Impact Analysis of Basketball Exercise Strength Based on Machine Learning in the Mental Health of College Students

Ran Zhang 

Research Article (9 pages), Article ID 9628446, Volume 2022 (2022)

Review on Security Issues and Applications of Trust Mechanism in Wireless Sensor Networks

Zhengxin Xia , Zhe Wei , and Huan Zhang 

Review Article (9 pages), Article ID 3449428, Volume 2022 (2022)

Design of Cross-Platform Information Retrieval System of Library Based on Digital Twins

Shanshan Shang , Zikai Yu, Kun Jiao, Yingshi Huang, Hua Guo, and Guozhong Wang

Research Article (10 pages), Article ID 7999091, Volume 2022 (2022)

Modeling and Robust Tracking Decoupling Control of a Coaxial Unmanned Helicopter Based on the Improved Alternating Direction Method of Multipliers

Anan Xu , Fang Wang , and Ming Chen

Research Article (12 pages), Article ID 3647784, Volume 2022 (2022)

Intelligent Identification of Coal Crack in CT Images Based on Deep Learning

Jinxia Yu, Chengyi Wu , Yingying Li , and Yimin Zhang

Research Article (10 pages), Article ID 7092436, Volume 2022 (2022)

Study on Personalized Recommendation Algorithm of Online Educational Resources Based on Knowledge Association

Ziqian Xu  and Sheng Jiang 

Research Article (9 pages), Article ID 2192459, Volume 2022 (2022)

Style Transfer of Chinese Art Works Based on Dual Channel Deep Learning Model

Yan Tang 

Research Article (11 pages), Article ID 4376006, Volume 2022 (2022)

Research on Movement Analysis and Guidance in Dance Learning Based on Data Mining

Guangle Yin  and Jing Liu

Research Article (9 pages), Article ID 9327442, Volume 2022 (2022)

Efficient Lattice-Based Ring Signature Scheme without Trapdoors for Machine Learning

Qing Ye , Yongkang Lang , Zongqu Zhao , Qingqing Chen , and Yongli Tang 

Research Article (13 pages), Article ID 6547464, Volume 2022 (2022)

Construction and Application of the Talent Training System in Colleges and Universities Based on the Fuzzy Analytic Hierarchy Process

Yan Yu  and Jun Qiu 

Research Article (10 pages), Article ID 7295875, Volume 2022 (2022)

Research on Monitoring of Gymnastics Facilities and Intelligent Optimal Distribution of Gymnastics Venues Based on Internet of Things

Hongbo Liu and Yuzhen Wang 

Research Article (9 pages), Article ID 6164448, Volume 2022 (2022)

SchizoGoogLeNet: The GoogLeNet-Based Deep Feature Extraction Design for Automatic Detection of Schizophrenia

Siuly Siuly , Yan Li , Peng Wen , and Omer Faruk Alcin

Research Article (13 pages), Article ID 1992596, Volume 2022 (2022)

Interactive Design of Business English Learning Resources Based on EDIPT Multimodal Model

Xiaomei Yang and Shi Qi 

Research Article (9 pages), Article ID 1264847, Volume 2022 (2022)

Personalized Information Service System of Smart Library Based on Multimedia Network Technology

Juan Wang 

Research Article (10 pages), Article ID 2856574, Volume 2022 (2022)

Using Pitch Feature Matching to Design a Music Tutoring System Based on Deep Learning

Jing Jiang 

Research Article (7 pages), Article ID 4520953, Volume 2022 (2022)

Evaluation of Enterprise Accounting Data Management Based on Maturity Model

Jun Xiang 

Research Article (9 pages), Article ID 3891475, Volume 2022 (2022)

A Fast Data Transmission Method of Vehicle-Road Cooperative Communication Based on the Clustering Algorithm

Weifeng Wang , Zijian Wang, Yang Xu , Xinpeng Yao, and Yulin Ma 

Research Article (8 pages), Article ID 9162360, Volume 2022 (2022)

Construction and Application of Farmers' Practical Teaching System in Vocational Education Based on Big Data Mining Technology

Wei Peng and Zhibin Tang 

Research Article (9 pages), Article ID 6075719, Volume 2022 (2022)

An English Flipped Classroom Teaching Model Based on Big Data Analysis

Wang Sa , Li Dan, Du Juan, Yu Fei, and Wang Wei 

Research Article (11 pages), Article ID 7391258, Volume 2022 (2022)

Detection and Analysis of Human Cells Based on Artificial Neural Network

Jun Yao and Hongji Yuan 

Research Article (10 pages), Article ID 4600840, Volume 2022 (2022)

Contents

Task Offloading and Resource Allocation Strategy Based on Deep Learning for Mobile Edge Computing

Zijia Yu , Xu Xu , and Wei Zhou 

Research Article (11 pages), Article ID 1427219, Volume 2022 (2022)

Text Analysis and Policy Guidance of Emotional Intonation of Enterprise Management Based on Deep Learning

Ni Yang and Jing Qiu 

Research Article (8 pages), Article ID 3428078, Volume 2022 (2022)

[Retracted] Artificial Intelligence-Based Recommendation and Application of Public Services in Smart Cities

Jin Zhou 

Research Article (10 pages), Article ID 8958865, Volume 2022 (2022)

Prediction and Evaluation Method of e-Commerce Service Satisfaction Based on Intelligent Computing Method

Fang Tu and Bo Tu 

Research Article (9 pages), Article ID 2730660, Volume 2022 (2022)

Application of Convolutional Neural Network in Motor Bearing Fault Diagnosis

Shuiqin Zhou, Lepeng Lin, Chu Chen, Wenbin Pan, and Xiaochun Lou 

Research Article (11 pages), Article ID 9231305, Volume 2022 (2022)

Intelligent Optimization Method of Resource Recommendation Service of Mobile Library Based on Digital Twin Technology

Shanshan Shang , Zikai Yu, Aili Geng, Xiuxiu Xu, Huizhen Ma, and Guozhong Wang

Research Article (10 pages), Article ID 3582719, Volume 2022 (2022)

Trusted Data Analysis and Consensus Mechanism of Product Traceability Based on Blockchain

Yang Kang, Qiang Li , and Yuanyong Liu

Research Article (10 pages), Article ID 3035231, Volume 2022 (2022)

Web Log Analysis and Security Assessment Method Based on Data Mining

Jingquan Jin and Xin Lin 

Research Article (9 pages), Article ID 8485014, Volume 2022 (2022)

Deep Learning-Based Correlation Analysis between the Evaluation Score of English Teaching Quality and the Knowledge Points

Yuanyuan Li 

Research Article (10 pages), Article ID 4102959, Volume 2022 (2022)

Deep Learning Algorithm for Online College Physical Education Teaching with Flipping Classroom

Zhengqiang Chen 

Research Article (12 pages), Article ID 8742661, Volume 2022 (2022)

Time Series Data Prediction and Feature Analysis of Sports Dance Movements Based on Machine Learning

DongXia Zheng  and Yi Yuan 

Research Article (12 pages), Article ID 5611829, Volume 2022 (2022)

Efficiency Evaluation and Influencing Factors Analysis of Logistics Industry based on Multiobjective Intelligent Computing

Tingyan Zhou  and Wenxing Li

Research Article (10 pages), Article ID 3098160, Volume 2022 (2022)

Lightweight Deep Learning Model for Marketing Strategy Optimization and Characteristic Analysis

Yang Su , Chonghong Wang, and Xuejiao Sun

Research Article (9 pages), Article ID 2429748, Volume 2022 (2022)

The Intervention of Data Mining in the Allocation Efficiency of Multiple Intelligent Devices in Intelligent Pharmacy

Xiaohua Li, Benren Tan , Jinkun Zheng, Xiaomei Xu, Jian Xiao, and Yanlin Liu

Research Article (12 pages), Article ID 5371575, Volume 2022 (2022)

Analysis of Teaching Tactics Characteristics of Track and Field Sports Training in Colleges and Universities Based on Deep Neural Network

Wei Wang 

Research Article (11 pages), Article ID 1932596, Volume 2022 (2022)

Intelligent Evaluation of Public Sports Service Based on Intuitionistic Fuzzy Set Theory

Yu Shao  and Rong Bo 

Research Article (8 pages), Article ID 4748730, Volume 2022 (2022)

Nonlinear Dynamic Response Analysis of a Three-Stage Gear Train Based on Lightweight Calculation for Edge Equipment

Dongdong Ren, Yangwu Yao , Huiyuan Wang , Huixian Qu, and Guoqiang Wang

Research Article (8 pages), Article ID 4724504, Volume 2022 (2022)

Prediction and Estimation of River Velocity Based on GAN and Multifeature Fusion

Yan Wang, Weiwei Chen , and Yulan Wang

Research Article (10 pages), Article ID 7316133, Volume 2022 (2022)

Optimized Deep Neural Network and Its Application in Fine Sowing of Crops

Bing Li  and Jiyun Li

Research Article (10 pages), Article ID 3650702, Volume 2022 (2022)

Video Image Moving Target Recognition Method Based on Generated Countermeasure Network

Zilong Li , DaiHong Jiang , Hongdong Wang , and Dan Li 

Research Article (8 pages), Article ID 7972845, Volume 2022 (2022)

Contents

Gear Fault Diagnosis and Life Prediction of Petroleum Drilling Equipment Based on SOM Neural Network

Linzhu Lu, Jie Liu , Xin Huang, and Yongcai Fan

Research Article (7 pages), Article ID 9841443, Volume 2022 (2022)

Identification of Sports Athletes Psychological Stress Based on K-Means Optimized Hierarchical Clustering

Jun Huang 

Research Article (7 pages), Article ID 6555797, Volume 2022 (2022)

[Retracted] Data Sharing Method of College Dance Teaching Resource Database Based on PSO Algorithm

Xulong ZhuGe and Haibin Cao 

Research Article (9 pages), Article ID 2162981, Volume 2022 (2022)

[Retracted] Construction and Analysis of Indicators of the Labor Education System Based on the Gray Correlation Degree Model

Ling Huang 

Research Article (8 pages), Article ID 2281469, Volume 2022 (2022)

[Retracted] Design and Optimization of Aesthetic Education Teaching Information Platform Based on Big Data Analysis

Xingxing Wu and Hai Gu 

Research Article (9 pages), Article ID 5109638, Volume 2022 (2022)

Personalized Recommendation Algorithm for Movie Data Combining Rating Matrix and User Subjective Preference

Chang Liu 

Research Article (11 pages), Article ID 2970514, Volume 2022 (2022)

Antiocclusion Visual Tracking Algorithm Combining Fully Convolutional Siamese Network and Correlation Filtering

Xiaomiao Tao , Kaijun Wu , Yongshun Wang, Panfeng Li, Tao Huang, and Chenshuai Bai

Research Article (9 pages), Article ID 8051876, Volume 2022 (2022)

[Retracted] Application of Intelligent Image Matching and Visual Communication in Brand Design

Ming Liu  and Wenyan Zhong

Research Article (9 pages), Article ID 5964851, Volume 2022 (2022)

An Improved Logistic Regression Method for Assessing the Performance of Track and Field Sports

Songling Zheng  and Xi Man

Research Article (10 pages), Article ID 6341495, Volume 2022 (2022)

Traffic Flow Prediction and Analysis in Smart Cities Based on the WND-LSTM Model

SuYuan Ma  and MingYe Zhao 

Research Article (9 pages), Article ID 7079045, Volume 2022 (2022)

A Lightweight CNN Model Based on GhostNet

Zhong Wang and Tong Li 

Research Article (12 pages), Article ID 8396550, Volume 2022 (2022)

Optimization and Analysis of Intelligent Accounting Information System Based on Deep Learning Model

Suzhen Feng and Ran Zhong 

Research Article (9 pages), Article ID 1284289, Volume 2022 (2022)

Research on the Evaluation of Moral Education Effectiveness and Student Behavior in Universities under the Environment of Big Data

Rui Zhu 

Research Article (9 pages), Article ID 2832661, Volume 2022 (2022)

Analysis of Strategies and Skills of English Translation Based on Coverage Mechanism

Bin Liu  and Jing Wang

Research Article (7 pages), Article ID 7767045, Volume 2022 (2022)

[Retracted] Construction and Analysis of Performance Evaluation Index System for Chinese Small and Medium-Sized Enterprises Based on Fuzzy Hierarchical Analysis Model

Mengning He  and Raquel Pérez Estebanez

Research Article (8 pages), Article ID 1230786, Volume 2022 (2022)

Research on Perceptual Integrity of Distributed Digital Media Based on AWTC-TT Algorithm Optimization

Xiaobo Zhang  and Rongrong Shen 

Research Article (9 pages), Article ID 9675529, Volume 2022 (2022)

Construction and Analysis of Discrete System Dynamic Modeling of Physical Education Teaching Mode Based on Decision Tree Algorithm

Caixia Wang , Xiaoyun Wei , Aiqian Yang , and Haiyan Zhang 

Research Article (11 pages), Article ID 2745146, Volume 2022 (2022)

Research on Architectural Planning and Landscape Design of Smart City Based on Computational Intelligence

Nan Shao 

Research Article (9 pages), Article ID 1745593, Volume 2022 (2022)

GMAIR: Unsupervised Object Detection Based on Spatial Attention and Gaussian Mixture Model

Weijin Zhu , Yao Shen , Mingqian Liu , and Lizeth Patricia Aguirre Sanchez 

Research Article (13 pages), Article ID 7254462, Volume 2022 (2022)

Secure Clustering Strategy Based on Improved Particle Swarm Optimization Algorithm in Internet of Things

Zhanbiao Bao 

Research Article (9 pages), Article ID 7380849, Volume 2022 (2022)

Contents

Design and Implementation of Trace Inspection System Based upon Hyperspectral Imaging Technology

Yuchen Wang and Zhongyuan Ji 

Research Article (13 pages), Article ID 9524190, Volume 2022 (2022)

Short-Term Demand Forecast of E-Commerce Platform Based on ConvLSTM Network

Zan Li  and Nairen Zhang

Research Article (10 pages), Article ID 5227829, Volume 2022 (2022)

Design of Intelligent Evaluation System for College Students' Mental Health Based on Big Data

Tao Hu, Xiaojun Zhang , and Na Li

Research Article (10 pages), Article ID 7119994, Volume 2022 (2022)

Innovation and Integration Development of the Cultural Industry Based on Mapping Knowledge Domains

Jiangong Lian  and Dan Liang

Research Article (8 pages), Article ID 4725196, Volume 2022 (2022)

Research on the Application of Artificial Neural Network-Based Virtual Image Technology in College Tennis Teaching

Ruizhe Hu  and Xiaocan Cui 

Research Article (12 pages), Article ID 4935121, Volume 2022 (2022)

MRI Radiogenomics in Precision Oncology: New Diagnosis and Treatment Method

Xiao-Xia Yin , Mingyong Gao, Wei Wang, and Yanchun Zhang

Review Article (13 pages), Article ID 2703350, Volume 2022 (2022)

Analysis of Diversified Radio and Television Data Based on Adaptive Least Squares Support Vector Machine

Jing Liu and Minnan Cang 

Research Article (14 pages), Article ID 4235088, Volume 2022 (2022)

[Retracted] Railway Traffic Emergency Management Relying on Image Recognition Technology in the Context of Big Data

Fei Dong and Yuanyuan Ma 

Research Article (12 pages), Article ID 1920196, Volume 2022 (2022)

Application of Human Posture Recognition Based on the Convolutional Neural Network in Physical Training Guidance

Qingyu Wang 

Research Article (11 pages), Article ID 5277157, Volume 2022 (2022)

Deep Learning-Based Optimization Algorithm for Enterprise Personnel Identity Authentication

Tiejun Chen 

Research Article (9 pages), Article ID 9662817, Volume 2022 (2022)

Research on Image Recognition of Gymnastics Sports Injuries Based on Deep Learning

Peng Jia  and Yixiong Xu

Research Article (12 pages), Article ID 8987006, Volume 2022 (2022)

Financial Data Analysis and Application Based on Big Data Mining Technology

Jinfeng Cheng 

Research Article (8 pages), Article ID 6711470, Volume 2022 (2022)

[Retracted] Research on Virtual Interactive Animation Design System Based on Deep Learning

Bing Liu 

Research Article (10 pages), Article ID 5035369, Volume 2022 (2022)

[Retracted] Analysis and Prediction of Corporate Finance and Exchange Rate Correlation Based on Machine Learning Algorithms

Ke Zhang, Xiaofei Wang , Junjie Wang, Sinan Wang, and Feng Hui

Research Article (9 pages), Article ID 2850604, Volume 2022 (2022)

Design and Optimisation of an Enterprise Digital Management System Based on IoT Monitoring

Shengwen Wang 

Research Article (7 pages), Article ID 3264485, Volume 2022 (2022)

High-Performance Computing Analysis and Location Selection of Logistics Distribution Center Space Based on Whale Optimization Algorithm

Lijuan Yang  and Xiedong Song

Research Article (9 pages), Article ID 2055241, Volume 2022 (2022)

[Retracted] Design of a Multimedia-Assisted Distance English Teaching System for College Students

Haili Feng 

Research Article (8 pages), Article ID 2184600, Volume 2022 (2022)

Design of Optimum Portfolio Scheme Based on Improved NSGA-II Algorithm

Yiqian Zhou, Weinan Chen, and Deqin Lin 

Research Article (9 pages), Article ID 7419500, Volume 2022 (2022)

Design of Cloud Storage-Oriented Sports Physical Fitness Monitoring System

Zhou Zheng and Yang Liu

Computational Intelligence and Neuroscience

Received 3 October 2023; Accepted 3 October 2023; Published 4 October 2023

Copyright © 2023 Computational Intelligence and Neuroscience. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

- (1) Discrepancies in scope
- (2) Discrepancies in the description of the research reported
- (3) Discrepancies between the availability of data and the research described
- (4) Inappropriate citations
- (5) Incoherent, meaningless and/or irrelevant content included in the article
- (6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

As we all know, sports have great benefits for students. However, with more and more learning pressure, students' physical education has not been paid attention to by teachers and parents, so the analysis and prediction of physical education performance have become significant work. This paper proposes a new method (factorization deep product neural network) for PE course score prediction. The experimental results show that, compared with the existing performance prediction methods (LR, SVM, FM, and the DNN), the proposed method achieves the best prediction effect on the sports education dataset. Compared with the traditional optimal methods, the accuracy and AUC of DNN are both improved by 2%. In addition, there is also a significant improvement in accuracy, recall, and F1. In addition, this study found that considering two or more features at the same time has a certain influence on the prediction results of students' grades. The proposed feature combination method can learn feature combinations automatically, consider the influence of first-order features, second-order features, and high-order features in the meantime, and acquire the relationship information between each feature and performance. Compared with single-feature learning, the proposed method in this paper can enhance prediction accuracy significantly. Moreover, several dimensionality reduction methods are used in this paper, and we found that the PCA model for data processing outperformed all the benchmark models.

1. Background

In the information age, a large amount of data has been accumulated in all walks of life, under which there is often some useful knowledge and valuable information. At present, technologies related to machine learning and data mining are widely used in business, finance, medicine, and other fields.

With the fast development of the Internet, universities have increasingly perfected their digital campuses, and all kinds of educational data have been accumulated. However, there is often some potential knowledge and information in the massive educational data that can promote the development of education. ML data mining and other related technologies are used to provide valuable information for teachers, students, and educational researchers, so as to

scientifically improve teaching methods and make comprehensive management decisions. Therefore, it is worth studying the way how better teaching efficiency and educational output are obtained from the big data of education. From the 1990s to the beginning of this century, with the fast development of the Internet, the education informatization has gradually entered the network era, and distance education and online education have attracted more and more educators' attention. The current mainstream education environment can be roughly divided into traditional classroom education and new online education, such as MOOC. Educational data mining deals with various problems in teaching, practice, and educational research through theories and technologies in multiple disciplines including pedagogy, computer science, statistics, and psychology. Currently, EDM application scenarios can be mainly divided

into four categories: student performance prediction, student modeling, a recommendation system, and visualization.

2. Related Works

At present, education quality has become the top priority in education. Improving the quality of education is one of the unyielding determinations of educators. Now many scholars have conducted research on the prediction of students' academic performance. Early research mainly focused on collecting student learning data (such as traditional classroom teaching test scores) from the educational administration system. Students' consumption behavior data are collected from students' campus cards to predict scores. Burman used the records collected by questionnaires to classify learners into high, average, and low levels according to their academic performance based on students' psychological parameters, including personality, motivation, psychosocial background, learning strategies, learning methods, and socioeconomic status, by using a multiclassifier support vector machine [1]. A team including Sweeney used SVD, SVD-KNN, factorizers, and other recommendation system methods to predict the grades of the next semester and made a comprehensive analysis of the predicted results [2]. Sweeney proposed a method of mixed decomposer and random forest to predict students' scores by taking advantage of the course scores learned by students [3]. A team including Polyzou proposed a sparse linear and low-rank matrix decomposition model to predict future course scores based on students' historical course scores [4]. Yi et al. predicted students' scores through a multikernel support vector machine combined with an optimization algorithm, and then successfully evaluated the teaching quality [5]. AI-based methods play an increasingly important role in teaching quality evaluation [6, 7] and student performance prediction [8, 9].

Recently, with the development of the Internet and the continuous improvement of online learning platforms, the data related to MOOC students' learning has attracted more and more attention from relevant researchers. A team including Jiang used the interaction records of learners' first week on the platform and the performance data of homework to predict whether learners would eventually obtain certificates based on the logistic regression model [10]. Brinton and MChiang developed an algorithmic model relying on the decomposing machine and K-nearest neighbors (KNN) to predict whether a student answers a question correctly for the first time in a MOOC [11]. Lorenzo and Gomez-Sanchez adopted logistic regression, stochastic gradient descent, stochastic forest, and support vector machine models to predict whether the indicator, compared with the previous indicator at the end of the chapter, the three participation indicators (video, exercise, and assignment), would decline [12]. Hlosta builds a student performance prediction model based on machine learning methods (logistic regression, support vector machine,

random forest, naive Bayes, and integrated learning XGBoost) in accordance with the data generated in the current course to evaluate whether students have the risk of dropping out [13]. A team including Aljohani deployed a deep long and short-term memory model based on student interaction records on online platforms (such as clickstream data) to explore student performance prediction, and the results showed that the model could predict pass/fail courses in the first 10 weeks of student interaction in a virtual learning environment with an accuracy of about 90% [14].

Compared with the application of the classical ML-based model to education such as LR [15], SVM [16], Decision Tree [17], GBDT [11], and BNs [18], the DL-based model such as RNN [19] and CNN [20] can also be used to enhance the results in the field of education.

To sum up, some achievements have been made in the study of performance prediction, but there are still some problems and shortcomings.

First, in the traditional classroom grade prediction problem, the main data information comes from some data generated during the course, such as the in-class assignment grades and unit test grades. The characteristics of the course grade prediction can be achieved until the end of the course, which leads to the late predicted results, so the method has a certain lag and the data are sparse and single, so that it cannot provide effective technical support for the teaching and management work in the early stage of the course.

Second, with a lack of other relevant course grade information, the existing online platform course grade prediction research mainly focuses on the log data of learners on the learning platform, such as the learning time on the online learning platform and the number of clicks on the learning video. In addition, in existing research, manual feature engineering is commonly used, which is highly dependent on the professional knowledge and experience of engineers, which affects the prediction accuracy of the method to a certain extent.

Third, most of the data used in the existing research on performance prediction come from the dataset constructed by researchers themselves, and the data are generally not enough. For mainstream research methods such as machine learning algorithms, there are certain requirements on the amount of data. If the data are insufficient, it is difficult to train a better model, which leads to low accuracy of prediction to a certain extent. In view of the above problems, in this paper, two kinds of different data are used to put forward different performance prediction models, so as to improve the accuracy of performance prediction.

To sum up, under the background of educational data mining, this paper carries out in-depth and systematic research on student performance prediction from the perspectives of traditional classroom teaching scenarios and MOOC online platform courses. The research focus is mainly on improving the predictability and accuracy of the method. In the following sections, the main research content of this paper is briefly introduced.

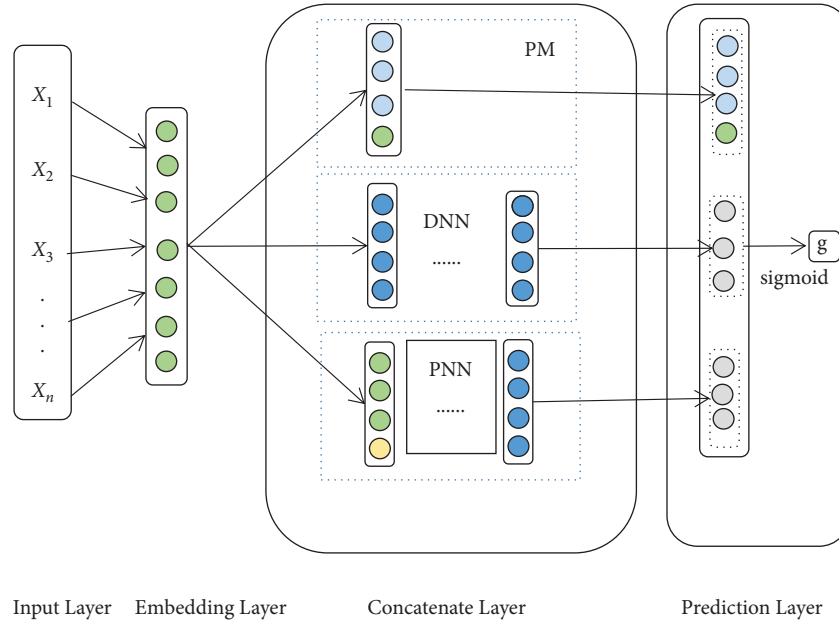

FIGURE 1: FDPN model framework.

3. Sports Course Score Prediction Model Based on Feature Combination

3.1. Problem Definition. Given a student feature set F determined by the student attribution features expressed as $student_attr = \{s_1, s_2, \dots, s_m\}$, course attribution features expressed as $course_attr = \{c_1, c_2, \dots, c_n\}$, and the student learning behavior feature expressed as $behavior = \{b_1, b_2, \dots, b_k\}$. Namely, $F = \{student_attr, course_attr, behavior\}$, where m , n , and k are the number of features, respectively. For the student, his final course score was y_i . $y = \{0, 1\}$ is a class set divided by grades, where 0 indicates a student grade failure and 1 indicates a student grade pass. Student grade prediction aims to predict the grade category y_i according to the student feature F .

3.2. Model Framework. This chapter aims at mining and analyzing the data related to students' learning based on deep learning technology to realize the accurate prediction of students' academic performance. By so doing, timely help and guidance can be provided to students at risk of failing exams. Therefore, this chapter proposes a performance prediction model (factorization deep product neural network, FDPN) based on feature combination, course attributes, and students' learning behavior features. The model framework is shown in Figure 1. The FDPN contains 3 layers:

- (1) Embedding layer: narrow the dimension of the original high-dimensional features and map them to the low-dimensional feature vector.
- (2) Concatenate layer: this layer is composed of three parts: factorization machine, DNN, and product neural network (PNN). FM is used to express

FIGURE 2: Structure of the embedding layer.

first-order and second-order features, and DNN and PNN are used to represent higher-level features.

- (3) Prediction layer: through splicing, the low-level and high-level features are combined to get the final features with richer information, so as to better predict students' performance.

3.2.1. Embedding Layer. Because the raw data are relatively sparse, a dimensional reduction is made to obtain a low-level representation of the features. Changing the initial feature to a lower-dimensional vector representation can make the data relatively dense and reduce computational effort. Figure 2 shows the structure of the embedding layer. Mapping the output of the embedding layer could be introduced as follows:

$$a = [e_1, e_2, \dots, e_p]. \quad (1)$$

Where a represents the embedding feature, e_i represents number i embedding feature, p refers to the number of embedding features, and $p \leq (m + n + k)$.

3.2.2. Concatenate Layer

(1) *Factorization machine.* The FM, as proposed by Rendle [21], is for learning feature interactions. As shown in the formula:

$$y_{fm} = w_0 + \sum_{i=2}^p w_i e_i + \sum_{i=1}^p \sum_{j=i+1}^p w_{ij} e_i e_j, \quad (2)$$

where w_0 , w_i , and w_{ij} are the weights of each feature. The factorization machine is represented by a first-order feature of logistic regression learning, and the second-order features of learning information are accumulated by the dots of vector. The last output value y_{fm} in the FM layer is transferred as input to the part of the input in the prediction layer.

DNN [22] is more capable of learning. The output of the embedding layer is the input of the first hidden layer of the DNN, and the calculation formula of the first hidden layer is shown in the following formula:

$$h_1 = f(w_o e_p + b_o). \quad (3)$$

Assuming that there are l hidden layers, which directly output y_{dm} to the input part of the prediction layer, the final output value of DNN is shown in the following formula:

$$y_{dm} = f(w_{l-1} h_{l-1} + b_{l-1}), \quad (4)$$

where $f(\cdot)$ is the activation function of the hidden layer, whose activation function is the ReLU [23].

(ii) *Product neural network.* The product neural network (PNN) is a feed-forward deep neural network [24] containing the product layer. In the PNN, the input information not only contains first-order feature-related information but also second-order features. Therefore, the product layer enriches the information of the input deep neural network. Its second-order features are calculated in (5), where p represents the inner product of the embedding layer vectors e_i and e_j .

$$p = \langle e_i \cdot e_j \rangle = \begin{bmatrix} e_j^1 \\ e_j^2 \\ \vdots \\ e_j^p \end{bmatrix} = \sum_{i=1}^p \sum_{j=i+1}^p w_{ij} e_i e_j. \quad (5)$$

The input vector of the PNN is composed of the first-order feature vector output by the embedding layer and the second-order feature vector generated by the interaction of the embedding layer. The calculation is shown as follows:

$$x_{pnn} = [a; p]. \quad (6)$$

The final output value y_{pnn} of the PNN is calculated, as in formula (4), which distinguishes itself from the DNN by varying the input feature vector from the embedded layer to the first hidden layer. The output values of the last hidden layer node of the PNN will be transmitted directly as input to the part node of the prediction layer input.

FIGURE 3: Learning process.

3.2.3. *Prediction Layer.* The prediction layer's primary task is to combine the low- and higher-order feature representations of FM, DNN, and PNN output in the network layer and predict the grade categories of the target students. More comprehensive and accurate students' performance can be predicted by integrating the features.

In this paper, features including y_{fm} , y_{dm} , and y_{pnn} are integrated through concatenation [25]. This process can be formalized as follows:

$$f = [y_{fm}; y_{dm}; y_{pnn}], \quad (7)$$

where f is the final feature after integrating of y_{fm} , y_{dm} and y_{pnn} . Finally, the feature f is input into the perceptron of the Sigmoid [26, 27] activation function to obtain the probability of the student course grade category.

From the above, FDPN includes three parts: FM, DNN, and PNN, and the final result is obtained from the following formula:

$$g = \text{Sigmoid}(f). \quad (8)$$

3.3. *Loss Function.* This paper employs the cross-entropy loss function and employs the L2 regularization parameter [27]. The loss function of the model is as follows:

$$\text{loss} = -\frac{1}{n} \sum_{i=1}^n y_i \log g + \lambda \|\theta\|^2, \quad (9)$$

where n is the total number of training data, y_i is the grade category of the data, g is the predicted probability of the number i grade category of the data, and $\lambda \|\theta\|^2$ is the L_2 regular term, θ is the set of all parameters of the model.

4. Experiments

4.1. *Data Set.* In this study, part of the data comes from the Open University Learning Analysis Data set (OULAD), which contains basic information, registration, and learner learning activity records from seven sport online courses from 2013 to 2014. Figure 3 shows the learning process of using the Open University platform. First of all, the Open University opens up a course for students to apply for the course registration, and then students begin their learning. The courses of the Open University usually last for nine months, and learners are required to complete corresponding learning tasks during the learning process. Finally, learners take the final examination, and the course ends.

TABLE 1: Data description.

Number	Features	Descriptions
1	Highest degree	The highest degree of students when enrolled in the course
2	Environmental index	The environment of the area during the course
3	Age group	Students age group
4	Times of attempts	The number of times a student tried a particular module
...
52	Shared information	Times of clicking on the course and faculties' shared information before class
53	Sources	Times of clicking on the PDF resources, such as books
54	Related information	Times of clicking on the information on the website and activities related to that information

TABLE 2: Confusion matrix.

Actual situation	Predicted results	
	Positive	Negative
Positive	TP (true and positive)	FN (false and negative)
Negative	FP (false and positive)	TN (true and negative)

The description of the data set is introduced in Table 1. Numbers 1 to 54 refer to the highest degree of students who register for the course, the environment index in school learning, age, times of trying a specific module, credits of students who are currently learning, . . . , and times of clicking additional information before the course, such as video, tape, website, environment index of learning the module, times of clicking shared information between staff before the course, times of click PDF resources like books before the course and clicking information on the website and related activities.

According to the above descriptions, 22347×33 valid data are preprocessed.

4.2. Evaluation Indicators. The evaluation indexes in this paper include accuracy, precision, recall, F1, and AUC (area under the curve), which measure the model classification prediction performance.

$$\begin{aligned}
 \text{Accuracy} &= \frac{TP + TN}{TP + TN + FP + FN}, \\
 \text{Precision} &= \frac{TP}{TP + FP}, \\
 \text{F1} &= \frac{2 * \text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}}.
 \end{aligned} \tag{10}$$

The meanings of TP, FP, FN, and TN are shown in Table 2:

5. Analysis

5.1. Influence of Different Parameters on FDPN Model Performance

5.1.1. Number of Neurons in the Hidden Layer. This model contains two deep neural networks. When a network contains multiple hidden layers and the number of neurons in each hidden layer is not the same, a lot of experimentation is

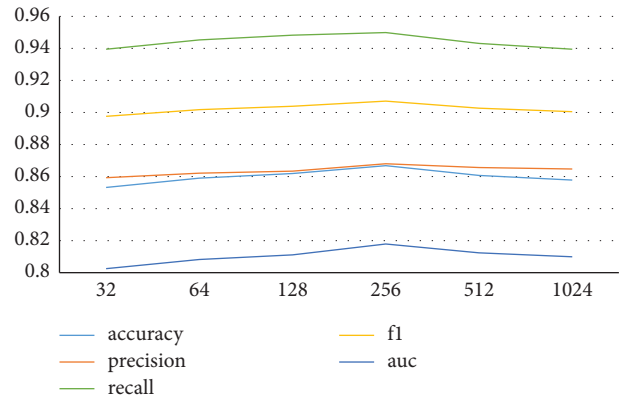

FIGURE 4: The comparison result of neural units in the hidden layer.

TABLE 3: The comparison result of neural units in the hidden layer.

Number	Accuracy	Precision	Recall	F1	AUC
32	0.8532	0.8593	0.9395	0.8976	0.8025
64	0.8590	0.8621	0.9453	0.9018	0.8082
128	0.8619	0.8634	0.9483	0.9039	0.8111
256	0.8668	0.8680	0.9499	0.9071	0.8179
512	0.8607	0.8656	0.9431	0.9027	0.8124
1024	0.8578	0.8647	0.9395	0.9005	0.8099

required. In this paper, the same number of neurons is set in the hidden layer of the two neural networks to simplify the experiment. The experimental results are shown in Figure 4 and Table 3. Six experiments are conducted in turn to change the number of neurons. From the experimental results, it can be seen that when the number of neurons is 256, the recall rate is about 95%, the AUC is about 82%, the accuracy is about 86.6%, and the precision rate is 86.8%. The model performance is optimal because, with the increase in the number of neurons, the model can learn more feature information. However, when the neurons increase to a certain number, no more effective information can be learned by the model, and even the noise that degrades the prediction performance of the model may be generated. Therefore, in deep neural network training, too many neurons should be moderated. Model training and learning comparison are needed to select the optimal number of neurons.

5.1.2. Different Activation Functions. The activation function of hidden layer neurons is related to the prediction

effect about DAF. Due to the binary classification model used in this paper, the model finally predicts the output unit with the Sigmoid function, and the settings of the remaining activation functions are the same. Among ReLU, Tanh, and Sigmoid, ReLU and Tanh are better used in deep learning models, so this experiment only compares the ReLU activation function and the Tanh activation function of the hidden neuron activation function. Table 4 introduces the experimental results. We can find that, when the activation function is ReLU, the prediction accuracy, recall rate, F1, and AUC of the FDPN model are increased by about 2%, and the prediction effect of the hidden layer neuron activation function with ReLU is better than that of the Tanh function. In particular, this chapter makes use of two feed-forward neural networks, in which the ReLU activation function performs better than the Tanh function and will be used in the last part of our study.

5.1.3. The Number of Layers in the Hidden Layer. The model presented in this paper contains two feed-forward neural networks, DNN and PNN, with different numbers of hidden layers and different predictive power of the models. To simplify the experiment, the number of hidden layers in two neural networks is the same; that is, the number of hidden layers is increased from 1 to 3 layers. The experimental results are shown in Table 5. From the experimental results, it can be seen that when the hidden layer is 1 and 2, the model has a good performance, and when the hidden layer is 3, the model prediction effect is significantly reduced. As the number of layers increases, the evaluation index drops, mainly because the more layers, the more complex the structure, and the larger the calculation amount, the more likely the problem of over-fitting the model will appear. Therefore, the number of layers of the hidden layer is still set to be 1 layer in the subsequent experiments of this paper.

5.2. Effect of the Model Structure on the Performance. The influencing factors mainly include first-order representations and second-order representations of FM learning features and different higher-order representations of DNN and PNN learning features. In this paper, the three structures are combined for learning to predict performance. In the experiments of this section, the different feature combination structures are compared to observe the effect of the structure on the model's performance. The experimental results are shown in Table 6.

Experimental results showed that the single-structure FM, DNN, and PNN slightly performed worse, and the Deep FM, DNN + PNN, and FM + PNN of both structures that have combined feature learning are slightly better than the single structure. The FDPN model is the optimal one because it considers both first, second, and two different higher-order feature representations, during which more potentially effective information is used in performance prediction. In conclusion, the FDPN performance prediction model has a significant prediction effect and can improve prediction performance.

FDPN	0.8668	0.8680	0.9499	0.9071	0.8179

5.3. Experiment Comparison. In this paper, LR, SVM, FM, DNN, DeepFM, PNN, and other deep learning models are used as comparative models. By performing comparative experiments on the sports dataset, the results are shown in Table 7 to verify that the proposed FDPN model has the best prediction performance.

The experimental results in Table 7 show that, compared with the existing performance prediction methods (LR, SVM, FM, and the DNN), this paper achieves the best prediction effect on the sports education dataset. Compared with the optimal traditional methods, DNN accuracy and AUC are both improved by 2%. In addition, there are also significant improvements in accuracy, recall, and F1. The method based on feature combination is better than the four traditional performance prediction methods. This is mainly because the traditional performance prediction method adopts features directly as a classification feature input for model learning training and only the low or high features are taken into consideration, with the exception of the different effects of low and high feature combinations on the final

TABLE 8: The result of the benchmark dimensionality reduction models.

Models	Accuracy	Precision	Recall	F1	AUC
LDA-FDPN	0.8616	0.8628	0.9442	0.9017	0.8130
LPP-FDPN	0.8710	0.8723	0.9545	0.9115	0.8219
PCA-FDPN	0.8789	0.8802	0.9632	0.9198	0.8294
FDPN	0.8668	0.8680	0.9499	0.9071	0.8179

performance. For the other two feature combination methods (DeepFM and PNN), this paper extracts the feature information, including first and second-order features and two different higher-order features, and thus the prediction ability of the model can be greatly improved to achieve a good prediction effect. Through the experiment, the effectiveness of the model was also confirmed. We use LDA (Latent Dirichlet Allocation) and LPP (Locality Preserving Projects) methods for combination comparison. LDA is a generation model for document topics. Make a guess about the topic distribution of the document. This model can represent all topics in the document set in the form of a probability distribution and realize topic clustering and text classification through the probability distribution of each topic. LPP is a linear manifold learning algorithm, which can preserve the local manifold structure of the original dataset and keep it in low-dimensional space. LPP is completely unsupervised; the eigenvectors of LPP are statistically correlated and not orthogonal. This means that LPP does not introduce category tags in the process of feature extraction, and category tags are of great significance for guiding feature extraction for classification problems.

Table 8 shows different performances under different dimensionality reduction methods. It can be found that the FDPN model after PCA dimensionality reduction achieves the best experimental results. In addition, we can also find that compared with the FDPN model alone, the use of the LDA method does not improve the final classification results; compared with the FDPN model alone, the LPP method improves the final classification result but is not as good as the PCA method.

6. Conclusion

This paper presents a new feature combination and structure model for the shortcomings of existing sports course performance prediction methods. We proposed a new method (factorization deep product neural network) for PE course score prediction. The experimental results show that, compared with the existing performance prediction methods (LR, SVM, FM, and the DNN), this paper achieves the best prediction effect on the sports education dataset. Compared with the optimal traditional methods, the DNN accuracy and AUC are both improved by 2%. In addition, there are also significant improvements in accuracy, recall, and F1. The model proposed by us provides an effective method for predicting students' performance in physical education courses.

With the continuous improvement of the network hardware environment, people turn the demand target to the network application environment and the construction of information resources. How to build a network teaching platform for general undergraduate teaching to ensure the stability of the system and high-quality services during operation especially large-scale concurrent access will inevitably lead to the increase in the business volume of each core part of the network, the number of visits, and data traffic. With the growth of the network, the corresponding processing power and computing intensity also increase rapidly, which causes problems such as overloading of core network equipment, network bottlenecks, and network congestion. Simply pursuing high-performance hardware to solve problems will undoubtedly result in high cost investment; moreover, equipment with excellent performance cannot meet the needs of the current rapidly growing business volume. According to the design goal of the dance online teaching platform, to meet the online teaching load requirements of many people at the same time, the pressure of the web server cluster must be great. Because many people in online at the same time put too much pressure on the web server, this part of the network cannot be processed in time, which leads to the phenomenon that the performance of this part and even the whole network is degraded. In severe cases, it will even cause network communication services to come to a standstill, that is, the so-called deadlock phenomenon. If the protocol software cannot detect congestion and reduce the packet sending rate, the network will be paralyzed due to congestion. This situation will cause the problem of movement delay for online dance teaching, which will seriously affect the quality of teaching. Therefore, the dance online course system should be continuously improved, the quality of online courses should be continuously improved, and the study of the practical application of load balancing technology in the network teaching environment has become an important means to solve the relationship between supply and demand of network teaching. According to the experimental analysis, when the number of Worker' actuators is fixed, the execution time span of MakeSpan increases with the increase of tasks, while the time required by the optimized load balancing algorithm proposed in this paper increases by 1.32 s on average with the increase of tasks, and the time required by heuristic algorithm and bee colony algorithm increases by 3.68 s and 3.45 s on average with the increase of tasks. On the whole, the optimized load balancing algorithm proposed in this paper has obvious advantages.

1. Introduction

The online dance teaching platform is a digital virtual environment for teachers and students to implement teaching activities. On it, teachers can easily design courses, prepare courses, make teaching courseware and guidance, guide students to study, check students' learning situation, and make scientific and nonquantitative evaluations of students' learning in a timely manner; students can easily obtain all kinds of required learning resources and various course

learning-related materials deposited on the network and conduct real-time or non-real-time two-way interaction with teachers, while managers use the dance online teaching platform to organize teachers and students of the whole school to effectively carry out teaching activities and understand and evaluate teaching activities such as teachers and students who choose courses at any time [1–3]. According to the goal of online dance teaching, to meet the load requirements of many people learning at the same time, the pressure on the server cluster is very great. If the server

processing is not timely to form a network jam, then the action will be delayed in teaching, which will seriously affect the teaching quality.

To deal with the increasingly prominent network bottleneck problem, the traditional solution is often to improve the performance of a single machine to achieve the optimal configuration, which has played a role in certain programs, but the problem of insufficient load is still prominent or multiple servers are used to share different tasks; that is to say, each server plays a different role; for example, one server provides static pages, another server provides dynamic pages, and so on. The structure of this server is asymmetric. The way of distribution, management, and maintenance is very inconvenient [4]. This paper highlights load balancing techniques based on this problem. Its basic design method is to dynamically distribute and allocate customer requests and make the servers in a symmetrical distribution structure; that is to say, each server can respond to the outside world and provide services independently, and each server is in the same position; through the software, the external requests are distributed reasonably and evenly to each server in the symmetrical structure, and the external response is completed independently, and the high load of the website is truly realized.

The focus of this paper is to study and improve a dynamic load balancing algorithm, so that tasks can be efficiently executed in parallel, and the load balance of each machine can improve the parallel resource utilization and overall performance of the task scheduling system. The basic idea is due to the different processing capabilities of each computing node in a task scheduling system, the speed of processing tasks will also be different [5]; lightly loaded nodes can be selected as Thief according to a certain strategy and then go to heavy-loaded nodes. It steals task execution and shares tasks with overloaded nodes, shortens the time span of the system MakeSpan, and improves the overall efficiency of the system [6]. Multitask scheduling in parallel computing is regarded as a classic problem in scheduling system research, and its computational complexity is also recognized as a strong NP problem. So far, the research has not found a most efficient scheduling algorithm. One of the advantages of cloud computing is that it can use a large number of heterogeneous and low-configured resources to realize collaborative computing, thereby reducing the total computing cost [7]. In the cloud computing environment, due to the diversity of computing nodes, geographical dispersion, and various types of resources, multiple tasks also have different characteristics. Businesses need to consider the service quality and cost of cloud computing data centers. The experimental heuristic algorithm and bee colony algorithm are compared with the optimized load balancing algorithm proposed in this paper to verify the performance and load balancing rate of the improved algorithm. During the experiment, the final completion time of the task is used, and compared with other algorithms, the overall performance is improved.

Chapter arrangement of this paper: the first chapter introduces the related research on dance online teaching by relevant scholars; the second chapter introduces the

optimized load balancing algorithm proposed in this paper; the third chapter introduces the dance online teaching based on the optimized load balancing algorithm. The problems existing in the platform are optimized; the fourth chapter is the summary of the full text.

The innovation of this paper: although online dance teaching has been developed for a period of time, a scientific and complete online course system has not yet been formed. The pressure on the server cluster must be great. Since many people online at the same time put too much pressure on the web server, this part of the network cannot be processed in time, which leads to the phenomenon that the performance of this part and even the whole network is degraded. This situation will cause the problem of movement delay for online dance teaching, which has a serious impact. Based on this problem, this paper proposes an optimized load balancing algorithm and studies how to distribute a large number of tasks equally to the appropriate computer nodes in the system for computing and executing tasks, so that the total task execution time MakeSpan is the shortest, and the load balance of each node in the system is achieved and can make full use of computer resources.

2. Related Work

The traditional teaching mode is limited to face-to-face teaching by deeds and deeds. Although this method allows students to see every dance posture and detail taught by the teacher, the students cannot quickly recall the details of the class over time, and the teacher's attitude towards each student is very difficult. Dance demonstrations are not replayable, which greatly limits their application. For the massive amount of information available on the Internet, in the same way that the majority of students often go online, they will browse the corresponding websites to obtain educational resources and access relevant question banks to obtain teaching materials and so on. All these provide huge resources for the development of distance education [8].

Wu design connects motion capture with contemporary sports, fully analyzes the role of motion capture in contemporary physical education teaching, and proposes motion parameters obtained by motion capture technology to monitor motion characteristics in real time and timely monitor motion technology. Diagnosis and analysis assist the coach to judge the standard degree of the athlete's movement in time, analyze the movement of the athlete, and give real-time correction and guidance to the standardization of the athlete's movement [9]. Jiang and Wang proposed to use motion capture to diagnose and analyze the situation in sports training in a timely manner. The coach can improve the training content purposefully based on the real-time activity data captured, thereby improving the effect of physical education and making physical education more effective [10]. Wu uses motion capture technology to assist golf teaching. Wallace uses the motion analysis system to analyze the professional technical movements of golfers, explores the golf players' postures of lifting and hitting the ball, and analyzes the players' movements through real-time captured motion data. It provides the theoretical basis for

the development of the field [11]. Raheb et al. combined motion capture technology with volleyball training, analyzed the volleyball players' movement postures such as serving and catching, and established a set of movement posture database. Through experimental data analysis, volleyball teaching was improved. The quality of education and the technical level of students have brought volleyball teaching into the digital age. Real-time acquisition allows for timely diagnosis and analysis of the situation during motion and reflects the quantitative parameters of the video and images [12]. Maggio et al. introduced the centerless load balancing algorithm and application in grid computing. However, the research on distributed load balancing algorithms is still in its infancy, lacking mature and reliable practical verification methods, and the existence of multiple coordinating nodes can easily cause system network congestion [13]. Han et al. proposed a walking mapping algorithm based on the premise of motion capture and applied it to a humanoid biped robot. Through the effective experimental verification of two robots with different sizes, weights, walking rules, and step lengths, the robot is similar to humans and effectively solves a series of problems caused by the sliding of feet and the ground. Using the Kalman filtering algorithm to predict motion states for unlabeled monocular video sequences of human gait, a quantitative method is proposed to automatically identify and track human motion poses and point out wrong poses [14]. Yan uses motion capture to create animation, optimizes the production process, and studies animation synthesis and elimination of slippage, pointing out that motion capture will become the development trend of animation creation in the future [15]. Aiming at the shortcomings of the current dance online teaching system, Xie proposed and developed a new dance online teaching system based on the B/S model from the perspective of the scale and regularization of online dance teaching [16]. Y. Zhang and M. N. Zhang analyzed the importance of online distance education in the new educational environment, combined with the reality of online teaching with multimedia technology, and expounded the specific design plan for the main functional modules of the system front desk [17]. Cheng et al. introduced the manifestations of online dance teaching resources, online learning methods, online dance teaching platforms, online teaching forms, and online dance teaching evaluation. The concept of education technology, including its specific connotation and theoretical basis, has been designed and developed in an all-round way, including the editing and directing process and online teaching process of online courses, which has broadened the vision of educational technology research and formed the theoretical prototype of the concept of curriculum editing and direction [18]. Wang and Zheng believed that the online teaching platform provides users with a wealth of online learning methods and resources. On the basis of introducing E-Learning, CC-MS, and OSCMS, combined with the online and offline teaching mode, an INM-based teaching method is proposed. The article uses the information network model to model the entity relationship, the entity complex information modeling, and the dynamic modeling for the online teaching system. Finally, the key technologies of the system

are given, including load balancing, database access, cascade query, schema-less data addition, and so on, to support the specific implementation of the system [19].

Classroom teaching based on the network environment provides objective conditions for practical research for the implementation of the learning theory of dance courses. At the same time, dance courses can better guide online interactive classroom teaching and promote the development of two-way activities between teaching and learning. Based on the research of the above related literature, the research on network congestion and online dance teaching is blank. Based on this problem, this paper proposes an online dance teaching model based on the optimized load balancing algorithm.

3. Optimize the Load Balancing Algorithm

In the current teaching reform with a high degree of integration of information technology and education and teaching, a series of education and teaching modes such as blended teaching mode, project-based teaching mode, and inquiry-based teaching mode have emerged, which will inevitably speed up the construction of data resource bases based on various disciplines. The construction of dance teaching resources is complex and diverse. In addition to the integration of online dance resources, data collection of students' learning evaluation, learning habits, and learning methods plays an important role in the generation of benign teaching [20]. The intelligent action analysis software scoring system provides the data generated by students' learning for the resource construction of dance discipline. Through the feedback information of students' learning effect and the evaluation data information of learning process, it is more convenient for teachers to formulate and adjust teaching strategies reasonably, summarize students' learning, provide high-quality and effective online resources for online teaching mode of dance, and give full play to the advantages of the network.

Load balancing is a cheap, effective, and transparent method based on the existing network structure, which aims at expanding the bandwidth of the original network equipment and servers, increasing the network throughput, strengthening the data processing capability and improving the flexibility and availability of the network, and solving the contradiction between the network supply and the business demand. Usually, load balancing is used for two purposes. One is to share a large amount of concurrent access or data traffic on multiple node devices for separate processing, so as to reduce the time for users to wait for a response; the other is to share a single heavy-load operation to multiple nodes. Parallel processing is performed on the node devices. After the processing of each node device is completed, the results are summarized and returned to the user, which greatly improves the processing capacity of the system. Therefore, in order to build an efficient and stable dance online teaching environment, it is necessary to consider how to construct the system hardware and design the software system to avoid the possible risks of network bottlenecks, network congestion, and even application service crashes. A software load

balancing solution refers to the installation of one or more additional software on the operating system of one or more servers to achieve load balancing. It is based on a specific environment, has the characteristics of simple configuration, flexible use, and low cost, and can meet general load balancing requirements. Its technical structure is shown in Figure 1.

Routing is a parameter that reflects the basic performance of a network. It can be used as a constraint condition for path selection and an important criterion for measuring the quality of a path. The measurement parameters often used in the network include bandwidth, delay, delay jitter, cost, packet loss rate, and so on. Based on the different properties of various metric parameters, these metric parameters have various synthetic forms, namely, additive metric, multiplicative metric, and concave metric. The additive metric is determined jointly by the characteristics of all links on the path, such as delay, delay jitter, cost, hop count, and so on, all belong to additive metrics. Its synthesis rule is the metric parameter value of the entire transmission path, that is, the sum of the metric parameter values of each component link, and the cumulative sum of the metric parameter values of the transmission path is shown in the following formula:

$$s(p) = \sum_{i=1}^n s(x_i). \quad (1)$$

The multiplicative metric is the product of all link metrics on the path, and the law is the product of each link metric parameter value, as shown in the following formula:

$$s(p) = \prod_{i=1}^n s(x_i). \quad (2)$$

Available bandwidth, remaining capacity of router buffer, and so on are commonly used concave metrics. The synthesis rule is that the metric parameter value of the path is the smallest among the metric parameter values of each link, and the concave metric is determined by the bottleneck link on the path, such as shown in the following:

$$s(p) = \min [s(x_i)]. \quad (3)$$

In order to reduce the complexity of routing calculation, the usual practice is to select a metric from the additive or multiplicative measures, such as delay or number of nodes, and combine the nonadditive and multiplicative measures such as bandwidth and resource type as constraints. A path selection is made. In addition, the establishment of the above theorem has a prerequisite; that is, the various additive or multiplicative measures should be independent and uncorrelated with each other.

The basic idea of load balancing technology is that multiple servers in a cluster system are symmetrical, and each server has the same status and can respond to service requests independently without the assistance of other servers. By using some load sharing technology, the task request submitted by the client is evenly distributed to a

server in the system, and the server that receives the task request can respond to the client independently. Consistency of server content often relies on shared storage, synchronized updates, or databases. This paper analyzes the number of three kinds of task stealing and gives its core implementation function code. For more clarity, comparison is shown in Table 1.

