, and somatization. The LLE algorithm was used to reduce the dimensionality of college students' mental health characteristics data to reduce the computational effort. The reduced dimensional data were divided into training samples and test samples, and the training samples were used to build the LLE-SVM model for evaluating the mental health status of college students, in which the reduced dimensional data were used as the input of the SVM and the mental health status of college students was used as the output of the SVM. The test sample data were used to verify the effectiveness of the LLE-SVM model for evaluating the mental health status of college students.

Machine learning can be used to discover dependencies between inputs and outputs by learning from training samples to make predictions about unknown inputs. This can usually be expressed as follows: there is some dependency between the variables y and x. And, it is based on the independently distributed sample data sources.

$$S = (x_1^2, y_1^2), (x_2^2, y_2^2), \dots, (x_l^2, y_l^2).$$
(1)

The goal of machine learning is to minimize the desired risk by training with sufficient training samples. In practice, the set of samples available for training is limited and does not achieve the minimization of the expected risk [17]. According to equation (1), it can be found that the final composition of the expected risk is influenced by various aspects such as the error function and the joint probability distribution; therefore, for the classification judgment problem involved in this paper, the empirical risk minimization principle is used.

$$R_{\rm emp}(\alpha) \approx \frac{1}{l} \sum_{i=1}^{l} L^2(y_i^2, f(x_i, \alpha)).$$
(2)

The theoretical use of empirical risk to approximate the expected risk assumes that the sample size l is infinitely large and that equations (1) and (2) expressed by mathematical calculation are equivalent when the sample size is infinite.

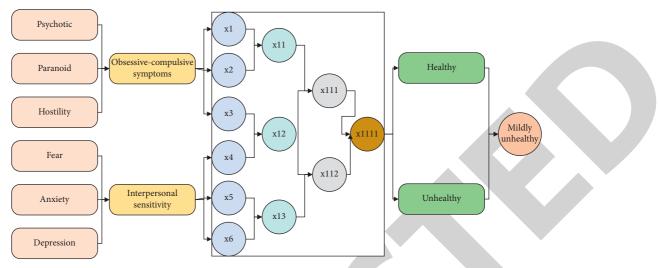

FIGURE 1: Mental health state evaluation model.

Because the training samples are limited in real life, the method of using such an approximation instead is not fully proven for the time being, so there are some errors between the empirical risk and the expected risk when considering practical problems where the training samples are far less than an infinite magnitude.

According to the foregoing, using the linearly divisible support vector machine classification technique, the linear decision function may be immediately generated in the feature space for linearly divisible data to be processed. However, building a nonlinear decision function directly in the feature space for linearly indistinguishable data is too difficult to execute, and it may also lead to a "dimensional catastrophe" when the dimensionality of the data features is enormous. It can be concluded from the statistical learning theory that the inductive ability of the learning system is independent of the dimensionality of the data; therefore, the data in the low-dimensional input space can be mapped to the high-dimensional space, the classification hyperplane can be found in the high-dimensional space to classify the data, and the decision function can be solved according to the classification hyperplane. The SVM algorithm is based on the idea of first mapping the low-dimensional data samples to the high-dimensional space by the kernel function and then finding the hyperplane that can classify the data samples reasonably in the high-dimensional feature space to achieve the classification of the data.

$$k(x_{i}, x_{j}) = \varphi(x_{i}^{2})\varphi(y_{i}^{2}),$$

$$Q(a) = \sum_{i=1}^{l} a_{i} - L^{2}(y_{i}^{2}, f(x_{i}, \alpha)),$$

$$f(x) = \sin\left(\sum_{i=1}^{l} a_{i} - L^{2}(y_{i}^{2}, f(x_{i}, b))\right).$$
(3)

Based on the network behavior of the malicious code detection system, the detection data come from the various types of operational data collected from the network, and the network data have the characteristics of large data volume and strong uncertainty. On the one hand, a large number of various types of data provide the detection system with a lot of valuable information, but on the other hand, there are many duplicate redundant data and features in the network data, the existence of these invalid data not only adds a burden to the storage of the detection system, increasing the cost of hardware storage equipment, but also increases the computational burden of the detection system, affecting the monitoring of real time and, more seriously, the existence of interference data. There is also the possibility of affecting the accuracy of the final detection. Therefore, feature extraction is to select relatively important features from a large amount of network data through some evaluation criteria, reduce the overall feature dimension, thus reducing the complexity of model computation, and improve the training time and detection time while ensuring the detection accuracy.

$$x_{i}^{2} = \frac{x_{i} - x_{\min}}{x_{\min} + x_{\max}} * (U + L) - L,$$

$$S = \frac{1}{n_{1}} \sum_{i=1}^{l} f(a_{i} - L^{2}(y_{i}^{2}, f(x_{i}, b))).$$
(4)

Data cleaning is an essential technique for resolving data quality issues caused by external influences, such as those mentioned previously. Missing data are filled in, errors are detected, duplicates are filtered out, and consistency is checked, among other things. Filling methods include zerovalue filling, mean value filling, and filling according to the probability distribution; for example, the missing of some age fields in the basic information can be filled by the mean value of the whole group; error detection means verifying some data records in some fields in the data content by the rules and the data missing because a certain reason need to be filled by a certain data association. Consistency check is necessary to ensure the consistency of data between multiple data sources when a data field has multiple data sources. For example, the college and major in the basic information of students and the college and major in the data of students' grades should ensure the consistency of data. Meanwhile, the consistency and the inconsistent data should be corrected by rules or handled manually, as shown in Figure 2.

Each university will establish various business departments according to different functional divisions. Each department's business systems are relatively independent and connected, such as grades and course selection data from the Registrar's Office, consumption, and access control data from the Logistics Department [18]. Therefore, before mining multidimensional student data, it is necessary to physically integrate the data from different data sources with different storage media and different data formats, a process called data integration. Data sources can be divided into online data and offline data according to the form: online data can be obtained directly through the online form of data, such as database data and interface data; offline data is usually obtained in an offline manner, such as excel tables and text files. At present, most of the data in universities are online data, such as consumption, access control, course selection, and grade data. Only very few data are stored in an offline way, such as student registration data when enrolling and class-based information statistics summary data. Data analysis is the interpretation of key information contained in or between data through visual data graphs or metrics such as correlation coefficients. The purpose of data analysis is to get a sufficiently accurate picture of the distribution of the data and the correlation between them, which helps in feature engineering to construct feature vectors with labels characterizing the data.

3.2. Experimental Design for Multidimensional State Evaluation of College Students' Mental Health. The process of model application is to classify unknown samples by the constructed model, and the model is applied to predict sample data with unknown labels only if the accuracy of the model is within an acceptable range. The estimated accuracy of a model is usually assessed using accuracy, where the prediction accuracy of an individual sample is judged by comparing the known labels of the test sample with the results predicted by the model, with the accuracy being the percentage of the test data correctly classified by the model. The test dataset should be independent of the training dataset to avoid model overfitting problems. The model may achieve excellent accuracy when categorizing imbalanced sample class labels by explicitly predicting the test sample as the majority sample class [19]. As a result, it is also important to think about the model's recall, which refers to the model's check-all rate or the proportion of positive cases in the test data that the model correctly predicts. In most classification issues, the F1 value, which is the summed average of the model's accuracy and recall, is used to determine the model's quality.

Although significant progress has been achieved in theoretical research and social services, the building of a mental health care system still lags behind and is unable to satisfy the demands of social growth. As China's comprehensive strength has grown, several institutions have progressively begun to construct a flawless psychological care system to promote students' mental health. At present, all colleges and universities have established mental health centers to provide professional psychological counseling for college teachers and students, and some colleges and universities will regularly conduct psychological assessment activities to comprehensively measure students' current psychological status and provide timely guidance and intervention for students with psychological abnormalities. This chapter further explains the correlation between the psychological assessment dimensions based on the data of the student psychological scale.

To verify the validity of the LLE-SVM for evaluating the mental health status of college students, the SCL-90 data of college students' mental health symptoms of a school entering college in 2020 were selected for the study, and the data of mental health characteristics of each college student were nine dimensions of indicators such as psychoticism, paranoia, hostility, terror, anxiety, depression, obsessivecompulsive symptoms, interpersonal sensitivity, and somatization. The data were categorized as unhealthy. The mental health status of college students was divided into three states: unhealthy, mildly unhealthy, and healthy, and the distribution of the three sample data is shown in Figure 3.

Data preprocessing is a very important part of the data mining process, but data preprocessing is very time- and effort-consuming. Experience shows that if the data preprocessing is done well, then it saves effort in building the model. Because the existence of a high number of noisy data, redundant data, missing data, and so on in the dataset influences the prediction results, we must preprocess the data. There are a variety of reasons for incomplete data in the dataset; for example, the student may have misplaced a card and failed to replace it on time, resulting in missing data for that period, or there may be a mechanical failure resulting in data loss and incorrect entry; all of these anomalies result in a large amount of redundant data in the database, and due to the presence of these incorrect data and vacant data, preprocessing is essential. For the processing of missing values, either direct deletion or interpolation of missing values can be performed. Direct deletion causes partial loss of information and loss of some important data with missing values, especially when the data are small, which is more harmful to the sample; missing value interpolation can be divided into mean interpolation, median interpolation, arbitrary value interpolation, and model interpolation. Missing values may also be a kind of information in some cases and can be captured by adding a feature to capture whether it is missing or not (i.e., adding a column of features, where 1 means it is a missing value NaN and 0 means it is not a missing value), and certain students in the dataset have missing values in some consumption patterns, as shown in Table 1.

For the missing values, different values need to be filled in using different values depending on the nature of each feature. Cartoon student consumption data have much vacant information, and only these missing data need to be populated with 0. Because the public database did not contain the required peripheral physiological signals for the previous studies in this section, it was not possible to conduct a mixed physiological signal emotion classification

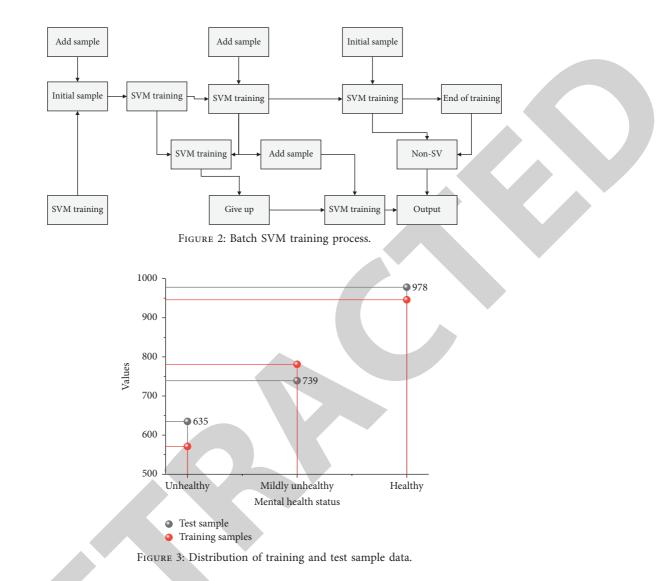

TABLE	1:	Dataset
-------	----	---------

Student ID	1	2	3	4	5
Library	11.52	1.94	12.66	3.57	14.35
Boiling water	7.54	7.59	7.26	6.25	13.35
Academic affairs office	13.18	7.86	12.78	4.46	4.96
Print center	3.08	6.73	1.71	13.12	14.65
School clinic	2.37	2.08	12.34	4.93	9.75
School bus	12.36	12.5	4.89	1.65	2.72
Laundry room	14.67	8.23	8.72	9.29	12.25

study, and the superiority of the spatiotemporal features was facilitated by the algorithmic analysis of the spatiotemporal features in the self-constructed dataset validation. Therefore, in this paper, we first conduct experiments on the mixed physiological signal acquisition of emotions to obtain experimental data and then validate the spatiotemporal features on the EEG signals in the collected experimental data.

The selection of emotional elicitation material is the first step of the whole experiment, and this experiment chose the audiovisual stimulus as the elicitation material, that is, the music + dynamic pictures as the whole elicitation material, giving the subjects visual stimulation from both visual and auditory dimensions. These two approaches require the selection of moving pictures and background music, which is also crucial because it is necessary to consider that different people respond differently to music and pictures, and this experiment requires the selection of background music and moving pictures that can effectively evoke most of the subjects, as well as considering factors such as the main groups of recruited subjects and their living environment. Considering that the subjects were mainly students of the university, music and pictures were selected to stimulate young students aged 20 to 24 years. Before the formal experiment, some students were selected for evaluation. After the music and pictures were completely selected, the experiment was conducted by playing 14 dynamic pictures for one minute for each emotion induced. The experiment was designed to collect physiological signals from a total of 60 subjects with an average age of about 24 years. When the subjects were recruited before the start of the experiment, the exact procedure and the purpose of the experiment needed to be explained clearly to the subjects, and those who were willing to participate in the experiment were required to sign an informed consent form. EEG, ECG, EDA, and RSP signals were collected during the experiment. The EEG acquisition equipment used was the Enobio system. The ProComp Infiniti device was used for peripheral physiological signals. The EEG signal was acquired at 500 Hz, the ECG signal was acquired at 2048 Hz, and the EDA signal and the RSP signal were acquired at 1024 Hz. The material was played back in a way that gave the subject a more visual stimulus, and an ASUS computer and a Holly 75-inch display were used to play the stimulus material. The experimental flow is shown in Figure 4.

Before the start of the experiment, it is necessary to explain the purpose of the experiment and the whole process to the subject. After the subject is informed, he/she needs to fill in the relevant information form and sign the informed consent form. The equipment will also need to be worn, and the equipment will need to be commissioned. The room must be darkened before the official experiment starts so that the emotions may be created more effectively. The collector must be aware of the signals acquired during the experiment, noting any noticeable anomalous signals or if the equipment is malfunctioning in order to assess whether the data has to be recollected [20]. The experiment started with the official admission into the physiological signal elicitation acquisition phase, and it went like this: the patient stayed quiet throughout the two-minute blackout; during this time, the subject's basal signal was captured. The stimulus material was presented after 2 minutes of basal signals had been recorded. There were four different sorts of content, each of which was played for one minute, followed by a two-minute black screen to allow the subject to rest and recuperate.

4. Analysis of Results

4.1. SVM Multidimensional State Data Dimensionality Reduction Results. The mental state perception model is to perceive students' mental state information based on their online behavioral data for psychological prediction. The output of the model is the categorization of the mental state information, that is, the classification of students' mental states according to the online behavioral data, the form of classification is binary, and the content is two kinds of student's mental health status, healthy and unhealthy, so the mental state perception model essentially belongs to the category of binary classification model in supervised learning. A preselection-elimination mechanism is used to construct the mental state perception model. Preselection means that several different types of classification models with classification ability are selected first, given the same training data set for training, and finally, the model with the best output is selected as the final perception model based on the average results of multiple experiments, and the rest of the models are eliminated. The reason for choosing this method to construct models is that the network behavior data used in this paper is a kind of data that has not been studied and applied, so some models need to be preselected to compare and analyze the advantages and disadvantages of different models' performance for this kind of data before finally determining the perceptual models.

The data used in this experiment came from two parts, respectively, the psychological status data obtained from the questionnaire platform and the web access log data obtained from the log server database; all the data have strict control over the privacy of students not to be leaked, such as psychological status data only have the student ID data, no student's name, major, class, and other information, so it only can be treated as a unique identification of the existence. The same applies to the weblog data, where the data collected are limited to the type of website visited by a student ID, the name of the website, and so on and do not relate to the specific content of the visit, as shown in Figure 5.

As can be seen in Figure 5, the P and R values corresponding to each model and the F score on the fold are marked, and all models except the SVM model have an F score above 0.6, and the optimal GA-RF model has an F score reaching 0.765, indicating that the model trained by the feature dimension data of the network behavior can achieve the judgment of the population's internal and external tendencies. Second, compared to the results of the model without the extraction of features by the genetic algorithm, all values of the model group with the genetic algorithm have improved, indicating that the data of these eight feature dimensions extracted by the genetic algorithm are more representative compared to the data without processing when based on the internal and external tendency labels, which are the regularity of WeChat, the degree of WeChat dependency, the regularity of WeChat posting friend regularity, microblog regularity, video viewing regularity, video viewing gauge dependency degree, reading regularity, and reading dependency degree.

By further statistical analysis of the data of these 5 dimensions, it was found that the depressed people have lower dependence on shopping and web, while the dependence on listening to music, regularity of using map websites, and dependence on games have higher values because the depressed people are cold not only to interpersonal relationships but also to life, so they are not interested in buying new things and maintaining. Instead, they are more dependent on music and games than others. For a normal person, there are more or less a few days in a month-long cycle when he or she goes out with friends to have fun, and then he or she will use the map. The use of the map-type website is regular, as it is not used every day, as shown in Figure 6.

The main purpose is to construct, analyze, and tune the models of three different kinds of students' mental health status, aiming to be able to grasp the information of students' mental status more comprehensively and accurately through

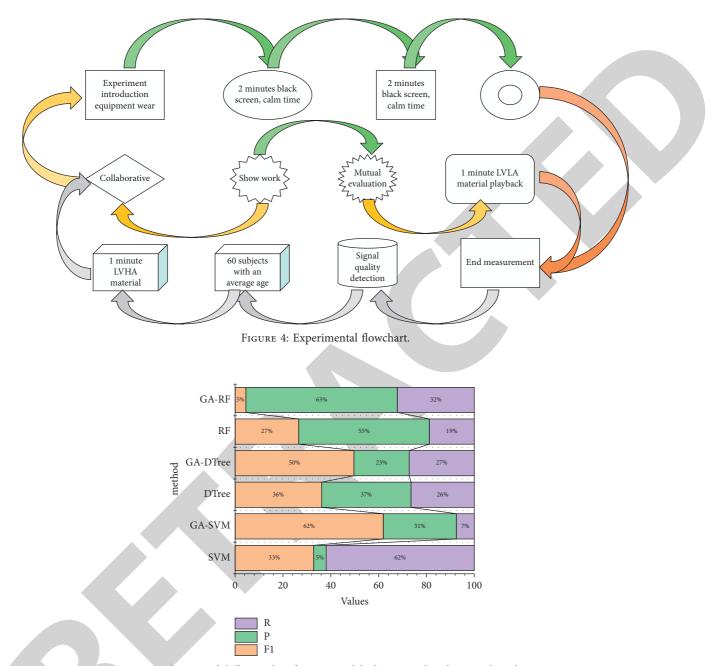

FIGURE 5: Evaluation of different classification models for internal and external tendencies.

their online behavior data at school. In this chapter, the labeling and feature dimension parts of the sample data set are processed in conjunction with Chapter 4 so that they can be used for the subsequent model training, and then the evaluation indexes of the classification model are selected. Firstly, when building the model, a series of classification models are designed for experiments by combining the contents of Chapter 3, and the results of multiple models are briefly analyzed by selecting the model with the best output for the parameter optimization work. After a series of steps down, the best model algorithm is selected in the case of horizontal comparison of different classification models, and the best model algorithm is selected in the case of vertical comparison of different optimal combinations of parameters and different combinations of parameters, and finally the good output of the model of the perceived mental health status of students was ensured.

4.2. Results of Multidimensional State Evaluation of College Students' Mental Health. As shown in Figure 7, the results are binary logistic regression results for univariate and multivariate factors, and the depression subscale of the symptom self-rating scale yields results as continuous-type values indicating different levels of depression, so it is also necessary to use multiple linear.

The goal of the student psychological state perception model is to be able to predict student psychology in real time

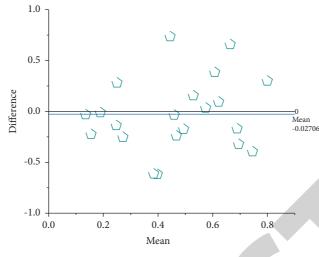

FIGURE 6: F1 values for a different number of iterations.

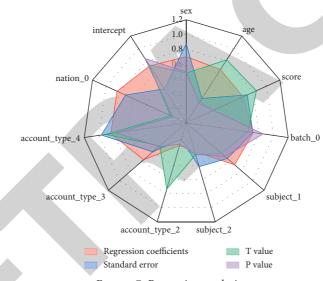

FIGURE 7: Regression analysis.

based on the behavioral data generated by students at school, so this section aims to construct dynamic features in three major areas from the behavioral data generated by students at school, including student consumption features, student behavior features, and social relationship features. The behavioral data generated by students at school include daily consumption data, containing the time, place, amount of consumption, and so on; library access data, containing access status, time, and so on; and course selection data, containing the semester of course selection, course type, and so on. The human psychological state has stability within a certain period; that is, no human psychological state will change much over a while, but to throw out the possible influence of expost behavior on the exante state, this topic only selects the behavioral data within the period from the entrance of new students to the test, which is also beneficial to the model in the application of the demand on the data period, as shown in Table 2.

The LLE algorithm involves two parameters: the embedding dimension a and the nearest neighbor parameter K. The magnitude of these two parameters directly affects the effect of college students' mental health status evaluation. When various K and d values are used as values, the parameters of SVM are set as penalty parameters, radial basis kernel function parameters, and the accuracy rate of college students' mental health status rating. The greatest accuracy percentage for assessing the mental health status of college students was 96.5 percent. The correlation between each factor and depression status was analyzed using multifactor binary logistic regression; finally, the scores of the depression subscale of the original symptom self-assessment scale were used as the target, that is, the magnitude of depression; and whether each factor was an influential factor in the degree of depression was investigated using a multivariate logistic regression mode.

Туре	K = 3	K = 4	K = 5	K = 6	K = 7	K = 8
d = 2	43	29	19	28	16	11
d = 3	21	10	26	26	22	31
d = 4	38	10	16	11	43	28

d = 6	45	12	47	23	45	12
d = 7	21	17	33	27	30	48
d = 8	25	24	15	20	44	35

TABLE 2: Behavioral data used in the student psychological state perception model.

5. Conclusion

In the early stage, through reading and detailed analysis of a large amount of relevant literature, we have a certain understanding of the current status of research on a mental state based on network data at home and abroad, and by comparing the advantages and disadvantages of different research methods, it is clear that the current research on mental state mainly focuses on the analysis of users on social network platforms; while there are fewer methods suitable for the analysis of mental health in a more closed environment like school students, in this context, this paper proposes the concept of a mental state perception model based on school students' online behavior data. The process of knowledge discovery is also the process of discovering the value of data, and data mining is the key link in the process of knowledge discovery. By analyzing and studying each step of the overall process of knowledge discovery, we have a grasp of the overall process for the subsequent establishment of the mental state perception model. It is clarified that there needs to be a process of data preparation stage before data mining and a process of result expression and interpretation stage after data mining. An improved SVM incremental learning algorithm that effectively utilizes the results of the above preselection algorithm and combines KKT conditional judgments and error-push strategies is proposed. In the case of using the above data preselection method, a new SVM incremental learning algorithm combining the traditional KKT conditional and error-push strategies is proposed. This algorithm improves the learning speed by effectively using the results of data preselection; by adding the relevant error score vectors to the added vectors, the detection accuracy is improved relative to the traditional incremental learning.

Data Availability

The data used to support the findings of this study are included within the paper.

In order to improve the quality of international law data, this paper designs a method to ensure the integrity of international law data based on an antiterrorism prediction algorithm. On the basis of introducing random function and deep learning technology, the prediction model set is split through the trusted seed model, the model selection is completed through iterative optimization, and then new terrorism-related factors are added to obtain the new prediction model set, so as to complete the antiterrorism data prediction. Based on the antiterrorism prediction data obtained by the above process, on the basis of identifying incomplete data, the antiterrorism data integrity guarantee method in international law database is designed through the process of determining data integrity operation parameters, eliminating worthless feature items, processing noise dimension reduction, and adding feature series of data integrity. Experimental results show that the frequency range and data sensitivity of international law data can be optimized by using this method, the audit process of data integrity is less time consuming, and the data integrity after processing can reach 0.967.

1. Introduction

Internationally recognized international law in which several states participate refers to the sum of the rule of law applicable between sovereign states and other international personality entities, also known as public international law, which is the law that distinguishes private international law or conflict of laws [1]. International law is also distinct from domestic law, which is the internal law of a state that regulates the conduct of individuals and other legal entities within its jurisdiction.

As a national code of conduct, the emergence and existence of international law must have a certain material basis, which is the communicative behavior and relations between states [2]. In the field of international law, the sum of such relations between states is traditionally called "international community," which is the social basis for the emergence and existence of international law. Since the middle of the 20th century, the understanding of the relations between countries has shown a trend towards the "international community." The term "international community" is used more and more frequently in academic research and practice of international relations and international law [3]. In the writing of international law, the scope of this community usually points to the whole world, not limited to a group composed of a few countries. This allows international societies to overlap geographically, and the social basis of international law evolves from international society to local politics.

With the development of the international legal system, after collecting case analysis and reports in the field of public international law, relevant organizations have constructed international law databases, including data of international courts, domestic courts, and ad hoc courts [4]. For the first time, this kind of database fully collects and analyzes international case law and provides in-depth analysis and guidance from legal experts. In the process of constructing such a database, however, due to factors such as network node deviation, susceptible to incomplete data, and with the extension of network transmission time, the data information keeps increasing; not only will the international law cause incomplete data balance level to continue declining, it can also severely affect information parameter aggregation behavior. In order to avoid the occurrence of the above situation, it is essential to ensure the integrity of international law data [5].

At present, in terms of data integrity guarantee research, [6] proposes a method of cloud storage data integrity audit and guarantee, which summarizes the advantages and disadvantages of existing data audit protocols from the three aspects of data ownership proof, data recovery proof, and data ownership proof. The performance of typical protocols is evaluated in terms of technical principle, time cost, reliability, and detection probability. It is found that most audit protocols can only be used in specific scenarios, and it is urgent to further study universal audit protocols with balanced performance in all aspects. Audit protocols matching cloud storage, fog storage, blockchain, and other technologies are still in the exploratory stage. Finally, this method predicts the future development trend of outsourcing data auditing from three aspects: cloud audit protocol, alliance chain audit protocol, and component pool audit protocol.

In [7], a method to ensure the integrity of outsourced spatial database was proposed, which improved on the existing verification tree structure and proposed a spatial verification data structure VSS-Tree. SS-tree is used as the basic structure and additional verification information, and boundary ball is used to divide regions to increase the degree of nodes, effectively reduce the height of the verification tree, and avoid unnecessary disk access, so as to improve the processing efficiency of spatial query verification. This ensures that the querying user can verify that the data in the query result is real and contains all data that meets the criteria.

Reference [8] proposed multicopy integrity based on DDCT list audit and security methods. In this method, first, DDCT list is introduced to solve the problem of dynamic data operation; at the same time, the block number copy, the version number, and the information such as timestamp are stored in the table; next, to resist malicious cloud service provider attacks, a copy of the data signature verification algorithm is designed based on timestamp. Then, the concept of the duplicate block, including blockhead and block body, is proposed. The blockhead stores the signature information of duplicate data based on timestamp identification and authentication, and the block body stores the encrypted duplicate data. Finally, a third-party audit institution audits the integrity of multicopy data in the cloud by adopting the signature authentication algorithm based on duplicate timestamps.

However, in practical application, it is found that the frequency range and sensitivity of data are not ideal after the application of the above traditional methods, the integrity audit process takes a long time, and the data integrity needs to be further improved. Based on the above analysis, this study takes antiterrorism behavior as the analysis basis and designs an antiterrorism prediction algorithm to ensure the integrity of antiterrorism data in the international law database. The following is a summary of the research: Section 1 contains the introduction. Section 2 discusses the literature review and background. Section 3 discusses the international law data integrity guarantee based on the antiterrorism prediction algorithm. In Section 4, experiment and analysis of the proposed concepts are provided. Finally, the conclusion brings the paper to an end in Section 5.

2. Background

International law has the following characteristics:

- International law provides a set of rules of conduct for states in dealing with their foreign relations, as well as their rights and obligations under international law
- (2) International law is mandatory, but the way of enforcement is different from that of domestic law; however, the special way of enforcement is still mandatory
- (3) Some important international treaties have clearly defined the effect of international law
- (4) International practice has proved that international law, as the law between states, is not only recognized by all countries in the world but also abided by, by all countries [9]

The specific division of international law is shown in Figure 1.

According to its scope of application, international law can be divided into general international law and special international law. General international law is the international law binding all countries, and special international law is the international law binding two or a few countries [10]. Geographically, there are universal international law and regional international law. Universal international law is the international law binding all countries in the world, while regional international law is the international law binding only countries in a certain region, such as "American international law" and "Latin American international law." These are manifestations of the diversity and complexity of relations between states. However, in essence, only general and universal international law is generally referred to as international law, and the so-called special international law or regional international law must be restricted by general and universal international law [11].

Theorists and practitioners in the field of international law, law, and international relations are trying to explore some questions about its nature, function, and status. For example, is international law equally binding all states? Does international law have common pursuit that transcends states? Why is international law so weak? Why does international law often pale in comparison with political power and powerful states? Is it possible that international law, like domestic law, will become more systematic, binding, enforceable, and authoritative? In order to explain the nature, state, application methods, and operation characteristics of international law, some research results have tried to put forward a lot of interpretations, among

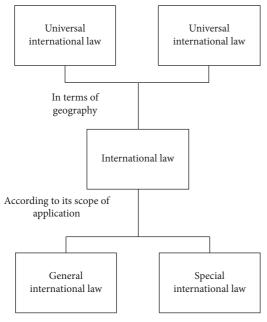

FIGURE 1: The division of international law.

which the fragmentation of international law is discussed. In addition to the exploration of specific problems, there are also some attempts on methods and perspectives, for example, the school of "new" natural law, which combines international law with ethics, and the interdisciplinary study of international law and international relations [12]. It can be seen that these question-based explorations and discussions on perspectives and methods can help us better understand what international law is, what state it is in, and why it is in this state and can help us to distinguish right from wrong.

The construction of an international law database plays an important role in case analysis and reports, latest updated articles, international organizations, and international cooperation in the field of public international law, as well as in-depth research on hot issues with a wide coverage [13]. Take Max Planck Encyclopedia of Public International Law as an example. It is a comprehensive and in-depth electronic reference library in the field of international law, including many latest articles on international law, international organizations, and international cooperation, as well as a wide range of hot issues. The database provides quick and advanced search methods and can be navigated by alphabetical lists of titles, authors, and topics. The homepage of Max Planck Encyclopedia of Public International Law is shown in Figure 2.

It can be said that the establishment and application of the international law database have promoted the development and reform of international law to a great extent. In the process of constructing such a database, however, due to factors such as network node deviation, susceptible to incomplete data, and with the extension of network transmission time, the data information keeps increasing; not only will the international law cause incomplete data balance level to continue declining, it can also severely affect information parameter aggregation behavior [14]. In order to avoid the above situation, it is

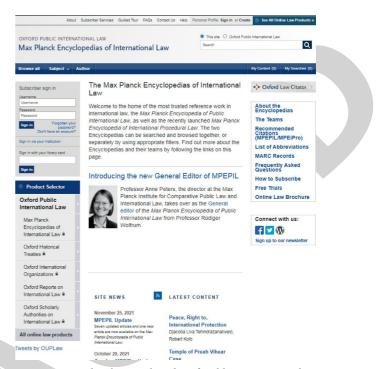

FIGURE 2: Max Planck Encyclopedia of Public International Law homepage.

essential to ensure the integrity of international law data. Therefore, this study designs an international law data integrity guarantee method based on an antiterrorism prediction algorithm. The design process of this method is described in detail below.

3. International Law Data Integrity Guarantee Based on the Antiterrorism Prediction Algorithm

Based on the analysis of antiterrorism behavior and the design of antiterrorism prediction algorithm, this study designs the integrity guarantee method of antiterrorism data in an international law database.

3.1. Analysis of Antiterrorism Prediction Algorithm. With the accelerated development of global informatization, international terrorist activities have been constantly upgraded, and in recent years, they have been rampant and have extremely bad effects. In the face of the rapid transformation and upgrading of international terrorism, the antiterrorism situation has become increasingly severe, seriously affecting the social order and causing huge casualties and property losses [15]. Under the guidance of international law, it has become a consensus that intelligence leads the fight against terrorism in the face of severe challenges in the new situation. The post-event analysis of international terrorism can often be found in advance. In fact, there is a lot of information about terrorist attacks. The key is the lack of prediscovery mechanisms and tools, which are required by the covered big data. However, antiterrorism prediction is faced with challenges such as difficult multidomain data fusion, small sample data, and few model evaluation methods. Therefore, how to use big data and antiterrorism prediction deep integration is the key link to win terrorist activities. Big data is used to mine and predict terrorism-related intelligence, build a new antiterrorism prediction model, and realize timely prediction, early warning, and prevention of terrorist organization behavior, which is of great significance to the study of antiterrorism prediction [16].

The application of the antiterrorism prediction algorithm can improve the decision-making ability to predict terrorist organizations and terrorists. In practical application, the purpose of the antiterrorism prediction algorithm is to predict when and where terrorist organizations and terrorists will create terrorist incidents, and then give decision-making suggestions to antiterrorism agencies, so as to avoid the occurrence of terrorist incidents as far as possible. Facts prove that antiterrorism prediction algorithms are often better than traditional manual analysis.

A tactical prediction algorithm and a target locking algorithm are part of the traditional antiterrorism prediction algorithm. It is a calculation process that involves feeding one set of numerical values into an algorithm model and receiving a different set of numerical values as a result. Because the antiterrorism prediction algorithm is essentially a machine learning algorithm, it is based on the machine learning working concept; that is, it continuously acquires new knowledge and skills by simulating human learning behavior, reorganizing its own knowledge structure, and improving its own performance in order to improve its own prediction level [17].

In general, the overall thinking of the traditional antiterrorism prediction algorithm mainly includes problem perception, data preparation, directional mining, evaluation and prediction, and feedback optimization. The process is shown in Figure 3.

In Figure 3, the core of the whole prediction algorithm is data mining and feedback optimization. Through data mining, the antiterrorism prediction model is built, and the accuracy of the prediction model is improved through several times of feedback optimization. However, antiterrorism prediction is faced with many challenges, such as difficult multidomain data fusion, small sample data, and few evaluation methods. Therefore, under the existing conditions, the practical feasibility of such methods is weak and the prediction universality is poor. At the same time, the research results obtained by investing a lot of manpower and material resources are easy to overturn or eliminate, and the cost is huge.

In view of the shortcomings of existing technologies, this study uses a random algorithm to optimize the traditional antiterrorism prediction process. The specific steps are as follows:

Step 1. Collect the required terrorism-related data based on the perception of terrorism-related data.

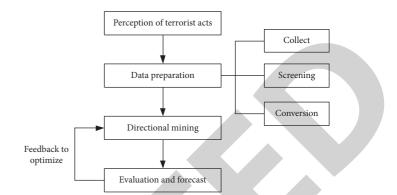

FIGURE 3: The whole idea of traditional antiterrorism prediction algorithm.

Step 2. Use deductive method to mine the behavior data of historical terrorist organizations.

Step 3. Obtain the trusted seed model *S* through deep learning.

Step 4. Assume that the prediction result of the *n*-th seed model is R_n , while the actual terrorist act is *v*. On the basis of the preset reliability *c*, input the terrorism-related factor vector, when

$$c > D\left(R_n(a_i)|va_i\right) = \frac{R_n(a_i)}{va_i},\tag{1}$$

where $D(\cdot)$ represents the data divergence, and the similarity evaluation of the two models is carried out, so the seed model *S* is called the trusted seed model.

Step 5. On the basis of several credible seed models, a random function fission prediction model is used to predict the parameter value M. The random function used here is the Monte Carlo algorithm.

Step 6. The model set M' was tested on the test set, and the models with poor prediction results were removed to screen out the model set M' with relatively excellent performance.

Step 7. Save the prediction model set M', and make antiterrorism prediction according to the prediction model set.

Step 8. Once a new terrorism-related factor f appears, return to Step 3 and add f to obtain a new prediction model set M''; the process is as follows:

$$M'' = D\left(R_n(a_i)|va_i\right) \times \frac{S+f}{M'+cM}.$$
(2)

The above antiterrorism prediction algorithm still adopts the data acquisition and mining part of the existing antiterrorism research, which retains the advantages of traditional research. Meanwhile, it makes up for the disadvantages of the current research through the idea of a seed model, improves the prediction accuracy, and supports the addition of new terrorism-related factors, thus improving the scalability of the algorithm.

3.2. Design of International Law Data Integrity Guarantee Method. Based on the antiterrorism prediction data obtained from the above process, the integrity assurance method of antiterrorism data in the international law database is designed.

3.2.1. Identifying Incomplete Data. The incomplete data identification process is composed of three processing steps: incomplete data subspace extraction, statistical element reconstruction, and separable amplitude calculation. The specific design process is as follows.

(1) Subspaces of Incomplete Data Extracted by Factor Analysis. Data subspace is a relatively fuzzy storage set of information parameters, and the larger the information coverage area involved in the subspace, the more the incomplete data samples to be screened [18]. Therefore, in order to obtain accurate extraction results of incomplete data subspace, the factor analysis method is used to integrate the obtained historical data into multiple information parameter sets; then, according to the multivariate statistical algorithm, the original set space is improved; and finally, all the information parameters are put into the subspace set structure.

It is assumed that g_1 and g_2 , respectively, represent two different parameter value factors of incomplete data information and that $g_2 > g_1$ is satisfied. It is stipulated that Δt represents the unit extraction time of data information parameters. In general, the physical value range of this indicator always exists between 0 and 1. By combining the above physical quantities, the subspace extraction results of incomplete data can be expressed as

$$h = \omega \times \frac{\Delta t^2 (g_2 - g_1)}{\partial \overline{q}},\tag{3}$$

where ∂ represents the reasonably defined term of incomplete data, ω represents the weight value of single extraction of data information parameters, and \overline{q} represents the mean value of single transmission of incomplete data information.

(2) Reconstructed Statistic. Statistics are standard conditions for measuring the transmission capacity of data information parameters. The higher the level of numerical quantity of statistical element nodes is, the stronger the constraint ability of the applied algorithm is [19]. With the increase of incomplete data screening, the number of statistical element nodes will decrease obviously due to the influence of computing, which will lead to the continuous decline of screening application ability. In order to solve this problem, the statistical element nodes are reconstructed in this study. On the one hand, the changing trend of the screening amount of incomplete data is avoided, and on the other hand, the computational amount of data information can be effectively controlled.

Suppose η_0 represents the minimum constraint value of statistical element coefficient, η_n represents the maximum constraint value of statistical element coefficient, and N represents the actual iterative transmission times of incomplete data information. Simultaneous formula (3) can be used to express the statistical element reconstruction result as

$$z = \frac{e \times h}{\sum_{\eta_0}^{\eta_n} N \times \overline{b}^2},\tag{4}$$

where *e* represents the transmission characteristic value of incomplete data information parameters, *p* represents the extraction permission value of information parameters, and \overline{b} represents the mean existence of statistical element nodes.

(3) Separable Amplitude Quantity. In the process of identifying incomplete data, the data cannot maintain the invariable existence state but will show obvious turbulent change with the increase of information parameter storage level. In this case, there is always a certain numerical comparison between the parameters of selectable and nonselectable data, which can separate the amplitude.

Separable amplitude is a piece of dynamic data information matching result. As the amount of data to be screened increases, the numerical coordination relationship is always in the existing state of absolute change. Therefore, in order to obtain effective calculation results of separable amplitude, it is necessary to accurately grasp the parameter value level of incomplete data information and, on this basis, to complete the overall planning and coordination of related information parameters.

Assuming that α and β are two different amplitude nodes, j_{α} represents the magnitude of amplitude separation when the coefficient is α , and j_{β} represents the magnitude of amplitude separation when the coefficient is β . Simultaneous formula (3) can be used to calculate the result of separable magnitude expressed as

$$S = \frac{z^2 + y(k_1 + k_2)}{(j_\beta - j_\alpha)^2},$$
 (5)

where *y* represents the basic separation conditions of amplitude parameters, and k_1 and k_2 represent two different incomplete data items to be counted as index definitions. To sum up, the identification and processing of incomplete international law data are completed.

3.2.2. Data Integrity Assurance. In order to guarantee the data integrity of international law, the operation parameters of data integrity must be determined first. Therefore, the text classification training is used to adjust the feature items of the data, some worthless feature items are removed by feature dimension, and the noise of international law data is removed by feature dimension reduction.

Assuming that the feature item of the data is c_i and the total number of data text categories is u_i , the calculation process of obtaining the data's worthless features is as follows:

$$\varphi_{\left(c_{i},u_{i}\right)} = \frac{P\left(c_{i} \cap u_{i}\right)}{X\left(c_{i}\right)X\left(u_{i}\right)}.$$
(6)

Among them, the frequency of feature item c_i in international law data text can be expressed as $P(c_i \cap u_i)$.

If the training sample of the complete feature item of data is $X(c_i)$, the expression of the complete category item of data contained in the training sample is $X(u_i)$. Therefore, when there is a parallel relationship between the corresponding data text category u_i and the feature term, the ratio of $P(c_i \cap u_i)$ presents a linear positive relationship, and there is a correlation between the integrity of the data in the feature term and $P(c_i \cap u_i)$. When $P(c_i \cap u_i)$ increases, data integrity also increases.

On this basis, feature terms of international law data are reduced in dimension, proportional relationship is set on the basis of data feature terms, data feature dimensions are calculated in combination with feature terms, and mutual information is used to improve the classification accuracy of data integrity feature dimension.

Knowing the chi-square value between data integrity features and text categories, as well as the relationship between feature dimensionality reduction, the total calculation is performed according to the data features, so that the total number of dimensionality reductions of text features can be obtained to determine the integrity of international data. The relevant test criteria of text categories need to be classified and identified. The process is as follows:

$$\omega_c = \frac{\varphi(c_i, u_i)}{\varepsilon \times \vartheta},\tag{7}$$

where the word frequency parameter of international law data is ε and the number of integrity feature items in the data feature category is ϑ . Then, feature items with integrity word frequency in data are separated from documents, and word frequency feature categories are introduced and associated. According to the weight parameters of high-frequency feature items, the weight values of low-frequency feature items of international law data are reduced [20]. Integrity operation parameters are determined as follows according to data integrity feature items:

$$\gamma = \omega_c \times \left(P(c_i) - \frac{\sum_{i=1}^m P(c_i)}{m} \right). \tag{8}$$

Among them, the frequency expression of feature items of international law data is $P(c_i)$. The data integrity guarantee mechanism of international law is established according to the integrity operation parameters obtained.

First of all, the international law data in the sample set is decomposed into *m* sets, and the number of text sets after classification is (m(m-1)/2). The correlation coefficient in the corresponding classification training texts is calculated by the corresponding classification collection. According to

the integrity operation parameter integrity guarantee range obtained above, the formula is as follows:

$$F = \frac{x_1 y_1 + x_2 y_2 + \dots + x_m y_m}{\sqrt{x_1^2 + x_2^2 + \dots + x_m^2} \sqrt{y_1^2 + y_2^2 + \dots + y_m^2}},$$
(9)

where x_m and y_m are vector values in the sample set of international law data. After processing the decomposed international law data text set according to the scope of text classification, the integrity feature item matrix is obtained as follows:

$$m' = \frac{m(m-1)}{2} \begin{bmatrix} x_1 y_1 & x_1 y_2 & \cdots & x_1 y_m \\ x_2 y_2 & x_2 y_2 & \cdots & x_2 y_m \\ \vdots & \vdots & \ddots & \vdots \\ x_m y_m & x_m y_2 & \cdots & x_m y_m \end{bmatrix}.$$
 (10)

On this basis, according to the setting of the detection prerequisites of integrity feature items by the detection function, the results are as follows:

$$\tau(c_i) = \frac{\lim_{n \longrightarrow m} \tau_n(c_i)}{n},$$
(11)

where the parameter value of the integrity feature function is τ and the measured international law data integrity feature category is $\tau(x_1, x_2, \ldots, x_n)$. When the parameter value of the characteristic function is $\tau_n = \tau$ and $\lim_{n \to m} K_n(f_i) = K(x_1, x_2, \dots, x_n)$, the positive definite relation formula is used to calculate the curve amplitude of international law data integrity, and at the same time, the overall characteristics of the data sample are identified. Assuming that the width of the integrity function of international law data is σ , vector values x_m and y_m are used to calculate the integrity characteristics of the data as a whole, and the process is as follows:

$$T = 0.5x_m \times \kappa \times \sigma + 0.5y_m \times (\kappa - 1) \times \sigma.$$
(12)

The new international law data sequence equation is obtained by summation of data integrity characteristic series as follows:

$$O = \sum_{\kappa=1}^{N} z(\kappa) \times T.$$
(13)

Thus, a complete international law data series can be obtained; that is, international law data integrity assurance processing is completed.

4. Experiment and Analysis

In order to verify the practical application performance of the international law data integrity guarantee method designed above based on antiterrorism prediction algorithm, the following experimental process is designed.

4.1. *Experimental Design*. Experimental data were obtained from Max Planck Encyclopedia of Public International Law database. The experiment was built on Matlab v10.0 (64 bit)

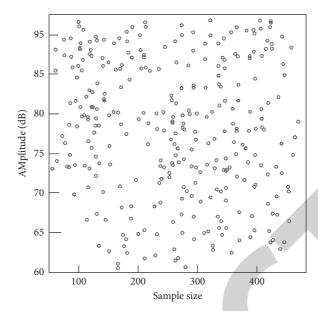

FIGURE 4: Sample distribution of international law data series.

	Number of experiments	Frequency range of data usage	Data sensitivity
	10	0.94	0.88
	20	0.95	0.96
The proposed method	30	0.91	0.91
	40	0.88	0.87
	50	0.93	0.91
	10	0.61	0.60
	20	0.30	0.73
Method of [7]	30	0.44	0.72
	40	0.66	0.65
	50	0.73	0.71
	10	0.51	0.67
	20	0.61	0.72
Method of [8]	30	0.64	0.75
	40	0.78	0.74
	50	0.52	0.78

TABLE 1: Comparison of experimental parameter values.

simulation platform, and the SR258 1U rack server was used to set up the data acquisition platform and console. A sample sequence of international law data is shown in Figure 4.

In order to improve the explicability of experimental results, the integrity assurance method of outsourcing spatial database (method of [7]) and the integrity audit and guarantee method of multicopy based on DDCT table (method of [8]) were taken as the comparison group. The method of this paper was taken as the experimental group for comparative test.

4.2. Experimental Results and Analysis. Firstly, using frequency range and sensitivity of data as indicators, the practicability of different evaluation methods is verified. The specific values of index parameters of different methods are shown in Table 1. According to Table 1, in the whole experiment, the frequency range of data used in the proposed method and the value level of data sensitivity index are always relatively close, there is no obvious fluctuation coefficient, and the value is very close to 1. However, there is a big gap between the frequency range of data use and the value of data sensitivity index of the two traditional methods and 1. Therefore, the method of this paper is more practical.

Then, the time consumption of the integrity audit process of different methods is used as an indicator for comparative verification, and the results are shown in Figure 5.

According to the results shown in Figure 5, in the 30th experiment, the integrity audit process of the method of this paper takes 17 min, and that of the method of [7] takes 21 min. The integrity audit process of the method of [8] takes 26 min. In the 50th experiment, the integrity audit process of

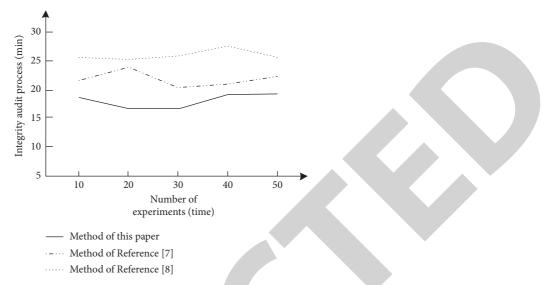

FIGURE 5: Comparison of the time consumption of the integrity audit process of different methods.

TABLE 2: Comparison of data integrity after the application of different processing methods.

Number of experiments/time	Method of this paper	Method of [7]	Method of [8]
10	0.944	0.861	0.829
20	0.967	0.860	0.865
30	0.921	0.825	0.856
40	0.925	0.853	0.836
50	0.966	0.842	0.844

the method of this paper takes 20 min, and that of the method of [7] takes 23 min. The integrity audit process of the method of [8] takes 25 min. In the whole experiment, the integrity audit of the method of this paper takes only 19 min at most, indicating that the method of this paper has high timeliness.

Finally, the validity of different evaluation methods is verified by using data integrity after the application of different methods. Statistical results of data integrity after the application of different methods are shown in Table 2.

According to the results shown in Table 2, data integrity varies between 0.921 and 0.967 after the application of the method of this paper. After the application of the method of [7], the data integrity varies between 0.825 and 0.861. After the application of the method of [8], the data integrity varies between 0.829 and 0.865. Furthermore, in the whole experiment process, the maximum data integrity after the application of the method of this paper can reach 0.967, indicating that compared with the two traditional methods, the proposed method is more effective.

5. Conclusion

In order to further optimize the quality of international law data, this paper studies the integrity guarantee method of international law data on the basis of designing antiterrorism prediction algorithm. Firstly, the prediction model set is split through the trusted seed model, the model selection is completed through iterative optimization, and then new terrorism-related factors are added to obtain the new prediction model set, so as to complete the antiterrorism data prediction. Based on the antiterrorism prediction data obtained by the above process, on the basis of identifying incomplete data, the antiterrorism data integrity guarantee method in international law database is designed through the process of determining data integrity operation parameters, eliminating worthless feature items, processing noise dimension reduction, and adding feature series of data integrity.

On the basis of the above research, experimental data prove that this method takes less time to audit the data integrity and that the data integrity after processing can reach 0.967. The frequency range and sensitivity of international law data can be effectively optimized by using this method.

As a peer-to-peer "P2P" distributed ledger, the blockchain has the advantages of decentralization, no trust, open autonomy, and nontampering. Therefore, many users are willing to conduct transactions in blockchain cryptocurrency systems such as Bitcoin and Ethereum. However, the throughput of traditional blockchain is extremely low, and the transaction is so delayed. The payment channel network is the most promising solution to expand the blockchain for widespread use. Achieving secure instant payment on the payment channel can significantly increase transaction throughput and reduce transaction delays. When the payment channel is closed, the balance in the channel will be returned to an account on the blockchain. In this paper, we discuss the design and the implementation of a multiparty payment channel network based on smart contracts. Where a two-party payment channel is designed based on blockchain and smart contracts, a new multiparty payment channel is established on the basis of the payment channel are designed. Moreover, we design a multiparty payment channel smart contract, deploy it to the local private blockchain, and conduct simulation and testing. The delay time of different transaction methods is counted, and the gas consumption of different transaction methods are analyzed through multiple sets of experimental statistics.

1. Introduction

With the rapid development of the Internet, the financial industry and third-party payment software have risen rapidly. According to statistics from the Ministry of Commerce in 2015, the national online retail transaction volume was 3.88 trillion yuan, a year-on-year increase of 33.3%. According to the "Report on the Development of China's Internet in 20 Years" released by the China Cyberspace Research Institute in Wuzhen, China's online retail transaction volume has leaped to the world's first place, and the number of mobile phone online shopping users has reached 270 million [1]. People have higher and higher requirements for online banking and payment functions. How to process more transactions in a shorter time while ensuring higher security and how to enable two users to directly trade without the complicated process of intermediate third-party inspection and to obtain a substantial increase in efficiency have become hot topics of discussion in transaction reform [2]. Therefore, the storage of ledger data based on blockchain technology has important development prospects. Traditional online transactions need to rely on third-party payment intermediaries. For users, user transaction information is stored in a centralized database by an intermediary. Users need to trust the intermediary before they can use the payment platform provided by the intermediary. In order to ensure the credibility of transactions, payment companies need to collect a lot of user privacy information to determine the credibility of user accounts. For users, the more the private information is disclosed, the less secure it is. In recent years, private information leakage has occurred from time to time, and its scope includes industries involving assets such as healthcare, law, and real estate. According to the "2015 Data Breach Investigation Report" report, in 2015, there were 79,790 data breaches in 61 countries around the world, of which 2,122 have been confirmed [3]. The data of many well-known hotels in my country was leaked, including Marriott Hotel and Starwood Hotel. The data leakage of these hotels has resulted in the fact that all the customer order information and personal information that has been consumed in these hotels can be easily obtained by hackers, and it can be seen by people who want to use this information. This kind of leakage of user privacy information is undoubtedly irresponsible for customers' sensitive information, and it also damages the reputation and market value of the hotel. For the transaction intermediary platform, in order to ensure the credibility of the accounts, clearing a large amount of transaction information requires high fees and lengthy time. Nevertheless, under the huge transaction volume, it is impossible to completely avoid mistakes, so it is necessary to pay more expenses and time to make up for these mistakes. This will cause unnecessary waste of funds and time loss for users. On the other hand, the traditional centralized management method [4] is to completely supervise the accounts by banks or third-party payment companies. The transaction process recorded by these intermediary companies is invisible to users, and the transparency and credibility of the ledger data are difficult to guarantee. Therefore, with the emergence of a trust crisis, many researchers want to establish a trustless, distributed privacy protection intermediary platform. Although there are many user privacy protection algorithms, such as differential privacy [5], k-anonymity [6], and t-closeness [7], there are also distributed storage systems, such as Google File System [8] and Big Table [9]. But none of them are distributed and trustless practical applications [10]. Smart contract technology helps to solve the above-mentioned problems faced by individuals and enterprises. The concept of smart contracts was first proposed by cryptographer Nick Szabo in 1994. It aims to establish a decentralized financial authentication system and free manpower from boring document processing. Although the vision of smart contracts is quite beautiful, the concepts and goals are also very clear. But in fact, smart contracts have not received widespread attention until blockchain currencies such as Bitcoin have become popular in recent years. Before the emergence of blockchain technology, the research on smart contracts progressed slowly. This is mainly caused by two reasons. First, it is difficult for computer programs to control actual assets, and there is a lack of an effective fund settlement channel between enterprises. In fact, to this day, crossborder transfers still need to go through multiple intermediaries, which makes it very difficult to automate smart contract procedures. Second, smart contracts are difficult to generate sufficient credibility. After one party breaches the contract, it is difficult for computer programs to work without personnel. In the case of intervention, the breaching party is guaranteed to be punished. The emergence of blockchain technology has changed this status quo. First, the blockchain currency led by Bitcoin is a natural settlement channel for digital assets; second, the openness and nonrepudiation characteristics of the blockchain ledger ensure that the contract execution process can be easily regulated. By establishing the contract in the form of code and recording it in the unalterable blockchain, the

authenticity and reliability of the contract can be guaranteed. At the same time, the smart contract system helps enterprises realize digital asset management and lays the foundation for enterprises to realize fully digital office. Blockchain is a decentralized system. According to the blockchain standard, the effect of mutual communication and mutual trust between enterprises can be realized, and the communication cost of enterprises can be effectively reduced. In addition, the unforgeable nature of the blockchain helps to reduce the labor cost of the third-party audit department.

Throughout this paper, we give a background on the related works in Section 2, where we proceed to Section 3 to discuss and analyze the stages of creation of a two-party payment channel, besides the types and methods of the channel, the channel close, and the performance of the two-party payment channel. Then, we introduce the multiparty payment channel, which is designed based on the two-party payment channel. In Section 4, experiments and results were done in order to reduce transaction delay and increase the throughput of blockchain transactions. Finally, in Section 5, we end our study with a conclusion.

2. Related Work

Current blockchain-based smart contract projects include Ethereum [11], Hyperledger [12], Codius [13], and Hawk [14]. Among them, Ethereum is the earliest open-source platform for smart contracts that supports Turing-complete programming languages, and it is also a relatively influential community in the blockchain field. Many companies and enthusiasts have used Ethereum as the underlying platform to implement applications covering market forecasting, supply chain source verification [15], crowdfunding-based financing, securities, and derivatives trading [16]. Hyperledger is an open-source project on advancing blockchain digital technology and transaction verification jointly initiated by the Linux Foundation in 2015 with more than 30 members, including major financial, technology companies, and related open-source organizations. The emergence of Hyperledger officially announced that blockchain technology is no longer just an open-source community technology but has been recognized by mainstream institutions and the market, which is of great significance to the development of blockchain. Some other open-source projects have their own focus. Taking Hawk as an example, the main feature of the project is to protect the data privacy of participating users, and users' transfer records are no longer recorded in the block in a public form. Smart contract is a concept proposed by Ethereum, a set of commitments defined in digital form, including agreements on which contract participants can execute these commitments. The execution process is transparent, traceable, and unchangeable. If Bitcoin is a distributed ledger, its transaction symbol is Bitcoin. Ethereum is a distributed platform without transaction symbols. It adds a core smart contract concept on the basis of Bitcoin [17]. The original Bitcoin mechanism was not scalable. It was an application that could only run Bitcoin

transactions. If a new developer wants to develop new applications on the basis of the blockchain, the blockchain needs to be completely redone. Ethereum is a platform provided to application vendors. Developers only need to pay a certain amount of Ether, build different contracts on this platform, and run different operations and different businesses. It no longer just records transactions but adds more parameter information to the contract. By establishing its own blockchain, a clear "state tree" representing the current balance of each address and a "transaction table" representing the transactions between the current block and the previous block are stored in each block [18, 19]. Ethereum solves the scalability problem. The business scope supported by Ethereum includes voting, financial exchanges, intellectual property management, crowdfunding, and artificial intelligence [20]. Ethereum provides a platform that enables storage and Turing's complete scripting language to make it possible to encode a complete currency in a single contract. Compared with Bitcoin without smart contracts, Ethereum with smart contract features has a broader future development direction, which can support more applications and larger transaction volumes. Coupled with its own high-efficiency characteristics, it will gain a longer-term advantage. But Ethereum also has obvious shortcomings; that is, the code of the application itself and the code generated by the application are in the same block, and the increase in the amount of accumulated data for a long time will cause the expansion of the block. At the same time, in the process of using contracts to form applications, multiple applications and contracts may be controlled by the same institution, which in turn will cause the same economic phenomenon as existing financial institutions. The entire system of Ethereum is controlled by the state or an institution. In this way, the freedom of blockchain transactions no longer exists. The blockchain can support many businesses more easily and conveniently, and it is no longer necessary to design all the blockchain storage by yourself. In order to support more applications, the Ethereum contract provides the simplest possible contract form so that any programmer can write a program that can run on Ethereum. Smart contracts will be allowed to store data in persistent memory. Projects such as Bitcoin and Ethereum are in the form of public chains. The characteristics of the public chain are no confidentiality, no traceability, long confirmation time, no finality, and low throughput, which cannot meet the needs of commercial use, so a blockchain in the form of a private chain appears. Hyperledger proposes to support blockchain based on private chains and alliance chains. It is a new commercial blockchain application that pays more attention to privacy and confidentiality than blockchain projects in the form of public chains. Hyperledger is an enterprise-level distributed ledger technology based on blockchain. It is used to build commercial application platforms for various industries. It has modularity and high performance and reliability and provides business-friendly licenses [21]. Compared with Bitcoin's digital currency system and Ethereum's general public chain platform, Hyperledger provides a general alliance chain platform, which is mainly managed by the Linux Foundation. It uses

public or private networks, which can provide developers with privacy, also inherit the concept of Ethereum smart contract, and support the use of Go, Java, and other development languages to write smart contracts. In Hyperledger, this kind of smart contract is called on-chain code to distinguish between the contract on the blockchain and the written contract, which allows enterprises to use consensus mechanisms and services in a plug-and-play manner. Since the launch of the Hyperledger project, new companies have continued to join the Hyperledger camp [22], including Samsung's IT service subsidiary, Chinese heavy machinery manufacturer Sany Heavy Industries, Huawei, and other large enterprises. The fabric subproject, which has made a huge contribution to the Hyperledger, provides basic privacy, confidentiality, and auditability and uses the Practical Byzantine Fault Tolerance consensus algorithm [23] to provide confidentiality, authority management, and control functions for transactions. At the same time, the functions of consensus mechanism and bookkeeping are separated, in which nodes can be dynamically expanded and contracted, with upgradeable smart contracts, which are expected to increase throughput. And another project Sawtooth Lake, which was originally a blockchain platform mainly contributed and led by Intel, supports a new consensus mechanism Proof of Elapsed Time. In terms of blockchain payment channel network, there are some studies in academia and industry, among which the two projects of Lightning Network [24] (the Lightning Network and Raiden Network [25]) are the most famous. The Lightning Network uses the idea of a payment channel to transfer transactions originally on the Bitcoin blockchain to the off-chain, that is, the Lightning Network, to complete fast instant transactions and return the balance in the channel to the block when the payment channel is closed. The Lightning Network uses the revocable sequence maturity contract RSMC to complete two-way payments while ensuring the security of the balances of both users. In order to realize the transaction between two users without a direct channel, the Lightning Network has designed a hash-based time lock contract HTLC to implement routing on the payment channel network. The Raiden Network uses the same solution as the Lightning Network, but it is a payment channel network for the Ethereum blockchain. Both of these projects are currently under development, and some users have already joined the Lightning Network and Raiden Network, but their availability and security have yet to be verified. To sum up, the existing research on payment channels or state channels mainly focuses on the design of channels and networks, channel routing, rebalancing, and so on; these researches are all in the initial stage, and most of them are based on theoretical research. Therefore, research in the direction of the blockchain payment channel network is very necessary, which will help solve the scalability problem of the blockchain itself and turn the blockchain into an electronic currency system suitable for large-scale applications. In this paper, we mainly study multiparty payment channels based on blockchain and smart contracts and conduct simulation experiments to study the impact of different factors on payment channels.

3. Method

In this section, we will discuss and analyze the stages of the creation of a two-party payment channel, the updates, types (off-chain update; on-chain update), and methods, besides channel closure, as well as the performance of the two-party payment channel. Then, we will introduce the multiparty payment channel, which is designed based on the two-party payment channel.

3.1. Payment Channel Design

3.1.1. Channel Creation Stage. In the channel creation phase, one user sends a request to create a two-party payment channel to another user and attaches his own signature. If the other party agrees to create, the message will be returned with a signature. After the signatures of both parties are collected, a consensus to create a channel is reached, and the requester initiates a request to create a channel to the smart contract. The smart contract will verify the signatures of the two users and check some necessary conditions (e.g., the accounts of both users on the blockchain must have sufficient balance to establish a channel, and a certain fee can be paid). Assuming that the payment channel to be created for both parties is t and the user sending the request is P, then the other user $P_2 = t$.counterparty (P_1). When requesting to create a channel, the message sent by P_1 is

$$tpc - creat = "creat TPCt, \delta_1".$$
 (1)

This means that P_1 requests to establish a new two-party payment channel t with P_2 , where t represents an instance of the channel and δ_1 is the signature of P_1 . If P_2 agrees to create the channel after verifying the signature, it will return a message of the following form:

tpc – creat – agree = "creat TPC
$$t, \delta_2$$
", (2)

where δ_2 is the signature of P_2 on the message. If P_2 does not agree to create the channel, it returns a rejection message:

$$pc - creat - reject = "reject to creat TPC t".$$
 (3)

If the two parties reach a consensus to create a channel, that is, P1 receives the message and signature agreed by P_2 , then P_1 can call the create TPC function provided in the smart contract through RPC and other methods. The smart contract verifies the signatures of both parties and completes the mortgage of funds and the creation of channels. At this time, the deposit required to establish the channel will be deducted from the blockchain accounts of P and P_2 through L.remove $(P1, t.b_1^0)$ and L.remove $(P_2, t.b_2^0)$ and add an instance of the payment channel of both parties to the storage space of the channel through C.addTPC(t). It should be noted that the stage when users reach a consensus to create a channel is a process of interaction under the blockchain. Therefore, the delay is extremely low, and the interaction in a more common network is only affected by the network status. When calling a smart contract to create a channel, both users need to mortgage the assets on their respective blockchain accounts into the smart contract. As a result,

transactions on the blockchain will occur, leading to a long delay in the process. However, in the entire life cycle of the payment channel between the two parties, the process of creating the channel only needs to be executed once, so a long delay here is acceptable.