Since the work-stealing algorithm needs to migrate related tasks when stealing tasks, there will be some communication and delay overhead. When considering reducing the overhead caused by these problems, this paper improves on Thief task stealing timing. The two stealing timings are stealing tasks when the node is idle and stealing tasks when the node is about to be idle.

Task reorganization is to estimate the node performance and regroup the tasks according to the estimated results. Research shows that the node performance mainly depends on RAM and CPU and is closely related to the number of completed tasks. Therefore, when the number of assigned tasks changes, the formula for calculating the number of tasks is shown as follows:

$$N = (1 - C)\alpha + (1 - M)\beta. \quad (4)$$

The memory size of a computer node is an important factor affecting computer performance. It is generally determined by the storage size of the memory card in the node, and usually the node is not simply performing a task; it is always in parallel. Multiple tasks are performed. Therefore, before it executes a task, it also needs to determine how much memory space there is in the node, which can be provided to the task to be executed to determine whether the memory requirement of the task can be met. The memory space calculation of the execution node is shown in the following formula:

$$\text{Ram } S = \text{Ram } R - \text{Ram } U. \quad (5)$$

When the ready task queue on a Worker is empty, that is, the Worker is currently in an idle state and needs dance teaching tasks, it will become thick and send a task dance teaching request to the central task scheduling server Scheduler. The central task scheduler Scheduler finds out the Worker with the largest load according to the stored load information of each Worker and sends the relevant information of the Worker to Thief; Thief can access the relevant Worker after receiving the relevant information sent by the Scheduler and perform dance teaching operations. Different next nodes can be selected in different areas, that is, in a load network environment, facing many choices, how to make the best choice will be a concentrated expression of the advantages and disadvantages of the algorithm. The first is the parameter value to measure the performance of a certain feature of the node, and its formula is shown as follows:

$$T_i = T(v_1, v_2, \dots, v_m). \quad (6)$$

The eigenvalue of a certain characteristic of a node is jointly determined by multiple vectors, and the eigenvalues of different load points are determined under the influence

FIGURE 1: Optimized load balancing technology model.

TABLE 1: Comparison of the number of stealing tasks in different tasks.

	Additive series	Multiplication series	Dichotomy
Initial value	Stealinitial	Stealinitial	None
Number of steals for the n th time	$N * stealinitial$	Stealinitial	Half the number of victim tasks
Functional interface	Intsetstealnum (worker victim)	Intsetstealnum (worker victim)	Intsetstealnum (worker victim)

of multiple vectors. The selection formula is shown as follows:

$$T(t + 2) = f(T(t), \kappa). \tag{7}$$

In the case of a large number of users accessing the web server concurrently, how to apply some software mechanism for load balancing in a cluster of web servers to ensure better quality of access for users. Ultimately, the purpose of building a complete, unified, technologically advanced, efficient, stable, safe, and reliable management information system is achieved.

4. Design of Dance Online Teaching System

4.1. Analysis of Correlation Causes of Network Congestion and Action Delay. At present, a series of education and teaching modes such as the high integration of information technology and education and teaching, blended teaching mode, project-based teaching mode, and inquiry-based teaching mode have emerged, which will inevitably speed up the construction of data resource bases based on various disciplines. The construction of online dance resources is complex and diverse. In addition to the integration of online dance resources, the data collection of students' learning evaluation, study habits, and learning methods plays an important role in the generation of benign teaching. The

platform server structure of dance online teaching is shown in Figure 2.

Because servlet runs on the server side, it can generate web pages dynamically and can share data among various programs, so it is easy to realize database connection pool.

Resin is a container for parsing JSPs and servlet, and it supports load balancing to improve reliability. Resin comes with its own Http server and also serves as an srun server. In addition, Resin supports the database buffer pool very well, and the DBPool it provides encapsulates the buffer pool, so long as it is configured in Resin.conf and then referenced in the compiled jsp or servlet. The dance online course system must be continuously improved, and the quality of online courses must be continuously improved. Although online dance teaching has developed over a period of time, a scientific and complete online course system has not yet been formed. Online courses are random, and many of them are not of high quality in terms of teaching content and recording, which affects the teaching effect. According to the design goal of the dance online teaching platform, to meet the online teaching load requirements of many people at the same time, the pressure of the web server cluster must be great. Because many people in online at the same time put too much pressure on the web server, this part of the network cannot be processed in time, which leads to the phenomenon that the performance of this part and even the whole network is degraded. In severe cases, network

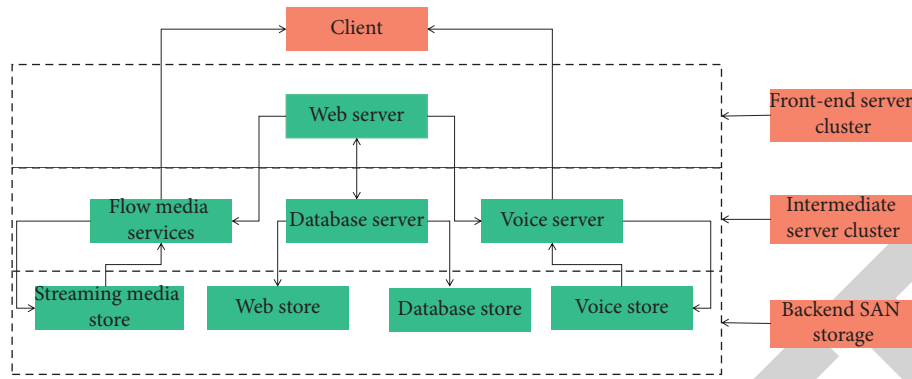

FIGURE 2: The logical structure of the server cluster of the dance online teaching platform.

communication services may even come to a standstill, that is, a so-called deadlock phenomenon occurs, causing data packets sent through the network to experience extremely long delays due to the network being crowded with data packets. If the protocol software fails to detect congestion and reduce the rate at which packets are sent, the network will be paralyzed by congestion. This situation will cause the problem of movement delay for online dance teaching, which will seriously affect the quality of teaching.

The action intelligence analysis software scoring system provides the data information generated by students' learning for the resource construction of dance disciplines. Through the feedback information of students' learning effects and the evaluation data information of the learning process, it is more convenient for teachers to formulate and adjust teaching strategies rationally. Summarize students' learning, provide high-quality and effective online resources for the dance blended teaching model, and give full play to the advantages of the network.

4.2. Dance Online Teaching Platform Based on Optimized Load Balancing. The reason for studying the load balancing technology in the dance online teaching system is that the dance online teaching platform is built for a large-scale user group, providing HTTP, FTP, RTSP, MMS, PNA, and other online or offline methods. It is a kind of network application, which has high requirements on the real-time performance, stability, and data consistency and integrity of the system, and integrates a variety of services.

Load balancing is based on the existing network structure, aiming to expand the bandwidth of the original network equipment and servers, increase the network throughput, strengthen the data processing capability, improve the flexibility and availability of the network, and solve the problem between the network supply and the business demand. Usually, load balancing is used for two purposes. One is to share a large amount of concurrent access or data traffic on multiple node devices for processing, so as to reduce the time for users to wait for a response; the other is to share a single heavy-load operation to multiple nodes. Parallel processing is performed on the node devices. After the processing of each node device is completed, the results are summarized and returned to the user, which greatly

improves the processing capacity of the system. Finally, the purpose of building a complete, unified, technologically advanced, efficient, stable, safe and reliable management information system is achieved.

According to the above analysis of the application characteristics and service types of the dance online teaching platform, this paper adopts a combination of hardware and software to balance the system load. That is, the server cluster technology is selected on the system hardware architecture, and the software load balancing solution is adopted at the same time. A software load balancing solution refers to the installation of one or more additional software on the operating system of one or more servers to achieve load balancing. It is based on a specific environment, has the characteristics of simple configuration, flexible use, and low cost, and can meet general load balancing needs. Cluster technology refers to the technical method of dividing the existing servers into several groups by analyzing the service types accessed by customers, so that multiple servers in the same group can handle certain or similar service requests, so that a large number of concurrent accesses can be shared to the corresponding servers or server groups for processing according to their types. By configuring Resin.conf, enable Resin's own load balancing engine. Resin's load balancing engine can actually start multiple Java response processes and perform load balancing through internal mechanisms. Assuming $n = 3$ here, this paper adopts the configuration scheme of multiple IP addresses and one port.

The test of the system is mainly aimed at concurrent access to examine the responsiveness of the system. The specific method is to use the concurrent access test tool to directly access the database query page in the platform. The test tool adopts the ab test tool that comes with Apache. The test process is divided into a single server running test and two servers running the test at the same time. In these two environments, the number of requests the system responds to per second and the processing time of each request are tested, respectively. The test results are shown in Figures 3 and 4.

It can be seen from the figure that the number of responses per second of the dual-server service is much higher than that of the single-server service when there is a small number of concurrency. With the continuous increase of the number of concurrency, the single and dual-machine

FIGURE 3: Number of responses per second in single-server and dual-server service environments.

services will reach a certain dynamic balance, but the dual-machine service waveform is higher than the single-machine service waveform. This is because Resin parsing and NFS services are required internally during dual-server services, which will temporarily affect the number of responses. However, as the number of concurrency continues to increase, the number of responses for dual-server services will increase; according to the number of user visits, the growth of the amount of stored data can flexibly increase the number of servers and the capacity of network storage to effectively control the service quality of the entire system.

4.3. Experiment on Scheduling Optimization of Dance Online Teaching Server. The web server cluster is the unified portal for the external services of the dance online teaching system, and the user generates a service request relationship with the web server cluster through the browser. On the corresponding servers in the web server cluster, each server responds separately. In the intermediate server cluster, the database server is used to store various dynamic information, courseware resources, and user data; the streaming media server mainly provides streaming media-based courseware on-demand and video services, and the voice server provides real-time online voice interaction services. And all the intermediate server clusters have their own network storage.

The modular combination of various functions of the system should be carried out in accordance with the principles of low coupling and high aggregation. The level of coupling itself represents the strength of the interdependence and connection between programs among the various modules of the system while the level of aggregation represents the intrinsic relationship between the functional programs of each module itself. Here, the module differentiation is carried out in the form of low coupling, which is to reduce the dependencies between modules as much as possible, so that their respective program codes are

independent of each other, so that it is not easy to be confused in development, and it is also conducive to the testing and maintenance of project code. The problem will not have too much impact on other modules; the purpose of using the high-aggregation form is to make the implementation codes within the module itself closely interconnected, so that the function of the module can be used more smoothly and closely. The ultimate goal of this design method is to improve the maintainability of the system design and its later scalability. This paper conducts experiments on the Cloud Sim platform and gives some experimental results for further verification. In order to make the experimental results of this paper more accurate, the number of virtual machines in the experiment is 50 and 100. Every time a group of data is tested, 20 task requests are input, and all the obtained values are recorded as the experimental data of this paper. The experimental results are shown in Figure 5.

The experimental results are stable in a certain range, which proves that the load balancing algorithm is stable in the process of executing cloud task allocation, which shows that the algorithm can ensure that the task allocation can be completed in a limited time when applied to the actual cloud platform. Due to the initial random selection of samples and assignment of tasks to select the first virtual machine, coupled with the uncertainty of the selection results in the iterative formula, the algorithm results will be unstable. Stability means that the experimental results will be stable in a certain range of values, and the curve of the optimal results will tend to be stable. This is because there will always be the best possible results in the system. Then, as the number of experiments increases, the optimal results of the system will tend to a stable value, while the worst results have no rules to follow, and the curve fluctuates greatly. In theory, concentrating all tasks on one virtual machine will produce the worst result, but in fact the algorithm selection strategy guarantees that this situation is impossible, and tasks will be allocated to different virtual

FIGURE 4: Corresponding time of each request in single-machine and dual-machine service environment.

FIGURE 5: 20 experimental results of cloud tasks under different virtual machines.

FIGURE 6: The results of different virtual machines changing the experiment.

machines for execution, so the most bad results do not appear stable. In this paper, the optimal result of the experiment is calculated by adjusting the number of virtual machines. The worst result and the average result are used to simulate the number of network task nodes in the simulation dance online teaching. The experimental results are shown in Figure 6.

In all graphs, the best, worst, and average curves grow roughly linearly. This is because when the virtual machine is fixed, as the number of cloud tasks grows, the system consumes more time complexity. Moreover, the linear growth of the average result in the figure can indicate that the load balancing algorithm does not depend on the change of the virtual machine, and the algorithm is stable and independent. The average curve in the graph measures the average efficiency of the algorithm. In the first half of the curve, the curve shows steady growth, which shows the stability of the algorithm. In the range that the virtual machine can bear, the algorithm has stable efficiency.

4.4. Comparison of Optimized Load Balancing Algorithms. In order to verify the validity of the experiment, the optimized load balancing algorithm proposed in this paper is compared with the heuristic algorithm and the bee colony algorithm, and three Work task executors are set to execute the task. The index test results are shown in Figure 7.

It can be seen from the figure that when the number of Worker executors is certain, as the number of tasks increases, the execution time span MakeSpan increases, and the time required for the optimized load balancing algorithm proposed in this paper to complete the task increases on average with the increase in the amount of tasks (1.32 s). As a comparison, the time required for the heuristic algorithm and the bee colony algorithm task increases on average by 3.68 s and 3.45 s with the increase of the task volume. Overall, the optimized load balancing algorithm proposed in this paper has obvious advantages. It is not difficult to find from the test results that the number of servers and the capacity of network storage can be flexibly increased to

FIGURE 7: Comparing the completion time of different algorithms under worker.

effectively control the service quality of the entire system according to the growth of the number of users accessing the platform and the amount of stored data.

5. Conclusions

Load balancing is an important aspect that affects the performance of the scheduling system. At present, with the reduction of computer hardware cost and the popularity of high-speed networks, network-based parallel computing and distributed computing are also popular. In the dance online teaching platform, by increasing the number of web servers and application servers, server clusters are realized, and at the same time, Resin analysis is used between the web server clusters to achieve load balancing, which effectively improves the system service performance and increases the number of users supported by the system. Quantity makes the system highly scalable and flexible. Practice has proved that with a certain number of Worker executors, with the increase of tasks, the execution time span of MakeSpan increases, and the time required for the optimized load balancing algorithm proposed in this paper to complete the task increases on average by 1.32 s; as a comparison, the time required for the heuristic algorithm and the bee colony algorithm task increases on average by 3.68 s and 3.45 s with the increase of the task volume. Overall, the optimized load balancing algorithm proposed in this paper has obvious advantages. Applying load balancing technology in the establishment of an online dance teaching platform for large-scale user groups is an inexpensive and effective method to expand server bandwidth and increase throughput. It can not only increase network data processing capacity but also improve network performance. This case has great reference significance for building similar large-scale network applications.

When studying the work of dynamic load balancing algorithm, the factors of resources, tasks, and other indicators are considered less, which is far behind the factors affecting scheduling in the actual scene. In the future research and design of dynamic load balancing algorithm, we

should try our best to make the defined indexes closer to the actual application scenarios.

Internet technology has a great impact on the application and development of libraries. In order to provide users with more convenient and efficient services, this paper puts forward the development strategy of unmanned intelligent digital libraries in the era of “Internet +.” Design by IntelliSense module, network transmission module, data storage and analysis module, and intelligent service module of no wisdom digital library service mode, IntelliSense module using RFID technology, close range wireless communication technology, and other Internet technologies to collect the wisdom of unmanned services of all kinds of information in the digital library; use network transmission module of the wireless LAN network, Internet technology such as RFID network to transmit information collected to store in a data storage and analysis module; and at the same time using k -means clustering algorithm in data mining techniques such as analysis of collected data, based on the analysis results provide users with intelligence services such as search, wisdom is recommended. The experimental results show that the developed strategy meets the expected functional requirements, can accurately perceive the location of data, and effectively realize the intelligent service function.

1. Introduction

Under the background of the Internet era, compared with previous libraries, the system service of smart digital libraries is becoming more and more perfect, and the information behavior of users presents the characteristics of the Internet [1]. Users’ access to information has taken on a new form and is constantly developing in the direction of intelligence, informatization, digitization, and modernization [2], and information behavior is becoming more and more convenient. In the “Internet +” era, information resources are more abundant and platform systems are more integrated. However, at present, there are some problems in the service of a smart digital library, which need to be handled in time, establish and improve the mechanism, and improve the service quality of the smart digital library. “Internet +”

brings a new development opportunity for the construction of a smart digital library. Combined with the construction of a smart digital library, it can use “Internet +” to fuse different information [3], cross-border integrate information, and achieve the goal of information service. “Internet +” is the product of social development and the crystallization of science, technology, and economic development [4]. The construction of the smart digital library is affected by the Internet. It combines other industries with library information so that library information can be combined with all industries and fields that can be connected and contact institutions in different places.

The concept of a smart digital library was first put forward by foreign library circles [5]. Whether it is theoretical research or practical research, its starting point and purpose are to realize the universality and intelligence of a

smart digital library, so as to provide users with intelligent and personalized services. Around 2003, the library of University of Oulu in Finland launched a service called “smart library” [6]. Smart library is a space-free and perceptible mobile library service that can be used anywhere there is Internet. As for the definition of a smart digital library, different scholars in China have given different expressions from different angles. From the perspective of sensor computing, Yan Dong proposed that smart digital library = library + Internet of Things + cloud computing + intelligent equipment [7]; from the perspective of big data and ubiquitous learning, Wang Weiqiu proposed that smart digital library was the integration of digital library, intelligent perception equipment, big data analysis, and ubiquitous learning space [8]; from the perspective of humanized service and management, Pingping proposed that the smart digital library had changed the interaction mode between users and library facilities, systems and information resources through modern information technology, so as to make the service and management of the library more intelligent [9]. Based on the views of the abovementioned scholars, it can be considered that the smart digital library should be a new generation library that takes the digitization of resources as the premise and is based on the Internet of Things technology, Internet technology, and mobile terminals, guided by the needs of readers, is not limited by space, can be perceived, and continuously improves the reader experience, which is the future development direction of the library.

In recent years, with the continuous development of ubiquitous Internet technology based on mobile Internet and Internet of Things and the continuous expansion of mobile terminal functions, the information service mode based on situational perception, ubiquitous computing, intelligent judgment, and multidimensional interaction will be the main direction of the development of smart library in the future. At present, some scholars have done relevant research on the development strategy of a smart digital library. Wu introduced the intelligent library personalized recommendation service system based on intelligent technology [10]; combined with the characteristics of a ubiquitous and intelligent smart library, Bi et al. constructed a hierarchical model of a ubiquitous smart library from the bottom-up from the perspective of user service [11]; and Cui and Wu introduced the intelligent service system of Library of Nanjing University, including the construction and transformation of physical venues, the construction of information service platform and the construction of intelligent services, and introduced the construction and implementation of its intelligent library in detail [12, 13].

In order to predict the future development of the unmanned service command digital library, this paper studies the development strategy of the unmanned service smart digital library in the era of “Internet +,” and provides users with smart search, smart recommendation, and other smart services, hoping that the research content can improve the service quality of the smart digital library.

2. Materials and Methods

“Internet +” refers to a new form of business developed by the Internet under the impetus of innovation 2.0, and a new form of economic and social development evolved and spawned by the Internet under the impetus of knowledge society innovation 2.0. “Internet +” is a further practical achievement of Internet thinking. It represents an advanced productive force, promotes the continuous evolution of economic forms, drives the vitality of social and economic entities, and provides a broad network platform for the reform, innovation, and development of unmanned smart digital libraries.

2.1. Resource Feature Extraction of Unmanned Intelligent Digital Library. The intelligent service mode of an unmanned intelligent digital library is composed of four main parts: intelligent sensing module, network transmission module, data storage and analysis module, and intelligent service module, as shown in Figure 1.

Intelligent sensing module refers to the use of a variety of Internet technologies to connect users, information resources, unmanned intelligent digital libraries, and so on so that they become an organic whole, so as to achieve the interconnection of information among the three.

When extracting the resource features of the unmanned service intelligent digital library, it is regarded as the combination of the user’s interests and the resource characteristics, that is, the matching of the student’s personalized portrait and the resource features of the unmanned service intelligent digital library. Therefore, after completing the construction of the personalized portrait of students, the resource features of the unmanned intelligent digital library are extracted [8]. Then the matching calculation is carried out for the attribute characteristics of the resources of the unmanned intelligent digital library, and the conditions are provided for the subsequent resource recommendation and detailed display. In the specific operation, it is necessary to determine the distribution of resource data of the unmanned intelligent digital library. In the heterogeneous data storage environment of the unmanned intelligent digital library, the decision-making feature preference of resource data is introduced, and the integration of student personalized portrait and resource feature data is realized. In this process, the following formula can be used:

$$W_{abc} = \frac{A_a}{\sum_{i=1} (B_i - C_i)}. \quad (1)$$

In Equation (1), W_{abc} represents the resource characteristic data of the unmanned intelligent digital library obtained through the abovementioned operation; A_a represents a user personalized portrait tag corresponding to the feature data; B_i represents the characteristic value of all unmanned smart digital library resources; C_i represents the personalized portrait label of the student corresponding to a specific unmanned intelligent digital library resource. According to the abovementioned equation, complete the

FIGURE 1: Intelligent service mode of unmanned digital library.

fusion of student personalized portrait and resource feature data, and then need to fuse all resource feature data. The specific equation is given as follows:

$$G_H = K_L \times K_J \times W_{abc}. \quad (2)$$

In Equation (2), G_H represents the objective function of resource feature extraction of unmanned intelligent digital library; K_J represents the weight coefficient during feature extraction under a certain recommended delay J condition; and K_L represents the feature extraction weight when the consumption is L in the feature extraction of the resources of an unmanned intelligent digital library. According to the abovementioned operations, the integration of various resources in the unmanned intelligent digital library is realized. After the integration, the feature data needs to be reconstructed in multidimensions. The fusion matching method can be introduced to reconstruct the data, and the reconstructed data can be imported into the recommendation database of the unmanned intelligent digital library according to the abovementioned operation, so as to complete the resource feature extraction task of the entire digital unmanned intelligent digital library.

2.2. RFID-Based Book Location Sensing Algorithm. FRID technology is used to collect book locations in an intelligent digital library without human service. According to the workflow of FRID technology, the sensing method based on frequency domain phase difference is used to sense the distance between tag reader and tag in the two-dimensional space of an intelligent digital library without human service; based on the two-dimensional spatial distance sensing results of the intelligent digital library without human service, the trilateral measurement method is selected to sense the three-dimensional coordinate position data of the book tag to be perceived in the intelligent digital library without human service.

2.2.1. Two-Dimensional Distance Perception. According to the working process of FRID technology, the reader transmits carrier signals with different frequencies [14–16]. After a certain distance, the signal is received and reflected by the book tag. The reader obtains the reflected signal and determines the distance between the book target (the tag to be perceived) and the tag reader (the location coordinates

are known) based on the signal phase difference. The specific process is given as follows.

Ignoring the time required for the process from book tag receiving to transmitting carrier signal, Δs and a are respectively used to represent the time required for the process from reader transmitting carrier signal to receiving reflected signal and the propagation speed of RF signal in the air, so as to obtain the expression of speed distance d :

$$d = a\Delta s, \quad (3)$$

where β and p are respectively represented the phase and carrier frequency experienced by the reader carrier signal from the transmission to reception.

2.2.2. 3D Position Perception. After determining the distance between the book tag to be perceived and the tag reader in the two-dimensional space of the intelligent digital library without human service, it can select the trilateral measurement method to perceive the three-dimensional coordinate position data of the book tag to be perceived in the intelligent digital library without human service [17].

d_i ($i = 1, 2, 3$) represents the distance between the three readers and the tag, and the coordinate (x_i, y_i) ($i = 1, 2, 3$) of each reader is known, so as to obtain

$$d_i = \sqrt{[(x_i - x_0) + (y_i - y_0)]^2}. \quad (4)$$

On this basis, the position coordinate (x_0, y_0) of the book tag to be perceived in the intelligent digital library without human service can be determined by constructing the equation.

The distance relationship between the reader i and the book tag to be perceived in the three-dimensional space of the intelligent digital library without human service can be described by the following equation:

$$d_i^2 = [(x - x_i) + (y - y_i) + (z - z_i)]^2. \quad (5)$$

Equation (5) is defined as a spherical equation. Since the tag is a common point, according to the geometric relationship, the position data of the book tag to be perceived in the intelligent digital library without human service determined by four readers [18] can be obtained, so as to obtain the distance equation group between the book tag and the reader.

From the abovementioned description, it can be seen that accurately obtaining the distance between the book tag to be perceived and the tag reader in the two-dimensional space of the intelligent digital library without human service is the basis for obtaining the high-precision three-dimensional position coordinate data of the books in the intelligent digital library without human service.

If the distance between each tag reader and the book tag has high accuracy, and the tag reader is set in different corners of the intelligent digital library without human service, which can avoid multiple tag readers from being in the same straight line with the book tag, then Equation (5) must have a unique solution. However, in the process of actually perceiving the book located in the intelligent digital

library without human service, the calculation result of the distance between the tag reader and the book tag has a certain error [19], resulting in no solution in Equation (5). In order to solve this problem, it is necessary to use the selected gradient descent method to calculate the solution that makes Equation (5) approximate.

A coordinate position of the book tag to be perceived in the environment of the intelligent digital library without human service is selected, and Equation (6) is used to determine the distance between each reader and the coordinate point of the book to be perceived as follows:

$$d_{0i} = \sqrt{[(x_0 - x_i) + (y_0 - y_i) + (z_0 - z_i)]^2}. \quad (6)$$

The actual distances d_i and d_{0i} between the book tag and the i th reader are subtracted to obtain the error w_{0i} .

After perceiving the relevant information of the intelligent digital library without human service, it can use the network transmission module to transmit the perceived data to the data storage and analysis module and store it. Data mining technology is used to analyze the perceived data, and realize different smart services according to the analysis results.

2.3. Data Storage Analysis of Intelligent Digital Library without Human Service Based on Data Mining. Based on the perceived data information of the intelligent digital library without human service, a personalized service-oriented big data mining process of the intelligent digital library without human service is designed, as shown in Figure 2.

According to Figure 2, data mining, also known as knowledge discovery in the database, is a hot topic in the field of artificial intelligence and database research. It helps decision-makers adjust market strategies, reduce risks and make correct decisions. In the big data mining implementation scheme shown in Figure 2, the main modules are divided into data collection, role modeling, algorithm implementation and result storage, and front-end application. Role modeling, algorithm implementation, and result storage belong to the offline part, and the online part involves data collection and front-end application [20].

2.3.1. K-Means Clustering Algorithm. The clustering algorithms in the process of data analysis stored in the intelligent digital library without human service mainly include hierarchy-based, partition-based, and density-based algorithms [21], among which the most commonly used and effective is the partition-based K-means clustering algorithm. Its specific implementation process is given as follows:

- (1) Firstly, randomly select k vectors as the center of each class.
- (2) Let E be a two-dimensional membership matrix of $c \times n$. If the j -th vector x_j belongs to class i , the element e_{ij} in matrix E is 1, otherwise, it is 0. That is, for each $k \neq j$ and when $\|X_j - C_i\| \leq \|X_j - C_k\|$, e_{ij} value is 1, otherwise the value of e_{ij} is 0.

FIGURE 2: Implementation process of data mining.

- (3) Calculate the value of objective function J according to e_{ij} , and stop if it is less than a threshold or the difference between two consecutive times is less than a threshold.
- (4) Calculate the center C_i of each cluster G_i according to e_{ij} : $C_i = \sum_{i \in G_j} X_i / |G_i|$, and G_i is the number of elements in the cluster. Then go back to step (2).

Although K-means algorithm has attracted much attention due to its advantages such as simplicity and efficiency, it still has some limitations, mainly as follows:

- (1) Clustering results are excessively dependent on the selection of initial values [22], and the accuracy and stability of clustering results are poor
- (2) The algorithm is very sensitive to outliers [23], and there are large errors in the clustering results

2.3.2. Improved K-Means Algorithm. To solve the above-mentioned problems, an improved K-means algorithm based on the principle of natural nearest neighbor density and maximum-minimum distance is proposed to optimize the selection of initial clustering centers. Starting from the internal distribution characteristics of the stored data in the intelligent digital library without human service [24], the algorithm can adaptively determine the data density, avoid the problem of artificial parameter setting, and objectively and truly reflect the distribution characteristics of the stored data in the intelligent digital library without human service, so as to find a high-quality initial center to solve the disadvantage that the initial center point randomly selected by the traditional K-means algorithm is not representative. At the same time, it can eliminate the influence of outliers on

the clustering results, so as to improve the accuracy and effectiveness of the final analysis results when clustering the relevant data of the intelligent digital library without human service. The improved algorithm flow is given as follows.

Step 1. For the relevant data set of the intelligent digital library without human service, find out the natural nearest neighbor of the relevant data sample point x_i of each intelligent digital library without human service according to the natural nearest neighbor search algorithm, and determine the density function of the relevant data points of each intelligent digital library without human service. The equation is given as follows:

$$d_e(x_i) = \frac{1}{\sum_{x_j \in NN_{nb(i)}(i)} k_i(x_i, x_j)} \times n_b(i). \quad (7)$$

In Equation (7), $n_b(i)$ represents the number of times that the relevant data sample points of the intelligent digital library without human service appear in the r neighborhood of the relevant data sample objects of the other unserviceable smart digital libraries, that is, the number of natural nearest neighbors of sample i , $NN_{nb(i)}(i)$ represents the natural nearest neighbor set of the relevant data points of each intelligent digital library without human service, and $k_i(x_i, x_j)$ is the European distance between the relevant data points x_i and x_j of the intelligent digital library without human service.

Step 2. Delete the relevant data sample points of sparse intelligent digital library without human service satisfying condition to obtain the relevant data intensive sample point set X' of an intelligent digital library without human service.

Step 3. Select the highest density in X' , i.e., x of $dens_{\max}(x)$, as the first initial clustering center c_1 ; the longest distance mentioned above is the standard [25], to look for the second center point c_2 ; and so on until we get k initial clustering centers $C = \{c_1, c_2, \dots, c_k\}$.

Step 4. Calculate the attribute weight of the dataset.

Step 5. Calculate the weighted Euclidean distance between all the relevant data sample points of the intelligent digital library without human service and the k initial cluster centers obtained in step 3, where $x \in X$ and $c \in C$. Assign each relevant data point of the intelligent digital library without human service to the nearest center [26], forming k clusters, and each cluster is represented by its cluster center.

Step 6. Recalculate the cluster center according to the clustering results of step 5.

Step 7. Repeat step 5 with the results in step 6 as input until the cluster center does not change or the cluster reaches the maximum number of iterations.

Step 8. Output k class clusters.

It can be achieved through the abovementioned process.

3. Experimental Results

This paper studies the development strategy of the intelligent digital library without human service in the “Internet +” era. Taking the University Library as the research object, this paper adopts the development strategy to build an intelligent digital library without human service and verifies the actual performance of the development strategy studied in this paper through experiments. The results are given as follows.

3.1. Functional Test. The main content of the functional test is to test the performance of book borrowing and automatic return under the development strategy studied in this paper. In order to ensure the robustness of book borrowing and automatic book return to the input content, the black box test method is adopted based on the functional requirements of different module designs.

3.1.1. Performance Test of Book Borrowing. The black box test method is used to test the book borrowing function under the development strategy of this paper. The test cases, expected outputs, and actual outputs are shown in Table 1.

According to the analysis of Table 1, under the development strategy of this paper, book borrowing first needs to scan the user’s library card to determine the user’s identity. After determining the identity of the book borrower, it needs to scan the books to bind the relevant information of the book borrower (library card number) and book information (ISBN number), and then click the OK button to complete the book borrowing. According to the analysis of Table 1, the book borrowing function under the development strategy of this paper can identify whether the user’s relevant information (library card number) is registered or not, judge the upper limit of books that can be borrowed according to the user’s relevant information (library card number), and prompt “user does not exist” for unregistered users.

The actual output of the relevant test cases in Table 1 is completely consistent with the expected output, which shows that the book borrowing function under the development strategy of this paper meets the expected requirements.

3.1.2. Performance Test of the Automatic Book Return Module. The black box test method is used to test the automatic book return function of the research object under the development strategy of this paper. The test cases, expected outputs, and actual outputs are shown in Table 2.

Analysis of Table 2 shows that the automatic book return function under the development strategy of this paper can identify whether the books exist, whether they are borrowed, whether they are returned, and the location of the returned books. The actual output of the relevant test cases in Table 2 is completely consistent with the expected output, which shows that the design of the automatic book return function under the development strategy of this paper meets the expected requirements.

3.2. Position Perception Error Analysis. Select different types of books (poetry books, astronomy books, and medical books) and analyze the perception results of book sample location data under the development strategy of this paper. The results are shown in Figures 3–5.

From Figure 3 to Figure 5, under the development strategy of this paper, the position perception error of different types of book samples in different directions is controlled within 4.5 cm, which is significantly lower than the standard position perception error threshold of 10 cm generally recognized in relevant fields. The reason is that this method designs a personalized service-oriented big data mining process for unattended smart digital libraries based on the perceived data information of unattended smart digital libraries, which is conducive to controlling errors to a certain extent. This shows that under the development strategy of this paper, the position perception accuracy of different types of book samples is higher.

3.3. Data Mining Performance Analysis. Taking the user information in the research object as an example, according to the cluster center obtained from the clustering results, the medical book users are divided into five interest groups, and the clustering accuracy under different K values is analyzed. The results are shown in Figure 6, the specific situation of clustering division is shown in Figure 7, and the book recommendation is realized according to the user clustering results, and results are shown in Figure 8.

According to the analysis of Figure 6, under the conditions of different K values, the clustering accuracy of the method in this paper shows a trend of gradually increasing at first and then significantly decreasing. When the K value is increased from 3 to 8, the clustering accuracy of this method is improved from 93.5% to 98.5%; with the continuous improvement of K value, the clustering accuracy of this method gradually decreases. When the K value reaches 12, the clustering accuracy of this method will be less than 90%. This shows that the optimal clustering accuracy can be obtained when the K value in this method is 8.

After the user’s interest group division results shown in Figure 7 are obtained, the borrowing record data of “Tonghao” users in the interest group can be analyzed as part of the reference basis for recommendation in the next step. For example, for target user 07, who likes traditional Chinese medicine, find out the most similar users in the interest group (user 33 and user 48), And recommend the relevant borrowing of these users to the user (see Figure 8). According to the analysis of Figure 8, most of the data borrowed by users 33 and 48 are borrowed by user 07, which shows that this method can effectively realize the intelligent recommendation function.

4. Recommendations

In view of the current development status of China’s intelligent digital library without human service, this paper puts forward the following suggestions for the development of intelligent digital libraries without human service.

TABLE 1: Test cases and output of book borrowing function.

Test case ID	Expected output	Actual output
1	Please scan books	Please scan books
2	Please scan the library card	Please scan the library card
3	Wrong library card number input	Wrong library card number input
4	Exceeding the maximum borrowing amount	Exceeding the maximum borrowing amount
5	Borrowing succeeded	Borrowing succeeded

TABLE 2: Test cases and output of automatic book return module.

Test case ID	Expected output	Actual output
1	Return the book successfully	Return the book successfully
2	The ISBN number of this book does not exist	The ISBN number of this book does not exist
3	Please scan books	Please scan books
4	The book has been returned	The book has been returned
5	This book is placed in column X of XX cabinet in XX district	This book is placed in column X of XX cabinet in XX district

FIGURE 3: Poetry books.

FIGURE 5: Medical books.

FIGURE 4: Astronomical books.

FIGURE 6: Clustering accuracy under different K values.

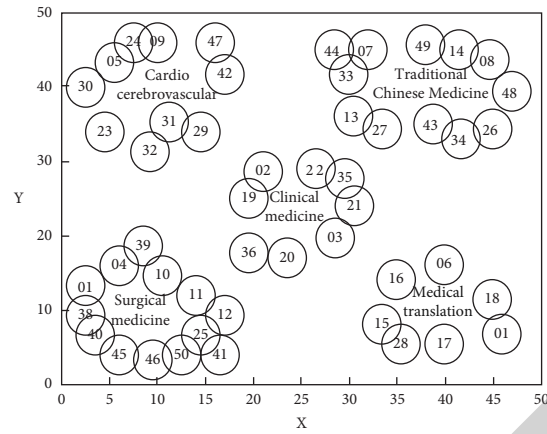

FIGURE 7: Clustering results.

FIGURE 8: Recommended results (a) User 07. (b) User 33. (c) User 48.

4.1. Strengthening Top-Level Design and Formulating the Action Plan of "Internet + Library". "Internet +" has become a new engine to promote social, economic, and cultural development. The state council, provinces and cities, and industries have successively formulated "Internet +" action plans. "Internet +" also has a profound impact on libraries and promotes the transformation and development of libraries. Libraries should seize the opportunity, strengthen top-level design, scientifically formulate the "Internet + library" action plan, clarify the objectives, paths, and key measures of library transformation under the "Internet +" background, explore the implementation scheme of the "Internet + library" action plan and accelerate the deep integration of the Internet and libraries; it should strive to explore the impact of "Internet +" on library service concept, service mode, resources, organization, management, etc., have the courage to break down various obstacles incompatible with the development of "Internet +," speed up the reform process, stimulate innovation vitality, and improve service efficiency and efficiency. In this regard, Zhejiang Provincial Public Library is at the forefront of national libraries. In July 2015, Zhejiang Library, together with 11 municipal public libraries in the province, jointly released the "Internet +" action plan of Zhejiang Public Libraries, proposing to make library services more accessible through cross-border integration, make resources easier to find, enrich resource supply, and enable the public to enjoy more fair, efficient, high-quality and convenient public cultural services.

4.2. Establishing and Improving the System and Articles of Association to Ensure the Storage Security of Digital Information Resources. In order to improve the service quality of digital library and ensure the effectiveness of information resources, colleges and universities need to constantly update the mechanism and concept, do a good job in the resource management and development of digital libraries, give full play to the role and value of digital library, and realize the goal of scientific management of digital library. In order to improve the service quality and order of digital library, during the construction of the university library, it is necessary to build an information resource service system, based on the interaction of administration, economy and law, give full play to the advantages of administrative and economic means, and give full play to the role of the legal system, so as to fully implement administrative, economic and legal standards, establish and improve systems and mechanisms, and form a service system for rational use and efficient management of information resources.

At the same time, it is necessary to do a good job in the management of professional equipment and computer equipment. In order to maintain and test the security of digital library in time and ensure the security and efficiency of electronic resources and network information, we should give full play to our own advantages, strengthen the management of electronic equipment and computer equipment, build and optimize the rules and regulations system so that it can have a legal basis. In the library service of colleges and

universities, only by doing a good job in the management planning of digital literature and information resources can the computer application level be improved, the digital and information resources can be stored safely for a long time, the utilization and development of information resources can be done well, and the scientific and technological achievements can be fully combined with social development so that the library service of colleges and universities can develop toward the direction of digital society and actively adapt to the digital era.

4.3. Making a Good Job in the Construction of Service Content. The digital library of colleges and universities has the characteristics of ubiquity and digitization. College teachers and students can obtain information for the first time in different environments and at different times. In order to ensure the scientificity and rationality of information construction, it is necessary to do a good job in the construction of information resource service content.

4.3.1. Providing Information Independently. This is an intelligent service mode. The service effect of information resources is good, and college teachers and students are in a passive receiving state. To predict the information of college teachers and students, it can analyze the topics of interest, analyze the information needs of college teachers and students and the contact and rules of information resources, and push the content of interest for college teachers and students, so as to provide information independently, mainly in the form of information push and data mining.

4.3.2. Transmitting Information Automatically. This information resource transmission mode focuses on the system construction mode. In the system construction, the intelligent construction function is added to achieve the goal of personalized service. After university teachers and students give keywords, intellectualization can respond in time, and provide a large amount of information resources and effective product information for university teachers and students after inquiry, sorting, collection, and arrangement. Information transmission is the main form of information automation. It increases the timeliness of information interaction and reflects the advantages of digital technology and information technology.

4.4. Increase Expenditure and Make a Good Job in Team Building.

- (1) Colleges and universities should do a good job in software and hardware construction, improve the expenditure on software and hardware, adjust and optimize the collection structure of the digital library, and reasonably divide the comparison between e-books and paper books. It also needs to reduce paper financial expenditure, give full play to the advantages of network resources, and increase the storage of e-book resources. During the construction of the digital library, it is gradually

transitioning from traditional library construction to digital library construction, to formulate a reasonable system and planning scheme, and constantly adjust the collection policy, information purchase, literature planning, and other work. In the document collection scheme and planning, we should improve the collection of electronic information text and increase the financial expenditure on electronic document information, so that the electronic document information resources occupy a large proportion in the library, which is conducive to the development of comprehensive digital library services.

- (2) Do a good job in team building. Paying more attention to the construction of a talented team is conducive to the realization of personalized and professional services of University Digital Library. It should introduce professional and technical personnel and management talents, realize technical and orderly management and improve the professionalism and gradient of talent structure. As for the digital library, it is different from the previous libraries. It does not need a large area of space, does not need to build a large number of reading rooms, changes the previous paper reading form, and realizes the goal of electronic reading. Therefore, colleges and universities can transfer the network resource information and digital information collected by the library itself, or act as the supporter and guides of the network resources of the digital library, and use guidance and training to make readers increase their ability to obtain network resources and improve the ability to obtain digital information resources. In detail, colleges and universities need to enrich the level of talents, educate and train librarians in network technology and digital technology, enhance the quality of librarians, establish a reward and punishment system, employ advanced technicians, and give full play to the maximum service goal of a digital library.

5. Conclusion

This paper studies the development strategy of unmanned intelligent digital libraries in the era of "Internet +" and draws the following conclusions:

- (1) The book borrowing function under the development strategy of this paper can identify whether the relevant information of users has been registered.
- (2) The actual output under the development strategy in this paper is completely consistent with the expected output, indicating that the automatic return function design under the development strategy in this paper meets the expected requirements.
- (3) The position sensing errors of different types of book samples in different directions are controlled within 4.5 cm, and the accuracy of position sensing is high.
- (4) The proposed method can obtain the optimal clustering accuracy and effectively realize the intelligent recommendation function, with strong practical application performance and more convenient and efficient service for users.

Data Availability

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding this work.

In the current environment of globalization, the communication between people is gradually getting closer, and the society is becoming more and more complex. With the continuous development and progress of science and technology, people are more skilled in applying science and technology to their own concerns. College students are about to enter the society, will feel multiple pressure from family, school, and society, study and life problems will gradually convert into mental health problems, and we need to use machine learning basketball exercise to positively affect the mental health quality of college students. The improvement of living conditions makes people pay more attention to their physical and mental health, and learn to use machine learning sports reasonably, not only basketball exercise, to improve mental health diseases. However, we need to use machine learning to identify the different effects of different basketball exercise intensity on mental health, in order to ensure that the most appropriate basketball exercise intensity brings good aspects to the mental health of college students. Through the investigation and data sampling, it can be concluded that the machine learning-based basketball exercise intensity has a positive impact on the mental health of college students.

1. Introduction

With the continuous development and progress of society, people pay more attention to their physical and mental health, not only due to physical health but also pay more attention to mental health. In the social environment with the rapid development of computer networks, the use of machine learning for emotion recognition has attracted wide attention. People care about the body of their family and friends. Emotional recognition has very broad application prospects in many fields of medical care, online education, and other fields. The designed emotion recognition algorithm is essentially a multi-classifier integration algorithm to achieve better results by integrating classical machine learning classifiers. After the data information collected by the sensor is processed centrally, it is inserted into the algorithm of emotion recognition for calculation. The calculated results are analyzed and the results are displayed, and the long and short results are summarized to provide guidance for the subsequent research path and direction [1].

This article introduces the data types and sources of machine learning for us, introduces a variety of machine learning algorithms, combined with the actual situation in the field of mental health, improve different machine learning algorithms, recognize its advantages and disadvantages, combined with the advantages of traditional psychological tools and machine learning to machine learning in the field of mental health. Finally, it is summarized to play a positive role in effectively solving the prevention of psychological problems [2].

Basketball as a kind of aerobic exercise is an important way to improve mental health problems and maintain mental health problems. After years of research, many research results have shown that basketball can improve psychological problems. This article is to study whether the intensity of basketball exercise has an impact on the mental health of college students. The machine learning method and statistical research results show that the different intensities of basketball exercise will indeed have different positive effects on the mental health of college students. But we need

more experiments to support this result [3]. In the moderate exercise intensity group and no exercise group, they had interpersonal social interaction, anxiety sensitivity, more than depression paranoia, and psychosis, which was in line with the comparable conditions in statistics. Through the experiment, small-intensity basketball has improved interpersonal social fear and other symptoms to a certain extent [4]. It discusses the influence of basketball exercise intensity on the mental health of college students, provides guidance methods and related research materials for college physical education activities, and concludes that basketball sports of different intensity can improve the mental health of college students [5].

Sports and mental health are interrelated. They restrain and influence each other. Strengthening sports basketball can enhance students' interest and learning motivation, and improve the mental health environment of college students. Effective exercise can make college students effectively control their psychological emotions and pressure, and also improve their interpersonal relationships and adaptability to the environment. Therefore, sports have a certain impact on the mental health of college students [6]. The article thinks that sports have a positive guide to college students' psychological problems. This phenomenon will produce different reactions because of the different intensity, frequency, and even time of exercise. Later, the calculation method of machine learning should be used to study the influence mechanism of physical activities on college students [7].

This study discusses the influence of low- and medium-intensity basketball on self-esteem and mental health and provides the basis for physical education and mental health education. There was no difference in self-esteem before and after intervention in the control group. Low-intensity basketball activities have an impact on the mental health of students in the experimental group. After the intervention, students in the moderate intensity group scored lower in obsessive-compulsive disorder, interpersonal sensitivity, depression, phobia and anxiety, mental quality, and general scores. In conclusion, middle- and low-intensity basketball is beneficial to boys' self-esteem and mental health, and the middle-intensity group is better than the low-intensity group [8].

After years of intensive study, the most pressing problem that college students must face is employment. With the sustained development of China's economy and the accelerated pace of social progress, the society's demand for talents comprehensiveness and adaptability is increasing. However, under the influence of long-term exam-oriented education, college students are only satisfied with the required courses at present, resulting in a lack of professional knowledge and the ability to solve practical problems, narrow-mindedness, poor flexibility, creativity, and operational ability. With the significant difference between campus and society, most college students will feel pressure from all aspects when they first enter the society. For example, they lack effective learning methods, have strong social responsibility and self-study ability, have poor understanding and mastery of professional knowledge, poor sense of unity, poor social practice and operation ability, and

poor cognitive ability. Moreover, they often have great communication barriers and cannot correctly evaluate themselves and others [9].

Strengthening sports can improve students' physical quality. Physical and mental exercise is to achieve physical health and mental happiness through physical activities. Academics have long studied the relationship between physical exercise and mental health and reached a consensus that physical exercise has a positive promoting effect. College students are the future talents of this country. Under the national policy of attaching importance to talent building, more and more attention is paid to students' mental health [3]. This study compares the students who use mastery learning methods with those who use nonmastery learning methods [10].

This study aimed to explore the influence of different sports events, intensity, and time on college students' anxiety and depression. College students' sports participation, perceived motor score, and self-rating anxiety scale were discussed in depth. The relationship between the intensity and frequency of basketball exercise and mental health anxiety and depression was studied. Anxiety and depression exist among most ordinary students. College students can take different sports to improve their mental health [11]. Basketball can effectively improve the emotional state and physical level of college students and promote the mental health of male college students [12]. College students' mental health education is playing an increasingly important role in higher education. How to cultivate good mental health through physical education is a difficult problem faced by all educators in China. Let students know more about basketball, and by participating in the basketball team experience, they can improve their social skills, so that college students can better deal with all kinds of social relationships in campus life and study, and build a good mental health quality [13]. Traditional exercise prescription is for physical health, but many current college students need mental health. We should pay attention to how to improve the traditional sports prescription and strengthen their mental health adaptability. Take basketball as an exercise form of mental health prescription [14].

2. Machine Learning Algorithm

2.1. KNN Algorithm. KNN algorithm is one of the classical algorithms in machine learning [15]. Its core idea is that if the K most adjacent samples in the feature space belong to a certain type, the sample also belongs to the current type and has the characteristics of that type. The formula for calculating the distance between the two samples is

$$L_p(x_i, x_j) = \left(\sum_{l=1}^n |x_i^{(l)} - x_j^{(l)}|^p \right)^{1/p}, \quad (1)$$

where P is the variable parameter, when $P=1$, the formula represents the Manhattan distance; when $P=2$, the formula represents the European distance; when $P \rightarrow \infty$ the formula represents the Chebyshev distance.

2.2. Random Forest Algorithm. Random forest algorithm cannot be separated from the decision tree. Random forest algorithm consists of multiple decision trees, and there is no connection between different decision trees. The prediction results of the random forest algorithm are the results of the classification displayed by most decision trees. The random forest algorithm is more accurate and stable compared to the results predicted by a single decision tree.

2.2.1. Detection Process of a Random Forest. The detection of random forest is using a single decision tree to detect characteristic samples step by step, and then uses the minority-obeying majority voting mechanism to judge the final boundary result. The binary segmentation function is defined as follows:

$$h(x, \theta_j) = \begin{cases} 0, & \text{left,} \\ 1, & \text{right,} \end{cases}$$

$$\theta = (k, \tau), h_1(x, \theta) = [x(k) < \tau],$$

$$\theta = (k_1, k_2, \tau),$$

$$h_2(x, \theta) = [x(k_1) - x(k_2) < \tau].$$
(2)

In the formula $h(x, \theta_j)$ —The binary segmentation function at the current node;

θ_j —Characteristic properties and the corresponding threshold of the sample x stored at the node j ;

τ —Threshold value of property k for sample x at node j .

2.2.2. Training Process in the Random Forest. Each decision tree was trained independently. The training sample set of the decision tree includes feature samples and the corresponding artificial labeled samples. Use the Gini exponentially split feature attributes to generate decision trees. The samples are processed as follows:

$$\text{Gini}_j = (S_j^L, S_j^R),$$

$$S_j^L = \{(x, y) \in S_j | h(x, \theta_j) = 0\},$$

$$S_j^R = \frac{S_j}{S_j^L}.$$
(3)

In the formula S_j —The training sample $S_j \in X \times Y$, X at the node j represents the feature sample, and Y represents the marker sample;

Gini_j —The Gini index at the node j ;

S_j^L —A nonboundary sample at the current node j ;

S_j^R —Samples belonging to the motion target boundary;

Redefining the Gini exponential splitting function for the dichotomy case:

$$H(S_j) = \sum_y p_y (1 - p_y),$$

$$\text{Split} = \sum_{k \in \{L, R\}} \frac{|S_j^k|}{|S_j|} H(S_j^k), \text{Gini}_j = H(S_j) - \text{Split}.$$
(4)

In the formula $H(S_j)$ —Split indicators at the nodes j calculated using the Gini index;

y —is a certain structured label, which has a variety of structures;

p_y —Probabilities corresponding to the structured label l ;

Split—Formula representation of the second half of the information gain standard function.

2.3. ID3 Algorithm. The ID3 algorithm is the earliest decision tree algorithm. The information gain is calculated by the following formula:

$$\text{info}(X) = - \sum_{i=1}^n p_i \log_2 p_i,$$

$$\text{info}_A(X) = - \sum_{j=1}^m p_j \text{info}(j),$$

$$\text{Gain}(A) = \text{info}(X) - \text{info}_A(X),$$
(5)

where X is the set of all training samples located at the current node, n is the n species of classification corresponding to the sample set, p_i is the i corresponding probability, m is the m value cases for the attribute A , and p_j is probability that the attribute A is worth j .

2.4. C4.5 Algorithm. ID3 algorithms are prone to fitting with few training samples and more algorithm parameters. In view of this deficiency, Quinlan has improved the ID3 algorithm, and the improved algorithm is called the C4.5 algorithm.

The C4.5 algorithm can disperse the continuous attributes based on the ID3 algorithm and can handle the training data with missing attribute values. C4.5. Definition of the algorithm:

$$\text{Split Info}_A(X) = - \sum_{j=1}^m p_j \log_2 p_j,$$

$$\text{Gain Ratio}(A) = \frac{\text{Gain}(A)}{\text{Split Info}_A(X)},$$
(6)

where m is the m values of the attribute A , $\text{Split Info}_A(X)$ is the amount of information that A contains in the current sample X , and $\text{Gain Ratio}(A)$ is information gain ratio corresponding to attribute A .

2.5. CART Algorithm. The CART algorithm adopts the Gini exponential splitting properties, and the splitting criteria are as follows:

$$\text{Gini}(X) = 1 - \sum_{i=1}^n p_i^2, \text{Gini}_A(X) = \sum_{k=1}^m \frac{N_k}{N} \text{Gini}(K).$$
(7)

In the formula $\text{Gini}(X)$ —The Gini index value of the current sample set X ;

p_i —The probability corresponding to the sample set category i ;

m —Attribute A has m values. The current sample can be divided into m subsets;

N_k —Total number of samples corresponding to the k th subset;

Gini $_A(X)$ —Gini split values for split by attribute A .

2.6. Expectation-Maximization Algorithm. The EM algorithm is an effective method to find maximum likelihood estimation or maximum posterior estimation with hidden variable models [16]. It is widely used in natural language processing, psychology, quantitative genetics, and other problems. The EM algorithm was proposed in 1977 by Arthur Dempster, Nan Laird, and Donald Rubin. The method is simple and effective in operation [17].

Log-likelihood function for a given Gaussian mixture distribution is as follows:

$$\ln p(X|\pi, \mu, \Sigma) = \sum_{n=1}^N \ln \sum_{k=1}^K \pi_k N\left(x_n | \mu_k, \Sigma_k\right). \quad (8)$$

Seek the maximum likelihood estimate of the parameter θ , namely:

$$\theta_{ML} = \arg \max_{\theta} \ln p(X|\theta). \quad (9)$$

Using the EM algorithm to estimate the parameters simplifies the problem.

First, finding the partial guide for the mean μ_k of each component of $\ln p(X|\pi, \mu, \Sigma)$ relative to the mixed Gaussian distribution can obtain:

$$0 = - \sum_{n=1}^N \frac{\pi_k N(x_n | \mu_k, \Sigma_k)}{\sum_{j=1}^K \pi_j N(x_n | \mu_j, \Sigma_j)} \gamma(z_{nk}). \quad (10)$$

Multiplies the above equation by \sum_k^{-1} and rearranges it to obtain

$$\mu_k = \frac{1}{N_k} \sum_{n=1}^N \gamma(z_{nk}) x_n, \quad (11)$$

where N is defined as

$$N_k = \sum_{n=1}^N \gamma(z_{nk}). \quad (12)$$

Through the calculation of the above formula, the mean μ_k of the Gaussian component is the case of the Gaussian mixture distribution. Then, following the same method, $\ln p(X|\pi, \mu, \Sigma)$ for each μ_k , you can obtain

$$\sum_k = \frac{1}{N_k} \sum_{n=1}^N \gamma(z_{nk}) (x_n - \mu_k)(x_n - \mu_k)^T. \quad (13)$$

Observing the equation above shows that the form of the solution of the parameter μ_k in a mixed Gaussian distribution is similar to the solution of the covariance in a single Gaussian distribution.