3.1.2. Channel Update Stage. There are two types of channel updates: off-chain updates and on-chain updates. The procedures of the two update methods will be described in detail as follows:

(1) Off-chain update is the key to both parties' payment channels to reduce transaction delay and increase transaction throughput. Because the process is carried out under the blockchain and no blockchain transaction is generated, there is no need to wait for the transaction to be packaged and confirmed by the block. Compared with the blockchain transaction, a lot of transaction time is saved. In the off-chain update phase of the channel, one user sends a request to update the payment channel of both parties to another user and attaches its own signature. If the other party agrees to update, it will return the message and attach the signature. After the signatures of both parties are collected, a consensus to update the channel is reached. Two users can update the local channel to a new state and initiate a settlement request to the smart contract when settlement is needed. Suppose the payment channel of both parties to be updated is t, and the user who sends the request is P_1 . When requesting to update the channel t, the message sent by P is

$$tpc - update = "update TPC t to t', \delta_1".$$
(4)

This means that P_1 requests to update the two-party payment channel t between $P_2 = t$.counterparty (P_1) , where t' represents a new channel state and δ_1 is the signature of P_1 . This message needs to satisfy $t.b_1^0 + t.b_2^0 = t'.b_1^{now} + t'.b_2^{now}$, because the total balance on a payment channel between two parties will not change. In addition, t1.version > t.version should also be satisfied because the version number is an increasing integer if t'.version < tversion; then, it shows that the requester sent an old version of the channel status, which is a malicious fraud. If P_2 verifies the content and signature of the message and agrees to create the channel, it will return a message as follows:

tpc – update – agree = "update TPC t to t',
$$\delta_2$$
", (5)

where δ_2 is the signature of P_2 on the message. If P_2 does not agree to create the channel, it returns a rejection message:

$$tpc - update - reject = "reject to update TPC t".$$
 (6)

(2) The on-chain update is to call the smart contract interface to update the latest state of the channel to the blockchain. If the two parties reach a consensus to update the channel, that is, P_1 receives the message and signature agreed by P_2 , then P_1 can call the updateTPC function provided in the smart contract through RPC and other methods. The smart contract verifies the signatures of both parties and checks some necessary conditions, such as whether the payment channel exists, whether the balance distribution is reasonable, and whether the channel version is correct, to verify the legitimacy of the updated content. If the verification is successful, you can update t to t' through C.update TPC(t, t'). Generally speaking, the update operation of the smart contract only needs to be performed once before the channel is closed. The remaining multiple updates can only be updated off-chain between the two parties of the channel. After the two parties reach an agreement, the latest channel version can be kept locally.

3.1.3. Channel Closing Phase. In the channel closing phase, one user sends a request to close the payment channel of both parties to another user and attaches his own signature. If the other party agrees to create it, the message will be returned and the signature attached. After collecting the signatures of both parties, a consensus is reached to close the channel. The requester initiates a request to close the channel to the smart contract. The smart contract will verify the signatures of the two users and check some necessary conditions, such as the version number and balance of the channel and distribution. Assume that the two payment channels to be closed are t, and the user sending the request is P_1 . When requesting to close the channel t, the message sent by P_1 is

$$tpc - close = "close TPC t, \delta_2".$$
(7)

This means that P_1 requests to close the two-party payment channel t between $P_2 = t$.counterparty (P_1), and δ_1 is the signature of P_1 . If P_2 verifies the content and signature of the message and agrees to close the channel, it will return a message as follows:

$$tpc - close - agree = "close TPC t, \delta_2",$$
 (8)

where δ_2 is the signature of P_2 on the message. If P_2 does not agree to create the channel, it returns a rejection message:

$$tpc - close - reject = "reject to close TPC t".$$
(9)

If the two parties reach a consensus to close the channel, that is, P_1 receives the message and signature that P_2 agrees to close, then P_1 can call the closeTPC function provided in the smart contract through RPC and so on, and the smart contract verifies the signatures of both parties and completes the refund of the deposit and the channel. At this time, by callingL.add (P_1 , $t.b_1^{now}$) and L.add (P_2 , $t.b_2^{now}$), the balance in the channel will be returned to the blockchain accounts of P_1

and P_2 according to the latest balance distribution status, and the instance of the payment channel of both parties in the storage space is deleted through *C*.removeTPC(*t*). The refund operation involves a blockchain account, which is an on-chain transaction, so a certain handling fee is required when refunding the deposit.

3.2. Performance Analysis of the Payment Channel between the Two Parties. For a two-party payment channel, the main performance indicator is transaction delay, and the transaction delay on the payment channel is mainly affected by the number of off-chain interactions between the two parties of the channel, the number of transactions on the chain, and the number of signatures. Next, in this section, we will analyze the performance of the above-mentioned two-party payment channels and analyze the four stages of channel creation, off-chain update channel, on-chain update channel, and channel closure. The three stages of creation, onchain update, and closing of the channel need to interact with the smart contract. In addition to completing these functions, the smart contract needs to check the legitimacy of the caller each time, for example, whether the channel exists, whether the balance distribution is correct, whether the signatures of both users are correct, and whether the channel version is correct; these operations ensure the security of user assets. In addition, because these three stages need to call the interface of the smart contract and change the channel state in the contract, there will be transactions on the blockchain, so the delay is longer. There is no need to interact with the smart contract when the channel is updated under the chain. It only needs to reach a consensus to update the channel state between the two users. Both users keep a copy of the same latest channel state and have the other's signature on the channel state, so both parties can initiate an on-chain update request to the smart contract at any time. In each stage, the main factors that affect performance are the number of on-chain transactions, the number of off-chain interactive messages, and the number of signatures on the payment channel of both parties. When creating a two-party payment channel, the two users at both ends of the channel need to interact to reach a consensus on creating the channel. The process includes a TPC-create request message and a TPC-create-agree return message, including two signatures in total. After reaching a consensus to create a channel, two users pledge a certain amount to the smart contract to create the channel, so two on-chain transactions will occur. When updating the channel state off-chain, there is no need to call the smart contract interface, and there is no time-consuming on-chain transaction. Two users request updates through the TPC-update message and agree to update the channel through the TPC-update-agree message. This process includes two interactive messages and two signatures, and the off-chain update is the advantage of the payment channel. When the channel is updated on the chain, that is, the latest state of the payment channel is updated to the smart contract, the update interface of the smart contract needs to be called once, so there will be an onchain transaction. Similarly, when two users interact, two messages and two signatures are generated. When closing the payment channel of both parties, the balance needs to be returned to the blockchain accounts of users at both ends of the channel according to the latest channel status in the contract, so two on-chain transactions will occur. In the same way, reaching a consensus to close the channel requires an interaction, including a request for closing the channel and a reply to two messages, which contain the signatures of the two users.

3.3. Multiparty Payment Channel Design. Similar to a twoparty payment channel, the life cycle of a multiparty payment channel mainly includes three stages: creation, update, and closure. This section will combine the model and definition to introduce in detail the specific content of each stage in the life cycle of the multiparty payment channel. In addition, in the following description, we will follow the definitions of related symbols and functions of the blockchain in the first two sections.

The multiparty payment channel in this paper is designed based on the two-party payment channel. The smart contract opens the interface to the user. The user calls the interface provided by the smart contract through RPC and other methods to complete the creation, update, and close of the multiparty payment channel. This paper designs three basic smart contract functions, and the specific content is as follows:

createMPC (parties, tpcs,
$$\delta$$
) \longrightarrow {*i d*, 0}. (10)

This function is used to request the creation of a new multiparty payment channel from the smart contract. parties is a collection of blockchain user addresses, representing all users who will join the multiparty payment channel. tpcs is a collection of the identifiers of a two-party payment channel, which means all the two-party payment channels that are added to the multiparty payment channel. Once a multiparty payment channel is added, the busy field of the payment channel of both parties will be set to 1, indicating that the channel has been added to a multiparty payment channel and cannot be used separately. δ represents the collection of signatures of all users, and the smart contract will verify these signatures and some necessary conditions. After the verification is successful, a new multiparty payment channel is created, and the identifier id of the channel is returned to the user. If the creation fails, it returns 0.

updateMPC(id, mpc',
$$\delta$$
) \longrightarrow {1, 0}. (11)

This function is used to request the smart contract to update the multiparty payment channel whose identifier is id. The input parameter mpc' represents the new state of the multiparty payment channel, including the new balance distribution and new version number of the two parties' payment channels. After the smart contract is successfully verified, the status of the multiparty payment channel is updated according to mpc'. If the update is successful, it returns 1; otherwise, it returns 0.

$$loseMPC(id, \delta) \longrightarrow \{1, 0\}.$$
(12)

After the channel parties reach a consensus, they request the smart contract to close the multiparty payment channel with the identifier id. After the smart contract completes the verification step, it will release all the two-party channels in the channel, that is, set the busy value of all the two-party payment channels in the multiparty payment channel to 0, which means that the channel is idle and can be used as a separate two-party payment channel or join other multiparty payment channels. The smart contract will delete the instance of the multiparty payment channel in the storage space and return 1 to the user if the closure is successful; otherwise, it returns 0.

с

3.3.1. Channel Creation Phase. In the creation phase of a multiparty payment channel, a user sends a request message to the server to create a multiparty payment channel with multiple other users and attaches its own signature, and the server notifies other users. Assuming that the user Pi initiates a request, the request message can be defined as

mpc – create = "create an MPC
$$m, \delta_i^{"}$$
. (13)

In the message mpc – create, δ_i is the signature of the requester P_i for the message, and *m* represents an instance of a multiparty payment channel. For example, *m. parties* represents the addresses of all users participating in the channel, and *m.*tpcs represents that the multiparty payment channel needs to be used, the payment channel for both parties. The server will forward the request to all other users in *m.*parties. For each user P_j who receives the request, if he agrees to create the channel, it will return a consent message to the server:

mpc – create – agree = "create an MPC
$$m, \delta''_i$$
. (14)

Otherwise, the user P_i will return a rejection message:

$$mpc - create - reject = "reject to create m".$$
(15)

If the consent of all users is obtained, that is, the server has collected the signatures of all users for the creation request message, it can call the interface for creating multiparty payment channels provided by the smart contract.

The createMPC (*m*.parties, *m*.tpcs, δ) function initiates a request to the smart contract, where δ is the set of signatures of all users. The smart contract will perform a series of verifications. If the verification is passed, a new multiparty payment channel instance will be created, the busy field of all two-party payment channels in *m*.tpcs will be set to 1, and the identifier of the channel will be returned to the user.

3.3.2. Channel Update Stage. The update phase of the multiparty payment channel, that is, the multiparty transaction phase, also needs to reach a consensus on channel update among all users. Due to the complexity of the multiparty payment channel update stage, the following content will be divided into four parts: multiparty

transaction generation, channel selection, multiparty transaction optimization, and multiparty payment channel update.

- (1) Multiparty transaction generation: The multiparty payment channel in this paper is built on the payment channel layer above the blockchain network layer, and its purpose is to provide services to the upper application layer. Therefore, multiparty transactions are generated in the application layer. For example, in a multiparty game where four people participate in $\{P_1, P_2, P_3, P_4\}$, the rules of the game are that each round has a winner, and other users pay 1 token to the winner. Then, every time a round of the game needs to be settled, a multiparty transaction will be generated at this time. For example, if P_3 is the winner of this round, multiparty transaction а mptx = { $(P_1, P_3, 1), (P_2, P_3, 1), (P_4, P_3, 1)$ }, meaning that each of P_1 , P_2 , and P_4 pays one token to P_3 . Obviously, a multiparty transaction contains multiple two-party transactions. If mptx is split into three separate two-party transactions, theoretically, the same settlement as a multiparty transaction can be completed, but the atomicity of the multiparty transaction cannot be guaranteed. For example, if the two parties' transactions $(P_1, P_3, 1)$ and $(P_2, P_3, 1)$ in *mptx* are successfully settled and the transaction $(P_4, P_3, 1)$ cannot be successfully settled due to insufficient channel balance or routing failure, then the multiparty transaction mptx only partially settled and its atomicity is destroyed. Such a transaction is obviously unreasonable, and the wrong settlement result is difficult to roll back. Therefore, multiparty transactions need to ensure atomicity; that is, all two-party transactions included in a multiparty transaction either all settle successfully or all settlement fails.
- (2) Channel selection: The function of channel selection is similar to routing in order to select the appropriate channel to complete multiparty transactions. The following will illustrate the importance of channel selection through an example.

As shown in Figure 1, it is a multiparty payment channel established by five users. The numbers at both ends of the arrow indicate the balances of the users at both ends of the channel. It can be seen that, in the multiparty payment channels, some channels are redundant, and not all two-party payment channels need to be updated. For example, when P_1 needs to pay a token to P_3 , the payment can be made directly through the channel $P_1 \leftrightarrow P_3$, or the transaction can be made directly through the path $P_1 \leftrightarrow P_5 \leftrightarrow P_3$. Assuming that after a round of the game, P_1 pays a token to P_3 through $P_1 \leftrightarrow P_3$, the balance of the channel becomes $[P_1: 0, P_3: 4]$. At this time, the channel is an extremely unbalanced channel because P is no longer possible to pay to the other party through the

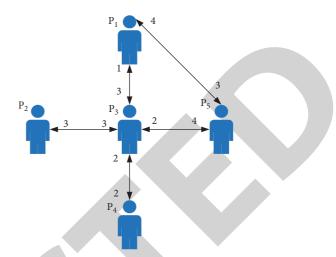

FIGURE 1: Schematic diagram of channel selection.

channel $P_1 \leftrightarrow P_3$. In the next round of settlement, if P1 needs to pay to P3, the channel $P_1 \leftrightarrow P_5 \leftrightarrow P_3$ will be selected for the transaction. Therefore, since each multiparty transaction will cause the balance status of multiple payment channels in the topology to change, we need to select the appropriate channel to complete a transaction. In order to measure the quality of a channel, this paper defines the following concepts:

$$\text{Dist}_{ij} = \frac{b_{ij+}b_{ji}}{b_{ij} + b_{ji} + \sum_{k \in N_{ij}} (b_{ik} + b_{ki} + b_{jk} + b_{kj})},$$
(16)

$$\operatorname{Bal}_{ij} = \frac{\left|b_{ij} + b_{ji}\right|}{b_{ij} + b_{ji}},\tag{17}$$

$$W_{ij} = k_1 * (1 - \text{Dist}_{ij}) + k_2 * \text{Bal}_{ij}.$$
 (18)

In formula (16), $Dist_{ij}$ represents the local proportion of the total channel balance between *i* and *j*, where b_{ij} represents the amount *i* can pay to *j*, b_{ji} represents the amount *j* can pay to $i, b_{ij+}b_{ji}$ is the total balance of channel ij, N_{ij} represents the set of neighbor nodes of channel ij, and a neighbor node of channel ij refers to the node that has established both the payment channel with *i* and the payment channel with *j*. Dist_{*i*} can indicate the local importance of the balance of the channel. The larger the value, the higher the proportion of the balance of the channel *ij*. The larger the value is, the more the channel should be selected. In formula (17), Bal_{ii} represents the balance of the channel subscription, the numerator $|b_{ij}|$ + b_{ii} represents the absolute value of the difference between the balances at both ends of the channel, and the denominator $b_{ii} + b_{ji}$ represents the total balance of the channel. The smaller the value, the more the balance at both ends. The smaller the gap, the more balanced the channel. A balanced channel can support two-way transactions. Formula (18) is a value obtained by combining Dist_{ij} and Bal_{ij}, which is used to express the weight of channel ij. k_1 and k_2 are two adjustable parameters. The smaller the W_{ij} value, the better the quality of the channel.

3.3.3. Channel Closing Phase. In the closing phase of the multiparty payment channel, a user P_i initiates a request to close the channel to the server. This message can be recorded as

$$mpc - close = "close MPC mpc, \delta''_i.$$
(19)

After receiving the request, the server will notify other users in the channel, namely, mpc.otherparties (P_i) . If other users *P* agree to close, they will return a message:

$$mpc - close - agree = "close MPC mpc, \delta''_{i}.$$
(20)

Otherwise, it will return a message that refuses to close:

$$mpc - close - reject = "reject to close MPC mpc".$$
 (21)

After a certain period of time, after the server collects all users' replies, if all users agree to close MPC, the instance of the multiparty payment channel will be deleted, and the busy value of all the two-party payment channels involved will be set to 0, indicating that the payment channel of both parties has withdrawn from the environment of multiparty payment channels and can be used as an independent two-party payment channel or join other multiparty payment channels. After closing the channel, an mpc – closed message is used to notify all users that the channel has been closed. If it is not successfully closed, an mpc – close – failed message is returned.

3.4. Multiparty Payment Channel Performance Analysis. This section will analyze the performance of the multiparty payment channel according to the various stages of its life cycle. If n users participate in the multiparty payment channel, its performance is shown in Table 1. In the channel creation phase, 1 user initiates an application, the server sends a request to other n-1 users, n-1 users will return a response message to the request, and the server will return m messages to n users, notifying them of the result of creating a multiparty payment channel, so there are a total of 3n - 1 messages in the interactive process at this stage. The smart contract is called to generate a transaction on the chain at a time, and each user needs to provide its signature, so there is a total of m signatures.

It should be noted that the multiparty payment channel proposed in this paper can theoretically support any number of users to establish a multiparty payment channel, but it may be limited in actual implementation. For example, in Ethereum, each block has a maximum gas limit, called a gas limit. The more the users in the channel, the more the signatures the smart contract needs to verify and therefore the more the gas it consumes. Only when the gas value consumed to create a multiparty payment channel is less than the limit value, can the multiparty payment channel be successfully created. In other blockchains without a gas limit, the number of users is not limited.

From the above analysis, it can be seen that, on the multiparty payment channel designed in this paper, except for the on-chain transactions necessary to create, update, and close the multiparty payment channel, the rest of the interaction process can be performed off-chain, so instant multiparty transactions can be realized. Compared with direct transactions through Ethereum, it can greatly reduce transaction delays, increase transaction throughput, and ensure the atomicity of multiparty transactions.

4. Experiments and Results

In this section, our aim is to view experiments and results done in order to mainly reduce transaction delay and increase the throughput of blockchain transactions, where we study the influence of factors, transaction amount, transaction distribution, and gas consumption.

4.1. Experimental Configuration. In this experiment, we mainly study three indicators of transaction delay, transaction success rate, and smart contract gas consumption. In the blockchain payment channel network, transaction delay is a key indicator. The purpose of payment channels is to significantly reduce transaction delays and increase the throughput of blockchain transactions. The transaction success rate is also an important indicator, which is related to the availability of the payment channel network. Higher transaction success rate means that the channel can withstand more transactions, and there will be no imbalance in a short period of time that will cause the channel to be unavailable. In this experiment, we studied the influence of factors such as network topology, transaction amount, and transaction distribution on the success rate of transactions. In addition, the gas consumption of smart contracts based on Ethereum is also an important indicator. In Ethereum, transaction fees are calculated according to the amount of gas consumed by the contract. Therefore, this paper also sets up several sets of experiments to study the gas consumption of different transaction methods. In order to verify the feasibility of the multiparty payment channel proposed in this paper in different networks, this paper uses random topologies of different scales to simulate the payment channel network. These random topologies are generated using NetworkX's algorithm. In addition, this experiment also intercepted network topologies of different scales from the real topology of the Lightning Network to conduct experiments.

4.2. Transaction Delay. Transaction delay is an important performance indicator for blockchain transactions and an important factor that limits the throughput of blockchain transactions. In Ethereum, the average block generation time is about 15 seconds, and the transaction throughput is about 15 TPS. Through the payment channel, we can transfer transactions on the blockchain to off-chain to achieve low-latency, high-throughput transactions. We set the block generation time of the simulated blockchain to 15 seconds, which is consistent with the real Ethereum block generation time. We separately studied the transaction delays of direct transactions through Ethereum, two-party payment channel transactions.

Journal of Mathematics

Function	Number of on-chain transactions	Number of off-chain transactions	Number of signatures
Created channel	1	3n - 1	n
Off-chain update channel	0	5 <i>n</i> + 1	Relevant to the actual
On-chain update channel	1	0	n
Closed channel	1	3n - 1	n

TABLE 1: The performance of each stage of the multiparty payment channel of *n* users.

Figure 2 shows the delay of direct transactions via Ethereum varies with the number of transactions. This is achieved by calling a specific interface. This interface can specify the account addresses of the payer and the payee and the transaction amount to initiate an Ethereum transaction. It can be seen from the figure that the more Ethereum transactions, the greater the transaction delay. Because each transaction needs to call the interface once, the average delay of each transaction is about 15 seconds, which is consistent with the block time.

Figure 3 shows the change of the delay of the payment channel transaction between the two parties with the number of transactions. In the simulation experiment, two users are set up, the payment channel between the two parties is established based on the smart contract of the two parties, and the off-chain interaction is completed through socket communication. The communication delay of the network is set to 50 ms. By calling the interface opened by the smart contract to complete the creation, update, and closing of the channel, it can be seen from the figure that the entire transaction process consists of four parts: creating a channel, off-chain transaction, updating the channel on the chain, and closing the channel. Among them, the creation, chain update, and closing of the channel need to call the smart contract interface to generate Ethereum's on-chain transaction, so the delay is longer. The delay in the off-chain transaction part is relatively low because off-chain transactions do not need to call the smart contract interface and will not generate on-chain transactions. Therefore, as the number of transactions increases, the total transaction delay will not increase significantly because once the channel is established, multiple off-chain transactions can be performed, which is extremely low compared to on-chain transactions.

Figure 4 shows the delay of multiparty payment channel transactions with the number of transactions. In this experiment, three users are set up. A multiparty payment channel is established based on a multiparty payment channel smart contract. The communication delay of the network is also set to 50 ms, and users complete off-chain transactions through socket communication. It should be noted that, as the number of users increases, the delay of multiparty payment channel transactions may increase because the number of off-chain interactions will increase.

4.3. Transaction Success Rate

4.3.1. The Impact of Network Topology on the Success Rate of Transactions. In the research on the payment channel network, some scholars mentioned that the hub-and-spoke topology is used to establish a multiparty payment channel;

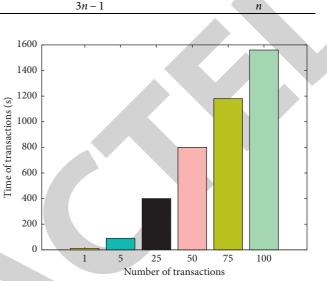

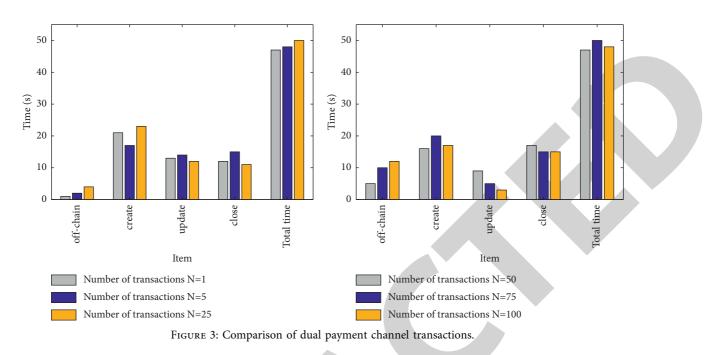

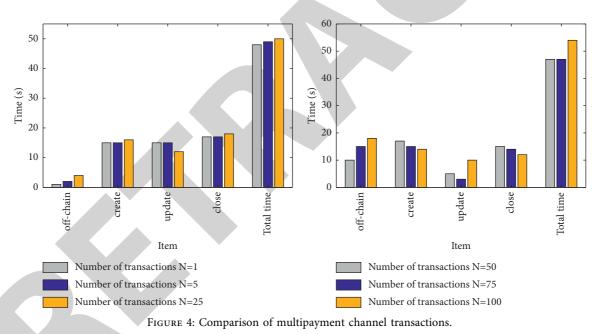

FIGURE 2: The relationship between the number of transactions and time in Ethereum.

that is, all users are connected to the same payment hub, and each user conducts transactions with other users through the hub. In order to study the impact of randomized topology and hub-and-spoke topology on the success rate of transactions, this paper sets up several sets of experiments to run on different networks while ensuring that the number of nodes in the network is the same as the total amount of channels. For the same batch of transactions, statistics on their transaction success rate indicators and the experimental results are shown in Figures 5-7. In this experiment, we set up three different scale pair topologies, consisting of 10 nodes, 50 nodes, and 100 nodes, respectively, and ran multiple sets of transactions with different numbers to study the changes in the success rate of transactions, where "ran" represents a randomly generated topology, and "hub" represents a hub-and-spoke topology. It can be seen from the results in the figure that, in networks of different sizes, the transaction success rate on random topology is higher than that on hub-and-spoke topology. The reason is that, in the hub-and-spoke network, each user only establishes a twoparty payment channel with the hub node. With more and more transactions, the channel will be exhausted. In a random network topology, a user's payment channels are usually established with multiple nodes, so when one channel is exhausted, other channels can be selected for transactions. In addition, it can also be seen that, as the number of transactions increases, the success rate of transactions in both networks will gradually decrease.

In addition to the network topology, the number of nodes in the network will also have a certain impact on the transaction success rate. Therefore, this paper sets up several sets of experiments to study the performance of transaction

success rates in networks with different numbers of nodes. The experimental results are shown in Tables 2–4. Table 2 shows the performance when the quota of each transaction is less than 5 ethers. Table 3 is the performance when the quota of each transaction is less than 10 ethers, and Table 4 is the performance when the quota of each transaction is less than 50 ethers. From these three sets of experiments, it can be seen that, in the case of the same number of transactions, the more the nodes in the network, the higher the transaction success rate because the more the nodes, the more the channels in the network. Each transaction has different paths that can be used for trading. When some channels are exhausted, alternative channels can be selected for trading, so the success rate of the transaction is higher.

4.3.2. The Impact of Transaction Quota on Transaction Success Rate. In addition to the network topology, the amount of each transaction also has an impact on the success rate of transactions in the network. Therefore, this experiment has set up several sets of experiments to explore the impact of transactions with different amounts on the same network. The experimental results are shown in Figure 8. It can be seen that the larger the amount of each transaction, the lower the success rate of transactions in the network. The larger the transaction amount is, the faster the channel will be consumed, and many channels will reach an unbalanced state sooner, so that some channels are no longer available, and the number of transactions that can withstand in the network is relatively small.

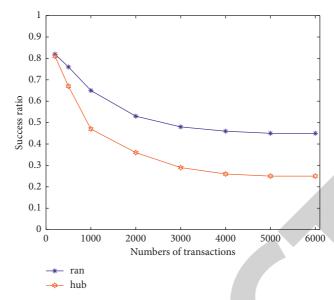

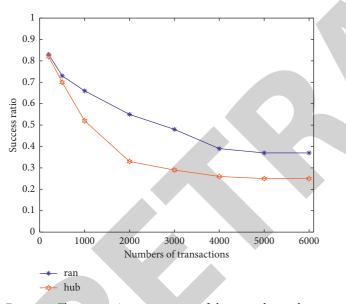

FIGURE 5: The transaction success rate of the 10-node topology.

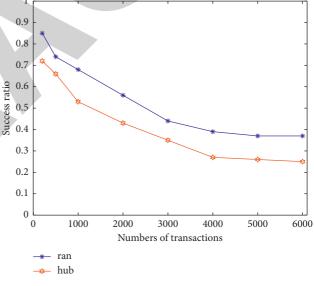

FIGURE 6: The transaction success rate of the 50-node topology.

4.4. Gas Consumption. Gas consumption may be the most concerned metric for users because it involves transaction fees. Therefore, this paper conducts experiments of different scales on the topology of the Lightning Network and the randomly generated topology to study the impact of different payment methods on gas consumption. In this experiment, the channel chain update interface of the smart contract is called once every ten state updates. In actual use, it can be called once before closing the channel to reduce gas consumption. The result is shown in Figure 9. "Ours" in the figure means using the multiparty payment channel proposed in this paper to complete multiparty transactions, "Dual" means using two-party payment channels to complete multiparty transactions, and "Eth" means not using payment channels. To conduct transactions directly

FIGURE 7: The transaction success rate of the 100-node topology.

on the Ethereum blockchain network, from the results in Figure 9, it can be seen that the multiparty payment channel transaction method proposed in this paper has great advantages in gas consumption, which benefits from the channel selection and multiparty transaction optimization proposed in this paper. The strategy reduces the number of interactions between users and also reduces the number of smart contract calls, making smart contracts consume less gas. The transaction method of the payment channel of both parties will reuse some of the same channels, so the performance on gas is slightly worse. If the transaction is performed directly through the Ethereum blockchain, each transaction needs to call the Ethereum transaction interface each time the gas consumption is fixed and the payment delay is long.

Number of transactions			Success ratio (%)		
	N = 100	N = 150	N = 200	N = 250	N = 300

5. Conclusion

In recent years, blockchain technology has developed rapidly, but its shortcomings cannot be ignored. Aiming at the shortcomings of high transaction delay and low throughput of the blockchain network, this paper designs a new multiparty payment channel based on blockchain and smart contracts, which aims to reduce the delay of blockchain transactions and improve blockchain transactions. Throughput, this paper mainly carried out the following tasks: (1) This paper researched the literature and projects related to the blockchain payment network and analyzed the current implementation of the blockchain payment network and its defects. (2) Based on the smart contract, the twoparty payment channel was designed, the process of its creation, update, and closing stages was introduced in detail, the subchannel was designed to support the parallel transaction of the payment channel, and the performance of the two-party payment channel was analyzed. (3) Based on the two-party payment channel, a multiparty payment channel based on blockchain and smart contracts is proposed, which extends the application scenario of the payment channel from a two-person application to a multiperson online application, so that the payment channel can be applied to multiperson online games, crowdfunding, auctions, and other application scenarios, and a trading strategy based on channel selection and multiparty transaction optimization is designed to ensure the balance of the channel and reduce the communication overhead and gas consumption during transactions. (4) This paper developed smart contracts for multiparty payment channels, performed blockchain simulation and client-side simulation, and researched the performance indicators of multiparty payment channels such as transaction delay, transaction success rate, and gas consumption. Through comparative experiments, the feasibility and advantages of the scheme proposed in this paper are verified.

At a time of rapid technological development, 3D stereoscopic images and virtual reality technology are being used in art and design, as well as in the digital conservation of ancient buildings and their restoration. Virtual reality art is a high degree of integration between art and digital technology and is a new form of digital art. As a means of presenting architectural art, digital restoration of ancient buildings is a form of expression that combines knowledge, art, and technology. The digital restoration of ancient buildings and the creation of a 3D interactive display system are of great value for the realization of real space and the preservation of ancient sites. In this paper, we design a system that combines 3D stereoscopic and virtual reality technologies for the restoration of ancient buildings. Through the research and practice of this system, it can be translated into relevant design application research in other art and design fields, which is of great practical significance for future virtual reality expansion space.

1. Introduction

The cultural heritage of ancient buildings carries a deep historical and cultural heritage [1], witnessing a city's stormy history over thousands of years. The unique style and rich cultural connotations of ancient buildings are the inheritors of traditional culture [2] and superior craftsmanship, the crystallization of the wisdom of the ancients. With thousands of years of history and civilization, the ancients have created immortal legends with their hands, and their understanding and creation of the art of architecture in particular has highlighted the characteristics of different civilizations [3]. However, the cultural heritage of ancient buildings cannot be immortalized and is not renewable and is constantly subject to the erosion of the natural environment and the destruction of human activities in the course of history [4]. It has been subjected to natural and human activity over the course of history [5]. All we can do is to preserve it, to slow down its demise, and to pass on its spirit. As people become more aware of the importance of the cultural heritage of ancient buildings, it is important to

preserve it for as long as possible without damaging the buildings themselves. The importance of preserving the cultural heritage of ancient buildings without damaging the buildings themselves is particularly important [6].

Digital restoration of ancient buildings as a means of presenting the art of ancient architecture is a form of expression that combines knowledge, art, and technology [7]. With the development and enhancement of information technology, 3D stereoscopic image technology [8] and virtual interactive technology [9], the digital means of ancient architecture restoration animation digital transformation and innovation, built 3D stereoscopic effect of virtual interactive ancient architecture restoration display system, for the real space to achieve the display, the preservation of ancient architectural sites is of great importance. It is of great importance to protect ancient architectural sites. Wellpreserved physical antiquities play a realistic role in demonstrating the historical process, architectural style, and human life [10]. However, damaged or corroded parts of ancient buildings are unable to demonstrate this cultural need to the world [11]. This is an incomplete presentation of

ancient architecture and culture as a whole. According to a certain phenomenon, ancient buildings that cannot be restored to their true proportions are supplemented by digital forms. Improving the full picture of ancient buildings is of great significance to human understanding of the history and culture of ancient buildings, their architectural patterns, and human life [12]. It will also be a forward-looking initiative.

In terms of application technology, 3D stereoscopic and projection technology and virtual reality (VR) interactive technology have been developed and applied to different fields of art [13]. For example, 3D stereoscopic and projection technology is being used in film industry today, and virtual interaction technology is being used successfully in online games. However, there has been very little research into combining the two together in one field. The reason is that, first, the development of technical procedures is complicated, and the investment of capital and equipment is high; second, the application carrier is not suitable, and people are not yet fully aware of the value and prospect of combining 3D stereoscopic and projection technology with virtual reality interactive technology in the same field. The digital restoration of ancient buildings is the best vehicle for the application of this technology [14], and it also provides a new technology and means for the artistic expression of the restoration of ancient buildings.

In response to the aforementioned technique, this paper presents a practical design and theoretical study of the application of 3D stereoscopic technology and virtual reality to the digital restoration of ancient buildings. The research mainly includes the design of ancient building structure reproduction, 3D stereo image production, and virtual reality interactive technology, as well as the combination of the two-application technology and multichannel stereo projection system application. For many years, people have wanted to experience the real experience of roaming through ancient buildings. Three-dimensional stereoscopic technology combined with virtual reality technology applied to ancient architecture restoration animation will enable the viewer to have the experience of roaming through the disappearance of ancient buildings, experience the construction style of ancient buildings, and the history and culture of ancient buildings. In the coming section, the related technologies are discussed in much detail, such as virtual reality and architecture restoration animation. Moreover, the design of model and production techniques for ancient buildings is also discussed. Section 3 proposed the design of a system for interactive three-dimensional effect technology. Section 4 presents the explanation of development and realization of threedimensional virtual reality technology in the digital restoration of ancient buildings. Section 5 is the conclusion section.

2. Related Technologies

2.1. Virtual Reality. Virtual reality (VR) is a high-tech tool that has emerged in recent years and is mainly used in the design of displays [15, 16], also known as aurora technology

or artificial environments. VR is an integrated and comprehensive technology that involves computer graphics, human-computer interaction technology, sensing technology, artificial intelligence, and other fields. It uses computergenerated software to generate realistic three-dimensional images, with senses such as hearing, touching, and smelling to enable the experiencer to naturally experience and interact with the constructed virtual world. For example, the computer immediately performs calculations when the participant moves position or changes gestures, causing the 3D world image to move or change to create a sense of presence. The technology integrates the latest developments in computer graphics (CG) technology, simulation technology, sensing technology, artificial intelligence, display technology, network parallel processing, and other technologies and is a high-tech simulation system generated with the aid of computer technology.

In a nutshell, virtual reality is a new way for people to manipulate and interact with computer data through visualization. Compared to traditional human-computer interaction, virtual reality has made a qualitative leap forward in terms of technology and ideas. "Virtual reality" is a computer-generated medium. The term "reality" refers to anything or environment that exists in the world in a physical or functional sense. It can be practically realizable, practically unrealizable, or simply unrealizable. Thus, virtual reality refers to a computer-generated environment in a new medium, that is, a simulated, fictitious environment. A person can place themselves into this environment using various special devices and achieve manipulation, control of the environment, and achieve special purposes, that is, the person is the master of this environment.

2.2. Architectural Restoration Animation. Architectural restoration animation refers to the use of computer threedimensional technology to produce animation works about the appearance of ancient buildings [17, 18] and is an important means of digital restoration of modern ancient buildings. Figure 1 shows a 3D restoration of the old Summer Palace site. Surface modelling is one of the most important directions of three-dimensional geometric modelling, which refers to the display of a surface on a computer through modelling and the interactive display and processing of its parameters.

Surfaces can be represented in two ways, nonparametric surfaces and parametric surfaces. Nonparametric surfaces, also known as functional surfaces, refer to surfaces that are described by surface equations over a defined range of domain values and can be expressed as

$$Z = f(x, y). \tag{1}$$

In determining the boundary of the domain of the function surface, the boundary equation y = g(x) is constructed to limit the interval of variation of *x*, so that *x* and *y* vary gradually in fixed steps within the boundary, which in turn operates the coordinate values corresponding to each grid point on the surface, resulting in a grid model of the function surface.

Journal of Mathematics

FIGURE 1: The 3D restoration of the old summer palace.

2.3. Model Design and Production Techniques for Ancient Buildings. Model building is the basis for completing the digital restoration of ancient buildings [19, 20] and the design of ancient building models should follow the following basic principles:

- (i) Accurate model structure, in line with the cultural characteristics of ancient buildings. The models must be built in strict accordance with the references provided by the documentation and original images. The scenic model must be historically accurate, and the furniture must be in accordance with the actual scale and position of the space design. For ancient buildings, the most difficult aspect to control is the structural interplay, especially as most of the buildings are wooden and brick structures, making the model complex to build. How to restore a realistic scene is the key to modelling.
- (ii) The material mapping is detailed and in line with the sense of chronological history. The restored animation of ancient buildings is a vehicle to disseminate information about ancient culture and to meet the needs of people for increased understanding, awareness, learning, and research of lost monuments. The aim is to increase people's understanding, awareness, learning, and research of the lost monuments. It is important to show a realistic image of ancient buildings. The material requirements for the mapping are a detailed analysis of the original building materials and a detailed mapping of the original architecture.

3. Design of a System for Interactive 3D Effect Technology

The technical means of application for the digital conservation of ancient buildings is to digitally produce and exhibit them [21]. The greatest purpose of digital conservation and restoration is to record and pass on history. Many countries and regions are now establishing digital museums and galleries for people to visit and study. With the improvement of modern technology and the transformation of people's needs, the original form of ancient architecture animation show can no longer meet the people's deeper, more thorough and more intuitive understanding of the disappearance of ancient buildings. People's understanding of ancient buildings is no longer limited to the perception of their physical structure, so 3D technology has revolutionized ancient buildings.

Restoration animation of ancient buildings is different from film and animation art. Its purpose is not only artistic expression and representation but more importantly, documentary and recording. For lost buildings, people want more than to be able to touch and feel them in real life, not as a third-person viewer of a restored animation. The most effective way to achieve this is through the use of virtual interaction technology for these buildings that cannot be authentically restored and reconstructed. By applying 3D technology and virtual interactive technology to the restored animation, although the real sense of touch cannot be realized, it is possible to view and navigate the ancient buildings as the first person in the animation and design the roaming route as you wish, while also feeling the real sense of space of the ancient buildings. A screenshot of the 3D restored image video is shown in Figure 2.

3.1. System Comparison. Virtual reality interactive display design for ancient buildings. It is based on the original restoration animation of ancient buildings to achieve 3D stereoscopic effects and interactive experience effects. The aim is to enable the experiencer to truly feel the realities of ancient restoration and interactive experience. At the same time, it can solve the current problems of restoration of ancient buildings, such as the problem of land needed for reconstruction, the technical problem of repairing the original appearance, the problem of long repair time cycles, and even the problem of whether many experts hold the need for restoration of ancient buildings that have been lost, as shown in Table 1.

3.2. Systematic Research Design Thinking Process. The development of a virtual reality interactive display system for three-dimensional effects of ancient buildings requires five stages, namely market research and demand analysis, system design, technology development and application, operation and testing, and effect evaluation as shown in Figure 3.

The system is designed to achieve the following functions:

FIGURE 2: (a) Screenshot from the Dunhuang Mogao Grottoes 3D restoration video—red and blue technology. (b) Screenshot from the Dunhuang Mogao Grottoes 3D restoration video—polarization technology.

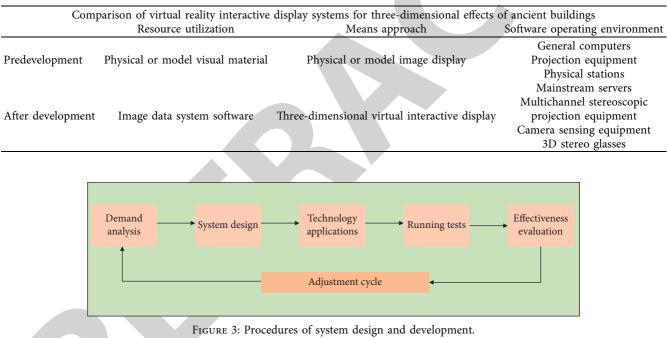

TABLE 1: Virtual reality interactive display design system for building body effects in antiquity.

- (i) 3D visualization of architectural model design and implementation (model design, material UV mapping design, and lighting design)
- (ii) Application of stereoscopic imaging technology
- (iii) Virtual interaction technology design
- (iv) Stereo display technology

A summary of the aforementioned points for the design and development of system can be seen in Figure 4.

3.3. *Technical Programmed Design*. The system is divided into two categories. One is the virtual interactive display design for the 3D effect of ancient buildings on a PC; the other is the virtual interactive display design for the 3D effect

of ancient buildings under multichannel stereoscopic projection. The procedure is the same, but the difference is that the second type is based on the first type with the addition of projection equipment and camera equipment. The control settings are the same as on the PC, except that the mouse directional control is transformed into a character walking motion capture (Figures 5 and 6).

4. The Development and Realization of 3D Virtual Reality Technology in the Digital Restoration of Ancient Buildings

4.1. Realization of the Software Production Process. We use three parts to describe in detail the interactive design and development process of the 3D effect of ancient buildings.

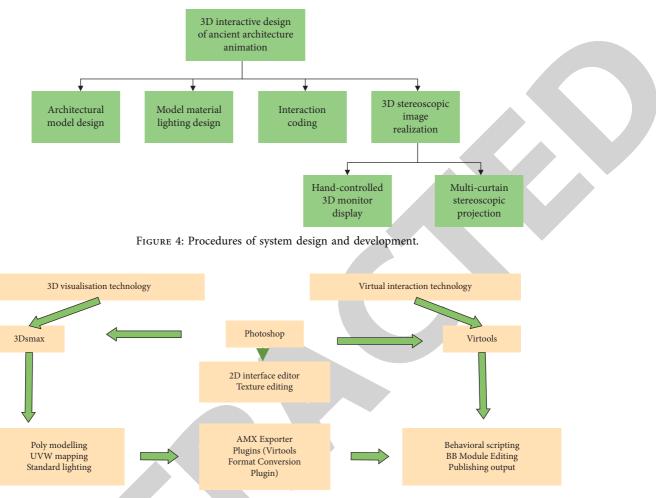

FIGURE 5: A virtual interactive display design to realize the 3D effect of ancient buildings on the PC.

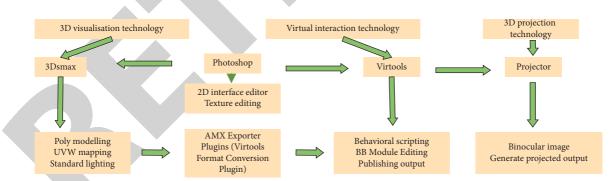

FIGURE 6: Virtual interactive display design to realize the 3D stereo effect of ancient buildings under multichannel stereo projection.

The specific content includes program structure design, resource file design, and specific realization of program difficulties. The software production application flow chart is shown in Figure 7.

4.2. Realization of 3D Visualized Ancient Building Model

4.2.1. Model Design. There are many platforms for visualizing 3D images, and this paper focuses on the field of 3D modelling technology. The 3DS MAX software platform was chosen for this study because of the variety of exported data types and the stability of the combination with Virtools. The most important part of the digital restoration of ancient buildings is the digitization of the display of ancient buildings, and the prerequisite step for the digitization of ancient buildings is the model, understanding the structure of ancient buildings is extremely important, the fundamental of the restoration of ancient buildings animation is to restore the original appearance of ancient buildings without modification.

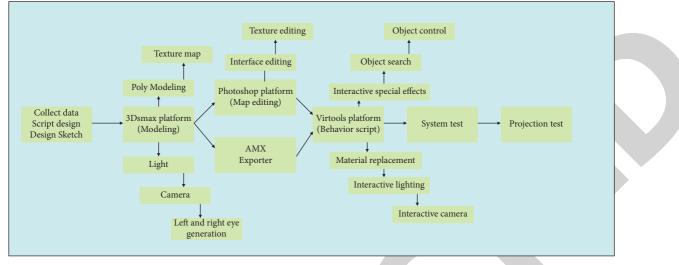

FIGURE 7: Procedures for software production.

The creation of a model of an ancient building generally starts with the geometry, creating box geometry that can be edited, adding lines to the layout based on the general shape of the model, adjusting the divisions, going from whole to partial in a gradual and progressive manner, adding new geometry to create new objects such as tiles, doors, windows, and stone benches if the number of geometry is insufficient. However, the reason for keeping the number of polygonal rows as well as the number of faces to a minimum is to save resources. The problem that also arises is that the model is simplistic and it is not detailed enough. As the model is an architectural model, the model does not produce its own shape changes, allowing for triangular or polygonal surfaces. If you are making a biological model, it is best to ensure that all surfaces are quadrilateral to avoid tearing of the mapping when the object is animated in motion. Once you are satisfied with the model, it is important to focus on the main points and not on everything and to simplify the model outside of the camera and control range. Also give due consideration to the size of the model, the type of material and the cost of production to ensure that art and reality are combined. Figures 8(a) to 8(d) show the process of modelling ancient buildings.

Based on old film, documentation and modern restoration of the building as a reference to create a model of the lost and destroyed parts of the building needed for the restoration animation, the challenge was to accurately represent the complex structural relationships of the ancient building and to control the number of surfaces and lines. The reason for this is that the smaller the amount of data that is transferred to the Virtools software, the better the interaction will be. This depends on the performance of the equipment. This is not normally a consideration if the model is put into operation in a large venue. The eaves and windows are shaped with a return pattern as shown in Figure 9.

4.2.2. Materials UV Mapping. The quality of the mapping depends on the quality of the model if you want to give it a realistic feel with a high level of visual spatial enhancement.

The coordinates of 3D space are divided into three axes X, Y, and Z, corresponding to the 3D space mapping coordinates U, V, and W, so the 3Ds Max mapping coordinates are called UV coordinates. In the architectural performance, according to the picture of the distant reality, primary and secondary relationship, detail requirements, generally will use two kinds of editing UV coordinate distribution tools. UVW map is a simple way of unfolding UV and is often used in architecture to create new objects and objects that are not very important in the distance. Unwrap is often used in architecture for old effects and for models in some close-ups and can often be used in distant views, such as a specific shape of stain in a specific position in a corner. The Unwrap mapping is shown in Figure 10, and the finished Unwrap mapping is shown in Figure 11.

4.2.3. Lighting Design. For architectural models, the lighting is arranged to create a realistic natural ambient light effect. To create the ideal lighting effect in software, it is necessary to have an understanding of light in nature. In the natural environment, there is only one source of light and that is the sun, whereas light comes from many directions, the reason being that the direct light from the sun is refracted or reflected by certain objects. This constitutes the primary and secondary light. For larger scenes, the building is generally illuminated using a multipoint method: one main light source and several auxiliary light sources, the role of the auxiliary light source is to fill in the light, making the outline of the object clear, while making the building have a contrasting relationship between light and dark without producing large contrasts. This is common in nature and is also done in the software to influence the material bump effect. As shown in Figure 12, the contrast between one light exposure and multiple light exposure is shown.

4.3. Application and Implementation of Binocular Stereo Imaging Technology. To create a stereoscopic image, it is important to understand the principles of stereoscopic

Journal of Mathematics

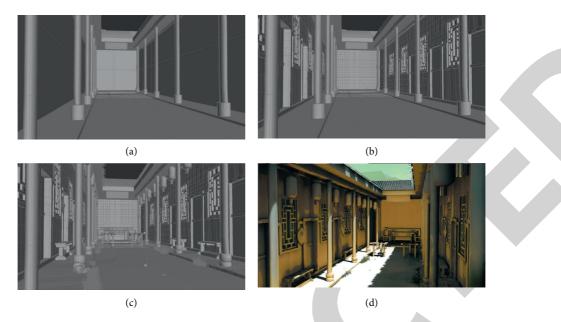

FIGURE 8: (a) Building for foundational model; (b) building for adjustment model; (c) building for modification model; (d) completed rendered model.

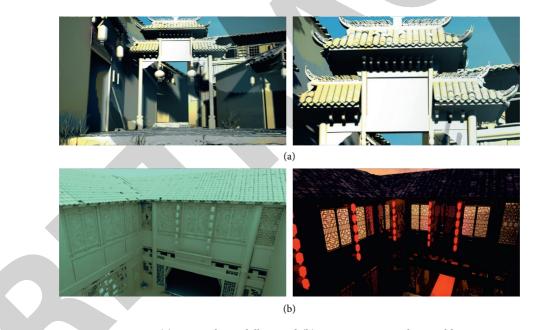

FIGURE 9: (a) Eaves tile modelling and (b) retrospective window molding.

imaging. Since the human eye has a pupillary distance of approximately 65 mm, when people look at an object with both eyes, the left and right eyes each see the left and right sides of the object. The details of the object on the left and right side of the scene are seen by both eyes. This means that two similar two-dimensional images with horizontal parallax are formed on the human retina, and the objects are imaged slightly differently on the left and right retinas. This means that the two two-dimensional images are reproduced with binocular parallax to form a three-dimensional image. We watch the stereoscopic film is to simulate the principle of three-dimensional image formation of the human eye, the first left and right eyes of the monocular image were recorded, through the projector and the corresponding stereoscopic projection equipment, so that the audience left and right eyes respectively see the corresponding monocular image, and then through the brain reproduced into a three-dimensional image. In technical terms, this means that the left and right double images are projected and reflected in the left and right eyes of the audience respectively. In order to achieve a binocular image, we had to create a binocular virtual camera to capture it. The left and right eye images created by the binocular camera are shown in Figure 13.

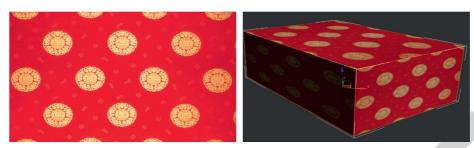

FIGURE 10: UVW map chartlet.

FIGURE 11: Completed unwrap chartlet.

FIGURE 12: One light illuminates the building with a high contrast of light and shadow (a); multiple lights illuminate the building with the right contrast of light and dark, making the picture more vivid (b).

FIGURE 13: Images of the left and right eyes created by the binocular camera, with the left eye sequence static needle image on the left and the right eye sequence static needle image on the right.

4.4. Virtual Interaction Technology Implementation. At the final stage of the model's completion, collision control is done on the objects because the model camera can go

through objects, while in real life, we humans cannot go through objects, so we have to do collision control on the photography. This means that the camera simulates the

FIGURE 14: The camera will not advance if it touches a chair.

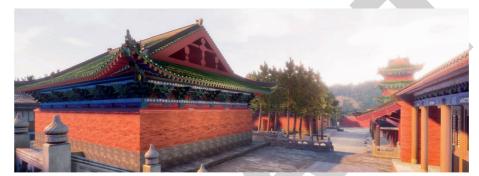

FIGURE 15: Schematic diagram of the digital restoration of the "Shaolin Temple" building applying the virtual reality approach of this paper.

human eye, the camera moves to simulate the character walking, and when we encounter walls and obstructions we cannot get through objects, so it is more realistic (Figure 14).

4.5. Stereoscopic Display Technology Implementation. "Stereo vision" is the brain's satisfaction with the "depth" perception of a stereoscopic image. It is not easy to obtain "depth perception" from the "monocular cues" of traditional flat displays. from the "monocular cues" of traditional flat displays is not easy, the difficulty lies in the habituation of people to two-dimensional images. The difficulty lies in people's habituation to two-dimensional images. These cues include light and shade, relative size, spatial perspective (or atmospheric perspective), motion parallax (by the movement of a nearby object across the field of view into the field of view), and the perception of depth (a visual cue created by the act of moving a nearby object across the field of view to a more distant object than a distant one), and most importantly (or atmospheric perspective), kinematic parallax (a visual cue created by the act of moving a nearby object across the field of view to a further distance than a distant object) and, most importantly, "occlusion cues" (objects obscured above and below or in front and behind) and perspective. All these influences play a key role in stereoscopic vision.

Virtual reality technology actually provides the viewer's eyes with two separate images to create a depth perception effect. When viewing a particular object presented by a pair of identical images. Depending on the difference in horizontal distance between the two images (pupil depending on the difference in horizontal distance between the two images (60 mm pupillary distance), the viewer's eyes will move to "converge" in front of, above or behind the screen, depending on the situation. But the human brain is always focused on the screen, which creates a sense of unreality, and this unreality is what makes our perception of a stereoscopic scene different from that of the real world. In the real world, the visual focus and convergence of our vision is consistent. This known response is broken when viewing stereoscopic images, and this is what causes the discomfort of stereoscopy. While most people are comfortable with the sudden difference in focus and convergence, some people are more sensitive to seeing stereoscopic images and experience discomfort or dizziness and image confusion. Figure 15 shows a schematic diagram of the digital restoration of the "Shaolin Temple" building by applying the methods in this paper.

5. Conclusion

The study of the application of virtual reality interactive technology in the digital restoration of ancient buildings has great application value and practical significance. The method provides a new digital display concept for the restoration of ancient buildings and provides a new virtual presence for the experience. The research is pioneering and highly integrative in the field of digital restoration of ancient buildings, broadening the field of application and interactive experience of virtual reality technology, and providing a very practical and effective means of digital restoration of ancient buildings through the practical development and research of

In view of the inaccuracy of rock movement observation data and the inaccuracy of mining subsidence prediction parameters, a prediction model of mining subsidence parameters based on fuzzy clustering is proposed. Through the analysis of the main geological and mineral characteristics of mining subsidence, the geological and mineral characteristics are simplified according to the third similar theorem. The feature equation is obtained by using the equation analysis method and dimension analysis method. The original fuzzy clustering method is improved, and the IWFCM_CCS algorithm based on competitive merger strategy is obtained. The data of rock movement observation are analyzed by fuzzy clustering. The membership matrix and clustering center of observation station data are obtained, and the regression model based on the weight of membership degree is established. The accuracy and feasibility of the parameter prediction model are verified by analyzing and comparing the actual measurement data and the predicted results of the model. The method reduces the error of the predicted parameters caused by the observation data and provides a method for the future calculation of the predicted parameters.

1. Introduction

Mining subsidence is expected to be developing in the direction of intelligence and visualization. Today, with the rapid development of technologies such as sensors, computers, Internet of Things, and data storage, enterprise information management systems have been continuously popularized. The advancement of modern surveying and mapping science and technology has resulted in more and more data generated from the observation of surface subsidence. If these data are analyzed and processed quickly, abnormal data can be eliminated, and useful data can be extracted; this will greatly improve the accuracy and efficiency of settlement predictions [1-6].

Coal mining affects the production and life safety of people around, so the prediction of mining area deformation becomes very important. The accuracy of rock movement parameters affects the accuracy of the predicted results. Aiming at the problem of inaccurate calculation of rock movement parameters due to the large amount of data generated by rock movement observation, a mining subsidence parameter prediction model based on big data has been established [7–12]. Through the analysis and processing of rock movement observation data, the mining subsidence parameter prediction model is derived, which improves the accuracy and calculation efficiency of rock movement parameters, thereby improving the accuracy of mining subsidence prediction and the safety of the coal mining process. The following is a summary of the research. Section 1 contains the introduction. Section 2 discusses the analysis of the main geological characteristics of mining subsidence. Section 3 discusses the preprocessing of rock movement observation data. Section 4 discusses the project example verification with tables, and finally, the conclusion is given in Section 5.

2. Analysis of the Main Geological Characteristics of Mining Subsidence

Mining subsidence happens when mining operations weaken or hollow out the Earth beneath or near a property's foundations. The ground beneath a building moves downhill as a result of this. Types of mining subsidence are given below.

2.1. Simplified Geological Features. As the stress state around the mining area is constantly unbalanced and balanced during the mining process, mining subsidence is caused by complex physical and mechanical changes. Figure 1 shows the main geological factors related to surface subsidence.

It can be seen from Figure 1 that many complex factors are involved in the mining subsidence process. The mining subsidence method must be simplified in order to conduct additional research on it.

From the similar third theorem [13], geological mining conditions can be obtained: mining conditions are the first mining, the coal mining method is longwall mining, and the roof management method is the full caving method.

2.2. Feature Extraction

2.2.1. Equation Analysis Method. Based on the linear elastic model of inclined coal seams, the following equations are listed:

$$\begin{cases} \frac{\partial \sigma_y}{\partial y} + \frac{\partial \tau_{yz}}{\partial z} + \lambda \rho g = 0 \\ \frac{\partial \tau_{yz}}{\partial y} + \frac{\partial \sigma_z}{\partial z} + \rho g = 0 \\ \varepsilon_y = \frac{\partial u}{\partial y} \\ \varepsilon_z = \frac{\partial w}{\partial z} \\ \gamma_{yz} = \frac{\partial u}{\partial z} + \frac{\partial w}{\partial y} \\ \gamma_{yz} = \frac{2(1+\mu)}{E} \tau_{yz} \\ \varepsilon_y = \frac{1+\mu}{E} \left[(1-\mu)\sigma_y - \mu\sigma_z \right] \\ \varepsilon_z = \frac{1+\mu}{E} \left[(1-\mu)\sigma_z - \mu\sigma_y \right] \end{cases}$$
(1)

In the formula, σ_y and σ_y , respectively, represent the normal stress in two directions; τ_{yz} represents the shear stress; ε_y and ε_z represent the normal strain, respectively; γ_{yz} represents the shear strain; and W and U represent the sinking value and horizontal movement, respectively.

When the two mining subsidence phenomena conform to the similar third theorem, we can get

$$\begin{cases} y'' = y_0 y' \\ z'' = z_0 z' \\ u'' = u_0 u' \\ w'' = w_0 w' \\ \varepsilon_y'' = \varepsilon_{y0} \varepsilon_y' \\ \varepsilon_z'' = \varepsilon_{z0} \varepsilon_z' \\ \gamma_{yz}'' = \gamma_{yz0} \gamma_{yz}' \\ \sigma_y'' = \sigma_{y0} \sigma_y' \\ \sigma_z'' = \sigma_{z0} \sigma_z' \\ \tau_{yz}''' = \tau_{yz0} \tau_{yz}' \\ E'' = E_0 E' \\ \mu = \mu_0 \mu' \\ \lambda'' = \lambda_0 \lambda' \\ \rho'' = \rho_0 \rho' \\ g'' = g_0 g' \end{cases}$$
(2)

Taking $Z_0 = H$, $W_0 = m \cos \alpha$, $E_0 = E_{mid}$, $g_0 = g$ and combining the boundary conditions that when z = H, then $\sigma_y = \sigma_z = \tau_{yz} = 0$, the similarity criterion can be obtained.

 $\begin{cases} \Pi_{1}' = \frac{y}{H} \\ \Pi_{2}' = \frac{z}{H} \\ \Pi_{3}' = \frac{w}{m \cos \alpha} \\ \Pi_{4}' = \frac{u}{m \cos \alpha} \\ \Pi_{5}' = \frac{H\varepsilon_{y}}{m \cos \alpha} \\ \Pi_{6}' = \frac{E}{E_{mid}} \\ \Pi_{7}' = \frac{\rho g H^{2}}{E_{mid} m \cos \alpha} \\ \Pi_{8}' = \lambda \\ \Pi_{9}' = u \end{cases}$ (3)

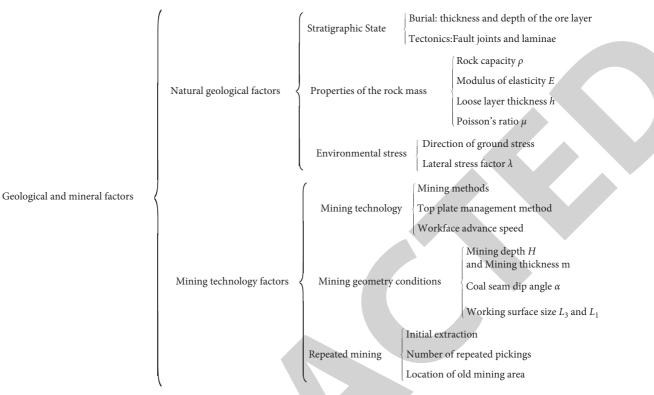

FIGURE 1: Factors of mining subsidence.

Because y, z, w, u, and ε_y are external features, $\Pi'_1 \sim \Pi'_5$ is a dependent variable feature. Therefore, four geological and mineral features $\Pi'_6 \sim \Pi'_9$ are extracted by the equation analysis method.

2.2.2. Dimensional Analysis. For mining subsidence, on the basis of formula (3), the loose layer thickness h, strike length l, and inclined width m are added. The mass system is

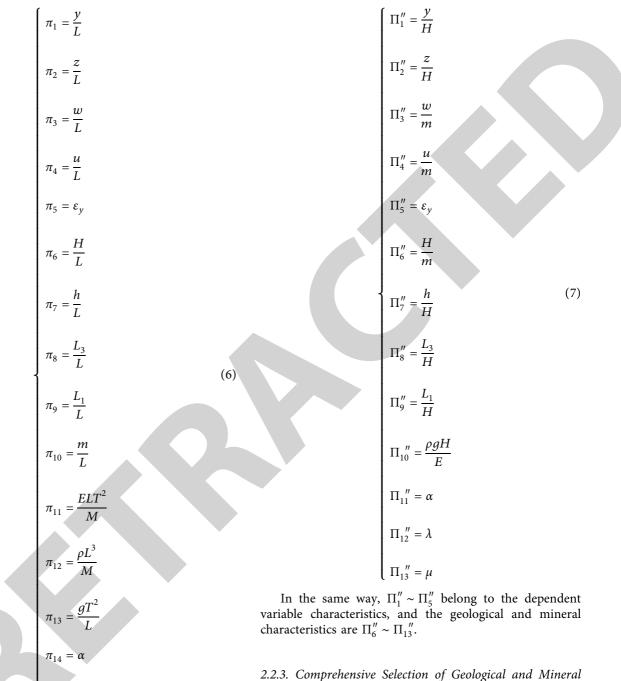

adopted, and the basic physical quantities are M, L, and T. Therefore, the mining subsidence equation is

$$f(y, z, w, u, H, h, L_1, L_3, m, \alpha, \varepsilon_y, E, \rho, g, \lambda, \mu, M, L, T) = 0.$$
(4)

Because of the homogeneity of the dimensions of equation (4), an exponential equation can be obtained.

$$\begin{cases} a_{11} + a_{12} + a_{17} = 0\\ a_1 + a_2 + a_3 + a_4 + a_6 + a_7 + a_8 + a_9 + a_{10} - a_{11} - 3a_{12} + a_{13} + a_{18} = 0\\ -2a_{11} - 2a_{13} + a_{19} = 0 \end{cases}$$
(5)

According to the similarity transformation of the matrix, 16 similarity criteria can be obtained:

 $\begin{bmatrix} \pi_{15} = \lambda \\ \\ \pi_{16} = \mu \end{bmatrix}$

Among them, $\pi_1 \sim \pi_4$, $\pi_6 \sim \pi_{13}$ have no actual physical meaning, and 13 similar criteria can be obtained.