Finally, the corresponding per-mixing coefficient π_k is obtained by maximizing $\ln p(X|\pi, \mu, \Sigma)$. Specifically, the constraint of π_k can be incorporated into the objective function by introducing the Lagrangian coefficient, subsequently maximizing the new objective function:

$$\ln p(X|\pi, \mu, \Sigma) + \left(\sum_{k=1}^K \pi_k - 1 \right). \quad (14)$$

Similarly, it can be obtained by finding the partial guidance for π_k :

$$0 = \sum_{n=1}^N \frac{\pi_k N(x_n | \mu_k, \Sigma_k)}{\sum_{j=1}^K \pi_j N(x_n | \mu_j, \Sigma_j)} + \lambda. \quad (15)$$

Subsequently, using the characteristic of $\sum_{k=1}^K \pi_k = 1$ to sum the probability π_k of each component, you can simplify the following results: $\lambda = -N$. Bring $\lambda = -N$ into the original to eliminate, and rearrange, and finally obtain

$$\pi_k = \frac{N_k}{N}, \quad (16)$$

where π_k is the mixing coefficient for the k th component in the mixed Gaussian distribution.

3. Status Quo of Basketball Sports in China

As is known to all, basketball has become a well-known popular sport in China. People from primary school students to middle-aged and elderly people participate in basketball. This sport spans all ages and gender races, and everyone gets together to play basketball.

With the development of artificial intelligence and the progress of machine learning methods, in recent years, domestic basketball research has gradually developed in the direction of combining theory and practice. Compared with foreign anaerobic basketball training, aerobic training is more inclined in China. In recent years, with the help of machine learning science concepts and equipment, China has enriched basketball training methods. However, the index system for assessing the level of basketball mainly lies in special speed, strength, and endurance. The research on basketball training in China mainly focuses on physical quality, thus ignoring the mental health state, but the real basketball sport should lie in the comprehensive combination of form, function, and quality, and then the physical fitness level combined with people's health. The difference in basketball exercise intensity not only brings us physical changes but also is a process of physical and mental pleasure, which can shed negative energy and negative emotions.

In the physical education activities of colleges and universities, basketball has always been a hot course, which shows the love of college students for basketball, and observing every college basketball court, is always people, full of, filled with the power of youth. Under the multiple pressure of contemporary college students, basketball is no good way to relieve pressure and relax, so basketball exercise under machine learning can really improve the mental health quality of college students.

Guo Haoran put forward the research [18] on the teaching and education of basketball courses in colleges and universities in the Experimental Research of Introducing Physical Fitness Education on Improving the Teaching Effect of Basketball Public Courses in Colleges and Universities. It means hoping to combine basketball with physical education practice, Add basketball education to physical education, While improving the quality of physical education in colleges and universities while promoting the benefits of basketball exercise, Has the following benefits: (1) is a major breakthrough to improve the traditional sports teaching, Better improve the traditional basketball teaching; (2) Improving the focus of traditional physical education teaching, Pay more attention to the physical and mental health of college students; (3) Better popularization of basketball exercise brings not only the physical benefits, It can also promote the development of mental health.

4. Mental Health Analysis

4.1. Implications of Health and Mental Health. The United Nations Health Organization defines health as: "Health is not only without physical defects, but also with a complete physical, psychological state and social adaptability." Thus, a healthy person is not only a healthy body but also needs a healthy mind. Although there are many controversies in society, even if each person's ideas are different, but mental health is a part of human health.

So what to measure the mental health of college students. Combined with the relevant research at home and abroad, and starting from the actual conditions of the psychological development and mental health of Chinese college students, it should be reflected from the following aspects: (1) healthy and stable mood; (2) strong and brave quality; (3) positive social adaptability; and (4) personality integrity and behavior coordination [19].

4.2. Physical Education Teaching and the Mental Health of College Students. Sports teaching relationship with college students' mental health [20], the characteristics of college students' psychological development, state, motivation development level and master sports knowledge, sports skills, and the main basis of design, arrangement of physical education teaching, reasonable arrangement, and scientific organization sports teaching can make some possibility of psychological development become reality to promote the healthy development of students' psychology. With the progress of sports psychology and the popularization of mental health knowledge, people also gradually realize that physical exercise can not only strengthen physical fitness but also promote mental health.

Physical education teaching is to consciously adjust students' emotions in the process of participation, enhance the communication between students, enhance students' confidence, cultivate the courage to struggle, cultivate a strong will quality, as well as physical education teaching to make students get healthy ideas, and establish healthy behavior. Its main aspects are to promote the development of

students' cognition, promote the development of students' emotions, promote the development of students' will and quality, promote the development of students' personality, slow down stress and improve mental health [21].

4.3. Current Quo of Mental Health of College Students. In the current rapidly developing information age, college students have to bear the triple pressure from their families, schools, and society. According to relevant statistics, about 20% of college students have different degrees of mental health problems, which we should take corresponding positive measures so that college education can cultivate high-quality talents to meet the social development and needs.

However, because of people's high expectations and requirements for college students, their self-concern and life goals, the mental health problems of college students are significantly higher than other groups of the same age, so they must be paid great attention to Colleges and universities are related to the mental health problems of college students. Schools should proceed from reality, carry out a large-scale psychological investigation and in-depth and meticulous research and analysis, use scientific sampling and standards to judge the mental health status of college students, and provide accurate and effective teaching methods for the development of mental health education [22].

4.4. Impact and Effect of Sports on the Mental Health of College Students. As we all know, physical exercise can effectively improve the sensitivity and coordination of the human body. But in fact, this is only one aspect of physical exercise in colleges and universities. In physical exercise, students get exercise not only physical exercise but also mental health exercise, like physical exercise, which is a process of self-improvement in continuous understanding and self-improvement. College students can improve their thoughts, morality, will, emotion, and other aspects through physical exercise. Basketball is an important branch in physical sports [23].

5. Example Analysis

5.1. Experiment Preparation. The 40 students from Chongqing University were selected. Among them, 20 basketball (10 male and female) and 20 ordinary college students (10 male and female) were selected for physical testing and psychological testing.

First, understand the acceptance intensity of basketball at each level and then make basketball prescription for ordinary college students; the basketball teacher is responsible for the guidance, three times a week, 1.5 hours, for 8 consecutive weeks according to the set intensity of fitness activities.

The following data were obtained from the identification survey of the value of physical exercise among 200 random students (Table 1) and the degree of daily physical and mental feelings of college students (Table 2).

It can be seen from Table 1 that most college students have a positive attitude towards physical exercise, and the positive influence of college students on physical activities is relatively

TABLE 1: College students' identification of the value of sports (unit: %).

Content	In full agreement	Largely agree	Disagree	Pussyfoot	Total
Sports can promote physical and mental health	76.8	22.8	0.4	0	100
Sports can enrich your spare time life	65.0	33.3	1.2	0.4	100
Sports can develop good living habits	46.3	46.7	3.7	3.3	100
Sports can relax	44.7	54.9	0.4	0	100
Sports can cause fatigue and affect learning	2.4	8.5	80.9	8.1	100

TABLE 2: Daily physical and mental feeling degree of college students (unit: %).

	Insentience	Sometimes feel	Often feel	Total
Physical fatigue	8.5	81.7	9.3	100
Mental fatigue	10.6	73.2	16.3	100
Feel underexercised	20.3	68.3	11.4	100
Feel that obesity is happening	44.7	37.4	17.9	100

high, indicating that college students have a relative sense of identity for the improvement of physical and mental health of physical exercise, including basketball exercise.

It can be seen from Table 2 that college students usually feel physical fatigue and mental fatigue in daily life. In addition, most students think that physical exercise can bring changes, which proves that contemporary college students have independent personality and positive attitude towards life.

5.2. Basketball Quality Test for Students. As for the statistics of the basketball level of the selected students (Figure 1), it can be seen that very few college students participate in the basketball level and obtain the basketball level certificate.

Considering the difference between basketball special students and ordinary college students at the speed of 5 km/h, Figure 2 shows the right step length of basketball special students is not significantly different from that of ordinary college students, but the left step length of ordinary college students is slightly larger than that of special basketball students. It can be seen that basketball exercise for step length and step width change is not big.

Figure 3 is a comparison of the gait cycle of basketball students and ordinary college students at 5 km/h. The gait cycle of basketball students is less than that of ordinary college students. After a long time of basketball training, basketball exercise has a certain effect on the gait cycle.

Figure 4 shows the statistics of step frequency speed change for special basketball special students and ordinary college students. Step frequency refers to the number of steps per unit time, expressed as in (times/per minute). At 9–13 km/h, with the increasing speed of basketball special students and ordinary college students, the pace frequency also showed an increasing trend. However, the pace frequency of basketball special students is more stable, which shows that basketball exercise has improved the stability of human sports.

5.3. The Impact of Basketball on College Students' Body

5.3.1. Effect of Basketball on Heart and Lung Function. Table 3 is an 8-week basketball training for ordinary college students. Through basketball training, the function

FIGURE 1: Basketball level.

of the body has a significant impact. Before and after 8 weeks of basketball training, the indicators of cardio-pulmonary function of college students after exercise are significantly improved compared with those before exercise. Basketball has a positive impact on improving the body's heart function and promoting the improvement of vascular function.

5.3.2. Influence of Basketball Exercise on the Physical Quality of College Students. As can be seen from Table 4, all the quality tests after exercise are higher than those before exercise. After exercise, the speed of running and 50 meters is significantly higher than before exercise, but the speed of 1000 meters is not much different, indicating that the sensitivity and speed of college students need to be improved, but the endurance is difficult to change. The improvement of pull-up quality shows that the upper limb strength quality of college students needs to be improved. Eight weeks of basketball exercise has a certain impact on the speed, endurance, sensitivity, and the explosive power of the upper and lower limbs of college students. The basic physical quality is improved greatly, and the effect is remarkable.

FIGURE 2: Step length and width of each group at 5 km/h (m).

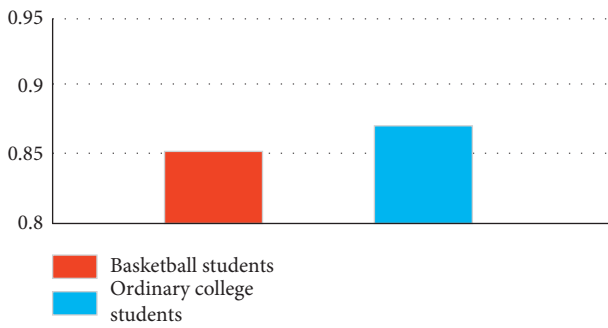

FIGURE 3: Gait cycle of each group at 5 km/h (seconds).

FIGURE 4: Changes in step frequency with speed in each group (times/minute).

5.3.3. *Impact of Basketball Exercise on the Physical Shape of College Students.* As can be seen from Table 5, before and after the basketball exercise, the muscle and bone weight of college students increased, the muscle volume increased, and the bone density and bone mass increased. Body mass index BMI: $18.5 < BMI < 23$ was within the normal range.

5.4. *The Influence of Basketball Exercise on Psychological Problems.* The results of Table 6 were obtained through the investigation:

Through the analysis of the results in Table 6 and Figure 5 above, we can see that the basketball exercise in machine learning has a positive impact on the mental health problems of college students, especially the differences in interpersonal relationships. It shows that the exercise of different intensities of basketball has a significant effect on improving the mental health level of college students. Through the basketball exercise activities, the physical quality and the mental health of college students have been

FIGURE 5: Comparison of SCL-90 test results of students before and after exercise.

improved. Using machine learning methods to achieve different degrees of basketball training intensity can indeed improve the mental health quality of college students [24].

6. Conclusion

In view of the impact of basketball exercise on the mental health of college students, the introduction of machine learning is preliminarily studied, but further research is still

needed. The application of machine learning technology methods, especially decision tree methods, has just started in the field of mental health research and faces many uncertainties and challenges, but it has broad application prospects.

- (1) Aiming at the forefront of machine learning development, we constantly introduce the latest machine learning technology methods. Taking the field of mental health research as the focus of research, we

can compare and analyze the characteristics of different basketball exercise intensity through simulation experiments, so as to further improve the ability of machine learning to judge and simulate the strength of basketball exercise.

- (2) In the face of the doubts in the field of traditional basketball education, to study the interpretability of deep learning. Based on domain knowledge, interpretable machine learning models should be established to promote the development of interdisciplinary research in the field of basketball sports education and mental health research.
- (3) For the basketball exercise fully reasonable use of machine learning technology and algorithm and exercise intensity of test and experiment, for the changes in mental health analysis, take the optimal scheme, not only can improve the students' sports and learning enthusiasm, but can also bring positive influence for college students' mental health.

Data Availability

The experimental data used to support the findings of this study are available from the author upon request.

The scale of wireless sensor networks changes depending on specific application tasks. How to design a relatively simple security mechanism that can extend with the expansion of network scale is an arduous task. As the wireless sensor network mostly adopts the decentralized organization form, once the network nodes are distributed adequately, it is difficult to find out the failure of any node. In addition, the node has weak resistance to physical damage, so any node in the network may potentially become a cause of security vulnerability. In this study, firstly, the security standards that wireless sensor networks should have and the current security challenges faced by the network are discussed in detail, and the importance of security issues in wireless sensor networks is pointed out. Secondly, this paper studies and analyzes the current situation of wireless sensor network security problems including the internal and external attacks and the active and passive attacks. Thirdly, this paper also discusses the significance, concept, and characteristics of reputation and trust, the division and composition of reputation and trust system, and the common applications of the reputation and trust mechanism in wireless sensor networks.

1. Introduction

The objects processed by computer systems are mainly abstract things, and these systems do not have insight into the real physical world. Sensors are able to measure the physical quantities such as temperature, pressure, light wave, velocity, electromagnetic wave, and so on and convert the measurement results into electronic signals. Therefore, for computer systems or computable devices, sensors build a bridge from the abstract world to the real world so that the former can obtain almost all kinds of physical information in the real world. However, different from the traditional wired networks, wireless sensor networks, or WSNs, we usually do not need centralized management or fixed infrastructure such as base station and access point. Sensor nodes form the network automatically, and the network cost is relatively low. Therefore, WSNs can be used in situations where there

is no infrastructure, or for security reasons, the existing infrastructure does not meet certain conditions. Although WSNs are widely used, security and reliability should be the prerequisite for these applications.

In this study, firstly, the security standards that wireless sensor networks should have and the current security challenges are discussed in detail, and the importance of security issues in wireless sensor networks is pointed out. Besides, it is of vital importance to develop new security technologies or modify existing security technologies for wireless sensor networks because some traditional security technologies cannot run directly on the network nodes due to their relatively complex algorithms. Secondly, this paper studies and analyzes the current situation of wireless sensor network security problems including the internal and external attacks and the active and passive attacks. Thirdly, this paper also discusses the significance, concept, and

characteristics of reputation and trust, the division and composition of reputation and trust system, and the common applications of the reputation and trust mechanism in wireless sensor networks.

2. Security Standards and Challenges

In any computer-related environment, security is considered as a nonfunctional requirement, which is not only used to maintain the availability and reliability of the whole system but also related to the protection of information and system. However, in wireless sensor networks, security issues are particularly important because on the one hand, the hardware functions of network nodes are seriously limited, and it is necessary to provide sufficient protection to protect them from malicious attacks; on the other hand, the deployment environment of wireless sensor networks makes it easy for the enemy to obtain sensor nodes illegally and destroy them [1–4]. Any destruction and interference to nodes will have a certain impact on the information obtained in the real world. It is due to the above reasons that WSNs security objectives should have the following standards [5–8], which is shown in Figure 1.

Confidentiality. Confidentiality generally refers to that unauthorized users cannot obtain confidential or sensitive information, such as network routing information, topology information, and node geographic location information. In wireless sensor networks, confidentiality provides a basic security service for the important data transmitted between network nodes. Confidentiality also ensures that the nodes cannot be eavesdropped or tampered by the third party during data transmission. In the specific implementation process, confidentiality is generally achieved by the secret key mechanism; that is, data packets are encrypted at the sender and decrypted at the receiver. Without the relevant secret key, it is difficult for attackers to access the encrypted information. In addition, it should be pointed out that the data transmitted between nodes does not need to be encrypted. For example, only the data part in the packet is encrypted during data transmission, while in other applications, only the header of the packet is encrypted to protect the identity information of nodes.

Availability. Availability ensures that network services exist for authorized users; that is, when authorized users need to use some network services, these services exist and are available. In wireless sensor networks, on the one hand, data availability ensures that all nodes submit data to the base station on time, and whenever necessary, the whole network can provide relevant services. In addition, the availability also ensures that nodes are safe and available in the presence of certain attacks.

Integrity. Integrity makes the data in the whole path between the sender and the receiver without being

changed by the enemy [9]. In wireless sensor networks, the integrity of data is particularly important because the nodes are often exposed and unattended, and the communication channel between nodes is also open. Therefore, the transmitted data are easy to be interfered by the enemy channel making the integrity of the data changed.

Authentication. Authentication enables one party to ensure the legal identity of the other party with whom to communicate, that is, to ensure that the other party is not illegal or fake. In wireless sensor networks, authentication makes the sensing data obtained by the network to come from reliable information sources, and authentication also ensures the reliable identity of communication nodes in the network. In the actual operation of the network, each node should check whether the data it receives come from the real sender.

Data Freshness. Data freshness ensures that the sensing data sent by nodes in wireless sensor networks is up to date rather than out of date. Data freshness also ensures that the data sent by nodes to base stations can reflect the current situation. At the same time, data freshness can also be used to prevent malicious nodes from sending outdated and invalid information [10].

Forward and Backward Secrecy. Because nodes in the wireless sensor network have certain constraints on energy supply, some nodes will quit the network due to energy exhaustion after working for a certain period of time. At the same time, according to different application scenarios, there might be new nodes in the network. Therefore, it is necessary to prevent the exiting nodes from breaking the confidentiality of the network, and similarly, it is also necessary to prevent nodes that have just joined the network from cracking any previously used confidential information [11].

Access Control and Nonrepudiation. Only authorized users can access and use the resources and services provided by the network. Generally, the network should specify the member's permission or the permission group to which the member belongs in advance. Nonrepudiation means that the receiving node cannot deny the data packets it has received, and the sending node cannot deny the data packets it has sent.

The scale of wireless sensor networks will change depending on specific application tasks. How to design a relatively simple security mechanism that can extend with the expansion of network scale is an arduous task. In most cases, it is necessary to find a compromise between the network performance and the of security mechanism. As the wireless sensor network mostly adopts the decentralized organization form, once the network nodes are distributed adequately, it is difficult to monitor the actual working state of each node, and it is difficult to find out the failure of any node. In addition, the node has weak resistance to physical damage, so any node in the network may potentially become a cause of security vulnerability.

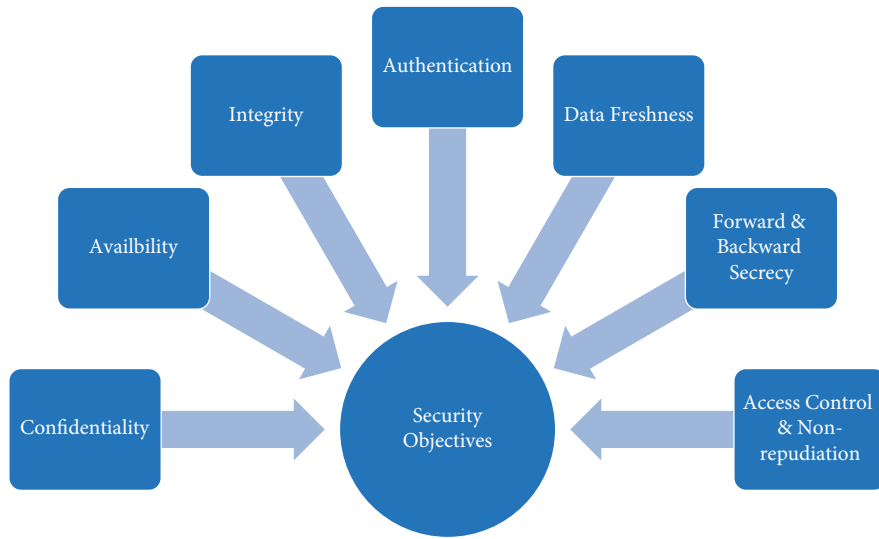

FIGURE 1: Security objectives of WSNs.

3. Internal/External and Passive/Active Attacks

In wireless sensor networks, due to the deployment environment and the limited hardware structure, sensor nodes are more vulnerable to the attacks. Wireless sensor network attacks can be divided into external attacks and internal attacks, and internal attacks are the main security risks of the network. This is because the malicious behavior of nodes in the network or network attacks launched by malicious nodes often disturbs and destroys the normal working nodes in the network. If these attacks are not prevented and handled, they will bring great harm to the whole network. In addition, network attacks can be further divided into active attacks and passive attacks, and active attacks are more harmful in ad hoc wireless sensor networks [12]. WSN attacks are shown in Figure 2.

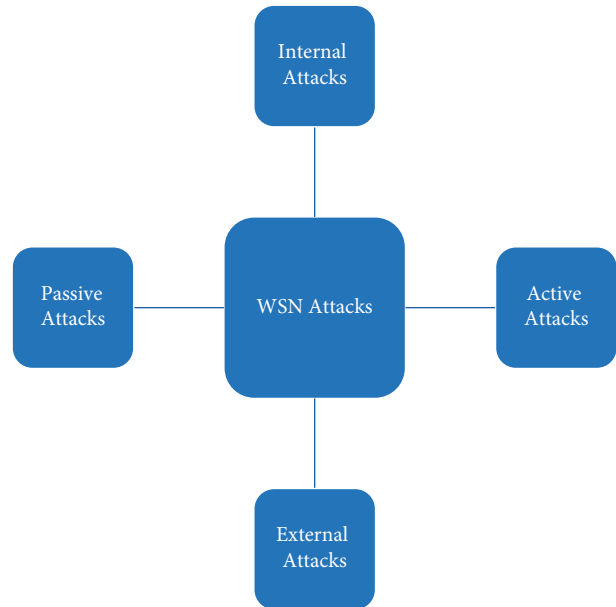

FIGURE 2: WSN attacks.

3.1. Internal Attacks and External Attacks. In wireless sensor networks, all nodes are cooperative entities. External attackers are isolated from the network and have no access to the network. Generally, the impact of attacks launched by external attackers on the network is limited, but once the attacker captures the internal nodes of the network and destroys them, such as programming the captured nodes again to execute malicious programs or using nodes with more computing and storage capabilities to replace the captured nodes, the attacks become internal attacks. In contrast, the internal attack is more destructive to the network because the internal nodes are often regarded as legitimate nodes. Internal attacks are more difficult to detect and prevent; for example, the captured nodes can steal confidential information from encrypted data, transfer false information, and modify routing data.

3.2. Passive Attacks and Active Attacks. In passive attacks, the attacker’s purpose is to eavesdrop on the flowing information in the network without being detected by the system. Through

passive participation in network internal activities, attackers can also obtain a large number of data and conduct data analysis to extract key information. However, due to the lack of clues left by passive attackers, it is difficult to be found.

In active attacks, the attacker can make use of the security loopholes in the network protocol to launch a variety of attacks, such as modifying and deleting the data packets in the routing to make the routing protocol unreliable; for example, in the replay attack, the attacker will maliciously resend the valid routing data packets sent before. The direct result is that the data packets are sent to the wrong destination or make invalid loops in the network, which will eventually lead to network congestion.

Further, a successful active attack by an attacker will seriously damage the function of the network and cause the system to make a wrong judgment and decision. In addition,

the more serious threat comes from the physical accessibility of nodes in ad wireless sensor networks. After the attacker locates the sensor node through the communication information, it captures the node and then obtains the key information and other encrypted contents of the captured node through a certain way. Once the attacker succeeds, the attacker can use the encrypted information to monitor the network or inject illegal information into the network. In addition, malicious nodes will also take the way of impersonating legitimate nodes for active attacks. However, different from passive attacks, since the attacker actively participates in the internal activities of the network, there will be signs of malicious attacks in the network.

Stealthy attack is the most common active attack in the data fusion of wireless sensor networks. Its purpose is to inject false data into the data fusion process and ultimately change the decision of base station nodes. In ad hoc wireless sensor networks, decision-making is usually based on all the data collected by nodes, so once there is false data injection, the whole decision-making result may be changed [13]. In response to stealthy attack, Ref. [14] uses eyewitness nodes to ensure that all fusion data are valid, while in Ref. [15], statistical methods are used to test the effectiveness of the fusion data.

4. Trust Mechanism

4.1. Concept and Definition. In social science, trust can be understood as follows [16–19]: in social networks, trust refers to the behavior that one party voluntarily relies on the other party in a special environment; trust can also be understood as an intention, i.e., one party intentionally relies on the other party.

In the field of computer science, for example, in a routing information request task, the former is the trustor and the latter is the trusted party. When the routing information is successfully transmitted, it is considered to be a node with good behavior, and then its trust value will be increased; on the contrary, when providing wrong routing information, a node is considered as a malicious node, and the corresponding reduced reputation value is applied as a punishment method. In this mechanism, trust is undoubtedly a double-edged sword. On the one hand, it will consume some resources of the system, and on the other hand, it will greatly improve the security of the system.

4.2. Division and Composition of Trust. According to the storage and access of reputation information, the reputation and trust system can be divided into centralized system and decentralized/distributed system. Large e-commerce websites such as Amazon mostly adopt the centralized reputation system and store reputation data in the database associated with websites [20]. For wireless sensor networks, although the centralized reputation system has certain advantages, due to the special structure of network and network nodes, the network system often adopts the decentralized reputation system. In wireless sensor networks, the reputation and trust mechanism has the following characteristics:

- (1) The mechanism of reputation and trust provides incentives for the benign development of node behavior; that is, it makes nodes more responsible for their own behavior
- (2) The reputation and trust mechanism provides the prediction of the future behavior of nodes, which can assist in decision-making;
- (3) The reputation and trust mechanism makes the nodes with good behavior avoid cooperating with the nodes that lack trust. The malicious behavior of nodes leads to the low reputation of nodes themselves, which also makes such nodes have no more opportunities to participate in network cooperation;
- (4) The reputation and trust mechanism is also conducive to the detection of selfish nodes in the network and timely isolation of malicious nodes in the network.

5. Common Applications of Trust

Reputation and trust mechanisms have been widely studied and applied in distributed systems such as ad hoc networks, P2P networks, grid computing, pervasive computing, and e-commerce. In wireless sensor networks, the reputation and trust mechanism can be combined with other network function algorithms to provide better guarantee and service for the network. Specifically, the reputation and trust mechanism can be applied to the following aspects of wireless sensor networks:

5.1. Trusted Data Fusion. In order to ensure the reliability and credibility of data fusion in wireless sensor networks, studies in Refs. [21–33] introduced the reputation mechanism into the network data fusion scheme. In order to deal with the potential malicious nodes in the process of data fusion, combined with reputation management and encryption technology, Ref. [21] proposed a trust-based security data fusion method named blind observation. By adapting the order preserved encryption technology and the sigmoid trust model, the blind observation method can distinguish malicious nodes without decrypting the data sent to the base station and checking the data inside. The security and reliability of data fusion can be ensured by this method. However, in ad hoc wireless sensor networks, the captured or attacked nodes still hold network encrypted information, which is not discussed in Ref. [21].

In order to improve the security of data fusion, Ref. [23] proposed a trust-based intranetwork data fusion method. This method uses the tree data fusion structure and a reputation model based on binomial distribution to detect malicious behavior of nodes. In Ref. [23], the reputation measurement of a node is evaluated by the data it sends, its routing behavior, and its availability. In order to achieve the purpose of reliable data fusion, network nodes only send data to the data fusion nodes whose credibility is higher than the specified threshold value for fusion operation. Although this method may provide security for data fusion, it does not discuss whether the qualified data fusion nodes can rotate to

balance the energy distribution of nodes. In addition to using the tree data fusion structure, Refs. [24, 25] also use the cluster structure. In Ref. [25], the data from the node are weighted according to the reputation of the corresponding node, and the common node selects the fusion point according to the reputation of the data fusion node.

To obtain high quality sensory data, Ref. [28] proposed an energy efficient data fusion method ETA based on the binomial reputation model. ETA adopts the cluster node topology structure and uses the reputation mechanism to select the nodes that meet the requirements as data fusion nodes. In addition, in order to find the best path from ordinary nodes to data fusion nodes, ETA also takes into account the residual energy of nodes on the path and the availability of links. In this method, each node maintains two reputation tables: the reputation table about the link availability of the neighbor node and the reputation table about the data fusion ability of the neighbor node. ETA assumes that the location of each node and base station are known in advance and that there is no malicious node injecting false data in the network. But ETA also has the following problems: each node in the cluster must send its data to the upstream node designated by the base station node, which will increase the complexity of the network; to determine the availability of the link between nodes, each node must send data to its neighbor nodes, which will bring extra cost to the network.

RDAs [22] improve the robustness of data fusion by using the reputation mechanism to identify and isolate malicious nodes in the wireless sensor network data fusion algorithm. The nodes in RDAs adopt the cluster structure and distributed-reputation mechanism. Each node keeps the reputation information of other nodes in the cluster locally and shares the reputation information with other nodes in the cluster. RDAs use LEACH as the underlying data fusion protocol and use the reputation model based on binomial distribution as the node reputation evaluation method.

To ensure the reliability and credibility of data transmitted in WSNs, Ref. [29] proposes a trust evaluation model and data fusion mechanism, which is composed of behavioral trust, data trust, and historical trust. The data trust can be obtained by processing the sensor data, and according to the sensing and forwarding behavior of nodes, the behavior trust is computed. Reference [30] proposes a data fusion and transfer learning empowered granular trust mechanism to handle the data reliability. In order to prevent privacy disclosure and task destruction, a dynamic reward and punishment mechanism is designed to encourage honest users and accurately assess user trust. Reference [31] introduces a data fusion trust model based on rational attributes. It relies on different time attributes to identify the trust of available services, and deep machine learning is used to recursively analyze the attributes and uncertainty characteristics of service providers in continuous shared instances to fuse data with less uncertainty. Reference [32] proposes a trust fusion method consistent with the consortium chain to reach consensus and complete self-organized trust decentralized collaborative learning. In this method, consensus candidates will check others' trust level

to ensure that they tend to integrate consensus with users with high trust. Reference [33] proposes a lightweight privacy protection trust evaluation scheme, which can fully balance trust evaluation and privacy protection under low cost so as to facilitate distributed data fusion.

5.2. Trusted Routing. In wireless sensor networks, all nodes are not only the sender of data sets but also the routing and transmission of data from third-party nodes. Therefore, how to route data to the destination through the reliable transmission path becomes one of the key problems in the design and operation of wireless sensor networks when some nodes in the network behave abnormally and violate the specified standards.

Most routing protocols in wireless sensor networks only consider how to maintain the path connectivity between the source node and the destination node and use methods such as the shortest path or minimum spanning tree to construct the data path. However, the above methods rarely consider whether the intermediate nodes involved in the path will cooperate with other nodes to complete the routing and transmission of data packets. Therefore, it is reasonable to think that some intermediate nodes for their own interests (such as legitimate nodes do not respond to the route to save their energy and illegal nodes tamper with data or selectively discard packets) do not complete the routing or packet delivery task according to the protocol. If the routing protocol in wireless sensor network does not have a method to identify selfish behavior or malicious behavior of nodes, the established path may contain the above two kinds of nodes. Therefore, the path may be unstable, the reliability and integrity of data transmission cannot be guaranteed, and the efficiency of the whole network is also low [34].

In order to improve the reliability and security of routing protocols in wireless sensor networks and protect the network from the influence of abnormal behaviors of nodes, the reputation system is combined with the routing protocols of wireless sensor networks in Ref. [34], and the abnormal behaviors of nodes are divided into two categories: selfish behaviors and malicious behaviors. Different processing methods are adopted according to different abnormal behaviors of nodes, the reputation mechanism based on Bayesian theory is combined into the network routing protocol, and the reliability of each node is evaluated according to the data packet delivery. Finally, the reliable data routing path is established according to the reliability of the node.

According to the observation results of data transmission behavior of nodes, Ref. [34] divides sensor nodes into three categories: friendly, selfish, and malicious. The friendly node will submit the received data packets as they are to ensure the integrity of the submitted data; selfish nodes will randomly discard all or part of the data packets due to their own physical conditions, such as lack of power supply energy, overload, and other reasons, so as to maintain their own physical conditions, and selfish nodes will undoubtedly reduce the reliability of the network; the security and integrity of the network system are often reduced by malicious

nodes modifying the contents of the received data packets or deliberately routing the data packets to the wrong receivers.

Reference [35] proposes a trust model based on node behavior to deal with malicious nodes in opportunistic routing and forwarding candidate set. By using pruning and filtering mechanisms, it deletes malicious suggestions and uses dynamic weight calculation method to combine direct trust and indirect trust to get the comprehensive trust. In order to resist attacks such as black hole and selective forwarding, Ref. [36] proposes a trust aware secure routing protocol to resist these attacks, in which each node calculates the comprehensive trust value of its neighbors based on the direct trust, the indirect trust, the volatility factor, and the residual energy. Reference [37] proposes an atomic search sunflower optimization method to provide trust based routing. The method is designed by combining sunflower optimization with atomic search optimization and uses multiple trust factors to identify and isolate attacks and optimize network performance. By using the Markov chain prediction model, Ref. [38] proposes a reliability trust evaluation model for secure routing based on the combination of internal states of nodes and external interaction between nodes. By selecting security nodes based on tolerance constants and selecting opportunity nodes from security nodes for routing, Ref. [39] proposes a routing algorithm based on energy aware trust and opportunity, which uses multipath routing technology with the multihop communication mechanism within and between clusters.

5.3. Malicious Node Detection. The security threats of wireless sensor networks come not only from external attacks but also from internal attacks of internal nodes. Although traditional security mechanisms such as the encryption mechanism and the authentication mechanism can prevent some external attacks, these security mechanisms are not so effective for attacks launched by internal nodes with abnormal behavior. Reference [40] proposed a malicious node detection mechanism based on the reputation mechanism. This method adopts the reputation model of Bayesian statistical inference and adds the indirect reputation recommendation from the third party. In Ref. [41], the behavior of malicious nodes modifying data packets was identified by every node monitoring each other. By analyzing the signal strength of data readings received by the physical layer of wireless sensor network nodes, Ref. [42] identifies and prevents malicious nodes that send noise to the network and cause channel conflict. Based on the binomial reputation model, Ref. [43] proposed a location aware method for malicious node isolation and deletion in wireless sensor networks.

In addition, in order to effectively isolate malicious nodes, Ref. [44] introduces the reputation system into the routing protocol. Its basic principle is that any node in the network uses a certain mechanism to monitor its neighbors and evaluates its trust value according to the behavior of the monitored node; when the reputation value of a neighbor node is less than the defined threshold value, the neighbor node will be considered as a suspicious node. In this

algorithm, the change of trust value of neighbor nodes only depends on the observer node. Each observer node shares its suspicious node information, so the noncooperative node will be punished soon. However, this method cannot identify the cheating behavior of malicious nodes. It is only a theoretical framework, and no specific and effective reputation evaluation method is given.

To avoid being judged as a malicious node by the reputation system when the reputation value is lower than the predefined reputation threshold value, and finally isolated by the system, some malicious nodes will attack intermittently and maintain good behavior in the period of not launching the attack so as to obtain a good reputation so that their reputation is generally higher than the reputation threshold. In order to solve the above problems, Ref. [45] proposed a malicious node identification method based on node reputation and time series analysis. In this method, malicious suspected nodes with the above characteristics are defined as subaggressiveness nodes. However, this method does not mention which specific reputation model to select nor does it discuss how to combine with the specific reputation model and gives the corresponding test results. It also does not present the specific method of selecting standard time series parameters.

Reference [46] proposes a malicious node detection method based on online learning algorithm. This method first calculates the credibility of each path in the network according to the collected data packets, then models the path reputation obtained through online learning algorithm, and calculates the trust of each node, and detects malicious nodes through the clustering algorithm. The collaboration-based malicious detection mechanism proposed by Ref. [47] includes a data trust module and a reputation calculation module, which ensures honest data communication and reduces the false positive rate of malicious nodes. Reference [48] proposes an effective malicious node detection scheme based on weighted trust, which can detect malicious nodes in clustered wireless sensor networks. By considering the false positive and false negative examples, the node behavior can be truly handled. Reference [49] proposes a method called perceptron based detection, which uses perceptron and K-means method to calculate the trust value of nodes and detect malicious nodes accordingly, and by optimizing the network routing, the detection accuracy is further improved. Reference [50] proposes a blockchain trust model for malicious node detection in wireless sensor networks. It uses the blockchain smart contract, the quadrilateral measurement and the positioning method of wireless sensor network to realize the detection of malicious nodes in the three-dimensional space.

Some common applications of trust are shown in Table 1.

As the sociologist Niklas Luhmann said, "Trust and integrity are necessary in our life, it makes the various components of society integrate into one." Reputation and trust are playing an increasingly important role in human society. In addition, in multiagent systems, due to the uncertainty of agent behavior and in order to protect well-behaved entities from malicious entities, reputation and

trust mechanism have been widely adopted and used as a social method [51]. However, the reputation and trust mechanism cannot be simply attributed to security issues. Security is used to prevent an entity from foreign invasion, ensure that another entity is designated with the entity, ensure that the sender and receiver of the message are designated entities, and prevent information from being illegally obtained by other entities. In contrast, reputation and trust are complex and diversified issues. Reputation and trust not only play a role in decision-making but also provide powerful tools for the establishment of relationships among entities in the insecure real world [43]. The reputation and trust mechanism has become an important supplementary tool for many types of network security solutions.

6. Conclusions

Due to the lack of infrastructure, wireless sensor networks are vulnerable to a variety of attacks. Without adequate security and physical protection, the number and types of applications of wireless sensor networks will be greatly reduced. Therefore, the security problems of wireless sensor networks need to be solved. As an effective supplement to the traditional security mechanism, the reputation and trust mechanism has attracted the attention of scholars and gradually introduced into ad hoc wireless sensor networks. Nowadays, it has obtained extensive theoretical research and application research, such as the selection of trusted routing

path, malicious node identification, and so on. The reputation and trust mechanism can effectively encourage nodes to cooperate and take certain measures to punish malicious behavior of nodes, which not only improves the performance of the network but also enhances the security of the network. In this paper, the security standards and security challenges in wireless sensor networks are discussed in detail. In addition, this paper also discusses the background, significance, concept, and characteristics of reputation and trust, the division and composition of reputation system, and the common applications of reputation and trust mechanism in wireless sensor networks.

In order to improve the library's ability of cross-platform information retrieval and data scheduling and distribution, a library cross-platform information retrieval system based on digital twin technology is designed. Using data warehouse decision support and data source structured query methods, the spectral characteristics of Library cross-platform information resources are extracted. Using the method of Hadoop data parallel loading, the library cross-platform operation data is divided into decision-making data, computing resource pool data, and Hadoop parallel loading data. A library cross-platform information digital twin parallel retrieval and information fusion feature matching model is established, and the retrieval channels are allocated through multiple complex and balanced task scheduling sequences. According to the queue configuration model of Library cross-platform information retrieval, the optimization design of Library cross-platform information retrieval system is realized. The simulation test results show that the designed system has good recall ability of cross-platform information retrieval data, and improves the utilization rate of cross-platform resources and the dynamic scheduling ability of online resources.

1. Introduction

The design of Library cross-platform information retrieval system is based on the analysis of cloud data quality of service (QoS) [1], combined with the load parameter analysis of mesos slave node. The method of dynamic scheduling of cloud resources is used to extract the characteristics of cross-platform virtual resource allocation of the library [2]. Using virtual machine matching and dynamic node adaptive allocation methods, the design of Library cross-platform information retrieval system is realized.

The design of library cross-platform information retrieval system is based on the analysis of the Quality of Service (QoS) of cloud data [3], combined with the load parameter analysis of Mesos-Slave nodes, using the method of dynamic scheduling of cloud resources, extracting the characteristics of library cross-platform virtual resource allocation, and using the methods of virtual machine

matching and dynamic node adaptive allocation to realize the design of library cross-platform information retrieval system [4]. The design methods of library cross-platform information retrieval system mainly include QoS dynamic resource node scheduling method, CaaS (Container-as-a-Service) scheduling method, and particle swarm optimization scheduling method. In 2011, the National Institute of Standards and Technology, NIST) proposes to use Tanimoto coefficient as the characteristic quantity of stable matching between container and virtual machine to carry out cross-platform information retrieval and resource scheduling in libraries, but the adaptability level of this method for cross-platform scheduling in libraries is not high. Reference [5] designed a library information retrieval system based on big data analysis technology. Firstly, the functions of library information retrieval system are described, and the overall framework of library information retrieval system is established; then the hardware subsystem and software

subsystem of library information retrieval are designed in detail, and the library information retrieval algorithm is described in detail. However, this method has a large computational cost, and the reliability allocation ability of physical machine selection is poor [6, 7].

In view of the above problems, this paper proposes a library cross-platform information retrieval system based on digital twin technology. According to the extracted spectrum features of Library cross-platform information resources, a digital twin parallel retrieval and information fusion feature matching model is established. Through the dynamic allocation of multiple complex and balanced task scheduling sequences, the optimization design of Library cross-platform information retrieval model is realized. The experimental results show that this method has better advantages in improving the cross-platform information retrieval ability of the library.

2. Overall Structure Design and Functional Components of the System

2.1. Overall Structure Design of the Cross-Platform Information Retrieval System of the Library. In order to realize the design of cross-platform information retrieval system of library based on digital twin technology, combining with the middleware design scheme, the API Server is established, the Kubernetes node model is stored, combining with the analysis of Web API (API server is an important management API layer of k8s). It is responsible for providing restful API access endpoints and persisting data to etcd server. In the kubernetes cluster, the API server acts as the location of the interaction portal. API server is not only responsible for interacting with etcd (other components will not directly operate etcd, only API server does so) but also provides a unified API call entry. All interactions are centered on API server. Storage kubernetes node model (kubernetes, or k8s for short) is an abbreviation that replaces the eight characters “ubernet” in the middle of the name with eight. It is an open source application used to manage containerized applications on multiple hosts in the cloud platform. Kubernetes’ goal is to make the deployment of containerized applications simple and efficient. Kubernetes provides a mechanism for application deployment, planning, updating, and maintenance. The traditional application deployment method is to install applications through plug-ins or scripts. The disadvantage of this is that the operation, configuration, management, and all life cycles of the application will be bound to the current operating system. This is not conducive to the upgrade, update/rollback of the application. Of course, some functions can be realized by creating virtual machines. However, virtual machines are very heavy and not conducive to portability. The new method is implemented by deploying containers. Each container is isolated from each other. Each container has its own file system. Processes between containers will not affect each other, and computing resources can be distinguished. Compared with virtual machines, containers can be deployed quickly. Because containers are decoupled from underlying facilities and machine file systems, they can be migrated between different clouds and

different versions of operating systems. Containers occupy less resources and deploy faster. Each application can be packaged into a container image. The one-to-one relationship between each application and the container also gives the container greater advantages. Containers can be used to create container images for applications at the build or release stage, because each application does not need to be combined with other application stacks, nor does it depend on the production environment infrastructure, which enables a consistent environment from R & D to testing and production. Similarly, containers are lighter and more “transparent” than virtual machines, which are easier to monitor and manage, and Web API (Message services are conceptually similar to traditional middleware). Due to the technical and commercial complexity, they have not been developed on a large scale. The web-based communication service visible in the short term is Amazon Simple Queue Service. This service facilitates secure and scalable queue based communication between any application. There is no general web computing service black box that can be accessed through API, but there are many technologies pointing in this direction. The first is ALEXA vertical search platform, which will be mentioned more in the search service section below. The second is grid computing, such as sun grid, datasynapse’s gridserver, or platform’s symphony. Encapsulating arbitrary computing tasks in the API is a very challenging task, and it may take many years for this service to become widely popular. Information services provide a large amount of specific information, including geographic data like Google Maps API, product data like Amazon e-commerce, Amazon historical pricing services. and the latest Yahoo! Answer’s API, etc. What these services have in common is that they all provide simple APIs to access massive amounts of data, which may lead to unpredictable cross applications between isolated information. Because of the foundation and dominance of search in the web domain, search services constitute a key part of the new web infrastructure. Google Search API is an earlier and now a typical search abstraction mechanism. Another example is the Alexa search platform, whose design has led to a series of vertical search engines that challenge Google’s position. It is quite interesting that technically, the Alexa search platform is more like a computing service, but it is limited to the search field. This means the possibility of other services, such as sorting services or data transformation services. The last category I broadly call Web2.0 services. The name is not necessarily relevant, but it includes services such as del.icio.us, flickr, basecamp. John Musser compiled some very influential APIs in programmable web. These specific services will become the users of other services mentioned above in the future, but their value is more reflected in the fact that they provide clear, specific, and simple APIs to view and change the information we have. Although they look more like molecules than atoms, they are such basic services in today’s web domain that it makes sense to treat them as components. New web platforms are changing the rules of the game. With the leverage of these infrastructures, it is possible to launch complex and intelligent applications in a very compact time slice. The mere fact that developers do not

have to worry about scaling the problem is encouraging. In other words, Amazon's ten-year experience in large-scale distributed computing was immediately presented to everyone at a very feasible price. It is possible to build intelligent web applications or desktop applications that make full use of the power of these web services because these applications do not have to worry about infrastructure, but focus more on availability, ease of use, context and semantics! Storage API. In order to unify and standardize the operation APIs of these clients, the storage API is introduced. Through the storage API, we can view the available storage space and the used space, and even control whether the user needs to be reminded when the user data are cleared. Harbo functional components. In the early versions, the functions of harbor mainly focused on the management of docker images. Harbor developers hope that users can push and pull images simultaneously through a unified address, and use the graphical interface to browse and manage images. As for the push and pull functions, docker's open source distribution project is widely used. It can support different types of storage, and is relatively mature and stable. Therefore, harbor chooses distribution to handle the push and pull requests for client images, and provides management functions by adding other components around distribution. On the one hand, this method reduces the development workload; on the other hand, since distribution is basically the de facto standard of the image warehouse, it ensures the stability of the image push and pull functions. Later, with the iteration of the version, harbor gradually reduced its dependence on distribution. However, in terms of image read-write, access, and other functions, distribution is still a bridge between harbor and user storage. The random link node forwarding control is adopted to realize the design of ES log service, monitoring service, alarm service, and other functional modules of library cross-platform information retrieval system [8–12]. The specific process is shown in Figure 1.

Data sharing is the key technology of library cross-platform information retrieval, which means that users in different places, using different computers and different software, can read the data stored in other systems, and can perform various operations, calculations, and analyses on library cross-platform information. If you want to share cross-platform information in libraries, you should first integrate cross-platform information and data in libraries. You need to analyze the characteristics of heterogeneous data sources, formulate a series of standards and specifications to realize the standardized design of cross-platform information retrieval system in libraries, and process data to achieve the purpose of integration. On this basis, you should provide access interfaces to users. Users do not need to care about the specific sources of data but only need to get the data they want through the provided data access interface for cross-platform information retrieval in libraries [13]. The data integration system model of library cross-platform information retrieval system is shown in Figure 2.

Library cross-platform information metadata is descriptive information of data and information resources, that is, data describing data. The metadata of HDFS is composed

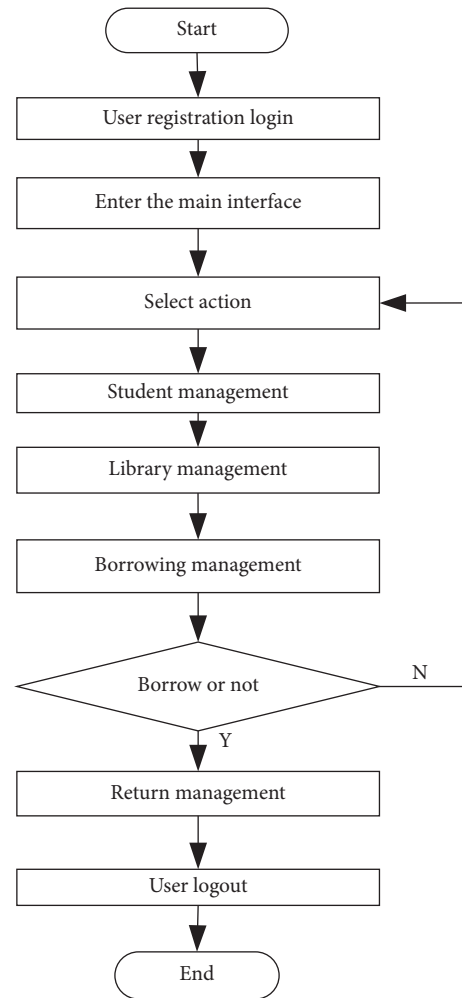

FIGURE 1: Library cross-platform information retrieval flow chart.

of the attributes, affiliation, and distribution location of Block. In HDFS, the management and maintenance of library cross-platform information metadata is completed by NameNode, which is the single failure point of the whole file system [14]. To ensure the reliability of cross-platform information metadata in libraries, HDFS uses two persistent ways, editlog and fsimage, to store metadata in disk. Among them, editlog records the historical information of cross-platform information metadata operation in the library in the form of operation log, and saves it after the record is completed; the fsimage is a kind of stored image file, which is mainly aimed at the checkpoint of regular backup of library cross-platform information metadata in HDFS steps and are expressed as follows: In the application resource pool, on the basis of the resource pool conversion of Slave node, a new log file is generated by the notification of Secondary NameNode, which is deployed in the access and retrieval node, and the data are fed into MySQL. The system logic framework of cross-platform information retrieval in the library is shown in Figure 3.

According to the system logic framework of library cross-platform information retrieval shown in Figure 2, based on image service, authentication service, and ES log

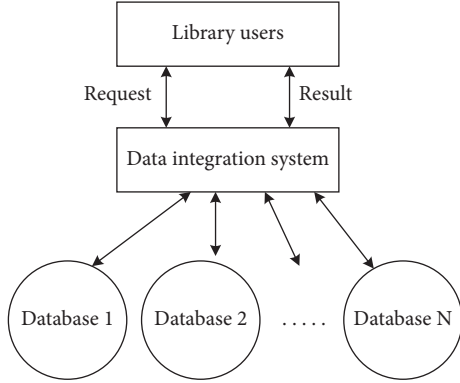

FIGURE 2: Data integration system model of cross-platform information retrieval system in library.

FIGURE 3: System logic framework of cross-platform information retrieval in libraries.

service control methods, the node automatic deployment system model of library cross-platform information retrieval is established [15]. The mirror image of compilation environment is pulled from Harbor warehouse, and Jenkins Master static scanning method is adopted to establish the distribution model of library cross-platform information retrieval system assembly line and core integrated deployment module [16]. The data extraction and program compilation of library cross-platform information retrieval are realized in MySQL underlying cloud database, and the dynamic monitoring model of library cross-platform information retrieval is established from the perspectives of source code construction, code compilation, and image construction, and the architecture diagram of library cross-platform information retrieval system is obtained, as shown in Figure 4.

According to the library cross-platform information retrieval system shown in Figure 3, the data warehouse decision support and data source structured query method are adopted to extract the spectrum characteristic quantity of library cross-platform information resources, and Dockerfile is used to generate the mirror image. The cross-platform information data packet of application library is deployed to Kubernetes cluster, and the functions of creating, configuring, executing, and deleting the cross-platform of library are realized through the module management of application package [17].

2.2. Library Cross-Platform Information Retrieval Module Function Component Analysis. The functional modules of the library cross-platform information retrieval system are divided into mirror compilation sub-module, application deployment sub-module, user interaction module, application package management module, dependency management module, and mirror management module. The specific process is shown in the Figure 5.

Among them, the mirror compilation sub-module is controlled by code version management and generates the mirror image through Dockerfile, which is also within the management scope of Kubernetes cluster. The network design of library cross-platform information retrieval platform is carried out by ZigBee and GPRS networking technologies [18]. The ZigBee data acquisition node of library cross-platform information retrieval is designed as the bottom node of library cross-platform information retrieval system, and the data of library cross-platform information retrieval is uploaded to the central server through GRPS. The original data collection, local information processing, and information fusion of library cross-platform information retrieval are realized at the sensor node [19–21]. The Kubernetes structure diagram of library cross-platform information retrieval system is shown in Figure 6.

In Figure 6, TCP/IP and X.25 protocols are adopted to realize the physical layer access and RF interface output control of the library cross-platform information retrieval system, and the distributed networking scheme is adopted to realize the online scheduling and resource virtualization configuration of the library cross-platform resources under MVB bus control protocol [22].

3. Mathematical Modeling of Cross-Platform Information Retrieval Model in Library

3.1. Feature Extraction of Retrieval Information. Based on the balanced allocation method of library cross-platform information retrieval physical space resources, the balanced allocation of library cross-platform resources is carried out [23], as shown in the Figure 7.

In the cross-platform data computing center of the library, a dynamic allocation model of resources between physical machines and virtual machines is established, and the physical machine set of the cross-platform data center of the library is $G(O) = (V, E, L, \mu, \eta)$, $\eta: E \rightarrow L_E$, and V, E, L, μ, η are the data set of CPU, memory, bandwidth, and hard disk resources in virtual machines, which, respectively, represent the corresponding CPU, memory, bandwidth, and hard disk resource data parameters [24]. Data set $G_1 = (M_1^\alpha, M_1^\beta, Y_1)$, a_{m_i} ($i = 1, 2, \dots, m$) are introduced into different library cross-platform information retrieval container numbers, and the number of hard disk resources as the library cross-platform information center constitutes a feature set. At the information sampling time t and $t + \tau$, the clustering center is initialized to satisfy t_i , so that

$$\begin{aligned} \dot{m}_i(t) &= -a_i m_i(t) + b_i (p_i(t - \sigma), p_2(t - \sigma), \dots, p_n(t - \sigma)), \\ \dot{p}_i(t) &= -c_i p_i(t) + d_i m_i(t - \tau), \end{aligned}$$

(1)

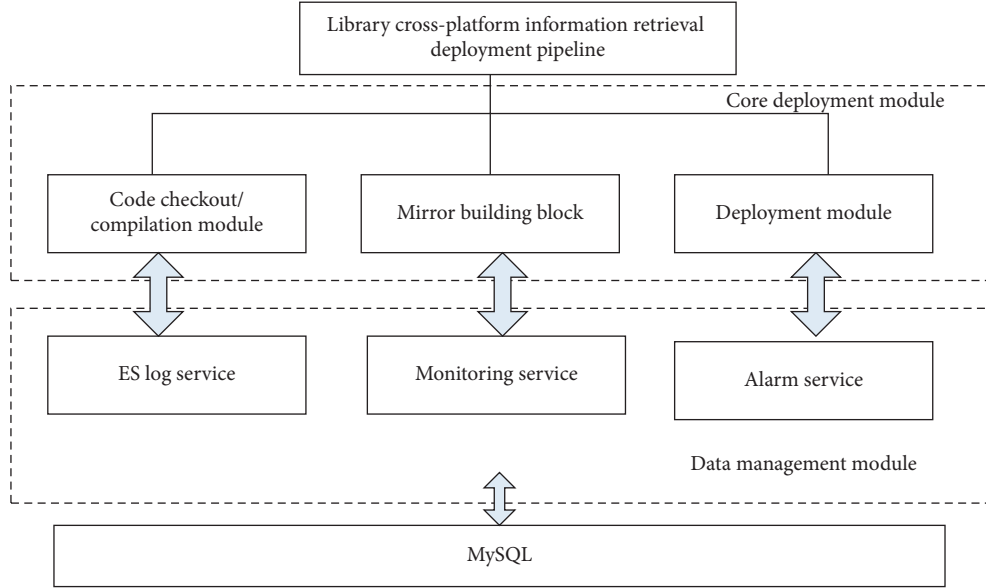

FIGURE 4: Architecture diagram of cross-platform information retrieval system in library.

is the fuzzy clustering center of user behavior attribute data feature vector in library cross-platform information retrieval. The attribute set of library cross-platform storage distribution space is obtained by using the feature sequence training reconstruction method of user behavior attribute data. $B = \{b_1, b_2, \dots, b_m\}$ is the attribute category set of the cross platform information retrieval user behavior attribute data of the library to be mined. Calculate the utilization rate of the physical machine at the time of initialization or migration, and obtain that the central link distribution of the cross platform switch of the library is a_i . The deployment attribute value of the library cross platform information retrieval on the virtual machine M is $\{c_1, c_2, \dots, c_k\}$. According to the deployment of library cross-platform information retrieval nodes on virtual machine M , the information entropy is obtained. By using the methods of information entropy feature extraction and dissimilarity measurement, the resource scheduling fuzzy set $(u, u_t) \in C_t(K, H_x^s \times H_x^{s-1})$ is obtained, the workload sum is obtained, and the CPU utilization rate of the moment is analyzed to obtain the control constraint parameters of library cross-platform information retrieval. The cross-platform running data of the library is divided into decision-making data, computing resource pool data, and Hadoop parallel loading data. By adopting digital twin technology and data clustering method, the digital twin parallel retrieval and information fusion feature matching model of the cross-platform information retrieval system of the library is established, and the information entropy analysis model of the cross-platform resource scheduling of the library is obtained, and the optimized analytical feature components of the cross-platform resource control of the library satisfy:

$$(u_k, \Sigma_k) \sim NiW(v_k, V_k), \quad (2)$$

where in

$$\begin{cases} u_k | \Sigma_k \sim N(\hat{u}_k, \hat{\Sigma}_k), \\ \Sigma_k \sim iW(v_k - d - 1, \Lambda_k), \end{cases} \quad (3)$$

where in $iW(\cdot)$ represents the conduction information function of library cross-platform resource scheduling, parameters v_k and V_k represent the association rule set of library cross-platform resource allocation, d is the information entropy dimension, \hat{u}_k is the load of library cross-platform physical machines, and $\hat{\Sigma}_k$ is the dynamic load balancing parameter of library cross-platform resources. Aiming at the checkpoint of regular backup of metadata in HDFS, the library cross-platform information output rule set of each physical machine is obtained as follows:

$$\begin{aligned} p(x_k | X_{k-1}, Y_{k-1}) &= p(x_k | x_{k-1}, y_{k-1}), \\ p(y_k | X_k, Y_{k-1}) &= p(y_k | x_k), \end{aligned} \quad (4)$$

where in x_k is the sum of the cross-platform information loads of T library, y_{k-1} is the utilization rate of all containers collected by the cross-platform information scheduling server of the library, and X_{k-1} and Y_{k-1} are the simulated minimum physical machine loads and energy consumption, respectively. The cross-platform running data of the library is divided into decision-making data, computing resource pool data, and Hadoop parallel loading data, and the model parameters of cross-platform information retrieval of the library are constructed based on digital twin technology estimation by adopting energy consumption simulation and sorting methods [25].

3.2. Cross-Platform Information Retrieval System of Library. The digital twin parallel retrieval and information fusion feature matching model of the cross-platform information

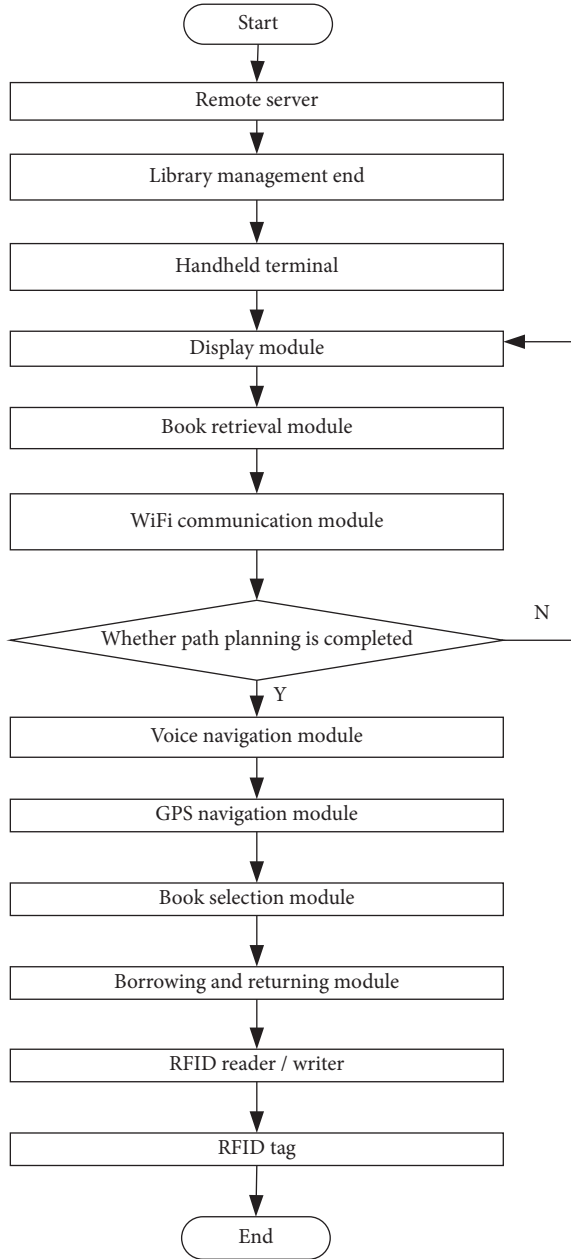

FIGURE 5: Functional component analysis flow chart of library cross-platform information retrieval module.

retrieval system of the library is established, and the four-dimensional parameters of the cross-platform information entropy distribution of the library by the dynamic allocation of multiple complex and balanced task scheduling sequences is given, which are described as follows:

- (1) Random: the random migration target under the guarantee of task service quality.
- (2) FirstFit: the optimization fitness value of library cross-platform scheduling according to the physical machine of the data center.
- (3) MostFull: Calculate the initial target probability density parameters of all available physical machines,

indicating the maximum information entropy under the polling scheduling mechanism.

- (4) LeastFull: Calculate the information entropy and waiting time of all available library cross-platform information.

Based on the construction of 4-dimensional parameters, under multiple Load Balance Service (LBS) mechanisms, the container complex balanced scheduling is carried out. Based on the digital twin technology estimation, the algorithm implementation steps of the library cross-platform information retrieval system are described as follows:

Step 1. Put the idle and closed physical machines into the resource scheduler at the cross-platform resource control end of the library, and get the load parameter X .

Step 2. The task quality mechanism is sorted by the maximum load to obtain the library cross-platform resource feature distribution set E , and the CPU utilization rate of each physical machine in the container E is estimated based on digital twin technology.

Step 3. Move the feature quantity of library cross-platform information retrieval resources in E into X .

Step 4. Set a proprietary conversion engine between the data source and the target data warehouse, and use the round-robin mechanism to calculate the energy consumption of the cross-platform resource retrieval of the library in E , so as to obtain the maximum complex resource ranking.

Step 5. NameNode receives the notification from Secondary NameNode to generate a new log file. Select the physical machine with the smallest simulation value in E .

According to the above algorithm design, the library cross-platform information retrieval channel is dynamically allocated through multiple complex and balanced task scheduling sequences, and the library cross-platform information retrieval queue configuration model [26] is adopted to realize the optimal design of the library cross-platform information retrieval system.

4. Simulation and Result Analysis

In order to verify the application performance of this method in realizing library cross-platform resource scheduling and monitoring, the following experiments are carried out with reference [4] and reference [5] as comparative methods.

4.1. *Establishment of Experimental Platform.* First, the HBase high availability cluster is built. The regionserver of HBase is deployed on the three dat nodes of the Hadoop cluster. Each node backs up each other to ensure high availability of data. HBase's HMaster service is deployed on two NameNode nodes of HDFS, and deploying two HMaster can ensure the high availability of the cluster and prevent single-point failure. Here, an independent ZooKeeper cluster is used, but the ZooKeeper that comes with

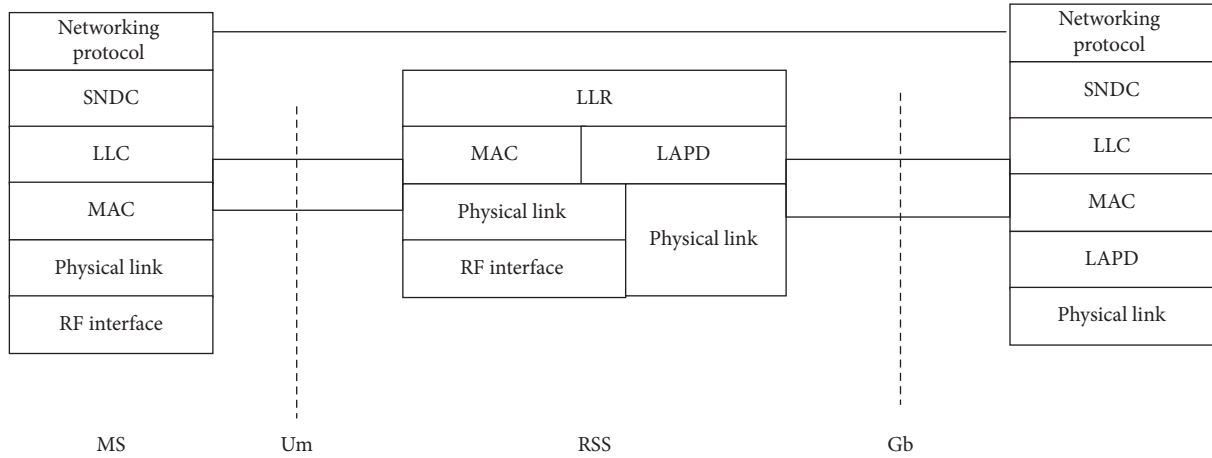

FIGURE 6: Kubernetes structure diagram of library cross-platform information retrieval system.

HBase is not used. When creating an HBase table, if the node failure, thus affecting the whole storage operation.

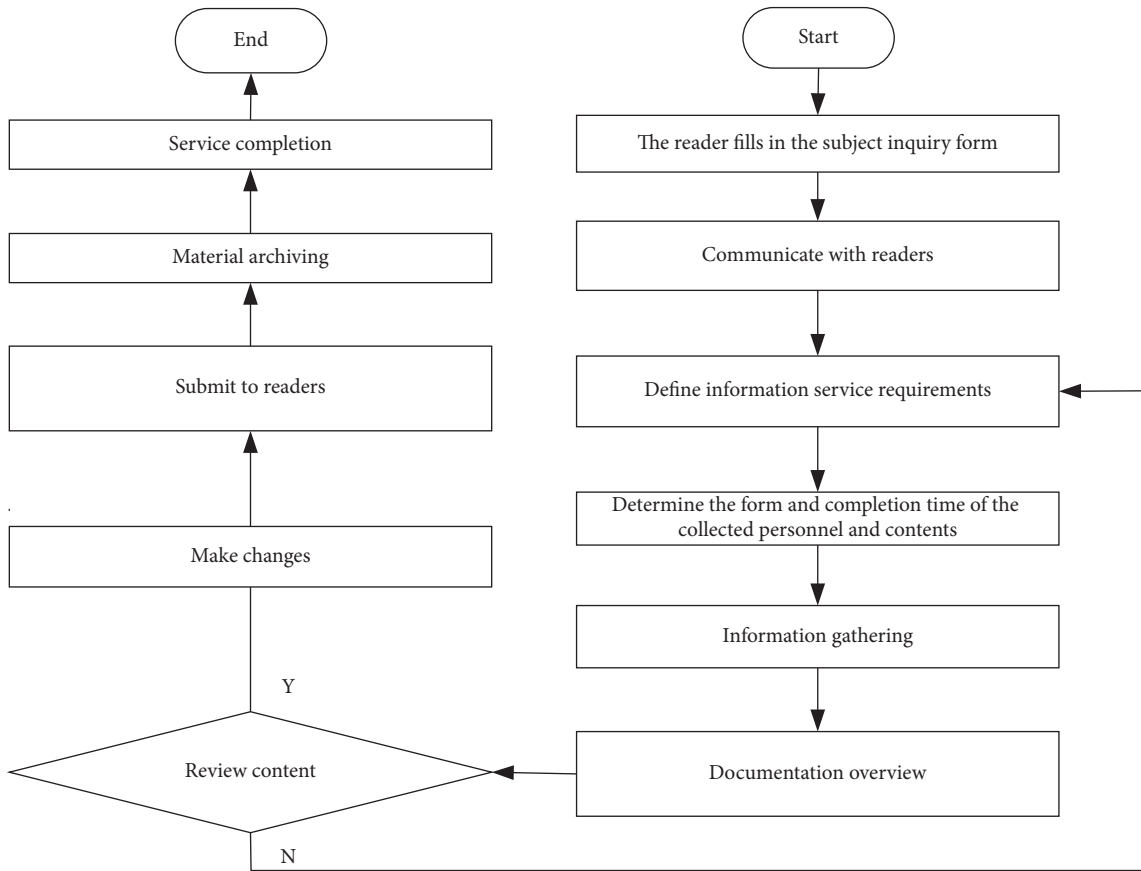

FIGURE 7: Flow chart of feature extraction for cross-platform information retrieval in library.

preallocated Region is not specified, a Region will be created by default. When massive data are written concurrently, all the data will be written into the default Region. Only when it is known that it cannot be loaded will the Split operation be performed, and it will be divided into two regions. In this process, there will be two problems: the data are all stored in one Region, which is prone to single

The underlying disk Split operation will consume a lot of cluster IO resources. Based on this problem, this paper integrates the RowKey characteristics of the cross-platform resource table of the library, designs a reasonable pre-partition scheme, solves the hot issues by creating multiple empty Region in advance, and adjusts the load balance of the cluster. Reasonable design of RowKey can make the

TABLE 1: Task allocation parameters of library cross-platform resource scheduling.

Platform	Memory buffer capacity/mb	Retrieve task queue length/kbps

Platform9	984.799	898.029
Platform10	801.790	151.836

FIGURE 8: Histogram sequence of cross-platform resource allocation in library. (a) Platform1. (b) Platform2. (c) Platform3.

concurrent requests in each Region evenly distributed (tend to be even), so that the IO efficiency can reach the highest. Matlab is used for simulation test. The number of cross-platform nodes in the library is 1200, the length of cross-platform information resource distribution sampling in the library is 1024, the number of training samples is 200, the data size is 800 Mbyte, and the maximum memory buffer capacity of each library is 5600. See Table 1 for the task allocation parameters of cross-platform resource scheduling in the library.

4.2. Cross-Platform Resource Allocation Histogram of Library. According to the parameter configuration in Table 1, the library cross-platform resources are monitored, and the histogram sequence of library cross-platform resources configuration is shown in Figure 8.

4.3. Experimental Results and Analysis. According to the library cross-platform resource allocation in Figure 8, the library cross-platform information retrieval queue

FIGURE 9: Convergence curve of resource allocation.

FIGURE 10: Comparative test of resource utilization rate.

configuration model is adopted to realize the optimal configuration of the library cross-platform information retrieval system. Taking the convergence value as the index, the resource allocation of this method is tested after 100 s. The faster the convergence speed is, the better the resource allocation performance of this method is. The convergence curve of resource allocation is shown in Figure 9.

By analyzing Figure 9, it can be concluded that the cross-platform information retrieval of the library by this method has good convergence for resource allocation.

After the application of this method [4] and [5], the library information retrieval resource utilization rate of 100 nodes is tested. The higher the value, the higher the resource utilization rate of the corresponding method and the better the retrieval performance. The comparison results are shown in Figure 10.

Analysis of the simulation results in Figure 10 shows that this method has better data recall ability for library cross-platform information retrieval, which improves the resource utilization rate by 32.3% compared with the traditional method.

5. Conclusions

In order to improve the performance of cross-platform library information retrieval, this paper designs a library cross-platform information retrieval system based on digital twins. The following conclusions can be drawn from the above research:

- (1) This paper constructs an optimized library cross-platform information retrieval and queue scheduling model, and controls and stores the library cross-platform information resource allocation through network server transmission.
- (2) The test shows that the resource utilization rate of information retrieval is higher and the convergence of resource allocation is better in 10 library cross platforms.
- (3) The next step is to refine the library information to further improve the retrieval performance of the design system.

In this paper, a robust tracking control strategy based on the dynamic feedback linearization method is proposed for the nonlinear and highly coupled dynamic characteristics of coaxial unmanned helicopter. The mathematical model of the coaxial unmanned helicopter is determined by fault analysis. Then the high-order state system is dynamically feedback linearized by extending the state variables, and the dynamic characteristics of the zeros are analyzed according to the expected tracking characteristics of the inner loop. The pole placement of the subsystem realizes robust monitoring of height and position commands by designing robust compensators. On this basis, an outer loop proportional derivative controller is designed for the horizontal positioning subsystem to realize position tracking. Loop tracking simulation ensures the good separation characteristics of feedback linearization method, and trajectory tracking simulation under fault conditions ensures the control ability and durability of the designed controller.

1. Introduction

Under the background of decentralized consensus optimization, composite proxy networks work together on a common decision variable to minimize the sum of their local target activities and limit the information exchange between neighbors. To do this, check the problem first, and then apply Alternating Direction Method of Multipliers (ADMM). In this method, individuals are iteratively calculated and data are exchanged among neighbors. It is found that this method converges rapidly and is considered to be sustainable [1]. For convex optimization problems, we propose an extended Lagrangian method, in which the cost function is the sum of two terms, one of which can be separated into variable blocks and the other lies between continuous variable blocks [2]. Loop is an effective algorithm for solving complex monotone inclusion and convex optimization problems, which consists of many simple blocks. Promoting PRS and ADMM can automatically adapt to the regularity of the problem and provide an

improved worst case without convergence regularity. All results are obtained through simple techniques [3]. ADMM is widely used to solve structural cone optimization problems. This paper proves that ADMM is a widely used method for solving large-scale multiblock optimization models, and it can also achieve good convergence [4]. ADMM odds are one of the most effective and successful methods to solve different combinations. Multiblock ADMM is a natural extension of ADMM and a general pattern that is very useful for solving various nonconvex optimization problems. Finally, we propose simulation studies and practical applications to support the correctness of the theoretical statements [5]. In this paper, a sPADMM method is proposed to solve the minimization problem of three-block separable cones, where the second block is the constraint of strong convex functions and connected linear equations (6). In this paper, the control problem of a new rotor/duct fan helicopter is studied. By observing the response of a helicopter to steering input, it is found that the coaxial duct fan has the general hinge characteristics different

from traditional helicopters, that is, the strong coupling between ascending and tilting, vertical and rotating motions. The simulation results ensure the correctness of the analysis and control scheme [7]. The design process of strong control of a coaxial micro helicopter is introduced. The process begins with the establishment of a nonlinear dynamic model reflecting all the key elements of a helicopter. Then, the position and climb control controllers are designed using the identified and verified models, and successful flight tests are carried out on the actual system [8]. In this paper, two different methods are used to model a new type of small assembled coaxial helicopter. The system is simulated in two ways and controlled by a PID controller. Simulation results show that the method is effective and can be used to design robust controllers [9]. In this paper, two different methods are used to model a new type of small assembled coaxial helicopter. The system is simulated in two ways and controlled by a PID controller. Simulation results show that the method is effective and can be used to design robust controllers [10]. The initial boundary of closed-loop control of the ideal model of a model autonomous helicopter on the arbitrary flight path is considered. In this paper, a theorem is proved, which sets the limits of the initial fault and trajectory parameters in advance to ensure the acceptable tracking performance of the system. The analysis is expected to be used to validate the work design process [11]. Aiming at the serious nonlinear coupling problem of hydraulic flight simulator, a dynamic robust disconnection compensation method is proposed. This method can disconnect without disconnecting the network. Simulation results show the efficiency of disconnecting the controller. The nonlinear coupling problem in the simulator system is repaired [12]. A robust adaptive fuzzy relative-derived inverse dynamic disengagement control based on the fuzzy linear extended state is proposed and applied to trajectory tracking of the two-degree-of-freedom spherical motion mechanism. The simulation and experimental results ensure the high performance of the controller [13]. Based on the high-dimensional nonlinear system model of the gyro-stabilized platform, a robust control design method for multiple input-output objects is proposed based on eigen structure assignment and quantitative feedback theory. Simulation results show that the EA/QFT method enables designers to understand the design process more intuitively and improves the flexibility between system performance and controller complexity. The results show that even if the spacecraft moves violently, the target tracking system still has good resolution and high-tracking accuracy [14]. The purpose of this paper is to monitor the position and trajectory of a three-stage pneumatic muscle-guided parallel robot without the pressure sensor. An adaptive and durable controller based on the pressure sensor is proposed. The experimental results show that the system not only has good steering accuracy and motion stability but also has strong anti-interference ability [15].

2. Unmanned Helicopter Classification

2.1. Unmanned Helicopter with the Rotor Tail Rotor. The rotor-tail rotor in unmanned helicopter is “rotor + tail rotor,” which is the most common unmanned helicopter type,

so it is also called the conventional unmanned helicopter. In the unmanned helicopter with this configuration, a pair of main rotors is used as lifting components on the fuselage, and the rotor traction is adjusted by controlling the common lifting of the main rotors. By adjusting the pitch angle of the main rotor regularly, the inclination angle of the front and rear wings is adjusted, thus controlling the flight of the helicopter. At the same time, a pair of stern rotors is designed in the vertical plane of the tail of the fuselage to balance the reaction torque generated when the rotors turn to the fuselage and realize stability and heading control. The rotor-tail rotor-unmanned helicopter has been proposed, and the related dynamic analysis and flight technology are mature, and the research results are abundant. As shown in Figures 1 and 2, the unmanned Hummingbird A160 T helicopter designed and manufactured by Boeing Company of the United States and the unmanned AV500 W designed and manufactured by China Aviation Industry Corporation both use this assembly design.

2.2. Variable Structure Unmanned Helicopter. When an unmanned helicopter flies forward at high speed, the supersonic speed of the front tip produces shock wave effect, which greatly increases the aerodynamic drag of the rotor and limits the forward speed of the helicopter. Variable lift unmanned helicopter adopts variable lift axis technology, flies at low speed in helicopter mode, and relies on rotor as lift and steering device to realize short-distance or vertical take-off. By changing the direction of rotor rotation axis to fixed-wing flight mode, the flight speed is gradually increased, which avoids the problems of supersonic overspeed and rotor vibration, and thus improves the forward flight speed. Improved from unmanned helicopters. However, this kind of unmanned helicopter has both aerodynamic characteristics of helicopter and fixed-wing aircraft, and its flight mode is complex. The aerodynamic characteristics of each mode are quite different, and its stability is poor, which increases the design difficulty. Flight control system and flight stability. As shown in Figure 3, only the V-22 Osprey tilt-rotor aircraft and V-22 unmanned V-247 tilt-rotor aircraft of Bell Helicopter Company of America were introduced. At present, China has also done a lot of research on tilt-rotor UAV. Figure 4 shows the first self-developed tilt-rotor UAV “Rainbow”-10 displayed in Zhuhai Flight Exhibition 2018.

2.3. Coaxial Unmanned Helicopter. A coaxial unmanned helicopter has two upper and lower rotors rotating in opposite directions, and the direction is controlled by manipulating the torque difference between the upper and lower rotors. The coaxial unmanned helicopter cancels the design and transmission structure of the stern machine, eliminates stern machine failure caused by the stern swing, reduces the weight of unmanned helicopter, and improves the conversion efficiency between the engine and the rotor elevator. At the same time, the fuselage volume of unmanned helicopter is reduced, the structural load is concentrated on the center of gravity, the moment of inertia of helicopter’s

FIGURE 1: "Hummingbird" A160T unmanned helicopter.

FIGURE 5: Ka-52 armed helicopter.

FIGURE 3: V-247 unmanned tilt-rotor aircraft.

FIGURE 6: TD450 coaxial unmanned helicopter.

rising and tilting is reduced, the steering torque of unmanned helicopter is improved, and the maneuverability of unmanned helicopter is improved. Figure 5 shows the Russian armed Ka-52 helicopter installed in the Russian Air Force for high-altitude reconnaissance and low-altitude operations. Figure 6 shows the TD450 coaxial unmanned helicopter developed in China, which is applied in the field of agricultural plant protection.

2.4. Unmanned Helicopter with Circular Duct. In the annular passage, the unmanned helicopter connects the fuselage with the passage and installs lifting components in the annular passage to reduce the aerodynamic drag of airflow to the rotor during flight. Unmanned helicopters usually use coaxial reversing rotors to balance reverse torque in annular pipes. It is characterized by small overall size and high aerodynamic efficiency at low speed. It is widely used in tactical intelligence, signaling, and other fields. As shown in Figures 7 and 8, the Cypher UAV designed by Sikorsky Company. Unmanned MAV aircraft designed by Honeywell

International Company of America and "Golden Eye" produced by Aurora Flight Science Company of America. All UAVs will adopt this structural design.

The unmanned helicopter with a coaxial rotor blower is a new type of unmanned helicopter composed of rotor, duct body, and fan. Different from the annular ducted unmanned

FIGURE 8: Mini ducted fan drone.

helicopter, this helicopter uses the rotor as the main lift device, providing about 70%–80% lift, and the fan in the duct as the auxiliary lift system matches the torque generated by the rotor to realize heading control. The sample unmanned helicopter has the structural characteristics of both the coaxial rotor helicopter and annular ducted helicopter, so it not only retains some aerodynamic characteristics of these two types of helicopters but also has new flight modes and flight control problems that need further study.

3. Introduction of the Classical ADMM Algorithm

3.1. Brief Introduction of the Development of Classical ADMM Algorithm

3.1.1. *Dual Ascending Method.* We first give one of the most commonly used models:

$$\min f(x), \text{ s.t. } Ax = b, \quad (1)$$

where $x \in X$ is an optimization variable, $f: R^n \rightarrow R \cup \{+\infty\}$ is a convex function, A is a matrix of $R^{p \times n}$, $b \in R^p$ is a given vector, and X is a closed convex set in R^n .

The above optimization problem is a linear convex-convex optimization problem. In optimization theory, we do not have algorithms to solve constrained problems directly, but we have many algorithms to solve infinite optimization problems, so our idea is to transform a constrained problem into an unsolvable problem first. The simplest method is the double ascending method. First, according to the constraint condition of binary variable λ , the independent variable X and binary variable λ are updated by using the idea of substitution solution so that the original variable X and binary variable λ are optimal at the same time. The following is a detailed introduction to the steps of solving the optimization problem by Shuang Li's method. First, the Lagrangian function of the optimization problem is constructed as

$$L(x, \lambda) = f(x) - \lambda^T (Ax - b). \quad (2)$$

The dual function of formula (2) is given as

$$d(\lambda) = \inf_x L(x, \lambda) = -f^*(-A^T \lambda) - b^T \lambda, \quad (3)$$

where $\lambda \in R^p$ is a binary variable. The dual problem is given as

$$\max d(\lambda), \quad (4)$$

where $\lambda \in R^p$ also stands for a binary variable. Strong duality assumptions (although minimizing the initial problem $\min f(x)$ is equivalent to maximizing dual problem $\max d(\lambda)$) give the same optimal solution to the initial problem as the optimal solution to the dual problem. Assuming that the optimal solutions of the original optimization problem and the double optimization problem are x^* and λ^* , we have a strong double hypothesis $x^* = \operatorname{argmin}_x L(x, \lambda^*)$; that is, we can get the optimal solution x^* of the original problem through the optimal solution λ^* . In the double ascending method, assuming that the dual function $d(\lambda)$ is differentiable, its gradient $\nabla d(\lambda)$ can be estimated by the following method: first, the updated value is obtained, then $d(\lambda) = \inf_x L(x^{k+1}, \lambda) = f(x^{k+1}) + \lambda^T (Ax^{k+1} - b)$, then $\nabla d(\lambda) = Ax^{k+1} - b$, which is also called the remainder of the difference of difference constraint $Ax = b$. Therefore, the updating process of the Shuang Sheng method is

$$\begin{cases} x^{k+1} := \operatorname{argmin}_x L(x, \lambda^k) \\ \lambda^{k+1} := \lambda^k + \alpha^k (Ax^{k+1} - b), \end{cases} \quad (5)$$

where $\alpha^k > 0$ is the step size, and when the step size α^k is selected correctly, the double function $d(\lambda)$ rises continuously.

Note that the independent variable $x \in R^n$ and binary variable $\lambda \in R^p$ of the original problem are in different linear states, which means that the double ascending method alternately optimizes in two linear spaces R^n and R^p , does not intersect, and develops towards the optimal motion direction. A solution is coming. However, the double slope method also has some disadvantages: if the step size α^k is chosen correctly and the objective function $f(x)$ is strictly convex and strongly dual, both the independent variable x^k and the binary variable λ^k converge to the optimal point, and the original optimization problem and the double optimization problem can reach the optimal solution time at the same time. Unfortunately, many practical problems can not satisfy the assumptions of strict convexity and strong duality of the objective function $f(x)$ at the same time, so the Shuang-Li method is useless at this stage.

3.1.2. *Dual Decomposition Method.* Although the strict conditions of Shuang-Li method are not suitable for solving most practical problems, the Shuang-Li method has a particularly good feature worth exploring. If the objective function $f(x)$ is separable, we decompose the initial problem into many small problems, optimize these small problems, and then integrate them together to achieve full renewal, which is a double decomposition method. Nevertheless, let us take the optimization problem as an example and look at its decomposition form as

$$\min f(x) = \sum_{i=1}^N f_i(x_i), \text{ s.t. } Ax = \sum_{i=1}^N A_i x_i = b, \quad (6)$$

where the independent variable is decomposed into $x = (x_1, x_2, \dots, x_N)$, $x_i \in R^{n_i}$ is a component of the independent variable X , and accordingly the matrix A is decomposed into $A = (A_1, A_2, \dots, A_N)$ and satisfies $Ax \in \sum_{i=1}^N A_i x_i$. Accordingly, the Lagrangian function of formula (6) can be converted into

$$L(x, \lambda) = \sum_{i=1}^N L(x_i, \lambda) = \sum_{i=1}^N \left(f_i(x_i) + \lambda^T A_i x_i - \frac{1}{N} \lambda^T b \right). \quad (7)$$

In a given iterative process, due to the decomposition of the objective function $f(x)$, the x -part problem of (5) can be divided into the following N -part problems, and optimization is carried out at the same time as

$$\begin{cases} x_i^{k+1} := \operatorname{argmin}_x L_i(x_i, \lambda^k) \\ \lambda^{k+1} := \lambda^k + \alpha^k (Ax^{k+1} - b). \end{cases} \quad (8)$$

It can be seen that in formula (8), decomposition and integration operations are performed at each stage. For subproblems $i = 1, 2, \dots, N$ and x_i , simultaneous optimization can be realized independently. In the renewal stage of the binary variable λ , we integrate the decomposed constraint residuals $A_i x_i$ to form the total residuals $Ax^{k+1} - b$. Parallel updating of subproblems of the double decomposition method provides theoretical basis and ideas for the following problems.

3.1.3. Augmented Lagrange Multiplier Method. In order to reduce the assumption of the method and improve the applicability and practicability of the method, the following Lagrange coefficient method is added. The solution of adding Lagrange coefficient is to add quadratic addition term $(\beta/2)\|Ax - b\|_2^2$ to Lagrange function first and the addition delay of formula (1) is obtained as

$$L_\beta(x, \lambda) = f(x) - \lambda^T (Ax - b) + \frac{\beta}{2} \|Ax - b\|_2^2, \quad (9)$$

where $x \in X$ is still the variable to be optimized, and $\lambda \in R^p$ is the Lagrange coefficient. $\beta > 0$ is the penalty parameter of constraint, which is also called penalty coefficient. Let $\beta = 0$ be the general Lagrangian function $L_0(x, \lambda)$ in formula (9), where the additional term $\beta/2\|Ax - b\|_2^2$ plays a major guiding role in the iterative process because after introducing the added Lagrangian function, the optimal solution of formula (1) is transformed into the minimum solution of the extended Lagrangian function (9), which is far from the feasible range, then $\beta/2\|Ax - b\|_2^2$ is larger. The minimum solution of infinite problem (*) or the solution of each iteration x', y' certainly cannot gradually approach the feasible range of the original problem by the limit term $\beta/2\|Ax - b\|_2^2$. When x', y' becomes a realizable point, this realizable point x', y' is the optimal solution of the model. In

fact, the extended Lagrangian function $L_\beta(x, \lambda)$ can also be equivalent to the general Lagrangian function of the following optimization model in the form:

$$\min f(x) + \frac{\beta}{2} \|Ax - b\|_2^2, \text{ s.t. } Ax = b. \quad (10)$$

Obviously, equality (10) corresponds to equality (1) because for every possible solution X in equality (10), there is a penalty term. The dual function formula corresponding to formula (10) of the optimization problem is

$$d_\beta(\lambda) = \inf_x L_\beta(x, \lambda). \quad (11)$$

The introduction of quadratic penalty term $\beta/2\|Ax - b\|_2^2$ makes the dual function $d_\beta(\lambda)$ uniformly separable under the most relaxed conditions. The updating steps of solving the model by the Lagrange coefficient method are given as

$$\begin{cases} x^{k+1} := \operatorname{argmin}_x L_\beta(x, \lambda^k) \\ \lambda^{k+1} := \lambda^k + \beta(Ax^{k+1} - b). \end{cases} \quad (12)$$

The difference between the above formula (12) and Shuang Sheng method is, firstly, the additive Lagrange coefficient method introduces the quadratic addition term $\beta/2\|Ax - b\|_2^2$; secondly, in the double ascending method of α^k , the update step of binary variable λ is E , which is the variable to be redefined in each iteration. In the Lagrange coefficient method, the update step of λ is extended to become β , that is, a fixed value. The increased Lagrangian coefficient method makes up for the deficiency of the Shuang Lift method and converges under looser conditions (for example, when the objective function $f(x)$ does not strictly satisfy the convex attribute). Although the extended Lagrange coefficient method is more applicable, it also makes use of the decomposition property of the objective function $f(x)$, that is, the additive Lagrange method destroys the parallel solution property of the double-lift method and the double decomposition method. In daily multiplication, when the objective function $f(x)$ must be decomposable, the enlarged Lagrangian function $L_\beta(x, \lambda)$ cannot be decomposed, so it is impossible to optimize several smaller x_i -subproblems when solving x -subproblem.

Some scholars put forward the precision ADMM algorithm on the basis of the Shuang Lift method, double scattering method, and Lagrange coefficient method, which will be explained in detail in the next section.

3.2. Introduction to Classical ADMM Algorithms

3.2.1. Classical ADMM Algorithm. Classical ADMM algorithm inherits the advantages of Shuang Lift method, double scattering method, and Lagrangian coefficient method. Especially, because the objective function $f(x)$ of optimization problem is complex, the classical ADMM algorithm is particularly prominent in solving such problems. Next, we give the problem model and basic framework of the classical ADMM algorithm.

We consider the following forms of problem optimization:

$$\min_{x,y} f(x) + g(y), s.t. Ax + By = b, \quad (13)$$

where $x \in X, y \in Y$ is the optimization variable and $f: R \rightarrow R \cup \{+\infty\}, g: R^m \rightarrow R \cup \{+\infty\}$ is a convex function, and these initial problems can be transformed into the form of formula (13) after redefining the variables. For example, given $y = Ax$, the original problem $\min f(x) + g(Ax)$ can be transformed into (13), where $B = -1, b = 0$. In some problems, object functions have good properties such as strictly convex or squared convex functions or having a continuous Lipchitz gradient and so on.

For formula (13), we obtain its augmented Lagrangian function as

$$L_\beta(x, y, \lambda) = f(x) + g(y) - \lambda^T (Ax + By - b) + \frac{\beta}{2} \|Ax + By - b\|_2^2. \quad (14)$$

The basic idea of the classical ADMM algorithm is to obtain the extended Lagrangian penalty function and then solve the original problem by solving a series of subproblems on X and Y and some iterative division as

$$\begin{cases} y^{k+1} := \operatorname{argmin}_y L_\beta(x^k, y, \lambda^k) \\ x^{k+1} := \operatorname{argmin}_x L_\beta(x, y^{k+1}, \lambda^k) \\ \lambda^{k+1} := \lambda^k + \beta(Ax^{k+1} + By^{k+1} - b). \end{cases} \quad (15)$$

Replace the extended Lagrangian function in (15) with Algorithm 1:

Let $k = k+1$ go to step 2.

Compared with the method of adding Lagrange coefficients to update independent variables x and y simultaneously, each iteration of the classical ADMM algorithm can be divided into the following three steps: the first step is to solve the minimization problem related to updating variable y ; the second step is to solve the minimization problem related to updating variable X ; and the third step is to update the Lagrangian multiplier λ . In the updating step, λ is taken as the extended Lagrangian penalty parameter β . The classical ADMM algorithm considers that the objective functions F and G which are separated from the independent variable X . It allows the algorithm to be divided into two subproblems of a variable and alternately update variables X and Y , which are the origin of the inverse multiplication name. In addition, in the classical ADMM algorithm, the order of these two subproblems can be arbitrary: first, solve subproblem y -, and then solve subproblem x -, such as algorithm 1. First, the subproblem can be solved in inverse x -. The order of different solutions has no effect on the convergence of the algorithm. Although alternative upgrades require more steps than general upgrades, because it is easier to calculate the two subproblems of alternative upgrades, the classical ADMM converges faster than other methods, so it is more widely used.

3.2.2. Simplified Form of the Classical ADMM Algorithm. Here is another similar classic ADMM form, which is relatively simple and common in practical application fields. Let $r = Ax + By - b, u = 1/\beta\lambda$ be

$$\begin{aligned} & -\lambda^T (Ax + By - b) + \frac{\beta}{2} \|Ax + By - b\|_2^2 \\ & = \lambda^T r + \frac{\beta}{2} \|r\|_2^2 = -\frac{\beta}{2} \|r\|_2 + \frac{1}{\beta} \|\lambda\|_2^2 + \frac{1}{2\beta} \|\lambda\|_2^2 \\ & = -\frac{\beta}{2} \|r + u\|_2^2 + \frac{\beta}{2} \|u\|_2^2. \end{aligned} \quad (16)$$

Accordingly, the augmented Lagrange function is also equivalent to

$$L_\beta(x, y, \lambda) = f(x) + g(y) - \lambda^T (Ax + By - b) + \frac{\beta}{2} \|Ax + By - b\|_2^2 \quad (17)$$

$$= f(x) + g(y) - \frac{\beta}{2} \|r + u\|_2^2 + \frac{\beta}{2} \|u\|_2^2.$$

By the same token, the iteration of the subproblem is

$$\begin{cases} y^{k+1} := \operatorname{argmin}_y \left(g(y) + \frac{\beta}{2} \|Ax^k + By - b + u^k\|_2^2 \right) \\ x^{k+1} := \operatorname{argmin}_x \left(f(x) + \frac{\beta}{2} \|Ax + By^{k+1} - b + u^k\|_2^2 \right) \\ \lambda^{k+1} := \lambda^k + \beta(Ax^{k+1} + By^{k+1} - b). \end{cases} \quad (18)$$

The simplified form of formula (18) is exactly the same as the original form of formula (15). The simplified form of ADMM is often used in practical applications, but if we want to emphasize the role of binary variables, we must use the original form of ADMM.

3.2.3. Extended Form of the Classical ADMM Algorithm. If the objective function can be decomposed into N parts, the form is

$$\begin{aligned} & \min_{x_1, x_2, \dots, x_N} g_1(x_1) + g_2(x_2) + \dots + g_N(x_N) \\ & s.t. A_1 x_1 + A_2 x_2 + \dots + A_N x_N = b \\ & x_i \in X_i, i = 1, \dots, N, \end{aligned} \quad (19)$$

where $g_i(\cdot), i = 1, \dots, N$ is a convex function of $R^{n_i} \rightarrow R, x_i \in X, i = 1, \dots, N$ is a closed convex set of R^{n_i} , and $A_i \in R^{p \times n_i}, i = 1, \dots, N, b \in R^p$ is a given vector. It is easy to know that the extended Lagrangian function of formula (19)

is $L_\beta(x_1, x_2, \dots, x_N; \lambda) = \sum_{i=1}^N g_i(x_i) + \lambda^T (\sum_{i=1}^N A_i x_i - b) + (\beta/2) \|\sum_{i=1}^N A_i x_i - b\|_2^2$. Similar to the classical ADMM algorithm, we can get the update steps of the extended ADMM algorithm as

$$\begin{aligned} x_1^{k+1} &:= \operatorname{argmin} L_\beta(x_1, x_2^k, \dots, x_N^k; \lambda^k) \\ x_2^{k+1} &:= \operatorname{argmin} L_\beta(x_1^{k+1}, x_2, \dots, x_N^k; \lambda^k) \\ &\vdots \\ x_N^{k+1} &:= \operatorname{argmin} L_\beta(x_1^{k+1}, x_2^{k+1}, \dots, x_N; \lambda^k) \\ \lambda^{k+1} &:= \lambda^k + \beta(A_1 x_1^{k+1} + A_2 x_2^{k+1} + \dots + A_N x_N^{k+1} - b). \end{aligned} \quad (20)$$

In recent years, the ADMM algorithm, which can decompose the objective function into several parts or several subblocks, has become a hot research topic for many researchers, and the research results are of great significance. This provides a very powerful method for dealing with large-scale optimization models.

3.3. Convergence of the Classical ADMM Algorithm

3.3.1. Convergence of the Classical ADMM Algorithm. A typical model of the classical ADMM algorithm is an optimization problem whose objective function is two distinguishable variables. For the model in this chapter, the convergence of the classical ADMM algorithm has been obtained in many literatures. We use the following two assumptions to prove the convergence of the algorithm:

Suppose 1 function $f: R^n \rightarrow R \cup \{+\infty\}$, $g: R^m \rightarrow R \cup \{+\infty\}$ is a closed convex function.

The closed convex property of the function of Hypothesis 1 can also be described by the following equivalent property: A function $f(x)$ satisfies Hypothesis 1 if and only if its graph $\operatorname{epi} f(x) = \{(x, \lambda) \mid (x, \lambda) \in R^n \times R, f(x) \leq \lambda\}$ is a nonempty closed convex set.

Suppose 2 Lagrange function $L_0(x, y, \lambda)$ has stagnation point.

If Hypothesis 1 holds true, then subtasks x - and y - have optimal solutions. In addition, suppose 1 can become infinity when the function is nondifferentiable. Although the optimization problem is set under such loose conditions, the solution of its subproblem can still be found. This secondary programming task is obviously solvable. If Hypothesis 2 holds true, then the optimal solution x^*, y^*, λ^* can be obtained for the two problems mentioned above, and for any x, y, λ satisfying the constraint, the following inequality holds for $L_0(x^*, y^*, \lambda) \leq L_0(x^*, y^*, \lambda^*) \leq L_0(x, y, \lambda^*)$. According to assumptions 1 and 2, the Lagrange function $L_0(x^*, y^*, \lambda^*)$ is limited to each optimal solution x^*, y^*, λ^* . It can be concluded that x^*, y^* is the solution of (13), so $Ax^* + By^* = b$ and $f(x^*), g(y^*) < \infty$. Of course, it can also be concluded that λ^* is the optimal solution, and we do not make additional assumptions about matrices A, B and vector B in constraints nor do we require matrices A and B to have perfect permutation.

The following will give the convergence result of solving formula (13) with the classical ADMM algorithm:

Theorem 1. *In Hypotheses 1 and 2, the iterative generation sequence of the classical ADMM algorithm satisfies what as follows:*

- (1) *When $k \rightarrow \infty$ is the constrained residual set $r^k = Ax^k + By^k - b \rightarrow 0$, the residual converges, that is, the boundary point of the iterative sequence (x^k, y^k) is the feasible point of formula (13).*
- (2) *The objective function is convergent. When $k \rightarrow \infty$, the sequence $f(x^k) + g(y^k) \rightarrow p^*$; that is, the limit point p^* of the objective function sequence is the optimal solution of formula (13).*
- (3) *When $k \rightarrow \infty$ is a set of bivariate $\lambda^k \rightarrow \lambda^*$, the bivariate is convergent; that is, the boundary point of a set of bivariate variables is a double optimum.*

Generally speaking, the higher the accuracy of the classical ADMM algorithm, the slower the convergence speed. Especially in practical applications, we faced quite a lot of large optimization problems. If the accuracy is too high, the convergence speed of the classical ADMM algorithm is very slow. If we want to solve this large-scale optimization problem quickly, our method often meets the accuracy requirements of the algorithm and realizes the fast convergence of the algorithm, thus slowly appearing the inaccurate ADMM algorithm.

3.3.2. Optimal Conditions and Stopping Criteria of the Classical ADMM Algorithm. Generally, the optimization problem satisfies the following relationship as

$$\begin{cases} Ax^* + By^* - b = 0 \\ 0 \in \partial f(x^*) + A^T \lambda^* \\ 0 \in \partial g(y^*) + B^T \lambda^*, \end{cases} \quad (21)$$

and vice versa.

The above formula (21) is called the optimal condition of the classical ADMM algorithm. If x^*, y^*, λ^* is the optimum of formula (13), then formula (21) is satisfied; on the contrary, if there is x^*, y^*, λ^* satisfying (21), it is the best point of (13). In equation (21), the first line is called the initial problem feasibility condition; that is, the best point must satisfy the equality constraint of equation (12); the second and third lines are called dual-use conditions, where Operator ∂ represents the subdifferential or subgradient operators that is described in detail in the previous section.

Specific to each iteration, we have formula (22) defined by x^{k+1}

$$\begin{aligned} 0 &\in \partial f(x^{k+1}) + A^T \lambda^k + \beta A^T (Ax^{k+1} + By^{k+1} - b) \\ &= \partial f(x^{k+1}) + A^T \lambda^k + \beta A^T r^{k+1} \\ &= \partial f(x^{k+1}) + A^T \lambda^{k+1}. \end{aligned} \quad (22)$$

Step 1 Given the initial point $x^0 \in R^n, \lambda^0 \in R^p, \beta > 0, k = 0$
 Step 2 Calculate $y^{k+1} := \operatorname{argmin}_y L_\beta(x^k, y, \lambda^k)$
 Step 3 Calculate $x^{k+1} := \operatorname{argmin}_x L_\beta(x, y^{k+1}, \lambda^k)$
 Step 4 Calculate $\lambda^{k+1} := \lambda^k + \beta(Ax^{k+1} + By^{k+1} - b)$

ALGORITHM 1: Classical ADMM algorithm standalone.

Likewise, we have formula (23) by definition $y^{k+1} = \operatorname{argmin}_y L_\beta(x^k, y, \lambda^k)$ of y^{k+1} as

$$\begin{aligned} 0 &\in \partial g(y^{k+1}) + B^T \lambda^k + \beta B^T (Ax^k + By^{k+1} - b) \\ &= \partial g(y^{k+1}) + B^T (\lambda^k + \beta r^{k+1} + \beta A(x^k - x^{k+1})) \quad (23) \\ &= \partial g(y^{k+1}) + B^T \lambda^{k+1} + \beta B^T A(x^k - x^{k+1}). \end{aligned}$$

The above formula (23) can also be written as the corresponding form $\beta B^T A(x^k - x^{k+1}) \in \partial g(y^{k+1}) + B^T \lambda^{k+1}$, where $\beta B^T A(x^k - x^{k+1})$ is denoted as s^{k+1} , where s^{k+1} can be considered as a residue (double residue) of the double feasibility condition of formula (21). In formula (22), we still have the remaining $r^{k+1} = Ax^{k+1} + By^{k+1} - b$ for the original feasibility condition.

The simplest stop criterion is request $|f(x^k) + g(y^k) - p^*| \leq \varepsilon$, where p^* represents the optimal solution of the objective function and ε is the predetermined precision. But please note that this stop criterion uses a certain value of p^* , and we do not know the value of the optimal solution p^* , so we cannot use this criterion. In practical application, the most commonly used stopping criterion is that when the original residual r^k and the double residual s^k are less than the specified accuracy, the algorithm jumps out of the loop and terminates the iteration as

$$\|r^k\|_2 \leq \varepsilon^{pri}, \|s^k\|_2 \leq \varepsilon^{dual}, \quad (24)$$

where $\varepsilon^{pri} > 0, \varepsilon^{dual} > 0$ is the accuracy of the principal and dual feasibility conditions.

4. Experimental Analyses

4.1. Performance Comparison. In order to make the modeling of coaxial unmanned helicopter more convenient and accurate, we have done five experiments to compare the performance of ADMM, BCD, and ALM in decoupling ability, iterative updating ability, and convergence. The results are shown in Figures 9–11.

Looking at Figure 9, we can see that in terms of decoupling ability, ADMM is the best, followed by BCD and ALM; From Figure 10, we can conclude that ADMM is the best in terms of iterative update capability, followed by BCD and ALM. From Figure 11, we can conclude that ADMM is the best in terms of iterative update capability, followed by ALM and BCD. Therefore, in order to have higher accuracy in the next experiment, we choose the ADMM method.

WL_h	Axis anteversion angle	0 rad
Ω	MR angular rate	190.5 rad/s
m_β	Main blade weight	0.18 kg
N_b	Number of main pulp blades	2
R	Plate radius	0.78 m
c	Chord length of main pulp	0.059 m
θ_t	Blade torsion	0 rad
K_l	Pitch-flap coupling rate	0

4.2. *Direct Measurement of Physical Parameters.* Most parameters can be measured directly, such as weight, length, angle, area, speed, and so on.

The weight of the helicopter rack can be weighed directly, but different tasks have different payloads, and the weight will also change, so consider the center of gravity below.

These directly measurable parameters are displayed in the helicopter assembly group.

It is assumed that all components of France and Italy are on the longitudinal axis of symmetry of the helicopter, so the longitudinal lines intersect, and it is shown in Tables 1–3.

The length of each control arm of the rotor head is measured separately, which is listed in Table 4. By measuring these lengths to determine the value of Bershiller coefficient, compared with other angle measurement methods, the estimation is more accurate.

In this case, gain can be obtained between the inclination changes of the stabilized wing tip as

$$K_f = \frac{L_0 L_7}{L_6 L_5} = 1.859. \quad (25)$$

Because there is no wind tunnel test condition, the frame is approximately a three-dimensional virtual plate, the vertical flow resistance coefficient is about 1, and only the windward side of the body axis is enough in the forward, transverse, and vertical directions. If the helicopter is equipped with shields and other components, the effective aerodynamic drag range within the block can be evaluated according to the relevant discussion of aerodynamic drag of various objects in the references, and it is shown in Table 5.

There are several parameters that are not easy to measure directly but can be estimated from the measured data, as shown in Table 6. The values of M_β , I_β , and I_β^{sb} have an important influence on the swinging dynamics, so it is advisable to divide the main blade and stabilizer bar with winglets into several homogeneous parts with regular geometric shapes, integrate them one by one, and then accumulate them to ensure the estimation accuracy. In the table, the dynamic pressure rates η_{hs} and η_{vf} of stabilizers are based on experience.

4.3. *Maneuverability Analysis of the Coaxial Unmanned Helicopter with the Blower.* It is known that the coaxial rotor blower-unmanned helicopter has introduced a new

R_n	Pulp tip separation from pulp hub	0.312

aerodynamic structure, and its control mode and motion mode are quite different from those of traditional unmanned helicopters, which need to be studied and analyzed. Therefore, this paper chooses hovering mode as the trim mode and tests the maneuvering and motion characteristics of the unmanned helicopter based on the completely nonlinear mathematical model proposed above.

As shown in Figure 12, applying the step signal to the collective rise of the rotor produces a rotational angle, rotational angular velocity, and vertical velocity response. This is due to the increase in the collective rise of the rotor at constant speed, which leads to an increase in lift, which leads to vertical upward acceleration and velocity. Because the vertical downward direction is the positive direction of the $O_b Z_b$ axis in the body coordinate system, the vertical velocity response is a burden with the increase of collective ascent. The vertical speed finally approaches a stable value, which indicates that there is a first-order inertia relationship between the rise of the collective rotor and the vertical speed without the influence of fans. At the same time, the increase of collective distance increases the torque of unmanned helicopters. In the balance of reversing torque or external torque of unventilated helicopter, the unmanned helicopter produces steering angle, and the horizontal steering angle responds to directional motion. This shows that the vertical steering input of the unmanned monster helicopter is of course associated with the heading channel.

As shown in Figure 13, the longitudinal periodic pitch signal input of the rotor will cause pitch angle pitch angular velocity and linear velocity response in the $O_b X_b$ direction while it will also affect the roll angular velocity roll angle and linear velocity in the $O_b Y_b$ direction. The increase of rotor longitudinal periodic pitch leads to positive pitch angular velocity so that the pitch angle increases and the fuselage rises, resulting in the opposite speed to the $O_b X_b$ direction. The negative inclination angle reduces the inclination angle,

and the frame inclines to the left and sideslip occurs, as

FIGURE 12: Rotor total pitch step response.

FIGURE 13: Longitudinal periodic variable pitch step response of the rotor.

FIGURE 14: Rotor transverse periodic variable pitch step response.

FIGURE 15: Variable pitch step response of the fan.

shown in Figure 14.