Features. According to formulae (3) and (7), the following analysis and processing can be made:

(1) Because of the similarity of y, z, w, u, $\Pi_1 = \Pi_1'', \Pi_1 = \Pi_2'', \Pi_1 = \Pi_3'', \Pi_1 = \Pi_4'', \Pi_1 = \Pi_5''.$ (2) Since $\Pi_6'' \times \Pi'' = \Pi_7' \times \cos \alpha$, which corresponds to the coal seam depth ratio, $\Pi_{10} = \Pi_7''.$ ③ Due to the influence of loose layers, Π₆ = h/(H - h).
④ Due to the influence of the working surface dimensions, Π₇ = L₃/H, Π₈ = L₁/H.

(5) Due to the effects of modulus of elasticity, inclination angle, lateral stress coefficient, and Poisson's ratio, let $\Pi_9 = E/E_{mi} d$, $\Pi_{11} = \alpha$, $\Pi_{12} = \lambda$, $\Pi_{13} = \mu$.

Similar criteria are selected from this:

In the same way, $\Pi_1 \sim \Pi_5$ belong to the characteristics of the dependent variable, and the geological and mineral characteristics are $\Pi_6 \sim \Pi_{13}$.

2.3. Characteristic Expressions of Expected Parameters.

Based on the observation data, the multiple correlation coefficient method is used to analyze the primary and secondary characteristics of geology and minerals, and the expression can be obtained as [14]

$$f\left(\frac{y}{H}, \frac{z}{H}, \frac{w}{m\cos\alpha}, \frac{u}{m\cos\alpha}, \frac{H}{m\cos\alpha}\varepsilon_{y}, \frac{h}{H-h}, \frac{E}{E_{mid}}, \frac{\rho g H^{2}}{E_{mid} m\cos\alpha}, \alpha\right) = 0.$$
(9)

Therefore, the characteristic expressions of ground subsidence and horizontal movement are

$$\begin{cases} w = f_1\left(\frac{y}{H}, \frac{z}{H}, \frac{h}{H-h}, \frac{E}{E_{mid}}, \frac{\rho g H^2}{E_{mid} m \cos \alpha}, \alpha\right) \\ u = f_2\left(\frac{y}{H}, \frac{z}{H}, \frac{h}{H-h}, \frac{E}{E_{mid}}, \frac{\rho g H^2}{E_{mid} m \cos \alpha}, \alpha\right) \end{cases}$$
(10)

The characteristic expression of the sinking coefficient is

$$q = \frac{f_1((y/H), (z/H), (h/H - h), (E/E_{mid}), (\rho g H^2/E_{mid} m \cos \alpha), \alpha)}{m \cos \alpha}.$$
 (11)

According to the boundary conditions of the mining area, z = H, and z has nothing to do with Y; then,

$$q = g_1 \left(\frac{h}{H - h}, \frac{E}{E_{mid}}, \frac{\rho g H^2}{E_{mid} m \cos \alpha}, \alpha \right).$$
(12)

The characteristic expression of the horizontal movement coefficient is

$$b = g_2 \left(\frac{h}{H - h}, \frac{E}{E_{mid}}, \frac{\rho g H^2}{E_{mid} m \cos \alpha}, \alpha \right).$$
(13)

The characteristic expression that mainly affects the angle tangent is

$$\tan \beta = g_3 \left(\frac{h}{H-h}, \frac{E}{E_{mid}}, \frac{\rho g H^2}{E_{mid} m \cos \alpha}, \alpha \right).$$
(14)

The characteristic expression of the inflection point offset is

$$\frac{s}{H} = g_4 \left(\frac{h}{H-h}, \frac{E}{E_{mid}}, \frac{\rho g H^2}{E_{mid} m \cos \alpha}, \alpha \right).$$
(15)

3. Fuzzy Clustering of Observation Data

3.1. Preprocessing Rock Movement Observation Data. Observation data are used as a classification sample, and clustering features are set as h/(H-h), E/E_{mid} , $\rho g H^2/E_{mid} m \cos \alpha$, and α , and feature matrix $X_{n\times 4}$ is established.

3.1.1. Calculation of the Average and Standard Deviations of Each Feature.

$$\overline{x}_{j} = \frac{1}{n} \sum_{i=1}^{n} x_{ij},$$

$$s_{j} = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (x_{ij} - \overline{x}_{j})} \quad (j = 1, 2, 3, 4).$$
(16)

3.1.2. Calculation of the Standardized Value of the Feature.

$$y_{ij} = \frac{x_{ij} - \overline{x}_j}{s_j}$$
 (*i* = 1, 2, ..., *n*; *j* = 1, 2, 3, 4). (17)

3.1.3. Calculation of the Normalized Value of the Feature.

$$z_{ij} = \frac{y_{ij} - y_{\min}}{y_{\max} - y_{\min}} \quad (i = 1, 2, \dots, n; \ j = 1, 2, 3, 4).$$
(18)

3.2. Fuzzy Clustering. Aiming at the problem that the point density search method may have outliers and inability to initial clustering, the density of the cluster centers is restricted to more than half of the average density, and the clustering validity function is used to determine the optimal number of clusters [15].

$$V_{CS}(C) = \frac{(1/n)\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^{m} \|x_{j} - v_{i}\|^{2}}{(2/c(c-1))\sum_{i,t=1;i\neq t}^{c} \|v_{i} - v_{t}\|^{2}}.$$
 (19)

Due to multiple re-initial clustering, multiple cluster centers with large differences appear. In order to solve this problem, here the sample set is determined first, and then the sample set is arithmetically averaged, so that a more reasonable clustering center can be obtained.

$$V'_{\text{new}} = \frac{n_i V_i + n_j V_j}{n_i + n_j} = \frac{1}{n_i + n_j} \sum_{k=1}^{n_i} x_k + \frac{1}{n_i + n_j} \sum_{k=1}^{n_j} y_k.$$
 (20)

The basic process of fuzzy clustering of the IWFCM_CCS algorithm based on competitive merger strategy is shown in Figure 2 [16–24].

It is calculated that C = 4, which is the optimal value, and the cluster center is

$$Vmat = \begin{bmatrix} 0.03049 & 0.39375 & 0.04195 & 0.23447 \\ 0.02354 & 0.45012 & 0.03571 & 0.08975 \\ 0.09503 & 0.23975 & 0.04427 & 0.09524 \\ 0.02247 & 0.43920 & 0.04074 & 0.46751 \end{bmatrix}.$$
(21)

Analyze the membership degree matrix and suppose that the *i*th station belongs to categories 1, 2, 3, and 4 as $U_1(i)$, $U_2(i)$, $U_3(i)$, and $U_4(i)$; then, $U_1(i)$, $U_2(i)$, $U_3(i)$, $U_4(i)$ are weights for linear regression calculation. In order to determine the relationship between the dependent variable Π_5 and the independent variables Π_1 , Π_2 , Π_3 , and Π_4 , a corresponding weighted linear regression model can be established:

$$Q_{j} = \sum_{i=1}^{n} \left(U_{j}(i) \left(a + b\Pi_{1}(i) + c\Pi_{2}(i) + d\Pi_{3}(i) + e\Pi_{4}(i) + f\Pi_{5}(i) \right)^{2} \right) j = 1, 2, 3, 4.$$
(22)

Through regression analysis, a linear model of expected parameters is obtained:

$$\begin{cases} q = 0.88575 + 0.03425 \frac{h}{H_0 - h} - 0.10526 \frac{E}{E_{\text{mid}}} - 3.60475 \times 10^{-5} \frac{\rho g H_0^2}{E_{\text{mid}} m \cos \alpha} - 2.75187 \times 10^{-3} \alpha \\ b = 0.24819 - 0.00316 \frac{h}{H_0 - h} - 0.00727 \frac{E}{E_{\text{mid}}} + 1.0402 \times 10^{-5} \frac{\rho g H_0^2}{E_{\text{mid}} m \cos \alpha} + 2.6088 \times 10^{-3} \alpha \\ \tan \beta_0 = 1.72130 + 0.01821 \frac{h}{H_0 - h} + 0.19523 \frac{E}{E_{\text{mid}}} - 1.30872 \times 10^{-5} \frac{\rho g H_0^2}{E_{\text{mid}} m \cos \alpha} + 2.93701 \times 10^{-3} \alpha \\ \tan \beta_1 = 1.86926 - 0.02731 \frac{h}{H_1 - h} - 0.05642 \frac{E}{E_{\text{mid}}} - 1.07727 \times 10^{-5} \frac{\rho g H_1^2}{E_{\text{mid}} m \cos \alpha} + 4.38102 \times 10^{-4} \alpha \\ \tan \beta_2 = 1.94122 - 0.18620 \frac{h}{H_2 - h} + 0.16602 \frac{E}{E_{\text{mid}}} - 3.05790 \times 10^{-5} \frac{\rho g H_2^2}{E_{\text{mid}} m \cos \alpha} + 5.03640 \times 10^{-3} \alpha \\ \frac{S_0}{H_0} = 0.14202 - 0.03801 \frac{h}{H_0 - h} - 0.01558 \frac{E}{E_{\text{mid}}} - 4.10583 \times 10^{-5} \frac{\rho g H_2^2}{E_{\text{mid}} m \cos \alpha} - 1.15100 \times 10^{-4} \alpha \\ \frac{S_1}{H_1} = 0.04025 - 0.00281 \frac{h}{H_1 - h} + 0.01443 \frac{E}{E_{\text{mid}}} - 1.67628 \times 10^{-5} \frac{\rho g H_1^2}{E_{\text{mid}} m \cos \alpha} + 2.54414 \times 10^{-3} \alpha \\ \frac{S_2}{H_2} = 0.07102 - 0.02515 \frac{h}{H_2 - h} + 0.00402 \frac{E}{E_{\text{mid}}} - 1.32990 \times 10^{-6} \frac{\rho g H_2^2}{E_{\text{mid}} m \cos \alpha} - 8.32504 \times 10^{-5} \end{cases}$$

4. Project Example Verification

Due to the influence of factors such as the distribution of structures (buildings), it is prone to problems such as missing data in the observation station, which seriously affects the accuracy of mining subsidence prediction. Therefore, taking the observation station data of a mining area in northwestern Liaoning for the same period as an example, the actual predicted parameters and the predicted parameter values are compared to calculate the error between them. Average error and maximum error of predicted parameters are shown in Table 1.

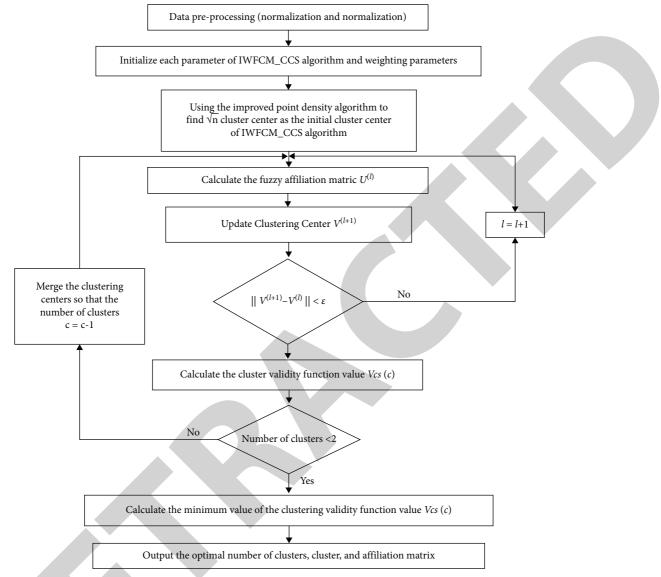

FIGURE 2: The flow of the IWFCM_CCS algorithm based on competitive merger strategy.

The following can be seen from Table 1. ① The average error of the measured parameters and the predicted parameters is roughly equivalent to the tolerance, which meets the engineering accuracy requirements. ② The maximum error of the measured parameters and the predicted parameters is within the tolerance requirements, which shows that the error range of the predicted parameters is comparatively stable. Relative error probability distribution of expected parameters is shown in Figure 3. Error probability distribution of predicted parameters is shown in Figure 4.

It can be seen from Figure 3 that ①the number of stations with the relative error of the subsidence coefficient q less than 5% accounts for 72.64% of the total number of stations, the number of stations with a relative error less than 10% accounts for about 88.72% of the total number of stations, and the number of stations with a relative error less than 15% accounts for about 99.10% of the total number of

stations. (2) The percentage of the number of stations with relative errors of the main influence angle tangents tan β_0 , and tan β_1 , tan β_2 less than 5% in the total number of stations is 70.42%, 68.20%, and 75.35%, respectively. The percentage of stations less than 10% to the total number of stations is 78.38%, 81.73%, and 83.68%, respectively. The percentages of stations less than 15% to the total number of stations were 97.87%, 98.53% and 99.29%, respectively.

The following can be seen from Figure 4. ① The number of stations with an error of less than 2% of the horizontal movement coefficient b accounts for about 62.10% of the total number of stations. The number of stations with an error less than 3% accounts for about 76.58% of the total number of stations. The number of stations with an error of less than 5% accounts for about 97.51% of the total number of stations. ② The percentage of the number of stations whose inflection point offset distances s_0/H_0 , s_1/H_1 , and s_2/H_2 is less than 2% accounts for 54.74%, 45.12%, and

Nowadays, the intercommunication and translation of global languages has become an indispensable condition for friendly communication among human beings around the world. The advancement of computer technology developed the machine translation from academic research to industrial applications. Additionally, a new and popular branch of machine learning is deep learning which has achieved excellent results in research fields such as natural language processing. This paper improved the performance of machine translation based on deep learning network and studied the intelligent recognition of English-Chinese machine translation models. This research mainly focused on solving out-of-vocabulary (OOV) problem of machine translation on unregistered words and rare words. Moreover, it combined stemming technology and data compression algorithm Byte Pair Encoding (BPE) and proposed a different subword-based word sequence segmentation method. Using this method, the English text is segmented into word sequences composed of subword units, and, at the same time, the Chinese text is segmented into character sequences composed of Chinese characters using unigram. Secondly, the current research also prevented the decoder from experiencing incomplete translation. Furthermore, it adopted a deep-attention mechanism that can improve the decoder's ability to obtain context information. Inspired by the traditional attention calculation process, this work uses a two-layer calculation structure in the improved attention to focus on the connection between the context vectors at different moments of the decoder. Based on the neural machine translation model Google Neural Machine Translation (GNMT), this paper conducted experimental analysis on the above improved methods on three different scale datasets. Experimental results verified that the improved method can solve OOV problem and improve accuracy of model translation.

1. Introduction

Language is the most important bridge in communication. With rapid development for modern society and the gradual construction of global integration, the intercommunication and translation of global languages has become an indispensable condition for friendly communication among human beings all over the world. With the development of the global economy, Chinese and English have become the two most influential languages. English-Chinese translation is a shortcut to cross-language communication and plays an important role in the process of global integration. Since the development of translation business, the word-by-sent translation by human translators has long been unable to adapt to this information explosion and fast-moving society. How to transfer information more efficiently, accurately, and conveniently between various English and Chinese has become the focus of research on English-Chinese language translation. Machine translation is a kind of applied technology research in natural language processing (NLP), and it is one of the important branches. At the same time, as a benchmark subject in NLP, research on machine translation is also leading research as well as development of other branches of natural language processing [1–5].

Machine translation studies use machines to achieve automatic conversion for different languages. It highly integrates the knowledge achievements of other disciplines such as mathematics, computer science, and linguistics and is one of the most challenging subjects in NLP. In 1954, IBM cooperated with Georgetown University in the United States to use IBM-701 to complete the English-Russian translation experiment and translate 60 Russian sentences into English. The research of machine translation also officially began at this time. After that, the upsurge of machine translation has swept the world, and countries have launched fierce competition in machine translation. However, machine translation has suddenly encountered obstacles on the road of vigorous development. In 1966, the United States' Automatic Language Processing Advisory Committee issued a report. The report almost completely negated the prospect and value of machine translation. The report caused a serious blow to machine translation. The investment in various machine translation projects dropped sharply until it almost disappeared, and machine translation fell into a trough. Until the mid to late 1970s, with development of computer as well as the needs of economic society, machine translation ushered in recovery and prosperity. Then, after decades of development, two major categories of rule-based machine translation and statistical machine translation are formed.

Since 1990s, statistical machine translation has gradually become the mainstream. Statistical machine translation includes rule-based statistical machine translation and phrase-based statistical machine translation. Statistical machine translation enables natural language to realize automatic conversion from one language to another through the establishment of a probability model. The established probability model is trained in a large-scale parallel corpus and the model parameters are debugged. Because of this, statistical machine translation has the advantages of low labor cost, short development cycle, and better performance, which improves translation efficiency and saves translation costs. The translation platforms of well-known international companies such as Google, Baidu, and Sogou all use statistical machine translation as their core technology. But, at the same time, statistical machine translation still has many unsolvable shortcomings, such as linear inseparability, data sparseness, and inaccurate semantic representation [6-10].

The rise of deep learning has opened up a new path for the research of machine translation. Researchers have found that some techniques in deep learning can alleviate a series of problems in statistical machine translation very well. The application of deep learning technology in machine translation can be divided into two types. The first is that the main framework of the translation model is still the statistical machine translation model, but deep learning techniques will be used to improve the key modules and deficiencies in the statistical machine translation model. The second is a machine translation model based entirely on end-to-end deep neural networks proposed in 2013. This model can directly realize the automatic conversion of source language to target language. This method only relies on neural networks to handle translation problems, and a machine translation model with deep neural networks was born. At the same time, some scholars have carried out special comparison work on the effect of neural machine translation and statistical machine translation. The neural machine translation model has been verified on multiple translation tasks, and its translation performance is much higher than that of the phrase-based statistical machine translation model [11–15]. In the following paper, Section 2 presents a comprehensive discussion on the related works and reviews

the literature. In Section 3, we discuss different methods and models for the machine translation processes. In Section 4, the comparative analysis is carried out through experimental discussions. In Section 5, we present the conclusion of our study.

2. Related Work

With the substantial increase in computer computing power, it is coupled with the expansion of data resources available on the network. As a result of the rapid development of deep learning, the field of machine translation has also undergone tremendous changes. The application of neural networks in machine translation was initially used as an auxiliary part of statistical machine translation. In terms of word alignment, literature [16] extends the hidden Markov word alignment model and uses a feedforward neural network to adjust each subcomponent. In the selection of translation rules, literature [17] uses an autoencoder to learn topic representation in the parallel corpus. By associating translation rule with information, the subject-related rules are selected based on distributed similarity with source language. In terms of sentence reordering, literature [18] uses semisupervised RAE to learn phrase representations. In terms of language models, literature [19] uses FNN to learn n-gram language models in continuous space.

With the aid of neural networks, statistical machine translation achieved the best translation results at the time. However, statistical machine translation also has shortcomings, such as data sparseness. With the increase of translation model subcomponents, training difficulties are caused. This has prompted people to explore the use of neural networks alone to achieve machine translation. Literature [20] proposed the first end-to-end encoder-decoder model structure. This model uses CNN as encoder and RNN as decoder, marking the beginning of neural machine translation. Due to the disappearance or explosion of gradients in the learning process of RNN, it is difficult to model the dependencies between the states in a long-time interval. To solve this problem, literature [21] proposed the RNN encoder-decoder model with new hidden layer nodes, and literature [22] proposed the Seq2Seq learning method, introducing LSTM into the encoder-decoder model.

Literature [23] applies the attention mechanism to the field of machine translation, and its basic idea is that the words in target language sentence are only related to some words in source language sentence. They proposed an encoder-decoder structure that combines attention, and since then machine translation has opened a new chapter. Literature [24] proposes two attention mechanisms, local and global, in NMT. Literature [25] published a translation system GNMT that combines attention mechanism and builds encoder-decoder model with LSTM. Literature [26] published a ConvS2S translation model with a translation effect comparable to RNN-based NMT but with extremely fast training speed using CNN structure. Although the model achieved the best translation results at the time, the limelight was quickly replaced by the Transformer model proposed in the literature [27]. The Transformer model is completely based on attention, and the main components are the multihead self-attention mechanism layer as well as position-by-position feedforward neural network layer. The proposal of Transformer pushes machine translation to a new level. Not only is the translation effect good, but also the model training time is shortened. Literature [28] uses the derived bilingual dictionary to initialize the translation model to achieve unsupervised machine translation. At the same time, the authors of the literature summarized the three principles of unsupervised machine translation and applied the principles to phrase-based statistical machine translation as well as neural machine translation to achieve best unsupervised machine translation results at the time.

3. Method

Neural machine translation model has been a hotspot in machine translation research in recent years, and its potential academic research value and commercial value are huge. With the in-depth research on NMT-related technologies, several versions of neural machine translation systems have been implemented at home and abroad. Based on the GNMT developed by Google, this chapter introduces the Seq2Seq model based on the three optimization technologies Bi-LSTM, residual network, and attention adopted by GNMT. On this basis, two improvement schemes are proposed to alleviate the OOV problem of NMT and the problem of incomplete translation.

3.1. Neural Machine Translation Model Based on GNMT. The most mainstream model currently used in neural machine translation is the RNN-based Seq2Seq. The Seq2Seq model solves the common long-distance dependency problem of word sequences by introducing a special neuron LSTM. The GNMT system released by Google in 2016 also adopted this mainstream model structure and used relevant optimization techniques to optimize the model very effectively.

3.1.1. Seq2Seq Model Based on Bi-LSTM. The mainstream Seq2Seq model is based on the encoder-decoder structure of one-way RNN. In the figure, the encoder receives the embedded word vector of the source language input word sequence at the bottom layer and propagates the context of the source language input word sequence to the next hidden layer through the LSTM. The decoder initializes with the output state of the last hidden layer LSTM of the encoder and starts to predict the output of the target language according to the indication mark at the input of the decoder. Finally, the projection layer of the decoder is calculated by Beam Search, and the word sequence with the largest posterior probability is selected as the predicted translation sequence.

Generally, the embedded word vector input by the encoder carries the relevant information about the context in its forward sequence and backward sequence, but a one-way RNN can only transmit information in a certain direction. By using bidirectional RNN on the said basis, a Seq2Seq model is proposed. Figure 1 is a schematic diagram of the encoder structure constructed by the GNMT model.

In fact, the Seq2Seq model constructed by GNMT consists of an 8-layer LSTM encoder and an 8-layer LSTM decoder. The lowest layer of the encoder uses a bidirectional LSTM network. The forward network layer of the encoder processes the following information of the input word sequence from left to right, and the backward network layer processes the input word sequence from right to left and then connects the output vector sum of the two networks as a vector.

3.1.2. Seq2Seq Model Incorporating Residual Network. GNMT uses a 7-layer unidirectional LSTM and a bidirectional Bi-LSTM in an 8-layer encoder. However, simply stacking multilevel LSTM networks does not necessarily improve the translation accuracy of the model. Experience has found that when the number of stacked layers exceeds 6, the neural network will become difficult to train and its performance will drop rapidly. This is most likely caused by gradient explosion or gradient disappearance. To remove the restriction on the number of network layers of the deep RNN, GNMT has introduced residual connections in both encoder and decoder based on the original Bi-LSTM Seq2Seq model.

Suppose that we use L_i and L_{i+1} to represent the *i*-th and *i*+1-th layers of the stacked LSTM network, respectively, and their corresponding weight parameters are represented by a^i and a^{i+1} , respectively. Then the iterative calculation process of the *i*-th layer and *i*+1-th layer of the LSTM without residual connection at the current time *k* is

$$c_{k}^{i}, h_{k}^{i} = L_{i} \left(c_{k-1}^{i}, h_{k-1}^{i}, x_{k}^{i-1}; a^{i} \right),$$

$$x_{k}^{i} = h_{k}^{i}$$

$$(1)$$

$$c_{k}^{i+1}, h_{k}^{i+1} = L_{i+1} \left(c_{k-1}^{i+1}, h_{k-1}^{i+1}, x_{k}^{i}; a^{i+1} \right).$$

In the above equation, c_k^i and h_k^i , respectively, represent the internal state and hidden layer state of the *i*-th layer of LSTM neurons at the current time *t*. At this time, if a residual connection is added between the output of the *i*-1-th layer and the output of the *i*-th layer, the iterative calculation process of the entire neuron state is changed to

$$\begin{aligned} c_k^i, \ h_k^i &= L_i \left(c_{k-1}^i, \ h_{k-1}^i, x_k^{i-1}; a^i \right), \\ x_k^i &= h_k^i + x_k^{i-1}, \\ c_k^{i+1}, \ h_k^{i+1} &= L_{i+1} \left(c_{k-1}^{i+1}, \ h_{k-1}^{i+1}, x_k^i; a^{i+1} \right). \end{aligned}$$
(2)

It can be seen that, on the original basis, the output items of the low-level LSTM are added. The addition of the residual connection layer allows the reverse gradient of the neural network to easily propagate from the *i*-th layer to the *i*-1-th layer. This method significantly improves the flow ability of the gradient in the back-propagation. This effectively reduces the explosion and disappearance of gradients in deep neural networks, making it a reality to build deep neural network structures.

Journal of Mathematics

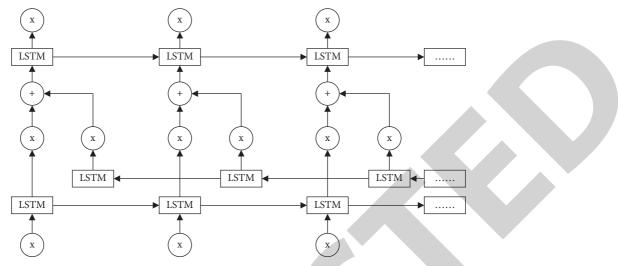

FIGURE 1: Seq2Seq model based on Bi-LSTM.

3.1.3. Seq2Seq Model Incorporating Attention Mechanism. Literature [36] proposed two different attention vector calculation methods, global attention and local attention. Global attention uses the output state of all hidden layers of the highest encoder layer to participate in the calculation. Local attention only selects the local state aligned with the current hidden layer of the decoder to participate in the calculation of the context vector, eliminating the defect of excessive calculation of global attention on long text.

To enable the decoder to be calculated in parallel on multiple LSTM layers as much as possible, GNMT has changed the method used by the above two to obtain the hidden state from the LSTM at the top of the decoder. Instead, it directly obtains the hidden state from the lowest layer of the decoder *st* 1 and adds it to the calculation of the attention vector. Figure 2 shows the complete Seq2Seq model structure of GNMT incorporating the attention mechanism. The entire attention calculation process is still the same as the original calculation process. The GNMT model uses a fully connected feedforward neural network with a single hidden layer as the calculation function of the attention vector.

3.2. Neural Machine Translation Model Based on Improved GNMT. Based on the GNMT model, this paper proposes two optimization schemes to improve the GNMT model from the perspective of solving the OOV (out-of-vocabulary) problem of NMT and the phenomenon of incomplete translation.

3.2.1. Improved Word Sequence Segmentation Method. English word segmentation usually uses spaces between words for segmentation, while Chinese uses characters as the basic unit. Therefore, the word segmentation method is relatively complicated. There are many Chinese word segmentation tools such as Jieba, THULAC, and HanLP that can help us achieve word segmentation. Although the word segmentation methods of the above two languages are different, their common point is that the segmentation of word sequences in the two languages is based on the word level.

The word-based sentence segmentation method is intuitive and easy to understand and conforms to the human cognitive model of language, but its drawback is that it will produce a large-scale vocabulary. Taking the dataset NLPCC2019 as an example, we segmented 4.79 million aligned Chinese and English sentence pairs. A total of 929,220 Chinese words and 815,978 English words were generated. However, due to the limitation of computing performance, the size of the vocabulary usually cannot be too large. The fixed-size vocabulary usually used is 30k~50k. If we limit the size of the Chinese and English vocabulary to 40k, then, in the Chinese and English vocabulary of the dataset NLPCC2019, the word frequency of the English vocabulary with the lowest frequency is 65, and the word frequency of the Chinese vocabulary is 111. Words below this frequency will be replaced with unregistered words UNK in the dataset, which affects the accuracy of the NMT translation model to a certain extent.

To alleviate the OOV problem caused by a fixed-scale vocabulary, the researchers proposed two types of solutions. We know that named entities such as English person names and place names are usually literally translated into Chinese text. Therefore, the first type of solution is to directly copy the unregistered words from the source language to the translation in the target language. Based on this idea, literature [29] proposed a solution to copy the text of rare words using the attention model. However, because the attention mechanism of deep neural networks is not stable and reliable, this method of simply copying the source language text to solve the OOV problem has certain limitations. The second type of solution is to decompose the word sequence of the sentence pair into a string sequence composed of morpheme subword units. For example, the document [30] proposed separating words into a sequence of characters with smaller structures. Literature [31] proposed HybridNMT combining word and character.

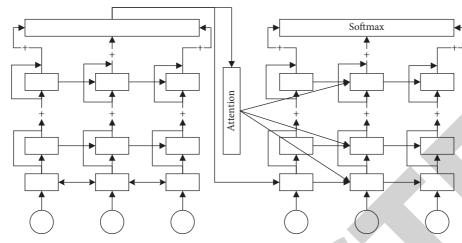

FIGURE 2: Seq2Seq model incorporating attention mechanism.

Literature [32] used the data compression algorithm BPE [33] to segment the original word into a string composed of morphemes and subwords. Although the character sequence based on character greatly reduces the time spent on data preprocessing, it also increases the length of the sequence, thus increasing the time and complexity of model training. Although HybridNMT based on a mixture of word and character can use more corpus, it cannot ensure the correctness of word separation. The subword segmentation based on the BPE compression algorithm balances the relationship between the size of the vocabulary and translation efficiency.

Based on subword, this paper proposes a word sequence segmentation method that combines stemming and BPE algorithm to solve the OOV problem that often occurs in open vocabularies.

(1) Stemming Technology. English belongs to the European language, and the same root of English words usually contains many variants, such as the singular and plural of nouns and the conjugation of verbs in different tenses. It can be seen that English contains a large number of inflections or compound words based on the same root. Stemming technology is the process of removing the affixes of inflection words or compound words to obtain the root of the word. The use of stemming technology can effectively reduce a part of the vocabulary without losing most of the semantics.

(2) Byte Pair Encoding and Stemming. Byte Pair Encoding (BPE) is a data compression algorithm. Its core idea is to replace the bytes pair with the highest frequency in the sequence with a new byte during each iteration. The one-iteration process of the BPE algorithm is described as follows. First, calculate the total frequency of adjacent cooccurring character pairs in the sequence in the vocabulary. Repeat the above statistics on all character sequences to obtain a set consisting of cooccurring character pairs and their total frequencies. Then select the character pair with the highest occurrence frequency in the set pairs, merge them, and finally update the corresponding character sequence in the vocabulary to complete an iteration process. To prevent the high-

frequency words in the original vocabulary from being segmented into morpheme subwords, we can set a threshold to ensure that words with a frequency higher than the threshold are not segmented and save this part of the word in the vocabulary. Combining the stemming technology, to avoid the polysemy problem caused by the use of stemming, all words in the range of the high-frequency word shortlist will not be stemming. All other words that are not in the shortlist will be replaced with stems, and a new dataset will be generated after the replacement.

Based on the above explanation, this article adopts a different word sequence segmentation scheme from GNMT. For the processing of English word sequences, we adopted a new word sequence segmentation scheme combining stemming and BPE. For the Chinese word sequence, a word segmentation method based on the unigram model is used to directly segment the Chinese sentence into characters. This segmentation method can significantly reduce the vocabulary of the Chinese vocabulary.

3.2.2. Improved Attention Structure. Using the attention mechanism is a very effective method for NMT to process long sentence translation. The reason is that using the attention mechanism can improve the ability of the NMT decoder to obtain the context information of the encoder and assist the decoder in making output predictions. Since attention was proposed, many variants have been derived.

To solve the incomplete translation problem of GNMT and further improve the decoder's ability to obtain context information, this paper proposes a new and improved attention calculation method to assist the calculation of the GNMT speculation layer.

The NMT decoder has three input values involved in the calculation at the hidden layer output s_k at the current time k. They are the hidden layer output state s_{k-1} of the decoder at the previous moment, the predicted output y_{k-1} of the decoder at the previous moment, and the context vector c_k at the current moment t generated by the attention calculation.

We noticed that the decoder has a corresponding context vector c_k that carries important contextual information at each

time k, and there must be some connection between the context vectors at different times. Considering that the semantic structure of the source language and the target language may be very different, the word sequence of encoder and decoder may not have the same context structure. Therefore, the context vector with the highest correlation with the current moment c_k is not necessarily c_{k-1} . When focusing on the context vectors that are close to it at the same time to ensure that current c_k can obtain the most accurate context information. Based on this idea, we give an improved attention structure that uses a deeper attention calculation to increase the attention to context information.

Assuming that the original context vector corresponding to the decoder from time 0 to time k is $C = (c_1, c_2, ..., c_k)$, the context vector that has been improved and updated is $\hat{c} = (\hat{c_1}, \hat{c_2}, ..., \hat{c_k})$. We define the correlation between the current context vector c_k and the historical context vector c_h as follows:

$$d_h = G(c_k, c_h). \tag{3}$$

Function G is a function mapping that measures the correlation between vectors, and d_h is called the correlation coefficient of the vector. According to mathematical experience, function G can be defined as the angle cosine operation of a vector, the distance of a vector, or the cross entropy of a vector. Similar to the calculation process of the attention vector, the correlation coefficient d_h needs to be normalized to a real number in the range of 0~1.

$$\alpha_h = \frac{\exp\left(d\right)}{\sum_{i=1}^{k-1} \exp\left(d_i\right)}.$$
(4)

Vector $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_h)$ composed of *t* correlation coefficients is called the correlation vector of the context vector. Let $c'_k = \sum_{i=1}^{k-1} \alpha_i c_i$; then the calculation formula of the context vector \hat{c}_k at the current moment of improving attention is

$$\widehat{c}_k = c_k + \sum_{i=1}^{k-1} \alpha_i c_i.$$
(5)

It can be seen that the calculation of the improved context vector $\hat{c_k}$ comprehensively considers the context vector c_k at the current moment and the weighted and quantized historical context vector c'_k . Therefore, the hidden state of decoder at time *t* is calculated as

$$s_k = f(y_{k-1}, s_{k-1}, \hat{c_k}).$$
 (6)

Since this article is based on GNMT's Seq2Seq model, it incorporates an improved deep attention.

4. Experiment and Discussion

In this section, we carried out the comparative analysis for the proposed methods and the existing ones. To this end, we performed different experiments and studied the experimental results carefully. As a result, it was verified that the proposed methods stand out as compared to the rest of the techniques.

4.1. Dataset. This paper uses two different scale datasets NLPCC2019 and OPUS to train, verify, and test the NMT model. The Chinese and English parallel corpora from three different sources are all downloaded from the Internet, and they are publicly available and free data materials. OPUS dataset is derived from the translation of Chinese and English movie subtitles, which contains 9,304778 aligned Chinese and English sentence pairs, with a total data size of 1.17 GB. After observation, it was found that the Chinese translation part contained garbled characters. Some Chinese translations are mixed with English original sentence information, which will interfere with translation. Some Chinese translations contain obvious translation errors. After data preprocessing and screening, we eliminated this part of the data, and a total of 7,256,783 pairs of sentences in Chinese and English were obtained. NLPCC2019 dataset provides 5.2 million aligned Chinese and English sentence pairs. The text corpus comes from various industries and the total data size is 1.1 GB. After sampling and analysis, a small number of sentence pairs in this dataset have translation errors. We screened the dataset on a large scale and selected 2,714,662 high-quality sentence pairs. According to statistics, in the filtered text corpus, the average length of Chinese sentences is 19 words, and the average length of English sentences is 37 words. There are few long sentences in the corpus, and we limit the maximum length of sentences to less than 100. Table 1 shows a simple comparison of the two datasets.

4.2. Experimental Environment. The experimental part of this article is carried out on the Ubuntu operating system, using the currently very popular deep learning framework PyTorch, combined with GPU for experimental model building and calculation. The details of the experimental environment are shown in Table 2. The evaluation metric is BLEU.

4.3. Evaluation on Network Training. In a deep learning network, one of the most important indicators is the convergence of the network. To evaluate whether the network designed in this paper can effectively converge on the dataset, this work analyzes the training loss and BLEU score. The results are shown in Figures 3 and 4.

It can be seen from the two figures that as the training progresses, the training loss gradually decreases, and the training BLEU gradually increases. On NLPCC2019 and OPUS, when the training epoch reaches 300, the loss value almost no longer decreases, and the BLEU almost no longer rises, which indicates that the deep learning network has reached a state of convergence. It also illustrates the reliability and effectiveness of the network designed in this project.

4.4. Comparison with Other Methods. To verify the validity and correctness of the method designed in this work, we compare the method in this paper with other English machine translation methods. The methods compared are

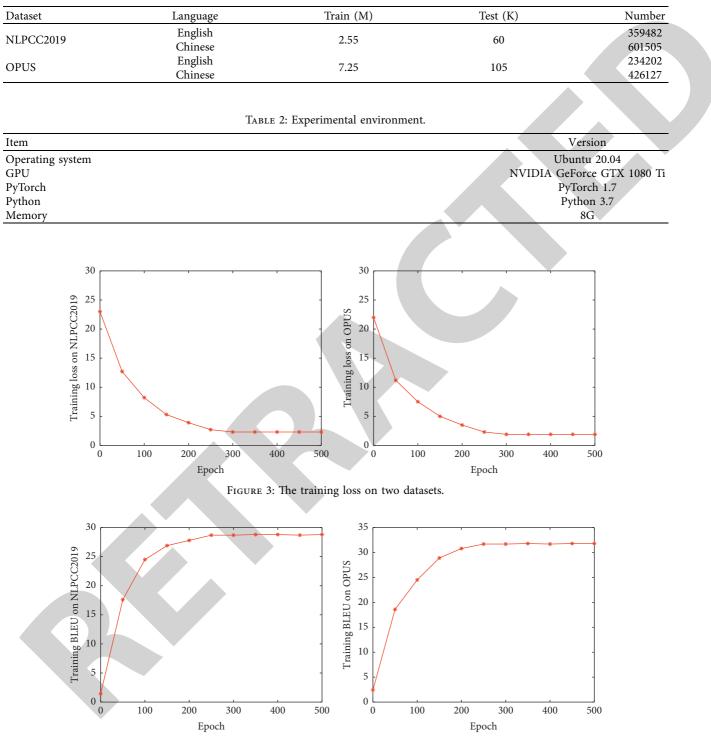

TABLE 1: Comparison of detailed information of two datasets.

RNN-Based, LSTM-Based, Seq2Seq-Based, and Attention-Based methods. The experimental results are shown in Table 3.

It can be seen that, compared with the other methods listed in the table, the improved GNMT (IGNMT) method designed in this article can obtain the best performance on the two datasets. In NLPCC2019 dataset, compared with the best performing method, IGNMT can achieve a 1.1% increase in BLEU. On OPUS, compared with the best performing method, IGNMT can achieve a 1.5% increase in BLEU. It can be proved that the method proposed in this paper can achieve advanced performance, and it also proves the effectiveness of the method proposed in this work.

TABLE 3: Comparison with other methods.

Method	NLPCC2019	OPUS
RNN-Based	12.7	13.4
LSTM-Based	14.4	14.9
Seq2Seq-Based	16.2	16.8
Attention-Based	17.4	18.2
IGNMT (Ours)	18.5	19.7

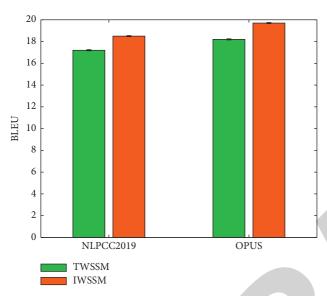

FIGURE 5: Evaluation on improved word sequence segmentation method.

4.5. Evaluation on Improved Word Sequence Segmentation Method. As mentioned early, this work proposes an improved word sequence segmentation method. To verify the effectiveness and correctness of this improvement measure, this work will compare and analyze the network performance when the traditional word segmentation method is used and the network performance when the improved word segmentation method is used. The experimental results on NLPCC2019 and OPUS are illustrated in Figure 5. TWSSM is the traditional word sequence segmentation method. IWSSM is the improved word sequence segmentation method.

Obviously, with the improvement of word segmentation methods, the performance of the network can be effectively improved. On NLPCC2019, using the improved word segmentation strategy can get a 1.3% increase in BLEU. On OPUS, using the improved word segmentation strategy can get a 1.5% increase in BLEU. This experiment can prove the validity and reliability of improved word sequence segmentation method proposed in this work.

4.6. Evaluation on Improved Attention Structure. As mentioned early, this work proposes an improved attention structure. To verify the effectiveness and correctness of this improvement measure, this work will compare and analyze the network performance when the traditional attention structure is used and the network performance when the

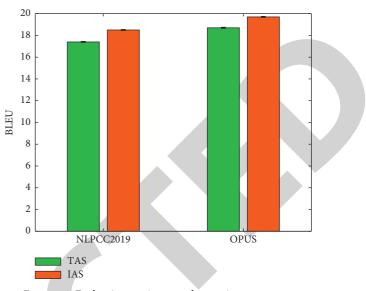

FIGURE 6: Evaluation on improved attention structure.

improved attention structure is used. The experimental results on NLPCC2019 and OPUS are illustrated in Figure 6. TAS is the traditional attention structure. IAS is the improved attention structure.

Obviously, with the improvement of attention structure, the performance of the network can be effectively improved. On NLPCC2019, using the improved attention structure strategy can get a 1.1% increase in BLEU. On OPUS, using the improved attention structure strategy can get a 1% increase in BLEU. This experiment can prove the validity and reliability of improved attention structure proposed in this work.

5. Conclusion

Since the introduction of deep learning-based neural machine translation, it has replaced traditional phrase-based statistical machine translation method and has become a research hotspot in English translation language processing. As GNMT has surpassed traditional statistical machine translation methods on multiple datasets several times, it has greatly encouraged researchers to study neural machine translation. Based on open-source GNMT, this research studied the application of neural machine translation in English intelligent recognition translation. In view of the current research status of neural machine translation, this work proposed two research contents in different directions. The first is to solve OOV problem of neural machine translation on unregistered words and rare words; this study combined common stemming techniques in English text preprocessing with BPE and proposed a different and improved word sequence segmentation method. Using this method, English text can be segmented into word sequences composed of subword units, and Chinese text can be segmented into character sequences composed of Chinese characters. Secondly, for the prevention of the decoder from experiencing incomplete translation, we adopted an improved attention mechanism that can improve the decoder's ability to obtain contextual information. In the improved attention mechanism, a two-layered calculation structure was used to focus on the connection between the context vectors at different moments of the decoder and to improve the ability of attention mechanism to obtain the global context information of the encoder.

Data Availability

The datasets used during the current study are available from the corresponding author upon reasonable request.

Conflicts of Interest

The author declares that he has no conflicts of interest.

Traditional methods have the problems of insufficient accuracy and slow speed in human posture detection. In order to solve the above problems, a limb movement detection method in competitive sports training based on deep learning is proposed. The force change parameters of sports limb movements in the process of sports are computed to achieve the detection of limb movements in competitive sports training, and the limb movement characteristics in competitive sports training are extracted using a deep learning algorithm. The experimental results show that the limb movement detection method based on deep learning in competitive sports training has significantly higher detection accuracy and faster speed.

1. Introduction

With the deepening of the research on artificial intelligence, the application direction of artificial intelligence technology has become more and more extensive. The detection of human posture is an important application direction [1]. It has a wide range of applications and rich application value in the fields of behavior detection, video capture, and computer graphics. An enhanced depth learning approach is presented based on the depth learning method, with the goal of increasing detection speed, reducing the number of parameters, and shrinking the model size to make practical application easier [2, 3]. The main modifications of the original model are as follows: speed and detection accuracy. The weight of the trained model is trimmed to compress the model and improve the detection speed. In addition, this paper also designs and tests a set of sit-ups based on the proposed improved open model. The hardware structure is simple, the human posture detection speed is fast, and the detection accuracy is high and has strong practicability.

2. Detection of Deep Learning of Limb Movements in Competitive Sports Training

2.1. Recognition of Limb Movement Characteristics in Competitive Sports Training. Human motion recognition is mainly composed of data acquisition and data analysis. Data acquisition is composed of multiple sensor nodes and data receiving equipment, which is used to complete the acquisition of human motion signal data. Data analysis is mainly composed of various analysis algorithms integrated in PC. The deep learning method is essentially a dual parallel convolution network model [4]. It uses two convolution networks at the same time. One convolution network locates the position of key parts of the human body from the image, and the other convolution network is used to connect candidate key parts to form limbs [5]. Then, the results of the two convolution networks are summarized for pose assembly to complete the detection of human pose in the image. Obviously, the construction of this dual parallel convolution network will greatly consume computing resources [6]. Therefore, in the implementation, the deep learning method, first, uses a convolution network to preliminarily extract image features and then inputs the features into the dual parallel convolution network for subsequent processing, which is equivalent to merging the lower part of the dual parallel convolution network into a convolution network to save computing resources.

Figure 1 shows the detection process of the deep learning method, which is the visualization of the process. First, the VGG-19 network 9 is used to extract the bottom features of the input image, as shown in Figure 1, which is the output of some convolution layers [7]. The underlying characteristics are then fed into two concurrent convolution networks, one of which generates the confidence graph using the nonmaximum suppression procedure. Depth picture sequences have shown to be very valuable in the development of quick 3D human skeletal joint estimation. Many depth sensors with high sample rates and inexpensive prices have lately been launched, owing to the fast development of depthsensing technology [8]. Table 1 gives some common depth sensor information. The depth image sequence with high resolution and high sampling rate provided by these sensors can provide accurate and sufficient information for 3D human skeleton joint estimation.

The behavior and motion capture platform is composed of an attitude and heading reference module and a computer. It can capture the motion of the human trunk, upper and lower arms, and large and small legs [9]. When the platform starts working, the attitude and heading reference module uploads the attitude data captured by human behavior at the frequency of 30 Hz through the wireless network, receives the data through the computer, and receives the data sent by the attitude and heading reference module by address query. In order to reduce the volume and electromagnetic wave interference, it is necessary to enhance the independence of the platform. The extended Kalman filter is used to collect the data in real time, conduct data fusion after denoising, capture the attitude angle, angular velocity, and acceleration, and then send the data to the upper computer through the wireless network module. The data are processed by the upper computer program and transformed into the signal form [10]. The Kalman filter is used to collect the original data, and the relative attitude angle is obtained through the conversion relationship between Euler angle and quaternion. The acceleration is collected and calculated the absolute attitude angle by using the direction cosine conversion of the magnetic field between the geographic coordinate system and the Kalman filter coordinate system, as shown in Figure 2.

It can be seen from Figure 2 that *G* represents the gravity direction, and the XYZ axis represents the coordinate system. When the attitude and heading reference module rotates around the *x*-axis and *y*-axis, the included angle between the two axes and the gravity direction g will produce a certain angle with the rotation. When the module rotates around the *z*-axis, the *z*-axis and the gravity direction *G* are collinear, and the included angle will not change, so it needs to be compensated by the magnetometer [11]. When using the magnetometer to calculate the *z*-axis attitude, the

data are divergent and cannot be used for a long time. However, the accelerometer is vulnerable to vibration factors and has poor dynamic performance. Therefore, it is necessary to fuse the data generated by the accelerometer to obtain a stable and accurate attitude angle. The filter gain of the accelerometer is updated in real time according to the vibration intensity to ensure the dynamic response characteristics of the attitude and heading reference module and quickly eliminate the steady-state error [12]. The Euler angle is utilized to determine the tilt angle roll and pitch angle based on the three-axis acceleration processed by the Kalman filter, and the yaw angle is derived based on the tilt compensation magnetometer value. The acceleration value is read and treated it according to normal orthogonalization procedures. The Euler angle conversion matrix is used to determine the high-precision attitude angle based on the state vector [13]. Through the tilt angle, the action signal of human walking and running behavior can be captured, the pitching angle can capture the action signal of human static behavior, and the yaw angle can capture the action signal of human jumping and squatting behavior. According to the design requirements of the software function, combined with the actual chip function, the embedded software program is compiled. The software design includes the software design of data acquisition node and data receiving gateway. The working mode can be divided into working mode I (real-time USB data communication), working mode II (nonreal-time USB data communication), and working mode III (nonreal-time network port data communication). The program flow chart is shown in Figure 3.

After connecting the information collection device with the computer through the USB interface, open the corresponding serial port and set the baud rate to 115200. In order to solve the problem that the refresh rate of reading inertial sensor data does not match that of manikin animation, a thread for reading inertial sensor data and a thread for reading attitude data are created [14]. The thread of the reading inertial sensor reads the original data from the inertial sensor, which is composed of a three-axis accelerometer, three-axis magnetometer, and three-axis gyroscope, and then uses CRC16 to verify the data. After verification, the data fusion algorithm is used to fuse the data into attitude data and then read the attitude data. The thread reads the attitude data from the queue and uses the attitude data to drive the dimensional manikin.

2.2. Numerical Calculation of Force Changes of Limb Movements in Competitive Sports Training. The human skeleton joint data are obtained based on deep learning, and it is necessary to remove the original skeleton joint coordinate data of human motion from the Kinect V spatial coordinate system (a', b', c') which map to the human body spatial coordinate system o(x, y, z). The human body coordinate system o(x, y, z) takes the center of gravity of the human body, that is, the spine base node as the origin o, and the right in front of the human body as the positive direction of the z-axis. Let P a'_0, b'_0 , and c'_0 be the 3D coordinate system,

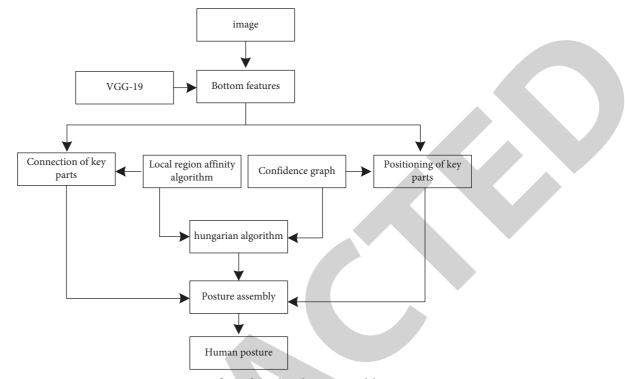

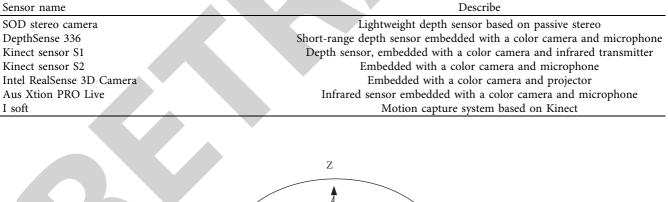

FIGURE 1: Processing flow of the deep learning model.

TABLE 1: Common depth sensor equipment.

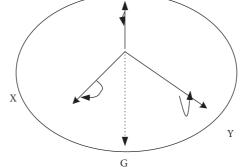

FIGURE 2: Schematic diagram of body gravity direction.

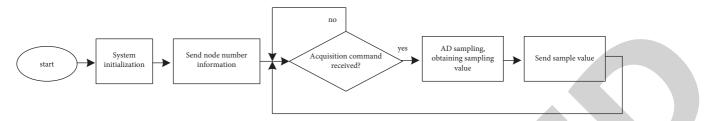

FIGURE 3: Collection processes of action characteristics of human motion nodes.

o(x, y, z) be the coordinate of P corresponding to the human spatial coordinate system o(x, y, z), then according to the translation and rotation transformation of the 3D graphics spatial coordinates.

$$o(x, y, z) = V(a', b', c') \begin{pmatrix} 1 & a & 0 & 0 \\ 0 & 1 & 0 & b \\ c & 0 & -1 & 0 \\ -a'_0 & -b'_0 & c'_0 & 1 \end{pmatrix}.$$
 (1)

Get

$$\begin{cases} s = k \cos a (z'_0 - z') (x' - x'_0) \\ m = w \tan c (y' - y'_0) (z'_0 - z'), \\ n = p \sin b (x'_0 - x') (y' - y'_0) \end{cases}$$
(2)

where k, w, and p, respectively, correspond to the coordinate quantities of "spine base" node o in Kinect G'_r spatial coordinate system. L'_r represents the rotation angle of the human body relative to xoy plane, and $a \in [-70, +70]$ can be obtained by calibrating specific joint points. Since "hile" and "upright" are symmetrical relative to Y'_l and X'_1 axis, these two points are selected as calibration points. Assuming that their coordinates in oxyz coordinate system are (x, y) and (x, y), respectively, then

$$\alpha = \arctan\left(\frac{(G'_r - X'_1)}{(L'_r - Y'_l)}\right).$$
(3)

The captured human behavior data may have outliers. The existence of outliers will affect the overall classification results, resulting in inaccurate classification results. Therefore, it is necessary to detect and eliminate outliers first [15]. Outlier detection approaches include statistics-based methods, clustering-based methods, and some unique methods. We employ interquartile distance to locate outliers in this article. Although the interquartile distance represents the degree of dispersion of each variable in statistical data, it is more trustworthy statistical data [16]. As indicated in the table, all values are sorted in the sample from small to big and then split the data into quartiles with three points, which are quartiles (Table 2).

The calculation method of the upper bound is shown in

$$U = a (Q_1 - Q_2 - Q_3)k.$$
(4)

The calculation method of the lower bound is shown in

$$D = C + k(B - A) \tag{5}$$

When the value of K in the formula is 1.5, it is the moderately abnormal data detected; when the value of K is 3, extreme abnormal data are detected. In this paper, moderate abnormal data are used to detect outliers; that is, the value of w is 1.5. Observing the captured human behavior data shows that the angle change of limbs changes obviously in different movements, and the angle change can be defined by the Euler angle. The key to the success of behavior recognition is to select good features [17]. The quality of feature selection greatly impacts the results of behavior recognition. Human behavior characteristics include the following: 1. average value; 2. maximum value; 3 minimum value; 4. standard deviation; 5. variance; 6. median value; 7. extreme difference; 8. slope absolute energy. When extracting features, the eigenvalues sampled in a dimension of the attitude Euler angle of an inertial sensor node at all times of an action are calculated, respectively.

Average value: it reflects the overall situation of a group of data, as shown in

$$\mu = \frac{\sum_{i=1}^{n} a_i}{Dn} - w. \tag{6}$$

The standard deviation describes the average of the distance that each data in the sample deviate from the sample average, as shown in

$$s = U \sqrt{\frac{1}{\mu n} \sum_{i=1}^{n} (a-1)^2}.$$
 (7)

After extracting behavior features, redundant features will increase computational complexity. Reducing features can reduce computational complexity and improve accuracy. However, feature reduction is not blind deletion of some features [18]. Blind deletion of features will lose a lot of information because when analyzing data samples, data analysis is often isolated rather than comprehensive [19]. Therefore, it is necessary to use the method of reasonable feature reduction to reduce the features and try not to lose the information of the original features to achieve the purpose of the comprehensive analysis of all features. The characteristic covariance matrix is found, as shown in

$$S = \frac{1}{s} (D - \mu)^2 (U - \mu) + \lambda.$$
 (8)

Here, λ is the average of the eigenvectors. The eigenvectors are given accordingly. The first *k* principal components are selected, and the value of *K* can be determined by

Quartile	Alias	Position in the sample
A Quartile (Q1)	Small quartile	Number of 26%
B Quartile (Q2)	Median	Number of 55%
C Quartile (Q3)	Big four digits	Number of 80%

TABLE 2: Quartile.

$$\frac{s+p}{\lambda-1} \ge K - \eta. \tag{9}$$

Here, η is the energy loss rate. The features after dimensionality reduction according to the projection matrix are calculated, as shown in

$$Y_{MK} = A(K - h) - S.$$
 (10)

When the loss rate is 0.08, 60 principal components can meet the requirements, so that the dimension of the eigenvector is reduced from 270 to 60.

2.3. Realization of Body Movement Detection in Competitive Sports Training. In the process of human motion capture, because the inertial sensor is self-sufficient and has no external reference point, it cannot obtain spatial displacement information, so it is necessary to use positioning technology to obtain displacement information in the process of human motion capture [20]. Wide-area positioning and short-range positioning are two types of wireless positioning technologies. Wide-area positioning is one of several types of positioning technology, which also includes satellite and mobile positioning. WLAN, RFID, UWB, Bluetooth, and ultrasonic are all examples of short-range location technology. The accuracy and positioning scale of various positioning modes are shown in Table 3.

There are two methods for attitude calculation. The first is to integrate the gyroscope into the inertial sensor. Although the gyroscope has a good dynamic response, the error will increase with the increase of time; the other method is to calculate the attitude through magnetometer and acceleration. Although the dynamic response is poor, it will not produce the cumulative error. Therefore, gyroscope, magnetometer, and accelerometer have complementary characteristics in the frequency domain [21]. The attitude calculation steps of the inertial sensor are shown in Figure 4 In the process of inertial sensor attitude data fusion, first, the quaternion is calculated according to the initial state of the inertial sensor, and then the gravity vector and magnetic line of force are inversely deduced to obtain the data of accelerometer and magnetometer, and normalized. The matrix is multiplied and then summed, then the proportional-integral controller is used to adjust the data, and finally, the quaternion is updated.

Human motion detection requires high accuracy, and most cases are carried out indoors. According to Table 2, UWB positioning technology has better performance and accuracy and is more suitable for indoor positioning than other positioning technologies [22]. In the process of motion change, using the motion estimation method based on image gray change to extract local feature points involves camera motion and produces large errors. Therefore, to accurately obtain the target motion estimation, it is necessary to eliminate the impact of camera motion [23]. The optical flow field obtained from the gray image is the sum of the local motion of the actual human body and the motion of the camera. The calculation formula is as follows:

$$\delta = \overrightarrow{S_r} z + \overrightarrow{S_c} - Y_{MK}.$$
 (11)

Here, S represents the optical flow field; S_r represents the actual local motion of the human body; S_c indicates camera motion. Decompose the above three vectors into x and Y axes in turn to obtain

$$S_x = S_{rx} + S_{cx},$$

$$S_y = S_{ry} + S_{cy}.$$
(12)

Of all moving points in a local area in the same image S_{rx} and S_{cx} , the components in different directions of camera movement are consistent. As long as the component is removed, the actual motion component can be obtained, and then the background motion can be found and the scene motion information can be calculated [24]. The range of motion of each human joint is limited, but the human joint tree composed of multiple joints can make unlimited actions, as shown in Table 4. By limiting the range of motion of each joint in the human joint model, the detected human action can be more in line with the action of normal people.

When detecting human motion, first the inertial sensor node to the specified joints of the body is bound, such as big arm, small arm, thigh, and lower leg [25]. The specific joints on which inertial sensor nodes are bound can be determined according to the actions of which joints need to be collected. Increasing the number of inertial sensor nodes can improve the accuracy of action detection and make the detected human actions more accurate.

3. Analysis of Experimental Results

On the windows 8x64 operation of Intel Core (TM) i7-4790k and 16 GB memory, Kinect for windows sdk v2.0 and visual studio 2013 are used as development tools to build an analysis platform with WPF, on which the key-frame extraction function of the action sequence is realized. Because there is currently no single standard for evaluating keyframe extraction outcomes, eye observation and manual comparison analysis are the primary methods of assessment. For action key-frame extraction, three exemplary action sequences are chosen from the provided motion dataset. Table 5 shows the particular details of the action sequence. The complexity of the movement is mainly related to the body parts involved in the movement; that is, it is related to the action types in Table 5.

On the windows 8×64 operation of Intel Core (TM) i7-4790k and 16 GB memory, the human motion recognition experiment based on deep learning is completed based on Visual Studio 2013 c + + language. The experiment uses 10 movements of motion datasets, with a total of 3750 samples for training and recognition. Table 6 shows the average

Positioning mode	Positioning accuracy (m)	Positioning scale		
GPS	About 11 meters	Outdoor wide area		
Mobile positioning	About 11 meters	Outdoor wide area		
Infrared, ultrasonic	1–11 m	Outdoor local area		
WLAN, Bluetooth	1–11 m	Indoor		
Ultra wideband	0.1–1 m	Indoor

Right knee	Thigh	2	0–145°
Left ankle	A lower leg	3	0-90°
Right ankle	A lower leg	3	0-90°

length and action type of each action. For each action sample, 90% of the action samples are selected for training each time, and the remaining 10% of the samples are used as the test set for 10 fold 10 times crossvalidation.

In this paper, the human motion recognition method based on deep learning has achieved a 100% recognition rate for most actions in the motion dataset, 97% minimum recognition rate, and 99.5% average recognition rate, so it has a high recognition rate. Simultaneously, Table 7 shows that this approach has a high recognition rate for three distinct kinds of activities and no evident recognition trend, indicating that it is resilient. However, because of the high complexity of the deep learning algorithm, the average recognition time of 10 actions by the human action

recognition technique based on deep learning is 148 ms, and the action recognition speed is poor, as shown in the table. This paper replaces the feature extraction model VGG-19 in the initial stage of an open pose with the lightweight network model MobileNetV2, introduces the weight and penalty term into the final loss function, and uses MobileNetV2 to process images on the local experimental platform to improve the accuracy and efficiency of attitude estimation. Although the model does not achieve the expected improvement in accuracy, the total parameters of the model are reduced. Table 7 shows the results of the MPI dataset. According to the results, it can be seen that the improved model structure can meet the experimental requirements of this paper.

Learning rate is a very important parameter in the decline of the deep learning gradient. The size of the batch determines the direction of gradient descent and the rate of convergence. If the batch size is set too much, the convergence speed is large, but there may be a local optimal solution if it is set too much. According to the above discrete points of human behavior data of static, walking, running, jumping, squatting standard deviation, skewness, peak value, and correlation coefficient collected from X, Y, and Z axes, in the process of extended Kalman filter (EKF) simulation, 100 groups of data are intercepted from each data for iterative optimization and correction, and the traditional identification method is compared with this method. The results are shown in Figure 5.