The structure of the unmanned helicopter with the coaxial rotor blower is completely symmetrical, so the unmanned model helicopter is basically the same in the $O_b X_b$ direction and $O_b Y_b$ direction. The signal input whose distance varies in the longitudinal period has the same dynamic characteristics.

As shown in Figure 15, applying a step signal to the fan pitch causes yaw angle, yaw angular rate, and vertical velocity response. Fan pitch change is the input signal of the heading channel, and the fan and rotor in ducted fuselage reverse coaxially. Controlling fan pitch change can offset the

FIGURE 16: Effect of flight speed on lift distribution.

FIGURE 17: Effect of flight altitude on lift distribution.

antitorque of rotor rotation for fuselage and control the heading motion of the unmanned helicopter through the differential torque between them. Similar to the input signal of the vertical channel, the input signal of the heading channel will also have an impact on the vertical channel, but the effect is smaller than that of the total rotor distance, and it is shown in Figures 16 and 17.

5. Concluding Remarks

In this paper, a robust trajectory tracker based on feedback linearization is designed, which is used for the dynamic model of the coaxial unmanned helicopter. Combined with the existing aerodynamic modeling of the coaxial rotor system, a dynamic model which can reflect the aerodynamic disturbance coupling characteristics between coaxial helicopter rotors is established in this paper. In the altitude subsystem, the dynamic feedback linearization of the subsystem is firstly carried out by extending the state variables and analyzing the zero dynamic stability of the system. Then the pole placement of the disconnected subsystem is carried out, and the robust compensator is designed to improve the strength. Finally, the trajectory tracking is realized by designing the outer loop PD control. Simulation results shows that the designed program has good detachment characteristics and still has good tracking performance and robustness in the presence of various model uncertainties.

Automatic segmentation of coal crack in CT images is of great significance for the establishment of digital cores. In addition, segmentation in this field remains challenging due to some properties of coal crack CT images: high noise, small targets, unbalanced positive and negative samples, and complex, diverse backgrounds. In this paper, a segmentation method of coal crack CT images is proposed and a dataset of coal crack CT images is established. Based on the semantic segmentation model DeepLabV3+ of deep learning, the OS of the backbone has been modified to 8, and the ASPP module rate has also been modified. A new loss function is defined by combining CE loss and Dice loss. This deep learning method avoids the problem of manually setting thresholds in traditional threshold segmentation and can automatically and intelligently extract cracks. Besides, the proposed model has 0.1%, 1.2%, 2.9%, and 0.5% increase in Acc, mAcc, MioU, and FWIoU compared with other techniques and has 0.1%, 0.8%, 2%, and 0.4% increase compared with the original DeepLabV3+ on the dataset of coal CT images. The obtained results denote that the proposed segmentation method outperforms existing crack detection techniques and have practical application value in safety engineering.

1. Introduction

Coal is an important energy source for human society. The phenomenon of deformation and damage of coal and rock mass under load is common, which has a huge impact on the safety of mining engineering. The research on digital core technology based on industrial CT scanning technology is of great significance for the mining safety, and its basis is the high-precision segmentation of cracks in industrial CT scanning images. As the key technology of digital core, 3D reconstruction needs high-precision segmentation results to reflect the original topology of cracks. However, artificial segmentation of coal crack CT images undoubtedly takes a lot of time and energy. And, most of the existing auxiliary software is based on traditional threshold segmentation methods which are still impossible to get rid of the interference of noise even working with some image preprocessing methods. Therefore, intelligent

and automated segmentation of coal crack CT images is particularly important.

Digital images contain a lot of important information, which can be extracted in different ways in different fields. For example, it can be used in the field of encryption technology [1, 2], information security [3–6], in the field of industrial engineering [7], in the field of agriculture [8], and so on. Digital image processing technology includes many categories [9, 10], and image segmentation is one of them. Noise is one of the difficulties in the segmentation of coal crack images. In order to reduce the noise and enhance images, methods that were applied in the segmentation of crack include morphological filter [11], wavelet transforms [12, 13], anisotropic diffusion filter [14], and so on. However, many noises cannot be fundamentally removed by the traditional methods. Machine learning algorithms can achieve automatic crack detection and segmentation to a certain extent including structured forests [15, 16], minimal

path selection [17], support vector machine [18], etc. Nevertheless, most features in machine learning need to be identified by experts and hand-coded. Deep learning models have powerful learning ability which can automatically complete the tasks of classification, detection, and segmentation after training. Starting from FCN [19], many high-performance semantic segmentation models have emerged such as U-net [20], SegNet [21], and PSPNet [22]. These models are based on convolution operations, apply feature extraction networks as backbones, and incorporate multiscale semantic information to achieve pixel-by-pixel segmentation of images. Deep learning methods have been applied in different crack segmentation fields [23–25] nowadays.

In this work, we present an end-to-end coal crack CT image segmentation method based on the deep learning model DeepLabV3+ [26]. Compared with existing deep learning methods, postprocessing is unnecessary for our method. Besides, our method achieves better performance on some evaluation metrics. These advantages are meaningful for the subsequent 3D reconstruction work and the establishment of digital cores.

2. Related Work

All data in this paper comes from the tomograms of high-precision industrial CT during the fracturing experiment of coal samples. The CT scanning equipment is from the Nation Key of Natural Gas Geology and Natural Gas Control of the Henan University of Technology Laboratory which is a phoenix v|tome|xm high-resolution industrial X-ray μ CT scanner [27]. The equipment diagram and CT imaging principle are shown in Figure 1. Images collected by this equipment have many noise points in the coal matrix, and different samples may have different colors. CT image samples of coal cracks are shown in Figure 2. The datasets used for training in this experiment are cut from CT images obtained by the aforementioned platform at different sizes. The diversity of the crack structure is fully considered in the interception process to adapt to the segmentation of different images.

The high performance of deep learning in computer vision was first demonstrated in classification tasks. Many CNN models can provide good classification accuracy such as Vgg [28], ResNet [29], Xception [30], and so on. Some of them are applied as feature extractors in segmentation models. FCN replaces the fully connected layer in the classification model with deconvolution to upsample the pooled feature map to its original size, pioneered semantic segmentation. The application of deep learning in crack detection can be roughly divided into three types, methods based on classification [31], object detection [32], and semantic segmentation [33, 34]. Xue et al. [35] modified the last few deconvolution modules of FCN to adapt to the needs of crack segmentation. However, this FCN-based method may not be able to guarantee the accuracy of segmentation and maintain the original topological structure of the crack when facing the crack of complex structures.

DeepLabV3+ is a high-performance semantic segmentation model derived from DeepLabV1, V2, and V3 [36–38]. In view of the adverse effect of excessive downsampling on segmentation accuracy, this model proposed to use atrous convolution to reduce downsampling and enlarge the receptive field simultaneously. This model also applied atrous spatial pyramid pooling to capture and fuse multi-scale semantic information which is beneficial to improving the accuracy of segmentation. Besides, Encoder-Decoder architecture is used to recover pixels of features better. DeepLabV3+ achieves new state-of-the-art performance on PASCAL VOC 2012 dataset. However, compared with the public semantic segmentation dataset, the crack image dataset has the characteristics of smaller targets and unbalanced positive and negative samples. So we have made some improvements to the original model for these characteristics. The coal crack CT image segmentation method that we proposed has the following contributions:

- (1) Given that there are no publicly available datasets for research in this field, we established a dataset of coal crack CT images for our research. All original pictures come from a professional coal sample fracturing experimental platform and all labels are made by hand marking.
- (2) We modified DeepLabV3+ to adapt to the need for coal crack CT images by adjusting the OS of the backbone, adjusting the encoder-decoder module, and changing the rates of the ASPP module. The modified model achieves better performance than the original model under some authoritative evaluation indicators commonly used in semantic segmentation: PA, MPA, MIoU, and FWIoU.
- (3) A new loss function is defined by combining the CE loss and Dice loss. While adding contour factors to the prediction, the curve fluctuation of the Dice function in the training is alleviated.

3. Methodologies

3.1. Dataset. Since there is no open-source dataset for CT segmentation images of coal crack, we established a coal crack dataset manually. All these images were taken from the original coal fracturing experimental images in different sizes and different length-width ratios. All data were captured in images acquired by high precision industrial CT introduced before. It consists of 437 RGB images and their segmentation labels, including different crack shapes, complexities, and different background colors. Some representative images and their annotations are shown in Figure 3. These samples can reflect the complexity of crack morphology, noise situation, and background differences in the dataset to a certain extent.

Data augmentation is a technique widely used in deep learning. In supervised learning, fine data annotation is a time-consuming and energy consuming work. Data augmentation can expand the dataset so that the parameters learned during model training are more reliable and can effectively avoid overfitting. So we enhanced the coal crack

FIGURE 1: (a) High-precision industrial CT scanning equipment; (b) Schematic diagram of the scanning device.

FIGURE 2: CT image samples of coal crack.

dataset to 5000 in different ways: rotation, flip and zoom. Angles of rotation were limited to -30 to 30 degrees, the flip direction is horizontal and the ratios of zoom were limited to 80% to 120% . Finally, after data augmentation, the training set contains 3500 images and the test set contains 1500 images.

3.2. Atrous Spatial Pyramid Pooling. Atrous convolution can be used to capture multiscale contextual information. The parameter can set different dilation rates of atrous convolution which can be regarded as the stride of the input signal we sample. The output of atrous convolution of a one-dimensional input signal with a filter of length is defined as follows:

$$y[i] = \sum_{k=1}^K x[i + r \cdot k]w[k]. \quad (1)$$

Combined with spatial pyramid pooling, ASPP is applied as a Multiscale information fusion module. The structure which is applied in the DeepLabV3+ model achieved multiscale information collection using four different rates of atrous convolutions (including image-level pooling). Different from the rates of (1, 6, 12, and 18) used in the original

DeepLabV3+, more kinds of combinations of rates were tried using to make the feature extractor more suitable for crack segmentation. As the OS (Output Stride) of the backbone was adjusted to 8 to reduce downsampling, a larger receptive field is required. We tried to make the enlargement of the receptive field follow the size of the feature map output from the backbone. And, the experiment proved that rates of (1, 12, 24, 36) can achieve a better performance. A more intuitive situation about ASPP can be seen in Figure 4.

3.3. Encoder-Decoder. The encoder-decoder structure is widely applied in the field of computer vision. As for the semantic segmentation field, the encoder gains semantic information from images with feature maps reducing as a feature extraction module. DeepLabV3+ model uses DeepLabV3 as the encoder block with some effective improvement. The decoder is applied to reconstruct the segmentation result by restoring the pixel and size of the feature map, at the same time, keeping the details of the original image as much as possible. DeepLabV3+ proposed a simple decoder as shown in Figure 4 and obtained a good effect practically. The first upsampling rate was adjusted to 2 as the OS of the backbone was changed to 8.

FIGURE 3: Some representative images in our datasets, their ground truth, and masks on original images. It shows that these pictures show that our dataset contains data of different sizes, different complexities, and different background color depths at the same time. Diversity allows the model trained on this dataset to adapt to most CT image environmental conditions.

FIGURE 4: Modified DeepLabV3+ model structure. Compared with the original DeepLabV3+ architecture, the OS (output stride) was adjusted to 8, and rates of the ASPP module were adjusted to (1, 12, 24, 36). At the same time, the first upsampling rate is changed from 4 to 2 to restore image pixels to their original size.

3.4. *Adjusted Xception as Backbone.* Xception, as a high-performance convolution neural network is applied as the feature extractor of ordinary DeepLabV3+. This deep structure is developed based on the Inception model and based

entirely on depthwise separable convolution. Unlike conventional convolution, in depthwise separable convolution, each feature map channel only needs to perform an operation with each channel of the convolution kernel. This kind of

convolution can effectively reduce the number of parameters and computing costs, and by using this, Xception expanded the scale of the model and became state-of-the-art CNN architecture in classification tasks. The ordinary Xception has an OS = 32 so that it can adapt to the needs of classification tasks. But excessive pooling makes the feature maps too small so that the detailed information can be damaged. In order to get dense feature maps, the OS of 16 or 8 is desirable.

Different from the OS of 16 which performed better in natural scene datasets, crack images need a denser way to extract features because the targets of these images are tiny in most cases. For these small targets, downsampling has a particularly serious loss of accuracy. So the OS of 8 was used in this model, at the same time, the ASPP was adjusted to get a larger receptive field and the decoder also made corresponding adjustments. To achieve this goal, compared with the Xception structure in the DeepLabV3+ original text, we adjusted the stride of the third block of entry flow to 1, and correspondingly doubled the rate of the atrous convolution in the middle flow and the exit flow. The adjusted Xception structure is shown in Figure 5.

3.5. Loss Function. DeepLab series model apply the cross-entropy (CE) loss function which is widely applied in classification tasks to classify every single pixel. This loss function checks each pixel separately and compares the class prediction (the pixel vector in the depth direction) with the hot encoding target vector. The cross-entropy function can be formulated as follows:

$$L_{ce} = -\frac{1}{N} \sum_i \sum_{c=1}^M y_{ic} \log(p_{ic}), \quad (2)$$

where M refers to the number of categories, y_{ic} refers to the sign function (0 or 1), and p_{ic} refers to the predicted probability that the observed sample i belongs to category c . Thus, we can consider that the pixels in the image are learned equally with the cross-entropy loss function, and this kind of equality does not apply to the situation where the sample is extremely uneven. In coal crack CT images, the number of pixels corresponding to the crack is much smaller than that of the background. Taking the dataset we established as an example, the proportion of crack pixels in the whole image is less than 5%. Dice Loss [39] was proposed in 2016, designed to deal with scenarios where positive and negative samples are strongly imbalanced in semantic segmentation. Different from distribution-based cross-entropy loss, the Dice function is based on region and is used to calculate the similarity between two images. The Dice coefficient and Dice loss function can be formulated as follows:

$$dice = \frac{2|X \cap Y|}{|X| + |Y|}, \quad (3)$$

$$L_{dice} = 1 - \frac{2|X \cap Y|}{|X| + |Y|},$$

where X and Y refer to two different samples, they are ground truth and predict mask in segmentation tasks. In a

different way, the Dice coefficient and the loss function can be formulated as follows:

$$dice = \frac{2TP}{2TP + FP + FN}, \quad (4)$$

$$L_{dice} = 1 - \frac{2TP}{2TP + FP + FN}.$$

Where FP , FN refer to true positive, false positive, and false negative. However, although Dice loss can calculate the similarity of two contours, it may cause the gradient to change drastically, and the training is difficult so it is not credible to a certain extent sometimes. In this experiment, we did a weighted additive combination of CE loss and Dice loss to add contour features to the classification of pixels and avoid the shock of loss in training. The new loss function is formulated as follows:

$$L_{new} = \beta \cdot L_{ce} + L_{dice}, \quad (5)$$

where β is a weight coefficient for adjusting the proportion of CE function. It is a constant in the range $[0, 1]$, and the value of this article is 0.5. The experiment proved that this new loss function effectively improves the accuracy of crack segmentation compared to using the cross-entropy loss function alone.

4. Experiments

All experiments were done in the following environment: Intel (R) Xeon(R) Bronze 3204 CPU @ 1.90 GHz, 32 GB RAM, GPU Tesla V100, CentOS Linux release 7.6.1810. And experiments related to deep learning are completed under PyTorch 1.10.0. We compare the proposed method with existing representative algorithms to the performance of the model on the dataset we established and also compare the visual effects of these segmentation results.

4.1. Metrics. In order to evaluate our work, in addition to the visual effects of segmentation images, we introduced four authoritative evaluation indicators commonly used in semantic segmentation. All experiments are performed on the dataset we established.

Suppose k is the number of categories (background is excluded), p_{ij} indicates that the total number of pixels that are mispredicted. p_{ii} means, p_{ij} means FP and p_{ji} means FN . Four evaluations are

- (1) PA, which means the rate of the number of predicted right pixels to total pixels. It can be expressed as follows:

$$PA = \frac{\sum_{i=0}^k P_{ii}}{\sum_{i=0}^k \sum_{j=0}^k P_{ij}}. \quad (6)$$

- (2) MPA, which means the average pixel accuracy of each category. It can be expressed as follows:

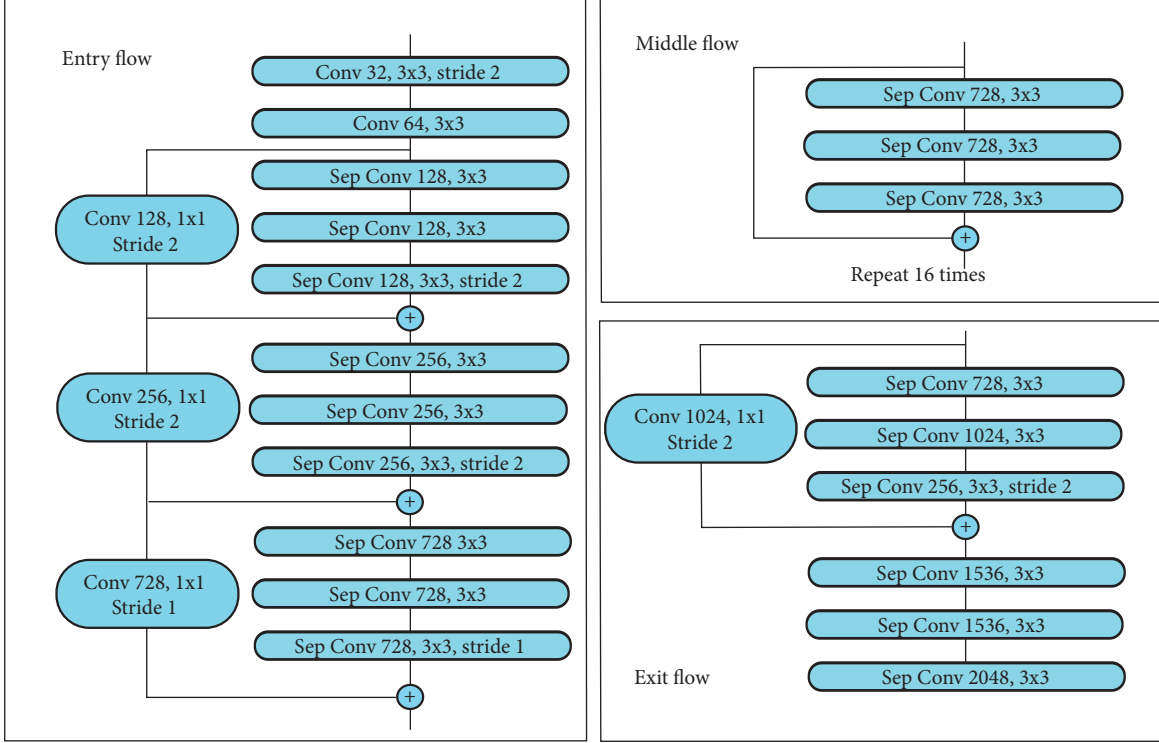

FIGURE 5: Modified Xception architecture. OS of the third block was adjusted to 1 to change the OS of the overall Xception to 8.

$$MPA = \frac{1}{k+1} \sum_{i=0}^k \frac{P_{ii}}{\sum_{j=0}^k P_{ij}}. \quad (7)$$

- (3) MIoU, which represents the IoU of each category. It can be expressed as follows:

$$MIoU = \frac{1}{k+1} \sum_{i=0}^k \frac{P_{ii}}{\sum_{j=0}^k P_{ij} + \sum_{j=0}^k P_{ji} - P_{ii}}. \quad (8)$$

- (4) FWIoU, which sets the weight for IoU of each class according to the frequency of its appearance. It can be expressed as follows:

$$FWIoU = \frac{1}{\sum_{i=0}^k \sum_{j=0}^k P_{ij}} \sum_{i=0}^k \frac{P_{ij} \sum_{j=0}^k P_{ij}}{\sum_{j=0}^k P_{ij} + \sum_{j=0}^k P_{ji} - P_{ii}}. \quad (9)$$

4.2. Ablation Experiments. To scrutinize the effectiveness of the methods we proposed, we conduct experiments with two different backbones which are used in the original DeepLabV3+. Hyperparameters used by these methods are shown in Table 1. When using the ResNet101 as the backbone, the model is trained by three following strategies: (1) DeepLabV3+-res, which is an unmodified DeepLabV3+ model applying ResNet101 [40] as the backbone. (2) DeepLabV3+-res-8 changes OS to 8 and ASPP rates to (1, 12, 24, 36) on the basis of DeepLabV3+-res. (3) DeepLabV3+-x-8-NL changes loss function to the new loss on the basis of DeepLabV3+-x-8. And, the experiment results are shown in Table 2. When

TABLE 1: Hyperparameters of six training strategies.

Batch size	LR	Epochs	LR scheduler	Weight decay	Momentum
16	0.007	100	Poly	$5e-4$	0.9

TABLE 2: Comparison of model modifications with the backbone of ResNet101.

Methods	Acc (%)	mAcc (%)	MIoU (%)	FWIoU (%)
DeepLabV3+-res	98.4	94.0	86.2	97.1
DeepLabV3+-res-8	98.5	94.5	87.1	97.4
DeepLabV3+-res-8-NL	98.5	95.1	88.5	97.5

using the Xception as the backbone, the model is trained by three following strategies: (1) DeepLabV3+-x, which is an unmodified DeepLabV3+ model applying Xception as the backbone. (2) DeepLabV3+-x-8 changes OS to 8 and ASPP rates to (1,12,24,36) on the basis of DeepLabV3+-x. (3) DeepLabV3+-x-8-NL changes loss function to the new loss on the basis of DeepLabV3+-x-8. Results are shown in Table 3. In order to more vividly reflect the advantages of our method, histograms were drawn in Figures 6 and 7.

It can be seen in Tables 2 and 3, adjusted the OS to 8 and using new loss improve all evaluation metrics. When the backbone is ResNet101, by our methods, the Acc, mAcc, MIoU, and FWIoU improved by 0.1%, 1.1%, 2.3%, and 0.4%. When the backbone is Xception, by our methods, the Acc,

mAcc, MIoU, and FWIoU improved by 0.1%, 0.8%, 2.0%, and 0.4%. Experimental results confirm the effectiveness of the proposed method.

4.3. *Comparing with Existing Methods.* We compare the proposed method in this paper with other three typical methods: (1) FCN, the most classic semantic segmentation

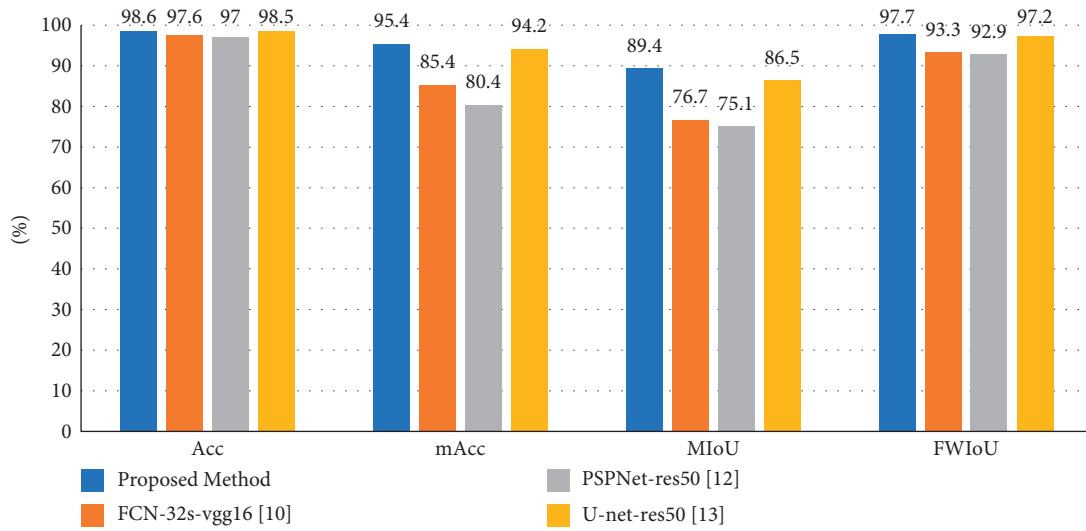

FIGURE 8: Histogram comparison of performance of our method and others.

FIGURE 9: Visual effect comparison of prediction results of different methods. The columns are (a) original image, (b) ground truth, (c) our method, (d) DeepLabV3+-Xception, (e) U-net, (f) FCN32s-vgg16, (g) PSPNet, (h) Ostu, and (i) Max Entropy.

network. (2) U-net, the most widely used segmentation network in the medical field. (3) PSPNet, a very efficient model which applies a pyramid pooling module to fusion features on different levels. The feature extractors of all networks apply transfer learning techniques and are fine-tuned on our augmented dataset. Besides, all these models have trained 100 epochs with regular hyperparameters, and the convergence of these models was guaranteed. We also implement two different threshold segmentation methods on our test set to compare the segmentation effects between traditional methods and deep learning methods: (1) Otsu [41] (2) Max Entropy [42]. The two methods represent different automatic threshold determination methods.

A comparison of evaluation metrics of all these methods is shown in Table 4. As we can see, since the proportion of cracks in the images is very low, and the judgment error rate of image background pixels is low so that the total pixel accuracy of every method is not very different. However, the performance of different methods can still be judged from the remaining evaluation indicators. PSPNet and FCN may have good performance in semantic segmentation under natural conditions, but they do not perform well on the coal crack CT image dataset. U-net is designed to deal with medical images which have similarities with the images we used, so this model can have a nice performance. As the best performing comparison method, U-net achieved an Acc of 98.5%, mAcc of 94.2, MIoU of 86.5%, and a FWIoU of 97.2% which are 0.1%, 1.2%, 2.9%, and 0.5% lower than proposed method. A histogram comparison of the experimental results is shown in Figure 8.

Figure 9 shows a visual effect comparison of segmentation results of all methods. It can be seen that the method we proposed has a certain improvement in the dataset in this paper. Compared with the original DeepLabV3+, the ability to capture details has been improved and cracks whose pixel values are close to the background can be identified. Many locations that should be connected become disconnected during the segmentation process of other models, this problem is also alleviated by our method. Other deep learning methods even have a large number of separation cracks sticking together, which is caused by the insufficient segmentation performance. In addition, the shape and structure of cracks is not guaranteed. Experiments show that less downsampling and the addition of the Dice loss function allow the details to be effectively preserved and recovered. Comparing deep learning methods and traditional threshold segmentation methods, the noise problem is difficult to solve for threshold even though different thresholding methods are used. Although some deep learning methods are rough for object segmentation, they often do not misidentify noise.

5. Conclusions

In this paper, we propose a deep learning method to complete the CT image segmentation task of coal crack CT images. Since the target in the crack image is small, and downsampling can lose the accuracy to some extent, the OS of the backbone was proposed to be reasonably adjusted to reduce the loss of accuracy and adjusted the structure of

ASPP to adapt to this adjustment. In order to solve the problem of uneven sample distribution, CE loss and Dice loss were combined to define a new loss function. The experimental results show that our method is effective and has practical application value.

Nevertheless, the presented method can be improved in the following directions. First, scale-up datasets to accommodate more complex environments. And, more data will be added to this dataset which has more complex topologies and tiny targets. Moreover, we will define a new loss function according to the specific target proportion in the data set combined with probability mathematics which may be more adaptable to the needs of the field than the loss function in this paper.

In order to overcome the problems of low accuracy, low recommendation efficiency, and low user satisfaction of educational resources recommendation algorithm, this paper proposes a personalized recommendation algorithm for online educational resources based on knowledge association. Firstly, online education resources are collected according to association rules. Secondly, firefly algorithm is used to classify online education resources. Then, the vector space function is constructed to filter the classified online education resources. Finally, the correlation between knowledge points is calculated by knowledge association theory, and the knowledge with the highest user interest is selected as the target recommendation resource to realize the personalized recommendation of online education resources. The resource recommendation accuracy of this method can reach 97%, the recommendation time is less than 5.0 s, and users are more satisfied with it, indicating that its recommendation effect is good.

1. Introduction

At this stage, Internet technology and information processing technology are developing at a rapid speed, making people enter the big data era. Information resources provide many conveniences for people's life and work [1]. People can use information technology to establish databases, access and apply various data resources, and realize data resource sharing [2]. Although big data technology has brought many conveniences to people's lives, with the enrichment of data resources and the increase of user information content requirements, how to obtain resources that meet their own requirements has become the main demand at present. This issue has also become a research hotspot in the field of resource application [3]. Due to the development of online education technology, the demand for online education resources is gradually increasing, and the recommendation of online education resources has become the focus of relevant researchers [4].

Reference [5] proposed a collaborative filtering and recommendation method for online learning resources based on learner model. Based on education and teaching theory, as well as taking the resource utilization status in the teaching platform as a reference, a learning resource recommendation model was established, in which the dynamic and static characteristics of learners were integrated, and the collaborative filtering method was used to improve the model so as to realize resource recommendation. The experimental results show that this method has a wide coverage and can effectively recommend most resources, but the accuracy of the recommendation results is not high. Reference [6] proposed a personalized learning resource recommendation method based on three-dimensional feature collaborative domination, constructed the matching relationship between learning resources and learners, constructed the learning resource recommendation model according to the relationship between them, optimized the model parameters using three-dimensional feature

collaborative matching method, and solved the model using particle swarm optimization algorithm to realize Learning Resource Recommendation. The experimental results show that this method has high recommendation efficiency. However, due to the lack of classification of resources, the adaptability between resources and users is not high, and there is a problem of low user satisfaction. Reference [7] proposed an online learning resource recommendation method based on multiobjective optimization strategy. Firstly, the objective function is established; that is, the learners' preference is the largest and the difficulty level is low. On the basis of meeting the above two objectives, the multiobjective particle swarm optimization algorithm is used to optimize and recommend online learning resources. The experimental results show that although this method can meet the needs of users it has the problem of low recommendation efficiency.

According to the above analysis, the existing methods not only have the problem of low accuracy of resource recommendation, but also have the problem of low recommendation efficiency, which affects the satisfaction of users. Therefore, a personalized recommendation algorithm for online education resources based on knowledge association is proposed. The specific research ideas of this paper are as follows.

Firstly, online education resource collection: Taking reliability, fault tolerance, and timeliness as standards, online education resources are collected according to association rules; Secondly, online education resources classification and online education resources filtering: Firefly algorithm is used to classify online education resources to improve the efficiency of resource recommendation and filter the online education resources by constructing vector space function classification.

Then, personalized recommendation of online educational resources: The correlation between knowledge points is calculated by knowledge association theory, and the knowledge with the highest user interest is selected as the target recommendation resource according to the measurement results so as to realize the personalized recommendation of online education resources.

Finally, the personalized recommendation effect of online education resources is verified by the accuracy of resource recommendation, the time of resource recommendation, and user satisfaction.

2. Personalized Recommendation Algorithm for Online Education Resources

2.1. Online Education Resource Collection. Because there are a large number of different types of educational resources in the network, in order to fully recommend online educational resources, first of all, we need to collect educational resources. This paper is mainly based on the theory of association rules. Association rules can not only reflect whether there is association between resources, but also describe the degree of association between resources [1, 8]. Understand the relationship between different educational resources,

clarify the attributes of various types of resources, and then mine the resources to collect online educational resources.

Based on the theory of association rules, association rules are described by $A \rightarrow B$. A and B represent itemsets, and there is no possibility of intersection between them; that is,

$$A \cap B = \emptyset. \quad (1)$$

Considering the need to protect some resources, it is necessary to effectively ensure the confidentiality and integrity of online education resources. In order to effectively avoid malicious dissemination and disclosure of online education resources, educational resources are collected based on the following principles [9].

2.1.1. Reliability. It is necessary to ensure that the online education resources collected through the network are accurate, true, and effective so as to effectively avoid misleading resource users.

2.1.2. Fault Tolerance. If some online education resources in the network are maliciously spread or leaked, it is necessary to cut off the propagation path in time and ensure that the transmission paths of other resources in the network can work normally so as to ensure the security of all online education resources and the reliability of online education resources' downloading, uploading, and other operations. At the same time, try to reduce the operation cost generated in the process of online education resource leakage prevention, such as storage space, network energy consumption, and so on.

2.1.3. Timeliness. Information resources in the network are changing rapidly, and users have high requirements for the efficiency of resource acquisition. Therefore, it is necessary to ensure a certain timeliness in resource acquisition so that users can obtain the most timely resource recommendation results.

Based on the above principles, the specific process of online education resource collection is given as shown in Figure 1.

According to the resource collection process in Figure 1, the online education resources obtained are represented by set U, $U = \{u_1, u_2, \dots, u_n\}$, where u_i represents the i educational resource and n represents the number of resource types.

Set the data change interval in the online education resource set as $[\alpha, \beta]$, and then set a threshold value K to judge the attributes of online education resources. The expression of threshold value K is

$$K = \sum_{k=1}^N H_k + S_k, \quad (2)$$

wherein H_k and S_k , respectively, represent the educational resources corresponding to the input and output target knowledge points and N represents the number of resources.

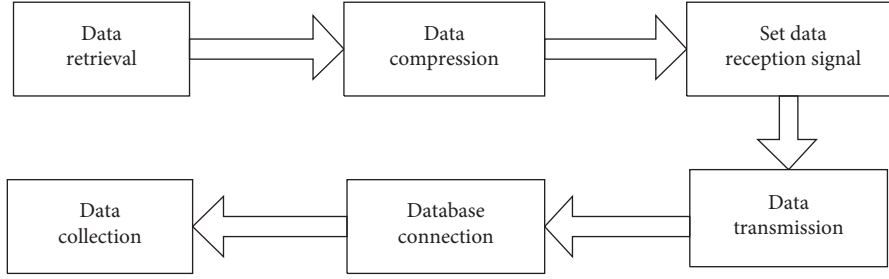

FIGURE 1: Flowchart of online education resource collection.

In order to clarify the application frequency of different education resource types, attribute values are given to different education resource types, and the attribute weights of education resources in set U are expressed in the form of matrix as follows:

$$W_k = \begin{bmatrix} w_{k11} & w_{k12} & w_{k1n} \\ w_{k21} & w_{k22} & w_{k2n} \\ w_{kn1} & w_{kn2} & w_{knm} \end{bmatrix}, \quad (3)$$

where m represents the resource attribute type. The specific calculation formula of the attribute weight of educational resources is

$$W_1 = \frac{(\max - W_k)}{(k - 1)}. \quad (4)$$

According to the attribute weights of different educational resources, the online educational resources are collected by comprehensively considering the threshold K ; namely,

$$U(A, B) = \sum_{i=1}^n K_i (A, B)^2, \quad (5)$$

where K_i represents resource coverage. To sum up, online education resources are collected.

2.2. Classification of Online Education Resources. In order to realize the omnidirectional recommendation of online education resources and further classify the resources, based on the resource collection results, this paper proposes a classification method of online education resources based on firefly algorithm so as to improve the efficiency of resource recommendation. Firefly algorithm is a heuristic optimization algorithm inspired by nature. The inspiration of the algorithm mainly comes from the flickering behavior of fireflies. The brightness of fireflies can be compared to a signal system to attract other fireflies and realize the clustering of fireflies [10, 11].

In order to successfully apply the firefly algorithm to the classification of resources, continuous variables must be converted into discrete variables. Therefore, the last two terms of formula (6) are converted into probability vectors by using logistic function. The logistic function is defined by the following formula:

$$P_{ij} = \frac{1}{1 + e^{\vartheta_{ij}}}, \quad (6)$$

where P_{ij} is the probability value of the j th dimension component of the feature vector represented by firefly i , wherein for ϑ_{ij} the function ensures that P_{ij} tends to 0 when ϑ_{ij} tends to positive infinity, and P_{ij} tends to 1 when ϑ_{ij} tends to negative infinity. The calculation formula of ϑ_{ij} is as follows:

$$\vartheta_{ij} = \beta_0 e^{-\gamma r_{ij}^2} (x_{kj} - x_{ij}) + \alpha \left(\text{rand} - \frac{1}{2} \right). \quad (7)$$

The position update rule of the i firefly during the iteration of the algorithm is as follows:

$$x_{ij}^{t+1} = \begin{cases} 1, & P_{ij} \geq \text{rand}, \\ 0, & P_{ij} < \text{rand}. \end{cases} \quad (8)$$

Based on the principle of the algorithm, online education resources are classified. Figure 2 shows the detailed operation steps of online education resources classification based on the firefly algorithm.

According to Figure 2, the detailed operation steps of online education resource classification are as follows:

- (1) Set the number of iterations to establish a solution space in which firefly individuals are randomly distributed.
- (2) Update the fluorescein values of different firefly individuals.
- (3) Calculate the neighborhood set of different firefly individuals, and the calculation formula is

$$F^2 = \exp \left[\frac{\left(|f_{i,j}|^2 \right)}{\left(|f_{i+1,j+1}|^2 \right)} \right]^2 \times f[a, b], \quad (9)$$

where $f_{i,j}$ represents the current neighborhood set; $f_{i+1,j+1}$ represents the next neighborhood set; and a and b represent subsets in the neighborhood set.

- (4) Calculate the probability that individuals i and j appear in the neighborhood set respectively:

$$\begin{cases} P(i) = A_{ij} - A_i, \\ P(j) = A_{ij} - A_j, \end{cases} \quad (10)$$

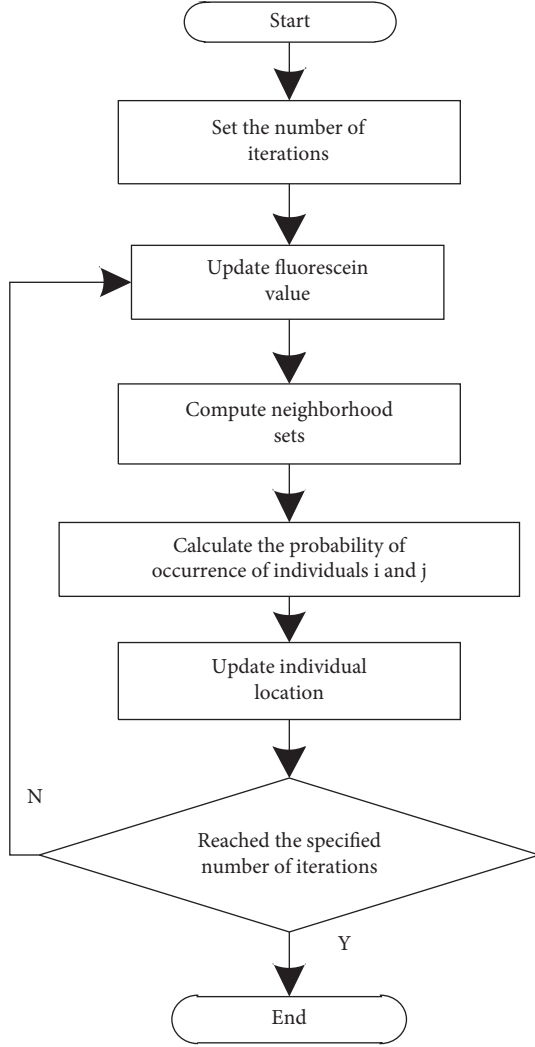

FIGURE 2: Classification flowchart of online education resources.

where A_{ij} represents the overall probability of occurrence of individual i and individual j ; A_i represents the probability of occurrence of individual i ; and A_j represents the probability of occurrence of individual j .

- (5) Calculate the probability that the target individual is selected, move the selected individual as the target, and update the position of the individual at the same time.
- (6) Judge whether the algorithm has reached the specified number of iterations, and if so, output the final result; that is, realize the classification of online education resources. If not, skip to step (2).

According to the above analysis, after fluorescein update and calculation of individual occurrence probability, we can obtain the probability of different education resources' appearance, will be able to distinguish between education resources together, form the same feature set, in accordance with the principle of the set U all education resources

classification processing, have access to education resources of different feature space vector, and realize the online education resources classification.

2.3. Online Education Resource Filtering. Based on the classification results of online education resources, further filter the resources. The purpose of this step is to avoid the impact of interference data on the effect of resource recommendation. In a broad sense, interference data refers to the data that does not meet the needs of users, repeated or wrong in the online education resource set. Recommending these data to users will not only affect the application effect of users on resources, but also affect the probability of useful resources being retrieved and recommended. Therefore, it is necessary to filter these resources [12]. This paper proposes an online education resource filtering method based on vector space function. Filtering resources using vector space function is mainly divided into two stages: training and filtering [13]. The training phase is to train the resource classification results to form a resource filter template. In the filtering stage, a filter board is mainly formed. The filter board is adjusted according to the user's feedback information to realize resource filtering.

According to the above analysis, firstly, the resource classification results obtained in Section 2.2 are trained to preliminarily screen out the invalid resources, and then the invalid resources are further screened out by taking the user's interest as a reference. Finally, the filtering and deletion process is realized to ensure the efficiency of educational resource recommendation. The educational resources in the network are not only diverse in content, but also constantly updated and iterated. It is very difficult to filter these resources. However, in order to recommend more comprehensive and accurate educational resources for users, it is necessary to preliminarily screen educational resources according to relevant standards.

Traditional filtering methods mainly reserve relevant resources according to users' interest points, while vector space functions provide users with resources with high interest and also remove the resources that users have no intention of establish a space vector model $S(\mu)$, whose expression is

$$S(\mu) = d_a + d_h + d_g + d_e + d_v. \quad (11)$$

Among them, d_a represents bad resources; d_h represents unbalanced resources; d_g represents duplicate resources; d_e represents special resources; and d_v represents effective resources.

Train the constructed spatial vector model: define ΔT as the time complexity, assuming that the model contains M nonvalid resources, form them into a document, and traverse the document to obtain the traversed document expression:

$$S'(\mu) = \frac{\sqrt{\sum_{k=1}^n \Delta T (e_i - e_k)^2 \times (g_i - g_k)^2}}{M}. \quad (12)$$

Among them, e_i and e_k , respectively, represent the state vector of valid resources and nonvalid resources in the document; g_i and g_k , respectively, represent the real distribution state of valid resources and nonvalid resources in the document.

Then, the goodness of fit of the distribution of ineffective resources in the document can be expressed as

$$F_{gk} = \omega_n^2 \times (e_k + g_k), \quad (13)$$

where ω_n^2 represents the sparsity of resources in the document. Under normal circumstances, as the F_{gk} value continues to increase, the filtering precision of educational resources also increases.

2.4. Personalized Recommendation of Online Educational Resources. The learner knowledge correlation function is constructed, and the learner knowledge correlation function is applied to the recommendation technology of basic content, and the content recommendation algorithm based on knowledge correlation is proposed. In this recommendation algorithm, the problem of learners' cold start is solved by considering the knowledge attribute information of learners. The knowledge correlation function is used to predict and modify the learning path of learners to solve the problem that the continuity and systematization of learning cannot be guaranteed. By introducing learning style, the problem of single interest in content recommendation is solved. Finally, solve the problem of knowledge trek and theme drift in the process of learning and improve learning interest and learning efficiency.

According to the filtering results of online education resources, the personalized recommendation algorithm of resources is designed. This paper proposes a personalized recommendation algorithm of online education resources based on knowledge association. Knowledge association can be divided into two types: the association between knowledge points and the association between learning resources and knowledge points. The following two knowledge association modes are specifically analyzed.

2.4.1. Correlation between Knowledge Points. The correlation between knowledge points means that the knowledge points of each subject are the basis of subject teaching. Although these knowledge points are divided in teaching research and practice, the knowledge points after the division are still related. This relationship can be divided into dependencies, siblings, and parent-child relationships.

2.4.2. Association between Learning Resources and Knowledge Points. At this stage, we mainly extract keywords from learning resources through semantic association technology and then calculate the association between keyword vectors and knowledge points so as to obtain the correlation between them.

The specific construction and updating steps of the learner knowledge resource association model are as follows:

Step 1. Obtain the domain knowledge attribute of the learner from the learner's personal information table, such as discipline, grade, major, and so on, and then obtain the root knowledge point set S_{K1} associated with the domain knowledge of the learner according to the association relationship between the knowledge in the knowledge base.

Step 2. Obtain the learner's learning behavior data from the learner's learning behavior information table and get the resource set S_R that the learner has learned after cleaning and filtering. Further, according to the association relationship between knowledge points and resources, the knowledge point set S_{K2} associated with S_R and the corresponding association weight W_i are obtained.

Step 3. After obtaining the knowledge point sets S_{K1} and S_{K2} , calculate the correlation weight between the knowledge point and the learner, wherein, if the knowledge point is not learned by the learner, the degree of association between the learner and the knowledge point is 0. On the contrary, the weight of the knowledge points and the learners is obtained by averaging the sum of the resources and the weights of the knowledge points.

Step 4. The updating of the association model of learners' knowledge resources mainly includes two situations: the change of learners' knowledge attribute information and the learners' learning of new learning resources. When these two situations occur, the above three steps are executed to obtain the latest knowledge set and association weight associated with the learner.

Based on the above theory, in order to realize the personalized recommendation of educational resources, the habit preference of learners is obtained from the needs of learners, the learning path of learners is mined, and the personalized recommendation of educational resources is realized in combination with knowledge association [14, 15].

First, establish a knowledge association model, select knowledge points Q_1 and Q_2 in the model, and calculate the weight of the two. The calculation formula is

$$\begin{cases} W(Q_1) = \frac{\delta_1(I - I_k)}{m_k}, \\ W(Q_2) = \frac{\delta_2(I - I_k)}{m_k}. \end{cases} \quad (14)$$

Among them, δ_1 and δ_2 represent the set of knowledge points; I represents the parent knowledge point; I_k represents the child knowledge point; and m_k represents the sum of the associated weights of the knowledge points.

The knowledge point set composed of knowledge points Q_1 and Q_2 is obtained by formula (8), and the similarity between them is calculated by formula (8):

$$S(Q_1, Q_2) = \frac{1 - (f_s + f_g)}{f_s}. \quad (15)$$

Among them, f_s represents the similarity relationship between resource attributes; f_G represents the similarity relationship between resource ontology.

Next, find the knowledge points related to learners' interest, measure the similarity between the knowledge points, and select the knowledge with the highest user interest as the target recommendation resource according to the measurement results. The measurement is mainly realized by calculating the cosine similarity between knowledge points:

$$S(Q_1, Q_2) = \cos \left[\frac{Q_1 \cdot Q_2}{|Q_1| \cdot |Q_2|} \right]. \quad (16)$$

Using formula (16) to get the similarity, recommend online education resources to learners, form a list of interest degrees, arrange the interest degrees in descending order, and then recommend education resources to learners in turn according to the arrangement results, and finally realize the personalized recommendation of online education resources. The personalized recommendation process of specific online education resources is shown in Figure 3.

Analysis of Figure 3 shows that online educational resources are collected according to the association rules, the firefly algorithm is used to classify the online educational resources, the classified online educational resources are filtered, the correlation between knowledge points is calculated by the knowledge association theory, and the user interest degree is selected. The highest knowledge is used as the target recommendation resource, and the personalized recommendation of online educational resources is completed.

3. Experimental Analysis

3.1. Experimental Design. There are two datasets used in this experiment:

- (1) *IntAddSub (Integer Addition and Subtraction) Dataset.* The dataset comes from an online learning platform and collects the real data of mathematics learning in grade 3 of a senior high school. The dataset mainly involves the function solving content in the senior high school mathematics of the people's education press, including 13 knowledge points. A total of 753 learners and 1056 exercises are collected. The time span is from February 23, 2021, to June 24, 2021. The data truly reflect the learning situation of learners. Personalized recommendation algorithm of online education resources based on knowledge association, which can personalized recommend online education resources to target learners
- (2) *FrcSub (Fraction Subtraction) Dataset.* This dataset is a public dataset. FrcSub collects exercise data on equation solving problems, which is often used by cognitive diagnostic models to validate the model's performance. The FrcSub dataset contains two parts of data: students' exercise scores and the relationship between exercise and knowledge points. It collects the score data of 536 learners on 20 exercises. Among

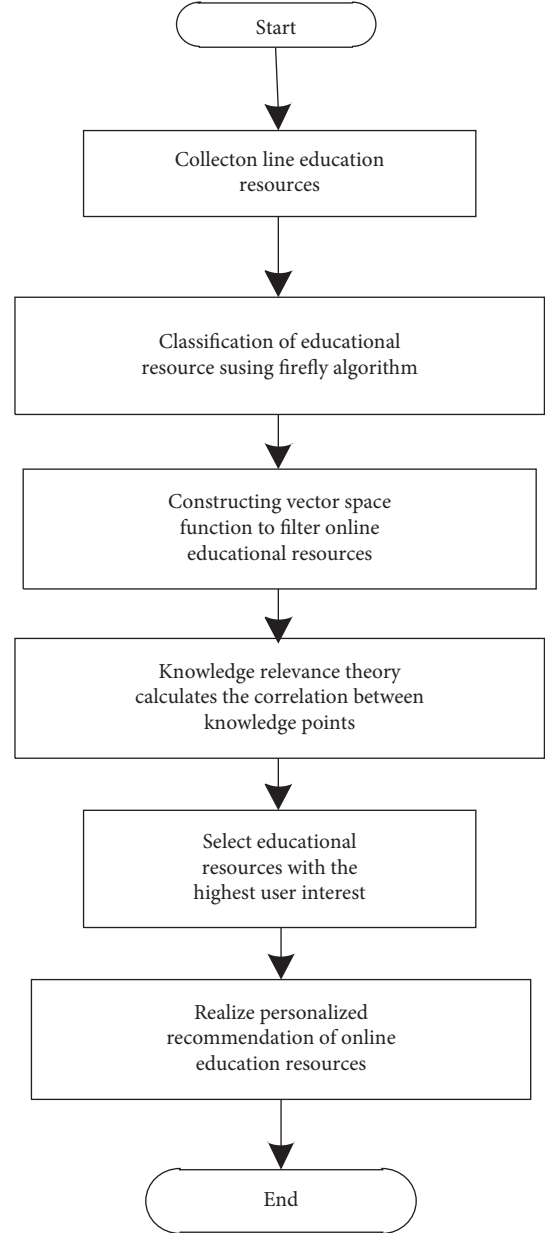

FIGURE 3: Personalized recommendation process of online educational resources.

them, 1 means that the exercise is answered correctly, and 0 means that the exercise is answered incorrectly. The relationship with knowledge points includes the investigation of 8 knowledge points in 20 exercises, among which, if the exercise examines the knowledge point, it is represented by 1; otherwise, it is represented by 0. The descriptive statistics of the two datasets are shown in Table 1.

On the basis of theoretical research, design experiments to verify the application performance of this method. Reference [5] method and reference [6] method are used as comparison methods to compare with this method. The specific experimental indicators are recommendation accuracy, recommendation efficiency, and user satisfaction.

TABLE 1: Dataset statistics.

Dataset	Number of learners	Number of exercises	Knowledge points
IntAddSub	753	1056	13
FrcSub	536	20	8

The data used in the experiment comes from the SQL Server database, in which the application statistics of online education of students in a university are extracted, including student resource retrieval data, resource download data, and resource submission data; based on the above data, the experimental research is carried out.

In this paper, recommendation accuracy, resource recommendation efficiency, and user satisfaction are selected as experimental evaluation indicators. The higher the calculation result, the better. On the contrary, the lower the calculation result, the worse.

3.2. Recommendation Effect Verification

3.2.1. Comparison of Online Educational Resources Recommendation Accuracy. In order to verify the effect of online education resource recommendation, reference [5] method, reference [6] method, and this method are used to verify the accuracy. The accuracy results of online education resource recommendation are shown in Figure 4.

As can be seen from Figure 4, compared with the traditional method, the online education resource recommendation accuracy of this method is significantly higher, always higher than 80%, and the maximum value reaches 97%. However, the online education resource recommendation accuracy of reference [5] method and reference [6] method is low. Among them, the maximum recommendation accuracy of reference [6] method is 78%, and the recommendation accuracy of reference [5] method is lower. It can be seen that this method has better recommendation effect and can provide more accurate resources for resource demanders. This is because this method uses firefly algorithm to classify online education resources and constructs vector space function to filter the classified online education resources, which effectively improves the accuracy of recommendation.

3.2.2. Comparison of Online Educational Resources Recommendation Efficiency. Recommendation efficiency describes the time consumed by resource recommendation. Therefore, under the same test conditions, the methods of reference [5], reference [6], and this paper are used to count the time consumed by resource recommendation. The results are shown in Table 2.

It can be seen from Table 2 that, during the testing process, the recommended time for resources of this method, reference [5] method, and reference [6] method has been increasing. Among them, the growth rate of this method is the smallest, and the recommended time is always controlled below 5.0s, which is far lower than the

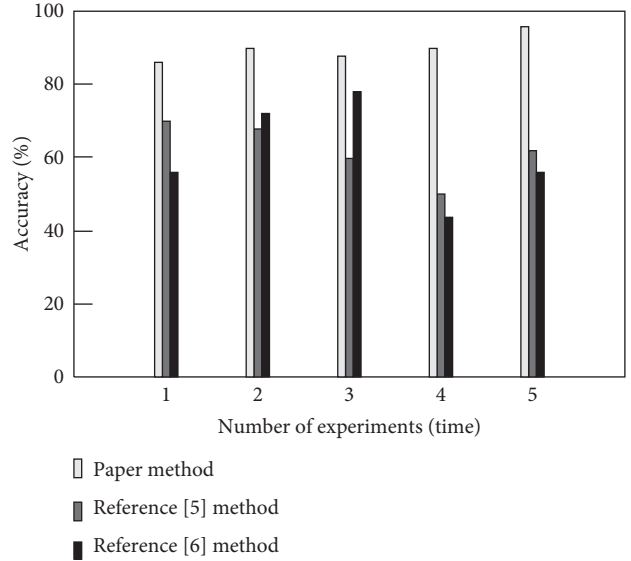

FIGURE 4: Recommendation accuracy of different methods.

recommended time of reference [5] method and reference [6], indicating that the recommended efficiency of this method is high. According to the above analysis, this method solves the problem of low recommendation efficiency of traditional methods and can provide users with educational resources faster. This is because this method uses association rules to collect online education resources and uses firefly algorithm to classify online education resources. The correlation between knowledge points is calculated by the knowledge association theory, and the knowledge with the highest user interest is selected as the target recommendation resource to effectively improve the recommendation efficiency.

3.2.3. Comparison of User Satisfaction. Online education resource recommendation is mainly for users, so users' satisfaction with the recommendation results is very important. By scoring the recommendation effect by 100 users, the users' satisfaction with the recommendation effect of the above method resources is tested. The test results are shown in Figure 5.

It can be seen from Figure 5 that, with the increase of the number of users, the average number of user scores gradually decreases. Through comparison, it can be seen that users are more satisfied with the recommendation effect of the method in this paper, and the score always remains above 80 points, [5] The satisfaction score of the method in [6] is basically below 80 points. It can be seen that users are more satisfied with the method in this paper, which also reflects the better recommendation effect of this method from the side. This is because this method uses firefly algorithm to classify online education resources. The correlation between knowledge points is calculated by the knowledge association theory, and the knowledge with the highest user interest is selected as the target recommendation resource, which effectively improves the user's satisfaction.