In the present paper, we will propose the novel notions (e.g., Q_p -closed set, Q_p -open set, Q_p -continuous mapping, Q_p -open mapping, and Q_p -closed mapping) in topological spaces. Then, we will discuss the basic properties of the above notions in detail. The category of all Q_p -closed (resp. Q_p -open) sets is strictly between the class of all preclosed (resp. preopen) sets and gp-closed (resp. gp-open) sets. Also, the category of all Q_p -continuity (resp. Q_p -open (Q_p -closed) mappings) is strictly among the class of all precontinuity (resp., preopen (preclosed) mappings) and gp-continuity (resp. gp-open (gp-closed) mappings). Furthermore, we will present the notions of Q_p -closure of a set and Q_p -interior of a set and explain some of their fundamental basic properties. Several relations are equivalent between two different topological spaces. The novel two separation axioms (i.e., Q_p - \mathbb{R}_0 and Q_p - \mathbb{R}_1) based on the notion of Q_p -open set and Q_p -closure are investigated. The space of Q_p - \mathbb{R}_0 (resp., Q_p - \mathbb{R}_1) is strictly between the spaces of pre- \mathbb{R}_0 (resp., $pre-\mathbb{R}_1$) and $gp-\mathbb{R}_o$ (resp., $gp-\mathbb{R}_1$). Finally, some relations and properties of $Q_p-\mathbb{R}_0$ and $Q_p-\mathbb{R}_1$ spaces are explained.

1. Introduction

In the early eighties, the novel notions of preopen and preclosed sets (i.e., as a novel type of generalized of open sets in $(\mathcal{X}, \tilde{\tau})$ (i.e., topological space) or a space \mathcal{X}) and preconlinuous mappings are proposed in [1]. Consequently, many researchers turned their study to the generalizations of many different notions in $(\mathcal{X}, \tilde{\tau})$ (for instance, semiopen sets [2], α -open sets [3], and β -open sets [4] or semi-preopen sets [5]). Furthermore, the notion of generalized closed (resp., generalized open) sets (for short, g-closed (resp., g-open) sets) in space \mathcal{X} is presented in [6]. The relationship among q-closed (resp., q-open) sets and generalizing closedness (resp., openness) sets (i.e., generalized preclosed (resp., generalized preopen) set (for short, gp-closed (resp., *qp*-open) set) [7], α -generalized closed (resp., α -generalized open) set (for short, αq -closed (resp., αq -open) set) [8], pregeneralized closed (resp., pregeneralized open) set (for short, pg-closed (resp., pg-open) set) [7], and generalized α -closed (resp., generalized α -open) set (for short, $q\alpha$ -closed (resp., $g\alpha$ -open) set) [9]. The basic properties of five generalizing continuous mappings (i.e., precontinuous mapping [1], *g*-continuous mapping [10], *gp*-continuous mapping [11], αg -continuous mapping [12], *pg*-continuous mapping [11], and $g\alpha$ -continuous mapping [12]) between $\tilde{\sigma}(\mathcal{Y})$ (i.e., a topology on \mathcal{Y}) and $\tilde{\tau}(\mathcal{X})$ (i.e., a topology on \mathcal{X}) are presented. Furthermore, the fundamental relations of generalizing open (closed) mappings (i.e., preopen (preclosed) mapping [11], αg -open (α -closed) mapping [14], *g*-open (*g*-closed) mapping [15], *gp*-open (*gp*-closed) mapping [11], αg -open (αg -closed) mapping [12], *pg*-open (*pg*-closed) mapping [11], *ga*-open (*ga*-closed) mapping [12]) between $\tilde{\sigma}(\mathcal{Y})$ and $\tilde{\tau}(\mathcal{X})$ are studied. On the contrary, the characterizations between separation axioms classes (i.e., pre- \mathbb{R}_0 , pre- \mathbb{R}_1 , *gp*- \mathbb{R}_0 and *gp*- \mathbb{R}_1 spaces) (see, [16, 17]) in ($\mathcal{X}, \tilde{\tau}$) are defined.

Regarding the above discussions, as the motivation of the present paper, we will define novel sets called Q_p -closed sets and Q_p -open sets and investigate several of their fundamental properties. The relation between Q_p -closed set (resp., Q_p -open set) and other sets (for example, preclosed set (resp., preopen set), α -closed set (resp., α -pen set), g-closed set

(resp., g-open set), gp-closed set (resp., gp-open set), ag-closed set (resp., ag-open set), pg-closed set (resp., *pg*-open set), and $g\alpha$ -closed set (resp., $g\alpha$ -open set)) in space ${\mathcal X}$ is introduced. Then, we define the Q_p -continuous mapping and study the relations between Q_p -continuous mapping and other mappings (for example, precontinuous mapping, q-continuous mapping, qp-continuous mapping, αq -continuous mapping, pg-continuous mapping, and $g\alpha$ -continuous mapping) between two different topological spaces. Also, we present the notion of Q_p -open (Q_p -closed) mapping and investigate relations between Q_p -open (Q_p -closed) mapping and other mappings (for example, preopen (preclosed) mapping, α -open (α -closed) mapping, g-open (*g*-closed) mapping, *gp*-open (*gp*-closed) mapping, αg -open (αg -closed) mapping, pg-open (pg-closed) mapping, and $g\alpha$ -open ($g\alpha$ -closed) mapping) between two different topological spaces. Finally, we propose the novel separation axioms classes (i.e., Q_p - \mathbb{R}_0 and Q_p - \mathbb{R}_1 spaces) in $(\mathcal{X}, \tilde{\tau})$.

Next, the sections of this paper are arranged as follows. In Section 2, we will present many notions related to topological spaces as indicated from Definitions 1 to 4. In Section 2, we propose the novel notions of Q_p -closed sets and Q_p -open sets and explain the interesting properties of them. In Section 3, we give the notions of Q_p -continuous mappings, Q_p -open mappings, and Q_p -closed mappings. In Section 4, we define Q_p - \mathbb{R}_0 and Q_p - \mathbb{R}_1 spaces. Section 5 is conclusions.

In the current paper, we will use several expressions (i.e., $\mathscr{C}(\mathfrak{A})$ (the closure of a set \mathfrak{A}), $\mathscr{F}(\mathfrak{A})$ (the interior of a set \mathfrak{A}), $\widetilde{\tau}(\mathscr{X})$ (the all of open sets in \mathscr{X}), and $\mathscr{F}_{\mathscr{X}}$ (the all of closed sets in \mathscr{X})).

Next, we will present several notions which are used in this section as indicated below.

Definition 1 (Cf. [1, 3]). Assume $(\mathcal{X}, \tilde{\tau})$ is a topological space. Then,

(1)

(i) \mathfrak{A} is preclosed set if $\mathscr{C}(\mathscr{F}(\mathfrak{A})) \subseteq \mathfrak{A}$

(ii) \mathfrak{A} is preopen set if $\mathfrak{A} \subseteq \mathscr{F}(\mathscr{C}(\mathfrak{A}))$

 $\mathbb{C}_p(\mathcal{X})$ (resp., $\mathbb{O}_p(\mathcal{X})$) is the set of all preclosed (resp. preopen) sets.

- (2)
 - (i) \mathfrak{A} is α -closed set if $\mathscr{C}(\mathscr{F}(\mathscr{C}(\mathfrak{A}))) \subseteq \mathfrak{A}$
 - (ii) \mathfrak{A} is α -open set if $\mathfrak{A} \subseteq \mathscr{F}(\mathscr{C}(\mathscr{F}(\mathfrak{A})))$

 $\mathbb{C}_{\alpha}(\mathcal{X})$ (resp., $\mathbb{O}_{\alpha}(\mathcal{X})$) is the set of all α -closed (resp. α -open) sets.

Definition 2 (Cf. [6–9]). Assume $(\mathcal{X}, \tilde{\tau})$ is a topological space. Then,

(1)

(i) \mathfrak{A} is *g*-closed set if $\mathscr{C}(\mathfrak{A}) \subseteq \mathfrak{A}$ whenever $\mathfrak{A} \subseteq \mathfrak{L}$ and $\mathfrak{L} \in \tilde{\tau}(\mathscr{X})$, where $\mathscr{C}(\mathfrak{A})$ is a closure of \mathfrak{A} , i.e.,

$$\mathscr{C}(\mathfrak{A}) = \cap \{\mathfrak{F} | \mathfrak{A} \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in \mathscr{F}_{\mathscr{X}} \}.$$
(1)

 $\mathbb{GC}(\mathcal{X})$ be the set of all *g*-closed sets.

- (ii) \mathfrak{A} is *g*-open set if $\mathcal{X} \setminus \mathfrak{A} \in \mathbb{GC}(\mathcal{X})$ and $\mathbb{GO}(\mathcal{X})$ be the set of all *g*-open sets.
- (2)
- (i) \mathfrak{A} is gp-closed set if $\mathscr{C}_p(\mathfrak{A}) \subseteq \mathfrak{A}$ whenever $\mathfrak{A} \subseteq \mathfrak{A}$ and $\mathfrak{A} \in \tilde{\tau}(\mathscr{X})$, where $\mathscr{C}_p(\mathfrak{A})$ is a preclosure of \mathfrak{A} , i.e.,

$$\mathscr{C}_{p}(\mathfrak{A}) = \cap \{ \mathfrak{F} | \mathfrak{A} \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in \mathbb{C}_{p}(\mathfrak{X}) \}.$$
(2)

 $\mathbb{GC}_p(\mathcal{X})$ be the set of all gp-closed sets.

(ii) \mathfrak{A} is gp-open set if $\mathfrak{X} \setminus \mathfrak{A} \in \mathbb{GC}_p(\mathfrak{X})$ and $\mathbb{GO}_p(\mathfrak{X})$ be the set of all gp-open sets.

(3)

(i) \mathfrak{A} is αg -closed set if $\mathscr{C}_{\alpha}(\mathfrak{A}) \subseteq \mathfrak{A}$ whenever $\mathfrak{A} \subseteq \mathfrak{A}$ and $\mathfrak{A} \in \tilde{\tau}(\mathcal{X})$, where $\mathscr{C}_{\alpha}(\mathfrak{A})$ is a α -closure of \mathfrak{A} , *i.e.*,

$$\mathscr{C}_{\alpha}(\mathfrak{A}) = \cap \{\mathfrak{F} | \mathfrak{A} \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in \mathbb{C}_{\alpha}(\mathscr{X}) \}.$$
(3)

 $\mathbb{C}_{\alpha}\mathbb{G}(\mathcal{X})$ be the set of all αg -closed sets.

(ii) \mathfrak{A} is αg -open set if $\mathfrak{X} \setminus \mathfrak{A} \in \mathbb{C}_{\alpha} \mathbb{G}(\mathfrak{X})$ and $\mathbb{O}_{\alpha} \mathbb{G}(\mathfrak{X})$ be the set of all αg -open sets.

(4)

- (i) \mathfrak{A} is *pg*-closed set if $\mathscr{C}_p(\mathfrak{A}) \subseteq \mathfrak{A}$ whenever $\mathfrak{A} \subseteq \mathfrak{Q}$ and $\mathfrak{Q} \in \mathbb{O}_p(\mathscr{X})$ and $\mathbb{C}_p \mathbb{G}(\mathscr{X})$ be the set of all *pg*-closed sets.
- (ii) \mathfrak{A} is pg-open set if $\mathscr{X} \setminus \mathfrak{A} \in \mathbb{C}_p \mathbb{G}(\mathscr{X})$ and $\mathbb{O}_p \mathbb{G}(\mathscr{X})$ be the set of all gp-open sets.

- (i) 𝔄 is gα-closed set if 𝔅_α(𝔄)⊆𝔄 whenever 𝔄⊆𝔅 and 𝔅 ∈ 𝔅_α(𝔅), and 𝔅𝔅_α(𝔅) be the set of all gα-closed sets.
- (ii) \mathfrak{A} is $g\alpha$ -open set if $\mathfrak{X} \setminus \mathfrak{A} \in \mathbb{GC}_{\alpha}(\mathfrak{X})$, and $\mathbb{GO}_{\alpha}(\mathfrak{X})$ be the set of all $g\alpha$ -open sets.

Definition 3 (Cf. [1, 10, 13–15]). Let $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ be mapping and $\tilde{\sigma}(\mathcal{Y})$ be a topology on \mathcal{Y} and $\tilde{\tau}(\mathcal{X})$ is a topology on \mathcal{X} . Then,

(1) ψ is precontinuous mapping (resp., α -continuous mapping and g-continuous mapping) if $\mathfrak{L} \in \widetilde{\sigma}(\mathscr{Y}), \psi^{-1}(\mathfrak{L}) \in \mathbb{O}_p$ $(\mathscr{X})(resp., \psi^{-1}(\mathfrak{L}) \in \mathbb{O}_{\alpha}(\mathscr{X}), \psi^{-1}(\mathfrak{L}) \in \mathbb{GO}(\mathscr{X})).$

(2)

- (i) ψ is preopen mapping (resp., α-open mapping and g-open mapping) if 𝔅 ∈ τ̃(𝔅), ψ(𝔅) ∈ Q_p𝔅(𝔅)(resp., ψ (𝔅) ∈ 𝔅_α(𝔅), ψ(𝔅) ∈ 𝔅𝔅(𝔅)).
- (ii) ψ is preclosed mapping (resp., α -closed mapping and g-closed mapping) if $\mathfrak{L} \in \tilde{\tau}(\mathcal{X})$, $\psi(\mathfrak{L}) \in Q_p \mathbb{C}(\mathcal{Y})$ (resp., $\psi(\mathfrak{L}) \in \mathbb{C}_{\alpha}(\mathcal{Y}), \psi(\mathfrak{L})$ $\in \mathbb{GC}(\mathcal{Y})$).

⁽⁵⁾

Definition 4 (Cf. [16, 17]). A topological space $(\mathcal{X}, \tilde{\tau})$ is said to be

(1) Pre- \mathbb{R}_0 space (resp., gp- \mathbb{R}_0 space) if $\forall x \in \mathfrak{L} \in \mathbb{O}_p(\mathcal{X})$ s.t. $\mathscr{C}_p(\{x\}) \subset \mathfrak{L}$ (resp., $\forall x \in \mathfrak{L} \in \mathbb{GO}_p(\mathcal{X})$ s.t., $\mathscr{C}_{gp}(\{x\}) \subset \mathfrak{L}$) and $\mathscr{C}_{gp}(\{x\})$ is a gp-closure of $\{x\}$, defined as

$$\mathscr{C}_{gp}(\{x\}) = \cap \left\{ \mathfrak{F}|\{x\} \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in \mathbb{GC}_p(\mathscr{X}) \right\}.$$
(4)

(2) Pre- \mathbb{R}_1 space (resp., gp- \mathbb{R}_1 space) if $\forall x, y \in \mathcal{X}$, with $\mathcal{C}_p(\{x\}) \neq \mathcal{C}_p(\{y\})$ (resp., $\mathcal{C}_{gp}(\{x\}) \neq \mathcal{C}_{gp}(\{y\})$), there exist disjoint preopen sets (resp., gp-open sets) \mathfrak{Q} and \mathfrak{M} s.t. $\mathcal{C}_p(\{x\}) \subseteq \mathfrak{Q}$ (resp., $\mathcal{C}_{gp}(\{x\}) \subseteq \mathfrak{Q}$) and $\mathcal{C}_p(\{y\}) \subseteq \mathfrak{M}$ (resp., $\mathcal{C}_{gp}(\{y\}) \subseteq \mathfrak{M}$).

2. ERROR!!Q_p-Closed Sets and Q_p-Open Sets

In the following section, we propose novel sets (i.e., Q_p -closed sets and Q_p -open sets) and discuss several interesting theorems and examples.

Definition 5. We call
$$\mathfrak{A}$$
 is Q_p -closed set in $(\mathcal{X}, \tilde{\tau})$ if
 $\mathscr{C}_{ap}(\mathscr{I}(\mathfrak{A})) \subseteq \mathfrak{A},$ (5)

where $\mathscr{C}_{qp}(\mathscr{F}(\mathfrak{A}))$ is a gp-closure of $\mathscr{F}(\mathfrak{A})$, i.e.,

$$\mathscr{C}_{gp}(\mathscr{I}(\mathfrak{A})) = \cap \left\{ \mathfrak{F}|\mathscr{I}(\mathfrak{A}) \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in \mathbb{GC}_p(\mathscr{X}) \right\}.$$
(6)

 $Q_p\mathbb{C}(\mathcal{X})$ is the set of all Q_p -closed sets in \mathcal{X} .

Lemma 1. Let $\mathfrak{F} \in \mathbb{GC}_p(\mathcal{X})$ s.t. $\mathscr{C}_{gp}(\mathscr{F}(\mathfrak{F})) \subseteq \mathfrak{A} \subseteq \mathfrak{F}$. Then, $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$.

 $\begin{array}{ll} \textit{Proof.} & \text{As } \mathfrak{F} \in \mathbb{GC}_p(\mathcal{X}) \text{ implies } \mathcal{C}_{gp}(\mathfrak{F}) = \mathfrak{F}, \text{ thus, } \mathcal{C}_{gp} \\ (\mathcal{I}(\mathfrak{A})) \subseteq \mathcal{C}_{gp}(\mathcal{I}(\mathfrak{F})) \subseteq \mathfrak{A}. & \text{Therefore, } \mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X}). & \Box \end{array}$

The converse of Lemma 1 (i.e., $\mathscr{C}_{gp}(\mathscr{F}(\mathfrak{F})) \not\subseteq \subseteq \mathfrak{F}$) does not hold by the following example.

Example 1. Assume that $\mathscr{X} = \{1, 2, 3\}$ (i.e., $(\mathscr{X}, \tilde{\tau})$ be topological space) and $\tilde{\tau} = \{\mathscr{X}, \phi, \{1\}\}$. Then,

$$\mathcal{F}_{\mathcal{X}} = \{\mathcal{X}, \phi, \{2, 3\}\},$$
$$\mathbb{C}_{p}(\mathcal{X}) = \{\mathcal{X}, \phi, \{2\}, \{3\}, \{2, 3\}\},$$
(7)

$$\mathbb{GC}_{p}(\mathcal{X}) = \{\mathcal{X}, \phi, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}\},\$$

$$Q_p \mathbb{C}\left(\mathscr{X}\right) = 2^{\mathscr{X}}.$$
(8)

Let $\mathfrak{A} = \{3\} \in Q_p \mathbb{C}(\mathcal{X})$ and $\mathfrak{F} = \mathcal{X} \in \mathbb{GC}_p(\mathcal{X})$. Then, $\mathscr{C}_{gp}(\mathscr{F}(\mathfrak{F})) = \mathscr{C}_{gp}(\mathcal{X}) = \not \subseteq \mathfrak{F}$.

Theorem 1. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$.

(1) If $\mathfrak{A} \in \mathbb{C}_p(\mathcal{X})$, then $\mathfrak{A} \in Q_p\mathbb{C}(\mathcal{X})$ (2) If $\mathfrak{A} \in \mathbb{GC}_p(\mathcal{X})$, then $\mathfrak{A} \in Q_p\mathbb{C}(\mathcal{X})$

- (1) As $\mathscr{C}_{gp}(\mathfrak{A}) \subseteq \mathscr{C}_p(\mathfrak{A})$ and $\mathscr{C}_p(\mathfrak{A}) \subseteq \mathscr{C}(\mathfrak{A})$ imply that $\mathscr{C}_{gp}(\mathfrak{A}) \subseteq \mathscr{C}(\mathfrak{A})$, since \mathfrak{A} is preclosed set (i.e., $\mathscr{C}(\mathscr{F}(\mathfrak{A})) \subseteq \mathfrak{A})$, then $\mathscr{C}_{gp}(\mathscr{F}(\mathfrak{A})) \subseteq \mathscr{C}(\mathscr{F}(\mathfrak{A})) \subseteq \mathfrak{A}$. Thus, $\mathfrak{A} \in Q_p \mathbb{C}(\mathscr{X})$.
- (2) Let $\mathfrak{A} \in \mathbb{GC}_p(\mathfrak{X})$ (i.e., $\mathscr{C}_{gp}(\mathfrak{A}) = \mathfrak{A}$). Then, $\mathscr{C}_{gp}(\mathscr{I}(\mathfrak{A})) \subseteq \mathscr{C}_{gp}(\mathfrak{A}) = \mathfrak{A}$. Thus, $\mathfrak{A} \in Q_p\mathbb{C}$ (\mathfrak{X}) .

The converse of Theorem 1 (i.e., $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ but $\mathfrak{A} \notin \mathbb{C}_p(\mathcal{X})$ and $\mathfrak{A} \notin \mathbb{G}\mathbb{C}_p(\mathcal{X})$) does not hold by the following example.

Example 2. (continued from Example 1). As $\{1,3\} \in Q_p \mathbb{C}(\mathcal{X}), \{1,3\} \notin \mathbb{C}_p(\mathcal{X}) \text{ and } \{1\} \in Q_p \mathbb{C}(\mathcal{X}) \text{ but } \{1\} \notin \mathbb{G}\mathbb{C}_p(\mathcal{X}).$

Theorem 2. Arbitrary intersection of Q_p -closed sets is Q_p -closed set.

Proof. Suppose that $\{\mathfrak{F}_k | k \in \Lambda\}$ be a collection of Q_p -closed sets in \mathcal{X} . Then, $\mathcal{C}_{gp}(\mathcal{I}(\mathfrak{F}_k)) \subseteq \mathfrak{F}_k$, for every k. As $\cap \mathfrak{F}_k \subseteq \mathfrak{F}_k$, for every k, $\mathcal{C}_{gp}(\cap \mathfrak{F}_k) \subseteq \mathcal{C}_{gp}(\mathfrak{F}_k)$ for every k. Thus, $\mathcal{C}_{gp}(\cap \mathfrak{F}_k) \subseteq \cap \mathcal{C}_{gp}(\mathfrak{F}_k), k \in \Lambda$. Hence, $\mathcal{C}_{gp}(\mathcal{I}(\cap \mathfrak{F}_k)) \subseteq \mathcal{C}_{gp}(\mathcal{I}(\mathfrak{F}_k)) \subseteq \cap \mathfrak{F}_k$. Therefore, $\cap \mathfrak{F}_k$ is Q_p -closed set. □

Remark 1. The union of two Q_p -closed sets need not be Q_p -closed set (i.e., $\mathfrak{A}, \mathfrak{B} \in Q_p \mathbb{C}(\mathcal{X})$, but $\mathfrak{A} \cup \mathfrak{B} \notin Q_p \mathbb{C}(\mathcal{X})$) as the next example; let $\mathcal{X} = \{1, 2, 3\}$ (i.e., $(\mathcal{X}, \tilde{\tau})$ be topological space) and $\tilde{\tau} = \{\mathcal{X}, \phi, \{1, 2\}\}$. Then,

$$\mathcal{F}_{\mathcal{X}} = \{\mathcal{X}, \phi, \{3\}\},$$

$$\mathbb{C}_{p}(\mathcal{X}) = \mathbb{G}\mathbb{C}_{p}(\mathcal{X}) = Q_{p}\mathbb{C}(\mathcal{X})$$

$$= \{\mathcal{X}, \phi, \{1\}, \{2\}, \{3\}, \{1, 3\}, \{2, 3\}\}.$$
(9)

Let $\mathfrak{A} = \{1\} \in Q_p \mathbb{C}(\mathcal{X})$ and $\mathfrak{B} = \{2\} \in Q_p \mathbb{C}(\mathcal{X})$. Then, $\mathfrak{A} \cup \mathfrak{B} = \{1, 2\} \notin Q_p \mathbb{C}(\mathcal{X})$.

Corollary 1. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$.

(1) Let $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ and $\mathfrak{B} \in \mathbb{C}_p(\mathcal{X})$. Then, $\mathfrak{A} \cap \mathfrak{B} \in Q_p \mathbb{C}(\mathcal{X})$.

(2) Let
$$\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$$
 and $\mathfrak{B} \in \mathbb{GC}_p(\mathcal{X})$. Then,
 $\mathfrak{A} \cap \mathfrak{B} \in Q_p \mathbb{C}(\mathcal{X})$.

Proof. From Theorems 1 and 2, the proof is clear. \Box

Definition 6. $\mathscr{C}_{Q_p}(\mathfrak{A})$ is called Q_p -closure of \mathfrak{A} in $(\mathscr{X}, \tilde{\tau})$ if

$$\mathscr{C}_{\mathcal{O}_{p}}(\mathfrak{A}) = \cap \left\{ \mathfrak{F} | \mathfrak{A} \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in Q_{p} \mathbb{C}(\mathcal{X}) \right\}.$$
(10)

Theorem 3. The following seven properties are holding in $(\mathcal{X}, \tilde{\tau})$.

(1)
$$\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X}) \Leftrightarrow \mathscr{C}_{Q_p}(\mathfrak{A}) = \mathfrak{A}$$

(2) $\mathfrak{A} \subseteq \mathscr{C}_{Q_p}(\mathfrak{A}) \subseteq \mathscr{C}_p(\mathfrak{A}) \text{ and } \mathscr{C}_{Q_p}(\mathfrak{A}) \subseteq \mathscr{C}_{gp}(\mathfrak{A})$

Proof.

Proof.

- Let 𝔄 ∈ Q_pC(𝔅), and from Definition 6, we have ^C_{Q_p}(𝔅) = 𝔅. Conversely, let C_{Q_p}(𝔅) = 𝔅. Then, from Theorem 2, we have 𝔅 ∈ Q_pC(𝔅) which fol- lows from Theorem 1 (1) and (2), respectively, and are obvious.
- (2) Let $\mathfrak{A} \subseteq \mathfrak{F}$ such that $\mathfrak{F} \in Q_p \mathbb{C}(\mathcal{X})$; then, from (1) above, we have $\mathscr{C}_{Q_p}(\mathfrak{A}) \subseteq \mathscr{C}_{Q_p}(\mathfrak{F}) = \mathfrak{F}$. Again $\mathscr{C}_{Q_p}(\mathscr{C}_{Q_p}(\mathfrak{A})) \subseteq \mathscr{C}_{Q_p}(\mathfrak{F}) = \mathfrak{F}$. Thus, $\mathscr{C}_{Q_p}(\mathscr{C}_{Q_p}(\mathfrak{A})) \subseteq \cap \{\mathfrak{F} | \mathfrak{A} \subseteq \mathfrak{F} \text{ and } \mathfrak{F} \in Q_p \mathbb{C}(\mathcal{X})\} = \mathscr{C}_{Q_p}(\mathfrak{A})$ and follows from (4). \Box

The equality of Theorem 3 (6) and (7) (i.e., $\mathscr{C}_{Q_p}(\mathfrak{A}) \cup \mathscr{C}_{Q_p}(\mathfrak{B}) \neq \mathscr{C}_{Q_p}(\mathfrak{A} \cup \mathfrak{B})$ and $\mathscr{C}_{Q_p}(\mathfrak{A} \cap \mathfrak{B}) \neq \mathscr{C}_{Q_p}(\mathfrak{A}) \cap \mathscr{C}_{Q_p}(\mathfrak{B})$) does not hold by the following example.

Example 3. (continued from Remark 1). As $\mathfrak{A} = \{1\}, \mathfrak{B} = \{2\}, \text{ and } \mathfrak{A} \cup \mathfrak{B} = \{1, 2\}, \text{ then } \mathscr{C}_{Q_p}(\{1\}) = \{1\}, \mathscr{C}_{Q_p}(\{2\}) = \{2\}, \text{ and } \mathscr{C}_{Q_p}(\{1, 2\}) = \mathcal{X}, \text{ and } \text{hence, } \mathscr{C}_{Q_p}(\mathfrak{A}) \cup \mathscr{C}_{Q_p}(\mathfrak{B}) = \{1, 2\} \neq \mathcal{X} = \mathscr{C}_{Q_p}(\mathfrak{A} \cup \mathfrak{B}).$

Example 4. Assume that $\mathcal{X} = \{1, 2, 3\}$ (i.e., $(\mathcal{X}, \tilde{\tau})$ be topological space) and $\tilde{\tau} = \{\mathcal{X}, \phi, \{2\}, t\{3\}n, q\{2, 3\}\}$. Then,

$$\mathcal{F}_{\mathcal{X}} = \mathbb{C}_{p}(\mathcal{X}) = \mathbb{G}\mathbb{C}_{p}(\mathcal{X}) = Q_{p}\mathbb{C}(\mathcal{X})$$

= { $\mathcal{X}, \phi, \{1\}, \{1, 2\}, \{1, 3\}$ }. (11)

Let $\mathfrak{A} = \{1\}$, $\mathfrak{B} = \{2\}$, and $\mathfrak{A} \cap \mathfrak{B} = \phi$. Then, $\mathscr{C}_{Q_p}(\{1\}) = \{1\}, \mathscr{C}_{Q_p}(\{2\}) = \{1, 2\}, \text{ and } \mathscr{C}_{Q_p}(\phi) = \phi$, and hence, $\mathscr{C}_{Q_p}(\mathfrak{A}) \cap \mathscr{C}_{Q_p}(\mathfrak{B}) = \{1\} \neq \phi = \mathscr{C}_{Q_p}(\mathfrak{A} \cap \mathfrak{B}).$

The relationship among the Q_p -closed sets and other sets (i.e., closed sets, α -closed sets, g-closed sets, $g\alpha$ -closed sets, αg -closed sets, and pg-closed sets) is presented by the following theorem.

Theorem 4. The following six properties is holding in $(\mathcal{X}, \tilde{\tau})$.

(1) If $\mathfrak{A} \in \mathcal{F}_{\mathcal{X}}$, then $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ (2) If $\mathfrak{A} \in \mathbb{C}_{\alpha}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ (3) If $\mathfrak{A} \in \mathbb{GC}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ (4) If $\mathfrak{A} \in \mathbb{GC}_{\alpha}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ (5) If $\mathfrak{A} \in \mathbb{C}_{\alpha} \mathbb{G}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$ (6) If $\mathfrak{A} \in \mathbb{C}_p \mathbb{G}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$

- (1) As $\mathscr{C}_p(\mathfrak{A}) \subseteq \mathscr{C}(\mathfrak{A})$ and by Theorem 1 (1), we have $\mathscr{C}_{gp}(\mathscr{I}(\mathfrak{A})) \subseteq \mathscr{C}_p(\mathscr{I}(\mathfrak{A})) \subseteq \mathscr{C}(\mathscr{I}(\mathfrak{A})) \subseteq \mathfrak{A}$. Thus, $\mathfrak{A} \in Q_p \mathbb{C}(\mathscr{X})$.
- (2) As $\mathscr{C}_{p}(\mathfrak{A}) \subseteq \mathscr{C}_{\alpha}(\mathfrak{A})$ and by Theorem 1 (1), we have $\mathscr{C}_{gp}(\mathscr{I}(\mathfrak{A})) \subseteq \mathscr{C}$ $_{p}(\mathscr{I}(\mathfrak{A})) \subseteq \mathscr{C}(\mathscr{I}(\mathfrak{A})) \subseteq \mathscr{C}(\mathscr{I}(\mathscr{C}(\mathfrak{A}))) \subseteq \mathfrak{A}.$ Thus, $\mathfrak{A} \in Q_{p}\mathbb{C}(\mathscr{X}).$
- (3) As $\mathscr{C}_{gp}(\mathfrak{A}) \subseteq \mathscr{C}_{g}(\mathfrak{A})$ and by Theorem 1 (2), we have $\mathscr{C}_{Q_p}(\mathfrak{A}) \subseteq \mathscr{C}_{gp}(\mathfrak{A}) \subseteq \mathscr{C}_{g}(\mathfrak{A}) \subseteq \mathfrak{A}$. Thus, $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$.
- (4) As $\mathscr{C}_{gp}(\mathfrak{A}) \subseteq \mathscr{C}_{g}(\mathfrak{A})$ and by Theorem 1 (2), we have $\mathscr{C}_{Q_{p}}(\mathfrak{A}) \subseteq \mathscr{C}_{gp}(\mathfrak{A}) \subseteq \mathscr{C}_{g}(\mathfrak{A}) \subseteq \mathfrak{A}$. Thus, $\mathfrak{A} \in Q_{p}\mathbb{C}(\mathfrak{A})$.

The converse of Theorem 4 (i.e., $\mathfrak{A} \in Q_p \mathbb{C}(\mathcal{X})$, but $\mathfrak{A} \notin \mathcal{F}_{\mathcal{X}}, \mathfrak{A} \notin \mathbb{C}_{\alpha}(\mathcal{X}), \mathfrak{A} \notin \mathbb{GC}(\mathcal{X}), \mathfrak{A} \notin \mathbb{GC}_{\alpha}(\mathcal{X}),$ $\mathfrak{A} \notin \mathbb{O}_{\alpha}\mathbb{G}(\mathcal{X})$, and $\mathfrak{A} \notin \mathbb{C}_p\mathbb{G}(\mathcal{X})$) does not hold by the following example.

Example 5. (continued from Example 1). Clearly,

$$\mathbb{GC}_{\alpha}(\mathcal{X}) = \mathbb{C}_{p}\mathbb{G}(\mathcal{X}) = \mathbb{C}_{\alpha}\mathbb{G}(\mathcal{X}) = \mathbb{C}_{\alpha}(\mathcal{X}) = \mathbb{C}_{p}(\mathcal{X}).$$
(12)

and $\mathbb{GC}(\mathcal{X}) = \mathbb{GC}_{p}(\mathcal{X})$. Thus, $\mathbb{GC}(\mathcal{X}) = \mathbb{GC}_{p}(\mathcal{X})$, but $\{1\} \notin \mathcal{F}_{\mathcal{X}}, \{1\} \notin \mathbb{C}_{\alpha}(\mathcal{X}), \{1\} \notin \mathbb{GC}$ $(\mathcal{X}), \{1\} \notin \mathbb{GC}_{\alpha}(\mathcal{X}), \{1\} \notin \mathbb{GC}_{\alpha}(\mathcal{X}), \{1\} \notin \mathbb{C}_{\alpha}\mathbb{G}(\mathcal{X}), \text{ and } \{1\} \notin \mathbb{C}_{p}\mathbb{G}(\mathcal{X}).$

Definition 7. \mathfrak{A} is called Q_p -open set if $\mathscr{X} \setminus \mathfrak{A} \in Q_p \mathbb{C}(\mathscr{X})$ and $Q_p \mathbb{O}(\mathscr{X})$ is the set of all Q_p -open sets in \mathscr{X} .

Lemma 2. The following properties are holding in $(\mathcal{X}, \tilde{\tau})$.

$$\begin{array}{l} (1) \ \mathcal{X} \backslash \mathscr{C}_{gp} \left(\mathcal{X} \backslash \mathfrak{A} \right) = \mathscr{F}_{gp} \left(\mathfrak{A} \right) \\ (2) \ \mathcal{X} \backslash \mathscr{F}_{qp} \left(\mathcal{X} \mathfrak{A} \right) = \mathscr{C}_{qp} \left(\mathfrak{A} \right) \end{array}$$

Proof. It is clear.

Theorem 5. The following properties are holding in $(\mathcal{X}, \tilde{\tau})$:

$$\mathfrak{A} \in Q_{p} \mathbb{O}(\mathcal{X}) \Leftrightarrow \mathfrak{A} \subseteq \mathcal{F}_{ap}(\mathscr{C}(\mathfrak{A})).$$
(13)

 \Box

 Proof. Suppose that 𝔄 ∈ Q_p □ (𝔅). Then, 𝔅 \𝔄 ∈ Q_p □ (𝔅)

 and 𝔅_{gp} (𝔅 (𝔅))⊆𝔅 \𝔄. From Lemma 2, we have

 𝔅 ⊆𝔅_{gp} (𝔅 (𝔅)). Conversely, 𝔅 ⊆𝔅_{gp} (𝔅 (𝔅)). Then,

 𝔅 ∧𝔅_{gp} (𝔅 (𝔅))⊆𝔅 \𝔄. Thus, 𝔅_{gp} (𝔅 (𝔅𝔅))⊆𝔅 \𝔄. Thus,

 𝔅 \𝔅 ∈ Q_p ℂ (𝔅), and hence, 𝔅 ∈ Q_p □ (𝔅). □

Lemma 3. Let $\mathfrak{L} \in \mathbb{GO}_p(\mathfrak{X})$ such that $\mathfrak{L} \subseteq \mathfrak{U} \subseteq \mathscr{F}_{gp}(\mathscr{C}(\mathfrak{L}))$. Then, $\mathfrak{U} \in Q_p \mathbb{O}(\mathfrak{X})$.

The converse of Lemma 3 (i.e., $\mathfrak{Q} \subseteq \mathcal{I}_{gp}(\mathscr{C}(\mathfrak{Q})))$ does not hold by the following example.

Example 6. (continued from Example 1). As

Proof.

$$Q_{p}\mathbb{O}\left(\mathcal{X}\right) = 2^{\mathcal{X}},\tag{15}$$

 $\begin{array}{l} \text{let} \ \mathfrak{A} = \{1,2\} \in \mathcal{Q}_p \mathbb{O}\left(\mathcal{X}\right) \quad \text{and} \quad \mathfrak{L} = \phi \in \mathbb{GO}_p\left(\mathcal{X}\right). \quad \text{Then,} \\ \mathfrak{L} \subseteq A \not \subseteq \phi = \mathcal{I}_{gp}\left(\mathcal{C}\left(\mathfrak{L}\right)\right). \end{array}$

Theorem 6. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$.

(1) If $\mathfrak{A} \in \mathbb{O}_p(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ (2) If $\mathfrak{A} \in \mathbb{GO}_p(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$

Proof. From Theorem 1 and Lemma 2, the proof is clear. $\hfill \Box$

The converse of Theorem 6 (i.e., $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$, but $\mathfrak{A} \notin \mathbb{O}_p(\mathcal{X})$ and $\mathfrak{A} \notin \mathbb{GO}_p(\mathcal{X})$) does not hold by the following example.

Example 7. (continued from Examples 1 and 6). {2} $\in Q_p \mathbb{O}(\mathcal{X})$, but {2} $\notin \mathbb{O}_p(\mathcal{X})$, and {2, 3} $\in Q_p \mathbb{O}(\mathcal{X})$, but {2, 3} $\notin \mathbb{GO}_p(\mathcal{X})$.

Theorem 7. Arbitrary union of Q_p -open sets is Q_p -open set.

Proof. From Theorem 2 and Lemma 2, the proof is clear. \Box

Remark 2. The intersection of two Q_p -open sets need not be Q_p -open set (i.e., $\mathfrak{A}, \mathfrak{B} \in Q_p \mathbb{O}(\mathcal{X})$, but $\mathfrak{A} \cap \mathfrak{B} \notin Q_p \mathbb{O}(\mathcal{X})$) as given in Remark 1. As

$$\mathbb{O}_p(\mathcal{X}) = \mathbb{GO}_p(\mathcal{X}) = Q_p \mathbb{O}(\mathcal{X})$$
$$= \{\mathcal{X}, \phi, \{1\}, \{2\}, \{1, 2\}, \{1, 3\}, \{2, 3\}\},$$
(16)

let $\mathfrak{A} = \{2, 3\} \in Q_p \mathbb{O}(\mathcal{X})$ and $\mathfrak{B} = \{1, 3\} \in Q_p \mathbb{O}(\mathcal{X})$. Then, $\mathfrak{A} \cap \mathfrak{B} = \{3\} \notin Q_p \mathbb{O}(\mathcal{X})$.

Corollary 2. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$.

- (1) Let $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ and $\mathfrak{B} \in \mathbb{O}_p(\mathcal{X})$. Then $\mathfrak{A} \cup \mathfrak{B} \in Q_p \mathbb{O}(\mathcal{X})$.
- (2) Let $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ and $\mathfrak{B} \in \mathbb{GO}_p(\mathcal{X})$. Then $\mathfrak{A} \cup \mathfrak{B} \in Q_p \mathbb{O}(\mathcal{X})$.

Proof. From Theorem 6 and Lemma 7, the proof is clear. \Box

Definition 8.
$$\mathscr{F}_{Q_p}(\mathfrak{A})$$
 is called Q_p -interior of \mathfrak{A} in $(\mathcal{X}, \tilde{\tau})$ if

$$\mathscr{I}_{Q_p}(\mathfrak{A}) = \bigcup \{ \mathfrak{A} | \mathfrak{Q} \subseteq \mathfrak{A} \text{ and } \mathfrak{A} \in Q_p \mathbb{O}(\mathscr{X}) \}.$$
(17)

Lemma 4. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$:

(1)
$$\mathscr{X} \setminus \mathscr{C}_{Q_p}(\mathfrak{A}) = \mathscr{F}_{Q_p}(\mathscr{X} \setminus \mathfrak{A})$$

(2) $\mathscr{X} \setminus \mathscr{F}_{Q_p}(\mathfrak{A}) = \mathscr{C}_{Q_p}(\mathscr{X} \setminus \mathfrak{A})$

Proof. It is clear.

Theorem 8. The following properties are holding in $(\mathcal{X}, \tilde{\tau})$.

 $\begin{aligned} &(1) \ \mathfrak{A} \in Q_p \mathbb{O} \left(\mathcal{X} \right) &\Leftrightarrow \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) = \mathfrak{A} \\ &(2) \ \mathcal{F}_p \left(\mathfrak{A} \right) \subseteq \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \subseteq \mathfrak{A}, \ \mathcal{F}_{gp} \left(\mathfrak{A} \right) \subseteq \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \\ &(3) \ \mathcal{F}_{Q_p} (\phi) = \phi \ and \ \mathcal{F}_{Q_p} \left(\mathcal{X} \right) = \mathcal{X} \\ &(4) \ If \ \mathfrak{A} \subseteq \mathfrak{B}, \ then \ \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \subseteq \mathcal{F}_{Q_p} \left(\mathfrak{B} \right) \\ &(5) \ \mathcal{F}_{Q_p} \left(\mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \right) = \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \\ &(6) \ \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \cup \mathcal{F}_{Q_p} \left(\mathfrak{B} \right) \subseteq \mathcal{F}_{Q_p} \left(\mathfrak{A} \cup \mathfrak{B} \right) \\ &(7) \ \mathcal{F}_{Q_p} \left(\mathfrak{A} \cap \mathfrak{B} \right) \subseteq \mathcal{F}_{Q_p} \left(\mathfrak{A} \right) \cap \mathcal{F}_{Q_p} \left(\mathfrak{B} \right) \end{aligned}$

Proof. It is similar to Theorem 3.

The equality of Theorem 8 (6) and (7) (i.e., $\mathscr{F}_{Q_p}(\mathfrak{A}) \cup \mathscr{F}_{Q_p}(\mathfrak{B}) \neq \mathscr{F}_{Q_p}(\mathfrak{A} \cup \mathfrak{B})$ and $\mathscr{F}_{Q_p}(\mathfrak{A} \cap \mathfrak{B}) \neq \mathscr{F}_{Q_p}(\mathfrak{A}) \cap \mathscr{F}_{Q_p}(\mathfrak{B})$ does not hold by the following examples.

Example 8 (continued from Remarks 1 and 2). As $\mathfrak{A} = \{2\}, \mathfrak{B} = \{3\}, \text{ and } \mathfrak{A} \cup \mathfrak{B} = \{2, 3\}, \text{ then } \mathcal{F}_{Q_p}(\{2\}) = \{2\}, \mathcal{F}_{Q_p}(\{3\}) = \phi, \text{ and } \mathcal{F}_{Q_p}(\{2, 3\}) = \{2, 3\}, \text{ and hence,}$ $\mathcal{F}_{Q_p}(\mathfrak{A}) \cup \mathcal{F}_{Q_p}(\mathfrak{B}) = \{2\} \neq \{2, 3\} = \mathcal{F}_{Q_p}(\mathfrak{A} \cup \mathfrak{B}).$

Example 9 (continued from Remarks 1 and 2). As $\mathfrak{A} = \{1, 3\}, \mathfrak{B} = \{2, 3\}, \text{ and } \mathfrak{A} \cap \mathfrak{B} = \{3\}, \text{ then } \mathcal{F}_{Q_p}(\{1, 3\}) = \{1, 3\}, \mathcal{F}_{Q_p}(\{2, 3\}) = \{2, 3\}, \text{ and } \mathcal{F}_{Q_p}(\{3\}) = \phi, \text{ and hence},$ $\mathcal{F}_{Q_p}(\mathfrak{A}) \cap \mathcal{F}_{Q_p}(\mathfrak{B}) = \{3\} \neq \phi = \mathcal{F}_{Q_p}(\mathfrak{A} \cap \mathfrak{B}).$

Theorem 9. The following properties is holding in $(\mathcal{X}, \tilde{\tau})$. Then,

$$x \in \mathscr{C}_{Q_{p}}(\mathfrak{A}) \Leftrightarrow \mathfrak{L} \cap \mathfrak{A} \neq \phi,$$

$$\forall x \in \mathfrak{L} \in Q_{p} \mathcal{O}(\mathcal{X}).$$
 (18)

Proof. The proof is clear.

Lemma 5. The following properties are holding in $(\mathcal{X}, \tilde{\tau})$. Then,

$$\begin{array}{l} (1) \ \mathfrak{A} \cap \mathcal{F}_{gp} \left(\mathscr{C} \left(\mathcal{F}_{gp} \left(\mathfrak{A} \right) \right) \right) \in Q_p \mathbb{O} \left(\mathscr{X} \right) \\ (2) \ \mathfrak{A} \cup \mathscr{C}_{qp} \left(\mathcal{F} \left(\mathscr{C}_{qp} \left(\mathfrak{A} \right) \right) \right) \in Q_p \mathbb{C} \left(\mathscr{X} \right) \end{array}$$

 $\begin{array}{ll} \textit{Proof.} & \mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathfrak{U}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right)\right) = \mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right)\right) = \mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right). \\ & (\mathfrak{U})))) = \mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right). \\ & \text{Then, we have } \mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right) = \mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right)) = \mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right) = \mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right)) = \mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right) = \mathfrak{U}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right))). \\ & \text{Hence, } \mathfrak{U}\cap\mathcal{I}_{gp}\left(\mathscr{C}(\mathcal{I}_{gp}\left(\mathfrak{U}\right))\right) \in \mathcal{Q}_{p}\mathbb{O}(\mathscr{X}). \end{array}$

 $\begin{array}{ll} \text{In (2), by (1), we have } \mathcal{X} \backslash (\mathfrak{A} \cup \mathcal{C}_{gp}(\mathcal{I}(\mathcal{C}_{gp}(\mathfrak{A})))) = \\ (\mathcal{X} \backslash \mathfrak{A}) \cap \mathcal{I}_{gp}(\mathcal{C}(\mathcal{I}_{gp}(\mathcal{X}\mathfrak{A}))) \in Q_p \mathbb{O}(\mathcal{X}). & \text{Therefore,} \\ \mathfrak{A} \cup \mathcal{C}_{gp}(\mathcal{I}(\mathcal{C}_{gp}(\mathfrak{A}))) \in Q_p \mathbb{C}(\mathcal{X}). & \Box \end{array}$

Theorem 10. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$. Then,

 $\begin{array}{l} (1) \ \mathcal{F}_{\mathsf{Q}_p}(\mathfrak{A}) = \mathfrak{A} \cap \mathcal{F}_{gp}(\mathscr{C}(\mathcal{F}_{gp}(\mathfrak{A}))) \\ (2) \ \mathscr{C}_{\mathsf{Q}_p}(\mathfrak{A}) = \mathfrak{A} \cup \mathscr{C}_{gp}(\mathcal{F}(\mathscr{C}_{gp}(\mathfrak{A}))) \end{array}$

Proof.

- (1) Suppose 𝔅 = 𝓕_{Q_p}(𝔅). Since 𝔅 ∈ Q_pO(𝔅) and 𝔅⊆𝔅, then, we have 𝔅⊆𝓕_{gp} (𝔅(𝓕_{gp}(𝔅)))⊆𝓕_{gp}(𝔅(𝓕_{gp}(𝔅))). Thus, 𝔅⊆
 𝔅(𝓕_{gp}(𝔅)))⊆𝓕_{gp}(𝔅(𝓕_{gp}(𝔅))). By Lemma 5, we get 𝔅(∩𝓕_{gp}(𝔅(𝓕_{gp}(𝔅))) ∈ Q_pO(𝔅). From Definition 8, we have 𝔅(∩𝓕_{gp}(𝔅(𝓕_{gp}(𝔅)))⊆𝔅. Therefore, 𝔅 = 𝔅(∩𝓕_{gp}(𝔅(𝓕_{gp}(𝔅))) and hence, 𝓕_{Q_p}(𝔅) = 𝔅(∩𝓕_{gp}(𝔅(𝓕_{gp}(𝔅))).
- (2) By Lemma 4, we have $\mathscr{C}_{Q_p}(\mathfrak{A}) = \mathscr{X} \setminus \mathscr{I}_{Q_p}(\mathscr{X} \setminus \mathfrak{A}) = \mathscr{X} \setminus ((\mathscr{X} \setminus \mathfrak{A}) \cap \mathscr{F}_{gp}(\mathscr{C} \cup \mathscr{C}_{gp}(\mathscr{X} \setminus \mathfrak{A})))) = \mathfrak{A} \cup \mathscr{C}_{gp}(\mathscr{F}(\mathscr{C}_{gp}(\mathfrak{A}))).$

The relationship among the Q_p -open sets and other sets (i.e., open sets, α -open sets, g-open sets, $g\alpha$ -open sets, αg -open sets, and pg-open sets) is presented by the following theorem.

Theorem 11. The following properties is holding in $(\mathcal{X}, \tilde{\tau})$.

(1) If $\mathfrak{A} \in \tilde{\tau}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ (2) If $\mathfrak{A} \in \mathbb{O}_{\alpha}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ (3) If $\mathfrak{A} \in \mathbb{GO}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ (4) If $\mathfrak{A} \in \mathbb{GO}_{\alpha}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ (5) If $\mathfrak{A} \in \mathbb{O}_{\alpha}\mathbb{G}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$ (6) If $\mathfrak{A} \in \mathbb{O}_p \mathbb{G}(\mathcal{X})$, then $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$

Proof. It is similar to Theorem 4.

The converse of Theorem 11 (i.e., $\mathfrak{A} \in Q_p \mathbb{O}(\mathcal{X})$, but $\mathfrak{A} \notin \tilde{\tau}(\mathcal{X}), \mathfrak{A} \notin \mathbb{O}_{\alpha}(\mathcal{X}), \mathfrak{A} \notin$

 $\mathbb{GO}(\mathcal{X}), \mathfrak{A} \notin \mathbb{GO}_{\alpha}(\mathcal{X}), \mathfrak{A} \notin \mathbb{O}_{\alpha}\mathbb{G}(\mathcal{X}), \text{ and } \mathfrak{A} \notin \mathbb{O}_{p}\mathbb{G}(\mathcal{X}))$ does not hold by the following example.

Example 10. (continued from Examples 1, 5, and 6). Clearly,

$$\mathbb{GO}_{\alpha}(\mathcal{X}) = \mathbb{O}_{p}\mathbb{G}(\mathcal{X}) = \mathbb{O}_{\alpha}\mathbb{G}(\mathcal{X}) = \mathbb{O}_{\alpha}(\mathcal{X}) = \mathbb{O}_{p}(\mathcal{X}).$$
(19)

and $\mathbb{GO}(\mathcal{X}) = \mathbb{GO}_p(\mathcal{X})$. Thus, $\{2,3\} \in Q_p \mathbb{O}(\mathcal{X})$, but $\{2,3\} \in \tilde{\tau}, (2,3) \in \mathcal{X})(\mathbb{O}_{\alpha}(\mathcal{X}), \{2,3\} \notin \mathbb{GO}(\mathcal{X}), \{2,3\} \notin \mathbb{O}_p \mathbb{G}(\mathcal{X}), \{2,3\} \notin \mathbb{O}_p \mathbb{G}(\mathcal{X})$.

3. ERROR!!Q_p-Continuous Mappings, Q_p-Open Mappings, and Q_p-Closed Mappings

Definition 9. A mapping $\psi \colon \mathcal{X} \longrightarrow \mathcal{Y}$ is called Q_p -continuous if

$$\mathfrak{L} \in \widetilde{\sigma}(\mathscr{Y}),
\psi^{-1}(\mathfrak{L}) \in Q_p \mathbb{O}(\mathscr{X}),$$
(20)

where $\tilde{\sigma}(\mathcal{Y})$ is a topology on \mathcal{Y} and \mathcal{X} is defined on a topology $\tilde{\tau}$

Theorem 12. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$ and $(\mathcal{Y}, \tilde{\sigma})$.

- (1) Every precontinuous mapping is Q_p -continuous mapping
- (2) Every gp-continuous mapping is Q_p -continuous mapping

Proof. From Theorem 6, the proof is clear.

The converse of Theorem 12 (i.e., ψ is Q_p -continuous mapping, but ψ not precontinuous mapping and ψ is Q_p -continuous mapping but ψ not gp-continuous mapping) does not hold by the following example.

Example 11. Assume that $\mathcal{X} = \{1, 2, 3\}$ (i.e., $(\mathcal{X}, \tilde{\tau})$ be topological space, $\tilde{\tau} = \{\mathcal{X}, \phi, \{1\}\}$) and $\mathcal{Y} = \{u, v, w\}$ (i.e., $(\mathcal{Y}, \tilde{\sigma})$ be topological space, $\tilde{\sigma} = \{\mathcal{Y}, \phi, \{u, v\}, \{w\}\}$).

(1) Suppose $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ be a mapping defined by

$$\psi(1) = \psi(2) = u$$
, and $\psi(3) = w$. (21)

Then,

$$\begin{aligned} \mathscr{F}_{\mathscr{X}} &= \{\mathscr{X}, \phi, \{2, 3\}\}, \\ \mathbb{C}_{p}(\mathscr{X}) &= \{\mathscr{X}, \phi, \{2\}, \{3\}, \{2, 3\}\}, \\ \mathbb{G}\mathbb{C}_{p}(\mathscr{X}) &= \{\mathscr{X}, \phi, \{2\}, \{3\}, \{1, 2\}, \{2, 3\}, \{1, 3\}\}, \\ \mathbb{O}_{p}(\mathscr{X}) &= \{\mathscr{X}, \phi, \{1\}, \{1, 2\}, \{1, 3\}\}, \\ \mathbb{G}\mathbb{O}_{p}(\mathscr{X}) &= \{\mathscr{X}, \phi, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}\}, \\ \mathbb{Q}_{p}\mathbb{C}(\mathscr{X}) &= Q_{p}\mathbb{O}(\mathscr{X}) = 2^{\mathscr{X}}. \end{aligned}$$

$$(22)$$

As $\{w\} \in \tilde{\sigma}(\mathcal{Y}), \psi^{-1}(\{w\}) = \{3\} \in Q_p \mathbb{O}(\mathcal{X}), \text{ but} \{3\} \notin \mathbb{O}_p(\mathcal{X}).$

Thus, ψ is Q_p -continuous mapping but ψ not precontinuous mapping.

(2) Suppose $\psi \colon \mathscr{X} \longrightarrow \mathscr{Y}$ be a mapping defined by

$$\psi(1) = u \operatorname{and} \psi(2) = \psi(3) = w.$$
 (23)

As $\{w\} \in \tilde{\sigma}(\mathcal{Y}), \psi^{-1}(\{w\}) = \{2, 3\} \in Q_p \mathbb{O}(\mathcal{X}),$ but $\{2, 3\} \notin \mathbb{GO}_p(\mathcal{X}).$

Thus, ψ is Q_p -continuous mapping but ψ not gp-continuous mapping.

Theorem 13. Assume that $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ be a mapping. Then, the following six properties are equivalent:

- (1) ψ is Q_p -continuous
- (2) For every x ∈ X and every open set 𝔅 ⊂ 𝒱 containing ψ(x), there exists Q_p-open set 𝔅 ⊂ 𝒱 containing x such that ψ(𝔅) ⊂ 𝔅
- (3) $\psi^{-1}(\mathfrak{F}) \in Q_p \mathbb{C}(\mathcal{X}), \mathfrak{F} \subset \mathcal{Y}$, be a closed set
- (4) $\psi(\mathscr{C}_{Q_n}(\mathfrak{A})) \subseteq \mathscr{C}(\psi(\mathfrak{A}))(\mathfrak{A} \subseteq \mathscr{X})$
- (5) $\mathscr{C}_{Q_{p}}(\psi^{-1}(\mathfrak{B})) \subseteq \psi^{-1}(\mathscr{C}(\mathfrak{B}))(\mathfrak{B} \subseteq \mathscr{Y})$
- (6) $\psi^{-1}(\mathscr{F}(\mathfrak{B})) \subseteq \mathscr{F}_{Q_p}(\psi^{-1}(\mathfrak{B}))(\mathfrak{B} \subseteq \mathscr{Y})$

Proof.

(1) \Rightarrow (2) Since $\mathfrak{L} \subset \mathscr{Y}$ containing $\psi(x)$ is the open set, then $\psi^{-1}(\mathfrak{L}) \in Q_p \mathbb{O}(\mathscr{X})$. Put $\mathfrak{P} = \psi^{-1}(\mathfrak{L})$ which contains *x*; hence, $\psi(\mathfrak{P}) \subset \mathfrak{L}$.

(2) \Rightarrow (1) Suppose $\mathfrak{L} \subset \mathscr{Y}$ be the open set, and let $x \in \psi^{-1}(\mathfrak{L})$; then, $\psi(x) \in \mathfrak{L}$ and hence, there exists $\mathfrak{P}_x \in Q_p \mathbb{O}(\mathscr{X})$ such that $x \in \mathfrak{P}_x$ and $\psi(\mathfrak{P}_x) \subset \mathfrak{L}$. Thus, $x \in \mathfrak{P}_x \subset \psi^{-1}(\mathfrak{L})$, so $\psi^{-1}(\mathfrak{L}) = \bigcup_{x \in \psi^{-1}(\mathfrak{L})} \mathfrak{P}_x$, but $\bigcup_{x \in \psi^{-1}(\mathfrak{L})} \mathfrak{P}_x \in Q_p \mathbb{O}(\mathscr{X})$. Therefore, $\psi^{-1}(\mathfrak{L}) \in Q_p \mathbb{O}(\mathscr{X})$, and thus, ψ is Q_p -continuous.

 $\begin{array}{l} (1) \Rightarrow (3) \text{ Suppose } \mathfrak{F} \subset \mathscr{Y} \text{ be closed set. Thus, } \mathscr{Y} \backslash \mathfrak{F} \text{ is } \\ \text{the open set and } \psi^{-1}(\mathscr{Y} \backslash \mathfrak{F}) \in Q_p \mathbb{O}(\mathscr{X}), \text{ i.e., } \\ \mathscr{X} \backslash \psi^{-1}(\mathfrak{F}) \in Q_p \mathbb{O}(\mathscr{X}). \text{ Hence, } \psi^{-1}(\mathfrak{F}) \in Q_p \mathbb{C}(\mathscr{X}). \end{array}$

(3) \Rightarrow (4) Suppose $\mathfrak{A} \subseteq \mathfrak{X}$ and \mathfrak{F} be a closed set in \mathscr{Y} containing $\psi(\mathfrak{A})$. By (3), we have $\psi^{-1}(\mathfrak{F})$ is Q_p -closed set containing \mathfrak{A} . Then, $\mathscr{C}_{Q_p}(\mathfrak{A}) \subseteq \mathscr{C}_{Q_p}(\psi^{-1}(\mathfrak{F})) = \psi^{-1}(\mathfrak{F})$, and thus, $\psi(\mathscr{C}_{Q_p}(\mathfrak{A})) \subseteq \mathfrak{F}$. Hence, $\psi(\mathscr{C}_{Q_p}(\mathfrak{A})) \subseteq \mathfrak{C}(\psi(\mathfrak{A}))$.

(4) \Rightarrow (5) Suppose $\mathfrak{B} \subseteq \mathscr{Y}$ and $\mathfrak{A} = \psi^{-1}(\mathfrak{B})$. By assumption, we have $\psi(\mathscr{C}_{Q_p}(\mathfrak{A})) \subseteq \mathscr{C}(\psi(\mathfrak{A})) \subseteq \mathscr{C}(\mathfrak{B})$. Then, $\mathscr{C}_{Q_p}(\mathfrak{A}) \subseteq \psi^{-1}(\mathscr{C}(\mathfrak{B}))$. Therefore, $\mathscr{C}_{Q_p}(\psi^{-1}(\mathfrak{B})) \subseteq \psi^{-1}(\mathscr{C}(\mathfrak{B}))$.

 $\begin{array}{l} (5) \Rightarrow (6) \text{ Suppose } \mathfrak{B} \subseteq \mathscr{Y}. \text{ By assumption, we have} \\ \mathscr{C}_{Q_{\rho}}(\psi^{-1}(\mathscr{Y} \backslash \mathfrak{B})) \subseteq \psi^{-1}(\mathscr{C}(\mathscr{Y} \mathfrak{B})). \text{ Then, } \mathscr{C}_{Q_{\rho}}(\mathscr{X} \backslash \psi^{-1}(\mathfrak{B})) \subseteq \psi^{-1}(\mathscr{Y} \backslash \mathscr{F}(\mathfrak{B})), \text{ and thus, } \mathscr{X} \backslash \mathscr{I}_{Q_{\rho}} \\ (\psi^{-1}(\mathfrak{B})) \subseteq \mathscr{X} \backslash \psi^{-1}(\mathscr{F}(\mathfrak{B})). \text{ By taking complement, we} \\ \text{obtain } \psi^{-1}(\mathscr{F}(\mathfrak{B})) \subseteq \mathscr{F}_{Q_{\rho}}(\psi^{-1}(\mathfrak{B})). \end{array}$

(6) \Rightarrow (1) Suppose \mathfrak{L} be any open set in \mathscr{Y} . Then, $\mathscr{F}(\mathfrak{A}) = \mathfrak{A}$. By assumption, $\psi^{-1}(\mathscr{F}(\mathfrak{A})) \subseteq \mathscr{F}_{Q_p}(\psi^{-1}(\mathfrak{A}))$, and hence, $\psi^{-1}(\mathfrak{A}) \subseteq \mathscr{F}_{Q_p}(\psi^{-1}(\mathfrak{A}))$. Thus, $\psi^{-1}(\mathfrak{A}) = \mathscr{F}_{Q_p}(\psi^{-1}(\mathfrak{A}))$, and we have $\psi^{-1}(\mathfrak{A}) \in Q_p \mathbb{O}(\mathscr{X})$. Therefore, ψ is Q_p -continuous. \Box

Remark 3. Composition of two Q_p -continuous mappings does not need to be Q_p -continuous mapping, as shown by the following example.

Example 12. Assume that $\mathscr{X} = \{1, 2, 3\}$ (i.e., $(\mathscr{X}, \tilde{\tau})$ be topological space, $\tilde{\tau} = \{\mathscr{X}, \phi, \{2\}, t\{1, 2\}\}$), $\mathscr{Y} = \{u, v, w\}$ (i.e., $(\mathscr{Y}, \tilde{\sigma})$ be topological space, $\tilde{\sigma} = \{\mathscr{Y}, \phi, \{u\}\}$), and $\mathscr{Z} = \{s, r, t\}$ (i.e., $(\mathscr{Z}, \tilde{\theta})$ be topological space, $\tilde{\theta} = \{\mathscr{Z}, \phi, \{t\}\}$).