TABLE 2: Online educational resource recommendation efficiency of different methods.

Number of experiments/times	Online educational resource recommendation time/s		
	Reference [5] method	Reference [6] method	This paper method
1	1.6	3.1	2.9
2	2.0	4.9	3.5
3	3.1	5.2	4.7
4	3.4	6.9	5.0
5	3.5	7.1	6.3
6	4.0	8.1	7.1
7	4.2	8.9	7.5
8	4.5	9.8	8.2
9	4.8	10.2	8.8
10	4.9	11.1	9.0

FIGURE 5: Users' satisfaction with different methods.

4. Conclusion

This paper proposes a personalized recommendation algorithm for online education resources based on knowledge association. Collect online education resources according to association rules, classify online education resources using firefly algorithm, filter the classified online education resources by constructing vector space function, calculate the correlation between knowledge points based on knowledge association theory, and select the knowledge with the highest user interest as the target recommendation resource according to the measurement results to realize the personalized recommendation of online education resources. The following conclusions are drawn through experiments:

- (1) The online educational resource recommendation accuracy of the method in this paper is significantly higher, always higher than 80%, and the maximum value can reach 97%.
- (2) The maximum resource recommendation accuracy rate of the method in this paper is 97%, the recommendation time is always controlled below 5.0 s, and the user's satisfaction with it is higher, indicating that its recommendation effect is better.

- (3) Users are more satisfied with the recommendation effect of the method in this paper, and the score is always above 80 points, which reflects the better recommendation effect of this method.

Under the method of this paper, the satisfaction of recommendation effect has been significantly improved, but the accuracy of education resources recommendation still needs to be further improved.

Aiming at the problems of style loss and lack of content in the style transfer of Chinese art works, this paper puts forward the style transfer technology of Chinese art works based on the dual channel deep learning model. On the basis of clarifying the technical principle of style transfer of art works, the image of art works is controlled and transformed based on the u-net network. The incomplete information in the restored image is filled, and the multiscale classification feature is used to calculate the color feature data items in the image. The sensitivity coefficient of color difference is calculated by using constraints, and the overlapping color discrimination and image segmentation of art images are realized. Poisson image editing is used to constrain the image spatial gradient to realize the style migration of art works. The experimental results show that this method can effectively avoid the problems of content error, distortion, and distortion in the process of art style migration, and has a better style migration effect.

1. Introduction

When appreciating the famous works of famous Chinese and foreign painters, we often hope to create a painting with a similar style. The emergence of image style transfer technology has helped people realize this wish [1]. People can convert any photo into any style of painting. In addition, in the era of the rise of a short video, various style filter effects are loved by people [2], and image style migration technology has been widely known by people. However, many image style migration methods can only target one style in a model, which is inefficient in an application.

Reference [3] proposes an example based image styling method based on the consistency of the target image during training. This method keeps the statistical data of neural response compatible with the data extracted from programmed sources and is widely used in video stylization, style conversion to panorama, face, and 3D models. Reference [4] mainly proposes improvements in the following two aspects: (1) adjust the structure of classical residual elements: convert the standard convolution into point convolution and depth convolution, and reduce the amount of computation while ensuring the convolution effect; (2)

simplify the loss network: the fourth and fifth layers of the model are highly consistent in structure, and the effect of style restoration and content reconstruction of these two layers is basically the same, which ensures the effect of style restoration and content reconstruction while reducing the amount of parameters. Reference [5] proposed an unsupervised image style migration method based on an image mask. In the experiment, cycleGAN architecture based on cyclic consistency is adopted, and a new generative model with a built-in image mask is designed by using the inception RESNET structure. Finally, the background of the image and the learned abstract features are automatically reorganized through unsupervised learning. Experiments show that the new method effectively separates and reorganizes the image background and abstract features, solves the problem of regional interference in the process of feature learning, and obtains considerable visual effect. Reference [6] in view of the difficulty of style extraction caused by the diversity of Mongolian clothing elements, large color differences, irregular patterns, and other characteristics, the method of combining K-means and a closed natural matting algorithm is used for image segmentation. The style and content of the image are extracted based on a neural network, and the resulting image is synthesized by image

reconstruction technology to realize the style transfer of Mongolian and Chinese clothing image. Aiming at the problem of serious artifacts in the output image, an improved image style migration algorithm is adopted. Transform the input parameter of the image into a local constraint, which can suppress the distortion of the image. Aiming at the problem of spatial inconsistency in the style transfer of real photos, smooth it to ensure the consistency of spatial style after style processing. This method greatly speeds up the operation speed. Reference [7] proposed a periodic consistency antagonistic domain adaptive method with four input channels for vegetation region segmentation based on an index. This method preserves the specific ratio between near infrared and RGB bands and improves the segmentation network performance of the target domain. Reference [8] proposes a style library composed of multiple convolution filter banks, and each filter bank explicitly represents a style. In order to convert the image into a specific style, the corresponding filter bank is operated on the intermediate features generated by a single automatic encoder. This method can obtain the same results as the single parameter setting method.

Based on the application of image style transfer technology in interior decoration design based on the ecological environment in reference [9], this paper proposes the style transfer of Chinese art works based on the dual channel deep learning model. The art work style transfer technology proposed this time refers to converting the style of an art work into an image similar to the style of the art work through learning (using the dual channel deep learning model). This paper mainly puts forward improvements in the following two aspects: first, adjust the lighting of art works; Secondly, based on the dual channel convolution transformation and control of the u-net network, the incomplete information in the restored image is filled to ensure the effect of style restoration and content reconstruction of art works while reducing the amount of parameters.

2. Art Style Transfer Technology

Using different styles of art works to express the semantic content of images, so the method of image processing is the transfer of style of art works [10]. That is, on the premise of retaining the central content and structure of the original image, an ordinary image is displayed in another art work style. For example, there are two images, one is the style image and the other is the content image. The style transfer of art works is mainly divided into the following steps:

Step 1: ensure that all the content and structure of the content image are preserved and then extract the main features of the style of the art work

Step 2: use the extracted features to reconstruct the features of the original content image

Step 3: perfectly combines the style of the style image and the content of the content image into a migration image, so as to obtain the output image

The implementation process of the above process is shown in Figure 1.

FIGURE 1: Flow chart of style transfer of art works.

2.1. Local Block Method of Double Threshold Image Based on Depth Convolution Neural Network

2.1.1. *Theoretical Analysis.* Full convolutional networks (FCNs) is a network model based on deep learning, which is widely used in image segmentation. FCN has the following advantages:

- (1) The convolution network training is realized by replacing the full connection layer with the convolution layer.
- (2) In order to achieve pixel level segmentation, all pixel features in the image are predicted and classified. However, for the images with complex visual environment, the sampling on the FCN network structure still adopts the simplest deconvolution method, resulting in the inability to recognize the detailed features of the image, the final segmented image contour is blurred and the adhesion is serious.

Therefore, mask r-cnn is proposed as an instance segmentation method, and the region of interest (ROI) is taken as the network branch of the deep convolution neural network to realize the instance segmentation of the target image. In order to preserve the accuracy of the target spatial position coordinates, the mask r-cnn network replaces the roipool operation with the roialign operation. Roialign can correct the misplaced layers of spatial quantization feature extraction. The bilinear difference keeps the spatial position accuracy between the input network and the output network unchanged, corresponding to the coordinate value on the ROI bin. The dependence between the judgment class and the output mask is minimized, and the average binary cross entropy loss is used to predict the binary mask separately for each target. This process reduces the competitiveness between categories and improves the efficiency of image segmentation.

Based on the mask r-cnn network structure, the network depth and width are optimized and adjusted, and the migration learning is carried out on the given training parameters. Based on the segmented target image, the optimal network parameters and network model are obtained by calculating the segmentation accuracy between different layers and different convolution kernels.

2.1.2. *Local Blocking of Double Threshold Image.* Based on the above-given theoretical analysis, this paper determines the optimal network model as the Pignet network structure and makes two optimization improvements on the mask r-cnn network structure in terms of the number of convolution layers and categories:

- (1) For different target areas in the image, the fourth stage of mask r-cnn network changes from 69 convolution layers to 12 layers, which can reduce the

feature loss on the one hand and the amount of convolution operation on the other hand.

- (2) The number of convolution layers in the last layer of the mask branch of mask r-cnn network is optimized and adjusted to Pignet and background. The specific structure is shown in Figure 2.

There are 44 convolution layers and five convolution layers, all of which adopt the Pignet structure. Each arc contains 3 convolution layers, $1 \times 1 \times 64$ layers indicate that the convolution kernel is 1×1 . Convolution layer with 64 channels. The residual learning structure reduces the number of parameters to a great extent, makes the calculation simpler and keeps the spatial position accuracy of the target unchanged. Through the arc part of the network diagram, the residual learning structure directly transmits the input information to the later layer, which also reduces some feature loss. The residual learning structure can also reduce the sliding step of each convolution layer from the original two pixels to one quarter, and the number of output channels increases continuously until 2048.

There are mainly two aspects of feature extraction in the Pignet backbone network structure: one is to analyze and process the feature map output by the network model conv4_12 convolution layer through the region proposal networks (RPN) [11] to extract the required feature information; on the other hand, it propagates forward to generate feature mapping, RPN can select the region of interest with the fastest speed.

The loss function L of the Pignet network is mainly composed of three parts: classification error L_{cls} , detection error L_{box} , and segmentation error L_{mask} . The calculation formula is shown as follows:

$$L = L_{cls} + L_{box} + L_{mask}. \quad (1)$$

Here, L_{cls} and L_{box} processes the full connection layer to predict the category of all regions of interest and the regression frame coordinate value of the target space. L_{mask} segment and mask the target image of each region of interest. Select the target image in which all regions of interest in the image are classified as pig, so that only the relative entropy error of pig needs to be considered when continuing to calculate the loss function generated by region segmentation. In order to avoid competition among classes, the background class is not considered when calculating the relative entropy error of pig class. L_{box} is mainly used to ensure that the position coordinates of the regression box of the target image do not deviate. L_{mask} is used to ensure the accuracy of the target image generation mask. Class branch predicts that the region of interest class is pig class, then L_{mask} only needs to predict pixels for pig class to ensure that the target image has clear contour and no adhesion, so as to ensure the accuracy of contour position coordinate information on different layer depths and realize accurate image segmentation. In this paper, the Pignet network model obtains two regions of interest from convolution calculation. L_{box} is used to predict the position coordinates of the target spatial regression frame. L_{mask} uses the combination of the

average binary cross entropy loss function and sigmoid function to separately predict the position coordinates of the target spatial regression frame to form a binary mask. The segmented image is represented by two different color masks and placed in two different layer depths. Even if more images are segmented, the Pignet model will form a corresponding binary mask for each segmented target.

2.2. Extraction of Light Component in Non-significant Area.

The multiscale Gaussian function can extract the illumination classification of different areas in the image by adjusting the adaptive parameters, so as to improve the quality of style migration of art works. The implementation process can be divided into the following steps:

Step 1: image acquisition: obtain the image of the art work to be migrated

Step 2: background removal: based on the HSI color space model, the i -component image is binarized according to the histogram selection threshold to form a binary mask image, and the two obtain the i -component image after removing the background through point multiplication

Step 3: construct multi-scale Gaussian function filter

Step 4: obtain the illumination component

Step 5: perform homogenization correction on the surface brightness of the i -component image after removing the background

There are pixel structures with various structures in the art works. When extracting the illumination component in the nonsignificant area, the multiscale Gaussian function is used to set adaptive parameters in the image area to correct the empirical parameters existing in the art works. The correction process can be expressed as follows:

$$I(x, y) = I \frac{\gamma(x, y)'}{\gamma(x, y)}. \quad (2)$$

Here, $I(x, y)$ represents the correction function formed, $\gamma(x, y)'$ represents the nonsignificant region extracted by bilateral filtering, and $\gamma(x, y)$ represents the light source point function in art works. According to the image processing experience and the original illumination parameters in the nonsignificant area, the empirical value is selected. There are many illumination levels in the nonsignificant image area. In order to deal with the weakening effect of different light and dark areas on the nonsignificant area, the illumination points are randomly selected for adaptive adjustment. In order to eliminate the influence of image noise on image details, the image structure with a linear structure is selected to process the image after adaptive processing, and the structure parallel to the linear structure is selected to be processed as a corrosion reflection component to eliminate the noise in the image. The processing process is shown as follows:

$$R_d = \frac{R \oplus H}{H}. \quad (3)$$

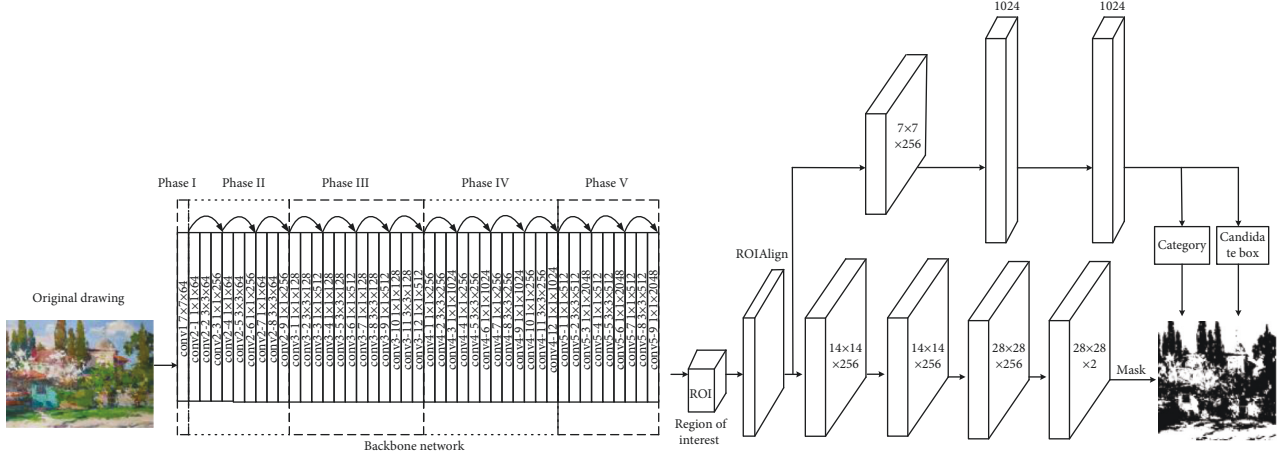

FIGURE 2: PigNet network structure.

Here, R_d represents the constructed denoising function, R represents the image expansion parameter, H represents the image structure parameter, and \oplus represents the image panoramic processing. After eliminating the noise in the image, divide the front and back scenes in the image structure, take the back scene image as the extraction object of the light component in the nonsignificant area and extract the light component by using the adaptive gamma function [12, 13]. The extraction process is shown as follows:

$$a = \frac{2R_d I(x, y)}{I_{\max}(x, y)}. \quad (4)$$

Here, a represents the extracted parameters, $I_{\max}(x, y)$ represents the maximum value of the image correction function, and the meaning of other parameters remains unchanged. In order to unify the dimension of the image illumination component, the above-extracted illumination component is linearly transformed by spatial image processing technology. The processing process is shown as follows:

$$g(x, y) = \frac{d-c}{b-a} [I(x, y) - a]. \quad (5)$$

Here, $g(x, y)$ represents the constructed linear function, abc and d represent the gray parameters of the illumination component, respectively, and the meaning of other parameters remain unchanged. After processing the illumination component in the image, the gray parameters in the image are divided according to the value size, and the gray level of small value is processed into a nonsignificant area [14]. For the image in this area, the image resolution is reconstructed by depth learning.

2.3. Poisson Image Editing Technology. The implementation process of Poisson image editing technology can be summarized as follows: assuming that the area occupied by the original image is Ω , according to the gradient of the original image and the boundary structure of the embedding position of the target image, the image pixel value of the transition region is constructed and seamlessly fused to the right

image. The image value of the right fusion part is unknown, and the energy function needs to be solved. That is, for an image, the macro significance is reflected in the texture features, so to make the two images integrate properly and seamlessly, it is necessary to make the texture of the fused part of the two images consistent. The texture is reflected in the gradient, so the gradient of the fused region should be consistent with that of the original image. The consistency of fused textures means that the variation difference between the inner and outer regions of the original image reaches a minimum; that is, the energy function takes a minimum.

The image used for the style transfer of art works is generally a fuzzy image. Logically, a fuzzy image is an image in which the contour of the object is not obvious and the gray change of the contour edge is not enough, resulting in a weak sense of hierarchy. In order to generate a clear image, we need to calculate the change rate of the image gray level and then obtain a clearer style transfer image. In the style transfer of art works, we should also pay special attention to not making the whole decoration look ambiguous. We should find the “change rate of image gray level” and then successfully fuse the source image with the target image. The image pixel construction diagram of the fusion area is shown in Figure 3.

In Figure 3, V represents the gradient field of the source image, u represents the source image of the art work, $\partial\Omega$ represents the boundary of the image, f^* represents the result of the combination of images other than Ω , Ω represents the area covered by the image, and f represents the image within Ω .

3. Realize the Style Transfer of Art Works

Due to the authenticity and complexity of the content in the style transfer process of art works, it is necessary to keep the consistency of the content image and the style as much as possible in the transfer process, so that there will be no error or distortion in the style transfer image content of art works [15, 16], which makes the effect after the transfer real and effective. The implementation process of style migration is shown in Figure 4.

FIGURE 3: Schematic diagram of image pixel construction in fusion area.

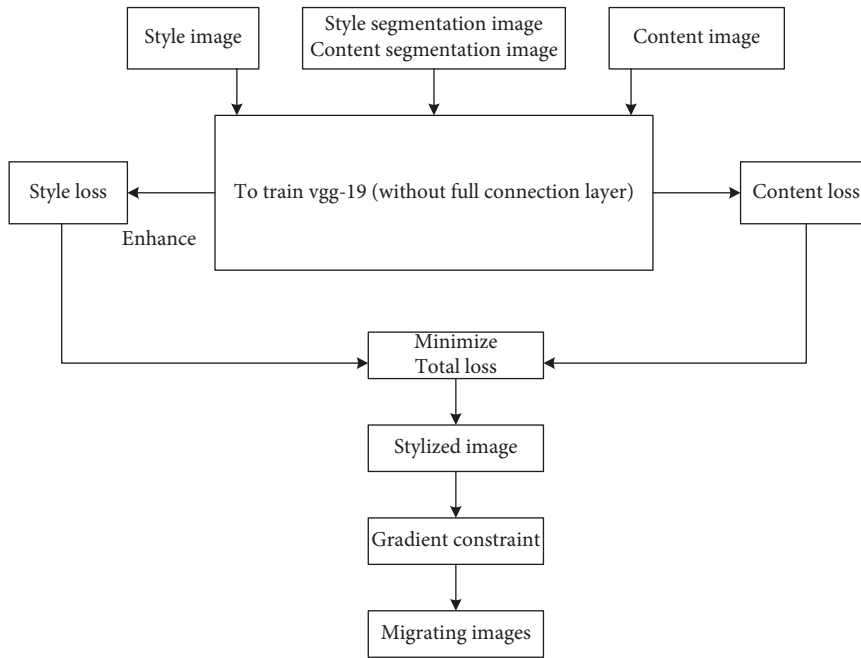

FIGURE 4: Style transfer process of art works.

According to the migration process shown in Figure 4, the migration process is analyzed in detail.

3.1. Image Segmentation of Art Works. The image segmentation technology of art works mainly through point by point convolution and pool layered recognition. After a series of processing of the image of art works, the final output feature vector of the image is clear and reliable, which is helpful to accurately distinguish the image category. Although the loss of pixels limits the pixel level classification, it does not affect the two-dimensional spatial information of the image. At this time, the full connection layer can be converted into a convolution layer, the original size of the image can be restored through deconvolution operation, and then each pixel can be classified one by one to realize the effective segmentation of the image of art works. This method is not limited by the size of the input image, reduces the repeated storage and convolution calculation of pixel blocks to a certain extent and improves the extraction efficiency of image features. In terms of data sets of different sizes, the image segmentation based on the u-net network [17, 18] has a good segmentation application effect.

The specific features of the u-net network include the following:

- (1) The image full connection layer can be transformed into a convolution layer in real time. The number of image convolution results output by the last convolution layer is equal to the number of image classification. For the image of art works, the parameter value of each coordinate point represents the probability corresponding to the pixel point and the relevant category, and the category to which the image feature belongs is the largest corresponding probability value.
- (2) When the input data in the image of art works passes through the pool layer, the output image features will be reduced to a certain extent. The size of the feature image obtained by the last down sampling will be reduced to 1/16 of the original image. On this basis, the restored image can be obtained by adding the deconvolution layer, recovering with the upper sampling, and fusing with the image after the change of the expansion path, and the size is the same as the original image.

- (3) The jump structure is added to the u-net network to extract the detailed features in the image of art works. At the same time, the semantic features are extracted through the network. After splicing and fusing the multiscale features, the image with complete and rich information is obtained.

Therefore, the u-net network is used for image segmentation of art works. The image of art works will produce color overlap in some special states. At this time, if only the color features in the image are used to judge the image information, it is easy to produce inaccurate boundary segmentation. Therefore, the data items in the image are calculated by using the multiscale classification features [19, 20].

$$D(a_u, \theta) = -1n(\gamma p_c(v'_u | a_u) + (1 - \gamma) p_s(v'_u)). \quad (6)$$

Here, Vu' represents the u -th color vertex in the adjacent pixel area in the target image, $a_u \in \{0, 1\}$ represents the correlation label between the foreground and the background in the image of art works, $p_c(v'_u | a_u)$ represents the constraint term of the color in the image background, $p_s(v'_u)$ represents the constraint term of the multi-scale classification feature on the image color, and γ represents the adjustment coefficient of the constraint term.

When the colors in the images of art works overlap, the multiscale classification feature plays a decisive role in the classification of graphics. Therefore, generally, the value of the adjustment coefficient γ will be relatively small. The specific calculation process is shown as follows:

$$\gamma = |P_c(v'_u | 1) - P_c(v'_u | 0)|^\beta \quad (\beta \in [0, 1]). \quad (7)$$

Here, β is the sensitivity coefficient to adjust the main color difference of the image, and the general value is set at 0.5. By calculating the shortest Euclidean distance between the vertex Vu' and the foreground seed and background seed in the image [21, 22], the degree of overlap of the main color distribution in the image can be obtained. The calculation method of Euclidean distance is shown in formulas (8) and (9):

$$d_u^F = \min \|I'_u - \theta_F\|, \quad (8)$$

$$d_u^B = \min \|I'_u - \theta_B\|. \quad (9)$$

In formulas (8) and (9), θ_F and θ_B represent the color values of foreground seed and background seed, respectively, and Iu' represents the vertex color value. After obtaining the above data, we can further obtain the color constraint value of the image of art works, as shown in the following formula:

$$P_c(v'_u | a_u) = \begin{cases} \frac{d_u^B}{d_u^F + d_u^B}, & \text{if } a_u = 1, \text{ and } d_u^F + d_u^B \neq 0, \\ \frac{d_u^F}{d_u^F + d_u^B}, & \text{if } a_u = 0, \text{ and } d_u^F + d_u^B \neq 0, \\ 0.5, & \text{if } d_u^F + d_u^B = 0. \end{cases} \quad (10)$$

The multiscale typing feature constraint is mainly determined by the eigenvalue S_{MP} . By adjusting the level variable eigenvalues in the foreground and background, the corresponding multiscale typing features are inversely increased. In this process, the adjustment is completed by adjusting the variable factor and the feature mean value is obtained. At this time, the foreground multi-scale typing eigenvalues, as shown in the following formula:

$$S'_{Fu} = \frac{P_c(v'_u | a_u) \times S_{MF}^2}{m}. \quad (11)$$

Here, m represents the mean value of typing characteristics. The calculated characteristic values of background multi-scale classification, as shown in the following formula:

$$S'_{Bu} = \frac{(1 - S'_{Fu})^2}{1 - m}. \quad (12)$$

The calculation formula of typing characteristic mean m , as shown in the following formula:

$$m = \frac{1}{n} \sum_{u=1}^n S'_{Bu}. \quad (13)$$

The constraint process of multi-scale segmentation between image foreground and background, as shown in the following formula:

$$\begin{cases} p_s(v'_u \in F) = \frac{S'_{Fu}}{S'_{Fu} + S'_{Bu}} \\ p_s(v'_u \in B) = \frac{S'_{Bu}}{S'_{Fu} + S'_{Bu}} \end{cases}. \quad (14)$$

In order to effectively improve the segmentation accuracy of the image of art works, the image area with a relatively high classification eigenvalue of the area with a relatively small area shall be subject to unified noise reduction. If $p_s(v'_u \in F) = 0.5$ and $A_u < A_{\text{avg}}$ conditions are met, then $p_s(v'_u \in F) = 0.5$ and A_{avg} represent the average area of the image. So far, the image segmentation of art works is completed.

3.2. Content Loss. For the image of art works, the style image is defined as s , the content image as C and the white noise image [23, 24], and it is input into the vgg-19 network to extract the style of the interior decoration art image through the low-level response, extract the content of the style migration image of art works through the high-level response and use the random white noise image as the initial input. In this way, we can make up for the deficiency of content feature map and white noise feature map, get many feature maps under the action of the convolution layer, and convert conv3_2, conv4_ The second layer is described as the content image of the style transfer of art works. An image is generated in the style transfer of art works, which is similar to the content image C in content design. The average loss function is introduced into the calculation of content loss,

and the calculation formula, as shown in the following formula:

$$L_{\text{coabut}}(c, g, l) = \frac{1}{2} \sum \|K_l(g) - K_l(c)\|^2. \quad (15)$$

Here, l represents the convolution layer and K_l represents the feature matrix of image g in the style transfer of art works.

Using the theory of error direction propagation, the gradient value of the generated image g in the style migration of art works is calculated and updated to the input image, so that the initial random image changes until the same response as the content image C appears in the style migration network of art works.

3.3. Enhanced Style Loss. Image style is expressed by the correlation between features. Art work style is texture information, which refers to calculating the relationship between features through Gram matrix, so as to capture the texture information of art work style migration image, and through conv2_1, conv1_1, conv4_1, conv3_1 conv5_1 as the style of the image, the gradient descent mode of the white noise image [25, 26] is used to match the image similar to the style of the art work. In addition, mark the segmented image in another channel and take it as the input mode to form the style loss for each semantic category. Use the segmented channel to enhance the algorithm of the convolutional neural network and form the style loss between the output image g and the style images through the calculation of function:

$$L_{\text{style}}(s, g, l, c) = \sum_{c=1}^c \frac{1}{2} \|G_{c,l}(g) - G_{c,l}(s)\|^2. \quad (16)$$

Here, $G_{c,l}$ represents the operation mode of Gram matrix, that is, the inner product between the style transfer graphs of art works and c represents the number of semantic segmentation mask categories in the style transfer of art works.

The loss function of art style migration image, as shown in the following formula:

$$L_{\text{total}} = \alpha L_{\text{content}} + \beta L_{\text{style}}. \quad (17)$$

After the minimization iteration of the loss function, the stylized image of art style transfer is obtained.

3.4. Poisson Image Editing Constraint Image Spatial Gradient.

In order to generate a clear style transfer effect in the style transfer of art works, take the style transfer image of art works after style processing as the input, then the gradient field of the content image can be expressed, as shown in the following formula:

$$g(x, y) = \nabla c(x, y). \quad (18)$$

While constraining the image spatial gradient, it also needs to meet the following requirements, as shown in the following formula:

$$L^* = \min \int_{\Omega} \|\nabla F - g\|^2 + (F - C_s)^2. \quad (19)$$

Based on the objective function of spatial gradient constraint, the Poisson equation is established, as shown in the following formula:

$$F(1 - \lambda \nabla^2) = C_s - \lambda \nabla g. \quad (20)$$

Here, λ represents the relative weight between the control content image and the style image.

To sum up, the style transfer steps of art work style transfer image are summarized as follows:

Step 1: input the art style migration style image, art style migration content image, and their segmented images into the trained vgg-19 network, initialize the white noise map of image pixels, and input them into the vgg-19 network together.

Step 2: conv3 in vgg-19 network_Layer 2 and conv4-2, extract the content feature matrix of the art work style migration content image and calculate the content loss value between the image pixel white noise image and the content image.

Step 3: conv1 in vgg-19 network_1st floor, conv2-1 floor, conv3_Layer 1, conv4-1, and conv5-1, extract the style feature matrix of the style transfer image of the art work, take the color marked segmented image as another channel of the style transfer of the art work, connect all the segmented channels, and calculate the enhanced style loss value of the image pixel white noise image and the style image.

Step 4: calculate the total loss function in terms of content loss and style loss of the style migration image of art works used for training.

Step 5: by training the style transfer image of art works, the white noise gradient of image pixels can be reduced, so as to minimize the total loss function. After several iterative calculations, the total loss function is adjusted to obtain the stylized image of interior decoration art; Poisson image editing technology is used to constrain the gradient of stylized images, and the migration effect picture of image content with both art work style migration style and art work style migration content is obtained.

According to the above process, complete the style transfer of art works.

4. Experimental Analysis

4.1. Experimental Data Set. In order to verify the practicality of the proposed style transfer method, 2200 art works of different styles are randomly selected from 15 groups of open art image data sets as pretraining data sets. And, input it into vgg-19 network model for pretraining to obtain model parameters. After setting the name of the image in 15 groups of open image data sets of art works, sort out the parameters of art works, as shown in Table 1.

TABLE 1: Parameters of art works data set prepared.

Artwork dataset name	Positive sample (%)	Size	Resolution (dpi)
Labeled faces in the wild	48273 (7.64)	640 × 480	100 million
MNIST-06	39390 (39.8)	1280 × 640	20 million
CIFAR-02	36640 (8.21)	640 × 480	100 million
AI-challneger-04	63605 (40.2)	1280 × 640	20 million
Pascal VOC-07	27001 (47.21)	640 × 480	100 million
COCO common objects dataset	75220 (4.1)	1280 × 640	20 million
CityScapes	51220 (46.9)	640 × 480	100 million
Lego bricks	19090 (38.67)	640 × 480	100 million
Visual genome	75904 (17.62)	640 × 480	100 million
VisualQA	72490 (25.05)	1280 × 640	20 million
MNIST-08	36257 (47.14)	640 × 480	100 million
KITTI-05	28284 (30.13)	1280 × 640	20 million
ApolloScape-02	33298 (18.37)	1280 × 640	20 million
TUM-08	68273 (1.9)	640 × 480	100 million

Using the data set of art works shown in Table 1, applying the parameters in the above table, the median difference method is used to calculate the regional gradient in the image. The numerical, as shown in the following formula:

$$\left\{ \begin{array}{l} G_x(i, j) = \frac{[V(i+1, j) - V(i, j)]}{2} \\ G_y(i, j) = \frac{[V(i, j+1) - V(i, j)]}{2} \\ gr(V(i, j)) = \sqrt{G_x(i, j)^2 + G_y(i, j)^2} \end{array} \right. \quad (21)$$

Here, $V(i, j)$ represents the pixel function of the art work, $gr(V(i, j))$ represents the amplitude value of the art work at the position of pixel (i, j) , $G_x(i, j)$ represents the horizontal gradient value of the image, and $G_y(i, j)$ represents the vertical gradient of the image. After the enhanced image is processed into regional gradient values, the gradient parameters in the data set are sorted out as the processing object, and the application performance of the proposed method is tested with reference [5] unsupervised image style migration technology based on image mask and reference [6] image style migration technology based on semantic segmentation.

4.2. Results and Analysis. In order to test the robustness of the proposed art work style migration technology, two art work scenes with different scenes are selected, and each scene selects different style types for migration and conversion. The results are shown in Figure 5. (from the Internet).

It can be seen from the migration results in Figure 5 that the content image corresponding to scene (a) belongs to the style of “lining people with objects,” and the corresponding style image belongs to the realistic style. A good migration effect can be generated between the content image and the style image; scene (b) is to test the style conversion effect of style migration images of art works with the same style and different contents. The corresponding style images and

content images belong to “lining people with objects,” but they can still produce a good migration effect.

Based on the above-given experimental preparation, the distortion parameters after image migration are defined by using the parameters obtained by the gradient processing; the numerical relationship is shown as follows:

$$D(v_1, v_2) = \sqrt{(v_1, v_2)^T \left(\frac{\Sigma_1 + \Sigma_2}{2} \right)}. \quad (22)$$

Here, v_1 and v_2 , respectively, represent the distortion vector of the image, Σ_1 and Σ_2 , respectively, represent the covariance value of the image, T represents the multivariate parameter in the image, and $D(v_1, v_2)$ represents the image distortion parameter. Corresponding to the numerical relationship constructed above, every three sets of art works data sets are processed into an independent variable. Finally, the image distortion parameter results after migration by the three methods are shown in Figure 6.

It can be seen from the experimental results shown in Figure 6 that 15 groups of open source images are integrated into 5 groups of image processing groups. Corresponding to the distortion parameter value relationship constructed above, the greater the calculated distortion value is defined, it means that the migrated image of this style migration technology has greater distortion. According to the values in Figure 6, the average distortion parameter obtained by the method of reference [5] is about 0.55, and the migrated image has great distortion. The average distortion parameter obtained by the method in reference [6] is 0.3, and the image migrated by this style migration technology produces less distortion. The average distortion parameter obtained by the proposed method is 0.15. Compared with the two comparison methods, the distortion parameter formed by the proposed style migration technology is the smallest, and the distortion generated by the actual migrated image does not affect the next image processing work.

In the above-given experimental environment, three methods are called to segment the nonsignificant region, and multiple overlapping measures are defined in the three methods. In the actual segmentation, when there is no overlap in the overlapping measures, it indicates that the

FIGURE 5: Style transfer of art works style transfer effect of art works (a) Premigration image (b) Post migration image.

FIGURE 6: Distortion parameters generated by three methods.

image style migration technology can accurately segment the nonsignificant region, and the overlap degree of the three methods is defined. The numerical relationship is shown as follows:

$$I = \frac{A \times V(i, j)}{B} \tag{23}$$

Here, I represents the calculated overlap, A represents the significant area segmented by image style transfer technology, and B represents the nonsignificant area segmented by style transfer technology. Under the control of the above numerical relationship, sort out the art works data set prepared for the experiment, and sort out the overlap results generated by the three methods, as shown in Figure 7.

After the images participating in the experiment are divided into five groups of image groups, the average value of overlap in the image group is calculated according to the above-constructed overlap value relationship. It is defined that the closer the overlap value is to 1, it means that the significant area and nonsignificant area segmented by this style of migration technology overlap. According to the

FIGURE 7: Overlap values generated by the three methods.

numerical relationship shown in Figure 7, the average overlap value obtained by the method of reference [6] is 0.9. There is a lot of overlap between the nonsignificant region and the significant region segmented by this style transfer technology, which has a great impact on enhancing the nonsignificant region. The average overlap obtained by the method of reference [5] is 0.5. The nonsignificant region segmented by this style of migration technology overlaps with the significant region, which has little impact on the process of image migration. The average overlap obtained by the proposed method is 0.2. Compared with the two comparison methods, the overlap between the nonsignificant region and the significant region actually segmented by the proposed method is small, which has little impact on the effect after migration.

Keeping the above-given experimental environment unchanged, the brightness of the art works processed by the three methods is stretched and processed into a light compensation process. After the stretching process of the same process, the gray level output by the three methods corresponds to the gray level output. The output gray level results are shown in Figure 8.

After the same illumination treatment, the art works prepared for the experiment are marked in order by comparing the gray level parameters of the output of the actual stretching enhanced image. It is defined that the larger the gray level parameter of the image output after migration, it indicates the loss of details of the image area after illumination compensation. According to the gray level parameter values sorted and calculated in Figure 8, when referring to the art works after migration according to the method of reference [6], the actual output gray level parameter is between 0.5 and 0.7, the actual output gray level parameter is the largest, and the nonsignificant area after migration loses the most details. The actual output gray level parameters of reference [5] method are between 0.4 and 0.5, the actual output gray level parameters are large, and the nonsignificant areas after migration lose more details. The

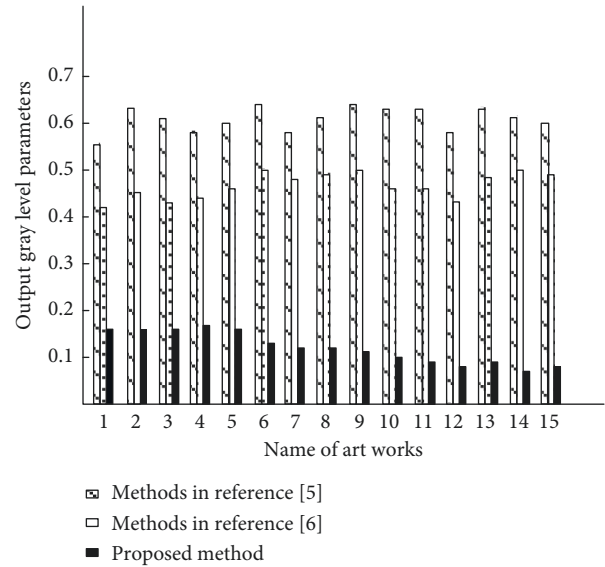

FIGURE 8: Gray level parameters output by three methods.

actual output gray level parameters of the proposed method are between 0 and 0.2. Compared with the two comparison methods, the output gray level parameters are the smallest, the details of the nonsignificant area of the migrated image are the least, and the quality of the migrated image is the best.

In conclusion, the experimental results prove the effectiveness of the proposed method. In the above tests, the average distortion parameter obtained by the proposed method is 0.15, the average overlap is 0.2, and the actual output gray level parameter is between 0 and 0.2. The test results of the three test indicators are low, which shows that the proposed art work style migration technology has very strong robustness and can achieve art work style migration. And this method can not only achieve a better migration effect but also will not make the style migration image of art works distorted.

5. Conclusion

Art works are an important tool of expression and communication in daily life and social life. However, with the changes of the times and the evolution of culture, the functions of the style of art works in reflecting cultural heritage, emotional appeal, visual beauty, as well as brand image, product information, industry characteristics, etc., have attracted more and more attention. Especially in recent years, with the vigorous development of digital carriers, digital design of art works has gradually become a daily demand of today's society and life. Therefore, aiming at the problems existing in the style image of art work style transfer, this paper proposes a style transfer technology of art work based on dual channel deep learning. Using the principle of art style migration technology and Poisson image editing technology, the style migration of art works is realized, so as to obtain a migrated image that can meet the modern style design. The experimental results show that the

proposed method has very strong robustness and can realize the style migration of art works. It can not only achieve a better migration effect but also will not make the style migration image of art works distorted.

In dance, we must understand the essential meaning of dance movements from the inside and express them on the basis of dance. Therefore, in the process of developing new dance teaching methods, it is necessary to improve the basic education of dance students, so that they can express the emotions conveyed by dance through body language and movements, and improve dance expression ability. In this context, we made the research and reached the following conclusions: (1) the number of frames of different dance types is also different, and the number of frames to be learned is also increasing. The dance with the highest number of frames is Latin2, which has 3635 frames, and the dance with the highest number of frames that need to be learned is also Latin2, which requires 2519 frames to learn. (2) The data mining method is still the highest among the three methods, and the accuracy of the complete teaching method is 82%, which is the lowest among the three methods, and the accuracy of the decentralized teaching method is 87%. No matter in the test set or the mixed test set, the curve values of deep mining are very stable. First of all, human movements emphasize that in dance, the essential meaning of dance movements needs to be understood from the inside and expressed through the foundation of dance. Therefore, when developing new dance teaching methods, it is necessary to strengthen the basic dance training of students so that students can express the emotions conveyed by dance through body language and movements and improve their dance expression ability. We conduct research in this ecological environment. Different types of dance learning process using different frames, different types of dance in the algorithm transport have different recognition methods, using better and different algorithms can achieve the best performance. Both groups in the Hip Hop dance had a shorter average learning time than both groups in the Latin dance.

1. Introduction

For representing, processing, and extracting knowledge for a variety of applications from the ever-increasing accumulation of data, which made the pervasiveness of computers possible, perhaps inevitable, and built a general framework for inspection and classification methods. Provide simple examples to demonstrate the nature of representative feature selection methods, compare them using datasets with a combination of intrinsic properties according to the goal of selecting features, propose guidelines for using different methods in various situations, and identify areas of research new challenge venue. A reference for researchers in machine learning, data mining, knowledge discovery, or databases [1]. As the ability to track and collect large amounts of data

using current hardware technologies continues to improve, there has been interest in developing data mining algorithms that protect user privacy. A recently proposed technique addresses the privacy preservation problem by perturbing the data and reconstructing the distribution at the aggregation level to perform mining. This approach preserves privacy when accessing information implicit in the original attributes. The distribution reconstruction process naturally leads to some information loss, which is acceptable in many practical situations, and the algorithm is more efficient than currently available methods in terms of information loss levels. Specifically, it is demonstrated that the EM algorithm converges to a maximum-likelihood estimate of the original distribution based on perturbed data. When large amounts of data are available, the EM algorithm provides robust

estimates of the raw data [2]. Interest in mining time series data has exploded over the past decade. In this work, the following claims are made. Much of the utility of this work is small because the amount of improvement provided by the contributions is entirely the variance that can be observed by testing on many real-world datasets, or by changing minor implementation details. To illustrate the point, the most exhaustive time series experimental reimplementation ever performed [3]. When used with statistical methods, graphical models have many advantages in data modeling because the model encodes the dependencies between all variables, can easily handle missing data, and can be used to understand problems and predict consequences. The article discusses methods for building networks from prior knowledge and summarizes Bayesian statistical methods for improving these models using data [4]. Using soft computing provides a survey of the available literature on data mining. Classifications have been provided based on the different soft computing tools used and the data mining functions they implement and the data mining functions implemented and preference criteria selected by the model. The utility of different soft computing methods is highlighted. Generally fuzzy sets are suitable for dealing with problems related to pattern comprehensibility, mixed media information and human interaction, and can provide approximate solutions faster. Genetic algorithms provide efficient search algorithms to select models from mixed media data, pointing out some challenges to data mining and applications of soft computing methods are presented. An extensive bibliography [5] is also included. Girls showed a higher personal interest in dance than boys, but the two groups were equally interested. Although girls were not as physically active as boys, their skills/knowledge outcome indicators were higher than boys. It appears that gender has little effect on the motivational effect of situational interest, and the quality of classroom learning in girls may be higher than in boys due to higher personal interest. The findings suggest that situational interest may motivate all students, but it is necessary to enhance personal interest in order for them to engage in high-quality learning [6]. We emphasize generating augmented reality environments for individual dancers based on dance annotation analysis. We have introduced a new interactive technique for dance animations required for educational purposes. This approach opens up new possibilities for interactive dance observation, fast and slow motion, different perspectives, and multiple functions to support high interactivity between users and 3D dancers [7]. All people have the urge to express themselves through dance, which represents a unique opportunity to artificially capture human creative expression. In particular, the spontaneity and relative ease of moving with music without any overall planning suggests a natural link between temporal patterns and motor control [8]. Four preschool dance classes, including 32 children aged 3–6, were randomly assigned to pretend imagination and traditional instruction. Ratings were based on the speed at which new motor skills were learned, future recall of the skills, concentration on the task, and enjoyment during the task. It was found that children in the pretend imagination group had significantly

better visual fixation, engagement, and enjoyment of the task process, required less time for prompting and recall, and took less time to learn skills [9]. These multimedia applications need to store and retrieve different forms of media such as text, hypertext, graphics, still images, animation, audio, and video. Dance is one of the important cultural forms of a nation, and dance video is such a multimedia form. Archiving and retrieving the required semantics from these dance media collections are a crucial and demanding multimedia application [10]. In recent years, with the increase of work pressure, more and more people have begun to pay attention to national fitness, in order to improve personal physical and psychological quality. Square dancing is a sport suitable for all ages. It integrates fitness, a healthy heart, and a strong and handsome brain. It is the best way to communicate in fitness and is deeply loved by people. The current situation of residents' square dance was investigated, and the characteristics of square dance practitioners themselves and the characteristics of square dance were analyzed [11]. Track their movements using an optical motion capture system. Many pose and kinematic features are extracted from motion data. Findings indicated that the positive effects of proximity motivation were associated with higher movement speeds of the hands and head, as well as the extended posture of the hands. In addition, positive effects were also associated with higher-dimensional movements, suggesting an association with more complex and varied dance movements [12]. Chinese classical dance steps with unique aesthetics are closely related to traditional Chinese opera. Classical Chinese dance steps can be traced back to ancient women's foot binding, which had a great impact on the physiology and morphology of the dance steps [13]. Develop a method for automatic classification of the correctness of basic dance movements to support dance beginners in their self-practice outside the classroom. We first worked with dance professionals to design two basic dance moves, the waltz and the merengue. Acceleration and angular velocity data of the chest and pelvis were collected [14]. The article provides information on the health benefits of several dances. It mentions that dancing is a weight-bearing exercise that causes osteoblasts to grow. It added that dancing like boogie can enhance brain power, especially mental function and creativity. Furthermore, it mentions that dancing, including spinning, also burns calories, which is essential for a healthy heart [15].

2. Dance Learning

2.1. Status Quo of Dance Learning

2.1.1. Classroom Learning Mode Is Single. Because the basic level of dance of the students varies, it is difficult to carry out high-level teaching, and only the intermediate level can be unified and standardized. Students with a good foundation feel that it is "tasteless to eat, and it is a pity to abandon it," and repeating the content they have learned in the past feels a little dull and long; while students with a weak foundation are "dazzled" by the basic content and "hesitant" for the advanced content. In actual learning, teachers lead students

to count the beats and jump over and over again, and “fill-in” mechanical imitations cause students to lose their enthusiasm for autonomous learning. The grasp of dance style is submerged in form, which restricts students’ innovation and creativity.

2.1.2. Curriculum Setting Is Biased toward Professional Technical Training. Although the construction of dance teaching materials tends to be perfect, the curriculum covers a wide range, and professional theoretical courses such as Chinese dance history and Chinese folk dance culture have not been properly used in teaching. Just by simply sorting out and forcing memory, students cannot think about the connotation and value of their cultural system and bring them into the process of dance performance.

2.1.3. Lack of Distinctive Course Content Settings. The content and methods of dance course materials in advanced colleges have been tested by long-term teaching practice and tend to be stable, perfect, and self-contained. Different schools have different school-running characteristics. If the theory is blindly copied and the exploration of teaching practice is ignored, the content of the courses is similar, and there is a lack of regional targeting. In this way, the theory and practice of teaching are disconnected. For example, in the ethnic dance courses in the southwest region, if the advanced dance courses in other regions are set up step by step, there will be very few professional practice opportunities for students after graduation, which is not conducive to the study of ethnic culture and the inheritance of art in the southwest region. The teaching effect is maximized.

2.2. Problems in Dance Learning

2.2.1. The Lack of Exemplarity in Dance Education. If there is a need, there will be a market, and schools will slowly emerge to teach dance. Whether it is teaching, teachers, or educational institutions, the conditions are relatively comprehensive, and the social recognition is relatively high, but more and more dance schools are social institutions that lack education and teaching. In response to this problem, the head teacher asked teachers to train students according to the grade-level learning materials and prepare for the exams that the students will take. As the class progresses, children are the main source of students in dance schools. Students in this age group are special because they are more playful, have shorter attention spans, and do not understand many technical terms. Many teachers do not pay attention to the details of students’ physical and mental development. This creates a vicious circle. Finally, some dance schools only shout slogans and do not provide a good learning environment. The poor quality of teaching materials is not suitable for teachers. They always use a variety of teaching methods without caring about what each student’s dance really means.

2.2.2. The Teaching Method of Dance Education Is Not Systematic. The teachers of some dance schools are not of high quality and cannot arrange courses according to the learning ability of students of different age groups. In order to make learning more effective, they blindly teach students difficult dance moves, ignoring the rules of easy and difficult to learn. Exceeding a student’s physical capacity can affect not only his or her long-term physical development but also many potential risk factors. Others say learning to dance is difficult. Only strengthen the physical development of students. The intensity of the internship provides good grades but does not allow for dangerous movements that exceed the student’s physical endurance. Doing too much to achieve course goals in a short period of time may be detrimental to the healthy development of students. Additionally, many teachers are unable to teach students based on information about the learning process. For example, some students have poor physical fitness and poor dance skills; so teachers have to learn to be careful not to trust each other, so that students eventually lose confidence in learning dance. It is shown in Figure 1.

2.3. Measures to Solve the Problems Existing in the Current Dance Learning

2.3.1. Build an Excellent Team of Teachers. Everything related to education is inseparable from a good teacher. A good teacher must not only have good professional dance skills but also teach students moral education through language and action, that’s how you can become a really good dance teacher.

2.3.2. Pay Attention to Reasonable Arrangements for Teaching. Since most dance classes take place outside of school because of the need for concentration, teachers should give students enough time to learn about the teacher in class rather than just looking for a lot of knowledge. In addition, when explaining dance movements, teachers should try their best to explain in clear, clear, and easy-to-understand technical language to attract children’s attention and stimulate their interest in learning.

2.3.3. Strengthen the Construction of Hardware Facilities. It is necessary to strengthen the supervision of dance schools in all walks of life, and safety issues must be put in place in a timely manner, and dangerous accidents should be prevented as much as possible. Dance schools must determine that there is no income limit and no students will be admitted. This eliminates the need for quality teaching, liberating teachers, and increasing classroom efficiency.

2.3.4. Strengthen the Construction of Dance Teaching Materials. Whether it is the Children’s Palace or various extracurricular dance schools, the teaching materials need to be strengthened with the help of experts or experienced dance teachers to prepare the teaching materials for children’s physical and mental development. Know how to do

FIGURE 1: Problems in dance learning.

teaching tasks according to the actual situation of students in the classroom. Make a study plan and try to complete the study tasks correctly. Don't prepare for the exam. It is shown in Figure 2.

3. Data Mining Algorithms

3.1. Data Mining Algorithm Design. Create the subspace S required for data mining. Location is the value of the data function in the collection, and the data are in form $o \in D$. According to the data distribution characteristics of outliers, the nearest neighbors (O, S) of data elements can be expressed as also Subspace with uneven distribution. Regarding the nature of multidimensional data, it is clear that the focus of the subspace is the data object O , and the formula for calculating the probability distance is the following:

$$d_s = \frac{1}{I_d(o, s)}. \quad (1)$$

In the formula, distance is represented by d . If the data object is always in the middle of the excavation set, the mean or distance of the data can be calculated by formula:

$$\sigma(o, s) = \sqrt{\sum_{x \in s} d(o, s)^2}. \quad (2)$$

Since local discrete data have nonuniform distribution conditions, the properties of discrete data must be represented by an approximation between the density of discrete data and the standard distance.

$$\lambda = \frac{I_d}{\sigma(o, s)}. \quad (3)$$

The segregated asset is obtained from equation (3) and the result provides the desired distribution of segregated data within the region. Combined with the above feature search method, the data entropy information algorithm is used to extract the information needed to retrieve big data objects from the Internet. Observe the distribution of the given data x , and use the probability function of the p value to obtain the information element $E(x)$ of the data x :

$$E(x) = - \sum_{x \in x} p(x) \ln p(x). \quad (4)$$

Due to the differences in the detected data dimensions, it will have a certain negative impact on the results of IoT big data mining, so it is necessary that the detected data are processed according to the standard format, as shown in

FIGURE 2: Measures to solve the problems existing in current dance learning.

$$\alpha = \frac{\alpha - \alpha_1}{Y_\alpha}. \quad (5)$$

The result of data normalization should be calculated based on the average attribute of the received data and the data standard deviation attribute. The calculation process uses standard deviation to increase the relevance of the data properties and to ensure the accuracy of the data retrieval.

The overall results of data processing should be calculated according to the method, the nature of the data observed, and the standard deviation of the data characteristics. The calculation process uses the standard deviation to make data attributes more important to the accuracy of data mining. In addition, mean deviations from known data characteristics can also be used to obtain standard data processing results. The calculation formula is the following:

$$\alpha_i = \frac{\alpha - \alpha_1}{G_a}. \quad (6)$$

The purpose of improving the anti-interference performance of the algorithm is achieved through the above formula, and the calculation formulas of the data attribute average α , the data attribute standard deviation Y_a , and the data attribute average deviation G_a are the following:

$$\alpha_1 = \sum_m \alpha \frac{1}{m},$$

$$G_a = \sum_m \frac{\alpha - \alpha_1}{m}, \quad (7)$$

$$Y_a = \sqrt{\sum_m \frac{(\alpha - \alpha_1)^2}{m}}.$$

In the formula, the number of iterations is m . After the data standardization is completed, artificial intelligence technology is applied to the processed data to obtain certain data mining results.

3.2. Realize Intelligent Data Mining. Neural network technology, an important branch of artificial intelligence technology, is used to carry out big data mining on the Internet of Things. The BP neural network with three-layer transmission structure is used as the main structure, and the normalized data are distributed into the neural network.

Due to the particularity of the neural network structure, the average value of the information entropy of the data is E :

$$\begin{aligned}\omega &= \frac{1 - H_i}{\sum_{i=1}^E H_i}, \\ \theta_1 &= u\theta_1 + (1 - u)\theta_2, \\ \theta_2 &= u\theta_2 + (1 - u)\theta_1.\end{aligned}\quad (8)$$

The two data in the formula and θ_1, θ_2 are linearly combined. The constant range of U is from 0 to 1, and the value range is narrowed according to the actual situation. If the constant value is fixed, it means that the hybridization operator is not constant during the calculation process. Since the constant value changes with the number of iterations, the average performance of the hybrid operator can be improved, and thereby realizing the integration of IoT big data.

$$v_k = v_k = \Delta(t, v_k - LB). \quad (9)$$

The data change value is generated from the left and right neighbors LB and UB of the variable k and the return value of the function. As the algebraic t increases, the value of the data change is likely to approach 0. Based on the above steps, a general operator search is performed on the dataset to create an IoT data view that meets the needs of data mining. In all the above processing steps, an IoT data mining algorithm based on artificial intelligence technology is developed.

3.3. Federated Average Algorithm. A unified learning algorithm distributes learning tasks to different devices to learn local model updates and, occasionally, interacts with a central server to coordinate learning objectives around the world. Unlike traditional machine learning methods, blended learning requires centralizing training models on a computer or data center so that each client device can use a local training data set to update the model. Federated learning is defined to solve the minimum loss of an objective function according to a formula.

The unified learning algorithm distributes learning tasks to different devices to learn local model updates and communicates with a central server from time to time to coordinate global learning goals. Unlike traditional machine learning approaches, blended learning requires training models to be centralized on a computer or data center so that each client device can use a local training dataset to update the model. Equation analysis is defined as the concentration of the dataset in a set of loss functions, which determine the solution to which Equation (10) is applied to the k samples of the dataset. The built-in analysis algorithm uses the generic, $n = \sum_k n_k, p_k = n_k/n$ algorithm trained on all k multifunctional devices in the dataset.

$$\min f(\omega) = \frac{1}{n} \sum_{k=1}^k n_k F_k(\omega) = \sum_{k=1}^k p_k(\omega). \quad (10)$$

The local prediction loss function for each client device k along the model parameters is $F_k(\omega)$. As shown in Equation

(11), when different local optima are computed they are combined to achieve an overall minimization of the learning loss:

$$F_k(\omega) = \frac{1}{n_k} \sum_{i \in n_k} f(x_k, \omega). \quad (11)$$

This will improve common patterns in connected learning systems. To solve the objective equation, FedAvg first randomly selects k units from a subset of system units at each computational iteration, and then uses a combined FedSGD optimization method to globally implement each selected unit, computing the location of the global state and local data.

During the calculation process, local search and global search are continuously amplified according to P1 and P2 points, which correspond to both yin and yang. If point P2 is better than point P1 the two points are exchanged, and the sympathy algorithm agrees. Yin and yang have repetitions according to P1 and P1 points. P2 exploration optimization is expected to achieve a balance between local development and global exploration, which is a balance of yin and yang. In this particular implementation, the yin–yang balance optimization algorithm typically consists of two steps: updating the solution based on the collection set and updating the solution based on the hypersphere the main content of these two terms is given as follows:

$$\begin{aligned}g_k &= \Delta F_k(\omega_k), \\ \forall k, \omega_{t+1}^k &\leftarrow \omega_t - \eta g_k.\end{aligned}\quad (12)$$

In each of the update round, the server collects training data from all devices participating in that training round of the pattern and calculates the weighted average system update pattern according to equation (13), where η represents the training learning rate:

$$\omega_{t+1} \leftarrow \omega_t \eta \sum_{k=1}^k. \quad (13)$$

The number of elements in the FedAvg algorithm plays a crucial role in the speed of convergence and the accuracy of predictions. Some people suggest adding the stack size to some value to approximate disk. When installing a large compressed package, each device can speed up the calculation of the same amount of data, improve the convergence speed of the system, reduce the number of iterations, and keep the training of the system at a high enough level of accuracy. In the calculation process, the local search and global search based on points P1 and P2 are continuously strengthened, which corresponds to both yin and yang. If point P2 is better than point P1, then these two points are exchanged, and the sympathetic algorithm corresponding to yin and yang is repeated based on points P1 and P1. The optimization search of P2 is expected to achieve a balance between local development and global search, corresponding to the balance of yin and yang. In the specific implementation, the yin–yang balance optimization algorithm mainly includes two stages: solution update based on archive set and solution update based on hypersphere. The main

contents of these two stages are given below. To update the search radius, the calculation method is as follows:

$$\begin{aligned}\delta_1 &= \delta_1 - \left(\frac{\delta_1}{\alpha}\right), \\ \delta_2 &= \delta_2 + \left(\frac{\delta_2}{\alpha}\right).\end{aligned}\quad (14)$$

4. Research on Action Analysis and Guidance of Data Mining in Dance Learning

4.1. Performance Test of Data Mining in Dance Movement Learning. To test the optimal performance of the data mining methods proposed in this dance review article, the models proposed in this article have been experimentally improved and research methods have been applied with subsequent tests and trials to make a complete and decentralized learning approach. Test kits are used to assess the generality of the final sample, and the hybrid test set meets the modern criteria of the model and is first used to assess the model's ability to write test results. Experimental data of different samples of the test group and the mixed test group are shown in Figure 3.

From the data in Figure 3, we can see that after performing a series of tests, the accuracy of the distributed learning method can be 89%, the accuracy can increase to 91%, and the accuracy can increase to 92% using data mining technology. The accuracy can increase to 93%, which is the highest value in the three test models. The complete teaching method has an accuracy rate of 85%, and the lowest of the three models. We can also see that the curve values of data mining technology are very stable, and the curve value of the decentralized teaching method remains around 0.90. The curve value of data mining is also always kept at 0.97, and the curve value of the complete teaching method is lower.

The data in Figure 4 and Table 1 shows that the performance of all three models decreases slightly after passing the mixed test series, but the data mining method proposed in the paper is still the highest of the three. The depth extraction curve is very stable whether it is a test series or a mixed test series.

4.2. Research on Movement Analysis and Guidance in Dance Learning. Based on the three aspects of human body structure, movement direction, and movement effect, the dance movement is reconstructed, the continuity and periodicity of dance movement data are determined, and a short and easy-to-understand language is developed to formally describe the MDL and application of dance movement. The structure of the MDL can be adjusted. As a description, language captures an individual's three-dimensional skeletal hierarchy, which is then described based on quantitative assessments of dance movements and biomechanical parameters (Tables 2 and 3). The action analyzes the spatial orientation of the human body, calculates the parameters of the movement characteristics from the key frame data, uses the description language to determine the

FIGURE 3: Data analysis on the test set.

FIGURE 4: Data analysis on hybrid experience.

movement trajectory of the human body, determines the correlation between the human body coordinates, and the spatial direction of the environment, and determines the description language to the human body movement trajectory.

There are many types of basic movements in dance learning, such as kicking the swallow, chest and waist, squatting, lowering the waist, stepping down, and rubbing the floor. The number of movements for dance learning needs to be systematically trained: 8 times/group of kicking swallows for a total of 5 groups; 10 times for chest and waist/group for a total of 3 groups; 15 times for squatting/group for a total of 3 groups; 5 times for lower back/group A total of 4 groups were completed; a total of 3 groups were completed under the span of 30 s/group; a total of 5 groups were completed by rubbing the floor 20 times/group.

From the data in Figure 5 and Table 4, we can see that the number of frames for different dance types is also different, and the number of frames to be learned is also increasing. The dance with the highest number of frames is Latin2, which has 3635 frames, and the dance with the highest number of frames that needs to be learned is also Latin2, which requires 2519 frames to learn. The dance with the

	Treatmentl	First stage course	20

TABLE 6: Statistics of learning time of control group and treatmentl group.

Dance	Group	Number of students	Ceaverage study time	Variance
Latin	Control	20	71.95	10.1
	Treatmentl	20	60.95	8.48
Hip hop	Control	20	97.4	7.56
	Treatmentl	20	84.7	10.8

FIGURE 6: Statistics of the learning time of the control group and the treatmentl group.

TABLE 7: *t*-Test results of learning time in control group and treatmentl group.

Group	Ceaverage study time	Variance
Control	71.95	10.1
Treatmentl	60.95	8.48
Control	97.4	7.56
Treatmentl	84.7	10.8

students were divided into two groups, group and group study using the free-view method, and group study in the first stage of the course, as shown in Tables 5 and 6.

From Figure 6 and Table 5, we see that the groups of students who learned to dance reported the average time spent (in minutes). The average learning time of the two groups of hip hop was 71.95 and 60.95, respectively, while the average learning time of the Latin group was 94.4 and 84.7, respectively. It can be seen that the average learning time of the two groups in hip hop dance is shorter than that of the two groups in Latin dance.

From the data in Table 7, it can be seen that the learning data of the two groups are very different (Hip hop: $T = 3.74$, $P = 0.0006$; Latin: $T = 4.3$, $P < 0.0001$). Therefore, we believe that the first stage of dance teaching two this dance is more effective than the free-view method, so it works well.

FIGURE 7: Comparison of control group and treatmentl group.

Given the data of the two groups of students on the questionnaire question “I think this system can help me learn dance,” from the experimental data in Figure 7, we can see that the proportion of those who hold opposing opinions is the largest in the control group. 16 people. In the Treatmentl group, the maximum proportion of people who agree with it reaches 13 people. It can be seen that there are more people in the control group who disagree with the Treatmentl group.

5. Conclusion

There is no direct connection between human movement and dance. In dance, the focus is on the movements of the people. The importance of dance moves must be understood from within and manifested on the basis of dance. Therefore, when developing new dance teaching methods, students need to improve their basic dance practice so that they can express the emotions conveyed by dance through body language and movements. In order to achieve the increase of dance performance. The goal of dance itself is to use the students’ internal motor activities to enable them to achieve a double improvement in movement and expression.

Machine learning (ML) and privacy protection are inseparable. On the one hand, ML can be the target of privacy protection; on the other hand, it can also be used as an attack tool for privacy protection. Ring signature (RS) is an effective way for privacy protection in cryptography. In particular, lattice-based RS can still protect the privacy of users even in the presence of quantum computers. However, most current lattice-based RS schemes are based on a strong trapdoor like hash-and-sign, and in such constructions, there is a hidden algebraic structure, that is, added to lattice so that the trapdoor shape is not leaked, which greatly affects the computational efficiency of RS. In this study, utilizing Lyubashevsky collision-resistant hash function over lattice, we construct an RS scheme without trapdoors based on ideal lattice via Fiat–Shamir with aborts (FSwA) protocol. Regarding security, the proposed scheme satisfies unconditional anonymity against chosen setting attacks (UA-CSA), which is stronger than anonymity against full key exposure (anonymity-FKE), and moreover, our scheme satisfies unforgeability with respect to insider corruption (EU-IC). Regarding computational overhead, compared with other RS schemes that satisfy the same degree of security, our scheme has the highest computational efficiency, the signing and verification time costs of the proposed scheme are obviously better than those of other lattice-based RS schemes without trapdoors, which is more suitable for ML scenarios.

1. Introduction

Machine learning (ML) and privacy protection are inextricably linked. On the one hand, ML itself requires privacy protection, i.e., the training datasets and models in ML systems should not be disclosed. On the other hand, ML can also be an attack tool for privacy protection, and how to protect users' sensitive information is a challenging task under the increasingly powerful ML technology.

Ring signature (RS), introduced by Rivest et al. [1] in 2001, is an effective technique for privacy protection in cryptography, which on the one hand enables the recipient of the data to believe that the source of the data is reliable, and on the other hand, obscures the identity of the data owner so that the recipient cannot be sure who is the real owner of the data. In an RS scheme, each user has a public key, and the signer can autonomously collect user's public keys to form a ring without the permission or assistance of other users (where the signer is contained in the set of ring

members), and the verifier only knows that the signature was generated under the ring, but is unsure which member's private key is used as the signing key. Due to the anonymity of RS, it is widely used in fields such as e-voting, anonymous membership authentication, and anonymous tip-off.

Since the seminal work of [1], the research on RS has been unprecedentedly active. A general framework for constructing 1-out-of- n signature schemes was introduced by Abe et al. [2], which can use different types of keys to construct signatures based on integer decomposition and discrete logarithm problems. After that, many RS schemes along with their associated authentication schemes [3–10] have been proposed. However, the security definitions of these RS schemes are weak, i.e., they have not considered for certain realistic attacks. Bender et al. [11] proposed new definitions of anonymity and the unforgeability of RS to cover these attacks. Bender et al. [11] divided anonymity into three levels according to the degree of security, where the strongest version is anonymity against full key exposure

(Anonymity-FKE), i.e., even if adversary is given the private keys of all ring members, the adversary is still unable to guess who is the genuine signer of the given RS. Regarding existential unforgeability, there are also three levels: unforgeability against fixed-ring attacks (EU-FRA), unforgeability against chosen-subring attacks (EU-CSA), and unforgeability with respect to insider corruption (EU-IC). Based on EU-CSA, the strongest EU-IC means the adversary cannot succeed in forging a signature, even if the adversary is allowed to obtain the private keys of ring members via asking a corruption oracle.

Most previous RS schemes [1–7, 9–11] are constructed under the assumptions of classical number theory, which are hardly resistant to quantum attacks [12]. In 1996, Ajtai [13] introduced the algebraic structure of lattice into cryptographic schemes. In the postquantum era, the new cryptosystem based on lattice has become a focus of research due to its merits of high asymptotic efficiency, simple operation, parallelizability, resistance to quantum attacks, and enjoying the average-to-worst reduction. The development of lattice-based provably secure encryption has developed rapidly and has made great progress [14–18], while lattice-based digital signature has experienced a tortuous and bumpy process in the earlier years. First, Goldreich et al. [19] made an attempt at a lattice-based signature, then NTRU signature was proposed by Hoffstein et al. [20], and it was repaired and enhanced in [21, 22]. However, these digital signature schemes [19, 20, 22] on lattice failed to be proved secure under the attacks of [23, 24]. To date, provably secure signature schemes on lattice can be divided into two main branches: schemes with trapdoors and without trapdoors. Digital signature schemes with trapdoors started from the “hash-and-sign” signature scheme constructed by Gentry et al. [25] based on SIS assumption, which is also the first lattice-based signature scheme, that is, provably secure. and Peikert [26] improved the structure of trapdoors, that is, proposed by [27], proposed the concept of G trapdoors on lattice, and remarkably improved the computational efficiency of trapdoor generation algorithm on lattice. A digital signature scheme on an ideal lattice was proposed by Ducas and Micciancio [28], and its trapdoor is constructed utilizing the technique of [26]. These trapdoors are deemed to be very suitable for lattice-based signature schemes, but the lattice is added with a hidden algebraic structure, which significantly affects the efficiency of signature schemes and is a payment that has to be considered. Digital signature schemes on lattice without trapdoors are mainly based on Stern’s zero-knowledge proofs. Although the Stern-type protocol is powerful, the soundness error of a single execution of the protocol is $2/3$. Such protocol needs to be repeated many times so that the soundness error drops to a negligible value, so it is difficult to further improve their efficiency. To the best of our knowledge, only Lyubashevsky signature schemes [29, 30] without trapdoors are constructed not based on the Stern-type protocol, but on the Fiat–Shamir with aborts (FSwA) protocol, via which a very efficient digital signature scheme on lattice could be constructed.

Similar to a digital signature over lattice, lattice-based (linkable) RS can also be mainly divided into two branches,

i.e., with trapdoors and without trapdoors. Lattice-based RS schemes with trapdoors have been extensively studied [31–36]. Notice that these lattice-based RS schemes with trapdoors, although are progressing about storage overhead, cannot always avoid the drawbacks brought by the structure of hash-and-sign, and the computational efficiency cannot be enhanced to a satisfactory level. Lattice-based RS schemes without trapdoors can be classified into membership proofs-based schemes and FSwA-based schemes. Several RS schemes [37–40] based on membership proofs have been proposed. Such RS schemes usually first construct a membership proof which is generally a zero-knowledge proof and then construct an RS scheme based on this proof. The efficiency of these RS schemes directly depends on that of underlying zero-knowledge proofs, which have the advantage that the signature length is usually $O(\log N)$, where N is the ring size, whereas the disadvantage is also obvious, i.e., the large and complex zero-knowledge proofs lead to low computational efficiency, and the length of RS could be large when N is small. (Linkable) RS schemes [41–44] based on FSwA are rather efficient in terms of computational efficiency, with the drawback that the signature length is common $O(N)$, yet it is very suitable in small-scale scenarios. For RS on lattice, several schemes [37–40] can satisfy the strongest Anonymity-FKE and EU-IC defined by Bender et al. [11]. In fact, Aguilar Melchor et al. [41] defined stronger anonymity, i.e., unconditional anonymity against chosen setting attacks (UA-CSA), and inspired by Lyubashevsky signature scheme [29], Aguilar Melchor et al. [41] constructed two RS schemes (AM1 and AM2) utilizing lattice-based collision-resistant hash function $h \in \mathcal{H}(D, D_x, m)$ [45], both of which can achieve UA-CSA for anonymity; regarding unforgeability, AM1 and AM2 satisfy EU-CSA and EU-IC, respectively. However, we deem that Aguilar Melchor et al. do not make good use of $h \in \mathcal{H}(D, D_x, m)$ in transforming Lyubashevsky digital signature [29] into RS, which causes the storage and computational overheads of both schemes of Aguilar Melchor et al. [41] to be large. In this work, via the FSwA protocol, we redesign an RS scheme on lattice without trapdoors using $h \in \mathcal{H}(D, D_x, m)$ again, the main contributions are as follows:

- (1) Different from the RS schemes of Aguilar Melchor et al. [41] on lattice, in our key generation algorithm, the input value of $h \in \mathcal{H}(D, D_x, m)$ is taken as a user’s private key, the output value of $h \in \mathcal{H}(D, D_x, m)$ is taken as a public key, that is, relevant to the private key, which makes the length of a public key is reduced from a polynomial vector of m dimensions to a polynomial. Our signing algorithm is designed based on the framework of the RS scheme of Abe et al. [2], which is based on the discrete-log assumption, and the proposed scheme will be more concise and efficient.
- (2) Under the improved security model of Aguilar Melchor et al. [41], the proposed RS scheme is rigorously proven to be safe. Regarding anonymity, our scheme satisfies the strongest UA-CSA; in terms of unforgeability, our scheme satisfies the strongest

EU-IC. And under the random oracle model, the unforgeability of the proposed scheme could be reduced to the approximate shortest vector problem (SVP_γ) over ideal lattice.

- (3) Finally, with respect to performance and security, the proposed scheme is comprehensively compared with several schemes [37, 38, 40, 41]. The results show that compared with AM1 and AM2 of [41], the storage and computational overhead of our scheme are significantly reduced. In addition, compared with the computational overhead of other schemes, our scheme is remarkably superior, and is more suitable for ML applications.

2. Preliminaries

2.1. Notations. The symbol $[N]$ represents the abbreviation of the set $\{1, 2, \dots, N\}$. Let \mathbb{R} be the set of real numbers, \mathbb{R}^+ be the set of positive real numbers, and \mathbb{Z} be the set of integers. For a finite set S , the symbol $y \leftarrow S$ denotes a random uniform sampling from S . The upper-case letter X is the random variable denoting a signature, and $X \leftarrow \mathcal{F}$ denotes X as the output of the signature algorithm \mathcal{F} . Vectors and matrices are denoted by lower-case (e.g., \mathbf{x}) and upper-case (e.g., \mathbf{X}) letters in italic & bold, respectively. In this work, we construct a cryptographic scheme on ring $D = \mathbb{Z}_q[x]/(x^n + 1)$, where $(x^n + 1)$ is an irreducible polynomial, and all logarithms we use are base 2. \mathbb{Z}_q is the set of integers modulo q , elements in \mathbb{Z}_q are denoted by integers selected from the interval $[-q/2, q/2]$, and then the elements in D are represented by $n - 1$ degree polynomials whose coefficients are taken from \mathbb{Z}_q . For $a = \sum_i f_i x^i \in D$, the common norms of a are given as follow:

$$\begin{aligned} l_1: \|a\|_1 &= \sum_i |f_i|, \\ l_2: \|a\|_2 &= \left(\sum_i |f_i|^2 \right)^{1/2}, \\ l_\infty: \|a\|_\infty &= \max_i |f_i|. \end{aligned} \quad (1)$$

For a polynomial vector $\mathbf{a} = (a_1, a_2, \dots, a_m)$, where $a_1, a_2, \dots, a_m \in D$, m is a positive integer, and the infinite norm with respect to \mathbf{a} is defined as follows:

$$\|\mathbf{a}\|_\infty = \max_i \|a_i\|_\infty. \quad (2)$$

Additionally, we will use the following notations:

$$\begin{aligned} D_c &= \{g \in D: \|g\|_\infty \leq 1\}, \\ D_s &= \{g \in D: \|g\|_\infty \leq \sqrt{n} \log n\}, \\ D_x &= \{g \in D: \|g\|_\infty \leq mn^{1.5} \log n + n \log^2 n\}, \\ D_y &= \{g \in D: \|g\|_\infty \leq mn^{1.5} \log n\}, \\ D_z &= \{g \in D: \|g\|_\infty \leq mn^{1.5} \log n - n \log^2 n\}. \end{aligned} \quad (3)$$

The complexity of algorithms is measured using the standard asymptotic notations ω, O :

$$f(n) = \omega(g(n)) \text{ if } \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = \infty, \quad (4)$$

$$f(n) = O(g(n)) \text{ if } \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} \neq \infty.$$

Use the symbol \tilde{O} to suppress poly-logarithmic factors, and for example, for any constant c and c' , $f(n) = O(n^c \log^c n)$, we have $f(n) = \tilde{O}(n^c)$.

2.2. Lattice and Ideal Lattice. Micciancio [46] first proposed the concept of cyclic lattice, which to a certain extent eliminated the drawbacks of big key size and operational inefficiency of cryptographic schemes on Euclidean lattice. Lyubashevsky and Micciancio [45] first proposed the definition of an ideal lattice, which is a lattice with a special algebraic structure and is a generalization of the cyclic lattice. In general, a Euclidean lattice is a subgroup of a group, and an ideal lattice is an ideal of a ring.

Definition 1 (lattice). Supposing matrix \mathbf{B} is composed of a set of linearly independent vectors $\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_m \in \mathbb{Z}^n$, then the integer lattice generated by \mathbf{B} is defined as:

$$\mathcal{L}(\mathbf{O}) = \{\mathbf{B}\mathbf{x} = \sum x_i \mathbf{b}_i: \mathbf{x} \in \mathbb{Z}^m\}, \quad (5)$$

$\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_m$ form a set of bases over $\mathcal{L}(\mathbf{B})$. In short, $\mathcal{L}(\mathbf{B})$ is a discrete additive subgroup in the n -dimensional real space \mathbb{R}^n .

Definition 2 (q -ary lattice). Given a prime q , positive integers m, n , for any matrix $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$, the integer lattice, that is, m -dimensional full-rank is described as follows:

$$\Lambda^+(A) = \{\mathbf{u} \in \mathbb{Z}^m \text{ s.t. } \mathbf{A}\mathbf{u} = \mathbf{0} \pmod{q}\}. \quad (6)$$

Definition 3 (ideal lattice). Let f be a monic irreducible polynomial of degree n , the ideal $I \subseteq \mathbb{Z}[x]/(f)$, then an integer lattice $\mathcal{L}(\mathbf{B}) \subseteq \mathbb{Z}^n$ such that $\mathcal{L}(\mathbf{B}) = \{g \pmod{f}: g \in I\}$ is called an ideal lattice.

2.3. Hardness Assumption

Definition 4 (R-SIS_{q,m,β} problem). Given a randomly chosen vector $\mathbf{a} \in D^m$, find the vector $\mathbf{x} \in D^m$ such that $\mathbf{a}^T \cdot \mathbf{x} = 0$ satisfying $0 < \|\mathbf{x}\|_2 \leq \beta$, where q, m are positive integers, $\beta \in \mathbb{R}^+$.

Definition 5 (SVP_γ). Given a lattice $\mathcal{L}(\mathbf{B})$ and an approximation factor $\gamma \geq 1$, find a nonzero vector \mathbf{v} on lattice such that $\|\mathbf{v}\|_\infty \leq \gamma \|\mathbf{u}\|_\infty$ holds for any vector $\mathbf{u} \in \mathcal{L}(\mathbf{B})$.

2.4. Collision-Resistant Hash Functions and Bounding $\|ac \pmod{(x^n + 1)}\|_\infty$. Lyubashevsky and Micciancio [45] defined a family of collision-resistant hash functions on ideal lattice, which are efficient functions based on the hardness of worst-case lattice problems, and showed that finding

collisions for $h \in \mathcal{H}(D, D_x, m)$ is at least as hard as solving SVP_γ , where $\gamma = \tilde{O}(n^2)$.

Definition 6 (family of hash functions). For any integer m and set D_x , the family of hash functions $\mathcal{H}(D, D_x, m) = \{h_{\mathbf{a}}: \mathbf{a} \in D^m\}$, where a hash function $h_{\mathbf{a}}: D_x^m \rightarrow D$. On input polynomial vectors $\mathbf{b} = (b_1, b_2, \dots, b_m) \in D_x^m$, then $h_{\mathbf{a}}(\mathbf{b}) = \mathbf{a} \cdot \mathbf{b} = a_1 b_1 + a_2 b_2 + \dots + a_m b_m$. There are two homomorphic properties about $h \in \mathcal{H}(D, D_x, m)$ as follows:

$$\begin{aligned} h(\mathbf{x} + \mathbf{y}) &= h(\mathbf{x}) + h(\mathbf{y}), \\ h(\mathbf{x}c) &= h(\mathbf{x})c, \end{aligned} \quad (7)$$

where $\mathbf{x}, \mathbf{y} \in D^m$, $c \in D$.

Definition 7 (collision problem $\text{Col}(h, D_x)$). Given a function $h \in \mathcal{H}(D, D_x, m)$, find two distinct vectors $\mathbf{z}_0, \mathbf{z}_1 \in D_x$ such that $h(\mathbf{z}_0) = h(\mathbf{z}_1)$.

The following lemma shows that when D_x is some limited domain (e.g., a set of small norm polynomials), solving the $\text{Col}(h, D_x)$ problem is as hard as solving SVP_γ in the worst case on the lattice corresponding to the ideal $\text{in}D_x$.

Lemma 1 (see [29]). Let n be any power of 2, ring $D = \mathbb{Z}_q[x]/(x^n + 1)$, and define the set $D_x = \{g \in D: \|g\|_\infty \leq d\}$, where d is an integer. $\mathcal{H}(D, D_x, m)$ is a family of hash functions as in Definition 6 such that $m > \log q / \log 2d$ and $q \geq 4dmn^{1.5} \log n$. For any $h \in \mathcal{H}(D, D_x, m)$, if there exists a polynomial-time algorithm that solves $\text{Col}(h, D_x)$ with some non-negligible probability, then there exists a polynomial-time algorithm that can solve SVP_γ over ideal lattice, where $\gamma = 16dmn \log^2 n$.

In addition, we recall the following boundary Lemma to justify the security of the proposed scheme.

Lemma 2 (Lemma 2.11 in [47] applied to our setting). Let $a \leftarrow D_s$, c be the response returned by the random oracle H (i.e., $c \leftarrow D_c$), then

$$\Pr[\|ac\|_\infty \leq n \log^2 n] \geq 1 - 4ne^{-\log^2 n/8} = 1 - n^{-\omega(1)}. \quad (8)$$

2.5. Statistical Distance and Probabilistic Lemma. The difference between two probability distributions can be measured by the statistical distance, and in the security proof of the proposed RS scheme, we complete the proof of anonymity by using it.

Definition 8 (statistical distance). For random variables X_0 and X_1 that are defined on a countable set S , if the set S is discrete, then the statistical distance between X_0 and X_1 is described as

$$\Delta(X_0, X_1) = \frac{1}{2} \sum_{x \in S} |\Pr[X_0 = x] - \Pr[X_1 = x]|. \quad (9)$$

If the random variables X_0 and X_1 satisfy $\Delta(X_0, X_1) \leq n^{-\omega(1)}$, then X_0 and X_1 are statistically close.

Regarding statistical distances, there are the following common properties:

- (1) $\Delta(X_0, X_1) \geq 0$;
- (2) $\Delta(X_0, X_1) = \Delta(X_1, X_0)$.

In addition, to prove the convergence of our algorithms, the following probabilistic lemma will be used:

Lemma 3 (Corollary 6.2 in [47]). For any $s \in D_s^m$,

$$\Pr_{c \leftarrow D_c, \mathbf{u} \leftarrow D_y^m} [\mathbf{s}c + \mathbf{u} \in D_z^m] = \frac{1}{e} - o(1). \quad (10)$$

3. Definition of RS and Security Model

3.1. Definition of RS. Suppose there exist N members in the ring and each member U_i ($i \in [N]$) has a pair of keys, i.e., public key pk_i and private key sk_i , a RS scheme can be composed of four polynomial-time algorithms:

- (1) **Setup** (1^λ): Taking a security parameter λ as input, it outputs the public parameters pp .
- (2) **KeyGen** (pp): Taking the public parameters pp as input, it generates a pair of keys (pk, sk) , where pk and sk denote the public and private keys, respectively.
- (3) **Sign** (pp, L_{pk}, μ, sk_π): On input public parameters pp , ring L_{pk} , message μ and the private key sk_π of the signer U_π (require that its corresponding public key $pk_\pi \in L_{pk}$), it outputs an RS sig of U_π on the message μ under ring L_{pk} .
- (4) **Verify** (pp, L_{pk}, μ, sig): On input public parameter pp , ring L_{pk} , message μ and RS sig, if sig satisfies the verification conditions, it outputs 1; otherwise, it outputs 0.

3.2. Security Model. For the above algorithms, an RS scheme is called to be secure if it satisfies the following definitions: correctness, anonymity, and unforgeability.

Definition 9 (correctness). If the signer signs honestly, i.e., according to the algorithms in Section 3.1, the Verify algorithm will always output 1 with overwhelming probability, that is, equality (11) holds.

$$\Pr \left[\text{Verify}(pp, L_{pk}, \mu, sig) = 1 \left| \begin{array}{l} pp \leftarrow \text{Setup}(1^\lambda) \\ (pk_\pi, sk_\pi) \leftarrow \text{KeyGen}(pp) \\ pk_\pi \in L_{pk} \\ sig \leftarrow \text{Sign}(pp, L_{pk}, \mu, sk_\pi) \end{array} \right. \right] = 1 - \text{negl}(\lambda). \quad (11)$$

Bender et al. [11] proposed the security definitions of RS under different security degrees, among which the highest degree in terms of anonymity is anonymity-FKE. Based on anonymity-FKE, Aguilar Melchor et al. [41] proposed a stronger definition, namely UA-CSA. In this work, the

security proof of anonymity is based on the security model of UA-CSA.

Let's define a game between adversary \mathcal{A} and challenger S Under UA-CSA since all secrets are known, the adversary can effectively simulate the signature and corrupt oracles, so these two oracles are no longer provided in the game and the procedure in which S generates pp and (pk, sk) is not required, since they will be generated by the adversary instead. The game is as follows:

- (i) Suppose l is the upper bound of ring member size in the system, the adversary submits to a set of public parameters pp , ring $L_{pk} = \{pk_1, pk_2, \dots, pk_N\}$, two private keys sk_{i_0}, sk_{i_1} , message μ , where $N, i_0, i_1 \in [l]$.
- (ii) S randomly selects $b \leftarrow \{0, 1\}$, invokes $\text{Sign}(pp, L_{pk}, \mu, sk_{i_b})$ to generate the signature sig_{i_b} , and returns sig_{i_b} to \mathcal{A} .
- (iii) Adversary \mathcal{A} outputs a bit b' , and if $b' = b$, then \mathcal{A} wins the game.

The advantage of winning the game is denoted by,

$$Adv_{\mathcal{A}}^{\text{anon}} = \left| \Pr [b' = b] - \frac{1}{2} \right|. \quad (12)$$

Definition 10 (anonymity). An RS scheme satisfies UA-CSA if $Adv_{\mathcal{A}}^{\text{anon}}$ is negligible for any polynomial-time adversary \mathcal{A} .

Bender et al. [11] consider two cases when defining the strongest unforgeability EU-IC: (1) An adversary can trick some honest user into using the public keys that are adversarially generated to generate a signature. (2) The adversary can adaptively corrupt some ring members and obtain their keys. The strongest EU-IC with respect to RS is depicted by the game between adversary \mathcal{A} and challenger \mathcal{A}' as follows:

- (i) Setup phase: Given security parameter λ , \mathcal{A}' runs the KeyGen algorithm to generate the user's public/private key pairs, and sends public parameters pp and the maximum set of user's public keys $S = (pk_i)_{i \in [l]}$ to adversary \mathcal{A} .
- (ii) Query phase: \mathcal{A} is allowed to make adaptive queries to the signature oracle SO and the corrupt oracle CO .
 - (a) Signing query: \mathcal{A} submits to \mathcal{A}' the set of user's public keys L_{pk} , message μ and $\pi \in [l]$, where π is an index such that $pk_{\pi} \in L_{pk}$. On receiving (π, μ, L_{pk}) , \mathcal{A}' invokes the Sign algorithm to generate sig and send it to \mathcal{A} .
 - (b) Corruption query: \mathcal{A} submits $i (i \in [l])$ to access corrupt oracle CO , then \mathcal{A}' returns the relevant private key sk_i to \mathcal{A} .
- (iii) Forgery phase: \mathcal{A} outputs $(\mu^*, L_{pk}^*, \text{sig}^*)$, and we call \mathcal{A} gets the triumph if the below conditions are satisfied:
 - (a) Verify $(pp, L_{pk}^*, \mu^*, \text{sig}^*) = 1$;

- (b) \mathcal{A} never queried for the signature on (μ^*, L_{pk}^*) ;
- (c) $L_{pk}^* \subseteq S \setminus C$, where C is the set of corrupted users.

The advantage of \mathcal{A} winning the game is depicted as:

$$Adv_{\mathcal{A}}^{\text{forge}} = \Pr [\mathcal{A} \text{ wins the game}]. \quad (13)$$

Definition 11 (unforgeability). A RS scheme is said to satisfy EU-IC if $Adv_{\mathcal{A}}^{\text{forge}}$ is negligible for any polynomial-time adversary \mathcal{A} .

4. Lattice-based RS Scheme without Trapdoors

4.1. Construction

- (1) Setup (1^λ): Given security parameter λ , it outputs the public parameter $pp = \{n, d, q, m, H, h, D_s, D_c, D_x, D_y, D_z\}$, where integer $n > \lambda$ and is a power of 2, $d = \sqrt{n} \log n$, prime $q \geq 4(mn^{1.5} \log n)^2$, integer $m > \log q / \log 2d$, $H: \{0, 1\}^* \rightarrow D_c$ is a cryptographic hash function, h is randomly chosen from the family $\mathcal{H}(D, D_x, m)$, and the other parameters are defined in Section 2.1.
- (2) KeyGen (pp): Given public parameters pp , it picks $\mathbf{r} \leftarrow D_s^m$, then generates the public key $pk = h(\mathbf{r})$ and sets the private key $sk = \mathbf{r}$.
- (3) Sign ($pp, L_{pk}, \mu, sk_{\pi}$): Given public parameters pp , ring $L_{pk} = \{pk_1, pk_2, \dots, pk_N\}$, message $\mu \in \{0, 1\}^*$ and private key $sk_{\pi} = \mathbf{r}_{\pi}$ of member U_{π} , it runs as follows:
 - (i) Pick $\mathbf{u} \leftarrow D_y^m$, calculate $c_{(\pi \bmod N)+1} = H(L_{pk}, \mu, h(\mathbf{u}))$;
 - (ii) For $i = \pi + 1, \dots, N, 1, \dots, \pi - 1$:
 - (a) Choose $\mathbf{r}_{z,i} \leftarrow D_z^m$;
 - (b) Calculate $t_i = h(\mathbf{r}_{z,i}) - c_i pk_i$, $c_{(i \bmod N)+1} = H(L_{pk}, \mu, t_i)$.
 - (iii) Calculate $\mathbf{r}_{z,\pi} = \mathbf{u} + c_{\pi} \mathbf{r}_{\pi}$;
 - (iv) If $\mathbf{r}_{z,\pi} \notin D_z^m$, then return to step (i);
 - (v) Output the signature $\text{sig} = (c_1, (\mathbf{r}_{z,i})_{i \in [N]})$.
- (4) Verify ($pp, L_{pk}, \mu, \text{sig}$): Given public parameters pp , ring $L_{pk} = \{pk_1, pk_2, \dots, pk_N\}$, message $\mu \in \{0, 1\}^*$ and signature $\text{sig} = (c_1, (\mathbf{r}_{z,i})_{i \in [N]})$, it accepts the signature and outputs 1 only if sig satisfies the below conditions, otherwise it rejects the signature and outputs 0.
 - (i) For $i \in [N]$, $\mathbf{r}_{z,i} \in D_z^m$;
 - (ii) For $i \in [N]$, calculate $t_i = h(\mathbf{r}_{z,i}) - c_i pk_i$, $c_{i+1} = H(L_{pk}, \mu, t_i)$, and determine $c_1 = H(L_{pk}, \mu, t_N) = c_{N+1}$.

4.2. Correctness and Convergence of the Scheme

Theorem 1 (correctness). *The proposed RS scheme satisfies correctness.*

Proof. When sig is a signature generated according to the signature algorithm, then (a) in step (ii) and step (iv) of Sign ensure that $(\mathbf{r}_{z,i})_{i \in [N]}$ are elements in D_z^m . In addition, we have the following equations:

$$\begin{aligned} c_2 &= H(L_{pk}, \mu, t_1), \text{ where } t_1 = h(\mathbf{r}_{z,1}) - c_1 pk_1, \\ c_3 &= H(L_{pk}, \mu, t_2), \text{ where } t_2 = h(\mathbf{r}_{z,2}) - c_2 pk_2, \\ &\vdots \\ c_\pi &= H(L_{pk}, \mu, t_{\pi-1}), \end{aligned}$$

where $t_{\pi-1} = h(\mathbf{r}_{z,\pi-1}) - c_{\pi-1} pk_{\pi-1}$,

since $\mathbf{r}_{z,\pi} = \mathbf{u} + c_\pi \mathbf{r}_\pi \in D_z^m$, we have

$$\begin{aligned} c_{\pi+1} &= H(L_{pk}, \mu, t_\pi) = H(L_{pk}, \mu, h(\mathbf{r}_{z,\pi}) - c_\pi pk_\pi) \\ &= H(L_{pk}, \mu, h(\mathbf{u} + c_\pi \mathbf{r}_\pi) - c_\pi pk_\pi) \\ &= H(L_{pk}, \mu, h(\mathbf{u})), c_{\pi+2} \\ &= H(L_{pk}, \mu, t_{\pi+1}), \text{ where } t_{\pi+1} \\ &= h(\mathbf{r}_{z,\pi+1}) - c_{\pi+1} pk_{\pi+1}, c_{\pi+3} = H(L_{pk}, \mu, t_{\pi+2}), \end{aligned}$$

where $t_{\pi+2} = h(\mathbf{r}_{z,\pi+2}) - c_{\pi+2} pk_{\pi+2}$,

\vdots

$$\begin{aligned} c_1 &= c_{N+1} = H(L_{pk}, \mu, t_N), \text{ where } t_N \\ &= h(\mathbf{r}_{z,N}) - c_N pk_N. \end{aligned}$$

(14)

To sum up, the polynomial sequence $\{c_1, c_2, \dots, c_N\}$ in the verification process is equal to that in the signature process, so it must pass the verification of the Verify algorithm, and the proposed scheme is correct. \square

Theorem 2 (convergence). *Under the parameter settings of algorithm Setup, the expected runtime of the proposed scheme is $\tilde{O}(n)$, and algorithm Sign is expected to repeat no more than three times.*

Proof. The proposed RS scheme is made up of four algorithms: Setup, KeyGen, Sign and Verify. The Setup algorithm selects a hash function $h \in \mathcal{H}(D, D_x, m)$ (i.e., pick mn random numbers from $\{-(q-1)/2, -(q-1)/2+1, \dots, (q-1)/2\}$), the time for the step is negligible. The step of generating a single user's private/public keys in KeyGen is to randomly select a vector $\mathbf{r} \leftarrow D_s^m$, which simply involves randomly selecting mn numbers from the set

$\{-\sqrt{n} \log n, \dots, \sqrt{n} \log n\}$, and then calculating $pk = h(\mathbf{r})$, which takes $\tilde{O}(n)$ time according to Lemma 2.16 from [47]. The Sign algorithm is to randomly select a vector $\mathbf{u} \leftarrow D_y^m$ and $N-1$ vectors $\mathbf{r}_{z,i} \leftarrow D_z^m$, then calculate small polynomial multiplication $c_i pk_i$ and hash function $h \in \mathcal{H}(D, D_x, m)N$ times, and access random oracles N times. The time of Sign algorithm running once is $\tilde{O}(n)$ from [47], but if $\mathbf{r}_{z,\pi} \notin D_z^m$, then the operations of Sign need to be repeated again. Lemma 3 states that for any $\mathbf{r} \leftarrow D_s^m$, $\Pr_{\mathbf{u} \leftarrow D_y^m, c \leftarrow D_s} [\mathbf{u} + c\mathbf{r} \in D_z^m] = 1/e - o(1)$. Therefore, we will iterate Sign no more than three times and the runtime of Sign is also $\tilde{O}(n)$. Finally, the Verify algorithm needs to calculate small polynomial multiplication $c_i pk_i$ and function $h \in \mathcal{H}(D, D_x, m)N$ times, and access random oracles N times, thus the running time is also $\tilde{O}(n)$. \square

5. Security

5.1. Anonymity. Before proving the anonymity of the proposed scheme, we first give and prove the following lemma, which shows that for an adversary who has the ability to distinguish two ring signatures based on adversarially-chosen private keys and the corresponding c_π associated with the private keys, the statistical distance between the following two sets of random variables Y_0 and Y_1 is negligible.

Define two sets of random variables $Y_0 = (\alpha_i \in D_z^m; i \in [N], \beta)$ and $Y_1 = (\alpha_i \in D_z^m; i \in [N], \beta)$ that are obtained from the Sign algorithm with input $(pp, L_{pk}, \mu, sk_{i_0})$ and $(pp, L_{pk}, \mu, sk_{i_1})$, where the first N components of Y_b represent the first N outputs $(\mathbf{r}_{z,i})_{i \in [N]}$ of sig_{i_b} , and the $(N+1)$ -th component of Y_b represents c_π corresponding to sig_{i_b} , $b \leftarrow \{0, 1\}$. In addition, we use $Y_b^{(i)}$ to represent the i -th component of Y_b , $i \in [N+1]$, e.g., $Y_0^{(N+1)}$ represents c_π .

Lemma 4. *If Y_0 and Y_1 are random variables obtained from two legitimate signatures, and these two legitimate signatures are generated by private keys sk_{i_0}, sk_{i_1} which are adversarially-chosen, we have*

$$\Delta(Y_0, Y_1) = n^{-\omega(1)}. \quad (15)$$

Proof. First define a set $D_c(sk_{i_0}, sk_{i_1}) = \{d \in D_c : \|sk_{i_0} d\|_\infty, \|sk_{i_1} d\|_\infty \leq n \log^2 n\}$. According to Lemma 2, it is concluded that almost all elements of D_c are in $D_c(sk_{i_0}, sk_{i_1})$. Even if the private keys $sk_{i_0}, sk_{i_1} \in D_s$, $n \geq \lambda$ are chosen by the adversary, Lemma 2 will also guarantee that $|D_c(sk_{i_0}, sk_{i_1})|/|D_c| = 1 - n^{-\omega(1)}$, where $n^{-\omega(1)}$ is a negligible function. Then divide the statistical distance $\Delta(Y_0, Y_1)$ into two parts, we have formulas (16) and (17).

Next we will discuss $\Delta(Y_0, Y_1)$ in two steps, first to prove that formula (16) is negligible (Step 1), and then to prove that formula (17) is equal to zero (Step 2).

$$\begin{aligned} \Delta(Y_0, Y_1) &= \frac{1}{2} \sum_{\alpha_i \in D_s^m; i \in [N], \beta} |\Pr[Y_0 = (\alpha_i; i \in [N], \beta)] - \Pr[Y_1 = (\alpha_i; i \in [N], \beta)]|, \\ &= \frac{1}{2} \sum_{\alpha_i \in D_s^m; i \in [N], \beta \notin D_c(sk_{i_0}, sk_{i_1})} |\Pr[Y_0 = (\alpha_i; i \in [N], \beta)] - \Pr[Y_1 = (\alpha_i; i \in [N], \beta)]|, \end{aligned} \quad (16)$$

$$+ \frac{1}{2} \sum_{\alpha_i \in D_s^m; i \in [N], \beta \in D_c(sk_{i_0}, sk_{i_1})} |\Pr[Y_0 = (\alpha_i; i \in [N], \beta)] - \Pr[Y_1 = (\alpha_i; i \in [N], \beta)]|. \quad (17)$$

□

Step 1. Considering the case of $\beta \notin D_c(sk_{i_0}, sk_{i_1})$, generally, since

$$\begin{aligned} (17) &\leq \frac{1}{2} \sum_{\alpha_i \in D_s^m; i \in [N], \beta \notin D_c(sk_{i_0}, sk_{i_1})} |\Pr[Y_0 = (\alpha_i; i \in [N], \beta)]| \\ &\leq \frac{1}{2} \sum_{\beta \notin D_c(sk_{i_0}, sk_{i_1})} |\Pr[Y_0^{(N+1)} = \beta]| \leq \sum_{\beta \notin D_c(sk_{i_0}, sk_{i_1})} |\Pr[Y_0^{(N+1)} = \beta]|, \end{aligned} \quad (18)$$

and since for any $b \in \{0, 1\}$, the variable $Y_b^{(N+1)}$ is calculated by the hash function $H(L_{pk}, \mu, t_{\pi-1})$, where $t_{\pi-1} = h(\mathbf{r}_{z, \pi-1}) - c_{\pi-1}pk_{\pi-1}$, thus $\beta \in D_c$ and the probability that $Y_b^{(N+1)}$ is equal to the given value β is $1/|D_c|$. Note that even hash function $h \in \mathcal{H}(D, D_x, m)$ is adversarially chosen, it does not affect the probability that $Y_0^{(N+1)}$ is equal to a given β . Further, for each $\beta \notin D_c(sk_{i_0}, sk_{i_1})$, $\Pr[Y_0^{(N+1)} = \beta] = 1/|D_c|$, and since almost all elements of D_c are in $D_c(sk_{i_0}, sk_{i_1})$ from Lemma 2, it is evident that the probability of $\beta \notin D_c(sk_{i_0}, sk_{i_1})$ is negligible. And then we get

$$\begin{aligned} (17) &\leq \sum_{\beta \notin D_c(sk_{i_0}, sk_{i_1})} \frac{1}{|D_c|} \\ &= \frac{|D_c| - |D_c(sk_{i_0}, sk_{i_1})|}{|D_c|} \\ &= 1 - \frac{|D_c(sk_{i_0}, sk_{i_1})|}{|D_c|} = n^{-\omega(1)}. \end{aligned} \quad (19)$$

Step 2. To prove that the value of formula (17) is zero, it is only necessary to prove that each term in formula (17) is zero. Since the last component $Y_b^{(N+1)}$ of $Y_b^{(N+1)}$ is derived from a random oracle H , the probability that $Y_0^{(N+1)}$ and $Y_1^{(N+1)}$ are equal to a given value β is the same. Then it is only necessary to prove that the following equation about conditional probabilities holds:

$$\begin{aligned} &\Pr\left[(Y_0^{(i)}; i \in [N]) = (\alpha_i; i \in [N]) \mid Y_0^{(N+1)} = \beta\right] \\ &= \Pr\left[(Y_1^{(i)}; i \in [N]) = (\alpha_i; i \in [N]) \mid Y_1^{(N+1)} = \beta\right]. \end{aligned} \quad (20)$$

For any $b \in \{0, 1\}$, $Y_b^{(i)} = \alpha_i \in D_z^m$ if $i \in [N] \setminus i_b$, thus the probability that $Y_b^{(i)}$ is equal to a given value is $1/|D_z^m|$; if $i = i_b$,

$$\begin{aligned} \Pr\left[Y_b^{(i_b)} = \alpha_{i_b}\right] &= \Pr\left[\mathbf{u}_b + sk_{i_b}\beta = \alpha_{i_b}\right] \\ &= \Pr\left[\mathbf{u}_b = \alpha_{i_b} - sk_{i_b}\beta\right]. \end{aligned} \quad (21)$$

Since $\beta \in D_c(sk_{i_0}, sk_{i_1})$, $\alpha_{i_b} \in D_z^m$, we have $\|sk_{i_0}\beta\|_\infty, \|sk_{i_1}\beta\|_\infty \leq n \log^2 n$, $\|\alpha_{i_b}\|_\infty \leq mn^{1.5} \log n - n \log^2 n$, then $\|\alpha_{i_b} - sk_{i_0}\beta\|_\infty = \|\alpha_{i_b} - sk_{i_1}\beta\|_\infty \leq mn^{1.5} \log n$. Thus, the values of both $\alpha_{i_b} - sk_{i_0}\beta$ and $\alpha_{i_b} - sk_{i_1}\beta$ belong to the set D_y^m . And since $\mathbf{u}_0, \mathbf{u}_1 \leftarrow D_y^m$, $\Pr[\mathbf{u}_0 = \alpha_{i_b} - sk_{i_0}\beta] = \Pr[\mathbf{u}_1 = \alpha_{i_b} - sk_{i_1}\beta] = 1/|D_y^m|$.

In summary, for any $b \in \{0, 1\}$,

$$\Pr\left[Y_b^{(i)} = \alpha_i \mid Y_b^{(N+1)} = \beta\right] = \begin{cases} \frac{1}{|D_z^m|}, & i \in [N] \setminus i_b, \\ \frac{1}{|D_y^m|}, & i = i_b. \end{cases} \quad (22)$$

Therefore, it can be proved that equation (20) holds, i.e., the proof of the lemma is completed.

Suppose that in the game of anonymity in Section 3.2, pk_{i_0} and pk_{i_1} are adversarially generated according to the Setup algorithm, message μ and ring L_{pk} are also chosen by adversary. The challenger chooses $b \leftarrow \{0, 1\}$ and invokes

$\text{Sign}(pp, L_{pk}, \mu, sk_b)$ to generate a signature, and give it to the adversary. Define the random variable $X_{b,pp,sk_{i_b},\mu,L_{pk}}$ to represent the signature generated by the challenger, and the following theorem shows that the statistical distance between $X_{0,pp,sk_{i_0},\mu,L_{pk}}$ and $X_{1,pp,sk_{i_1},\mu,L_{pk}}$ is negligible.

Theorem 3 (anonymity). *The proposed scheme satisfies UA-CSA, i.e., for the adversary in Definition 10, $X_{b,pp,sk_{i_b},\mu,L_{pk}} \leftarrow \text{Sign}(pp, L_{pk}, \mu, sk_{i_b})$, $b \in \{0, 1\}$, we have*

$$\Delta\left(X_{0,pp,sk_{i_0},\mu,L_{pk}}, X_{1,pp,sk_{i_1},\mu,L_{pk}}\right) = n^{-\omega(1)}. \quad (23)$$

Proof. Regarding $X_{b,pp,sk_{i_b},\mu,L_{pk}}$, it is known from the signing process, $\mathbf{r}_{z,i} \leftarrow D_z^m$ if $i \neq i_b$, $\mathbf{r}_{z,i} = \mathbf{u} + c_i \mathbf{r}_i$ if $i = i_b$. By Lemma 3 and Theorem 2, we know that $\mathbf{r}_{z,i}$ is indistinguishable from a randomly selected vector in D_z^m . And since the first component c_1 in $X_{b,pp,sk_{i_b},\mu,L_{pk}}$ is from a random oracle, the statistical distance $\Delta(X_{0,pp,sk_{i_0},\mu,L_{pk}}, X_{1,pp,sk_{i_1},\mu,L_{pk}}) = n^{-\omega(1)}$ for an ordinary adversary \mathcal{A} . However, for an UA-CSA adversary, obviously, such an analysis is not rigorous enough. The following will focus on the verification process, whether the adversary can distinguish the two signatures based on adversarially-chosen private keys and c_π associated with the private keys.

Since the first component c_1 of $X_{b,pp,sk_{i_b},\mu,L_{pk}}$ is obtained by accessing a random oracle, and it is not directly related to the associated private key, thus the discussion with respect to c_1 is not necessary. We only need to prove that for an UA-CSA adversary, the statistical distance between the defined Y_0, Y_1 is negligible. By Lemma 4 it is known that $\Delta(Y_0, Y_1) = n^{-\omega(1)}$, thus for an UA-CSA adversary, the probability of winning the anonymity game is also negligible. That completes the proof. \square

5.2. Unforgeability. Before proving unforgeability, the following lemma is first given and proved.

Lemma 5. *Let $\mathbf{r}, \mathbf{r}' \leftarrow D_s$, $\mathbf{v}, \mathbf{v}' \leftarrow D_z$, $c, c' \leftarrow D_c$ and $c \neq c'$, if $\mathbf{v} - c\mathbf{r} = \mathbf{v}' - c'\mathbf{r}$, $\mathbf{r} \neq \mathbf{r}'$, then the following inequality holds:*

$$\|\mathbf{v} - c\mathbf{r}' - \mathbf{v}' + c'\mathbf{r}'\| \neq 0. \quad (24)$$

Proof. Assume that both $\mathbf{v} - c\mathbf{r} = \mathbf{v}' - c'\mathbf{r}$ and $\mathbf{v} - c\mathbf{r}' = \mathbf{v}' - c'\mathbf{r}'$ hold. By subtracting the two equations, we have $(\mathbf{r}' - \mathbf{r})(c' - c) = 0$. Since the equation holds in ring $\mathbb{Z}_q[x]/(x^n + 1)$, it does not directly deduce that $\mathbf{r}' = \mathbf{r}$ or $c' = c$ holds. Due to $\|\mathbf{r}'\|_\infty, \|\mathbf{r}\|_\infty \leq \sqrt{n} \log n$, $\|c'\|_\infty, \|c\|_\infty \leq 1$, then the absolute values of the coefficients of $\mathbf{r}' - \mathbf{r}$ and $c' - c$ are no more than $2\sqrt{n} \log n$ and 2, respectively. When $\mathbf{r}' - \mathbf{r}$ is multiplied by $c' - c$ in ring $\mathbb{Z}[x]/(x^n + 1)$, the absolute value of the coefficients of $(\mathbf{r}' - \mathbf{r})(c' - c)$ is no more than $4n^{1.5} \log n$. Since $q \gg 4n^{1.5} \log n$, if $(\mathbf{r}' - \mathbf{r})(c' - c) = \mathbf{0}$ holds in ring $\mathbb{Z}_q[x]/(x^n + 1)$, then it must also hold in ring $\mathbb{Z}[x]/(x^n + 1)$. And since $c \neq c'$, then it must have $\mathbf{r}' = \mathbf{r}$,

which is contradictory to the assumption, thus the lemma is proved. \square

Theorem 4 (unforgeability). *Under the random oracle model, if there exists a polynomial-time adversary \mathcal{A} who can validly forge a RS signature about the proposed scheme with probability ε , then for a random-chosen $h \in \mathcal{H}(D, D_x, m)$, there is a polynomial-time algorithm \mathcal{A}' that can obtain a solution to $\text{Col}(h, D_x)$ with probability at least $\varepsilon^2/2(\psi + 3N\zeta)$, where N , ζ and ψ are the number of ring members, the maximum times that \mathcal{A} accesses SO and directly accesses HO, respectively.*

Proof. Suppose there exists an EU-IC adversary \mathcal{A} who can validly forge a signature against the proposed scheme with non-negligible probability ε , then there exists a challenger \mathcal{A}' who can solve $\text{Col}(h, D_x)$ with non-negligible probability ε' .