(1) Suppose $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ be a mapping defined by

$$\psi(1) = v, \psi(2) = u, \text{and}\psi(3) = w.$$
 (24)

Then,

$$\begin{aligned} \mathscr{F}_{\mathscr{X}} &= \{\mathscr{X}, \phi, \{3\}\{1, 3\}\}, \\ \mathbb{C}_{p}(\mathscr{X}) &= \{\mathscr{X}, \phi, \{1\}, \{3\}, \{1, 3\}\}, \\ \mathbb{GC}_{p}(\mathscr{X}) &= Q_{p}\mathbb{C}(\mathscr{X}) = \{\mathscr{X}, \phi, \{1\}, \{3\}, \{1, 3\}, \{2, 3\}\}, \\ \mathbb{O}_{p}(\mathscr{X}) &= \{\mathscr{X}, \phi, \{2\}, \{1, 2\}, \{2, 3\}\}, \\ \mathbb{GO}_{p}(\mathscr{X}) &= Q_{p}\mathbb{O}(\mathscr{X}) = \{\mathscr{X}, \phi, \{1\}, \{2\}, \{1, 2\}, \{2, 3\}\}. \end{aligned}$$

$$(25)$$

Thus, ψ is Q_p -continuous mapping.

(2) Suppose
$$\varphi: \mathscr{Y} \longrightarrow \mathscr{Z}$$
 be a mapping defined by

$$\varphi(u) = \varphi(v) = s$$
, and $\varphi(w) = t$. (26)

Then,

$$\mathcal{F}_{\mathcal{Y}} = \{\mathcal{Y}, \phi, \{v, w\}\},$$

$$\mathbb{C}_{p}(\mathcal{Y}) = \{\mathcal{Y}, \phi, \{v\}, \{w\}, \{v, w\}\},$$

$$\mathbb{G}\mathbb{C}_{p}(\mathcal{Y}) = \{\mathcal{Y}, \phi, \{v\}, \{w\}, \{u, v\}, \{u, w\}, \{v, w\}\},$$

$$\mathbb{O}_{p}(\mathcal{Y}) = \{\mathcal{Y}, \phi, \{u\}, \{u, v\}, \{u, w\}\},$$

$$\mathbb{G}\mathbb{O}_{p}(\mathcal{Y}) = \{\mathcal{Y}, \phi, \{u\}, \{v\}, \{w\}, \{u, v\}, \{u, w\}\},$$

$$\mathbb{Q}_{p}\mathbb{C}(\mathcal{Y}) = Q_{p}\mathbb{O}(\mathcal{Y}).$$

$$(27)$$

Thus, φ is Q_p -continuous mapping.

From (1) and (2), $\{t\} \in \tilde{\theta}(\mathcal{X})$, but $(\varphi^{\circ}\psi)^{-1}(\{t\}) = \psi^{-1}(\varphi^{-1}(\{t\})) = \psi^{-1}(\{w\}) = \{3\} \notin Q_p \mathbb{O}(\mathcal{X})$. Thus, $\varphi^{\circ}\psi$ is not Q_p -continuous mapping.

Definition 10. A mapping $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ is called

(1)
$$Q_p$$
-open if
 $\mathfrak{L} \in \tilde{\tau}(\mathcal{X}), \ \psi(\mathfrak{L}) \in Q_p \mathbb{O}(\mathcal{Y}),$

where $\tilde{\tau}(\mathcal{X})$ is a topology on \mathcal{X} and \mathcal{Y} is defined on a topology $\tilde{\sigma}$.

(2) Q_p -closed if

$$\mathfrak{F} \in \mathscr{F}_{\mathscr{X}}, \, \psi(\mathfrak{F}) \in Q_p \mathbb{C}(\mathscr{Y}), \tag{29}$$

(28)

where $\mathscr{F}_{\mathscr{X}}$ is the closed sets of \mathscr{X} .

Theorem 14. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$ and $(\mathcal{Y}, \tilde{\sigma})$.

- (1) Every preopen (resp. preclosed) mapping is Q_p -open (resp. Q_p -closed) mapping
- (2) Every gp-open (resp. gp-closed) mapping is Q_p -open (resp. Q_p -closed) mapping
- *Proof.* It follows from Theorem 6.

Example 13. (continued from Example 11).

(1) Suppose $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ be a mapping defined by

$$\psi(1) = \psi(2) = v, \text{ and } \psi(3) = u.$$
 (30)

- (i) As $\{2\} \in \tilde{\tau}(\mathcal{X}), \psi(\{2\}) = \{\nu\} \in Q_p \mathbb{O}(\mathcal{Y}), \text{ but}$ $\{v\} \notin \mathbb{O}_p(\mathcal{Y})$. Thus, ψ is Q_p -open mapping but ψ not preopen mapping.
- (ii) As $\{3\} \in \mathcal{F}_{\mathcal{X}}, \psi(\{3\}) = \{u\} \in Q_p \mathbb{O}(\mathcal{Y}), \text{ but}$ $\{u\} \notin \mathbb{C}_p(\mathcal{Y})$. Thus, ψ is Q_p -closed mapping but ψ not preclosed mapping.
- (2) Suppose $\varphi: \mathscr{X} \longrightarrow \mathscr{Y}$ be a mapping defined by

$$\varphi(1) = v, \varphi(2) = w, \text{ and } \varphi(w) = u.$$
 (31)

- (i) As $\{1,2\} \in \tilde{\tau}(\mathcal{X}), \ \varphi(\{1,2\}) = \{v,w\} \in Q_p \mathbb{O}(\mathcal{Y}),$ but $\{v, w\} \notin \mathbb{GO}_p(\mathcal{Y})$. Thus, φ is \bar{Q}_p -open mapping but φ not gp-open mapping.
- (ii) As $\{3\} \in \mathcal{F}_{\mathcal{X}}, \{u\} \notin \mathbb{GC}_{p}(\mathcal{Y})$. Thus, φ is Q_p -closed mapping but φ not gp-closed mapping.

Theorem 15. Assume that $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ is a mapping. Then, the following two properties are equivalent:

- (1) ψ is Q_p -open.=
- (2) For every $x \in \mathcal{X}$ and \mathfrak{U} is a neighborhood of x, there exists Q_p -open set $\mathfrak{B} \subset \mathcal{Y}$ containing $\psi(x)$ such that $\mathfrak{B} \subset \psi(\mathfrak{U})$

Proof. The proof is clear.

Theorem 16. Assume that $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ is Q_p -open (resp. Q_p -closed) mapping and $\mathfrak{B} \subset \mathcal{Y}$. If $\mathfrak{A} \subset \mathcal{X}$ is a closed (resp. open) set containing $\psi^{-1}(\mathfrak{B})$, then there exists Q_p -open (resp. Q_p -closed) set $\mathfrak{H} \subset \mathcal{Y}$ containing \mathfrak{B} such that $\psi^{-1}(\mathfrak{H}) \subset \mathfrak{A}$.

Corollary 3. For every set $\mathfrak{B} \subseteq \mathscr{Y}$, if $\psi: \mathscr{X} \longrightarrow \mathscr{Y}$ is Q_p -open, then $\psi^{-1}(\mathscr{C}_{Q_{p}}(\mathfrak{B}))\subseteq \mathscr{C}(\psi^{-1}(\mathfrak{B})).$

Proof. Obvious.

Theorem 17. For any subset \mathfrak{A} of \mathcal{X} , a mapping $\psi: \mathscr{X} \longrightarrow \mathscr{Y} \text{ is } Q_p \text{-open} \Leftrightarrow \psi(\mathscr{F}(\mathfrak{A})) \subseteq \mathscr{F}_{Q_p}(\psi(\mathfrak{A})).$

Proof. Assume that $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ is Q_p -open mapping and $\mathfrak{A} \subseteq \mathfrak{X}$. Then, $\mathscr{F}(\mathfrak{A}) \in \tilde{\tau}(\mathfrak{X})$ and $\psi(\mathfrak{F}(\mathfrak{A}))$ is Q_p -open set

contained in $\psi(\mathfrak{A})$. Hence, we have $\psi(\mathcal{F}(\mathfrak{A})) \subseteq \mathcal{F}_{Q_p}(\psi(\mathfrak{A}))$. Conversely, for every \mathfrak{A} of \mathfrak{X} , $\psi(\mathscr{F}(\mathfrak{A})) \subseteq \mathscr{F}_{Q_p}(\psi(\mathfrak{A}))$ and $\mathfrak{L} \in \widetilde{\tau}(\mathfrak{X})$. Then, $\mathscr{F}(\mathfrak{L}) = \mathfrak{L}$, $\psi(\mathfrak{L}) \subseteq \mathscr{F}_{Q_p}(\psi(\mathfrak{L}))$. Therefore, $\psi(\mathfrak{L}) = \mathscr{F}_{Q_p}(\psi(\mathfrak{L}))$, and we have $\psi(\mathfrak{L})$ is Q_p -open mapping.

Theorem 18. Assume that $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ is a bijective mapping. Then, the following three properties are equivalent:

(1) ψ^{-1} is Q_p -continuous (2) ψ is Q_p -open (3) ψ is Q_p -closed

Proof.

 $(1) \Rightarrow (2)$ Let $\mathfrak{U} \in \tilde{\tau}(\mathfrak{X})$. Then, $\mathfrak{X} \setminus \mathfrak{U} \in \mathscr{F}_{\mathfrak{X}}$. Since ψ^{-1} is $(\psi^{-1})^{-1}(\mathscr{X}\backslash \mathfrak{U}) =$ Q_p -continuous, $\psi(\mathscr{X}\backslash \mathfrak{U}) = \mathscr{Y}\backslash \psi(\mathfrak{U}) \qquad \in Q_p\mathbb{C}(\mathscr{Y}).$ So, $\psi(\mathfrak{U}) \in$ $Q_p \mathbb{O}(\mathcal{Y})$. Hence, ψ is Q_p -open mapping (2) \Rightarrow (3) Let $\mathfrak{F} \in \mathscr{F}_{\mathscr{X}}$. Then, $\mathscr{X} \setminus \mathfrak{F} \in \tilde{\tau}(\mathscr{X})$. Since ψ is Q_p -open, $\psi(\mathcal{X} \setminus \mathfrak{F}) = \mathscr{Y} \setminus \psi(\mathfrak{F}) \in Q_p \mathbb{O}(\mathscr{Y}).$ $\psi(\mathfrak{U}) \in Q_p \mathbb{C}(\mathcal{Y})$. Hence, ψ is Q_p -closed mapping. (3) \Rightarrow (1) Let $\mathfrak{F} \in \mathscr{F}_{\mathscr{X}}$. Since ψ is Q_p -closed, $(\psi^{-1})^{-1}(\mathfrak{F}) = \psi(\mathfrak{F}) \in Q_p \mathbb{C}(\mathscr{Y}).$ Hence, ψ^{-1} is Q_p -continuous mapping.

Remark 4. Composition of two Q_p -open (Q_p -closed) mappings do not need to be Q_p -open (\dot{Q}_p -closed) as shown by the following example.

Example 14. Assume that $\mathscr{X} = \{1, 2, 3\}$ (i.e., $(\mathscr{X}, \tilde{\tau})$ be topological space, $\tilde{\tau} = \{\mathcal{X}, \phi, \{1, 2\}, \{3\}\}), \quad \mathcal{Y} = \{u, v, w\}$ (i.e., $(\mathcal{Y}, \tilde{\sigma})$ be topological space, $\tilde{\sigma} = \{\mathcal{Y}, \phi, \{u\}\})$, and $\mathscr{Z} = \{r, s, t\}$ (i.e., (\mathscr{Z}, θ) be topological space, $\overline{\theta} = \{\mathcal{Z}, \phi, \{s\}, t\{r, s\}\}).$

(1) Consider $\mathscr{F}_{\mathscr{Y}}, \mathbb{C}_{p}(\mathscr{Y}), \mathbb{O}_{p}(\mathscr{Y}), \mathbb{GC}_{p}(\mathscr{Y}), \mathbb{GO}_{p}(\mathscr{Y}),$ $Q_p\mathbb{C}(\mathcal{Y})$, and $Q_p\mathbb{O}(\mathcal{Y})$ are computing in Example 12. Suppose $\psi: \mathcal{X} \longrightarrow \mathcal{Y}$ be a mapping defined by

$$\psi(1) = u, \psi(2) = v, \text{ and } \psi(3) = w.$$
 (32)

Thus, ψ is Q_p -open (Q_p -closed) mapping. (2) Suppose $\varphi: \mathscr{Y} \longrightarrow \mathscr{Z}$ be a mapping defined by

$$\varphi(u) = s, \varphi(v) = r, \text{ and } \varphi(w) = t.$$
 (33)

Then,

$$\begin{aligned} \mathscr{F}_{\mathscr{Z}} &= \{\mathscr{Z}, \phi, \{t\}, \{r, t\}\}, \\ \mathbb{C}_{p}(\mathscr{Z}) &= \{\mathscr{Z}, \phi, \{t\}, \{r\}, \{r, t\}\}, \\ \mathbb{GC}_{p}(\mathscr{Z}) &= Q_{p}\mathbb{C}(\mathscr{Z}) = \{\mathscr{Z}, \phi, \{r\}, \{t\}, \{s, t\}, \{r, t\}\}, \\ \mathbb{O}_{p}(\mathscr{Z}) &= \{\mathscr{Z}, \phi, \{s\}, \{s, t\}, \{r, s\}\}, \\ \mathbb{GO}_{p}(\mathscr{Z}) &= Q_{p}\mathbb{O}(\mathscr{Z}) = \{\mathscr{Z}, \phi, \{r\}, \{s\}, \{r, s\}, \{s, t\}\}. \end{aligned}$$
(34)

Thus, φ is Q_p -open (Q_p -closed) mapping.

From (1) and (2), as {3} is open in \mathcal{X} , $\varphi(\psi(\{3\})) = \varphi(\{w\}) = \{t\} \notin Q_p \mathbb{O}(\mathcal{X})$. Therefore, $\varphi^{\circ} \psi$ is not Q_p -open mapping. Also, as {1,2} is closed in \mathcal{X} , $\varphi(\psi(\{1,2\})) = \varphi(\{u,v\}) = \{r,s\} \notin Q_p \mathbb{C}(\mathcal{X})$. Therefore, $\varphi^{\circ} \psi$ is not Q_p -closed mapping.

4. ERROR!! Q_p - \mathbb{R}_0 and Q_p - \mathbb{R}_1 Spaces

Definition 11.

K_{Q_p}(𝔄) is called Q_p-kernel of 𝔄 (i.e., 𝔄 be subset of a space 𝔅) if

$$\mathbb{K}_{Q_{p}}(\mathfrak{A}) = \cap \left\{ \mathfrak{L} \in Q_{p}\mathbb{O}(\mathcal{X}) | \mathfrak{A} \subset \mathfrak{L} \right\}.$$
(35)

(2) K_{Q_p}({x}) is called Q_p-kernel of x (i.e., x be a point of a space X) if

$$\mathbb{K}_{Q_p}(\{x\}) = \cap \left\{ \mathfrak{L} \in Q_p \mathbb{O}\left(\mathcal{X}\right) | x \in \mathfrak{L} \right\}.$$
(36)

Lemma 6. The following properties are holding in $(\mathcal{X}, \tilde{\tau})$. Then,

(1) $y \in \mathbb{K}_{Q_p}(\{x\}) \Leftrightarrow x \in \mathcal{C}_{Q_p}(\{y\}) \ (x \in \mathcal{X})$ (2) $\mathbb{K}_{Q_p}(\mathfrak{A}) = \cap \left\{ x \in \mathcal{X} | \mathcal{C}_{Q_p}(\{x\}) \cap \mathfrak{A} \neq \phi \right\}$

Proof. It is similar to Lemmas 3.1 and 3.2 of [16].

Lemma 7. For any elements x and y in $(\mathcal{X}, \tilde{\tau})$, then the following two properties are equivalent:

(1) $\mathbb{K}_{Q_p}(\{x\}) \neq \mathbb{K}_{Q_p}(\{y\})$ (2) $\mathscr{C}_{Q_p}(\{x\}) \neq \mathscr{C}_{Q_p}(\{y\})$

Proof. It is similar to Lemma 3.6 of [16].

Definition 12. We call $Q_p \cdot \mathbb{R}_0$ space in $(\mathcal{X}, \tilde{\tau})$ if $\forall x \in \mathfrak{L} \in Q_p \mathbb{O}(\mathcal{X})$ such that $\mathscr{C}_{Q_p}(\{x\}) \subset \mathfrak{L}$.

Theorem 19. The following two properties are holding in $(\mathcal{X}, \tilde{\tau})$:

- (1) Every pre- \mathbb{R}_0 space is Q_p - \mathbb{R}_0 space
- (2) Every gp- \mathbb{R}_0 space is Q_p - \mathbb{R}_0 space

Proof. It follows from Theorem 6. \Box

Theorem 20. Let $x, y \in \mathcal{X}$. Then, $Q_p - \mathbb{R}_0$ space in $(\mathcal{X}, \tilde{\tau}) \Leftrightarrow \mathscr{C}_{Q_p}(\{x\}) \neq \mathscr{C}_{Q_p}(\{y\})$ implies $\mathscr{C}_{Q_p}(\{x\}) \cap \mathscr{C}_{Q_p}(\{y\}) = \phi$.

Proof. From Definition 12, the proof is clear. \Box

Theorem 21. Let $x, y \in \mathcal{X}$. Then, $Q_p - \mathbb{R}_0$ space in $(\mathcal{X}, \tilde{\tau}) \Leftrightarrow \mathbb{K}_{Q_p}(\{x\}) \neq \mathbb{K}_{Q_p}(\{y\})$ implies $\mathbb{K}_{Q_p}(\{x\}) \cap \mathbb{K}_{Q_p}(\{y\}) = \phi$.

any

Proof. From Lemmas 6 (1), Lemma 7, Definition 12, and Theorem 20, the proof is clear. \Box

Theorem 22. The following five properties are equivalent in $(\mathcal{X}, \tilde{\tau})$:

- (1) $(\mathcal{X}, \tilde{\tau})$ is an Q_p - \mathbb{R}_0 space
- (2) For any $\mathfrak{A} \neq \phi$ and $\mathfrak{L} \in Q_p \mathbb{O}(\mathcal{X})$ such that $\mathfrak{A} \cap \mathfrak{L} \neq \phi$, there exists $\mathfrak{F} \in Q_p \mathbb{C}(\mathcal{X})$ such that $\mathfrak{A} \cap \mathfrak{F} \neq \phi$ and $\mathfrak{F} \subset \mathfrak{L}$
- (3) For any $\mathfrak{L} \in Q_p \mathbb{O}(\mathcal{X}), \mathfrak{L} = \bigcup \{\mathfrak{F} \in Q_p \mathbb{C}(\mathcal{X}) | \mathfrak{F} \subset \mathfrak{L} \}$

(4) For

$$\mathfrak{F} \in Q_p \mathbb{O}(\mathcal{X}), \mathfrak{F} = \cap \{\mathfrak{L} \in Q_p \mathbb{O}(\mathcal{X}) | \mathfrak{F} \subset \mathfrak{L} \}$$

(5) F

(5) For any $x \in \mathcal{X}$, $\mathscr{C}_{Q_p}(\{x\}) \subset \mathbb{K}_{Q_p}(\{x\})$

Proof. It is similar to Theorem 3.8 of [16].

Corollary 4. The following two properties are equivalent in $(\mathcal{X}, \tilde{\tau})$:

(1)
$$(\mathcal{X}, \tilde{\tau})$$
 is an $Q_p \cdot \mathbb{R}_0$ space
(2) $\mathscr{C}_{Q_r}(\{x\}) = \mathbb{K}_{Q_r}(\{x\}) (\forall x \in \mathcal{X})$

Proof. From Definition 12 and Theorem 22, the proof is clear. \Box

Theorem 23. The following two properties are equivalent in $(\mathcal{X}, \tilde{\tau})$:

(1) $(\mathcal{X}, \tilde{\tau})$ is an $Q_p \cdot \mathbb{R}_0$ space (2) $x \in \mathcal{C}_{Q_p}(\{y\}) \Leftrightarrow y \in \mathcal{C}_{Q_p}(\{x\}) (\forall x, y \in \mathcal{X})$

Proof. The proof is clear.

Theorem 24. The following four properties are equivalent in $(\mathcal{X}, \tilde{\tau})$:

(1) $(\mathcal{X}, \tilde{\tau})$ is an $Q_p \cdot \mathbb{R}_0$ space (2) If $\mathfrak{F} \in Q_p \mathbb{C}(\mathcal{X})$, then $\mathfrak{F} = \mathbb{K}_{Q_p}(\mathfrak{F})$ (3) If $\mathfrak{F} \in Q_p \mathbb{C}(\mathcal{X})$ and $x \in \mathfrak{F}$, then $\mathbb{K}_{Q_p}(\{x\}) \subset \mathfrak{F}$ (4) If $x \in \mathcal{X}$, then $\mathbb{K}_{Q_p}(\{x\}) \subset \mathscr{C}_{Q_p}(\{x\})$

Proof. From Lemma 6, Theorem 23, and Definition 12, the proof is clear. \Box

Definition 13. We call $(\mathcal{X}, \tilde{\tau})$ is $Q_p \cdot \mathbb{R}_1$ space if

- (i) $\forall x, y \in \mathcal{X}$ with $\mathscr{C}_{Q_p}(\{x\}) \neq \mathscr{C}_{Q_p}(\{y\})$
- (ii) There exist disjoint Q_p-open sets 𝔅 and 𝔐 s.t.
 𝔅_{Q_p}({x})⊆𝔅 and 𝔅_{Q_p}({y})⊆𝔐

Theorem 25. Let $(\mathcal{X}, \tilde{\tau})$ be a topological space. Then,

- (1) Every pre- \mathbb{R}_1 space is Q_p - \mathbb{R}_1 space
- (2) Every gp- \mathbb{R}_1 space is Q_p - \mathbb{R}_1 space

In order to improve the quality of college English vocabulary teaching, this paper studies the application of mobile technology in college English vocabulary teaching. The advantages of mobile technology are analyzed, and different mobile technology communication deployment schemes are determined according to different needs and environments of English vocabulary learning, so as to build a college English vocabulary teaching system, which is mainly composed of the user layer, mobile network layer, and English vocabulary data layer. Among them, the main functions of the user layer are user login, system information setting, English vocabulary resource browsing, uploading English vocabulary homework, etc., and determine user preference data through user logs. The mobile network layer is designed using mobile technology to create the delay control technique of the system mobile communication, and the system mobile network layer's LAN is set up to increase data transmission speed. Finally, set up the database according to the English vocabulary of English words field, calculating Euclidean distance to determine the relationship between them, and then through random set classification vocabulary data types, calculate the similarity degree of the data extraction vocabulary data characteristics and remove high similarity of the English vocabulary data to reduce the difficulty of system storage. The experimental findings suggest that the mobile technology-based system has high performance and dependability and may be widely used in practice.

1. Introduction

With the continuous development of computer technology, mobile technologies such as multimedia and network technology are widely used in many fields. Among them, the mobile technology industry is widely used in the field of education [1]. This technology is also used in college English vocabulary education. The application of mobile technology has greatly promoted the teaching efficiency of education and provided great convenience for students of different majors. Among them, personal learning environment and virtual classroom built through the wireless network in mobile technology have become important ways to improve learners' learning interest [2]. Due to the special structure of knowledge in college English vocabulary teaching, students are often not interested, which affects students' performance and the application of employment English in the future. Moreover, only vocabulary learning in the classroom is far

from enough. Through the application of mobile technology, we can continuously expand the vocabulary and learning time of English learning [3]. Although more interactive teaching methods have been used in English vocabulary teaching in recent years, students' vocabulary learning and vocabulary resources cannot be well transformed when they leave the classroom [4]. Therefore, using mobile technology to promote the quality of college English vocabulary teaching and provide students with more mobile English vocabulary resources has become a hot issue in current research.

Cui [5] proposed a computer intelligent proofreading system for English translation. The system is applied to college English vocabulary teaching to help students effectively improve the accuracy of vocabulary translation. The system pays much attention to the translation of English phrases and words. The core meaning of words is derived from the search module, and the user habits are established with the assistance of the log module, thanks to the design of the intelligent proofreading module, search module, translation module, and occasional log module. The phrase translation model is enhanced in the software design, the model is used to identify the proper meaning of English vocabulary translation, and the system design is finished. The system's architecture increases the quality of English vocabulary translation and assists students in correcting learning faults. However, this strategy takes into account a smaller amount of English vocabulary and has several drawbacks that need to be addressed. A machine learningbased English vocabulary adaptive learning approach is proposed in [6]. In the model design, machine learning is used. To identify the main parameter likelihood of English vocabulary, a dynamic modeling learning technique is used. The learning fitness of English vocabulary is matched via various determinations, the fitness is continually changed, and the adaptive process of English vocabulary learning is decided using the AdaBoost algorithm. This method mainly considers the learning adaptability of users, does not fully realize the application of mobile technology, and considers less about the extraction of English learning vocabulary and features, so it has some limitations. Yuan and Huang [7] proposed a semantic feature extraction and translation method based on the graph regularization algorithm. This method studies the errors in English vocabulary translation. With the help of the graph canonical nonnegative matrix decomposition method, the features of English vocabulary are extracted, the digraph of extracted data is constructed, and the accuracy of English vocabulary translation is determined according to the digraph. This method improves the accuracy of vocabulary translation by analyzing the hidden features of English vocabulary. However, there are some limitations in the application of this method in English vocabulary teaching. Due to the noise of vocabulary characteristics, translation errors in learning are caused.

In order to solve the shortcomings of the above methods, this paper applies mobile technology to college English vocabulary teaching in order to enhance students' interest in learning. This article examines the benefits of mobile technology and how it is used to teach vocabulary to improve the quality of the college English vocabulary instruction.

2. Application of Mobile Technology in College English Vocabulary Teaching

A college English vocabulary teaching system based on mobile technology is built in this research to increase the impact of college English vocabulary teaching. First, the benefits of mobile technology are examined in the system design. The general architecture of the college is built on this foundation. English vocabulary teaching system is designed. Based on this architecture, the system hardware and software are designed to complete the application research of mobile technology in college English vocabulary teaching. 2.1. Mobile Technology Analysis. Mobile technology includes mobile communication technology and terminal equipment. In the English vocabulary teaching system, the main mobile technologies supporting the system's operation include wireless communication and cellular mobile communication systems. Mobile technology is the basis of English vocabulary learning and application. Different mobile technologies are applied according to different English vocabulary learning needs and learning environments to determine different mobile technology communication deployment [8]. The mobile communication deployment mode selected in the college English vocabulary teaching system in this paper is shown in Table 1.

In the design of the college English vocabulary teaching system, this paper mainly applies the cellular mobile network, which is widely used in multinetworks and can realize effective communication. According to the mobile technology analyzed above, the college English vocabulary teaching system environment constructed in this paper should maintain integration [9], support college English vocabulary learners to learn autonomy and uniqueness, and provide them with a more effective virtual learning system [10]. The basic framework of the college English vocabulary teaching system based on mobile technology is shown in Figure 1.

2.2. Functional Module Design of the College English Vocabulary Teaching System. In the design of the college English vocabulary teaching system, the system user layer, mobile network layer, and English vocabulary data layer are mainly designed. Mobile technology is applied to the module design to improve the performance of the college English vocabulary teaching system.

2.2.1. User Layer of the English Vocabulary Teaching System. The main users of the college English vocabulary teaching system are teachers and students. Through the interaction between them, the user layer is designed. The main functions of this layer are user login, system information setting, browsing English vocabulary resources, uploading English vocabulary homework, and other functions [11]. The module records the user's access behavior and forms log data for integration. In the user login data log integration, the user's repeated behavior data are integrated to help analyze the user's preferences [12]. Set the data collection accessed by the user as

$$X = \{x_1, x_2, \dots x_n\}.$$
 (1)

In the formula, $x_1, x_2, ..., x_n$ represents the user login log data, and *n* represents the number of log data.

Calculate the similar data in the user log data in formula (1) to obtain

$$\sin X = \frac{u(x^2 + y^2)}{\sqrt{\sin(x^2 + y^2)}}.$$
 (2)

English vocabulary data

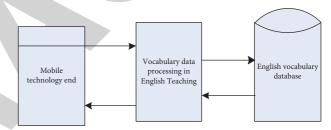

Data exchar

According to the determined similar data of the user login log, determine the main preferences of users logging in the system [13], which is the basis of system development. The basic operation flow of the user layer is shown in Figure 2.

The user layer design's main functions are user login, system information setting, English vocabulary resource browsing, uploading English vocabulary homework, and other functions, and the user preference data are determined through the user log.

2.2.2. Mobile Network Layer of the English Vocabulary Teaching System. The mobile network layer set in the college English vocabulary teaching system mainly relies on mobile technology. This layer's architecture facilitates the system's network connectivity and serves as the foundation for its regular operation [14]. As a result, owing to the huge scale and broad coverage of data in the college English teaching vocabulary system, the speed of real-time English vocabulary data exchange in the mobile network layer design in the system design [15] must be addressed in the network layer design of this study. As a result, the system's mobile communication latency is critical in the module's design. The network transmission delay in a WAN communication network is the time it takes for data to travel from the vocabulary starting node to the user receiving end point [16]. The transmission delay diagram of the mobile network layer is shown in Figure 3.

As can be seen from Figure 3, the calculation formula of time delay caused by the operation of the mobile network layer in the application of the college English vocabulary teaching system is as follows:

Lexical resources

System

application effect

FIGURE 2: Basic operation flow of the user layer.

$$E = e_1 + e_2 + e_s + e_p + e_q.$$
(3)

In the formula, E represents the total end-to-end communication delay of the university English vocabulary teaching system and e_1 and e_2 represent the delay [17] for university English vocabulary data transfer processing, including the time required to package the output communication protocol and the data received by the user. e_s represents the delay of the output of the English vocabulary system. Since the node in the storage mechanism of the exchange device in the mobile network needs a certain transmission medium when receiving the English vocabulary data, the time delay of the system when exporting the English vocabulary operated by the user is

$$e_s = \frac{R}{w}.$$
 (4)

In the formula, R represents the English lexical data frame, and w represents the network link bandwidth.

In this system, the protocol delay of communication processing is directly related to the mobile network performance of communication processing, and this value is relatively fixed. The Ethernet switch is used in the system designed in this paper, and its processing delay generally

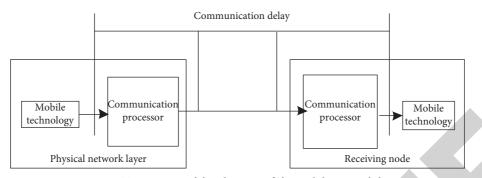

FIGURE 3: Transmission delay diagram of the mobile network layer.

does not exceed $10 \,\mu s$ [18]. The MAC address table, VLAN, priority, and other functions processed by the switch chip of the mobile device are determined by the speed. The failure of the system in the college English vocabulary teaching system will also result in an increase in output delay [19]. As a result, system failure should be included in the time delay control in order to enhance the college English vocabulary teaching system's performance.

In the mobile network layer design of the English vocabulary teaching system, mobile technology is applied to design the system mobile communication delay control method, set the system mobile network layer LAN, and improve the system data transmission speed.

2.3. Design of the English Vocabulary Data Layer. According to the English network module set above, the English vocabulary data layer is designed, which contains all college English vocabulary data. In this module, the database's English vocabulary field [20] is basically set according to the English vocabulary data. The setting results are shown in Table 2.

Due to the enormous number and varieties of college English vocabulary curricular materials, it is required to extract the characteristics of English vocabulary data and effectively fuse the features of English vocabulary data in the design of the English vocabulary data layer [21]. We should examine the distance between English vocabulary data stored in the system while extracting features and use that distance to identify the link between the college English vocabulary [22]. The first multidimensional data of vocabulary data in the college English vocabulary teaching system contain a big number of English vocabulary data. In order to determine the distance between English vocabulary data, it is used as the credibility of feature extraction of English vocabulary data. This paper calculates the distance between English vocabulary data by calculating the Euclidean distance. In the English vocabulary system, the real distance between English vocabulary data in the *n*-dimensional space [23], the straight-line segment distance between vocabulary data in the system, is expressed as

$$g = \sqrt{(a_1 + b_1)^2 + (c_1 + d_1)^2}.$$
 (5)

In the formula, a, b represent two adjacent university English vocabulary data, and c, d represents the twodimensional coordinate point in the English vocabulary teaching system.

The properties of English vocabulary data are derived by calculating the distance between college English vocabulary data. The normal distribution state between the two vocabulary data is assessed [24, 25] based on the calculated distance between English vocabulary data in order to fulfill the needs of system data storage. Suppose that, in the normal distribution diagram of English vocabulary data, one data point is A and the distance between the two data is A1. At this time, the normal distribution state between English vocabulary data is shown in Figure 4.

Under this distribution set, set the total of English vocabulary data *m* as the element, that is, all English vocabulary data distributed in the system. At this time, the mean vector of English vocabulary data is

$$q = \{q_1, q_2, \dots q_n\}.$$
 (6)

The covariance matrix calculation of the English lexical data in the system determined at this time is

$$\sigma = \sum (S_i)_{m \times n}.$$
 (7)

In the equation, the result of the covariance matrix calculation is σ .

According to the above analysis, the characteristics of the university English vocabulary data in the obtained system are

$$\xi(a,b) = (X - \sigma) \sum_{i=1}^{n} (a,b).$$
 (8)

In the formula, $\xi(a, b)$ represents the vocabulary characteristics in university English vocabulary teaching, and *X* represents the scale factor.

According to the characteristics of the college English vocabulary obtained above, it is stored in the teaching system of this study. However, since there are so many comparable vocabulary data and certain words have a lot of noise, it is simple to impair the system's efficiency. As a result, the vocabulary elements of English education must be preprocessed in the system, comparable vocabulary data must be removed, and the system's reaction speed must be improved [26–28].

UINTtitle	Varchar(100)	100	English vocabulary unit title

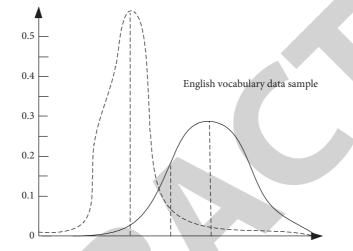

FIGURE 4: Normal distribution status between university English lexical data in the system.

The set of college English vocabulary features is set as *A*, which contains more typical English data. Firstly, the data in the set are effectively classified. In this paper, the features are classified with the help of the random forest algorithm, and the calculation formula is as follows:

$$F(x) = \frac{1/f(k)}{\sum_{i=1}^{k} (1/f(k))}.$$
(9)

In the formula, f(k) represents the predicted distance between English vocabulary data at different times, and krepresents the state value of the categorical English vocabulary data.

The above classified English vocabulary data were processed for data noise reduction in different data groups, and the results are

$$\tau(x) = \tau(x) \times F(x), x = 1, 2, ...m.$$
(10)

In the formula, $\tau(x)$ represents English vocabulary data after noise reduction, and F(x) represents the noise interference coefficient.

Calculate the similarity of the above noise-free English vocabulary data, and delete the data with high similarity, so as to reduce the complex work of data processing in the system. The similarity calculation formula is

$$h_i(k) = yx + h_i(k)' \sum_{k=1}^n \tau(x).$$
(11)

In the formula, $h_i(k)$ ' represents the observations of English lexical data, and y represents the similarity coefficient.

Based on the above calculated word similarity, the English vocabulary data with high similarity are removed to reduce the difficulty of system storage, obtaining

$$\theta_i(x) = l \sum_{i=1}^n u_i \frac{(x)}{k}.$$
(12)

In the formula, $u_i(k)$ represents typical English lexical data, and l represents key features in lexical data.

In the design of the system data layer, the English vocabulary field of the database is basically set according to the English vocabulary data, the Euclidean distance between words is calculated to determine the relationship between them, and the characteristics of college English vocabulary data are extracted by randomly classifying the vocabulary data types and calculating the similarity of the data, and the English vocabulary data with high similarity are removed to reduce the difficulty of system storage.

3. Experimental Analysis

3.1. Experimental Scheme Design. In order to verify the application effect of mobile technology in this paper, experimental analysis is carried out. In the experiment, the system is improved on the basis of the original system, and

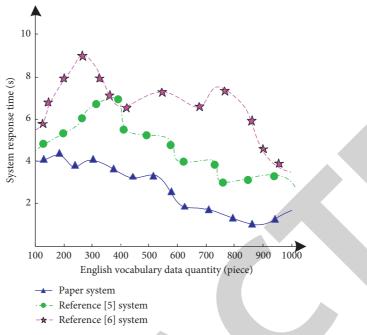

FIGURE 5: Comparison of response time-consuming results of different systems.

TABLE 3: Comparison of English vocabulary data transmission speed in different systems (s).

English vocabulary data/entry	This paper's system	Cui's [5] system	Liu and Huai-Long's [6] system
100	0.21	0.35	0.38
200	0.20	0.39	0.41
300	0.21	0.41	0.43
400	0.23	0.42	0.44
500	0.22	0.45	0.45
600	0.23	0.46	0.47
700	0.24	0.45	0.51
800	0.26	0.43	0.52
900	0.24	0.42	0.53
1000	0.23	0.43	0.54

the system is programmed with C language. The designed system can run normally. In the experiment, part of the vocabulary of CET-4 of the English network is input into the system database as the research data of this system. Taking the freshman class of English major in a university as the research object, this paper makes an experimental study based on the application effect of the students in this class.

3.2. Experimental Index Design. The experimental test compares this system, Cui's [5] system, and Talha's [29] system. In the experiment, the time consumption of the system response and the speed of English vocabulary data transmission are taken as experimental indicators to analyze the performance of the designed system.

3.3. Analysis of Experimental Results. In order to verify the effectiveness of this system, the time-consuming analysis of the system response in the application of this system, Talha et al.'s [30] system, and Liu and Huai-Long's [6] system is

analyzed in the experiment. Among them, with the change of the amount of vocabulary data, the shorter the response time, the faster the response speed of the system and the higher the performance of the system. The experimental results are shown in Figure 5.

By analyzing the experimental data in Figure 5, it can be seen that, with the change of the amount of English vocabulary data, there are some differences in the time consumption of the system response in the application of this system, Cui's [5] system, and Liu and Huai-Long's [6] system. When the quantity of data is 300, the reaction time of the system described in this study is around 4 s, Cui's [5] system is about 7 s, and [6, 27] system is about 9 s; although there are some changes in the general trend of the reaction times of the three systems, the response time of the system in this article always displays a decreasing trend, indicating that the response speed of the system in this paper is quick and practicable.

In order to further verify the effectiveness of the proposed system, the speed of transmitting English vocabulary data in this system, Cui's [5] system, and Talha et al.'s [31] system is experimentally analyzed. The results are shown in Table 3.

By analyzing the experimental results in Table 3, it can be seen that there are some differences in the speed of transmitting English vocabulary data using this system, Cui's [5] system, and Liu and Huai-Long's [6] system. Among them, the transmission speed of this system changes with the continuous change of the amount of English vocabulary data, but it can be seen from the overall data that the transmission speed of this system is fast. This is because the system adopts mobile technology and sets the delay of network layer control data transmission, which improves the effectiveness of the system.

4. Conclusion

In order to improve the effect of college English vocabulary education, this paper designs a new teaching system with the help of mobile technology. Based on the original system, the functional module considers the response speed and transmission delay of the system in the network layer and completes the effective application of mobile technology. Through experiments, the effectiveness of the system designed in this paper is verified, which provides some help for English vocabulary teaching [32].

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The author declares that there are no conflicts of interest regarding the publication of this paper.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant). Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

This paper summarizes the relevant literature through the content analysis method and combines expert advice. The company built a four-level indicator including traffic knowledge and skills, and 13 pilot-level traffic literacy evaluation indicators system including traffic rules and mechanical common sense. The Analytic Hierarchy Process (AHP) analysis method is used to determine the weight of each indicator of urban driver traffic literacy evaluation, and conduct pilot survey and evaluation of motor vehicle drivers in Zhengzhou. The results show that the evaluation value of motor vehicle driver traffic literacy in Zhengzhou is 72.07, including a traffic knowledge score of 77.09, traffic awareness score of 73.95, traffic skill score of 78.12, and traffic behavior score of up to 84.3. It shows that the respondents have relatively more active and responsible traffic behaviors and have a certain degree of understanding of traffic skills and traffic knowledge. However, they are relatively low in traffic awareness.

1. Introduction

With the rapid development of the country's economy, road congestion is becoming more and more serious; traffic accidents occur frequently, and road traffic laws and regulations are violated in an endless stream, which seriously affects urban development and a resident's quality of life in transportation [1]. Traditional transportation concepts can no longer adapt to this rapid development era. People must establish a new type of modern transportation awareness to solve a series of transportation problems caused by this. However, the practice has proved that only relying on the construction of large-scale transportation facilities cannot fundamentally alleviate the urban transportation problems [2]. During the implementation of traffic management, we should be people-oriented and combine the awareness of traffic participants and traffic managers to deal with Traffic problems jointly.

At present, some domestic scholars have researched related issues of transportation literacy. For example, Chen

and Chen [3] investigated the traffic literacy of Hefei citizens on the spot and pointed out that the main problems are pedestrians and vehicles not observing traffic lights, citizens' driving violations from time to time, citizens occupying roads, and parking. It also proposed that the promotion and education of civilized traffic laws and regulations should be strengthened, and three educational networks of families, schools, and society should be established; also, the level of traffic management should be improved through the construction of law enforcement teams, infrastructure planning, and design, and the introduction of market mechanisms. Strengthening people's comfort can genuinely realize the purpose of convenient transportation; it is necessary to improve public transportation literacy and rationally deal with "Chinese-style of crossing the road." Yan [4] discussed traffic quality from drivers' perspective, pointed out that the civilized traffic quality of drivers is the leading factor affecting modern traffic, and put forward relevant suggestions. Xiao [5] pointed out that the civilized literacy of drivers in the country has been continuously improved based on the comparison of data research from 2004 to 2017. Tracing back to the source, the current lack of driver's traffic literacy is the root cause of frequent traffic problems. However, everyone's learning and understanding of traffic safety awareness are different. The behavior and habits are mainly based on acquired propaganda and education, which triggers discussion on driver's traffic literacy, pays attention to the research of driver's traffic literacy, and establishes a good personality at the personal level.

Traffic literacy awareness aims to fundamentally improve drivers' awareness of road responsibilities and develop good road travel habits, thereby preventing road traffic accidents and ensuring safe driving. Some domestic scholars have also researched carbon transportation literacy. For example, Hu [6] analyzed the low-carbon awareness, low-carbon knowledge, and low-carbon behaviors of Zhengzhou, Luoyang, and Kaifeng residents. The status quo of residents' low-carbon transportation literacy in transportation shows that urban residents' educational level and income level have a clear positive correlation with the degree of concern about low-carbon transportation. Li [7] analyzed the problems of low-carbon transportation construction in Zhengzhou City through data collection, investigation, and analysis, and proposed to improve road construction regulations, divert vehicles and pedestrians on congested roads in urban areas, and increase the public transportation network system, that is, address three aspects to solve the existing problems.

The above studies focus on exploratory studies on the status and reasons for traffic literacy, and few studies have focused on the factors that affect drivers' traffic literacy. Based on the connotation and composition of urban driver's traffic literacy, this paper analyzes and summarizes the relevant literature on the influencing factors, formation mechanism, evaluation purpose, and index selection principles of the traffic system and constructs an evaluation index system for urban driver's traffic literacy. We use the analytic hierarchy process to optimize the urban driver's traffic literacy evaluation index system and conduct a pilot survey and evaluation of Zhengzhou motor vehicle drivers, intending to assess urban drivers further. The traffic literacy evaluation lays a theoretical foundation. It provides specific policy suggestions for improving urban traffic. In Section 2, the distinguishing factors of Urban motor vehicle drivers' traffic literacy are analyzed. Section 3 of this paper constructed the weight model of traffic literacy based on the Analytic Hierarchy Process (AHP). Section 4 evaluates the traffic literacy of motor vehicle drivers in Zhengzhou. In section 5, the conclusion to the current study is presented.

2. Analysis of Characteristic Factors of Urban Motor Vehicle Drivers' Traffic Literacy

This section analyzes the characteristic factors of traffic literacy of urban motor vehicle drivers. First, we define the concept of driver's traffic literacy. Then, we discuss the basic idea of extraction of characteristics of urban motor vehicle drivers' traffic literacy. Moreover, the preliminary construction of the traffic literacy evaluation index system is discussed.

2.1. Definition of Driver's Traffic Literacy Concept. Through the analysis and combing of the literature and learning from previous research experience, we believe that the concept of literacy can be introduced into the actual driving process of drivers, and the solution to traffic problems is regarded as a "human action." Traffic literacy is a kind of professional literacy with practical significance. It refers to the traffic behavior or tendency that traffic participants gradually develop during long-term driving activities and are not easy to change for a while and the knowledge, attitude, and control of driving activities. Ability is gradually summarized from people's actions and mainly refers to people's awareness of traffic, the relationship between people and the traffic environment, and humans' treatment of traffic conditions that are gradually accumulated in response to various road traffic conditions [8]. Comprehensive quality consists of specific knowledge and experience, reasonable methods and skills, and people-oriented green awareness. The formation of traffic literacy starts with the personal mastery of traffic knowledge, cultivates and forms a healthy traffic awareness, then turns traffic knowledge into a skill, establishes a good traffic safety awareness, and uses it to guide actions.

2.2. Basic Idea of Extracting Characteristic Factors of Traffic Literacy of Urban Motor Vehicle Drivers. The construction of the urban driver's traffic literacy evaluation system is a multi-index, multi-level comprehensive evaluation problem. It contains more content and involves a wide range. Therefore, it is necessary to set up a quantitative evaluation and transform qualitative problems into quantitative problems for analysis. An evaluation index system is established according to the index level and the defined size relationship. The traffic literacy of different cities is evaluated to lay a solid foundation for improving the overall traffic literacy and enhancing national traffic safety awareness.

2.3. Preliminary Construction of the Evaluation Index System of Traffic Literacy. Determining traffic literacy evaluation indicators is a complicated issue. Since harmonious traffic involves many issues, the corresponding influencing factors can be divided into dozens or hundreds of categories. To facilitate the research and the operability of the evaluation model, combine the influencing factors, formation mechanism, evaluation purpose, and index selection principles of the transportation system [3-5, 9-12], and after analysis and summarization, a subjective index system of traffic literacy is constructed. Specifically, it includes 13 subjective indicators such as traffic rules, general knowledge of machinery, knowledge of laws and regulations, safety awareness, treatment of others, facility safety, situation prediction, vehicle control, preventive measures, emergency measures, self-management behaviors, driving control behaviors, safe and civilized behaviors, etc. After analysis and classification, 13 indicators are combined into 4 main evaluation factors: traffic knowledge, traffic awareness, traffic skills, and traffic behavior, as shown in Table 1.

Evaluation goal	Evaluation factor	Evaluation index
		Traffic rules X_{11}
	Traffic knowledge X ₁	Mechanical knowledge X ₁₂
		Knowledge of laws and regulations X_{13}
		Safety consciousness X_{21}
	Traffic awareness X_2	Treat others well X_{22}
		Facility safety X ₂₃
Fraffic literacy X		Situation foreseeing X_{24}
		Vehicle control X ₃₁
	Traffic skills X_3	Precaution X_{32}
		Emergency measures X_{33}
		Self-management behavior X_{41}
	Traffic behavior X_4	Driving control behavior X_{42}
		Safe and civilized behavior X_{43}

TABLE 1: Structure of traffic literacy evaluation indicators.

3. Construction of the Weight Model of Traffic Literacy Based on the Analytic Hierarchy Process

Since each evaluation index needs to set up corresponding weights, all the indexes in this paper use the combination of the Delphi method and analytic hierarchy process to determine the evaluation index weights. The analytic hierarchy process is a multi-target group's decision-making ideas and methods. In the application of group decision-making, there are two different ways to deal with the pairwise judgments of the group matrix. One of them is to first determine the individual weights according to the individual judgment matrix and then combine them. The second method is to synthesize the individual judgment matrix and then determine the group weight. The evaluator first decomposes the complex problem into many constituent elements and forms these elements into an orderly hierarchical structure according to the dominance relationship. The total evaluation value is determined, and the decision is made. The advantage is that the thinking process of analysts can be systematized, mathematicized, and modeled, and many impact indicators can be classified and processed so that the corresponding importance of each indicator can be determined.

3.1. Hierarchical Analysis Model Construction. The questionnaire survey form is adopted for this model to facilitate the analysis of various indicators, and the corresponding AHP model is established, as shown in Figure 1. The comparative judgment matrix uses the Delphi method to invite relevant experts to make corresponding decisions. It uses questionnaires for statistical analysis, summarizes the comparative judgment matrix between indicators at various levels, and calculates the weight of each indicator based on the judgment matrix.

First, select the evaluation index system, select experts according to the range of knowledge required for the traffic literacy evaluation problem, ask all experts to make decisions and related requirements, and attach all relevant background materials. At the same time, ask the experts to suggest what other materials are needed and supplemented. After the experts receive the materials, they compare the importance of the evaluation indicators according to a scale of 1–9. After normalizing the comparison matrix, the relative weight of each indicator at the same level is obtained. Generally speaking, after returning the questionnaire, the expert's judgment matrix should be checked for consistency. Specific steps are as follows:

If the activity relative activity has a score value, the activity relative activity score is reciprocal. The initial pairwise comparison matrix R can be expressed as follows:

$$R = \begin{pmatrix} 1 & a_{12} & \cdots & a_{1n} \\ a_{21} & 1 & \cdots & a_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & 1 \end{pmatrix}.$$
 (1)

In equation (1), $a_{ij} = (1/a_{ji}), a_{ij} > 0$. The calculation of the weight of each level index, that is, the calculation of the root mean squares of all elements in each row of the judgment matrix; the formula is as follows:

$$C_{ij} = n \sqrt{\prod_{j=1}^{n} a_{ij}}, \quad i = 1, 2, \dots, n.$$
 (2)

Generally speaking, the comparison matrix is not necessarily a consistent matrix, the characteristic root of the norder consistent matrix is n, and the characteristic root of the n-order reciprocal matrix is λ , where $\lambda \ge n$. And, $\lambda = n$ when the matrix is uniform, since λ continuously depends on a_{ij} , λ can be more than *n*, the inconsistency of the matrix will be more serious, so the value of $\lambda - n$ is used to measure the degree of inconsistency. The formula is as follows: $CI = \lambda - n/n - 1$

Among them, in order to determine the allowable range of matrix inconsistency, a random consistency index is also introduced RI, when CR = CI/RI (If it is 0.1, it can be considered that the inconsistency of the matrix is within the allowable range, and the matrix that cannot pass is modified accordingly), Then, normalize the matrix to obtain the relative weight of the index layer.

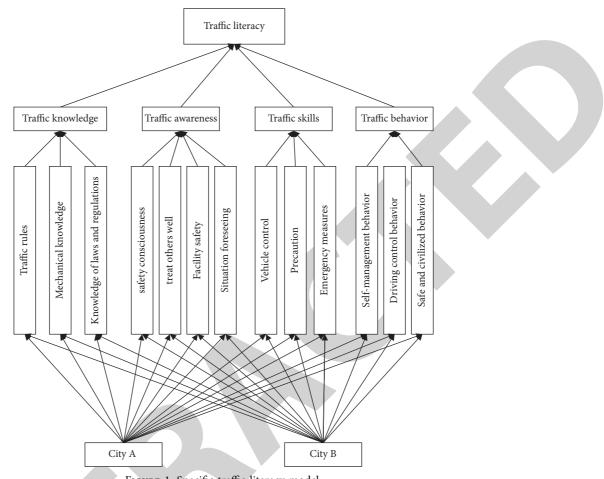

FIGURE 1: Specific traffic literacy model.

$$C_{ij} = \frac{a_{ij}}{\sum_{i=1}^{n} a_{ij}},$$

$$W_{ij} = \frac{\sum_{j=1}^{n} C_{ij}}{n},$$

$$(3)$$

$$\sum_{i=1}^{n} W_i = 1.$$

This study adopts software combined with a questionnaire survey based on experts to compare the importance of indicators at various levels and calculate the weights. Finally, the geometric average of all statistical experts' data is used as the relative weight.

3.2. Determining the Weights of All Levels of Traffic Literacy *Evaluation*. According to the results of questionnaire analysis and expert decision-making, this part realizes the weight calculation of the first-level index and the second-level index through the operation of the software. All judgment matrices and calculation results are shown in Tables 2 to 6.

Based on the above research and calculation results, it can be seen that the analytic hierarchy process is used to solve the weight of each indicator, and the detailed calculation process of each indicator is realized with the aid of the analysis software "yaahp." The detailed summary information of the weight of each level is shown in Table 7.

When the total weight is obtained, the consistency test index of the total arrangement is calculated, namely, CR = 0.0173, and the total index can pass the consistency test when the test is passed.

4. Evaluation of Traffic Literacy of Motor Vehicle Drivers in Zhengzhou City

This section intends to evaluate the traffic literacy of motor vehicle drivers in Zhengzhou city. Henceforth, the design of the questionnaire and scoring rules are defined. Furthermore, an overview of sample and data acquisition is also explained. In addition, the results are analyzed and evaluated. Finally, an overall evaluation of traffic literacy of motor vehicle drivers in Zhengzhou is given.

4.1. Questionnaire Design and Scoring Rules. To obtain adequate data and ensure the scientificity and standardization of the evaluation, the design of the questionnaire follows the principles of matching, conciseness, and completeness. The confidentiality commitment is made in the questionnaire instruction section, and the research purpose is explained [10]. A survey questionnaire for traffic literacy evaluation of

motor vehicle drivers in Zhengzhou is designed. The questionnaire is composed of three parts: the headline, the basic situation of the surveyed person, and the main body of the questionnaire. The basic information of the surveyed person includes seven demographic indicators of gender, age, education, occupation, place of residence, annual family income, and driving age of the surveyed person. The main body of the questionnaire contains four topics: traffic knowledge, traffic awareness, traffic skills, and traffic behavior. Questions are set according to the weights of 13 three-level indicators, with a lower weight setting of 1-2 questions, and a higher weight setting of 2-3 questions per problem. A total of 19 questions are set.

When designing each questionnaire item, we learned from the relatively mature scale paradigm and used the Likert scale to measure traffic knowledge, awareness, skills, and behavior. This study's answer is designed into five measurement levels, corresponding to the five points of "5, 4, 3, 2, and 1." According to different questions, different combinations of statement languages are designed to investigate the respondents, enabling them to make choices more clearly and conveniently so that the attitudes or opinions of the respondents can be more clearly reflected. By consulting experts and teachers in related fields, such as psychology, sociology, and statistics, and drawing on relatively mature scales, such as scientific literacy, environmental literacy, water literacy, etc., the language expression of the questionnaire is refined to form the "Vehicle Driver Traffic Literacy Evaluation Questionnaire."

4.2. Data Acquisition and Sample Overview. The questionnaire of this research selected people with driving experience within the administrative area of Zhengzhou City. The

	Secondary indicator layer	Weights	Three-level indicator layer	Weights

TABLE 7: Driver's traffic literacy system indicators comprehensive weighted weight assignment.

questionnaire is distributed online through electronic questionnaires and face-to-face hard copy questionnaires. Considering that the online questionnaire still has certain limitations, filling is done in the paper questionnaire face to face to supplement. The paper questionnaire is distributed to select locations such as a vehicle management office in Zhengzhou, a comprehensive service hall of a traffic police brigade, and a vehicle repair shop to make the data obtained more comprehensive. A total of 980 questionnaires were distributed in this study, and 693 valid questionnaires were obtained after excluding unqualified questionnaires (for example, the online questionnaire has a short answer time, more than 80% of the questions are answered in a certain order, and the paper questionnaire is not completely filled out, etc., all of which will be regarded as unqualified questionnaires). The effective sample rate is 70.71%. The demographic information of the sample is described in five items: gender, age, education level, occupation, and average monthly household income, as shown in Table 8.

4.3. Result Analysis and Evaluation. Statistical analysis of the traffic literacy questionnaire survey of motor vehicle drivers in Zhengzhou City shows each evaluation factor score (the score is between 1 and 5, the higher the score, the better the evaluation), as shown in Table 9.

Judging from the traffic literacy evaluation factor scores of motor vehicle drivers in Zhengzhou, the highest-scoring question is question 7, "Do you care more about the feelings of passengers and be kind to others during driving?" with a score of 4.42. The corresponding evaluation index is traffic awareness, which shows that the respondents have an obvious subjective idea of being kind to others. In the second place is question 14, "Can you perform better self-management during driving, with a score of 4.29, and its corresponding evaluation index is traffic behavior, which reflects that the respondent's clear self-management behavior is projected on the performance of traffic behavior. It also shows that the respondents have good self-management habits in daily driving. The question with the lowest score was Question 3, "Do you have a common sense of the various components of the motor vehicle you drive?" which was only 3.15, indicating that most respondents did not have

a common sense of the various components of the motor vehicle. In addition, a similar question is question 4, "Do you have a knowledge of traffic-related laws and regulations?" with a score of 3.63, ranking second from the bottom. Question 13 "Do you know relevant emergency measures for traffic emergencies?," with a score of 3.64, indicating that the respondent does not know much about the emergency measures and is not familiar with the same related laws and regulations.

4 questions correspond to traffic knowledge, among which the first question is "Do you understand traffic rules?" and the second question is "Have you studied traffic rules knowledge content?" The scores are relatively close, allaround 4 points. This shows that the respondents have a better knowledge of traffic rules. The third question, "Do you know a common sense of the various components of the motor vehicle you drive?" has a shallow score, only 3.15 points, indicating that some respondents are more aware of motor vehicles but do not know much about the components.

In traffic awareness, in addition to the highest score for question 7, questions 5 and 6 have relatively high scores, indicating that motor vehicle drivers have a high level of safety awareness. The scores of questions 8 "Do you often pay attention to the safety of the various parts and facilities of the vehicle you drive?" and 9 "Do you think you can anticipate situations better while driving?" are not very high, which shows that motor vehicle drivers are not too concerned about the safety of auto parts and facilities. They cannot predict the situation very well.

The score was 4.14 when asked, "Do you think you can handle a vehicle well?" but only 3.92 when asked "Do you intend to learn vehicle handling skills?"; this result shows that most of the respondents think that they have better vehicle control skills and do not want to carry out new learning. In traffic skills, preventive measures and emergency measures have low scores, and the training of emergency and preventive measures for motor vehicle drivers should be strengthened.

Compared with traffic knowledge, traffic awareness, and traffic skills, traffic behavior scores were higher, with an average score of about 4.2. In particular, the self-management behavior score of the respondents was 4.29, and they all

had good traffic civilized behaviors. It also shows that the traffic behavior of motor vehicle drivers in Zhengzhou is relatively good.

4.4. Overall Evaluation of Traffic Literacy of Motor Vehicle Drivers in Zhengzhou. According to the abovementioned analytic hierarchy process to determine the index weights at all levels, based on the average value of the traffic literacy evaluation factor scores of motor vehicle drivers in Zhengzhou City, the traffic literacy of motor vehicle drivers in Zhengzhou City is evaluated. To show the scores of each factor more intuitively, normalize each factor index and convert it into a percentile system. Taking the traffic literacy evaluation value of motor vehicle drivers in Zhengzhou *s* as an example, the converted traffic literacy evaluation of motor vehicle drivers in Zhengzhou Value $s = 4/5 \times 100 = 80$ uses the same method to process the index scores of each factor and get Table 10.

The traffic literacy evaluation value of motor vehicle drivers in Zhengzhou is 72.07, of which the traffic knowledge score is 77.09, traffic awareness score is 73.95, and traffic skills score is 78.12. The traffic behavior score is 84.3, reflecting that the respondents have a relatively more active

TABLE 10: Zhengzhou city motor vehicle driver traffic literacy evaluation score.

and responsible traffic behavior and have a certain degree of understanding of traffic skills and traffic knowledge, but are relatively low in traffic awareness.

Among the various scores of traffic knowledge, motor vehicle drivers are more familiar with traffic laws and regulations but do not know much about the car's components. Most motor vehicle drivers pay more attention to traffic knowledge during driving and do not need to know much about the car's components, which is also in line with the driver's daily life status. The highest score in traffic awareness is to be kind to others, indicating that motor vehicle drivers can better put themselves in other's place and consider them. The attribute with the highest score in traffic skills is vehicle control, indicating that the motor vehicle driver can control well the driving of the vehicle. The highest traffic behavior score indicates that drivers behave well during motor vehicle driving. This is due to the observance of traffic rules and the self-cultivation of drivers. Overall, the traffic literacy score is only 72.07, which is not too high. It may be due to relatively low traffic knowledge, traffic awareness, and traffic skills. Therefore, it is necessary to strengthen the traffic knowledge, traffic awareness, and traffic skills of motor vehicle drivers.

5. Conclusion

Based on the concept of traffic literacy and the elemental composition of traffic literacy, this article combines the analysis of the influencing factors, formation mechanism, evaluation purpose, index selection principles of the traffic system, and after analysis and induction, constructs a subjective index system of traffic literacy. The specific subjective index layer has 13 indicators, namely, traffic rules, machinery knowledge, knowledge of laws and regulations, safety awareness, kindness to others, facility safety, situation prediction, vehicle control, preventive measures, emergency measures, self-management behaviors, driving control behaviors, and safe and civilized behaviors. The 13 indicators are classified and combined into 4 evaluation factors: traffic knowledge, traffic awareness, traffic skills, and traffic behavior.

Through the investigation and analysis of the analytic hierarchy process, the weights of the four evaluation factors, traffic knowledge, traffic awareness, traffic skills, and traffic behavior, are respectively: 0.2397, 0.1127, 0.0819, and 0.5657. The results show that the weight of traffic awareness is relatively high in the driver's traffic literacy evaluation index. The indicators with higher weights of the third-level indicators are traffic rules (0.4163), safety awareness (0.6950), vehicle control (0.6759), and self-management behavior (0.5266). After clarifying the importance of the secondary and tertiary indicators, the total weighted value of the driver's traffic literacy system indicators is obtained. Based on the evaluation index system of motor vehicle drivers' traffic literacy, a questionnaire was designed, and a questionnaire survey was conducted in the pilot city of Zhengzhou to analyze the primary status of the traffic literacy of motor vehicle drivers in Zhengzhou and conduct an overall evaluation of the traffic literacy of motor vehicle drivers. It shows that the traffic literacy evaluation value of motor vehicle drivers in Zhengzhou is 72.07, of which the traffic knowledge score is 77.09, the traffic awareness score is 73.95, the traffic skills score is 78.12, and the traffic behavior score is 84.3, reflecting that the respondents are relatively more active and responsible. Traffic behavior also has a certain degree of understanding of traffic skills and knowledge, but is relatively low in traffic awareness.

Because of the limitations and subjectivity of the traffic literacy index system constructed in this study and the results based on the questionnaire survey, there are specific differences with the literacy of actual drivers. Respondents had a self-glorifying mentality when answering the questionnaire, which led to discrepancies between actual results and survey results. The survey results are pretty different, so follow-up research work needs to improve the construction of the indicator system further, and according to the current advanced technology in the era of big data, enrich the data basis of motor vehicle drivers' traffic literacy, and use network data (accident rate, vehicle service life). Such indicators more intuitively reflect the traffic literacy of motor vehicle

In this paper, security ability refers to the standard of evaluation that is used to measure the implementation performance of the basic endowment insurance system for China's urban and rural residents (EIUR). To evaluate security ability, a three-level evaluation index system with a total of 19 indicators is designed. The research results show that it is low and even does not coincide with the country's level of economic development, for the security ability of EIUR, due to the top-level design of the insurance system under analysis, the operating environment, and residents' willingness to participate and contribute. Moreover, there are regional differences in regard to security ability; the development of various targets is not balanced. These findings suggest that it is necessary to promote the balanced development of various targets between regions and improve the completion of each target, especially in regard to "flexibility" and "fairness" targets.

1. Introduction

With the rapid development of China's basic endowment insurance system for urban and rural residents (EIUR), the national fund revenue and expenditure scale, and per capita pension level was improved obviously. By the end of 2018, the number of residents who had enrolled in the system reached 524 million people, of whom 159 million had received treatment. Fund income was 383.8 billion renminbi (RMB), fund expenditure was 290.6 billion RMB, and the pension reached 152.33 RMB per month. (The data in the "2018 Human Resources and Social Security Development Statistical Bulletin" on the official website of the Ministry of Human Resources and Social Security of China are quoted here.)

However, in regard to the development of the system, numerous problems persist, such as low treatment levels [1–3] and regional treatment differences [4]. Additionally, low individual contribution levels [5, 6] and excessive dependence on financial subsidies [7, 8] are persistent problems. Some scholars have evaluated the implementation effect of the EIUR from the economic, sustainability,

fairness, and satisfaction perspectives [9–13]. On this basis, they have made suggestions for its improvement.

The extant research of the EIUR lacks a macro-level evaluation of the system; rather, it focuses primarily on a certain aspect of the system, which it evaluates from the micro-level. For instance, some research focuses on qualitative descriptions, comments, and policy suggestions; others have evaluated the implementation effect of EIUR from system treatment and fund operation. Therefore, this paper will construct a comprehensive scientific evaluation index system based on multiple dimensions and perspectives, such as the basic principles of system design, security functions, and development vision. It will analyze the current status of the implementation of the EIUR in China's provinces and put forward suggestions to deepen the reform of the system.

2. Research Area and Data

The research area comprises 31 provinces (autonomous regions and municipalities that are directly under the central government) in China, excluding Hong Kong, Macao, and

Taiwan. (Due to the "one country, two systems" system, Hong Kong, Macao, and Taiwan have implemented a social system that differs from that of China's mainland.) Based on the Chinese government's regulations on the minimum standard subsidies for urban and rural residents' basic insurance pensions (BIP) in 2014 (according to the basic pension standard, the central government provides full subsidies to the central and western regions and 50% subsidies to the eastern regions), the 31 provinces are divided into two major blocks as follows: (The eastern provinces are Beijing, Tianjin, Hebei, Liaoning, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong, and Hainan, while the central and western provinces are Shanxi, Jilin, Heilongjiang, Anhui, Jiangxi, Henan, Hubei, Hunan, Inner Mongolia, Guangxi, Chongqing, Sichuan, Guizhou, Yunnan, Tibet, Shaanxi, Gansu, Qinghai, Ningxia, and Xinjiang.) the eastern region and midwestern region.

The data used in this paper were sourced from yearbooks, such as China Statistical Yearbook 2019, China Labor Statistics Yearbook 2019, and China Population and Employment Statistics Year 2019, as well as public data retrieved from the China Statistics Bureau. There are three main data categories as follows: macroeconomic data, (The macroeconomic data include China's GDP and per capita GDP from 2011 to 2018, the per capita disposable income of urban and rural residents, the per capita living consumption expenditure of urban and rural residents, and the minimum living consumption level.) population data, (The population data include the number of permanent residents by province from 2011 to 2018, the number of older people by region, and the number of people by age across the country.) and operation data, (The operating data include the number of insured persons, the number of people receiving benefits, fund income, fund expenditures, accumulated fund balances, individual contributions, and individual contribution rates.) and these three types of data can be collectively referred to as original data. Owing to the very nature of indicators, some original data cannot be directly utilized to calculate the evaluation index. Therefore, we preprocessed some of the original data, and we call it processed data. The processed data includes the number of people aged 16-59 years who are eligible for insurance coverage, the number of people over 60 years old who are eligible for the insurance coverage, per capita pension, per capita contribution, per capita government subsidy, and per capita income fund (see Table 1 for the specific processing methods). Some of the above three types of data cannot be directly used in the calculation of the indicator system.

3. Method

3.1. Index System Construction. To fully reflect our respect for objective facts and advanced thinking, based on the current research results, combined with the actual operation process of the EIUR and select targets and indicators related to individual contribution and treatment, we determined the evaluation indicators of the effect of citizens' insurance implementation (see Table 1 for the definitions and explanations of the specific indicators). 3.2. Determination of the Index Weight. The entropy weight method is a widely used objective weighting method. Based on the varying degrees of each index, the information entropy can be used to calculate its entropy weight. The weight of each index is then corrected by the entropy weight, thereby obtaining a more objective index weight. Because we constructed a three-level index system to evaluate the security ability of the EIUR, we propose a layered entropy weight method to measure the actual weight of each index.

3.2.1. Normalized Calculation of Indicator Data. The data for each index need to be normalized to eliminate the difference between the statistical standards and dimensions of the data. To unify the description, X_i represents the target, and X_{ij} represents the indicator. Let y_{ij}^t represents the normalized calculation of the t statistical data in indicator X_{ij} .

$$y_{ij}^{t} = \frac{x_{ij}^{t} - \min_{j \in \Lambda} \left(x_{ij}^{t} \right)}{\max_{t \in \Lambda} \left(x_{ij}^{t} \right) - \min_{t \in \Lambda} \left(x_{ij}^{t} \right)}.$$
 (1)

3.2.2. Calculation of the Index Weight. The index weights are measured using the layered entropy weight method. First, the indicator index weights are calculated according to the indicator index statistics; then, the indicator indexes are calculated; finally, the target weights are calculated according to the indicator indexes.

(1) Indicator Index Weight Calculation. To determine the weight of index X_{ij} , the information entropy of index X_{ij} must be calculated first. Let $H(X_{ij})$ denote the information entropy of index.

$$H(X_{ij}) = -\frac{1}{\ln(n)} \sum_{t=1}^{n} w_{ij}^{t} \ln(w_{ij}^{t}),$$

$$w_{ij}^{t} = \frac{y_{ij}^{t}}{\sum_{t=1}^{n} y_{ij}^{t}}.$$
(2)

In (2), if $w_{ij}^t = 0$, then $w_{ij}^t \ln(w_{ij}^t) = 0$. According to the information entropy, the weight of the index can be obtained as $p(X_{ij})$.

$$p(X_{ij}) = \frac{1 - H(X_{ij})}{k - \sum_{j=1}^{k} H(X_{ij})}.$$
(3)

(2) Calculation of Target Index. Based on the weight and data of the indicator index, the target can be calculated. Let SI_i^t denote the target index.

$$SI_{i}^{t} = \sum_{j=1}^{k} p(X_{ij}) y_{ij}^{t}.$$
 (4)

In (4), SI_i^t is used to measure the role of targets in evaluating the EIUR.

Goal	Target	Indicator		Indicator description (definition)	Indicator interpretation
	Full coverage	Participation ratio of urban and rural residents aged 16–59	(0.198)	Number of participants/number of people who meet the conditions of participation	The larger the participation rate, the wider the coverage
		Participation ratio of	(0.039)	Number of participants/number of people who meet the conditions of participation	The larger the participation rate, the wider the coverage
	(0.161)	Growth rate of insured persons aged 16–59	(0.280)	Insured rate for the current year/ insured rate for the previous year-1 Number of people receiving	The larger the growth rate, the wider the coverage
Security ability of EIUR		Growth rate of insured persons over 60	(0.484)	treatment in that year/number of people receiving treatment in the previous year-1	The larger the growth rate, the wider the coverage
		Pension replacement rate	(0.329)	Pension per capita ×12/per capita disposable income of rural residents	The greater the replacement rate, the higher the security level
	Basic protection (0.111)	Pension growth rate	(0.375)	Pension per capita in that year/ pension per capita in the previous year-1	The greater the growth rate, the higher the security level
	Flexibility (0.363)	Pension contribution rate to minimum living security	(0.296)	Per capita pension/minimum living standard	The greater the contribution rate, the higher the security level
		Resident income flexibility of individual contributions	(0.054)	Growth rate of per capita contribution/growth rate of per capita disposable income of rural residents	The greater the flexibility, the more sensitive the individual's contribution to the residents' income
		Individual payment flexibility of payment subsidies	(0.502)	Government subsidy growth rate	The greater the flexibility, the more sensitive the government subsidies of individual contributions
		Resident income flexibility of basic pension	(0.108)	Basic pension growth rate/per capita disposable income growth rate of rural residents	The greater the flexibility, the more sensitive the basic pension to residents' income
		Economic development flexibility of pension	(0.336)	Pension growth rate per capita/ gross domestic product (GDP) growth rate per capita	The greater the flexibility, the more sensitive the pension to economic development
		Aging population	(0.002)	1-Elderly population/total population	The larger the numerical value, the stronger the sustainability
	Sustainability (0.163)	Fund cumulative balance growth rate	(0.618)	Cumulative fund balance of the current year/cumulative fund balance of the previous year-1	The larger the numerical value, the stronger the sustainability
		Institutional maintenance rate	(0.279)	1-Number of people receiving treatment/number of paying people	The larger the numerical value, the stronger the sustainability
		Local government maximum subsidy ability	(0.031)	1-Maximum local government subsidies per capita/per capita fiscal revenue	The larger the numerical value, the stronger the sustainability
	Fairness (0.202)	Personal ability to pay	(0.070)	1-Minimum living standard/per capita disposable income	The larger the numerical value, the stronger the sustainability
		Maximum rate of return on personal account pension	(0.048)	Expected income of each pension account/amount paid per file-1	The higher the rate of return, the greater the fairness
		Contribution rate of economic development	(0.713)	capita	The higher the contribution rate the greater the fairness
		Maximum ratio of government subsidy to individual contribution	(0.239)	Each level of government subsidy/ each level of individual contribution	The larger the numerical value, the greater the fairness

TABLE 1: Evaluation index system and weights of security ability of EIUR.

Note: the number in parentheses represents the weight of each index. (1) Number of persons aged 16–59 eligible for participation = population aged 16–59number of students aged 16 and above-number of employees in enterprises and institutions-number of retired enterprise employees aged 55–59-institutions and institutions' number of retirees 50–59 years old; (2) number of people who meet the conditions for participation = the number of people 60 years old and above-number of retirees over 60 years old who have enrolled the basic pension insurance for urban employees; (3) per capita pension = fund expenditure \div number of recipients \div 12; (4) per capita contribution = individual contribution income \div (number of participants-number of receiving benefits); (5) government subsidies per capita = (fund income-individual contribution income) \div number of participants; and (6) fund income per capita = fund income \div number of participants. (3) Weight Calculation of Target. According to the calculation result of the target, the target index weight can be calculated. First, the information entropy of X_i is calculated. Let $H(X_i)$ denote the information entropy of X_i .

$$H(X_i) = -\frac{1}{\ln(n)} \sum_{t=1}^n w_i^t \ln(w_i^t),$$

$$w_i^t = \frac{\mathrm{SI}_i^t}{\sum_{i=1}^n \mathrm{SI}_i^t}.$$
(5)

In (5), if $w_i^t = 0$, then $w_i^t \ln(w_i^t) = 0$. According to the information entropy, the weight $p(X_i)$ of the index X_i can be obtained.

$$p(X_i) = \frac{1 - H(X_i)}{5 - \sum_{j=1}^5 H(X_i)}.$$
(6)

3.2.3. Index Weight Analysis. This article uses a layered entropy weight method: the more significant the changes in the indicators, the more substantial the weighting. As Table 1 shows, among the five targets, "flexibility" is the most heavily weighted, followed by "fairness," "full coverage," "sustainability," and "preservation of basics." The results show that after years of stable development, the EIUR has made significant progress in regard to coverage, flexibility, and fairness.

The accelerated development of the aging population will lead to an increase in the number of people receiving treatment of the EIUR, thereby resulting in serious challenges to the long-term stable development of the system. These challenges will be reflected in the stability and continuity of urban and rural residential maintenance pension treatment levels, as well as in the sustainability of urban and rural residential insurance fund revenues and expenditures.

Owing to the influence of the design model of the existing EIUR, the development of the system is increasingly dependent on finance from the government. Therefore, the benign development of the EIUR continues to depend on the financial ability of the government—especially local governments—in the short term. This way, a strong financial ability can ensure that the fruits of economic development benefit more urban and rural residents.

3.3. Evaluation Index Calculation and Classification. Based on the index and weight of the five targets—coverage, security level, elasticity, sustainability, and fairness—we can quantitatively evaluate the security ability of the basic endowment insurance system for China's urban and rural residents, and its model can be expressed as follows:

$$BPCI_t = \sum_{i=1}^{5} p(X_i) SI_i^t.$$
(7)

In (7), BPCI_t represents the evaluation index of security ability. Its value is between 0 and 1; the larger the value, the stronger the security ability.

Based on the calculated evaluation index of the security ability of each province, this paper uses the ArcGIS 10.5 software's natural breakpoint method to divide security ability into five levels: "high level," "higher level," "medium level," "lower level," and "low level" (see Figures 1 and 2).

The completion of the five targets is divided into three levels: "basic implementation," "at risk," and "serious challenge."

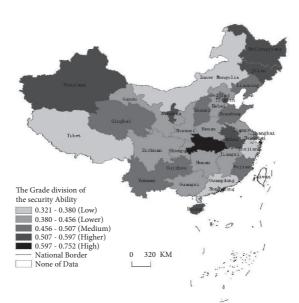

4. Evaluation Results and Analysis

4.1. Low Level of Security Ability of the EIUR. As shown in Table 2, the security ability of EIUR in China is currently low. First, Hubei, which ranks first in the national security ability index, has only 0.752. The security ability indexes for Jilin, Tianjin, and Anhui are all below 0.6–0.597, 0.586, and 0.561, respectively—and much lower than that of Hubei. There are only nine provinces with a security ability index of between 0.5 and 0.6; however, there are 21 provinces with an index below 0.5, accounting for 67.74%. In addition, four provinces (autonomous regions)—Inner Mongolia, Tibet, Guangdong, and Zhejiang—have a security ability index below 0.4. Among them, Zhejiang has an index of only 0.321, which is the lowest in the country.

Second, from a security level perspective (Figure 2), a few provinces have a higher level of security ability while others have medium and low levels. Specifically, Hubei is the only high-level province, and there are only seven higher-level provinces, nine medium-level provinces, and then other provinces that are at a lower level and below, accounting for 45.16%.

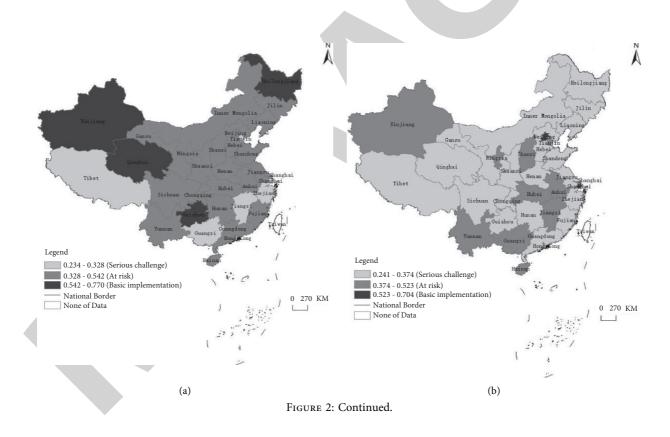

There are several reasons for the low level of security ability. First, target completion is poor. As shown in Table 2, regarding the five targets, the provinces facing "certain risks" and "serious challenges" account for a high proportion: 87.10%, 93.55%, 90.32%, 67.74%, and 96.77%. Second, none of the provinces have been able to implement the targets. For example, Hubei, which ranks first in the country in regard to the security ability index, has only two targets—"flexibility" and "sustainability"—that have been "basically achieved," while the "fairness" target is still facing "serious challenges." Inner Mongolia, Guangdong, and Zhejiang, which have lower security ability index rankings, have the lowest target completion. Four targets in each province face "serious challenges," and none can achieve "basic implementation."

4.2. Uneven Development of the Targets of the EIUR. Table 2 and Figure 2 show that among the five targets, "sustainability" and "full coverage" are developing well, followed by "basic protection." In contrast, the "fairness" and "flexibility" targets are not being achieved. First, the "sustainable" target has the highest degree of completion among the five targets, and 10 provinces have reached the "basic implementation" level. The "full coverage" target is second only to the "sustainable" one, and in regard to the former, more than half of the provinces are above the national average. Second, the "basic protection" target's performance was average, with 12 provinces above the national

Å

FIGURE 1: Grade division of the security ability of the EIUR in 2018.

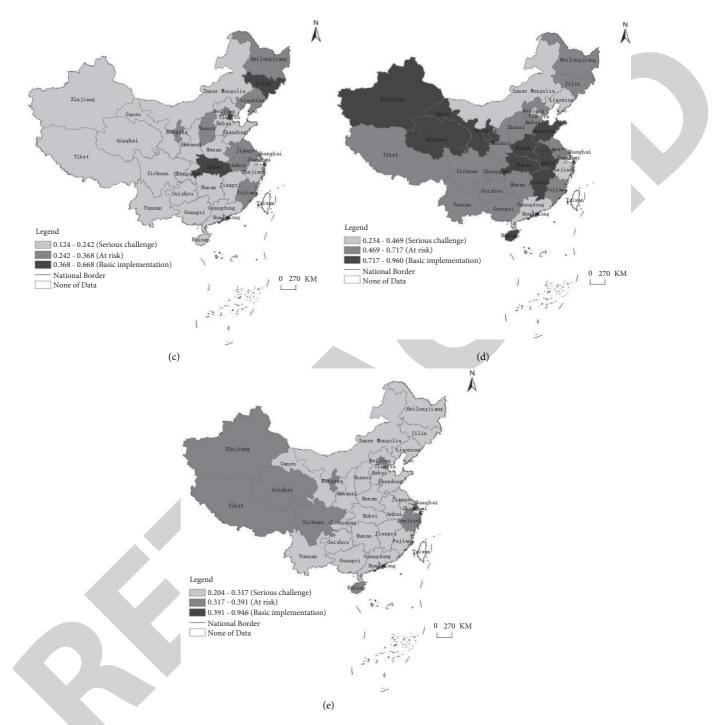

FIGURE 2: Grade division of the targets of the EIUR in 2018. (a) Grade division of full coverage. (b) Grade division of basic protection. (c) Grade division of flexibility. (d) Grade division of sustainability. (e) Grade division of fairness.

average and the others below. The only provinces in which "basic protection" can be "basically realized" are Shanghai and Beijing, signifying that the treatment level of the EIUR is low. Third, "fairness" and "flexibility" have the worst performance. Insurance flexibility has become the biggest shortcoming in the development of the EIUR. Regarding the "flexibility" index, the national average is only 0.261, and only nine provinces are above this threshold. "Fairness" is another target with poor performance, as 21 provinces are below the national average and are facing "serious challenges." Moreover, there is an apparent gap in the degree of realization regarding the "fairness" target. In regard to this target, only Shanghai has achieved "basic realization," and its index of 0.946 is 0.555 higher than that of Sichuan, which ranks second in the country.

Based on the indicator calculation, we identified some reasons for the poor performance of "fairness" and "flexibility" targets: On the one hand, the low "fairness" index is

due primarily to the failure of the incentives for government subsidies for individual contributions, which are reflected in the indicator such as individual account pension return rate and the financial subsidy ratio. However, we found that the lowest individual contribution level had the highest return rate, with the improvement of the individual contribution level, the pension return rate, and the financial subsidy ratio showing a downward trend. Obviously, residents will choose the lowest contribution level to pay, thereby enabling them to maximize their interests. This also explains why the individual contribution level has continued to decline in the past 5 years. (In recent years, the income funds of the basic endowment insurance system for China's urban and rural residents have gradually increased. However, the proportion of individual contributions has gradually decreased from 38.79% in 2014 to 24.52% in 2018, indicating that the funds' dependence on finance is higher than the income of the individual contributions.)

On the other hand, the lowest "flexibility" index was due primarily to the mismatch between the individual's contribution level and income level. Generally, with the improvement of residents' income level and the increase in oldage awareness, the degree of residents' participation should increase accordingly. However, the data analysis showed that a few provinces, including Jiangxi, Hainan, and Hunan, have greater flexibility in regard to personal payments. In most provinces, such as Tianjin, the individual contribution flexibility of the EIUR is deficient. It must be noted that residents' per capita disposable income in China is increasing year by year, while individual contributions are decreasing. This means that the degree of urban and rural residents' participation is decreasing. The question of how to reverse this trend and ensure that personal contributions are compatible with economic development and residents' income is a significant issue in the development of the system. Moreover, the existing system design causes "flexibility" and "fairness" to influence each other. However, the system design's contribution model is not conducive to the improvement of "flexibility" and "fairness" targets. In the future, the improvement of the system's security ability needs to focus on "flexibility" and "fairness" targets.

4.3. Significant Regional Differences in Security Ability. There are regional differences in the security ability of the EIUR in China. In the midwestern region, performance in regard to security ability is better than in the eastern region. The completion of the targets between regions varies. As Figure 3 shows, there are 8 provinces in which the insurance security ability index has reached a higher level and above. Among the above 8 provinces, only Tianjin and Hainan in the eastern region have reached a higher level. Based on the

7

TABLE 2: EIUR: security ability index and rank in 2018.

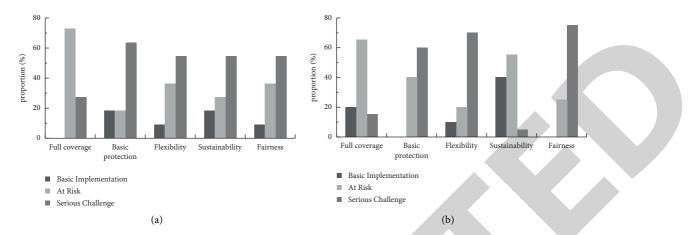

FIGURE 3: The differences between the targets in the (a) eastern region and (b) the central and western regions.

rankings (Table 2), there are seven midwestern provinces in the top 10 in the country, and Hubei ranks first, with an absolute advantage of 0.752. Most provinces in the eastern region, such as Jiangsu, Guangdong, and Zhejiang, are ranked lower than those in the midwestern region, even appeared at the bottom of the rankings.

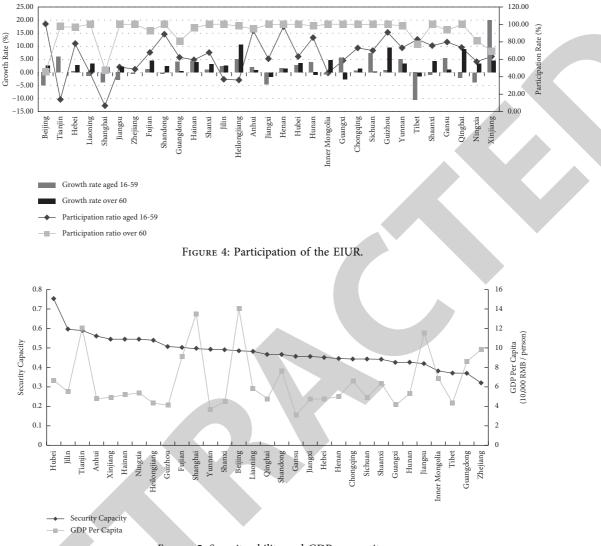

There are also regional differences in the completion of targets. On the one hand, the "full coverage" target of the provinces in the eastern region is underdeveloped. As shown in Figure 1, none of the eastern provinces "basically achieved" "full coverage," and most have "certain risks." For example, Shanghai, Tianjin, and Zhejiang still face "serious challenges" in achieving the "full coverage" target. Based on the participation rate of urban and rural residents in the provinces of the eastern region, as shown in Figure 4, in all except Beijing, the participation rate of residents aged 16-59 is lower than that of residents over 60 years old. This shows that the residents in the eastern region, especially the residents between youth and middle age, are less enthusiastic about participating than residents in the midwestern region in the EIUR. The system's severe lack of attractiveness lowers the eastern provinces' scores and rankings on the "full coverage" index.

On the other hand, the provinces in the midwestern region are poorly developed in terms of the "basic protection" target. No provinces in the midwestern region have reached the "basic realization" level. In addition, all provinces in the midwestern region face "certain risks" and "serious challenges." This is due primarily to the lower level of the basic endowment insurance treatment in these regions. Although most provinces in the central and western regions raised the basic pensions of the EIUR in 2018, (In May 2018, the Chinese government issued the "Notice on Raising the Minimum Standards of Basic Pension Insurance for Urban and Rural Residents in China in 2018." Most provinces in the central and western regions-such as Shanxi, Anhui, Jiangxi, Guangxi, Chongqing, Sichuan, Guizhou, Shaanxi, Gansu, and Xinjiang-have raised the basic pension standard only slightly since 2014, and some did not adjust basic pension standards between 2015 and 2017.) they cannot change the current low level of treatment. According to the perspective of system design, the low level

of treatment is directly related to individual contributions and financial subsidies. The central and western regions have no advantage in terms of individual contribution or financial subsidy ability; consequently, the government can provide only a relatively low subsidy amount due to downward economic pressure and financial affordability.

4.4. Mismatched Security Ability and Economic Development Level. At present, there is an apparent mismatch between the security ability of the EIUR and the level of economic development. As shown in Figure 5, the economically underdeveloped areas have high security abilities. For instance, Hubei, Jilin, Heilongjiang, Anhui, Ningxia, Guizhou, and Xinjiang, which have a relatively low per capita GDP, have relatively high system security abilities. In contrast, the economically developed areas, such as Shanghai, Beijing, Jiangsu, Guangdong, and Zhejiang, show low security abilities in regard to both ranking and index. The purpose of the EIUR is to protect the basic living needs of citizens in old age. However, if the security ability is too low, it cannot provide sufficient protection for citizens who have not participated in other endowment insurance, especially in regions with high economic development levels.

The study found that "basic protection" and "flexibility" are the main factors that lower the security ability index of the EIUR in each province. In practice, this is reflected primarily in the low treatment level, lack of flexibility in the system adjustment mechanism, and low contribution level of citizens who have not participated in other endowment insurance; these factors have, in turn, led to an increase in financial dependence. (According to the "China Pension Fund Report 2018," between 2011 and 2017, the proportion of personal contributions to the income fund of the basic pension insurance of urban and rural residents decreased from 38.79% to 24.52%.) Because it is a pay-as-you-go system, the increasing financial burden year by year will force the local government to devote most of its energy to maintaining the regular operation of the current system rather than increasing the level of treatment, thereby resulting in the financially supported payment subsidies, and basic pensions have been at a low level for a long time, and it

will not effectively attract residents whose living consumption level is increasing with the economic development to actively participate and choose higher-level payment, and *t*. In addition, increased financial subsidies and low personal contributions will cause personal contributions to income funds to decrease year by year. Such repeated cycles will eventually lead to a situation in which the system's security ability does not coincide with the economic development of the province.

The fundamental reason for the above is that the system is ineffective in regard to guiding residents to choose a higher level of contribution. It is not difficult for residents to afford a higher level of contribution. However, due to the system's defect in the setting of government subsidies for individual contributions, the individual account pension return rate of the lowest contribution level for each province is the highest, and the proportion of government subsidies for individual contributions shows a downward trend as the contribution level increases. Therefore, the system does not encourage insured persons to increase their contribution levels. Whether the residents make "smart choices" or follow the herd mentality after making their cost-benefit calculations, they are more inclined to choose a lower contribution level.

5. Conclusions and Recommendations

Upon the evaluation method and indicator system, the study found that factors such as the top-level design of the EIUR, the operating environment, and the willingness of the residents affected the EIUR in China, resulting in low security ability that does not coincide with the level of economic development. In addition, there are regional differences in security ability, and the development of various targets is uneven. To further enhance the security ability and facilitate the steady development of the security system, two areas need to be improved.

First, there is a need to improve the completion of each target and to focus on strengthening the development of "flexibility" and "fairness" targets. On the one hand, it is necessary to improve the residents' individual insurance contribution model and to establish and improve the

Learning difficulty is a significant issue that comprehensively needs to be taken care of by university instructors with a focus on altering their ways of educating students since various degrees of learning difficulty could be observed among students. Hence, proper approaches should be adapted and utilized that provide chances for each student, securing his/her educational right. By doing so, it guarantees that each student has a right of learning with a different pace of conducting it. For example, the same educational and teaching materials cannot be adapted to each student. Hence, the training of students with learning difficulty should follow a model that is characterized as "from bottom to top," namely, "normal to learning with difficulties." The characterization of this approach is very similar to that of the treatment of human beings: biological malfunctions by medicine and mechanical malfunctions by psycho-sociology. This paper proposes a diagnostic model to determine the cognitive ability of students who deal with learning disabilities. The computerized model is proposed based on a combination of fuzzy logic and machine learning utilizing association rules and cellular automata. The advantage of the proposed method is that it helps find the needs of these types of students, so the widely implemented practices that shape his/her learning behavior are avoided. Therefore, practical recognition of each student with a different pace of learning should be realized.

1. Introduction

The ability of every human being to learn is a phenomenon associated with the maintenance and evolution of life, education, progress, and the development of culture [1]. Nevertheless, the learning process does not finalize thoroughly and satisfactorily. Some observable hinders negatively impact the learning process due to personal issues. Therefore, the learning process ends up with incomplete, fragmented, or even failed outcomes [2].

In the contemporary world, acquiring more knowledge at a faster pace is expected. On the other hand, individuals encountering problems pertinent to learning and acquisition of knowledge naturally are observed. Besides, mass educational implementations, relatively higher living standards, and awareness of educational rights of disabled people are the core issues in modern societies. Hence, people with learning disabilities become an entity that needs to be taken care of regarding educational, psychological, and social dimensional perspectives [3]. Therefore, it is one of the focused research areas by researchers and professionals of education, so the scientific and educational aspects of this issue can be characterized by the following:

- (1) Gradual paradigm changes from the "medical-biological model" to the "psycho-pedagogical model" are needed.
- (2) The psycho-pedagogical research provides a new way of understanding to deal with cognitive functions taking part in the learning processes and difficulties observed in the learning processes, for example, in reading, spelling (e.g., dyslexia), and mathematics.
- (3) Students who have learning difficulties can be promptly identified, diagnosed in detail, and helped systematically.

(4) Dealing with those issues requires professors to get informed about areas of cognitive functions, such as learning difficulties, dyslexia, dysgraphia, and difficulty with mathematics.

Given that each subject has specific cognitive requirements, a more functional approach to categorizing learning disabilities would be to examine whether a student's abilities and weaknesses meet the cognitive requirements of the subjects (i.e., courses) that he or she deals with. Based on this reasoning, we can assume that if a person has a weakness in one or more of the areas involved and is required for the cognitive processing of a learning object, he/she will certainly face difficulties during the above process [5].

Also, universities and colleges are increasingly aware of the needs of students with disabilities and learning difficulties. They can offer support in some ways, and students may be able to benefit from extra financial help.

In this spirit, this work aims to construct a realistic diagnostic model of a student's cognitive ability based on his/her learning disabilities. This modeling is based on a hybrid neuro-fuzzy system [6], which combines the use of association rules [7] and cellular automata [8] for its application when the investigation of special learning difficulties in special education programs is a concern [9, 10].

Although this application is an innovative approach that is presented for the first time in the research community, various attempts have been made to use innovative technologies in various types of special education in the literature. What the proposed method brings as a novelty can be summarized as follows. (1) Ambiguity and uncertainty are common features in the assessment of educational output since different evaluators have different evaluation measures. (2) The proposed method provides a great amount of flexibility to reach a fuzzy inferential diagnostic assessment in managing and updating data.

2. Related Literature

The literature related to the educational approaches to differentiate the training of students with disabilities mainly focuses on methods dealing with overcoming the learning complexities.

A model was proposed by Manghirmalani et al. [11] to diagnose and classify learning disorders. Fuzzy expert systems, called a soft computing technology, help learning disabilities be classified into several types. Besides, the requirements to implement this system and outcomes were provided in this research.

Prentzas [12] presented a survey about artificial intelligence methods used in early educational technologies. Intelligent tutoring and adaptive educational hypermedia systems, as well as robots, were discussed in the article. The results showed that students were encouraged to participate in learning and social activities, and they remained interested in technology resources even after long periods of interaction.

An intelligent agent-based classification model, proposed by Elsayed [4], provides a psycho-pedagogical assessment for professors, helping determine students with learning impairments in classrooms. Disabilities of pupils are classified based on the information of the agents. The model functions based on previously classified examples and stored data in the system. Besides, interactive problemsolving assistance and a new knowledge domain can be gained by deriving generalizations from studying the stored data.

Two data mining methods, called fuzzy and neuro-fuzzy, were employed by David and Balakrishnan [6] to devise a new strategy predicting learning disabilities in school-aged kids. The objective of the strategy depends on constructing an algorithm to impute missing values and evaluate the performance of the classifier based on preprocessing methods. When the basic assessment approach was utilized in the prediction of learning difficulties, checklists were commonly employed. Thus, there exists a dependence between the mood of the students and data cases so redundancy and missing values could be contained.

Garg and Sharma [13] attempted to investigate how artificial intelligence has impacted the schooling of students with exceptional needs. The data were gathered through a qualitative study involving targeted interviews with both professors and kids needing special attention. The information was also gathered from academic databases, newspapers, periodicals, and blogs. Content analysis was used to examine the responses received. Finally, the study attempted to suggest a paradigm for an inclusive future of special needs education based on targeted interviews [14–16].

The literature suggests that various aspects of the research dealing with students having learning difficulties have been conducted. However, a gap still exists in the research regarding the differences between students when learning processes are under investigation.

3. The Proposed Method

3.1. Hybrid Neuro-Fuzzy System. ANFIS, the adaptive neuro-fuzzy inference system, is one of the adaptive networks that consists of both adaptive and non-adaptive nodes [17]. The adaptive network consists of a multilayer feed-forward network where each node is assigned to a specific function based on the incoming signals. Each specific node is denoted by a set of parameters. All nodes are connected via directional links. Customizable nodes are the ones depending on the parameters associated with that node. To minimize the predefined error, the parameters should be changed based on the learning rules [18].

The type of operation of each node can vary. The choice of the operation of a node depends on the total processing of the inputs and the output on which the adaptive network must perform. The parameter set of an adaptive network is composed of the union of the parameters of each adaptive node. Then, these parameters are updated based on the provided training dataset. Thus, the construction of the desired relationship between input and output is realized by a gradient-based learning process [19].

ANFIS is a systematic effort to generate "if-then" rules between input-output pairs. The model acquires a set of data (pairs of incoming-outgoing data) and divides them into datasets for training and control. Training data form a set of data, input, and output vectors.

This information is normalized to be appropriate in form for the training process. This is achieved by assigning to each term a value between 0 and 1 using the max-min method. The normalized data are then used as input and output values to train the ANFIS model. This creates two vectors for ANFIS training such as an input vector and an output vector. Training data are used to find the introductory initial parameters for the participation functions.

The least squares method is employed to find the resulting parameters. For each data pair, if an error computed becomes greater than a specific value set, the gradient descent method is employed to update the initial parameters of the input.

The process ends when the error becomes less than the specified value [20]. The proposed hybrid system then applies association rules with a learning method to discover correlations and patterns between variables [7]. The problem of correlation rule mining is defined as follows:

- (1) Let $I = (i_1, i_2, ..., i_n)$ be a set consisting of *n* binary properties called objects.
- (2) Let $D = (t_1, t_2, ..., t_m)$ denote a set consisting of transactions.
- (3) Let *D* denote a unique transaction ID and contain a subset of *I*.
- (4) Let the correlation rules be defined by the following [21]:

assume that
$$X \cap Y = \emptyset$$
 and $X \Rightarrow Y$, (1)

.)

where X and $Y \in I$.

The following three rules are defined based on this logic [22, 23]:

Rule:
$$X \Rightarrow Y = \begin{cases} \text{Support} = \frac{\text{frq} q(X, Y)}{N}, \\ \text{Confidence} = \frac{\text{frq}(X, Y)}{\text{frq}(X)}, \\ \text{Lift} = \frac{\text{Support}}{\text{Supp}(X) \times \text{Supp}(Y)}. \end{cases}$$
 (2)

Association rules are embedded in cellular automata to automate their implementation process [8]. Cellular automata are computing system models with emerging complexity that model the behavior of dynamic systems [24]. They are called cellular because they are inspired by cellular devices where each cell interacts with its neighbors in space and is automatic. Then, the behavior of each cell is completely determined by the corresponding model [8, 25].

It is a "society" of digital systems that move, mate, give birth, or die as time passes in a two-dimensional grid based on predetermined simple rules [7, 26]. They are implemented in a grid of cells where each cell can be in a predefined number of distinct states with specific neighborhood relationships, predetermining and indicating its neighbors in the process of updating their states in each cell.

Each cell renews its state based on a predefined transition rule that takes the states of adjacent cells as inputs since the renewal of all cells takes place synchronously. Thus, there is a deterministic evolution of the system over time [26]. Therefore, time is called discrete.

The proposed embodiment consists of C, Σ , N_f , where C denotes a d-dimensional grid of cells identified by vectors of Z^N , Σ denotes the possible states that a cell can take, N denotes the neighborhood with $N \subset Z^d$, and f is a transition function form $\Sigma^N \longrightarrow \Sigma$. The configuration consists of states of the cells, and the initial state has a vital role and needs to be determined when the initial design is set.

Let *C* be the set of cells in a grid, and the neighborhood function, denoted by n, can be defined as [25, 27]

 $n(x, y): C \times C \longrightarrow B = \{\text{True, False}\}.$ (3)

This function will return True if the pair of cells that constitute the input in *C* are neighbors. For example, in a two-dimensional grid, a particular neighborhood function n(x, y) will return True if *x* and *y* are neighbors within the neighborhood of c_o where the relationship is defined by [24–27]

$$N_{c_{a}} = \{c \in C \mid n(c_{o}, c) = \text{True}\}.$$
(4)

The size of the neighborhood $|N_{c_o}|$ is independent of c_o . If the set of possible cell states is determined, the transition function applied to all cells simultaneously can be defined as follows [8, 25]:

$$u: S^{|N|} \longrightarrow S. \tag{5}$$

Hence, the transition function takes the states of all cells in the neighborhood of a cell at time t and sets the state of that cell at the next time. The proposed method helps simplify the diagnostic procedure whose outcomes are not governed by a random state of disorders [28, 29].

3.2. Experiments. Utilizing the proposed approach that combines the findings of studies concerning both the processed information and the categorized students having learning difficulties helps identify the groups of weaknesses that characterize most students. The framework presented herein suggests that three main groups or categories of cognitive impairments typically occur in students with learning difficulties such as reading, spelling, and mathematics. These weaknesses are expressed in [4, 15, 16] as follows:

- (1) Coding symbols.
- (2) Processing the language.
- (3) Perceiving and processing space and numbers.

If students have learning difficulties in reading, spelling, and mathematics, one or more of the mentioned problems above may be observed. The experimental process for the implementation of the model was based exclusively on the feedback of the system with data extracted after interaction with students.

When a student is assessed concerning the reception and comprehension of oral speech, two different and related functions or skills, namely, the distinction and perception of the phonological elements of the language, as well as the understanding of the semantic content of the language are tested. While the former is associated with the development of the phonological system of language and the function of hearing, the second is pertinent to the development of the semantic and syntactic system of language [4]. The way of evaluating these functions was implemented by asking the student to repeat words or phrases or to present the meaning of some words used in daily life with his/her sentences. Besides, some words with more than one meaning and sentences with the complex syntactic structure are used to assess him/her. During the evaluation, we pay attention to the completeness of the semantic definition of the words, the ability to choose the correct meaning of the word, the ability to identify the deep structure (semantic content) of the sentence, etc. Also, by providing instructions to the student, we assess whether he/she can perform them without the need to repeat or explain the instructions.

Also, the evaluation of learning difficulties in mathematics starts from the general to the specific element. This practically means that by evaluating a student's mathematical level, we start from the general mathematical elements and abilities to the more specific ones. In general, the mathematical skills of the specific students are tested to relate weaknesses and abilities to the level of problem solving, so the student's ability to apply mathematical concepts and mathematical manipulations to problems in real-life situations is determined.

Also, the recording of the student's attitude towards mathematics as well as the emotions that he/she experiences through his/her involvement is evaluated. Besides, interviewing students and observing the process is helpful to assessment. When the process of active construction of knowledge is realized, the assessment based on the data must be continuous and comparisons should be conducted since individuals use different ways and means of representation of reality, which are called practical, pictorial, and symbolic representations.

The student in the practical way of representing knowledge uses specific objects (fingers, sticks, numerator, and so on) to perform various operations. Then, pictures, drawings, graphs, and lines are used to calculate some quantities such as sum or difference. Finally, the symbolic way of representing the various operations is realized that is considered the most difficult part [30, 31].

To assess the learning abilities and to identify the respective learning difficulties of the students, indicative skills tests were performed. For example, to better understand the analysis of each number as a sum of two additives, an activity was performed for the analysis of 10. The process can be described as follows: we have two groups with 10 green and 10 red pegs. We want to make a team with 10 pegs by taking a few pegs from the green and a few from the red team. The students work in groups with their objects and then each group announces one of the many ways of composing 10 pegs, which is conducted by a makeshift abacus with pegs (in a tightrope that we have to fasten at both ends of the board, we have hung 10 green and 10 red pegs). Thus, students are given the opportunity, after forming the 10 in a way, to write on the board and the symbolic representation, e.g., 6+4=10. In the end, after all the ways are suggested by the students, the specific objects (pegs) are removed, and the symbolic representations remain for mnemonic retention in the long-term memory.

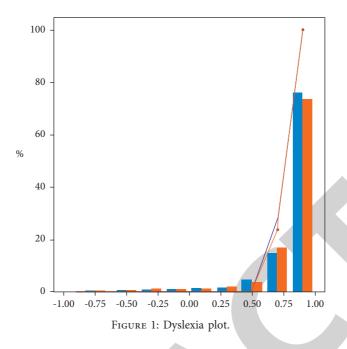

The results of each process with intermediate assessment steps are placed as input to the intelligent system to identify its learning abilities. Some indicative diagrams of the display of the results after the various tests performed are shown in Figures 1 and 2.

It is important to say that to decide if the cause of reading problems is dyslexia, the process should be further evaluated with a set of brain functions. Each of the sensory areas must be checked for any learning disabilities [4, 31]. The areas to be explored are the visual, the auditory, the motion, the mnemonic, and the successor abilities.

- (1) Decoding, reading, and optical detection tests are conducted by the optical tests.
- (2) Repetition of words and sentences, spelling tests, and acoustic perception are conducted by acoustic tests.
- (3) Drawing copies, writing, tactile detection, and quick naming of objects (e.g., language expression) are conducted by kinetic tests.
- (4) Multiplication tables, months of the year, alphabet, repetition of polysyllabic words, and determination of rhythmic succession are conducted by succession tests.

3.3. The Implementation of the Proposed Method. The desired result of a test array is to be able to assess which brain functions are involved in learning to read, spell, and learn in general. It is important for the computer assessment tool to include multiple tests and preferably more than one measurement of each sensory area to be examined.

It should be noted that the tests mentioned herein are an attempt to make this possible. It is not a definitive and unique solution, but a proposal as to which areas should be considered. A prerequisite, to carry out such an assessment, is that the examiner is fully acquainted with how the specific areas can be assessed. Therefore, the test array is a tool in which each assessor can bring his/her assessment material. Accordingly, in addition to cognitive tests, the assessment, e.g., a WISC (Wechsler's Intelligence Scale for Children) or a WAIS (Wechsler's Adult Intelligence Scale) test or equivalent [32–34].

4. Discussion and Conclusions

The educational treatment of learning disabilities is the goal of the whole process for both timely identification and correct diagnostic evaluation. It is the phase in which the professor demonstrates in practice how well he/she knows not only to interpret the results of the diagnostic evaluation but also to find ways to help the student learn [35].

Fuzzy inferential models rely heavily on the uncertainty that has to do with information and especially with its lack in our attempt to model the problem. Information may, for example, be incomplete, inaccurate, fragmentary, unreliable, vague, or controversial. The use of fuzzy logic in assessment is considered necessary since each education system contains an amount of uncertainty. The reason for adopting this approach is that when it comes to educational evaluation, different evaluators have different evaluation measures. Three important factors that favor the vague approach to assessment are initially that the grades given by professors for student performance are not always accurate. Second, the exams consist of uncertain data, while finally many professors grade students in verbal terms.

It, therefore, becomes clearer that fuzzy logic and fuzzy systems can deal with the ambiguity and uncertainty that exist in the process of educational evaluation. A fuzzy inferential model uses the process of approximate reasoning which mimics human reasoning. It utilizes the advantages of the natural language and the process of programming and building the system that become easier and more practical. It is obvious that a fuzzy inference system can be constructed quickly and has a higher utility value with minimal cost.

Fuzzy inference systems make the best use of the experience and data derived from it. As we saw in the construction of the fuzzy diagnostic evaluation system presented herein, its foundation was based on data from human experience. The specialized knowledge of the developer was used in every step of the construction of the system.

The proposed method provides a great amount of flexibility to reach a fuzzy inferential diagnostic assessment in managing and updating data. This system is based on the general principle of the evaluation process concerning the goals that we have set at the beginning. From these objectives, the system input variables are taken, and the language rules are set. Thus, the same procedure can be applied to other educational, medical, or evaluative procedures by changing variables and rules.

Early diagnosis and educational intervention not only have great significance for the students having learning disabilities to avoid unnecessary negative consequences but also provide preparation to construct valuable special education programs. Learning problems such as dyslexia tend to weaken people's self-confidence due to their daily familiarity with failure. Before diagnosis, a dyslexic person is often forced to deal with difficult and frustrating learning situations for several years.

Data Availability

The data used to support the findings of this study are included within the article.

perhaps an impressive step towards the ways of initial di-

agnosis and treatment of learning educational difficulties.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Information and communication technologies play an important role in education. This fact was emphasized even more due to the significant upheavals, globally, caused by the pandemic of COVID-19 and because distance education uses tools of modern technology that prove to be significantly important. Particularly, virtual reality immersion systems, which may include 3D spatial representations, multisensory interaction channels, and real-time intuitive physical interaction, can extend the learning process by providing learners with stimuli that represent a real advanced training environment. In the present work, based on the most modern technologies of computational intelligence, virtual and augmented reality, wireless communications, and space-sensitive positioning applications, an Artificial Intelligent Virtual Reality (AI-VR) interactive model for distance education is presented. This is a case study of escape-room-type educational application, wherewith appropriate practices and methodologies promote individual and collective participation, enhance the active role of the learner, personalize the educational experience, and upgrade the process of participation in distance education, strengthening and assisting role of the educator. Specifically, a Newton polynomial is used for max-polynomials arising from the stereoscopic problem of augmented reality used to indirectly indicate the number of linear regions in order to optimize the problem. The proposed application is related to the training course of agricultural education and methods of modernization of crops, including additional sound, 3D graphics, and short film projection. The history-space-objects relationship takes and evolves with various versions such as the parts of the story to be unlocked as the trainee moves from one tool to the next or the story to guide the trainee to explore the space-time continuum, giving a new dimension to the technological development of agricultural education and the methods of modernization of crops. This finding shows that they learn best when they receive information in a style that incorporates visual, auditory, and kinetic stimuli so that learning improves when learners can examine an idea or concept using a multidimensional approach.

1. Introduction

Following the rapid development of both computer hardware technology and software capabilities in the last decade, a new trend is emerging today that places particular emphasis on human-machine interaction. Virtual reality, which is a key representative of this new trend, is a means for people to visualize, manage, and interact with computer systems as well as extremely complex data in a virtual environment. The result produced by a virtual reality system is called a virtual environment, which is based in part or whole on data generated by a computer system. The goal of the virtual environment is to create to the user the illusion that he is naturally placed in a synthetically produced environment, through his representation (embodiment) by an entity.

Regarding the application of multimedia in education, there is the view that information that circulates in the form of direct experience using different senses, as opposed to reading, which is a purely visual and mental process, maintains and cultivates its correlations. This is one of the reasons that educational multimedia applications manage to convey more quality information to their users, as has been proven in practice. Based on this view, the use of virtual reality systems in educational applications further engages the user in the learning process, offering him various options for exploring the cognitive space and leading to a more efficient educational process. The main advantage of virtual reality is its ability to facilitate constructive learning activities and to provide alternative forms of learning that can help different types of students (e.g., visual-type students). They also offer the possibility of educational use of shared virtual spaces (or network virtual environments) [1–3] for distance learning and collaborative learning. Such applications can be used as collaboration and training tools, as they can allow students and teachers to take part in virtual meetings, seminars, and lectures in real time.

In general, virtual reality technology can be used in a variety of ways to support the educational process [4], especially in cases where traditional teaching methods are not sufficient, such as the following:

- (1) *Simulation of Complex Systems*. The advantage over traditional teaching methods is the ability of learners to observe the operation of the system from many angles using high-quality imaging but also to interact with it.
- (2) Macroscopic and Microscopic Imaging [5]. The advantage lies in the ability to observe phenomena, systems, objects, and so on, which are too small or too large to become visible or to understand their operation on a normal scale.
- (3) *Simulation of Dynamic Events* [6]. The advantage lies in the ability to observe the dynamic event through its different playback speeds. This function is equivalent to the fast forward function on a video device.

Other important features of virtual reality that can be used to support the educational process are the following:

- (1) The high level of interaction offered by virtual reality technology: most people learn through practice.
- (2) The sense of immersion: in immersive virtual reality environments, users are fully immersed in the virtual world using special input/output devices. This is a useful feature for various applications, like training in architecture where the sense of size is very important for the impact of the design of a building on the external environment and the inhabitants.
- (3) The inherent flexibility and adaptability of virtual reality systems: these features come from the nature of the software that supports the virtual environment. A virtual reality system can be used in various ways depending on the software application to be used. So, it can be used for various educational applications.

In addition to the above uses, virtual environments and more specifically the collaborative ones [7–9] offer many useful features to assist the educational process through the following:

- (1) Supporting students' social awareness
- (2) Increasing the possibility of interaction and active collaboration between students

- (3) The up-to-date and varied information available to users and the possibility for collaborative knowledge exchange
- (4) The provision of virtual experiences for the perception and understanding of complex concepts
- (5) The fusion of aspects and characteristics of direct and indirect learning.

Various proposals have been made related to the use of virtual environments and the exploitation of their advantages in education, some of which are particularly interesting:

- (1) The use of avatars [10, 11] to upgrade user presence and collaboration: virtual environments provide a sense of user presence with techniques that shift their focus from the real world to the virtual. Presence is associated with upgrading users' sense of their responsibilities as students in the virtual world, while at the same time feeling more comfortable during the educational process. This is enhanced by the sense of the presence of other users in the virtual environment, through their representation (avatars), which in addition helps the cooperation of users. In addition, the gestures and actions that can represent the avatars of users raise the awareness of other users about their actions.
- (2) The design of virtual spaces in correspondence with the real world. Virtual environments place the learning process in a virtual space with a specific purpose. The design of the virtual environment with objects and content similar to a traditional classroom seems to play an important role because of the active interaction with objects familiar to students, like a whiteboard, blackboard, presentations, etc.

Web virtual environments can be the basis for creating educational environments for collaborative distance learning over other technologies, such as video conferencing systems, because of their key advantages over other distance learning technologies. More specifically, they provide important tools for creating communication and collaboration systems with easy access and use at the same time. A fairly large number of users can communicate simultaneously through multiple channels such as voice communication, text messaging, and gestures, without the need to install additional computer hardware.

In addition, avatars provide a set of benefits, offering additional communication channels and helping users to express actions in the virtual environment. At the same time, their use is rather straightforward, which allows users to blend more easily in the general use of the system and not distract them from the educational process.

It should be noted, however, that the existing systems of virtual environments do not take full advantage of their potential in terms of user awareness of the social presence and consequently of the educational function. For this reason, in collaborative distance learning, the term "Educational Virtual Environment" is used.

An educational virtual environment seeks to harness the potential of his online nature to support flexible learning. More specifically, it is based, from a pedagogical point of view, on the concepts that govern collaborative learning and, from a technological point of view, on virtual network environments. A virtual educational environment is therefore a virtual network environment framed with additional functionalities and technologies to effectively support collaborative distance learning communities. Such features include text chat, voice communication, private messaging, application sharing, collaborative text reading, and document management, recognizing the presence of other users and representing users with humanlike avatars that support gestures related to the educational process (e.g., raising hands, pointing, applause, etc.) and observing objects and space from different angles.

Despite these promises, Educational Virtual Environment is still not perfect from technological, organizational, and psychological points of view since it suffers from a number of challenges:

- (1) AR is often considered as a game, which is not taken very much seriously—it is fun to play with, but not a real learning process. Students can show the attitude which assists in winning the game but not fully engage their mind to acquire new knowledge and critical thinking.
- (2) AR requires intensive graphics capabilities that are not at all times possible with standard computer equipment and it could take significant efforts to achieve smooth implementation and worth.
- (3) Immersion and interaction.
- (4) AR is often delivered as propriety solutions that could not be matched with similar environments from other developers—many companies offer their own tools to create VR environments that are not compatible with the rest regarding hardware and software.
- (5) AR, after its initial adoption as a new technology, will require unified standards for the preparation of professional curriculums that are compatible between different educational institutions regarding content preparation, implementation, and educational result achievement.
- (6) AR training time—depending on the size of the organization, cultural characteristics of the workforce, and the existing used methodologies, training time could be minimal or extensive.
- (7) AR training could provide participants with a higher level of realism and immersion in comparison to classroom instructions and web-based educational material. However, AR scenarios still lack the direct hands-on experience and face-to-face interactions that real-life exercises provide. The novelty of Educational Virtual Environment requires preliminary training with such environments to enable users to effectively use new systems.

In this work, based on the most modern technologies of computational intelligence, virtual and augmented reality, wireless communications, as well as space-sensitive positioning applications, an AI-VR interactive model for distance education is presented. This is a case study of escaperoom-type educational application, wherewith appropriate practices and methodologies promote individual and collective participation, enhance the active role of the learner, personalize the educational experience, and upgrade the process of participation in distance education, strengthening and assisting role of the educator.

The study is organized as follows: Section 2 gives a detailed description of the related review of the topic. Section 3 presents the proposed AI-VR interactive model. Section 4 has a discussion on our study, and finally, the last section draws the conclusions and outlines future research directions.

2. Related Literature

The literature of Artificial Intelligence research in E-Learning, especially in recent years, is becoming more and more frequent because of the great potential of AI in the field of the educational process and especially the personalization aspect.

Montebello [12] presented a comprehensive picture of AI in E-Learning and its future in his substantial work. He aimed to provide answers on how to maximize the contribution of AI to E-Learning through the use of tools, technologies, and approaches. He provided an in-depth examination of multiple future evaluations of various key E-Learning variables, as well as a comprehensive overview of the most recent and relevant technology. The book ended with a foreshadowing of how such a model might manifest in the future, based on the multiple interposing circumstances.

Drozdova and Guseva [13] presented a specific report on E-Learning in the banking industry. The article discusses the characteristics and criteria that should be included in a training course, as well as the outcomes of its implementation. They used Donald Kirkpatrick's four-level training efficiency evaluation approach. The author advocated that the relevant indicators are calculated for each level of this model to give a fuller picture of the overall evaluation of the training course. This method includes objective and accurate efficiency evaluations, faster processing of the collected results, and a clear organization of the outcomes and evaluations.

Holmes and Anastopoulou [14] in their research looked at remote education students' perceptions of the benefits and risks of Artificial Intelligence (AI) technologies, which are rapidly being used in distant education. They presented the preliminary findings of a survey of students from the UK's largest distant institution as a first step toward answering the question of what students at distance universities think about AI.

Cruz-Benito et al. [15] attempted to investigate students' opinions of artificial intelligence and education. They wondered if they would be hesitant to be influenced by nonhuman actors in a human process like education. This work developed a research model based on the Technology Acceptance Model to answer these issues. They presented the model's many primary structures and variables to describe it, and then they analyzed the model's main implications.

Adamu and Awwalu [16] in their paper covered the components of Adaptive E-Learning Systems (AES), the function of AI in AES content aggregation, potential hazards, and accessible opportunities. They also emphasized the need for Intelligent Tutoring Systems (ITS).

Krendzelak [17] in their research looked into machine learning and how it may be applied in E-Learning frameworks. They attempted to investigate the fact that students must devote a significant amount of time to adjusting their profiles to meet the training's learning objectives.

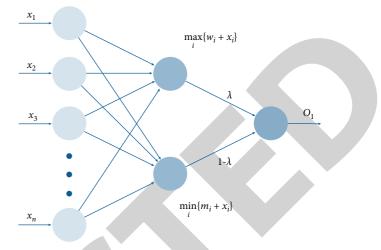

Finally, Demertzi and Demertzis [18] proposed the Adaptive Educational eLearning System (AEeLS), which can acquire and analyze data from learning repositories and modify it to the educational curriculum based on the student's skills and experience. It is a new hybrid machine learning system that combines a Semisupervised Classification method for ontology matching with a Recommendation Mechanism that employs a hybrid method trying to combine neighborhood-based collaborative and contentbased filtering techniques to provide each student with a personalized educational environment.

3. THE Proposed AI-VR Interactive Model

Augmented reality is realized with various devices such as helmets and glasses with more common mobile devices, such as mobile phones and tablets. The built-in cameras of these devices are used to connect the real with the virtual world, giving the user the feeling that he is navigating the real world which has been enhanced with additional objects/information and/or functions as virtual objects are superimposed on the real ones. We note that several augmented reality applications can remove some of the real-world objects. An augmented reality application displays virtual world objects when it recognizes a predefined pattern within the image captured by the device's camera. These patterns are divided into marker-less patterns in which the application displays the virtual world when the camera displays specific parts of the real world and patterns using markers such as a QR (Quick Response) Code. These codes are usually small square images, resembling barcodes and which may include digital information that can be revealed when scanned by appropriate software that accompanies each mobile device, the QR readers.

Specifically, a simple architecture of a network consisting of 2 tropical perceptrons is proposed: the first of which is based on (max; +) and the second on (min; +) algebra, while the total output (maxout) is the sum of the 2 responses. The architecture of this network is summarized in Figure 1.

As shown in the figure above, given an input pattern $x \in \mathbb{R}^n$, this network calculates 2 responses, the first of which is a dilation and the second an erosion, respectively:

$$\delta(x) = \bigvee_{i=1}^{n} w_i + x_i,$$

$$\epsilon(x) = \bigwedge_{i=1}^{n} m_i + x_i,$$
(1)

choosing a = 1 and b = 1 and vectors w = Bs; m = B, we end up with the morphological gradient, which is used as an edge detection operator and is defined as

$$\nabla^{B}I(x) = (I \oplus B) - (I \oplus B).$$
⁽²⁾

So basically, we have a neural network which at its output calculates the sum of 2 partially continuous convex functions of the form

$$h_{i}(x) = \max_{j \in 1, 2, \dots, k} \left\{ W_{ij} x + b_{ij} \right\} = \bigvee_{k}^{j=1} \left[\left(\sum_{m=1}^{n} W_{ijm} x_{m} \right) + b_{ij} \right].$$
(3)

For the optimal solution of the resulting polynomial systems, the polytope continuation method is used to divide the original system into simpler problems and to solve them optimally. Specifically, the Newton polynomial is used for max-polynomials arising from the stereoscopic problem of augmented reality used, to indirectly indicate the number of linear regions, to optimize the problem.

A graphical representation of the proposed technique is presented in Figure 2 above, where we illustrate the idea of creating a thinner system by creating polyhedral homeopathy that reduces a polyhedral to a linear system. The lower hull of the polytone Newton causes triangulation, which is used to count the roots while creating homeopathy with as many paths to follow as the volume of the cell, as shown in the following equations:

$$P(x_{1}, x_{2}) = \begin{cases} x_{1}x_{2} + c_{11}x_{1} + c_{12}x_{2} + c_{13} = 0, \\ x_{1}x_{2} + c_{21}x_{1} + c_{22}x_{2} + c_{23} = 0, \end{cases}$$

$$\widehat{P}(x_{1}, x_{2}, t) = \begin{cases} x_{1}x_{2}t^{1} + c_{11}x_{1}t^{0} + c_{12}x_{2}t^{0} + c_{13}t^{0} = 0, \\ x_{1}x_{2}t^{1} + c_{21}x_{1}t^{0} + c_{22}x_{2}t^{0} + c_{23}t^{0} = 0. \end{cases}$$

$$(4)$$

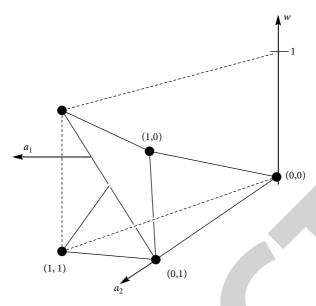

FIGURE 2: Polyhedral homeopathy proposed technique.

Finally, the calculation follows the extension for the determinant, as it corresponds to the sum of the roots by solving the corresponding linear system:

$$P^{(0)}(x) = \begin{cases} \prod_{i=1}^{4} (x_1 - \alpha_{1i}) \prod_{i=1}^{1} (x_2 - \beta_{1i}) = 0, \\ \prod_{i=1}^{3} (x_1 - \alpha_{2i}) \prod_{i=1}^{2} (x_2 - \beta_{2i}) = 0. \end{cases}$$
(5)

Thus, with a relatively simple calculation at the end of the multipath paths, we obtain important structural algebraic information, which is sufficiently utilized by the system. We define this model as follows:

$$g(\mathbf{x}) = \lambda \begin{pmatrix} K_{\max} \\ \bigvee \\ i=1 \end{pmatrix} c_i + \mathbf{W}_i^T \mathbf{x} + (1-\lambda) \begin{pmatrix} K_{\min} \\ \wedge \\ i=1 \end{pmatrix} d_i + \mathbf{M}_i^T \mathbf{x},$$

$$\lambda \in [0, 1].$$
(6)

So, the initial problem becomes now

$$\delta(\mathbf{x}) = \bigvee_{i=1}^{K_{\text{max}}} c_i + \mathbf{W}_i^T \mathbf{x},$$

$$\varepsilon(\mathbf{x}) = \bigwedge_{i=1}^{K_{\text{min}}} d_i + M_i^T \mathbf{x}.$$
(7)

The proposed application is related to the training course of agricultural education and methods of modernization of crops. The application focuses on the evolution of agricultural equipment and in particular the tools used in ancient times for agricultural work. The trainees are connected to a natural space where some natural objects are exhibited. They can read with QR code information about the tools used in the past, as well as about their development history, receiving the relevant information on their device. Each tool combines multimedia content (photos, videos, etc.) as well as information and comments from the Internet, news, as well as natural exhibition spaces of the wider area, with information on how and when to visit them. Respectively, the implementation of augmented reality systems supports dynamically changing virtual wanderings, offering interactive games, customizable paths during which the learner moves in the virtual space and determines the evolution of the narrative and the projection of the corresponding content. Essentially, with the use of augmented reality, complex images and physical objects are recognized as stimuli to display the selected multimedia content to the user, enhancing his experience. This way learners can use their mobile device, mobile phone, or tablet and get more information about an item.

Based on the virtual reality methodology in question, the learner can choose to play in a virtual escape room based on a story suggested by the application itself based on an AI recommendation system. The virtual escape room is a themed, adventurous game, in which individuals or groups enter a themed virtual era room and are supposedly locked into it. The goal is to escape in a short time, solving a series of puzzles or missions. The time usually varies and ranges from 15 to 60 minutes. Virtual escape rooms can vary and take place in virtual locations depending on the theme.

The creation of the script, which involves learners in a knowledge game, is completed using QR codes, which can accompany the description of an object and can provide the additional information that accompanies the object. Accordingly, the digital augmented reality information that accompanies the object is displayed on the screen of the device when the user focuses with the device on the specific object. This technology includes additional sound, 3D graphics, and short film projection. When the user focuses on a plow exposed to natural space, a digital augmented reality representation is displayed, with the plow in its traditional form being dragged by oxen.

The history-space-objects relationship takes and evolves with various versions such as the parts of the story to be unlocked as the trainee moves from one tool to the next or the story to guide the trainee to explore the space-time continuum giving a new dimension to the technological development of agricultural education and the methods of modernization of crops.

4. Discussion

According to research and the corresponding case study, individuals learn best when they receive information in their preferred learning style (e.g., auditory, visual, kinetic, and aesthetic). This finding shows that they learn best when they receive information in a style that incorporates visual, auditory, and kinetic stimuli.

The above findings are in full agreement with research that says that learning improves when learners can examine an idea or concept using a multidimensional approach. In this case, synapses and neural circuits develop, and different areas of the brain are activated, depending on the activity and the way the learner performs this activity.

In the context of online learning, the multidimensional approach can be attempted through a variety of teaching and learning approaches. It is important in the design context that the trainer incorporates a range of activities of different strategies. In this way, learners could engage in experiential activities using a variety of technological approaches. In general, a multidimensional approach provides alternative ways for learners to acquire new knowledge, overcome obstacles, and apply this practice in their daily jobs.

In summary, it seems that in the context of online learning, the educator is important to focus on the following: (a) the active participation of learners in the learning process, (b) how he will integrate the evaluation of learners in the educational process, (c) the utilization of tests the trainees undergo, and (d) the multidimensional approach of both his presence and the activities that will be given to the trainees. The teacher has to ensure that the above focal points need to take place in a properly designed educational environment such as the proposed.

5. Conclusions

Modern information and communication technologies in combination with the Internet offer pedagogy, innovative technical solutions for the culmination of the educational experience, and the promotion of the value of distance education. Environments that adopt virtual reality and its technology can provide several possibilities in the way the learner communicates and interacts with the virtual system or with other trainees. Their suitability to facilitate flexible learning as well as their educational applications can be widely used in the field of education as they manage on the one hand to overcome spatial and temporal constraints and on the other hand provide incentives for enjoyable and immediate learning. Given that pedagogy sets the general framework, the features and capabilities of these technologies can enrich the already known and tested practices used, adding an active factor in shaping the educational experience and highlighting the experiential nature of learning. Respectively, the role of technologies and at the same time the developments that they signal is the main springboard that can lead to new practices, which promote participation in actions, cultivate respect for educational practices, emphasize the need to preserve educational diversity, and shape the experience of distance education with new methods, discovering new unexplored aspects of it.

In conclusion, it should be noted that the upgrading of the educational process of distance education is a highpriority creative process. For this reason, it must include an evolving dialectical relationship concept between the achievements and practices of modern technology and the traditional educational goals.

Data Availability

The data used to support and prove the findings of this study are available from corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the publication of this paper.

Music is an important carrier of emotion and an indispensable factor in people's daily life. With the rapid growth of digital music, people's demand for music emotion analysis and retrieval is also increasing. With the rapid development of Internet technology, digital music has been derived continuously, and automatic recognition of music emotion has become the main research focus. For music, emotion is the most essential feature and the deepest inner feeling. Under the ubiquitous information environment, revealing the deep semantic information of multimodal information resources and providing users with integrated information services has important research and application value. In this paper, a multimodal fusion algorithm for music emotion analysis is proposed, and a dynamic model based on reinforcement learning is constructed to improve the analysis accuracy. The model dynamically adjusts the emotional analysis results by learning the user's behavior, so as to realize the personalized customization of the user's emotional preference.

1. Introduction

With the rapid growth of the number of digital music, the traditional music analysis and retrieval methods are more and more difficult to meet people's needs. In the ubiquitous information environment, anyone can connect with the network and obtain personalized information services through appropriate terminal equipment anytime and anywhere [1]. This new environmental change is bound to be accompanied by the changes of information generation mode, information dissemination channels, and information utilization mechanism and also objectively promote the vertical deepening, personalized, and diversified development of users' information needs [2]. For information service organizations, this situation is not only an opportunity but also a challenge. There are massive multimedia data on the vast Internet. How to effectively store, organize, and retrieve such a large amount of information has become an urgent problem to be solved [3]. The purpose of affective computing is to give computers the ability to recognize, understand, and express various emotions similar to

humans so that computers can interact with humans more naturally and harmoniously [4]. Music is an emotional medium that conveys the true feelings of human beings. Therefore, music has specific emotional labels, and explicit emotional labels are conducive to the audience to quickly select the songs they want to listen to at the appropriate time and place [5]. In multimodal fusion, decision level fusion is the highest level fusion. The existing decision level fusion first models the multimodal data of decision, and then obtains the linear weighting of decision, so as to generate the decision results [6].

Music is a symbol used by performers to express their thoughts and convey their emotions. It contains rich emotional information. Therefore, emotion-based music retrieval is also one of the key research contents of music information retrieval systems [7]. The characteristics of cross-platform, multisource, heterogeneous, and high-dimensional information and the development trend of dynamic and active services make people pay more attention to the multimodal information fusion theory and technical methods initially applied in the military field and begin to actively explore possible solutions to extend it to the field of information services [8]. With the development of digital storage technology and mobile Internet, digital music also has a serious problem of information overload [9]. Therefore, the automatic analysis of music emotion has also become one of the hotspots of today's research and has broad application prospects in music retrieval and recommendation [10]. With the gradual expansion of the music scale, the era of digital music has ushered in. At this time, the scientific management of music has attracted much attention [11]. Different from traditional manual retrieval methods, automatic retrieval will save a lot of labor costs. At the same time, compared with manual analysis, improving the accuracy of analysis will be a difficult problem for automatic analysis [12]. As an important means of automatic music retrieval, classifying music according to the expressed emotion is attracting the attention of researchers from different fields.

For music, emotion is the most essential feature and the deepest inner feeling. Music emotion recognition based on computer automation plays a key role in promoting the development of artificial intelligence [13]. For music emotion analysis, the most common method is to analyze the acoustic features extracted from music and get the emotional analysis results. However, the first mock exam is usually not satisfactory. The traditional single-mode research based on can only express some characteristics of the object, just as people observe the world through only one sense, which has considerable limitations [14]. In contrast, multimodal information has richer semantic information, and the information of each mode can complement each other. At the same time, the correlation between different modal data is also helpful to improve the accuracy of analysis results to a certain extent [15]. As an important branch of music labeling, emotion labels can reflect the artistic conception to be expressed by music to a certain extent. People can find music in line with Tun and emotion through emotion labels, which can relieve depression in their hearts and find happy resonance [16]. Compared with other music analysis problems such as genre analysis, emotion analysis is closer to people's perception, and the melody of music often contains the expression of emotion. In this paper, a music emotion analysis algorithm based on multimodal fusion based on reinforcement learning is proposed to improve the analysis accuracy.

In this article, the innovative concept of analysis of music characteristics is studied. Moreover, we discussed the analysis of music features based on lyrics and the music emotion feature analysis method based on multimodal fusion to improve the analysis accuracy. Music feature analysis is a very important step in the process of music emotion analysis and the multimodal music emotion analysis method is to analyze music emotion based on music content and lyrics, respectively, and then combine the two analysis results to get the final music emotion analysis. The relationship between music structured information and human emotion cannot be fully reflected by using existing common features. Therefore, we can further explore the feature extraction method with more musical emotion analysis ability. The following is a summary of the research: Section 1 contains the introduction; Section 2 discusses the related work and background. Section 3 discusses the analysis of music characteristics. Section 4 discusses the music emotion feature analysis method is based on multimodal fusion; finally, the conclusion brings the paper to a finish in section 5.

2. Related Work

In the task of attribute-level emotion analysis, the literature [17] conducts joint learning through two tasks of attribute extraction and attribute-level emotion analysis, which greatly improves the performance of the attributelevel emotion analysis task. Literature [18] puts forward a joint model, which can simultaneously model the two tasks of emotion analysis and emotion cause recognition and effectively improve the recognition performance of the two tasks. Emotion analysis and emotion analysis are two different subtasks in emotion analysis. Because of the strong relationship between emotion tags and emotion tags, the two tasks are closely related. Literature [19] improves the performance of the two tasks by labeling an extra data set with emotional tags and emotional tags. However, it is difficult to obtain similar data sets in real scenes. Literature [20] adopts integer linear programming (ILP) to study emotion and emotion analysis tasks jointly and obtains the connection between the output of the emotion analyzer and the output of the emotion analyzer through constraints.

Literature [20] shows that music lyrics do contain some special semantic information, including emotion. Therefore, the comprehensive utilization of audio and lyrics modes can effectively improve the accuracy of music emotion analysis. We can analyze the relationship between lyrics, music modes, and human perception and explore the intrinsic relevance between the two modes and complement each other to improve the accuracy of the analysis. Literature [21] has proposed some simple multimodal fusion methods, which comprehensively use the information of lyrics and audio modes to analyze music. The experimental results prove that using multimodal information can improve the accuracy of emotion analysis to a certain extent compared with using only a single mode. Literature [22] preliminarily uses deep neural networks to extract advanced feature representation from original audio data and verifies the effectiveness of deep neural networks in speech emotion recognition. Literature [23] uses a convolution neural network to extract audio features to train audio data, and the accuracy of audio emotion analysis has been greatly improved. Based on reinforcement learning technology, this paper studies the emotional analysis of music from the perspective of audio visualization. According to the demand analysis of music emotion analysis, this paper explores a model framework of music emotion analysis based on multimodal information fusion function and level.

3. Analysis of Music Characteristics

The characteristics of music are sound (overtone, duration, amplitude, pitch, and timbre), melody, rhythm, structure or form, expression, and texture.

3.1. Music Feature Analysis Based on Audio. Music feature analysis is a very important step in the process of music emotion analysis. Different music features may show different emotions. Therefore, the main task of music feature analysis is to find an optimal feature space to represent music [24]. This feature space can not only reflect the emotion of music but also have a certain degree of discrimination, which can distinguish music with different emotions. The framework of multimodal music emotion analysis is shown in Figure 1.

Music is mainly composed of several basic elements, including sound nest, sound length, sound intensity, sound color, and so on [25]. Then, two or more basic elements are integrated to form the basic characteristics of music, mainly including ① rhythm: the rhythm of music reflects the speed and urgency of music tunes, in which the emotion expressed by gentle music is calm and gentle, while the emotion expressed by sudden rhythm music is strong. 2 Melody: what people used to call melody actually refers to the melody. It is the most basic element of music. It is a series of organized and rhythmic sequences composed of several musical sounds by artists according to a certain pitch, time value, and volume. Melody can reflect the emotion expressed in music. For example, the emotion expressed by music with a light melody should also be light. ③ Strength: strength can also express the emotion of music. For the same music, the emotion expressed by different degrees is different. Usually, the greater the intensity, the louder and more exciting the music. The smaller the degree, the more soothing and soft the music is. ④ Timbre: timbre refers to people's sensory characteristics of different sounds so that people can distinguish different sounds. Different people or musical instruments produce different timbres.

The choice of music emotion model is the basis of music emotion analysis. Music carries a variety of emotions. The music analyzed by the early music emotion research is mostly classical music. Among them, the vocal content is small, and the emotional characteristics are mostly reflected by the rhythm, melody, pitch, and timbre expressed by musical instruments, and a piece of classical music may contain several completely different emotions. The study of this music needs to intercept a music fragment for analysis. According to the basic and complex characteristics of music, the overall characteristics of music are identified, including music form structure, style, and emotional connotation. The specific structure is shown in Figure 2.

For the music emotion analysis task, the feature extraction method is an important component module, and a good feature extraction method has a great influence on the result of the analysis task. Feature extraction solves the problem of how to better represent the analysis sample set. Usually, samples are converted into feature vector

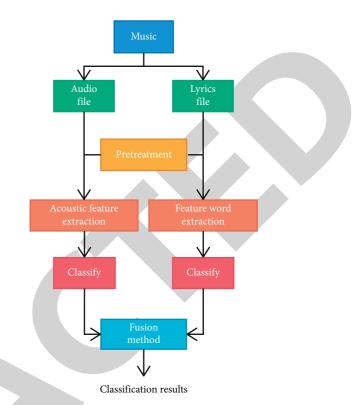

FIGURE 1: The framework of multimodal music sentiment analysis.

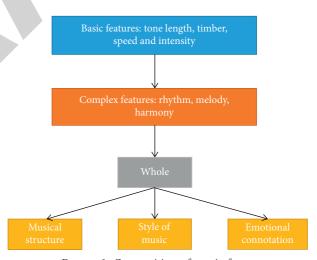

FIGURE 2: Composition of music form.

representation for the analysis model. Music feature acquisition is an important link in music emotion analysis. Early music acquisition mainly focused on audio attributes of sound killing. The basic audio features of a song, such as a rhythm, timbre, tone, volume, melody, and harmony, can reflect the emotional characteristics of music to varying degrees. Due to the structural heterogeneity between audio features and text features, there is an insurmountable gap between the emotions expressed by the two features. This makes it a serious problem to mine the correlation between the two expressions in emotional expression for multimodal analysis. Time-domain characteristics of music refer to the timedomain parameters of each post calculated from music signals. Typical time-domain features include short-time energy, short-time average amplitude, short-time average zero-crossing rate, short-time autocorrelation function, and short-time average amplitude difference function.

The short-term energy of the nth frame music signal is defined as follows:

$$E_n = \sum_{m=n-(N-1)}^{n} \left[x(m)w(n-m) \right]^2.$$
(1)

In the formula, w(n - m) is the moving wins function, N is the effective width of the window, and n is the time position of the window. It can be the starting point of the window or the midpoint or end of the window.

Short-term energy E_n is a time series, from which we can see how the signal energy changes with time. Generally speaking, the short-term energy of voiced sound is much larger than that of unvoiced sound, so it is easy to distinguish voiced sound from unvoiced sound by short-term energy sequence. In addition, the short-time energy sequence can also be used to determine the starting and ending points of music.

The process of extracting the characteristics of pitch and time value of music performance is shown in Figure 3.

Because the calculation of short-time energy needs a square operation, which enlarges the difference between magnitude and amplitude, it cannot accurately reflect the characteristics of signal short-time energy changing with time. Therefore, a short-term average amplitude describing the time-varying characteristics of signal energy is proposed, which is defined as follows:

$$M_{n} = \sum_{m=n-(N-1)}^{n} |x(m)w(n-m)| = \sum_{m=n-(N-1)}^{n} |x(m)|w(n-m).$$
(2)

The different signs of adjacent sampled values are called zero crossing, and the number of zero crossings per unit time is called the zero-crossing rate. The short-term average zerocrossing rate of a frame of music signal is defined as follows:

$$Z_{n} = \frac{1}{2N} n \sum_{m=n-(N-1)}^{n} \left| \operatorname{sgn} [x(m)w_{R}(n-m)] - \operatorname{sgn} \{x(m-1)w_{R}[n-(m-1)]\} \right|$$

$$= \frac{1}{2N} \sum_{m=n-(N-1)}^{n} \left| \operatorname{sgn} [x(m)] - \operatorname{sgn} [x(m-1)] \right|.$$
(3)

In the formula, sgm[x(m)] is the symbolic function of x(m), defined as follows:

$$\operatorname{sgn}[x(m)] = \begin{cases} 1, & x(m) > 0, \\ 0, & x(m) = 0, \\ -1, & x(m) < 0. \end{cases}$$
(4)

In order to overcome the short-term average zerocrossing rate is very sensitive to noise, the formula (3) can be modified as follows:

$$Z_n = \frac{1}{1N} \sum_{m=n-(N-1)}^{n} \{ |\operatorname{sgn}[x(m) - A] - \operatorname{sgn}[x(m-1) - A]| + |\operatorname{sgn}[x(m) + A] - \operatorname{sgn}[x(m-1) + A]| \}.$$
(5)

Whether or not it crosses zero is not judged by the different signs of the adjacent sampled value of the signal but judged by the different sign after the adjacent sampled value of the signal exceeds a set appropriate positive and negative limit. This eliminates false zero crossings caused by noise. Normally, the short-term average zero-crossing rate of unvoiced and noise is much larger than that of voiced sounds, so the short-term average zero-crossing rate can be used to distinguish them easily. The short-term autocorrelation function is defined as follows:

$$R_{n}(k) = \sum_{m=n-(N-1)}^{n} [x(m)w(n-m)]\{x(m+k)w[n-(m+k)]\},$$

$$n-m = m \sum_{m=0}^{N-1-k} [x(m+n)w(m)][x(m+n+k)w(m+k)].$$
(6)

In the formula, k is the autocorrelation lag time. Equation (6) shows that $R_n(k)$ of each frame of the signal is a sequence with lag time k as an independent variable. The formula of the short-term average amplitude difference function is as follows:

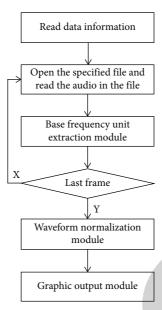

FIGURE 3: The process of extracting the pitch and time value feature of music performance.

$$\gamma_{k=} \sum_{m=0}^{N-1} \left| x \left(n+m \right) w_1(m) - x \left(n+m+k \right) w_2(m-k) \right|.$$
(7)

In the formula, $w_1(n)$ and $w_2(n)$ are rectangular windows with widths N and N + K, respectively, where K is the maximum possible hysteresis value. For any periodic signal, when the lag time is equal to the period or an integer multiple of the period, there will be a short-term average amplitude difference function $\gamma_k = 0$. The voiced signal is approximately a periodic signal, so γ_k will reach its minimum value at a lag time point equal to the pitch period or an integer multiple of the pitch period. Using this property, we can distinguish between voiced and unvoiced sounds based on the γ_k curve and estimate the pitch frequency of voiced sounds.

Pitch depends on the frequency and loudness of sound. Bass gives people a thick and deep feeling, while treble gives people a bright and sharp feeling. Audio features have strong objectivity and can be easily extracted from songs by digital signal processing. The key problem of audio feature extraction is which features are extracted. The results show that the energy, rhythm, melody, and timbre of music are the four characteristics that can best reflect music emotion. Therefore, in the digital signal processing of music, we should focus on these four characteristics. In the existing research, the music characteristics based on audio are usually borrowed from the parameters of speech signals, and the characteristics of speech signals change with time, but the changes are slow. Therefore, it is usually divided into short segments with phase dimensions, and each segment is processed separately by the processing method of a stationary random signal, which is the short-time processing technology of speech signal. The energy characteristics of music are closely related to the degree of motivation that music can bring to people. The higher the energy of music, the stronger the sensory stimulation to the listener. Songs

such as metal and rock generally have higher energy value, while songs such as light music generally have lower energy value.

3.2. Analysis of Music Features Based on Lyrics. As an important part of music, lyrics also contain rich emotional information. Therefore, mining emotions from lyrics is a good supplement to music emotional analysis. The core problem of sentiment analysis based on lyrics is how to construct a feature space that can reflect lyrics sentiment, which mainly focuses on the selection of the expression model of lyrics text and the selection of feature selection methods. Lyrics data usually incorporate the expression of the music writer's own emotion, so it has rich semantic information related to emotion. How to extract this emotion from sparse and messy lyrics files will be a great challenge. A typical text emotion recognition system is shown in Figure 4.

Assuming that a document is composed of m feature words, the contribution of each feature word to the document is reflected by its weight. Expressed by a mathematical formula is as follows:

$$D = D(t_1, w_1; t_2, w_2, \dots, t_m, w_m),$$
(8)

where w_i is the weight and $1 \le i \le m$. The similarity of the two documents is expressed by finding the cosine of the angle between the corresponding vectors. The formula is as follows:

$$\sin(D_1, D_2) = \cos\theta = \frac{\sum_{i=1}^n w_{1i} \times w_{2i}}{\sqrt{\left(\sum_{i=1}^n w_{1i}^2\right) \left(\sum_{i=1}^n w_{2i}^2\right)^2}}.$$
 (9)

Among them, w_{1i} and w_{1i} represent the weight of the w_{2i} feature item of documents i^{th} and D_1 , respectively.

Suppose there is $sim(D_1, D_2)$, a document set with a total of *n* documents. After preprocessing, a total of *m* feature words are extracted, and a matrix of "feature words-documents" can be constructed:

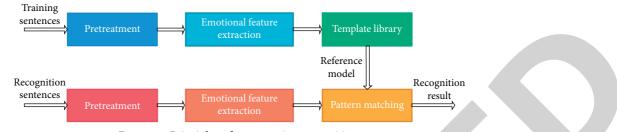

FIGURE 4: Principles of text emotion recognition.

$$X_{m \times n} = \begin{bmatrix} x_{ij} \end{bmatrix}. \tag{10}$$

Among them, x_{ij} represents the weight of the *i*th feature word in the *j*th article search. The weight is used to measure the distinguishing ability of the feature word to the document, or the degree of contribution to the analysis. Since the length of each document is different, the weight tends to favor longer documents. In this case, it can be normalized when calculating the weight to avoid this situation. This leads to the following formula:

$$w(t_i, d_j) = \frac{\left(\log_2\left(1 + tf(t_i, d_j)\right)\right) \times \log_2\left(N/N_t\right)}{\sqrt{\sum_{t_i \in d_j} \left[\left(\log_2\left(1 + tf(t_i, d_j)\right)\right) \times \log_2\left(N/N_{t_i}\right)\right]}}.$$
(11)

Among them, $w(t_i, d_j)$ represents the weight of feature word t_i in document d_j . $tf(t_i, d_j)$ represents the number of times the feature word t_i appears in the document d_j , and $(1 + tf(t_i, d_j))$ is to prevent the occurrence of $tf(t_i, d_j)$. N represents the number of documents in the document set, and N_{t_i} represents the number of documents in the document set that contain characteristic words.

4. Music Emotion Feature Analysis Method Based on Multimodal Fusion

Multimodal information fusion is an information processing process that comprehensively utilizes natural language processing, semantic analysis, statistical analysis, and other technical methods to detect, correlate, estimate, combine, and analyze multimodal information in multiple levels and dimensions. The multimodal music emotion analysis method is to analyze music emotion based on music content and lyrics, respectively, and then combine the two analysis results to get the final music emotion analysis. If stress is defined as anxiety and happiness, and energy is defined as vitality and calmness, the final analysis result is determined by combining the two analysis results. To study the local form of the melody line, we should not only look at the connection of two notes but at least look at the ups and downs of four or five notes and five or six notes in a bar, so as to see the characteristics of linear form from the harmony interval and disharmony interval in music acoustics and law, for example, Table 1.

The energy of the audio signal changes significantly over time, and its short-term energy analysis gives an appropriate description method to reflect these amplitude changes. For the signal $\{x (n)\}$, the short-term energy is defined as follows:

$$E_n = \sum_{m=-\infty}^{\infty} \left[x(m)w(n-m) \right]^2 = \sum_{m=-\infty}^{\infty} x^2(m)h(n-m) = x^2(n) \times h(n).$$
(12)

Among them, $h(n) = w^2(n)$. Equation (12) represents the short-term energy when the window function is started at the nth point of the signal. The short-term energy can be regarded as the output of the square of the audio signal through a linear filter, and the unit impulse response of the linear filter is h(n), as shown in Figure 5.

If $x_w(n)$ is used to represent the signal after x(n) is windowed, the length of the window function is N, and the short-term energy is expressed as follows:

$$E_n = \sum_{m=n}^{n+N-1} x_w^2(m).$$
 (13)

The requirement of music emotion analysis is based on the multimodal, complex, multisource, and heterogeneous characteristics of music emotion. The service has the quick adaptability of universal access, aggregation on demand, context processing, and seamless application and can realize the interoperability and autonomous cooperation of heterogeneous data across fields and platforms. Through the evaluation of the direction of notes, take the bar as the unit. No matter whether the notes go down or up, as long as a series of notes with the same direction appear continuously, an upward or downward melody line can be generated, which means that the evaluation value is higher.

The feature vector of lyrics is extracted based on the reinforcement learning model, and the feature value of each dimension is calculated. Then labeled lyrics are clustered to get a cluster set, and the similarity between lyrics and each cluster and the similarity of each cluster and the ratio of each category in the cluster are tested. The assignment of melody weights is shown in Table 2. The relationship between melody weight and melody trend is shown in Figure 6.

Compared with sentence-level emotion classification of automatic encoder, the accuracy of sentiment classification of article-level lyrics based on word vector sentence coding is improved. The dual-mode fusion method based on the neural network has a remarkable effect in audio emotion classification because it can set the weight of each mode. The linear regression curve is calculated according to the stepwise multiple linear regression equation, as shown in Figure 7. feature extraction model is stronger than that of common multimodal information emotion analysis.

In the speech modality experiment, the method of capturing context information is better than other baseline methods, whether in the main task or the auxiliary task. The above baseline method only uses the phonetic features of the main task or auxiliary task. Due to the weak representation ability of speech modal features and the very small number of samples of "disgust" and "fear" categories, our model cannot predict the corresponding categories, and its performance in individual categories cannot reach the best. Different modes of music data often have a certain correlation in emotional expression; that is, different modes are not independent of each other. This correlation can often enhance the accuracy of sentiment analysis. Because the feature extraction methods used in different modal music data are different from each other, the dimensions and attributes of the obtained features are quite different. This difference makes it impossible for music features of different modes to operate and calculate each other directly, which makes it difficult to fully explore and apply the correlation between music data of different modes. In order to make full use of the temporal correlation of music data of different modes and improve the accuracy of emotion analysis, it is necessary to design an effective mechanism to aggregate music features of different modes and different time scales according to emotion categories.

5. Conclusions

In order to effectively manage music resources and help people efficiently obtain interesting content from massive music, music emotion analysis has always been a hot spot for scholars. Under multimodal fusion, based on the fusion of existing linear weighted decision-making layers, the reinforcement learning method is introduced, which can highly fuse different types of analysis effects of multiple modes, so

as to guarantee the overall fusion effect. Based on reinforcement learning technology, this paper studies the emotional analysis of music from the perspective of audio visualization. According to the demand analysis of music emotion analysis, this paper explores a model framework of music emotion analysis based on multimodal information fusion function and level. The experimental results on multimodal emotion analysis data set show that this method can greatly improve the performance of emotion analysis tasks through emotion auxiliary information, and at the same time, the performance of the emotion analysis task is also improved to a certain extent. Music emotion analysis is an important means for automatic music retrieval. The heterogeneity and semantic gap between different modal music data make it a challenging problem to use multimodal information for music emotion analysis. The relationship between music structured information and human emotion cannot be fully reflected by using existing common features. Therefore, we can further explore the feature extraction method with more musical emotion analysis ability.

A more flexible two-parameter model named the Topp Leone inverse Lindley model is investigated. Some basic mathematical properties such as quantile, moments, order statistics, and Rényi entropy of the new distribution are considered. Plot analysis for mean, variance, skewness, and kurtosis is performed. The density of the new model can be right skewed and decreasing with unimodal and bimodal shapes. Also, its hazard rate function can be decreasing and upside-down. The maximum likelihood (ML) estimation method is used to estimate the parameters of the distribution. The simulation study is executed to investigate the effectiveness of the estimates. The potential of the distribution is demonstrated through the application of the real biomedical dataset.

1. Introduction

The Topp Leone (TL-G) class of distributions was introduced by Al-Shomrani et al. [1]. A random variable *X* has TL-G class of distributions if the distribution function (cdf) and probability density function (pdf) are given by

$$F(x) = G(x)^{\alpha} (2 - G(x))^{\alpha} = \left(1 - \overline{G}(x)^2\right)^{\alpha}, \quad x \in \mathbb{R},$$
(1)

and

$$f(x) = 2\alpha g(x)\overline{G}(x) \left(1 - \overline{G}(x)^2\right)^{\alpha - 1},$$
 (2)

where $\overline{G}(x) = 1 - G(x)$, G(x) is the baseline distribution, and α is a positive shape parameter.

The equation (2) can be rewritten as

$$f(x) = \sum_{i,j=0}^{\infty} W_{i,j}g(x)G(x)^{j},$$
(3)

where $W_{i,j} = 2\alpha (-1)^{i+j} {\alpha - 1 \choose i} {i+2 \choose j}$. The quantile function of TL-G is given by

$$Q(u) = G^{-1} \left(1 - \sqrt{1 - \sqrt[a]{u}} \right), \quad 0 < u < 1.$$
 (4)

Many distributions have been studied by using TL-G for different baselines. Aryal et al. [2] studied TL Weibull distribution, Abbas et al. [3] introduced and studied TL inverse Weibull, Reyad and Othman [4] studied TL Burr-XII distribution, the TL Nadarajah-Haghighi distribution was proposed by Yousof and Korkmaz [5], the odd Lindley-G was proposed by Gomes et al. [6], Reyad et al. [7] proposed TL generalized inverted Kumaraswamy distribution, TL compound Rayleigh distribution is studied by Rasheed [8], odd Nadarajah-Haghighi-G was proposed by Nascimento et al. [9], Oguntunde et al. [10] introduced TL Lomax distribution, Al-Marzouki et al. [11] studied type II TL power Lomax distribution, Al-Marzouki et al. [12] studied TL odd Fréchet-G family, and Al-Babtain et al. [13] proposed sine TL-G family.

The inverse Lindley (IL) distribution was studied by Sharma et al. [14], and it has the following pdf and cdf, respectively,

$$g(x) = \frac{\theta^2}{1+\theta} \left(\frac{1+x}{x^3}\right) e^{-\theta/x}, \quad x > 0, \theta > 0, \tag{5}$$

and

$$G(x) = \left(1 + \frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}, \quad x > 0, \theta > 0.$$
(6)

The IL distribution has been generalized by many statisticians in last years: Alkarni [15] introduced a more flexible model named extended IL distribution, Sharma et al. [16] proposed the generalized IL distribution, Barco et al. [17] studied the power IL distribution, Dey et al. [18] introduced alpha power transformed IL distribution, Eltehiwy [19] studied extended exponentiated IL distribution, and logarithmic IL model was studied by Eltehiwy [20].

The main goal of this article is as follows:

- (i) To propose a new two-parameter life time model, so called, Topp Leone inverse Lindley (TLIL) distribution
- (ii) The density of the new model can be right skewed and decreasing with unimodal and bimodal shapes. Also, it is hazard rate function can be decreasing and upside-down.

- (iii) To study some of its various statistical properties such as quantile function, moments, incomplete moments, order statistics, and Rényi entropy
- (iv) To discuss the statistical inference of the TLIL model by using the ML method
- (v) To investigate a simulation study to show the behavior of the parameters model
- (vi) To give leading fits than some known models with favourable results for the TLIL model

The new model is very flexible, and we can get the cdf and pdf by inserting (1) and (2) in (5) and (6) as

$$F(x) = \left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}\right)^2\right)^{\alpha}, \quad x > 0, \theta, \alpha > 0,$$
(7)

and

$$f(x) = \frac{2\alpha\theta^2}{1+\theta} \left(\frac{1+x}{x^3}\right) e^{-\theta/x} \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right) e^{-\theta/x}\right) \left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right) e^{-\theta/x}\right)^2\right)^{\alpha-1}.$$
(8)

The plots of the pdf and cdf of the TLIL distribution are shown in Figures 1 and 2.

Figure 1 shows the pdf can be decreasing, unimodal, and right skewed.

The remaining part of this article is organized as follows: the reliability analysis of the new distribution is given in Section 2, Section 3 concerns with the linear representation for the new model, the derivation of the mathematical properties of the distribution is proposed in Section 4, the estimation of parameters of the distribution is discussed in Section 5, in Section 6, a simulation study is executed to investigate the performance of the estimates, applications of real-life data to illustrate the potentials of the new distribution is presented in Section 7, and in Section 8, the concluding remarks are presented.

2. The Reliability Analysis

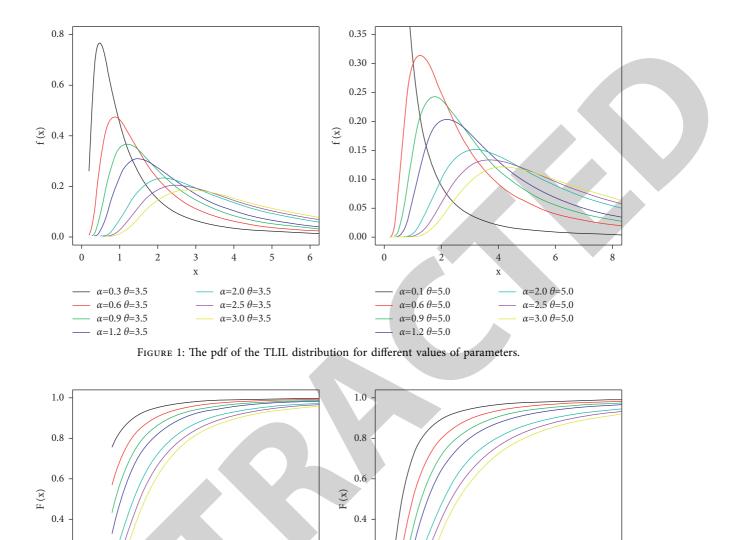

Suppose a random variable *X* follows the TLIL model, then the reliability function R(x), hazard rate function (hrf) h(x), inverse hazard rate function $\tau(x)$, and cumulative hazard rate function H(x) for the TLIL distribution are given by

$$R(x) = 1 - \left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}\right)^2\right)^{\alpha},$$

$$h(x) = \frac{2\alpha\theta^2/1 + \theta\left((1+x)/x^3\right)e^{-\theta/x}\left(1 - (1+\theta/(1+\theta)x)e^{-\theta/x}\right)\left(1 - (1-(1+\theta/(1+\theta)x)e^{-\theta/x})^2\right)^{\alpha-1}}{1 - \left(1 - (1-(1+\theta/(1+\theta)x)e^{-\theta/x}\right)^2\right)^{\alpha}},$$

$$\tau(x) = \frac{2\alpha\theta^2/1 + \theta\left((1+x)/x^3\right)e^{-\theta/x}\left(1 - (1+\theta/(1+\theta)x)e^{-\theta/x}\right)}{1 - (1-(1+\theta/(1+\theta)x)e^{-\theta/x})^2},$$

$$H(x) = -\ln\left(1 - \left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}\right)^2\right)^{\alpha}\right).$$

3. Important Representation

0.2

0.0

0.0

In this section, representations of the pdf for TLIL distribution are calculated.

By using the three equations equation (3), (5), and (6), we can rewrite (8) as

$$f(x) = \sum_{i,j=0}^{\infty} W_{i,j} \frac{\theta^2}{1+\theta} \left(\frac{1+x}{x^3}\right) e^{-\theta(j+1)/x} \left(1 + \frac{\theta}{(1+\theta)x}\right)^j.$$

х

3

4

 $\alpha = 2.0 \ \theta = 1.5$

α=2.5 *θ*=1.5

 α =3.0 θ =1.5

5

By applying the binomial expansion in the previous equation, we can rewrite it as

$$f(x) = \sum_{k=0}^{\infty} W_k \left(\frac{1+x}{x^{k+3}}\right) e^{-\theta(j+1)/x},$$
 (11)

where
$$W_k = \sum_{i,j=0}^{\infty} W_{i,j} (j/k) \theta^{k+2} / (1+\theta)^{k+1}$$

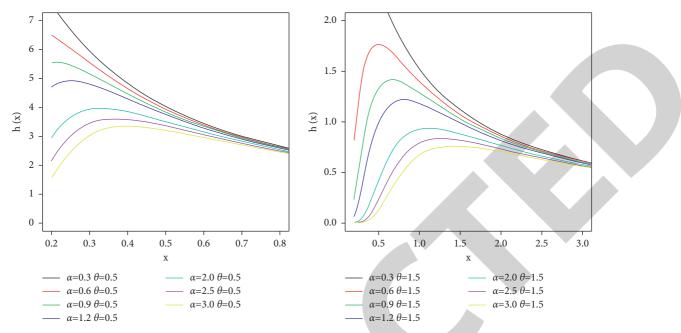

FIGURE 3: The hrf of the TLIL distribution for different values of parameters.

4. Mathematical Properties

4.1. *Quantile Function*. Let *X* has a random variable with pdf (8). The quantile function, say Q(u), defined by F(Q(u)) = u is the root of the equation:

$$\left(1 + \frac{\theta}{(1+\theta)Q(u)}\right)e^{-\theta/Q(u)} = 1 - \sqrt{1 - \sqrt[6]{u}}, \quad 0 < u < 1.$$
(12)

By multiplying (12) both sides by $-(1 + \theta)e^{-(1+\theta)}$, we get

$$-\left(1+\theta+\frac{\theta}{Q(u)}\right)e^{-(1+\theta+\theta/Q(u))} = -(1+\theta)e^{-(1+\theta)}$$

$$\left(1-\sqrt{1-\sqrt[4]{u}}\right).$$
(13)

By using the Lambert W function which is the solution of the equation $W(z)e^{W(z)} = z$, where z is a complex number, we have

$$W_{-1}\left(-(1+\theta)e^{-(1+\theta)}\left(1-\sqrt{1-\sqrt[\alpha]{u}}\right)\right) = -\left(1+\theta+\frac{\theta}{Q(u)}\right),\tag{14}$$

and then,

$$Q(u) = -\left[1 + \frac{1}{\theta} + \frac{1}{\theta}W_{-1}\left(-(1+\theta)e^{-(1+\theta)}\left(1 - \sqrt{1 - \sqrt[\alpha]{u}}\right)\right)\right]^{-1}.$$
(15)

Corollary 1. If $X \sim TLIL$, the median M of X is given by

$$Q(u) = -\left[1 + \frac{1}{\theta} + \frac{1}{\theta}W_{-1}\left(-(1+\theta)e^{-(1+\theta)}\left(1 - \sqrt{1 - \sqrt[\alpha]{0.5}}\right)\right)\right]^{-1}.$$
(16)

4.2. *Moments.* The r^{th} moments of a random variable having TLIL distribution is defined as

$$E(X^{r}) = \int_{0}^{\infty} x^{r} f(x) dx$$

= $\sum_{k=0}^{\infty} W_{k} \int_{0}^{\infty} x^{r} \left(\frac{1+x}{x^{k+3}}\right) e^{-\theta(j+1)/x} dx$ (17)
 $\sum_{k=0}^{\infty} W_{k} \int_{0}^{\infty} (x^{-k-3} + x^{-k-2}) e^{-\theta(j+1)/x} dx$

$$= \sum_{k=0}^{\infty} W_k \int_0^{\infty} (x^{i-k-1} + x^{i-k-2}) e^{-i(j+1)/x} dx.$$

Letting $y = \theta(j+1)/x$ $x = \theta(j+1)/y dx$

Letting $y = \theta(j+1)/x$, $x = \theta(j+1)/ydx = -\theta(j+1)/y^2dy$ and simplifying further,

$$E(X^{r}) = \sum_{k=0}^{\infty} W_{k} \int_{0}^{\infty} \left(\left(\frac{\theta(j+1)}{y} \right)^{r-k-3} + \left(\frac{\theta(j+1)}{y} \right)^{r-k-2} \right) e^{-y} \frac{\theta(j+1)}{y^{2}} dy$$
$$E(X^{r}) = \sum_{k=0}^{\infty} W_{k} (\theta(j+1))^{r-k-2} \int_{0}^{\infty} (y^{k-r+1} + \theta(j+1)y^{k-r}) e^{-y} dy$$

Journal of Mathematics

$$\sum_{k=0}^{\infty} W_k \left(\theta(j+1)\right)^{r-k-2} \left(\Gamma(k-r+2) + \theta(j+1)\Gamma(k-r+1)\right).$$
(18)

The moment generating function of the TLIL model can be calculated by

$$M_X(t) = \sum_{r=0}^{\infty} \frac{t^r}{r!} E(X^r) = \sum_{r,k=0}^{\infty} \frac{t^r}{r!} W_k(\theta(j+1))^{r-k-2}$$
$$(\Gamma(k-r+2) + \theta(j+1)\Gamma(k-r+1)), \quad r < k+2.$$
(19)

Figure 4 shows the mean, variance, skewness, and kurtosis curves of the TLIL model for numerous values of α and θ .

4.3. Incomplete Moments. The incomplete moments, say $\omega_s(t)$, is given by

$$\bar{\omega}_{s}(t) = \int_{0}^{t} x^{s} f(x;\varphi) \mathrm{d}x.$$
 (20)

Using (11), $\omega_s(t)$ can be taken the next formula:

$$\bar{\omega}_{s}(t) = \sum_{k=0}^{\infty} W_{k} \int_{0}^{t} x^{s} \left(\frac{1+x}{x^{k+3}}\right) e^{-\theta(j+1)/x} \mathrm{d}x.$$
 (21)

Then, using the lower incomplete gamma function, we obtain

$$\begin{split} \tilde{\omega}_{s}(t) &= \sum_{k=0}^{\infty} W_{k} \left(\theta(j+1) \right)^{s-k-2} \Big(\nu \Big(k-s+2, \theta(j+1)t^{-1} \Big) \\ &+ \theta(j+1) \nu \Big(k-s+1, \theta(j+1)t^{-1} \Big) \Big), \quad s < k+2, \end{split}$$
(22)

where $v(s, t) = \int_0^t x^{s-1} e^{-x} dx$ is the lower incomplete gamma function.

The Lorenz and Bonferroni curves are given by

$$L_{F}(x) = \frac{\int_{0}^{t} xf(x)dx}{E(X)} = \frac{\sum_{k=0}^{\infty} W_{k}(\theta(j+1))^{-k-1} \left(\nu(k+1,\theta(j+1)t^{-1}) + \theta(j+1)\nu(k,\theta(j+1)t^{-1})\right)}{\sum_{k=0}^{\infty} W_{k}(\theta(j+1))^{-k-1} \left(\Gamma(k+1) + \theta(j+1)\Gamma(k)\right)},$$

$$B_{F}(x) = \frac{\int_{0}^{t} xf(x)dx}{E(X)F(x)} = \frac{L_{F}(x)}{F(x)} = \frac{\sum_{k=0}^{\infty} W_{k}(\theta(j+1))^{-k-1} \left(\nu(k+1,\theta(j+1)t^{-1}) + \theta(j+1)\nu(k,\theta(j+1)t^{-1})\right)}{\left(1 - \left(1 - (1 + \theta/(1 + \theta)x)e^{-\theta/x}\right)^{2}\right)^{\alpha} \left(\sum_{k=0}^{\infty} W_{k}(\theta(j+1))^{-k-1} \left(\Gamma(k+1) + \theta(j+1)\Gamma(k)\right)\right)}.$$
(23)

4.4. Order Statistics. Suppose $X_1 < X_2 < \ldots < X_n$ is an order sample from TLIL population, the pdf of the *i*th ordered statistics is given as

Substituting (7) and (8) and applying general binomial series expansion (24) become

$$f(x_{i:n}) = \frac{n!}{(i-1)!(n-i)!} f(x)F(x)^{i-1}(1-F(x))^{n-i}$$
$$= \frac{n!}{(i-1)!(n-i)!} f(x) \sum_{j=0}^{n-i} (-1)^{j} {\binom{n-i}{j}} F(x)^{i+j-1}.$$
(24)

$$f(x_{i:n}) = \sum_{j=0}^{n-i} \frac{2\alpha\theta^2 (-1)^j \binom{n-i}{j} n!}{(\theta+1)(i-1)!(n-i)!} \left(\frac{1+x}{x^3}\right) e^{-\theta/x} \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right) e^{-\theta/x}\right) \left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right) e^{-\theta/x}\right)^2\right)^{\alpha(i+j)-1}.$$
(25)

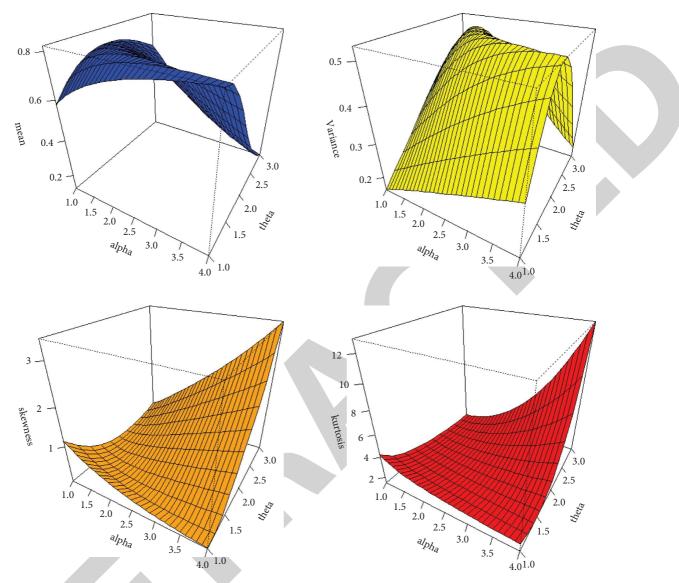

FIGURE 4: 3D plots of mean, variance, skewness, and kurtosis.

4.5. Rényi Entropy. For a given pdf, the Rényi entropy is defined by

$$I_R(\delta) = \frac{1}{1-\delta} \log \int_0^\infty f(x)^\delta dx, \quad \delta > 0, \delta \neq 1.$$
 (26)

The function $f(x)^{\delta}$ is given by

$$f(x)^{\delta} = \left(\frac{2\alpha\theta^2}{1+\theta}\right)^{\delta} \frac{(1+x)^{\delta}}{x^{3\delta}} e^{-\theta\delta/x} \left(1 - \left(1 + \left(\frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}\right)\right)^{\delta} \left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}\right)^2\right)^{\delta(\alpha-1)}.$$
 (27)

By applying the binomial expansion three times in the previous equation, we get

$$f(x)^{\delta} = \frac{(2\alpha)^{\delta} \theta^{2\delta+k}}{(1+\theta)^{\delta+k}} \sum_{i,j,k=0}^{\infty} (-1)^{i+j} {\delta(\alpha-1) \choose i} {\delta+2i \choose j} {j \choose k} x^{-k-3\delta} (1+x)^{\delta} e^{-\theta(j+\delta)/x}.$$
(28)

By applying the the binomial expansion to the term $(1+x)^{\delta} = \sum_{l=0}^{\infty} {\delta \choose l} x^{l}$, we can write the previous equation as

$$f(x)^{\delta} = \sum_{l=0}^{\infty} t_l x^{l-k-3\delta} e^{-\theta(j+\delta)/x},$$
 (29)

where

$$t_{l} = \frac{(2\alpha)^{\delta} \theta^{2\delta+k}}{(1+\theta)^{\delta+k}} \sum_{i,j,k=0}^{\infty} (-1)^{i+j} \\ \binom{\delta(\alpha-1)}{i} \binom{\delta+2i}{j} \binom{j}{k} \binom{\delta}{l}.$$
(30)

Now, we will calculate the integral

$$I = \int_{0}^{\infty} f(x)^{\delta} dx = \sum_{l=0}^{\infty} t_{l} \int_{0}^{\infty} x^{l-k-3\delta} e^{-\theta(j+\delta)/x} dx$$

$$= \sum_{l=0}^{\infty} t_{l} [\theta(j+\delta)]^{l-k-3\delta+1} \Gamma(k+3\delta-l-1).$$
 (31)

Then, the Rényi entropy is

$$I_{R}(\delta) = \frac{1}{1-\delta} \log \sum_{l=0}^{\infty} t_{l} \left[\theta(j+\delta)\right]^{l-k-3\delta+1} \Gamma(k+3\delta-l-1).$$
(32)

5. Maximum Likelihood Estimation

Suppose $X_1, X_2, ..., X_n$ is a random sample of size *n* from a population having TLIL pdf, the log-likelihood function is given by

$$Log L = n \log (2\alpha) + 2n \log(\theta) - n \log(1+\theta) + \sum_{i=1}^{n} \log\left(\frac{1+x_i}{x_i^3}\right) \\
- \theta \sum_{i=1}^{n} \frac{1}{x_i} + \sum_{i=1}^{n} \log\left(1 - \left(1 + \frac{\theta}{(1+\theta)x_i}\right)e^{-\theta/x_i}\right) \\
+ (\alpha - 1) \sum_{i=1}^{n} \log\left(1 - \left(1 - \left(1 + \frac{\theta}{(1+\theta)x}\right)e^{-\theta/x}\right)^2\right).$$
(33)

The score functions which correspond to equating the first-order partial derivative of the last equation to zero is given by

$$\frac{\partial \log L}{\partial \alpha} = \frac{n}{\alpha} + \sum_{i=1}^{n} \log \left(1 - \left(1 + \frac{\theta}{(1+\theta)x} \right) e^{-\theta/x} \right)^2 \right) = 0,$$

$$\frac{\partial \log L}{\partial \theta} = \frac{2n}{\theta} - \frac{n}{1+\theta} - \sum_{i=1}^{n} \frac{1}{x_i} + \sum_{i=1}^{n} \frac{Z_i}{N_i} - 2(\alpha - 1) \sum_{i=1}^{n} \frac{N_i Z_i}{(1-N_i^2)} = 0,$$
(34)

where $Z_i = 1/x_i e^{-\theta/x_i} (1 + \theta/(1 + \theta)x_i + 1/(1 + \theta)^2)$ and $N_i = 1 - (1 + \theta/(1 + \theta)x_i)e^{-\theta/x_i}$. The solutions, say $\hat{\alpha}$ and $\hat{\theta}$ of the score functions correspond to the maximum likelihood estimators of TLIL distribution. However, the score functions are nonlinear functions; the numerical values of the maximum likelihood estimates can be obtained using the Newton-Raphson iterative optimisation method.

An approximate confidence interval (CI) of model parameters for TLIL distribution is calculated. It is known that the asymptotic distribution of ML estimates of elements of parameters α and θ is given by

$$((\widehat{\alpha} - \alpha), (\widehat{\theta} - \theta)) \longrightarrow N(0, I^{-1}(\alpha, \theta)),$$
(35)

where Γ^{-1} is the variance covariance matrix of unknown parameters; hence, the approximate $(1-\nu)$ 100% two-sided CIs for α and θ are, respectively, given by

$$\widehat{\alpha} \pm Z_{\nu/2} \sqrt{\operatorname{var}(\widehat{\alpha})}, \, \widehat{\theta} \pm Z_{\nu/2} \sqrt{\operatorname{var}(\widehat{\theta})}, \tag{36}$$

where $Z_{\nu/2}$ is the upper $\nu/2^{\text{th}}$ percentile of the standard normal distribution.

6. Simulation

This section provides a simulation study to assess the behavior of the estimators in case of complete samples. Mean square errors (MSEs), biases, lower bound (LB) of CI, upper bound (UB) of CI, and average length (AL) of 90% and 95% are calculated via Mathematica 9. The following algorithm is designed as follows.

- (i) 5000 random samples of size n = 50, 100, and 200 are generated from TLIL distribution
- (ii) Exact values of parameters are choiced
- (iii) The ML estimates, MSEs, biases, LB, UB, and AL for selected values of parameters are calculated
- (iv) Numerical outcomes are given in Tables 1–5 based on complete

7. Application

The potential of the new model TLIL is illustrated by modelling a real-life dataset. We compare the fits of the TLIL model with five models: IL, generalized IL (GIL),

exponentiated generalized IL (EGIL), exponentiated IL (EIL), and inverse Weibull (IW) distributions. The Kolmogorov–Smirnov (KS) statistic is used to determine how well the distributions fit the dataset. The Akaike information criterion (AIC), Bayesian information criterion (BIC), and the negative two log-likelihood values of the distributions are also computed. The least values of the –2LogL, AIC, BIC, and KS statistics have a better fit.

Dataset I is taken from Sharma et al. [14] and it represents the survival times of a group of patients suffering from head and neck cancer disease. The patients were treated using radiotherapy.

Dataset II is taken from Bjerkedal [21] and it represents the survival times (in days) of 72 guinea pigs infected with virulent tubercle bacilli.

The two datasets are concerned with biomedical data. Many works studied biomedical datasets such as the studies by Alanazi et al. [22], Iskanderani et al. [23], and Antor et al. [24]. Some descriptive analyses of the both datasets are given in Table 6.

Tables 6–9 present the parameter estimates including the standard errors in parentheses and the goodness-of-fit statistics of the competitive distributions, respectively. The

values in Tables 7 and 9 indicate that the TLIL distribution has the least values of the goodness-of-fit statistics which imply that it has a better fit among the competitive models.

The graphical fit of the competing distributions on the dataset is shown in Figures 5 and 6. The estimated pdf, ecdf, esf, and pp plots plot of TLIL is closest to the empirical plots. Figures 5 and 6 also confirm the goodness-of-fit statistics values given in Tables 8 and 10 that the TLIL has a better fit.

8. Conclusion

In this study, a new statistical distribution called the Topp Leone inverse Lindley model is introduced. The density of the new model can be right skewed and decreasing with unimodal and bimodal shapes. Also, its hazard rate function can be decreasing and upside-down. Some of the mathematical properties such as quantile function, ordinary moments, incomplete moments, and pdf of the i^{th} ordered statistics are established. The estimation of the parameters of the new distribution using the maximum likelihood method is considered. The simulation study is assessed to investigate the performance of the estimates. The usefulness and potentials of the new distribution are demonstrated by comparing its fit to a real-life dataset with other distributions. The goodness-of-fit statistics indicated that the new distribution has a better fit than other competing distributions.

Most of the existing traffic optimization control methods are based on accurate mathematical models. As an uncertain and complex system, the urban traffic system faces difficulty in accurately calibrating the model parameters. Therefore, the existing methods become very difficult in the actual application process. Based on the massive data contained in the urban traffic system and the repetitive characteristics of traffic flow, this paper proposes a hierarchical traffic signal control method for urban road network based on iterative learning control. The simulation results show that the algorithm can achieve better control effect and can solve the problem of urban traffic congestion more effectively than traditional traffic control methods.

1. Introduction

Traffic signal control is an effective method to change urban road traffic conditions and improve road capacity. Because the current transportation system has the characteristics of complexity, variability, uncertainty, and strong randomness, it is difficult to create an accurate mathematical model [1, 2]. The current control of traffic signals at intersections is to divide the day into several time periods, and the cycle length is fixed in each time period. However, due to the strong randomness of the traffic flow of the road section, the phased traffic congestion is unavoidable, and it cannot be based on specific conditions. It will make real-time adjustments [3]. If the green signal ratio of each phase can be controlled to respond to changes in traffic flow in real time, the waiting time of vehicles will be minimized.

Iterative learning control [4, 5] is a control method for repetitive motion processes. At the same time and place, the traffic flow at the intersection will appear to be approximately repetitive. Ding [6] changed the traffic conditions and selection behaviors in the area according to different road network conditions, established a combined feedforward feedback iterative learning control model, and

effectively controlled system interference. Simulation analysis is used to improve the accuracy of tracking error, but the selected traffic model is relatively simple and cannot be applied to complex urban intersections. Jing [7] took the traffic density of main and auxiliary roads as the control target, and the macro-traffic flow model proposed simplifies the store-and-forward model. Iterative learning is applied between the main and auxiliary roads to achieve equilibrium control in local sections, so that the equilibrium control error converges, but the disadvantage is that the model ignores the impact of changing lanes on traffic conditions and cannot be applied to traffic intersections in daily life. In [8], for the entrance of expressway, PD type iterative control law was used to control the traffic flow diffusion model, and then the center of gravity method was used to model and adjust the iterative learning gain, so that the output of the system has better tracking performance. The disadvantage is that it uses 3 types of traffic flow models which are all macroscopic traffic flow models, which will affect the accuracy of the results under microscopic characteristics. Zhou et al. [9] came up with the method of iterative learning control for green signal ratio of single intersection with fixed period. Luo [10] researched iterative control algorithm for descriptor systems. Lv et al. [11] accelerated the control of random initial state errors through iterative learning control. References [12–17] present the urban intersections, roads, signals verifications, and optimizations problem. Li and Li [18] gave the green wave signal setting and simulation analysis of bus lane. Xiao [19] researched on control group decision and dynamic optimization of arterial round intersection. Wang [20] modelled the traffic control signal optimization. Ge and Zhou [21] worked on the dual-layer hierarchical control solution for traffic signal.

Since iterative learning control is mainly applied to fast intersections with relatively fixed traffic flow and relatively simple vehicle conditions, there are few studies on applying iterative learning control to daily intersection traffic light control. This article first uses the iterative learning control method to determine the best effective green light time for each phase and finally verifies the green signal ratio of a certain road section through simulation. The simulation results show that the control method can effectively reduce the queuing phenomenon of vehicles and play a great role in improving the traffic efficiency. After the introduction and literature review, Section 2 presents the principle of iterative learning control algorithm. Section 3 discusses the timing of traffic signals. In Section 4, the iterative learning was used to design the timing scheme. In Section 5, the simulation research was carried out. Finally, Section 6 concludes the study.

2. The Principle of Iterative Learning Control Algorithm

Assuming *t* within a certain period of time, the controlled object undergoes multiple iterations from the initial state $x_k(0)$; according to the algorithm, the expected value $y_d(t)$ and the result value of the dynamic process are superimposed continuously. When the number of downscaling approaches infinity, the control of the system will fail. The input function is

$$u_k(t) \longrightarrow u_d(t).$$
 (1)

The control output function of the system is

$$y_k(t) \longrightarrow y_d(t).$$
 (2)

When it runs to k times, its expression is

$$\begin{cases} x_k(t) = f(x_{k(t)}, u_{k(t)}), \\ y_k(t) = g(x_{k(t)}, u_{k(t)}). \end{cases}$$
(3)

Assuming that the expected value $y_d(t)$ of the system is set within the finite time of [0, T], the obtained input signal $u_k(t)$ makes the output signal $y_k(t)$ infinitely approach the output value $y_d(t)$. The error accuracy of system tracking is

$$e_k(t) = y_d(t) - y_k(t).$$
 (4)

If the number of iterations is $k \longrightarrow \infty$, the tracking error of the system is

$$\lim_{k \to \infty} e_k(t) = 0.$$
 (5)

3. Timing of Traffic Signals

The point control method is often adopted for the signal lights of a single intersection. This article uses the British TRRL method to optimize the signal timing of the current intersection. The number of phases and periods of the point are obtained based on field survey samples, and then the green light duration of each phase is determined separately. This signal timing optimization scheme can minimize the traffic delay time at the intersection, reasonably allocate the traffic flow of each phase to make the control system operate in an orderly manner, and then perform error corrections according to the actual situation to find the most ideal timing plan.

3.1. Optimal Period of Traffic Signal. The formula for calculating the optimal period of signal control is

$$C_0 = \frac{1.5L + 5}{1 - Y},\tag{6}$$

$$L = \sum_{i} (l + I - A), \tag{7}$$

where C_0 is the size of the period, *L* is the time wasted for the system, *l* is the delay time for signal activation, *A* is the time for the yellow light, *I* is the time interval of the signal, *i* is the number of phases, and *Y* is the traffic ratio.

Among them, the calculation formula of the flow ratio is as follows:

$$\begin{cases} Y = \sum_{i=1}^{n} Y_{i}, \\ Y_{i} = \frac{q_{i}}{S_{i}}, \end{cases}$$

$$(8)$$

where Y_i is the flow ratio of the phase, q_i is the traffic flow *i* of phase, and S_i is the flow threshold of the phase.

3.2. The Best Effective Green Signal Time. According to the obtained signal period, the time of the green signal in each phase needs to be allocated reasonably. Because the green light time is affected by the delay of traffic flow, the traffic flow ratio and the green light signal ratio show a linear relationship; then:

$$\frac{g_1}{g_2} = \frac{Y_1}{Y_2},$$
 (9)

where g_1 is the effective time of the first phase green signal, g_2 is the effective time of the second phase green signal, Y_1 is the flow ratio of the first phase, and Y_2 is the flow ratio of the second phase.

From this, it can be deduced that the relational formula with multiple intersection phases is

$$\frac{g_i}{\sum_{i=1}^n g_i} = \frac{Y_i}{\sum_{i=1}^n Y_i}.$$
 (10)

Then, the time of each phase of the green light is

$$g_i = \frac{Y_i}{Y} \left(C_0 - L \right). \tag{11}$$

The green signal ratio of each phase is

$$\lambda_i = \frac{g_i}{C_0}.$$
 (12)

The traffic saturation of each phase is

$$x_i = \frac{\max(Y_i)}{\lambda_I}.$$
 (13)

This article will take the traffic intersection in a certain area as the research object, as shown in Figure 1. After investigating the traffic situation at this intersection, the time lost for each phase is 3.2 s, the saturated flow is 103 veh/h, and the time for all red lights is 2.3 s.

After the actual investigation, the traffic intersection signal light data are statistically analyzed. We optimize the statistical data as parameters, such as the original traffic signal timing plan shown in Table 1 and the traffic data traffic flow statistics in Table 2.

The timing design adopted for the two-phase and three-phase signal control is shown in Figures 2 and 3. The figures assume that the critical saturation flows of the three phases are 600, 300, and 100, respectively. According to formulae (6)-(13), the optimal cycle length, green signal ratio, and saturation are different. The calculation result of the green signal time of the phase is shown in Table 3.

In summary, after the preliminary optimization of the signal lights, the timing scheme with the least delay is derived, and the saturation of each phase is relatively uniform, which further shortens the whole cycle time, ensures the passage of vehicles, and increases the flow per unit time to maximize the application of green light time.

4. Timing Scheme Design Based on Iterative Learning

At each intersection, there is *i* that presents the phase, suppose the arrival rate of the first phase vehicle is q_i , the waiting distance for this vehicle is x_i , saturated traffic flow rate s_i , the arrival rate of phase *i* is d_i , and the effective time when the green light is on is g_i . The ultimate goal of the traffic control signal light is to reduce the length of the vehicle queue and pass as many vehicles as possible within a certain period of time, so as to achieve the purpose of intelligent control. For this reason, in a certain signal period, the length of the queue becomes the state quantity of the system, and the dynamic state equation of the system is

$$x_i(t+1) = x_i(t) + C_0 d_i(t+1) - s_i g_i(t).$$
(14)

Among them, for the time when the green light is on, the constraint condition is

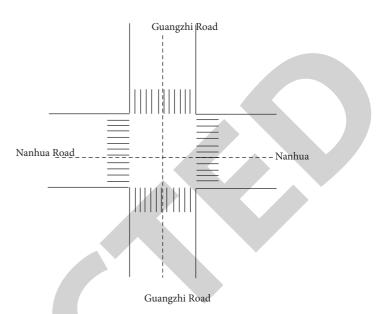

FIGURE 1: Intersection of Guangzhi Road and Nanhua Road.

TABLE 1: The original timing plan of traffic lights.

Project	Phase 1	Phase 2	Phase 3
Cycle	120	120	120
Phase time	71	18	24
Red light time	46	103	93
Green light time	70	18	26
Yellow light time	3	3	3

$$\left\{\sum_{i=1}^{3} g_{i}(t) = C_{0} - Lg_{i}(\min) \le g_{i}(k) \le g_{i}(\max), \quad (15)\right\}$$

where g_i (min) is the minimum time for the green light to turn on (15 s); g_i (max) is the maximum time of the first phase (90 s); and *L* is the total time lost while waiting for the vehicle (15 s).

Control the signal lights to realize that the queue length of each entry vehicle is in a balanced state, that is, control the queue length of different phases. If the queue length is uneven, the green light time will not be fully utilized, which will cause traffic congestion. Therefore, the queuing length difference of each phase becomes the output of this article, and a reference phase needs to be selected here. In this article, the reference phase selects phase 1. Taking the difference between the other two phases and the queue length of phase 1 as the system output y(t), the system output is

$$y(t) = \begin{bmatrix} y_{2,1}(t), y_{3,1}(t) \end{bmatrix}^{T} = \begin{bmatrix} x_{2}(t) - x_{1}(t), x_{3}(t) - x_{1}(t) \end{bmatrix}^{T}$$
$$= \begin{bmatrix} -1 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_{1}(t), x_{2}(t), x_{3}(t) \end{bmatrix}^{T} = cx(t),$$
(16)

where $x(t) = [x_1(t), x_2(t), x_3(t)]^T$; $y_{2,1}(t)$ is the output of phase 2; and $y_{3,1}(t)$ is the output of phase 3.

From this, it can be calculated that the queuing length of vehicles at the intersection is

Traffic direction	Tu	rn left	Sti	raight	Tur	n right	Total traffic

Guangzhi Road

Phase3

FIGURE 3: Timing design adopted for three-phase signal control.

$$s = \begin{bmatrix} -s_1 & -s_1 \\ s_2 & 0 \\ 0 & s_3 \end{bmatrix}.$$
 (19)

After introducing the number of iterations, formula (18) can be changed to

$$x_k(t+1) = x_k(t) + C_0 d_k(t+1) - sg_k(t) - (s_1c_1, 0.0)^T, \quad (20)$$

where *k* is the number of iterations.

Because of the large and unstable traffic flow at traffic intersections, the traffic flow has strong repetitiveness. Therefore, this paper adopts iterative learning control to control the periodic signal at each intersection, so as to draw the corresponding laws according to the calculation results.

Assume that in iterative control, the vehicle queue length satisfies the following conditions:

$$x_k(0) = x_0(0). \tag{21}$$

If the traffic volume at the intersection remains constant within a given period, then:

$$d_k(t) = d_0(t).$$
(22)

The resulting timing plan for the intersection is

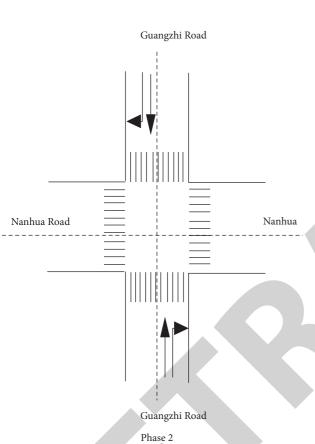

FIGURE 2: Timing design adopted for two-phase signal control.

$$x(t+1) = x(t) + C_0 d(t+1) - sg(t),$$
(17)

where $d(t) = [d_1(t), d_2(t), d_3(t)]^T$, $g(t) = [g_1(t), g_2(t), d_3(t)]^T$ $[g_3(t)]^T$, $s = diag\{s_1, s_2, s_3\}$. $d_i(t)$ is the traffic flow for phase i and, $g_i(t)$ is the time when the green light of phase *i*. It is the time when the green light of phase i is on.

According to the above expression, the vehicle queue length is determined by the vehicle queue length x(t+1) of the current signal cycle, the traffic demand d(t+1) of the next cycle, and the time g when the green light is on in the current cycle. x(t) and d(t) jointly decided the cycle.

According to formula (16), the green time $g_1(t)$ of phase 1 can be obtained from the green time of the other two phases, so formula (17) can be changed to

$$x(t+1) = x(t) + C_0 d(t+1) - sg(t) - (s_1 c_1, 0.0)^T.$$
 (18)

In the formula (18), *c*₁, *c*, and *l* indicate the period, size of the signal, and the time lost in queuing, respectively.

where y_d is the expected queuing difference and α is the iterative learning gain matrix.

If the queuing length at the intersection controlled by traffic lights is close to balance, the phase queuing length at each intersection requires $y_d = 0$.

5. Simulation Research

This paper takes the intersection composed of Nanhua East Road and Guangzhi Road as the object of simulation study. There are 3 phases in the intersection. The arrival rates of each phase are, respectively, 0.52 veh/s, 0.16 veh/s, and 0.24 veh/s, and the saturation flow rate of each phase is 0.27 veh/s. The learning gain is -0.83, the loss time of each phase is 2 s, the signal period is 114 s, and the green light time of the three phases is 51 s, 15 s, and 34 s. Considering the complexity of the actual situation, while optimizing the model, the green light time and queue length obtained by MATLAB simulation should be integer values. The simulation results are shown in Figures 4–6.

From the simulation results of Figures 4 and 5, it can be seen that after the number of iterations exceeds 15 times, the difference and error of the queue length almost approach zero, and the timing of the entire traffic signal system is in a uniform distribution state.

Figure 6 shows the time curve of the three-phase green traffic signal lights. After adopting the iterative learning control signal, the green light time of each phase is adjusted in real time according to the specific traffic volume, and reasonable time allocation is carried out, which proves the effectiveness and reliability of the algorithm.

6. Conclusion

In this paper, the controlled object is the traffic light at intersections. The reasonable signal period is determined according to the TRRL method timing plan, and then based on the idea of iterative learning control law, a method to control signal lights is constructed to avoid the establishment of a complex traffic flow model. It can use very few priors. We use real-time traffic flow data to control the traffic lights at intersections. The experimental results of iterative learning control show that the control method of this algorithm is reasonable and can be changed according to the changes of traffic flow. It has the effect of adaptive adjustment and improves the traffic efficiency. The optimization effect of the iterative algorithm is far better than the traditional timed and fixed cycle traffic system. It can adaptively adjust the cycle length and the green light time of each phase. It can pass more vehicles at the same time without additional equipment. Support and additional costs can reduce people's unnecessary waiting time, thereby saving people's travel time and improving work efficiency. However, the scope of application of this article has certain limitations. When there are few or many vehicles at the intersection, the adjustment effect is not obvious.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no known conflicts of interest or personal relationships that could have appeared to influence the work reported in this paper.

This paper introduces a qualitative analysis on the efficiency evaluation of the knowledge supply chain by combining the analytic hierarchy process (AHP) with data envelopment analysis (DEA), drawing on existing literature to determine the index weight through the scoring of industry experts, and selecting appropriate input and output indicators to construct a knowledge supply chain efficiency evaluation system. The system was then applied to the supply chain of a number of high-tech enterprises. The results identified innovation efficiency differences of the knowledge supply chain in these enterprises, along with best practices and suggestions for the current knowledge supply chain efficiency.

1. Introduction

In the supply chain, there is not only logistics, information flow, and capital flow, but also knowledge flow based on products. The intensification of market competition has broken the original competition mode among enterprises and has gradually formed competition among supply chains. Previous academic research has also focused mainly on supply chain management, such as integrating the concept of environmental protection into the supply chain by studying "low-carbon supply chain" [1, 2]; combining natural environmental risks and economic political risks into the supply chain, studying the impact of external factors on the food supply chain [3, 4]; integrating knowledge management into the supply chain and some papers and a conference proceedings previously been published studying the "knowledge supply chain" [5–7].

The supply chain is centered on core enterprises, and it forms a network chain structure model around the R&D, manufacturing, warehousing, logistics, distribution, and sales of commodities. Suppliers not only undertake production and manufacturing operations, but also conduct different types of knowledge exchange and knowledge transfer with customers [8, 9]. In today's rapid digital development of industry, the use of knowledge management to enhance the digital performance of the supply chain plays a crucial role in the digital transformation of the supply chain [10].

The knowledge supply chain was proposed by the "Next Generation Manufacturing Project" in the United States. It refers to the adjacent knowledge nodes in the process of supply, innovation, dissemination [6] and the use of knowledge through the relationship between demand and supply. Link up and convert the concept into a knowledge product and then to a functional network chain for the end user. J. Rechard Hall and Pierpaolo Andfiam put forward the concept of a knowledge chain from the perspective of the supply chain. The knowledge supply chain extends and deepens the traditional physical supply chain.

Compared to the traditional entities that form the supply chain, high-tech enterprises are knowledge-intensive entities. Knowledge-based products and technologies flow through the supply chain upstream and downstream of the enterprise, forming a knowledge supply chain which promotes the supply and dissemination of knowledge and scientific research results. It plays a key role in the landing transformation of scientific research results [11]. Therefore, improving knowledge conversion, or the efficiency of knowledge flow in the supply chain, and maximizing the benefits of the knowledge economy have become the main problems of enterprises today.

In terms of supply chain performance evaluation, Ramish and Aslam [12] determined indicators for measuring knowledge management in the supply chain, including resource utilization, output measurement, new process performance evaluation, etc. based on the principle of doubleloop and three-loop learning. Murata et al. [13] constructed two knowledge supply chain subsystems for Japanese SMEs, including the team building process subsystem and the team management subsystem. The team building process subsystem includes the execution, consulting, and demonstration phases. The team management system includes three steps of management experience accumulation: attention, memorization, and confirmation. Wiig [14] believed that the key to the performance evaluation of the knowledge supply chain lies in the assessment of knowledge management. The indicators should include the promotion of knowledge activities, the infrastructure related to knowledge activities, accumulated knowledge assets, and knowledge learning.

From the perspective of the research index system, there are many ways to evaluate supply chain management and knowledge management, which involve many comprehensive economic indicators. However, the current research aims to build an index system based on the research experience of scholars, which is highly subjective. This study intends to use AHP to screen the efficiency evaluation indicators of the knowledge supply chain. It would effectively draw on the subjective knowledge and experience of experts, while maintaining good objectivity at the same time. In the construction of evaluation models, previous studies mainly used factor analysis and fuzzy synthesis evaluation [15], the entropy method, etc. While using a certain method alone may have certain drawbacks, a combined evaluation method can effectively solve those disadvantages. Thus, it is now trending in comprehensive evaluation research.

Therefore, this study focuses on the efficiency evaluation of the knowledge supply chain, combining the AHP analytic hierarchy process with the DEA data envelopment analysis, and using the authoritative expert scoring method in the industry to determine the key indicators and their weights that need to be considered in the knowledge supply chain efficiency evaluation. Drawing lessons from existing literature research and expert scoring methods, the article screens appropriate input indicators and output indicators, constructs a knowledge supply chain efficiency evaluation system, and further combines supply chain data to calculate the efficiency value. Finally, this article takes the supply chains of high-tech enterprises in four provinces and cities in the Yangtze River Delta as examples to study their innovation efficiency in the process of knowledge and technology innovation, provide certain references for knowledge supply chain management, and put forward relevant policy recommendations.

Journal of Mathematics

2. Construction Method of Evaluation Index System

2.1. Knowledge Supply Chain Model. American scholars Holsapple and Singh [16] constructed a systematic knowledge supply chain model from the relationship between organizational knowledge and organizational core competitiveness. The model includes the main part of the knowledge chain and the output of the knowledge chain. The main part of the knowledge chain includes five primary knowledge activities and four advanced high-level activities. The five primary knowledge activities are knowledge acquisition, knowledge selection, knowledge generation, knowledge internalization, and knowledge externalization. The four high-level knowledge activities are leadership, cooperation, control, and measurement. While managing knowledge (output of the knowledge chain) in the supply chain adds additional complexity to the supply chain management process, knowledge sharing between supply chain partners is nonetheless an important element of the supply chain knowledge management (SCKM) system [17].

In the supply chain of high-tech enterprises, the spatial agglomeration effect between enterprises in the industrial park will accelerate the acquisition and generation of knowledge, while the government, financial institutions, and enterprises' own technological R&D investment will promote knowledge transfer, thereby promoting technological innovation and conversion. Once the process of internalization and externalization of knowledge is over, new technologies and processes suitable for the long-term development of the enterprise will be introduced to the consumer, which will bring economic benefits to the enterprise. Therefore, based on the knowledge supply chain model, combined with the process of knowledge acquisition and creation of high-tech enterprises, this study establishes the following knowledge supply chain model (Figures 1 and 2).

2.2. Construction of the Innovation Efficiency Evaluation System of the Knowledge Supply Chain. When selecting supply chain efficiency evaluation indicators, they are usually selected from the two dimensions of input and output. This article will select indicators from the two dimensions of input and output elements based on existing relevant research and evaluation. The input elements include organizational input, human input, and financial input. The output elements include the measurement of innovation output and economic benefits.

Input elements: Since the technological innovation process is an integrated system, all partners involved in this process must group together to establish mutual trust and promote the transfer of tacit knowledge such as experience and technical know-how, thus effectively playing their role in the system. The spirit of collaboration can lead to better acquisition of high-quality tacit and complex knowledge [18]. Therefore, for the supply chain of high-tech enterprises, the spatial agglomeration effect between enterprises in the industrial park can accelerate the acquisition of knowledge

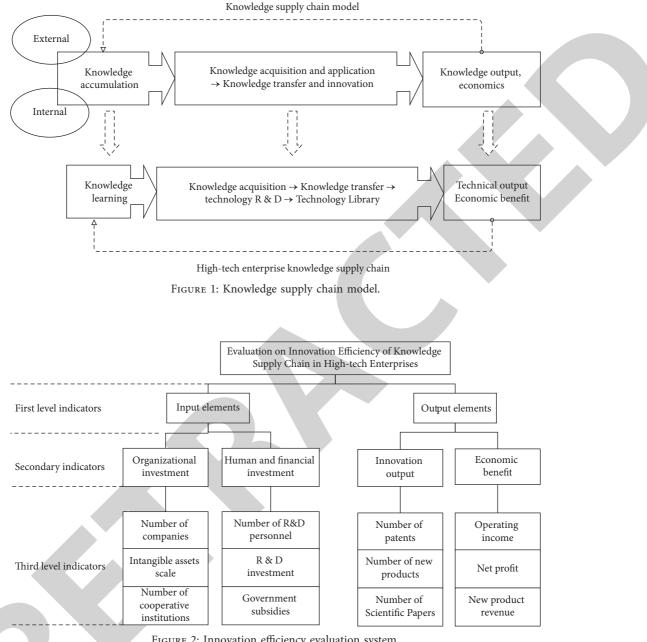

FIGURE 2: Innovation efficiency evaluation system.

to a certain extent. In addition, cooperation between external institutions and the intangible assets owned by the enterprises within the organization can also accelerate the flow of knowledge. This has an important impact on the dissemination and transformation of knowledge. Carneiro [19] also suggested that, in addition to using financial indicators, organizations can use nonfinancial personnel to measure knowledge management. Based on this, this study considers the number of technical R&D personnel as one of the factors to measure human and financial inputs.

Output elements: In traditional supply chain performance evaluation, financial indicators are often selected to measure economic benefits. However, using only economic benefits to measure performance may lead to bias in the results. In the knowledge supply chain of hightech industries, the flow of commodities has nothing to do with physical commodities, but with the flow of R&D commodities. R&D products include patents, technologies, research services, and research projects, etc. In hightech industries, their development and commercialization are considered just as important as real products [20]. Therefore, based on the research of scholars such as Alessandra Alletto, this study uses the number of new patent application and development as the measurement index of knowledge output elements in the measurement of technology output in addition to traditional financial indicators such as the changes in operating income and net profit.

Based on the above analysis, this paper establishes the following level analysis model.

2.3. Calculating Method of Innovation Efficiency of Knowledge Supply Chain. Because there are many supply chain innovation performance evaluation indicators of high-tech enterprises, we needed to ensure the operability of the methods and the simplicity of the indicators and to reduce the complexity of calculations. The many types of indicators present have to be screened and the input and output cover a wide range. The indicators are difficult to screen solely based on the data, so they require the judgment of experts with many years of industry experience. The pairwise comparison method provided by AHP can effectively reduce the difficulty of expert judgment and reduce errors. At the same time, the DEA method has advantages in handling multiinput and multioutput effectiveness evaluation and is widely used in financial resource operation efficiency [21], risk performance evaluation, etc.

Therefore, this study uses the AHP method to screen the established high-tech enterprise knowledge supply chain evaluation indicators and the DEA method to evaluate and rank the innovation efficiency of the knowledge supply chain in the Yangtze River Delta. This calculation method effectively integrates AHP and DEA methods and can reasonably evaluate multiattribute problems. The analytic hierarchy process can fully reflect the preferences of decision makers, while the DEA model can objectively evaluate the efficiency of technological innovation, technological effectiveness, and scale effectiveness. This research uses comprehensive AHP and DEA modeling to evaluate the innovation efficiency of the knowledge supply chain of high-tech enterprises and effectively realize horizontal comparison and sorting, which is beneficial to knowledge management-related research on the supply chain.

3. Model Principles

This article combines analytic hierarchy process (AHP) and data envelopment analysis (DEA) to evaluate and rank the innovation efficiency of the knowledge supply chain. The AHP combines qualitative analysis and quantitative analysis and selects the most representative evaluation indicators by comparing the importance of the elements. The DEA method can be used to calculate the innovation efficiency value based on the objective observation and carry out a numerical evaluation. Therefore, this article first selects representative indicators, uses data envelopment analysis methods to calculate indicators, and finally calculates the efficiency value comprehensively and realizes the efficiency ranking.

3.1. Principles of Analytic Hierarchy Process. The analytic hierarchy process (AHP) was formally proposed by the American operations researcher T. L. Saaty in the mid-1970s. It is a systematic and hierarchical analysis method that combines both qualitative and quantitative analyses. It compares the importance of each element in pairs, calculates the relative weight of each element through mathematical methods, and finally sorts the importance of the elements

based on their relative weight. Because of its practicality and effectiveness in dealing with complex decision-making problems, it quickly gained attention worldwide [22, 23]. Its applications have spread throughout the fields of economic planning and management, energy policy and distribution, behavioral science, military command, transportation, agriculture, education, human resources, medical care, and the environment. The main steps of the analytic hierarchy process are as follows.

3.1.1. Weight Calculations. To establish a quantitative judgment matrix based on input and output indicators, we invited 10 technical field supply chain management experts to compare *n* indicators at each level in pairs and give a judgment matrix $A = (a_{ij})_{m \times n}, a_{ij}$ represents the importance of element *i* relative to element *j*, and each element of the judgment matrix satisfies $a_{ij} > 0, a_{ij} = 1/a_{ji}, a_{ii} = 1$. The arithmetic average method is used to calculate the maximum eigenvalue λ max of each judgment matrix and its corresponding eigenvector $(W_1, W_2, W_3, \ldots, W_n)$, which is the weight of the index.

3.1.2. Consistency Inspection. Calculate the consistency index CI and random consistency ratio CR of each judgment matrix:

$$CI = \frac{\lambda \max - n}{n - 1},$$

$$CR = \frac{CI}{RI}.$$
(1)

RI represents the average consistency index of the judgment matrix. If the consistency ratio is CR < 0.10, the consistency test is passed. The eigenvector obtained above is the weight vector reflecting the relative importance of the indicators. The experts are invited to adjust the judgment against the value of the matrix until satisfactory consistency is achieved.

3.2. Principles of DEA Data Envelopment Analysis. The data envelopment analysis (DEA) method is the most widely used nonparametric performance evaluation method, which was jointly proposed by Charnes and Cooper [24]. The DEA method is widely used in many fields, such as production management of industrial enterprises and efficiency evaluation of scientific research institutions. The DEA algorithm treats each object to be evaluated as a decision-making unit (DMU) and multiple decision-making units together as the evaluated group. The efficiency and effectiveness of each decision-making unit are determined by dividing the indicators into two types of input and output indicators and then using the weight of the input and output indicators as variables to perform optimization calculations.

Commonly used DEA models include the CCR and BCC models. The former is used to evaluate the overall effectiveness of the decision-making unit, and the latter is used to evaluate the technical effectiveness of the decision-making

unit. The use of the CCR model is based on the assumption of constant return to scale (CRS), which assumes that the decision-making unit can increase their output scale return by increasing their input in equal proportions. In practical application, as the input elements increase, the return to scale gradually saturates before entering the stage of diminishing returns to scale. Therefore, this study chooses to incorporate the variable returns to scale (VRS) DEA-BCC model instead.

The basic principle is that, for each decision unit, $DMU_k (k = 1, 2, ..., n)$. Each decision-making unit has m inputs and outputs. The *i*-th input of DMU_k is $X_k = \{X_{ik}, i = 1, 2, ..., m\}$, and the *j*-th output is $Y_k = \{Y_{rk}, r = 1, 2, ..., s\}$. The BCC model is established as follows:

$$\begin{cases} \min \Theta = V_{D1} \\ \text{s.t.} \sum_{j=1}^{n} \lambda_j x_j \le \Theta X_0 \sum_{j=1}^{n} \lambda_1 = 1 \lambda_j \ge 0, \, j = 1, 2, \dots, n. \end{cases}$$
(2)

Its dual formula is

$$\begin{cases}
\operatorname{Max}(u^{T}Y_{0} + u_{0}) = V_{P1} \\
\operatorname{s.t.} w^{T}X - u^{T}Y_{j} - u_{0} \ge 0, \, j = 1, 2, \dots, n \\
w^{T}X_{0} = 1 \\
w \ge 0, \, u \ge 0
\end{cases}$$
(3)

If there is an efficiency optimal solution w_0, u_0, \hat{u}_0 in the formula which satisfies $V_{P1} = u_0^T Y_0 + \hat{u}_0 = 1$, it is a weakly valid unit of DEA. If there is $w_0 > 0, u_0 > 0$ in the formula, it is called DMU_{j0} is a fully effective unit of DEA. Finally, after the introduction of non-Archimedean infinitesimal ε , input slack variable S^- , and output slack variable S^+ , the final BCC model is as follows:

$$\begin{cases} E_{BCC} = \min \Theta - \varepsilon \left(s^{-} + s^{+} \right) \\ \text{s.t.} \sum_{k=1}^{n} \lambda_{k} x_{k} + S^{-} = \Theta X_{0} \\ \sum_{k=1}^{n} \lambda_{k} x_{k} - S^{+} = Y_{0} \\ \sum_{k=1}^{n} = 1 \\ \lambda_{k} \ge 0, k = 1, 2, \dots, n \\ s^{-} \ge 0, s^{+} \ge 0 \end{cases}$$

$$(4)$$

The goal of the BCC model is to maximize the efficiency of decision-making units. This study uses the BCC model to evaluate the innovation efficiency of multiple decisionmaking units in the input and output of the high-tech enterprise knowledge supply chain. DEA's comprehensive technical efficiency is composed of pure technical efficiency and scale efficiency. Pure technical efficiency comes from the influence of management and technology on the efficiency of output units, and scale efficiency comes from the influence of scale factors on the efficiency of output units. When the pure technical efficiency is 1, technical efficiency is completely effective. When the scale efficiency is 1, the scale efficiency of the decision-making unit is completely effective. If both are 1, the decision-making unit is a fully effective DEA unit. If only the technical efficiency or scale efficiency is 1, the DEA of the unit is weakly effective. If both are not 1, the DEA of the decision-making unit is invalid.

4. Sample Analysis

This article selects high-tech enterprises in the Yangtze River Delta region of China as the research sample. The Yangtze River Delta region includes four provinces, Shanghai, Jiangsu, Zhejiang, and Anhui, and contains many high-tech enterprises. It is an important strategic economic belt in China, and the integration of the Yangtze River Delta is one of China's national strategies. Therefore, the economic development and various data indicators in this area are representative. As the 2019-nCoV in 2020 will have an impact on the economy, this article selects a sample of knowledge supply chain data from 75 listed high-tech companies in the Yangtze River Delta in 2019 for analysis.

4.1. Expert Scoring and Data Collection. To establish a quantitative judgment matrix based on the input and output element indicators in this study, we invited 10 technical field supply chain management experts to brainstorm and compare indicators at each level in pairs, give a judgment matrix, and calculate the weightage of each index (W represents the weight of the indicator) (Tables 1–3).

Through the weight analysis of the first-level indicators, we can see that, in the measurement of innovation efficiency, the measurement of output elements takes a larger proportion, and the importance of innovation output and economic benefits is equal. In the measurement of input elements, human capital and capital investment are more important. The following is an analysis of the three-level indicator weights contained in the two second-level indicators, as shown in Tables 4–7.

4.2. AHP to Determine the Index Weight. Based on the above index scores, the overall index weights are listed in Table 8.

Based on the results of our analysis, it can be seen that, among the organizational input elements, the weight of the number of enterprises is higher than that of the other indicators, indicating that the greater the number of enterprises in a region, the greater the convergent effect on the acquisition and creation of regional knowledge as well as the rapid flow of knowledge. Among the human and financial input elements, the weight of R&D expenditure and the number of R&D personnel are obviously higher than others, which reflects the importance of human capital and capital investment in knowledge creation. Among the elements of innovation output, the weight of the number of patents is significantly higher than that of new products and papers, indicating that technology creation is an important part of innovation output. Among the indicators of economic benefits at all levels, operating revenue and net profit have a

TABLE 10: The efficiency value of the Yangtze River Delta region.

significantly higher weight. It is not difficult to understand that revenue and profit are the most obvious indicators reflecting the actual capital flow and operating conditions of the supply chain. Therefore, this study selects the economic indicators (X4, X5, Y1, Y4, Y5) with significantly higher weights among all levels of indicators for subsequent DEA analysis.

4.3. Analysis and Evaluation Based on DEA. In actual production activities, input factors can often be controlled artificially, while the output factors are not highly controllable, which makes them more appropriate for the measurement of efficiency values from the perspective of input. Therefore, this study selects an input-oriented DEA model to examine the knowledge supply chain of 75 listed high-tech enterprises in the Yangtze River Delta in 2019, which includes 34 in Shanghai, 20 in Zhejiang, 18 in Jiangsu, and 3 in Anhui. With the help of Deap 2.1 software, we use the input-output indicators selected above to calculate and comprehensively calculate DEA efficiency by province, and the results are as follows. In Table 9, Crste represents the overall efficiency of the knowledge supply chain, Vrste represents pure technical efficiency, and Scale represents scale efficiency.

Further, we grouped and calculated the supply chain of each region to obtain the innovation efficiency of the regional knowledge supply chain (Table 10).

We can see that the overall efficiency (Crste) of the regional knowledge supply chain is ranked as follows: D4 > D2 > D3 > D1. When considering the return to scale (VRS perspective), the order of pure technical efficiency (vrste) is D4 > D3 > D2 > D1. From the overall efficiency level, the indicators of the four regions were higher than the overall average. Anhui's supply chain innovation efficiency is relatively high, while Shanghai's is relatively low. Jiangsu was slightly better than Zhejiang in terms of pure technical efficiency.

5. Conclusions and Policy Recommendations

5.1. Research Conclusion. This paper combines AHP with DEA to introduce qualitative analysis in the efficiency evaluation of the knowledge supply chain by combining relevant research in the existing literature before selecting and determining the appropriate input products through the scoring method of authoritative experts in the industry. After that, the index weights were calculated, and an efficiency evaluation system for the knowledge supply chain was constructed, which was later used to measure the supply chain efficiency of high-tech enterprises in four provinces

and cities in the Yangtze River Delta in 2019. The results of this study are as follows:

- (1) All indicators in the four regions are higher than the overall average, indicating that the innovation vitality of the Yangtze River Delta region remains at a high level and that there is no significant difference in development between the four provinces and cities.
- (2) In terms of specific ranking, Anhui's supply chain innovation efficiency is relatively high, while Shanghai's is relatively low. In terms of overall economic situation, while Shanghai is the leader in the Yangtze River Delta, their innovation efficiency remains low, which could be a reflection on their use of resources or internal limitations in deployment, which requires further attention from relevant management.
- (3) In terms of pure technical efficiency, the Jiangsu region is slightly better than the Zhejiang region. Overall, both regions were at the middle level of overall development. Therefore, stabilizing the current development trend and seeking future innovation efficiency improvement is an issue worthy of attention.

5.2. Policy Recommendations. This study focuses on the knowledge supply chain of the Yangtze River Delta, which is an important economic belt in China. The integration of regional talent, technology, capital, and other resources is relatively complete. The problems reflected in the various economic data are forward-looking and reference. Based on the above research conclusions, this article puts forward the following policy recommendations:

First, improvements in innovation efficiency can be achieved by improvement in both input and output elements. In terms of input, attention should be paid to the cooperative innovation and technological exchanges between enterprises in the industrial park and the utilization of upstream and downstream knowledge accumulation in the supply chain. In addition, high-tech talent should also be strengthened. Strengthening the cultivation of knowledge and research investment in important fields can maximize the input of human capital and social capital within the knowledge supply chain. In terms of output, it is necessary to strengthen the assessment model that pays equal attention to the output of technology patents and economic benefits, which can promote the transformation of knowledge and the application of technology.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Globalization has brought increased attention to the balance of payments situation from a variety of countries. The traditional method of measuring balance of payments may not be applicable in certain situations. This paper draws on the idea of economic resilience, uses the transmission mechanism of balance of payments imbalance, and establishes a system of balance of payments imbalance resilience to provide a complement to the traditional measure. In this article, we establish a system of balance of payments resilience and ensure its reasonableness and effectiveness. The main conclusions are as follows: (1) balance of payments resilience score can be used as a reference and early warning indicator of a country's balance of payments situation and improves the measurement of balance of payments. (2) Improving the country's unemployment rate and boosting adjusted net savings will significantly upgrade the balance of payments situation. Improving foreign capital adequacy and foreign exchange market conditions is more beneficial for improving the country's rank of resilience score.

1. Introduction

Politics, economy, and culture of countries around the globe are becoming increasingly intertwined through globalization and international trade. In such a situation, various countries use the balance of payments (BOP) to measure their gains and losses in international trade. A stable BOP gives a country a competitive edge in international transactions and vice versa. It is common to use the current account balance for the purpose of measuring the BOP internationally [1], and the bounds of the imbalance were set at 5% of GDP [2]. This type of BOP measurement method, however, has some negative aspects. The BOP closely relates to the level of economic development in a country. Having a moderate and stable current account surplus is conducive to a country's economic development, whereas a deficit, especially a large deficit, is strongly unfavorable. We examine the latest data from some countries and find that it conflicts with the above.

2. Literature Review

The literature review of this paper is divided into three parts: (1) we briefly describe the BOP theory and traditional methods of measuring the imbalance. (2) We describe the idea of economic resilience. This article uses this to establish an index system. (3) The rationale for the selection of the BOP imbalance resilience indicators is introduced using the foundation for the selection of the indicators, which is the core portion of the literature review.

2.1. Balance of Payments Theory and Traditional Imbalance Measurement Methods. It should be noted that the BOP does not emphasize the accounts in which the deficit is incurred. According to the sixth edition of Balance of Payments and International Investment Position Manual (BPM6) [3], autonomous transactions are recorded in the current account and capital account, whereas financial accounts have both records, and it is not easy to distinguish between them within the account. As a result, current and capital account deficits should be given greater attention when correcting BOP imbalances. Measures of imbalances have focussed on current accounts and relative deficits in recent years. The most popular method of calculating BOP balance is to utilize the current account balance [1]. The current account is more indicative of the supply and demand situation in the foreign currency market than the capital account [4], and recent Western research has concentrated on current account imbalances [5]. A BOP imbalance exists in industrial nations with a current account balance to GDP ratio of higher than 5%. [2]. As a boundary of imbalance, many international organizations and summits use 5%.

To sum up, the current BOP measure is based on the ratio of current account balance to GDP with 5% as the alert line for imbalance. We consider the use of a single indicator and a fixed alert line to be inappropriate and not helpful in explaining some economic phenomena. Thus, this article constructs an indicator system for the resilience of BOP imbalances, thereby supplementing the existing imbalance measurement methods.

2.2. Economic Resilience. Economic resilience is a relatively new field that involves disciplines such as development economics and regional economics. Holling [6] first proposed the concept of resilience to describe the ability of ecosystems to recover after trauma. Through decades of development, resilience has gradually included ecology, engineering, and economics. In this paper, we adopt the concept of economic resilience in macroeconomics, which describes a country's ability to recover after an external shock to its economy [7]. Briguglio et al. [8] succeeded in developing a system of indicators for estimating economic resilience by looking at four areas: macroeconomic stability, micro market efficiency, better economic governance, and social development. Those areas reflect not only the ability of an economy to resist external shocks, but also the severity of an economic recession resulting from external shocks. As a result, the indicators selected should satisfy two requirements in this paper: (1) This indicator can be used to judge a country's capacity to resist BOP imbalances and its economic strength. (2) Indices will change when a country's BOP imbalances are unbearably high, reflecting the loss and vulnerability of its economy.

2.3. Literature on Unbalanced Resilience System Construction Indicators. In this section, we discuss the criteria that are relevant to resilience indicators selection. Indicators should meet both requirements of Section 2.2 and have literature support. We have finally generated a path of BOP imbalances transmission, containing indicators of resilience.

2.3.1. The Impact of BOP Imbalances on the Domestic Economy. BOP changes may directly impact a country's foreign currency exchange market [9]. The foreign currency

reserves, the foreign investment, the exchange rate, and the BOP all interact, according to Lu [10]. The BOP will have an influence on international commerce and investment in addition to foreign money. Foreign direct investment is linked to foreign currency reserves, which in turn is linked to the BOP [11]. Sun [1] and Chen [12] determined that a country's BOP situation is linked to its international trade competitiveness and that the terms of trade index may be used to quantify that competitiveness. As a result, we may deduce that BOP variations have a first-order impact on the foreign exchange and international trade markets and that the BOP limited growth model serves as a link to the domestic economy.

The BOP constrained growth model argues that BOP affects the growth of the domestic economy, especially GDP, through foreign trade and foreign exchange markets. This model, first proposed by Thirlwall [13], considers the impact of BOP on economic growth (GDP). Thirlwall concluded that failure to achieve BOP equilibrium inhibited a country's economic growth, and Thirlwall and Hussain [14] optimized the model to require fewer constraints. Kvedaras et al. [15] analyze new empirical data to demonstrate the current applicability of the model, which means that it is reasonable to apply the model theory in this paper. Scholars have also applied the model to various countries, concluding that the terms of trade index, real interest rate, exchange rate, and other indicators can be affected by the BOP, and using the model to limit GDP growth.

In addition to affecting GDP growth, foreign exchange reserves and exchange rate movements also have an impact on inflation [16]. Li and Ren [17] found that BOP can affect the quality of economic growth by affecting domestic macroeconomic stability; that is, BOP affects macroeconomic stability indicators, such as inflation and employment. The BOP can also reach deep within the macroeconomy and have an impact on fiscal conditions, real interest rates, and economic growth rates [18].

Thus, we can conclude that the BOP affects the foreign exchange rate, foreign trade, domestic economic growth, macroeconomic stability, and other macroeconomic indicators. Some indicators, such as fiscal policy and exchange rate, also affect the BOP.

2.3.2. BOP and Quality of Economic Growth. As clarified above (according to Section 2.3.1), BOP can influence the quality of economic development by affecting the foreign exchange market and the foreign trade market. The quality of economic development itself can be a measure of the economic strength and the ability to resist imbalances, which is precisely what indicators need.

Liu et al. [19] concluded that BOP is conducive to improving the quality of a country's economic growth. Kong et al. [20] conducted research on the relationship between the foreign openness and the quality of economic growth in a changing exchange rate environment from 1994 to 2018 and established a system for measuring the quality of economic growth, the indicators of which could be used to select indicators to construct resilience of BOP. Long and Ji [21] studied the GPI of Chinese provinces and optimized the measure of GPI. The GPI is highly sensitive to the welfare of people and can be used to complement quality of economic growth.

Thus, we can conclude that indicators such as industrialization level, technical efficiency, TFP growth rates, research expenditures, environmental depletion, and poverty measure will also be added to the system of BOP imbalances resilience indicators.

2.3.3. BOP Crisis Theory and Events. The BOP crisis is a special case of imbalance. By studying the theoretical model of the BOP crisis and the economic variables affected by the crisis, we can choose resilience indicators from another perspective.

Krugman [22] proposed the first generation of BOP crisis model, arguing that when a country's money supply exceeds its money demand for a long period of time, foreign exchange reserves will continue to fall and currency speculators will attack at some point to disintegrate the fixed exchange rate system, causing the country's currency to devalue and the economy to collapse. Obstfeld [23] proposed a second-generation model of BOP crises, noting that when domestic macroeconomics is weak, currency speculation leads governments to abandon fixed exchange rate regimes on their own initiative, which triggers a chain reaction. Third-generation BOP crisis models are more inclined to examine the financial sector, which is called "capital item crisis theory."

Sen [24] optimizes the first generation of the BOP model to make the model's predicted timing of BOP crises more reasonable. Wang [25] examined the third-generation BOP crisis model and concluded that the crisis would result in a significant currency depreciation, which would have a negative impact on macroeconomic stability, and a sharp drop in real investment, which would have a negative impact on the real economy. According to Yin and Li [11], the crisis will result in a massive fiscal deficit. Wang [25] explores the causes of contagions associated with the three BOP crises that have occurred, such as inflation and fiscal conditions.

Studies of this type generally confirm the transmission path of the BOP imbalances derived from Sections 2.3.1 and 2.3.2 from a different angle. As a result, the transmission path obtained in this article will be more reliable.

The paper ultimately briefly describes this component as the transmission path of BOP imbalances, as described below. BOP imbalances will impact the foreign exchange market, resulting in changes in exchange rates, foreign exchange reserves, and foreign investment. As a result of the abovementioned market changes, the imbalance will further affect domestic macroeconomic growth and stability, as well as inflation, unemployment, and GDP growth rate, which can affect quality of economic growth. Table 1 shows the final results of the election of the BOP imbalance resilience system indicators.

2.4. Summary of the Literature Review. Globally, the ratio of current account deficits to GDP is commonly used rather than large deficits in BOP theory. Using a fixed value as a warning line for imbalances is internationally common, but it also has some disadvantages. Thus, this paper draws on the idea of economic resilience in the macroeconomic field and summarizes two requirements for the selection of imbalance

resilience indicators, on the basis of which the transmission path of BOP imbalance is derived to provide reference for the establishment of the resilience system in the next section.

3. Methodology and Data Resources

3.1. Indicator System Construction Method. This article's index system will calculate the BOP resilience score and weighting factors between the basic indicator and resilience score. Thus, the chosen method can express the resilience system in a formula, and the weight coefficients also have economic significance. The gray box-based model cannot give the weight coefficient, so this article does not use this type. Thus, this paper constructs the resilience system using the two-stage weighting evaluation method based on minimum variance. The method first calculates objective weights to the indicators and calculates a resilience score for each year, followed by a time weighting to obtain the total score.

3.2. Data Description. This section introduces the countries, period of time, indicators, and sources of the data.

We began the analysis with Russian Federation's establishment in 1992 and ended it in 2019, making a 28-yearperiod total. Among them, 2010 is the base year for the relative indicators, so 27 years of data are included in the analysis.

The article aims to analyze as many countries as possible, but for the reliability of the results, the countries included in the analysis must meet the data requirements. The missing value boundary is set at 10%; if a country has more than 3 missing values for an indicator, the country is not selected for analysis, and if only a few countries meet the missing value boundary for an indicator, the indicator is discarded. Table 1 shows the BOP imbalance resilience indicators selected in this article. Table 2 and Figure 1 show the countries that participated in the analysis.

As shown in Figure 1, many African countries did not participate in the analysis, mainly due to data acquisition limitations.

4. Resilience System Results and Reasonableness Analysis and Improvement

4.1. BOP Resilience Results. In this part, the initial weights are first obtained from the entropy value method, the panel data of the resilience scores for each year are obtained using the initial weights, the initial values of the secondary weights are obtained, and the secondary weights are further obtained. Next, the panel score data are weighted by the secondary weights to obtain the final total score of each country, and the initial indicator weights are weighted to obtain the reference weights of the indicators.

4.1.1. Resilience Scores for Each Country by Year. In this paper, we calculated panel data of resilience scores for 37 countries between 1992 and 2019 by entropy method and also calculated the indicators weights for each year. Figures 2 and 3 show the results of the resilience scores and the indicator weights, respectively.

Туре	Abbreviation	Name	Positive/negative	Data source

TABLE 2: Countries participating in the analysis.

As shown in Figure 2, F refers to the resilience score; Figures 2(a), 2(c), and 2(e) show the resilience scores by scatter plots, where the size of the scatter points shows the level of resilience; and Figures 2(b), 2(d), and 2(e) are the kernel density distribution of resilience scores, which is another way of showing the score more visually. We can see visually that countries such as Switzerland (CHE), China (CHN), and Singapore (SGP) have significantly higher resilience scores than other countries, whereas countries like the United States and the United Kingdom are not performing so well.

Figure 3 shows the kernel density distribution of the weights of each indicator, from which it can be seen that most of the indicator weights are relatively concentrated, but the distribution of fdin/gdp is more dispersed, and its change over 27 years is large. *fdin/gdp*, *fera*, and *ftd*, which have

relatively large weights, will make the resilience score more differentiated.

4.1.2. Time Weights and Final Total Score. Calculate the initial and final weights at first. In this paper, we present multiple nondimensionalization methods for weight distance data, and the obtained clustering and separation years were all 2001 and 2018. Table 3 shows the time weights of the initial and final weights.

Then, using time weighting, reweigh the panel data of resilience scores for each year and calculate the final score. Figure 4 shows the final resilience score, where the F refers to the resilience score (the F in Figures 5–7 also refers to the resilience score). The resilience score of each country has now been calculated.

1

4.2. Reasonableness Analysis for Resilience. In this section, we consider the reasonableness of BOP resilience indicators system in three ways: (1) The indicators selected meet the theoretical requirements of the resilience system. (2) There should be a correlation between resilience score and BOP. (3) The resilience score at key points needs to be consistent with history.

4.2.1. The Reasonableness of Indicators Selection. The indicators underlying the construction of the resilience system are all involved in the transmission path of BOP imbalance and meet the two requirements for the selection of indicators (according to Section 2.3). Additionally, the indicator data are obtained from the international organization database after a strict evaluation of missing values and outliers is performed. Countries and indicators with inadequate data are excluded.

4.2.2. Resilience Score and BOP Correlation. The BOP imbalance resilience score should be correlated with the ratio of current account balance to GDP. This is because a country with low resilience will face greater difficulty recovering from a severe shock to its BOP. Similarly, the larger the deficit in a country's current account balance to GDP ratio is, the more the economy suffers, leading to a lower resilience score. In this article, we use the Granger causality test of panel data to see whether the above relationship exists.

The method was proposed by Clive Granger in 1969 and is based on the following idea: if x is a cause of y, but y is not a cause of x, then past values of x can help predict future values of y, but past values of y cannot help predict future values of x. Consider the time series model below:

$$y_t = \gamma + \sum_{m=1}^p \alpha_m y_{t-m} + \sum_{m=1}^p \beta_m x_{t-m} + \varepsilon_t.$$
(1)

In (1), *p* is the lag order, and the null hypothesis tested is

$$H_0: \beta_1 = \beta_2 = \ldots = \beta_p = 0.$$
 (2)

The null hypothesis indicates that the past value of x does not predict the future value of y. If the H_0 is rejected, then xbecomes the "Granger factor" of y. Changing x and y in (2), we can test whether y is a Granger factor of x. The following models can be applied to panel data:

$$y_{it} = \gamma + \sum_{m=1}^{p} \alpha_m y_{i,t-m} + \sum_{m=1}^{p} \beta_m x_{i,t-m} + u_i + \varepsilon_{it}.$$
 (3)

In (3), u_i is the heterogeneity of individual *i*. For dynamic panel models, differenced GMM and system GMM are used for estimation. There are two assumptions when estimating the model. The first is that the cross-section coefficients are the same. The panel data is regarded as stacked data, and a Granger causality test is conducted similarly to that performed on time series data. The second is that coefficients of cross sections are different, and each section member is subjected to the Granger causality test. In this paper, causality tests of up to 6th order were conducted for both assumptions.

The Granger causality test requires that the panel data are stationary. Table 4 demonstrates the results of the panel unit root test.

The results of all four tests are significant, and it can be concluded that the panel data do not have unit roots. Table 5 shows the results of Granger causality tests under two assumptions.

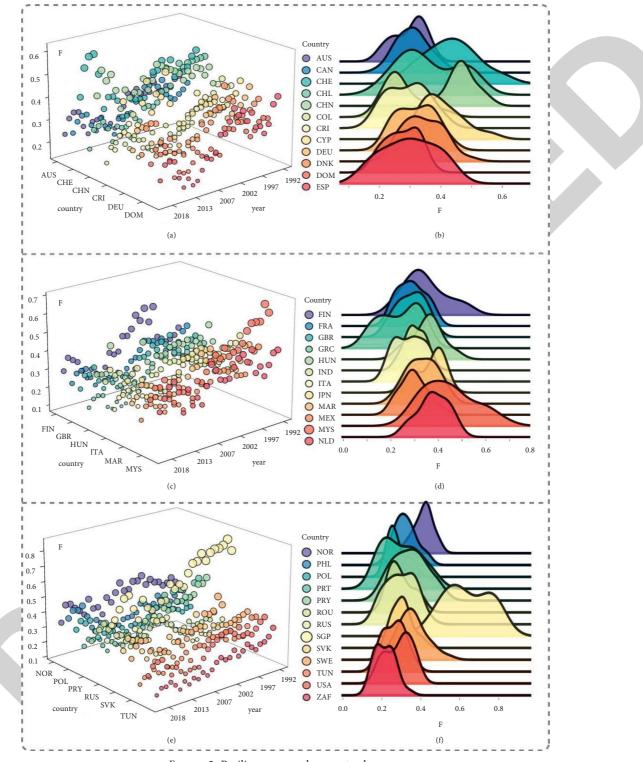

FIGURE 2: Resilience scores by country by year.

In Table 5, CA refers to the ratio of BOP current account balance to GDP ratio, and F is the resilience score. There is significant evidence that BOP current account balance to GDP ratio and resilience score are causally correlated in the fixed coefficient model. The resilience scores of orders 1, 2, and 4 in the variable coefficient model are the cause of BOP current account balance. Based on the results, it can be shown that the two are causal and that the resilience score correlates with theoretical expectation.

4.2.3. Historical Consistency of Time Points. At the time of the event, BOP imbalance resilience score calculated in this article should fluctuate and trend accordingly. This section

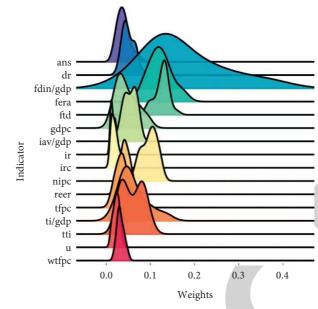

FIGURE 3: Distribution of indicator weights.

analyzes BOP crisis events, financial crisis events (the financial crisis will damage the country's economy [26, 27], which will affect BOP resilience), and individual country cases.

First is the BOP crisis event. There was the European Monetary System Crisis in 1994–95, the Latin American Debt Crisis in 1995–97, and the 1997 Asian Financial Crisis (actually BOP crisis) during the period covered by this article. These crises relate to the countries involved in the study of this paper as shown in Table 6. Germany and Russia are among the countries affected by the Asian Financial Crisis, so they are also included in the analysis.

Figure 5 illustrates the resilience scores of the countries involved in the crisis events.

In Figure 5, the green shading in Figure 5(a) is the time period of the European Monetary System Crisis, the orange shading is the time period of the Asian Financial Crisis, and Figures 5(b) and 5(c) show their scores specifically, respectively. The countries involved in the European Monetary

System Crisis underwent a significant decline in resilience scores starting in 1992, bottoming out in 1994 or 1995 before slowly recovering. Mexico, which is in the midst of a Latin American Debt Crisis, had the same trend. In the Asian Financial Crisis, Russia and Malaysia also experienced a decline in their resilience scores in 1997. Thus, the reflection of the resilience score at BOP crisis is in line with realistic expectations.

The next step is to analyze the resilience score during the financial crisis.

The research period of this paper starts from 1992, so this section examines the international financial crisis in 2007–2011. At the end of our study time period, the high foreign exchange reserves of China and Switzerland may have financial crisis risk [28]. However, this phenomenon is not universal, so it will not be analyzed further.

The crisis (2007–2011) was not prompted by BOP imbalances, but the outburst of the crisis has resulted in huge

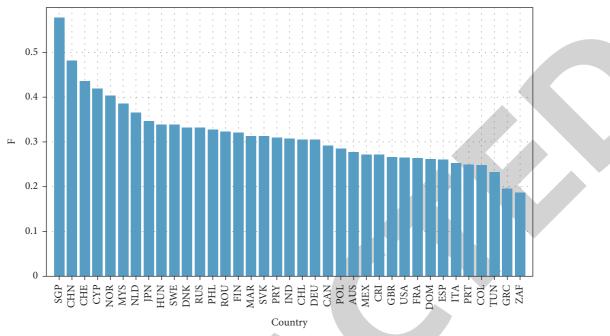

FIGURE 4: Final resilience scores for each country.

losses, and thus the resilience score should also trend in the same direction. Figure 6 illustrates the change in resilience scores during the financial crisis.

Based on the scores, we can see that most countries had their lowest scores in 2007 and 2009, respectively. Such a score result is consistent with the perception of reality.

Finally, we assess China's and America's BOP resilience separately. Figure 7 shows the resilience scores of the two countries.

In the aftermath of the international financial crisis, the resilience scores of both China and the US trended sharply downward and then upward, with the difference that China's resilience score eventually remained the same as it was before 2007, while the US rarely returned to its previous level. The above scores are consistent with the US focus on its BOP deficit in recent years.

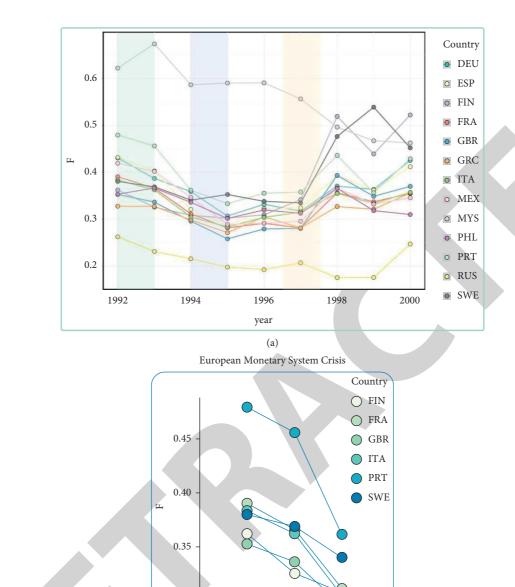

4.3. *Improvement of Resilience System*. As a result of the limitation of the method for establishing a system, in this paper we propose to use a more appropriate method for determining the importance of resilience system construction indicators.

4.3.1. Limitations in the Construction of the Resilience System. Min-max normalization is particularly sensitive to outliers; if one indicator has a very minor outlier, all other nations' indicators will be near to 0.99. As a result, the indicator's range of fluctuation will be limited. As a consequence, the indicator's weight in the entropy approach will be quite minimal. However, the outlier, not the indication, is to blame for this outcome. The meaning of the indicator weights derived by the entropy technique, in addition to data sensitivity, is "distinctness," which does not entirely match "importance." With a greater weight, the difference between nations in this indicator widens, whereas a lower weight narrows the gap between countries, implying that countries get similar (rather than lower) ratings in this indicator. As a result, the indicator's weight can merely mean that it is more distinct, not that it is more significant or useful in a BOP context. As a result, we choose to utilize the random forest approach to assess the relevance of the indicators and interpret them in conjunction with the weights in this study.

The following is a brief description of the random forest importance score. Random forest method is one of the ensemble methods of decision trees. A decision tree is essentially a collection of judgments, and the input samples are judged layer by layer to form one node of the tree, through which the input space is divided into different regions, and the child nodes continue to divide the regions to get many subregions. The same layer's input and output (leaf nodes) do not overlap, and the final leaf nodes correspond to the areas, so the input and output (leaf nodes) are the same. Ensemble trees are created by combining the outcomes of numerous smaller decision trees and then voting on each class's findings (classification issue) or calculating the mean (regression problem). Although each tree makes errors, making judgments as a group increases accuracy while avoiding the issue of out-of-sample prediction. Each decision tree is given a feature importance score, i.e., the importance of the input variable in making a decision in the tree, with a value between 0 and 1, where 0 means that the variable does not contribute to the decision and 1 indicates a perfect prediction of the target value. In this paper, feature importance is used as a complement to the indicator weights.

Figure 8 shows the results of the indicator importance scores. The time-adjusted importance is the result of weighting the importance scores using the weights above (Table 3).

It can be seen that the importance of the annual average does not change much from the time-adjusted importance,

ð

1994

0.30

1992

1993

year

(b) FIGURE 5: Continued.

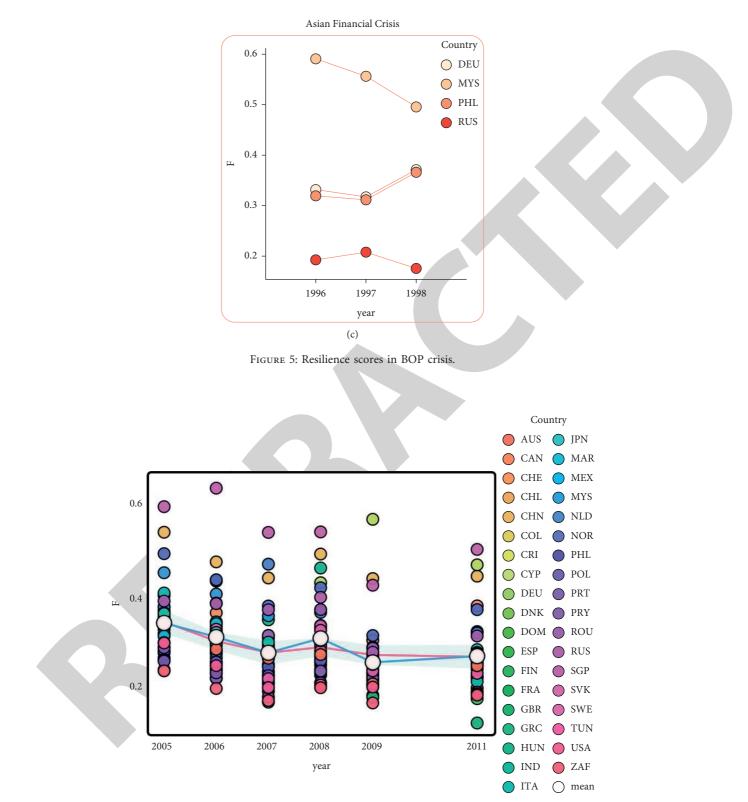

FIGURE 6: Country resilience scores during the financial crisis.

which means that the importance of the indicators is more stable across years compared to the indicator weights, which has a complementary effect. We can conclude that the unemployment rate and adjusted net savings are more important, while net foreign direct investment to GDP ratio, foreign reserve adequacy, and foreign trade dependence are better at distinguishing between countries' resilience scores.

TABLE 6: Countries involved in BOP crisis.

FIGURE 8: Importance of indicators.

5. Conclusion

5.1. Establishing a System for BOP Imbalance Resilience. This paper draws on the idea of economic resilience and establishes a BOP imbalance resilience score system based on the transmission mechanism of BOP imbalance to measure a country's ability to tolerate BOP imbalance.

The indicator system has been proven to be reasonable in the selection of indicators and the relevance of the result data, and its changes are consistent with historical events and can provide a complement to the traditional measure of BOP imbalance.

5.2. Adjustment of the Balance of Payments. The analysis in this paper concludes that a country that wants to change its disadvantaged BOP position should improve unemployment and increase adjusted net savings, and if it wants to change its resilience ranking among the countries researched, it should improve the net foreign direct investment to GDP ratio, foreign exchange reserve adequacy, and foreign trade dependence.

5.3. The Complementary Effect of Resilience. BOP resilience can provide complementary analysis for countries with surpluses and deficits and can be used as a reference and early warning indicator for BOP position. When the surplus or deficit performance and the resilience score are both good, it is more reliable to conclude that the country is in a positive BOP position.

Introducing categorical variables for further analysis, Asia and Africa have slightly higher resilience scores than Europe and America, and high-development countries perform better than very high-development countries. Asia and Africa are more sensitive to whether they are reserve currency issuers, while in Europe and America, whether they are capital exporters has a greater impact on the score.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Manipulated or compromised peer review

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation. The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

With the popularization of higher education, the scale of urban higher education continues to expand, and the contradiction between the supply and demand of educational resources becomes increasingly prominent, which restricts the steady development of urban higher education. Based on the rough set theory, this paper constructs a rough set of big data of urban higher education resource carrying capacity from the three levels of higher education core resources, urban economic resources and urban basic resources, and evaluates the entropy weight of the city where the university is located. According to the theoretical knowledge of higher education resource carrying capacity, the system deconstructs and expounds the balance mechanism of higher education resource carrying capacity, which provides solid theoretical support for the development of the paper. The research shows that the agglomeration development of higher education resources can improve the carrying capacity of urban higher education resources. The second section performed well on the whole, and the index distribution was more uniform. The third interval index structure distribution is complex and uneven, and the overall performance is general. The fourth section belongs to the poor section of educational carrying capacity with a low overall index. It can be seen that the carrying capacity of higher education resources and theoretical and policy basis for realizing rational allocation and sustainable carrying capacity of higher education resources.

1. Introduction

With the acceleration of the modernization of the governance system and the deepening of normalization construction, the construction and development of urban higher education have become a new landmark for different regions to show their new achievements in reform, new progress in economic and social development, and a new level of scientific, technological, and cultural development [1]. In the struggle for urban and regional development, resources, as the foundation supporting the growth of higher education in cities, regions, and nations, play a key role. Higher education resources may easily migrate across areas as a result of economic globalization and regional integration. Cities, as a highly concentrated regional area for human production and living, eventually become the center of higher education resources in the process of free flow of higher education resources [2]. As higher education moves from popularization to popularization, regional center cities progressively become the collecting site for higher education resources, and their capacity to aggregate resources has a significant influence on regional higher education development. For a long time, researchers have been interested in the strategic impact of higher education resource agglomeration on regional higher education growth.

Educational resources refer to the human, material, and financial resources used, occupied and consumed in the course of education, including the human resources of educators and educatees, etc. Material resources include fixed assets, materials, and low-value consumables in the school. Financial resources are the monetary form of human and material resources, including personnel consumption and public consumption, which are the material basis for the development of education and education work [3]. Educational resources are regarded as the sum total of human resources, financial resources, and material resources. To analyze the attribute of educational resources, we must first understand the connotation of the attribute. The so-called attribute is an abstract description of things, reflecting the homogeneity or difference between things is the attribute. A lot of properties and relations of a thing can be attributed to the attribute of this thing. Therefore, the analysis of the attributes of educational resources is helpful to further distinguish the relationship between educational resources and other resources and then distinguish and separate different core elements in the theory of resource allocation. Scarcity, flexibility, multifunctional, imbalance, and potential are all characteristics of educational resources. Regional imbalances, urban-rural imbalances, and class imbalances are all examples of educational resource imbalances. The difference between imbalance and equilibrium is that the former is absolute and the latter is relative. Bearing capacity is a term adopted from the area of engineering geology. Its initial purpose was to define the strength of a building's foundation bearing capacity, but it has since developed into one of the most often used terms to express the degree of growth limitation. This notion was initially introduced to this field by ecology. Carrying capacity shows the support capacity of ecosystem resources and environment to the benign growth of the human social system, as discussed in the early talks on the interaction between ecosystem resources and environment and human social system [4]. Subsequently, related concepts such as resource carrying capacity, population carrying capacity, and ecological environment carrying capacity are derived. These concepts mainly express the supporting capacity or development limitation of the bearing subject to the growth of the bearing object under certain conditions. In the case of taking a certain region and period as the research scope, if based on the above concepts of "educational resources" and "carrying capacity," the carrying capacity of educational resources is also one of the derivative concepts of carrying capacity. If the research goal is the geographical region where the educational population congregates, the carrying object and main bodies are the educational school-age population and educational resources, respectively. The carrying capacity of educational resources may be separated into two categories based on these two standards: educational resources and specific space. The logical deployment of educational resources and the long-term growth of education are the core of educational resource carrying capacity. However, it is not only a matter of educational resources; it is a multifaceted issue that must take into account a variety of aspects such as population, resources, education, and space. The lower the proportional ratio, the greater the educational resource carrying capacity; the more resources per student, the lower the risk of overloading.

Big data has penetrated into every industry and field and has become an important factor in production. The rapid development of mobile Internet, cloud computing, and the Internet of Things is pushing mankind into the era of big

data. The higher education system can be regarded as an ecosystem, which has the same bearing capacity as the natural ecosystem. Once the scale of higher education exceeds the bearing capacity of certain education and the corresponding environment, its resource supply and regeneration capacity will be destroyed, and the system will lose balance [5]. Carrying capacity of educational resources refers to the supporting capacity of existing educational resources for the population of a country or region to receive all kinds of education under the premise of reasonable allocation and quality assurance of various educational resources. The research on education carrying capacity mainly focuses on higher education and vocational education, analyses the concept and elements of education carrying capacity in the higher education system, and analyses the scale of higher education carrying capacity, its relationship with social development and promotion strategies based on the analysis model of ecosystem carrying capacity. It provides useful theoretical reference and measurement methods for the subsequent research on the carrying capacity of compulsory education resources in big cities. The lack of an analytical model and theoretical index system that directly refers to the urban internal connection environmental background, influencing factors, and specific pressure performance provides a new space for the academic development of this study.

This study combines the connotation of educational resources and carrying capacity to produce a stable and logical technique of combining by examining the connotation of educational resources and carrying capacity. The value of educational resource carrying capacity can be maximized to ensure the smooth implementation of educational activities, and social subjects or educational subjects can integrate necessary resources to support the effective operation of educational activities by constructing a rough set of big data of urban higher education resource carrying capacity.

2. Related Work

With the popularization of higher education, the demand for educational resources increases, facing a series of problems such as resource shortage and ecological destruction of education. In this context, it is very important to study the carrying capacity of higher education resources. The resource carrying capacity of higher education is restricted by many factors. Rough set theory is a data mining method that has emerged in recent years, which is mainly used in data simplification, data significance assessment, object similarity or difference analysis, causality, and paradigm mining. Xue et al. discuss the concept, evaluation indexes, and evaluation methods of carrying capacity of educational resources based on the characteristics and influencing factors of educational resources [6]. Ding et al. analyzed the ecological carrying capacity of the education system of overseas students in China from three dimensions of "resource carrying capacity," "environmental carrying capacity," and "ecological elastic force" [7]. Peng et al. define its carrying capacity and, on this basis, put forward three core indicators for