Suppose the number of maximum ring members in the system is $l = l(\lambda)$, and given a hash function family $\mathcal{H}(D, D_x, m)$, \mathcal{A}' obtains an instance (h) from the $\text{Col}(h, D_x)$ oracle as an input. \mathcal{A}' maintains two lists L_1 and L_2 , which are initialized to be null. For $i \in [l]$, \mathcal{A}' honestly runs the Keygen algorithm to generate the key pair (pk_i, sk_i) , and stores the tuple (i, pk_i, sk_i) in list L_1 . \mathcal{A}' gives the public key set $S = \{pk_1, pk_2, \dots, pk_l\}$ to \mathcal{A} , and then \mathcal{A}' simulates oracles and responds to the queries from \mathcal{A} in the following manner:

Hash query HO: \mathcal{A} submits a set of ring members $L_{pk} = (pk_1, pk_2, \dots, pk_N) \subset S$, message $\mu \in \{0, 1\}^*$ and $t_i \in D$, \mathcal{A}' inquires the list L_2 , and if the tuple $(L_{pk}, \mu, t_i, c_{i+1})$ exists, \mathcal{A}' returns c_{i+1} to \mathcal{A} . Otherwise, \mathcal{A}' randomly selects $c_{i+1} \in D_c$ and returns it to \mathcal{A} , and adds $(L_{pk}, \mu, t_i, c_{i+1})$ to the list L_2 .

Signing query SO: \mathcal{A} submits an index π , a message $\mu \in \{0, 1\}^*$ and a set of ring members $L_{pk} = (pk_1, pk_2, \dots, pk_N)$ (which may contain some public keys generated by \mathcal{A} in an arbitrary way). Note that since \mathcal{A}' knows the private keys of all members in set S , and in general, \mathcal{A} will not query signatures about a user outside S , which is meaningless. \mathcal{A}' responds to this query by honestly running the Sign algorithm.

Corruption query CO: \mathcal{A} can make corruption query about any user U_i ($i \in [l]$). If \mathcal{A} makes a query on (i, pk_i) , \mathcal{A}' first obtains the tuple (i, pk_i, sk_i) by looking for the list L_1 , and then returns sk_i to \mathcal{A} .

Forgery phase: Suppose that after finishing the above queries, \mathcal{A} outputs a valid forgery $(\mu^*, L_{pk}^*, \text{sig}^*)$ with non-negligible probability, ε and \mathcal{A} did not ask for any signature on $(*, \mu^*, L_{pk}^*)$, where $L_{pk}^* \subseteq S \setminus C$ and C is the set of corrupted users.

Analysis. Define p as the maximum times HO is queried during \mathcal{A} 's attack. By Theorem 2, we know that it takes at most $3NH$ queries to produce a RS, and since \mathcal{A} can make SO queries at most ζ times, the value of p is at most $\psi + 3N\zeta$. Suppose that $\text{sig}^* = (c_1^*, (\mathbf{r}_{z,i}^*)_{i \in [N]})$ can pass the verification

of Verify, then in general, it can be assumed that for some j , we have $H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^*) = c_{j+1}^*$.

If \mathcal{A} did not query HO on $(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^*)$, then the probability of producing c_{j+1}^* such that $H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^*) = c_{j+1}^*$ is only $1/|D_c|$. Hence, the probability that $c_{j+1}^* \in \{s_1, s_2, \dots, s_p\}$ is $1 - 1/|D_c|$, where $s_1, s_2, \dots, s_p \leftarrow D_c$ is the sequence of return values from HO . Further, the probability that \mathcal{A} succeeds in a forgery and $c_{j+1}^* \in \{s_1, s_2, \dots, s_p\}$ is at least $\varepsilon - 1/|D_c|$. Suppose $c_{j+1}^* = s_j$, then there are two cases: (1) s_j is a response to SO query (Case 1); (2) s_j is a response to HO query (Case 2). We first analyze Case 1. \square

Case 1. Suppose c_{j+1}^* appears during signing query, and suppose that the corresponding response \mathcal{A} obtains is the signature $\text{sig} = (c_1, (\mathbf{r}_{z,i})_{i \in [N]})$ (i.e., $c_{j+1}^* = H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^*)$). Then compare the signature forged by \mathcal{A} with the legitimate signature $\text{sig} = (c_1, (\mathbf{r}_{z,i})_{i \in [N]})$, we have

$$c_{j+1}^* = H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^*) = H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}) - c_j pk_j). \quad (25)$$

Then either $L_{pk}^* \neq L_{pk}$ or $\mu^* \neq \mu$ (or $\mathbf{r}_{z,j}^* \neq \mathbf{r}_{z,j}$), since if all three equations hold, this means the adversary simply outputs a signature that has already been asked. If at least one of $L_{pk}^* \neq L_{pk}$ and $\mu^* \neq \mu$ holds, it implies that a collision has occurred in H . Hence there is $L_{pk}^* = L_{pk}$, $\mu^* = \mu$ and $\mathbf{r}_{z,j}^* \neq \mathbf{r}_{z,j}$ with overwhelming probability, that is, $H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^*) = c_{j+1}^* = H(L_{pk}^*, \mu^*, h(\mathbf{r}_{z,j}) - c_j pk_j)$. Therefore either $h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^* \neq h(\mathbf{r}_{z,j}) - c_j pk_j$, which implies there is a collision in H , or $h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^* = h(\mathbf{r}_{z,j}) - c_j pk_j$, which implies there is $h(\mathbf{r}_{z,j}^*) = h(\mathbf{r}_{z,j})$. Then we find a collision for h , and since $\mathbf{r}_{z,j}, \mathbf{r}_{z,j}^* \in D_x^m \subset D_x^m$, we find a solution to $\text{Col}(h, D_x)$. Note that after HO is queried p times, the probability that a collision happens in H is no more than $p/|D_c|$, therefore, the probability of \mathcal{A} outputting a forgery as a solution to $\text{Col}(h, D_x)$ is at least,

$$\frac{\varepsilon - p}{|D_c|}. \quad (26)$$

Case 2. The next is to consider the case that s_j is obtained by \mathcal{A} calling HO . In this scenario, suppose that \mathcal{A}' runs \mathcal{A} with some randomness and \mathcal{A}' obtains a valid forgery $\text{sig}^* = (c_1^*, (\mathbf{r}_{z,i}^*)_{i \in [N]})$ of μ^* . Suppose that $s_1, \dots, s_p \leftarrow D_c$ is the sequence of response values from HO during this forgery. Then generate fresh random elements $s'_1, \dots, s'_p \leftarrow D_c$, and \mathcal{A}' runs \mathcal{A} with the same randomness and responds to \mathcal{A}' 's HO query with $s_1, \dots, s_{j-1}, s'_j, \dots, s'_p$, by forking lemma from [48], \mathcal{A}' will obtain another forged signature $\text{sig}' = (c_1', (\mathbf{r}_{z,i}')_{i \in [N]})$ on message μ^* and $s_j \neq s'_j$ with probability at least $(\varepsilon - 1/|D_c|) / ((\varepsilon - 1/|D_c|) / (\psi + 3N\zeta) - 1/|D_c|)$. Since the input of HO query is the same in both forgeries, we have $h(\mathbf{r}_{z,j}^*) - c_j^* pk_j^* = h(\mathbf{r}_{z,j}') - c_j' pk_j'$. By the homomorphic

properties of h in Definition 6, it follows that $h(\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^*) = h(\mathbf{r}_{z,j}' - c_j' \mathbf{r}_j')$. If $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^* \neq \mathbf{r}_{z,j}' - c_j' \mathbf{r}_j'$ and $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^*, \mathbf{r}_{z,j}' - c_j' \mathbf{r}_j' \in D_x^m$, then \mathcal{A}' finds a collision for h .

Next, we analyze the probability of $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^* \neq \mathbf{r}_{z,j}' - c_j' \mathbf{r}_j'$. By Lemma 5.2 in [47], we know that there is a distinct private key \mathbf{r}_j' such that $\text{pk}_j = h(\mathbf{r}_j') = h(\mathbf{r}_j^*)$ with overwhelming probability. And by Lemma 5, if the private key \mathbf{r}_j^* satisfies $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^* = \mathbf{r}_{z,j}' - c_j' \mathbf{r}_j'$, then for another private key \mathbf{r}_j , we have $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^* \neq \mathbf{r}_{z,j} - c_j \mathbf{r}_j$. By Theorem 6.5 from [47], it is statistically impossible to distinguish which one of \mathbf{r}_j and \mathbf{r}_j^* is used by the signer, and thus the probability of $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^* \neq \mathbf{r}_{z,j}' - c_j' \mathbf{r}_j'$ is at least $1/2 - n^{-\omega(1)}$. And for any response from HO , $s_i \in D_c$, then by Lemma 2, we have $\|\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^*\|_\infty, \|\mathbf{r}_{z,j}' - c_j' \mathbf{r}_j'\|_\infty \leq mn^{1.5} \log n$, i.e., $\mathbf{r}_{z,j}^* - c_j^* \mathbf{r}_j^*, \mathbf{r}_{z,j}' - c_j' \mathbf{r}_j' \in D_y^m \subset D_x^m$, which implies that \mathcal{A}' finds a solution to $\text{Col}(h, D_x)$.

From the above analysis, we know that the probability of \mathcal{A}' breaking $\text{Col}(h, D_x)$ via \mathcal{A} calling SO is at least $\varepsilon - p/|D_c|$, while the probability of \mathcal{A}' breaking $\text{Col}(h, D_x)$ via \mathcal{A} calling HO is at least,

$$\left(\frac{1}{2} - n^{-\omega(1)}\right) \left(\varepsilon - \frac{1}{|D_c|}\right) \left(\frac{\varepsilon - 1/|D_c|}{\psi + 3N\zeta} - \frac{1}{|D_c|}\right). \quad (27)$$

By comparing formulas (26) and (27), we have the inequality (26) > (27). Thus, the probability of \mathcal{A}' running \mathcal{A} to solve $\text{Col}(h, D_x)$ successfully is,

$$\varepsilon' \geq \left(\frac{1}{2} - n^{-\omega(1)}\right) \left(\varepsilon - \frac{1}{|D_c|}\right) \left(\frac{\varepsilon - 1/|D_c|}{\psi + 3N\zeta} - \frac{1}{|D_c|}\right). \quad (28)$$

6. Discussion

From Theorem 4, it is known that if an adversary succeeds in forging an RS against the proposed scheme, then the challenger can find a collision for a randomly chosen hash function $h_a(\cdot)$ in $\mathcal{H}(D, D_x, m)$. From [29], solving $\text{Col}(h, D_x)$ is equivalent to finding a vector $\mathbf{u} \in \Lambda_q^\perp(\mathbf{A})$ on lattice $\Lambda_q^\perp(\mathbf{A}) = \{\mathbf{u} \in \mathbb{Z}^{mn} \text{ s.t. } \mathbf{A}\mathbf{u} = 0 \pmod{q}\}$ satisfying $\|\mathbf{u}\|_\infty \leq 2(mn^{1.5} \log n + n \log^2 n)$ where $\mathbf{A} = [\text{Rot}(a_1) \parallel \text{Rot}(a_2) \parallel \dots \parallel \text{Rot}(a_m)] \in \mathbb{Z}_q^{n \times mn}$, a_i is the i -th component of \mathbf{a} , $i \in [m]$.

It was shown in [49] that in a reasonable amount of time, the algorithm for finding short vectors on a random lattice will generate a vector no less than 1.01^n times the shortest vector over the lattice. Furthermore, based on the experiments of [49], Micciancio and Regev [50] conduct experiments on lattices very similar to $\Lambda_q^\perp(\mathbf{A})$, and proves that the length of the shortest vector, which can be found on $\Lambda_q^\perp(\mathbf{A})$ by using the well-known lattice reduction algorithm, is $\|\mathbf{z}\|_2 \geq \min \left\{ q, 2^{2\sqrt{n \log q \log 1.01}} \right\}$ and the corresponding $\|\mathbf{z}\|_\infty$ at least,

$$\min \left\{ q, 2^{2\sqrt{n \log q \log 1.01}} \cdot \left(\frac{n \log q}{\log 1.01}\right)^{-1/4} \right\}. \quad (29)$$

Therefore, in order to make $\text{Col}(h, D_x)$ be intractable, we should set the parameters in such a manner that requires $2(mn^{1.5} \log n + n \log^2 n)$ to be smaller than formula (29). For example, $n = 512$, $q \approx 2^{41}$, then calculate $2(mn^{1.5} \log n + n \log^2 n) \approx 2^{20.1}$, while the infinite norm of the shortest vector $\|z\|_\infty$ that can be found by formula (29) is around $2^{29.6}$. Table 1 gives several sets of parameter settings and security levels for our scheme.

7. Efficiency

In this section, in respect of efficiency and security, we compare our scheme with five lattice-based RS schemes without trapdoors: the RS schemes of [37, 38, 40] and the two RS schemes AM1 and AM2 of [41]. The comparison results of storage overhead and computational overhead are listed in Table 2 and 3, respectively. λ is a security parameter, $n > \lambda$ is a power of 2, N is the number of ring members, and q is a large prime number. In estimating the computational efficiency of each scheme, we mainly focus on the relatively time-consuming operations, such as polynomial inversion and polynomial-polynomial multiplication, while ignoring

the less time-consuming operations such as polynomial-polynomial addition and cryptographic hash operation H . The notation $T_{\text{poly-inv}}$ denotes the computational overhead of running polynomial-polynomial multiplication in D once, $T_{\text{poly-mul}}$ denotes the computational overhead of running polynomial inversion once, normally $T_{\text{poly-inv}} > T_{\text{poly-mul}}$. T_v denotes the time spent in performing λ times sanity checks of parameters in the signing phase of AM2. T_c denotes the computational overhead of selecting a compliant signing key in the signing phase of AM2.

From Table 2, the signature size of [37, 38, 40] is $O(\log N)$, while the signature size of AM1, AM2 and ours is $O(N)$. Without loss of generality, $n \geq \sqrt{n} \log n$, thus compared with AM1, AM2, our scheme has smaller public/private key size and signature size.

These schemes [37, 38, 40] all use complex and bloated zero-knowledge proofs, and it is very difficult for us to calculate their computational overheads. Among these schemes [37, 38, 40], only the relatively concise scheme of [38] gives its computational overheads analysis. Therefore, we only compare the computational cost of [38, 41] and our scheme. We adopt the calculation method of efficiency in

FIGURE 1: Comparison of computational overhead in the signing phase.

FIGURE 2: Comparison of computational overhead in the verification phase.

[38], and reduce the operations of KeyGen, Sign and Verify to polynomial-polynomial multiplication operations. To make the comparison results more intuitive, the parameters of [38, 41] and ours are set under the same security level $\lambda = 128$. Here, n in [38], AM, and ours are set to 256, 128, and 512, respectively; m in [38], AM, and ours are set to 15, 21, and 5, respectively. In terms of KeyGen, Sign and Verify, our scheme obviously has the smallest computational cost as shown in Tables 3 and 4.

To make the comparison results more intuitive, Figures 1 and 2 show the comparison between [38, 41] and ours in terms of computational overhead under different ring sizes.

8. Conclusions

Although lattice-based RS schemes are resistant to attacks by quantum computers, there still exists a big gap between them and the schemes that are based on traditional number-theoretic assumptions with respect to computational efficiency. To further boost the computational efficiency of RS on lattice, this work constructs a lattice-based RS scheme without trapdoors under the random oracle model. Based on a collision-resistant hash function on ideal lattice, our scheme is designed via the FSwA protocol. Our scheme avoids the use of trapdoors or sampling techniques that have high computational overhead and does not involve complex zero-knowledge proofs which are usually used in RS schemes without trapdoors. The proposed scheme is more concise

and efficient. Meanwhile, in terms of anonymity and unforgeability, our scheme is proven to satisfy the strongest UA-CSA and EU-IC, respectively. Next, we plan to investigate NTRU lattice-based RS scheme without trapdoors, which will be the first combination of NTRU lattice and RS without trapdoors.

At present, the competition among talents to seize jobs is becoming more and fiercer. How to stand out in the fierce competition for talents and seize market resources is a problem that every graduate must think deeply. Domestic research on the composition of the implementation elements of talent training in colleges and universities from the perspective of excellent school talent training has achieved fruitful results. Their measures and implementation ideas mainly include the following aspects: first, analyze the system of talent training in colleges and universities; second, analyze the teaching methods of college teachers; third, analyze the future development direction of talents. Taking a university as a pilot unit, this paper constructs a talent training system based on the combination method of fuzzy hierarchy, determines the training goal according to students' own ability, formulates the talent training scheme according to the goal, determines the rectangular array relationship between the training system and students' own ability requirements and attaches importance to practical teaching. The algorithm used in this paper firstly establishes a hierarchical structure model and then combines the relevant measures of AHP to sort the weights of indicators and finally calculates the entropy value by quoting entropy weight. We use the fuzzy method combined with hierarchical analysis to evaluate the five indexes of students' own influencing factors, such as learning attitude, basic knowledge, cooperation ability, development ability, and professional ability. It can be seen that the algorithm model is more accurate and the error value is the smallest. Compared with their combination method, the fuzzy evaluation method and the hierarchical analysis method are practical, and the fuzzy method combined with the hierarchical analysis combination method has more practical significance. Finally, the employment situation of graduates is compared and analyzed to further highlight the effectiveness of the model.

1. Introduction

Fuzzy map is generated by fuzzy membership function of each parameter in a suitable karst area, and the weight of each layer is assigned by the AHP method, and finally the final fuzzy-AHP map is generated [1]. For the popular Novel Coronavirus, fuzzy AHP is used to determine the weight of the existing criteria, and fuzzy TOPSIS is used to determine the safest area, that is ready to implement the new normal [2]. The competitive technology between China and Africa is transferred at any time, and the method in this paper is used to calculate the weight [3]. An appropriate proposed

framework was implemented using the fuzzy analytic hierarchy process in a palm oil industry in Indonesia to confirm its applicability and usefulness. Research shows that the environmental dimension is the most sustainable supplier standard, followed by the economic and social dimensions [4]. Taking Herat, Afghanistan as an example, the suitability of the GIS wind farm is evaluated by the fuzzy AHP multi-criteria method [5]. We combine the fuzzy analytic hierarchy process with the fuzzy mixed multi-criteria method and study the most influential and conflicting criteria in economy, service level, environment, society, and risk [6]. Our evaluation model of financial audit research in

the financial shared service mode is established by the fuzzy method combined with the hierarchical analysis combination method and order estimation methodology through similarity of solutions [7]. We use the fuzzy method and the hierarchical analysis combination method to find the optimal system of processing cigarette manufacturing [8]. We use the fuzzy method and the hierarchical analysis combination method to calculate the relative weights of relevant criteria. Finally, based on these weights, we use the ranking technology approaching the ideal solution to rank banks, and the results show that the major banks rank in the top three, respectively [9]. In the Craig–Harris method to measure the productivity level of farms, a fishbone diagram is used to analyze the reasons for productivity decline, and the fuzzy method combined with the class analysis combination method is proposed to improve productivity, which is based on the Craig–Harris method to measure productivity [10]. Researchers have developed and applied various standards and methods to find suitable rainwater harvesting sites and technologies. The main goal of the work is to use the fuzzy method combined with the hierarchical analysis combination method to assign weights to various standards involved in selecting suitable RWH sites in the Kandi subdivision of Murshidabad District, India [11]. Spectrum seems to be the lifeblood of wireless communication, and the fuzzy analytic hierarchy process seems to be an appropriate solution for spectrum allocation among SUs without interference between themselves [12]. Double-skin sickle (DSF) has been paid more attention by manufacturers in recent years because of its practical and aesthetic characteristics. In the previous research, our research group used the AHP method to evaluate DSF [13]. The fuzzy method combined with the hierarchical analysis and combination method is used to evaluate the quality of online commercial services, and the research results can be used by other e-commerce enterprises to improve the service quality according to the standards and sub-standards that experts think are important [14]. The supply chain adopted in medicine and medicine requires an orderly implementation plan for each strategic element of the pharmaceutical supply chain and uses the fuzzy method combined with the hierarchical analysis and combination method to minimize its weight on cost and time, so that decision makers can optimize the economy of PSC and create space [15]. In this paper, an extended FAHP model is proposed, in which two fuzzy comparison rectangular matrices are represented by a special class of fuzzy numbers. Then it is proved that a large number of FAHP methods can be simply written into the proposed E-FAHP structure [16]. We use the fuzzy method combined with hierarchical analysis to improve the understanding of the determinants of effective hotel websites and provide practical suggestions in order to formulate appropriate strategies to transform website visitors into customers [17]. In various cases of decision analysis, we adopt two popular methods: analytic hierarchy process (AHP) and fuzzy AHP. Both methods deal with random data, and the decision results can be determined by some criterion decision processes [18]. The purpose of this study is to assist the catering industry and credit card issuing banks

to establish performance evaluation indicators of marketing alliance by means of expert Delphi method, fuzzy method combined with hierarchical analysis, and balanced scorecard [19]. Fuzzy analytic hierarchy process (FAHP) is used to determine the weight of each sub-criterion according to the evaluation of experts. When there is no pairwise comparison of existing alternatives, we adjust to use sustainable development [20]. Fuzzy method combined with hierarchical analysis and ARAS-G is used to evaluate the performance of logistics in OECD countries [21]. Application of the fuzzy analytic hierarchy process and the TOPSIS method in cross-domain collaborative recommendation with fuzzy visual representation [22]. Researchers use the fuzzy method combined with hierarchical analysis to analyze the effective judgment of trademark infringement compensation cases in Beijing Intellectual Property Court in 2018 [23]. In the case study of an Indonesian sole manufacturer seeking to expand its business to the international market, the weights of the fuzzy method combined with the hierarchical analysis and combination method are adopted, and PROMETHEE is used to sort the schemes [24]. Fuzzy AHP and completely consistent implementation are used to rank the relative importance of these CSFs and their dimensions for continuous academic quality assurance and ABET certification [25].

2. The Necessity of Personnel Training in Undergraduate Colleges and Universities

2.1. Connotation of Personnel Training. To construct the talent training mode system in colleges and universities, the first point is to determine what system should be adopted to train talents. That is, through what kind of thinking mode and practical means to cultivate talents who conform to the development of the times. Therefore, to cultivate talents, we must first master the correct talent training system, so as to realize the terminal of talent training in the true sense for people's needs. The way of talent training is the professional knowledge, learning ability, future trend, and the way to achieve the ideal goal determined by the school for students. It collects and determines the characteristics that talents should have and also effectively embodies the educational philosophy and practice. Choose the appropriate way to realize the talent training mode and reference blueprint and cultivate talents with certain innovative ability. We can neither be subject to the traditional theoretical classroom teaching experience, blindly go with the flow, nor reform the training system that is arbitrarily enlarged to the whole school. Similarly, as the standard style of personnel training, it is formed by the integration and adjustment of many scientific theories, practical operations, and other factors, and many influencing factors together form a complex entity, which not only includes the theoretical chapters of personnel training but also reflects the reality of traditional educational practice training talents in recent years. This is a compound combination formed by the mutual influence and combination of many different links, and their multiple ideas together constitute the connotation of the current standardized talent training mode.

2.2. *Attach Importance to Vocational Education.* The implementation elements of vocational personnel training should pay attention to the cultivation of students' double-base ability. While improving vocational ability, we should uphold the sustainable development concept of lifelong learning and establish a training system in the field of vocational education that runs through from top to bottom and connects from left to right. Pave a smooth road for continuously improving professional quality and learning and development ability. This step is often realized through the school cultural education system. The school provides a basic place for students to cultivate and improve their professional ability. Only by receiving a certain period of school culture education and acquiring basic professional knowledge in school to meet the graduation requirements can students realize their personal value and further enhance their professional ability when they really go to work in the future. Vocational education is dominated by technical and professional characteristics, upholds the basic concepts of employment orientation, quality-oriented, unity of knowledge and practice, and lifelong development and cultivates students' vocational ability to meet the needs of social development.

2.3. *Education around Students.* Around the mode of students' education, the main object of talent education is the students who have received ordinary school education and have a certain knowledge base, and the training of vocational education talents at an undergraduate level is no exception. Students who graduated from ordinary high schools are also the main body of talent education. Therefore, we must adhere to the basic principle of "taking students as the main body and teachers as the leading factor". Talent education focuses on the basic teaching principles of the students' teaching mode, in order to explore the development laws of nature and society and constantly learn and pursue progressive learning. When formulating the implementation elements of personnel training, colleges and universities must pay attention to taking students as the main body, carry out education around students and accurately understand the training information fed back by students through the evaluation of teaching methods and students' questionnaire survey, which can also make schools clearly recognize their own shortcomings and correct them. We should not only take this measure but also formulate a personalized training mode for students, carefully understand the real needs of students and give full play to the leading role that school education can play in the process of personnel training. After the talent training mode has been tested in practice, we can get feedback by investigating the previous students' evaluation of the implementation of teaching content and the employment situation after graduation, so that the training mode can be continuously improved and the talent training mode can be continuously reformed. Realize the trinity consultation mechanism among schools, enterprises, and students. Both sides understand each other's pursuit of interests, so that the training of talents in schools is more

realistic, and the implementation elements of personnel training tend to be more ideal.

3. Fuzzy Analytic Hierarchy Process Algorithm

3.1. *Building a Hierarchical Model.* According to the analysis of their own needs, the goal, key impact factors, and program objects can be divided into goal level, method level, and program level according to their connection relationship, and the corresponding hierarchical structure diagram is constructed to form a hierarchical structure model.

3.1.1. *Constructing Judgment Matrices against Each Other.* According to the weights of the two factors, a judgment matrix is formed:

$$Judgment\ matrix = \left\{ \begin{array}{c} a_{11}, a_{12}, \dots, a_{1(n-1)}, a_{1n} \\ a_{21}, a_{22}, \dots, a_{2(n-1)}, a_{2n} \\ \dots, \dots, \dots, \dots, \dots \\ a_{n1}, a_{n2}, \dots, a_{n(n-1)}, a_{n(n-1)}, a_{nm} \end{array} \right\}. \quad (1)$$

3.1.2. *Single Layer Weight Calculation.* Multiply the factors of each row of matrix A to calculate the product as

$$M_i = a_{i1} * a_{i2} * \dots * a_{i(n-1)} a_{in}. \quad (2)$$

Calculate the root of N to the n th power, and the expression is as follows:

$$\bar{V} = \left[\sqrt[n]{N_1}, \sqrt[n]{N_2}, \dots, \sqrt[n]{N_{(n-1)}}, \sqrt[n]{N_n} \right]. \quad (3)$$

The weight vector of each factor is obtained by processing vector \bar{V} with the following normalization formula:

$$V_i = \frac{\bar{V}_i}{\sum_{i=1}^n \bar{V}_i}. \quad (4)$$

3.1.3. *Consistency Test of Matrix.* Calculate the maximum eigenvalue of matrix A as

$$\lambda_{\max} = \frac{1}{\sum_{i=1}^n (AV)_i / V_i},$$

$$(AV)_i = (V_1, V_2, V_3, V_4) \left\{ \begin{array}{c} A_{11}, A_{12}, A_{13}, A_{14} \\ A_{21}, A_{22}, A_{23}, A_{24} \\ A_{31}, A_{32}, A_{33}, A_{34} \\ A_{41}, A_{42}, A_{43}, A_{44} \end{array} \right\}. \quad (5)$$

Expressions for calculating consistency metrics is

$$C.I = \frac{\lambda_{\max} - n}{n - 1}. \quad (6)$$

According to the judgment matrices of different orders, the corresponding average random consistency index R.I. can be obtained by looking up the table, and finally the consistency ratio can be calculated by using it.

3.1.4. *Total Sort of All Hierarchies.* After sorting the importance and weight of the above single-level factors, all levels will be sorted in this way. The calculation method is as follows:

$$V_i^{(k)} = \sum_{j=1}^m p_{ij}^{(k)} w_j^{(k-1)}; i = 1, 2, 3, \dots, n. \quad (7)$$

In the same way, the consistency test of the total ranking is also carried out.

3.2. *Fuzzy Analytic Hierarchy Process.* The phase test of fuzzy matrix is established, and a matrix is defined as

$$R = (r_{ij})_{n \times n}. \quad (8)$$

The fuzzy complementary matrix of the matrix can be obtained by satisfying the following conditions:

If the formula satisfies: $0 \leq r_{ij} \leq 1$, ($i = 1, 2, \dots, n$; $j = 1, 2, \dots, n$), then fuzzy array R is a fuzzy complementary matrix.

The fuzzy consistent matrix can be obtained by satisfying the following conditions:

$$r_{ij} = r_{ik} - r_{jk} + 0.5. \quad (9)$$

3.3. *Index Scoring Weight Setting.* We use the fuzzy analytic hierarchy process to construct all indicators and calculate the basic steps of scoring weights as shown in Figure 1.

Construct fuzzy complementary judgment matrix, compare the importance of different influencing factors in pairs and transform it into fuzzy complementary judgment matrix as

$$R = \begin{Bmatrix} R_{11}, R_{12}, R_{13}, R_{14} \\ R_{21}, R_{22}, R_{23}, R_{24} \\ R_{31}, R_{32}, R_{33}, R_{34} \\ R_{41}, R_{42}, R_{43}, R_{44} \end{Bmatrix}. \quad (10)$$

The fuzzy complementary matrix is summed by rows, and the expression is

$$r_i = \sum_{j=1}^n r_{ij}, i = 1, 2, \dots, n. \quad (11)$$

Carry out mathematical transformation into the following formula:

$$r_{ij} = \frac{(r_i - r_j)}{2n + 0.5}. \quad (12)$$

For the neat fuzzy consistency matrix, the factor of each row of the matrix is multiplied by the power product method:

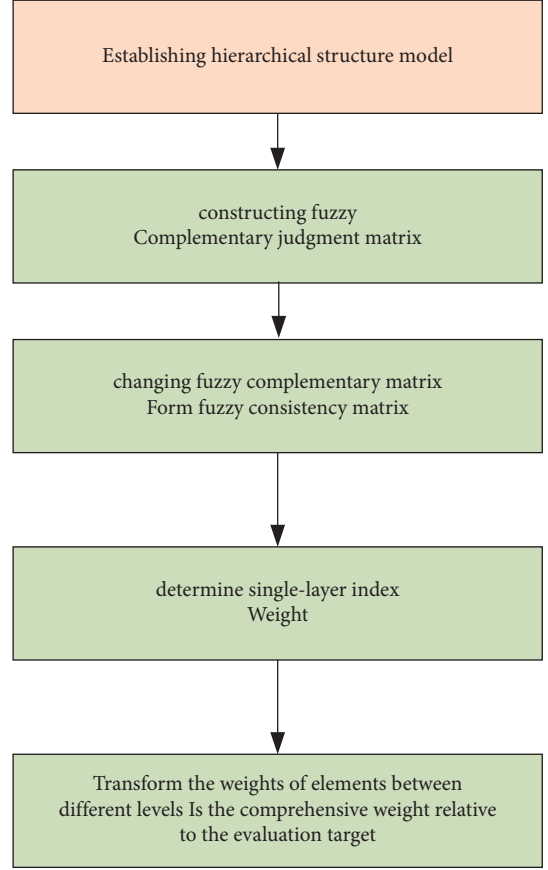

FIGURE 1: Weight setting steps of the bidding score.

$$R_i = r_{i1} \times r_{i2} \times \dots \times r_{i(n-1)} \times r_{in}. \quad (13)$$

Calculate the n th root of R_i as

$$\bar{R} = [\sqrt[n]{R_1}, \sqrt[n]{R_2}, \dots, \sqrt[n]{R_{n-1}}, \sqrt[n]{R_n}]. \quad (14)$$

Normalizing the above vectors as

$$R_i = \frac{\bar{R}_i}{\sum_{i=1}^n \bar{R}_i}. \quad (15)$$

Ranking vectors of fuzzy complementary judgment matrices as

$$w = (w_1, w_2, \dots, w_n)^T. \quad (16)$$

Its constraints are as follows:

$$w_i = \frac{\sum_{j=1}^n r_{ij} + n/2 - 1}{n(n-1)} \quad i = 1, 2, \dots, n. \quad (17)$$

Calculate the compatibility index of fuzzy judgment matrix: as

$$I(A, R) = 1/n^2 \sum_{i=1}^n \sum_{j=1}^n |r_{ij} - p_{ij}|. \quad (18)$$

3.4. *Triangular Fuzzy Number.* The relative importance of the two influencing factors is calculated. If W_1, W_2 are triangular fuzzy numbers, the probability degree of ($W_1 \geq W_2$) is defined as $V(W_1 \geq W_2)$.

TABLE 1: Basic information of respondents.

Category	Investigation items	Percentage proportion
Gender	Men	48%
	Women	52%
	Senior year	
Grade	Ken-ichi	20%
	Yanji	21%
	Yan san	25%
		34%
Areas of interest	Big data application	32%
	Finance	24%
	Construction engineering	20.8%
	Teacher training	20%
	Scientific research	3.2%

When

$$m_1 \geq m_2, V(W_1 \geq W_2) = 1. \quad (19)$$

When

$$m_1 \leq m_2, V(W_1 \geq W_2) = \begin{cases} \frac{l_2 - u_1}{(m_1 - u_1) - (m_2 - l_2)}, & l_2 \leq u_1, \\ 0, & l_2 > u_1. \end{cases} \quad (20)$$

The probability that the triangular fuzzy number W is greater than k triangular fuzzy numbers W_1 is defined as

$$V(W \geq W_1, W_2, \dots, W_k) = \min V(W \geq W_i) (i = 1, 2, \dots, n). \quad (21)$$

In order to introduce entropy weight into the model, several definitions are introduced below.

Set projection of all indicators as

$$P_{ij} = \frac{x_{ij}}{\sum_{i=1}^m x_{ij}}. \quad (22)$$

According to the information conclusion, the entropy value output by each index i is

$$E_i = k \sum_{i=1}^m P_{ij} \ln(P_{ij}), i = 1, 2, \dots, n, \quad (23)$$

$$k = (\ln m)^{-1}.$$

Deviation is

$$d_i = 1 - E_i (i = 1, 2, \dots, n). \quad (24)$$

4. Experimental Study

4.1. Basic Information of Research. In this experiment, the fuzzy analytic hierarchy process is used to investigate college students at different levels to better build a talent system in colleges and universities, involving basic information such as students' age, gender, grade, interest field, and school. The subjects of this survey are 200 students from 20 universities

in China, and their interest research fields are mainly concentrated in 5 fields. The investigation status are shown in Table 1.

Among the 200 respondents, we can see that the proportion of students majoring in scientific research is the least, and students are more inclined to study big data applications and financial fields. According to the fuzzy analytic hierarchy process studied in this paper, we carry out feedback analysis and statistics of the existing personnel training situation.

Whether the respondents in the five research fields are satisfied with the training system used by talents in schools today, the survey results are shown in Figure 2.

Continue to investigate whether the respondents in the five types of research fields recognize the teaching methods in colleges and universities today. The survey results are shown in Figure 3.

Finally, whether the respondents in the five research fields have a clear understanding of the future employment direction, the survey results are shown in Figure 4.

4.2. Model Comparison. In order to highlight the advantages of the fuzzy method combined with hierarchical analysis in the talent training system of colleges and universities, this paper studies and analyzes the students' self-influence indicators in the talent training system of five research fields together with the fuzzy average algorithm and the analytic hierarchy process.

$$MAE = \frac{1}{K} \sum_{K=1}^K |\hat{y}^k - y^{(k)}|,$$

$$RMSE = \sqrt{\frac{\sum_{K=1}^K (\hat{y}^k - y^{(k)})^2}{K}}, \quad (25)$$

$$R^2 = \frac{[\sum_{K=1}^K (y^k - \hat{y}_{Ave})(y^{(k)} - \hat{y}_{Ave})]^2}{\sum_{K=1}^K (\hat{y}^k - \hat{y}_{Ave}) \sum_{K=1}^K (y^{(k)} - \hat{y}_{Ave})}.$$

Fuzzy method combined with the class analysis method to evaluate students' self-learning attitude, basic knowledge,

FIGURE 2: Students' satisfaction with the training system of colleges and universities.

FIGURE 3: Students' recognition of teaching methods in colleges and universities.

cooperation ability, development ability, and professional ability. The research data are shown in Table 2.

Carry out histogram statistics on the data in the above table as shown in Figure 5.

Fuzzy evaluation method evaluates students' self-learning attitude, basic knowledge, cooperation ability, development ability, and professional ability. The research data are shown in Table 3.

Carry out histogram statistics on the data in the above table as shown in Figure 6.

Analytic hierarchy process (AHP) evaluates students' learning attitude, basic knowledge, cooperation ability, development ability, and professional ability. The research data are shown in Table 4.

Carry out histogram statistics on the data in the above table as shown in Figure 7.

4.3. Contrast Experiment. In view of the construction of the talent training system, this paper investigates the students in 5 fields in 20 universities, and use the fuzzy method combined with the hierarchy analysis combination method to construct and apply it. Finally, show whether the model is effective according to their employment situation and compare and analyze the fuzzy evaluation method and the analytic hierarchy process of constructing the talent training system with their combination method, as shown in Figure 8:

5. Conclusion

The construction of talent education and training system in colleges and universities needs a first-class education system with perfect functions, efficient operation, excellent service, and strong guarantee. Among them, it needs the joint efforts of teachers and students to become the winner in the talent market. Based on the fuzzy method combined with the class analysis and combination method, this paper has the following research results:

- (1) The proportion of students involved in scientific research is the least. We should encourage students to conduct scientific research and strengthen the motherland with the power of science.
- (2) Students in various research fields have low recognition of teachers' teaching methods, and teachers can change their inherent teaching thinking and mode in accordance with their aptitude.
- (3) Fuzzy analytic hierarchy process combined method is superior to the single fuzzy evaluation method and the analytic hierarchy process, and its root mean square error is the smallest, and its determination coefficient is closest to 1.
- (4) In the comparative experiment, the employment situation of students after graduation is used to test whether the talent training system in colleges and universities is effective, and the method advocated in this paper is superior to the other two methods.

In view of the low level of gymnastics facilities monitoring and intelligent management of gymnastics venues, which cannot effectively manage gymnastics venues in real time, this paper proposes a method of gymnastics facilities monitoring and intelligent optimization distribution of gymnastics venues in the Internet of Things. This paper will build an information monitoring model, introduce a particle swarm optimization algorithm to participate in the location layout, and explore the actual effect of gymnastics and the Internet of Things. The research results show that (1) the system can measure the mechanical error of facilities and ensure that the controllable fault tolerance rate is less than 1%. (2) The quality of system monitoring is evaluated in accuracy, time, delay, and satisfaction, and the results are basically satisfactory, but the accuracy and time still need to be improved. (3) Using the evaluation system of sports facilities to test the temperature, humidity, facility pressure, and energy consumption suitable for gymnastics and to verify the injury tendency of athletes. When the damage tendency is between 70% and 100%, the actual damage rate is 1. (4) The speed of the PSO algorithm is faster than other methods, which is used to optimize the layout of gymnastics venues and has a certain role in promoting the construction of gymnastics venues. The system model designed in this paper performs well in gymnastics and needs to be further improved and optimized.

1. Introduction

The Internet of Things era breaks down the barrier between reality and virtuality and launches a great change in intelligent and efficient life. Under the background of the 5G network, all walks of life have entered a new stage of development by applying the Internet of Things, and at the same time, massive data information has been formed, and great progress has been made in connecting everything in the world. From the aspect of sports events and industry development, with the Internet of Things changing life, people's spiritual needs have become rich and diverse, and the attention to sports culture has increased. How to innovate and develop sports on the existing technology has become a new research topic. Gymnastics, as a sport with both aesthetics and mechanics, has high requirements for technology, venues, and facilities in order to avoid injuries to

athletes as much as possible. This paper will face the gymnastics, to build an intelligent Internet of Things system, which can be used for both teaching and scientific research and can also be used for sports events. The system model meets the monitoring requirements of gymnastics facilities and can also be connected with sports facilities through intelligent wearable devices to measure the physical condition of athletes. In addition, we should optimize the location and layout of gymnastics venues and strive for the most intelligent distribution layout.

Because the research on sports in China is still in the preliminary theoretical research stage, there are few references in the application field of the Internet of Things, and the experimental data are missing or incomplete. Therefore, in this case, we read a large number of experiments and cases using modern information technology for reference, so as to build the ideological line of the paper, and hope to fill in the

blank of this research by the content of this article. We use IoT to perceive sports resources for development and utilization and build the application architecture of related content [1]. Using the advantages of data mining and IoT, an intelligent sports health management system is constructed to control physical fitness [2]. H2T Internet of Things is used to monitor heart rate data, and NFC and mobile intelligent devices are used to build a sports evaluation platform [3]. This paper studies the overall structure and system functionality of an intelligent venue system and optimizes the design based on IoT [4]. We optimize various methods and technical routes, integrate them with a physical fitness test, and transform the original equipment and systems [5]. We organize the sensors and application principles of the Internet of Things and apply wearable devices to sports science [6]. This paper expounds the scope and main contents of sports facilities detection and puts forward prospects and suggestions for sports function detection [7]. Taking the public sports facilities of national fitness in Hebei Province as the object, this paper studies the resource allocation and service optimization [8]. We design a model to monitor the emission law of volatile pollutants in large stadiums and gymnasiums [9]. Combined with the concept of low carbon, we plan the resettlement, construction, and service quality of urban community sports facilities [10]. According to the experience and enlightenment of Finnish schools, referring to the result-oriented concept of sports quality monitoring, this paper studies the monitoring framework structure and system operation mechanism [11]. The intelligent management and monitoring system of sports training hall based on the Internet of Things is deeply analyzed and studied [12]. Based on automatic detection technology, sports machinery is detected and processed, and errors are analyzed [13]. Discrete wavelet transform (DWT) and random forest algorithm are used to construct sports injury training set, and the monitoring system of athletes' injury possibility is established [14]. Drawing lessons from the American experience, this paper analyzes the regional distribution characteristics and causes of venues in the four major sports leagues and provides theoretical and practical guidance for optimizing the layout [15]. The Internet of Things proposed in this paper is applied to the monitoring and management of gymnastics facilities, which can effectively improve the intelligence and utilization rate of sports venues. Compared with the application of other Internet of Things scenarios, it lacks the overall design and optimization. There are few application scenarios in sports venues, especially gymnastics venues, and the intelligent effect is not realized from the theoretical point of view and combined with artificial intelligence technology.

Applying Internet of Things technology in gymnastics venues can effectively improve the economic efficiency of venues. In this paper, we consider evaluating the quality of system monitoring in gymnastics venues in terms of accuracy, time, delay, and satisfaction, and the results are basically satisfactory, but the accuracy and time still need to be improved. Using sports facilities evaluation system, the temperature, humidity, facility pressure, and energy consumption suitable for gymnastics are tested to verify athletes' injury tendencies.

2. Theoretical Basis

2.1. Concept of Internet of Things Technology. International Organization for Standardization [16]: The technical term of this technology can be interpreted as "Internet of Things." It first appeared in AUTON-ER Research Center in 1999, which can realize intelligent identification and management and combine sensing devices with the Internet. Nowadays, IoT goes beyond the original traditional network and eliminates the communication restrictions between people. It belongs to a form of information sensing and network integration. It has broad prospects and is widely used in the interactive scenes of "IoT" in all walks of life, showing brand-new vigor and vitality. It uses sensing devices to connect to a network to promote information communication and data exchange between people and things, things and things; with the help of various computer technologies, the requirements of monitoring, identification, intelligent management, and positioning can be perfectly realized. It is worth noting that the Internet of Things industry is a new strategic industry, which still has great potential and room for transformation. The technical standards and commercial development related to it in China are still in the primary stage of development. People's concept of IoT is still vague, and the relatively sophisticated core depends on the introduction of foreign technology, so more efforts should be made in this respect.

Transducer/Sensor [17]: That is, a device can be used for detection. It can change the sensed measurement information into the required information by law and meet the requirements of data collection, storage, and recording. In the special network of IoT, the basic equipment plays a vital role in various sensors. Without sensors to realize automatic detection and control functions, objects cannot be anthropomorphic and have senses such as touch, taste, and vision, and human beings will lose a channel to obtain accurate and reliable information. In this paper, we will install different sensors in gymnastics facilities to detect pressure, temperature, gas, and other aspects in order to create a good suitable sports environment. Then, wearable intelligent sensors are installed on the athletes, which work together with the sensors on the facilities to monitor the physiological signals of the athletes and intelligently analyze the injury possibility of the athletes doing gymnastics based on environmental factors. The sensor hardware architecture realized in this paper can receive the sensor data sent by the microcontrol unit through communication technology and finally present a visual interface for easy viewing as shown in Figure 1.

2.2. DWT and Random Forest Algorithm. DWT [18]: It is called discrete wavelet transform. It can discretize the scale parameters and displacement parameters of the basic wavelet. According to the three-dimensional data collected by sensors, the acceleration data including X, Y, and Z directions are processed, and the characteristics can be processed and summarized by the computer after transformation. Each wavelet is scaled by translation, and the acceleration is

FIGURE 1: Display of sensor data monitoring structure.

replaced by a binary discrete wavelet. Formula (1) sets the total energy release in a period of time as E_1 and decomposes it into i levels, where A_i represents the approximate coefficient of wavelet; A_i^1 represents the result after transposition; D_i represents the actual coefficients of the wavelet. Formula (2) represents the energy ratio of approximate coefficients; formula (3) represents the energy ratio of coefficients in actual cases.

$$E_T = A_i A_i^T + \sum_{j=1}^i D_j D_j^T, \quad (1)$$

$$EDR_A = \frac{A_i A_i^T}{E_T}, \quad (2)$$

$$EDR_{D_j} = \frac{D_j D_j^T}{E_T}, j = 1, \dots, i. \quad (3)$$

This paper introduces how DWT transforms the original three-dimensional acceleration data into binary processable data. We also need to introduce classifiers in machine learning in order to automatically classify the activities of athletes efficiently and accurately so as to effectively monitor the sports situation of athletes and improve the success rate of exploring the possibility of injury. In this paper, the stochastic forest fusion algorithm with the statistical self-sampling method as the ideological root is adopted. A strong predictor [19] is composed of a plurality of weak decision-makers [20]. It has a good performance in practical application. The basic steps of the algorithm are as follows:

- (1) Bootstrap resampling is carried out on the original data to generate training sets, and then, a decision tree is formed

$$T(\theta): \{T(x, \theta_1)\}, \{T(x, \theta_2)\}, \dots, \{T(x, \theta_k)\}. \quad (4)$$

- (2) Achieve maximum prediction [21]
- (3) The observed value X belongs to leaf nodes and is not equal to zero, so the distribution weight is defined

$$\omega_i(x, \theta) = \frac{1\{X_i \in R_{l(x, \theta)}\}}{\{j: X_j \in R_{l(x, \theta)}\}}, i = 1, 2, \dots, n. \quad (5)$$

- (4) Set the sum of the weight values of a single decision tree as 1, and weigh the observed values of each dependent variable

$$\hat{\mu}(x) = \sum_{i=1}^n \omega_i(x, \theta) Y_i. \quad (6)$$

- (5) The predicted values shown in formula (6) are summed up, and the weights of formula (5) are combined to finally obtain the weights of each observed value

$$\omega_i(x) = \frac{1}{k} \sum_{i=1}^k \omega_i(x, \theta_i) Y_i. \quad (7)$$

Finally, the predicted value is obtained.

$$\hat{\mu}(x) = \sum_{i=1}^n \omega_i(x) Y_i. \quad (8)$$

2.3. Facility Site Selection and Site Layout

2.3.1. Address Selection of Site. The construction of gymnastics facilities belongs to the government construction project. Therefore, before formally optimizing the internal layout of the venue, we need to analyze the principle of venue location. Considering the principles of fairness, efficiency, integration, and networking, we should not only ensure the transportation convenience, benefits, facilities, and services of venues but also arrange facilities from the overall situation. Two classical models, P-center [22] and P-median [23], are selected.

(1) *Classical P-Center Model.* This model can embody the fairness principle of venue location and can find the

maximum and minimum distance from any demand point to the location. Let I be the number of demand points, where $i = \{1, 2, 3, \dots, I\}$; J is the number of candidate position points, where $j = \{1, 2, 3, \dots, J\}$; P is the number of newly added sites; d_{ij} is the distance between i and j . Get the mathematical expression of the model:

$$F_1 = \text{Min} \left\{ \text{Max} \sum_{j \in J} d_{ij} y_{ij} \right\} \forall i, \quad (9)$$

$$\text{st. } \sum_{j \in J} y_{ij} = 1, \quad \forall i, \quad (10)$$

$$y_{ij} \leq X_j, \quad \forall i, j, \quad (11)$$

$$\sum_{j \in J} X_j = P, \quad (12)$$

$$X_j \in \{0, 1\}, \quad \forall j, \quad (13)$$

$$y_{ij} \in \{0, 1\}, \quad \forall i, j. \quad (14)$$

Formula (9) refers to minimizing the length between the location points closest to the demand position. Formula (10) assigns each demand point to its nearest location. Formula (11) ensures that each candidate site is equipped with a facility site. Formula (12) indicates that there are P places in the candidate sites. Formulas (13) and (14) indicate binary constraints on variables.

(2) *Classical P-Median Model*. This model was first proposed in 1964 [24]. It mainly reflects the efficiency principle of site selection and calculates the shortest time from each demand point to the selected address. The mathematical expression of the model is obtained. Except for different objective functions, the constraint conditions of the model are the same as those of the P -center model, so it is not listed separately here.

$$F_2 = \text{Min} \sum_{j \in J} \sum_{i \in I} d_{ij} y_{ij}, \quad \forall i, j. \quad (15)$$

2.3.2. *Intelligent Optimal Distribution of Site*. Determining the position of objects [25] is the basis of all layout optimization problems. In this paper, the distribution of sports facilities in gymnastics venues can be simplified as a continuous space layout optimization problem. Taking a venue as an example, the length and width of the venue are H and K , respectively, so it is necessary to set up D sports facilities.

$$F = (f_1, f_2, \dots, f_D). \quad (16)$$

Set the total cost of moving sports facilities in the venue and make mathematical modeling. Solve the minimized objective function:

$$\min C = \sum_{s=1}^S \sum_{j=1}^D \sum_{k=1}^D P^S \cdot Q_{jk}^S \cdot D_{jk}, \quad (17)$$

$$D_{jk} = |x_j - x_k| + |y_j - y_k|$$

$$A_{jk} \cdot B_{jk} = 0.$$

3. Research on the Whole Model Framework

3.1. *Overall Functional Design*. In order to realize the construction of gymnastics venues and facilities, it is necessary to build a system engineering that can support the operation. The system is mainly used to monitor the environmental data of facilities, select the best venue address, and intelligently optimize the venue's spatial layout. The whole system is connected through the Internet of Things, and the system facilities are constructed through intelligent facilities, sensors, intelligent wearable devices, cloud management platform, and ArcGIS system. After completing a series of Internet infrastructures, the system automatically uploads the data of daily movement process to the cloud by using an automatic classification method and can quickly extract, cloud, classify, and exchange data through big data and cloud computing platform. Finally, we can view and use the results through the visual operation interface of the system. The specific design situation is shown in Figure 2.

3.2. *Mechanical Error Diagnosis of Gymnastics Facilities*. Our facilities and equipment for gymnastics are mainly electronic sports machinery. Due to the limitation of technical problems, it is difficult to control the quality of these machines in actual production and operation, so it is easy to cause inaccurate measurement results due to mechanical errors. In this section, we use some measures to detect and analyze the errors of sports facilities and strictly control the product quality of sports facilities. In order to achieve this step, we take the internal hardware circuit as the main research goal and extract error features. Where R is composed of different relative leakage resistors; C is the parallel equivalent of different relative ground capacitors. ω stands for frequency, and φ stands for the phase difference angle between error current and U_0 ; we can use $\tan \varphi$ to represent the mechanical error characteristics, as shown in the following formula :

$$\begin{cases} R = \frac{1}{3/r_0 + 1/r_L}, \\ C = 3C_0, \end{cases} \quad (18)$$

$$I_\delta = \frac{U_0}{R} + j\omega C_0 + \frac{U_0}{j\omega L} = I_R + j(I_C - I_L),$$

$$\tan \phi = \frac{(I_C - I_L)I_R}{I_C I_\delta} RC.$$

FIGURE 2: Overall architecture of monitoring and optimization facility system.

3.3. Damage Likelihood Monitoring. Based on DWT and random forest algorithm, a large-scale sports injury monitoring database is constructed by fusing the data collected by wearable smart devices and facility sensors. According to the motion monitoring results, various effective motion displacement curves are drawn, and the mechanical feedback of sports injuries is analyzed. Phase shift registration method is adopted.

$$\begin{aligned} x_i^*(t) &= x_i(t + \delta_i), \\ SSE &= \sum_{i=1}^N \int [x_i(t + \delta_i) - \mu(t)]^2 ds. \end{aligned} \quad (19)$$

Read the waveform until it does not change significantly, and get the activity classification. Look at the curve trend of eigenvalue and motion displacement, and discuss whether there is the possibility of injury.

$$SSE_{n-1} \leq SSE_n \approx SSE_{n+1}. \quad (20)$$

3.4. Location and Layout Optimization. Combining P -median and P -center models, considering the original gymnastics facilities, the location function is modified.

$$W = \alpha_1 F_1 + (1 - \alpha_1) F_2. \quad (21)$$

Gymnastics field layout problem needs to be in a certain internal space, and all the equipment and all kinds of resources are needed for gymnastics reasonable organization and layout. Venues need to determine the venues that meet all needs, and set up competition venues, warm-up venues, training venues, and competition platforms according to the level, scale, and athletes of competition or training. In order to ensure that athletes have good space and visual effects, there should be no direct natural light, and the

safe distance and space between edges should be guaranteed. Optimizing the layout of gymnastics venues with PSO intelligence is as follows:

$$P = (x_1, \dots, x_d, y_1, \dots, y_d),$$

$$V = (v_{x1}, \dots, v_{xd}, v_{y1}, \dots, v_{yd}),$$

$$F = \frac{1}{\sum_{s=1}^S \sum_{j=1}^D} \sum_{k=1}^D p^s \cdot Q_{jk}^s \cdot D_{jk} + Pe(i),$$

$$Pe(i) = 1/2 \left(t_1 \cdot (|h(i)| + h(i)) + t_2 \cdot \sum_{b=1}^4 (|g_b(i)| + g_b(i)) \right),$$

$$\omega = \omega_{\max} - \frac{\omega_{\max} - \omega_{\min}}{k_{\max}} \cdot k.$$

(22)

4. Experimental Analysis

4.1. Introduction of Experimental Environment. In this section, we show the software or hardware used in the experimental part as shown in Table 1.

4.2. System Monitoring Test

4.2.1. Mechanical Error Evaluation of Facilities. For all sports equipment, it is impossible to achieve 100% error-free production, and it can be qualified production within an error range. Especially for sports equipment, when the precise value is emphasized, the analysis of electro-mechanical error is also very important for the normal operation of the equipment. In this paper, the mechanical error

FIGURE 3: Monitoring results of facility accuracy error.

of our control facilities is less than 1% (i.e., fault tolerance rate), and if it exceeds this value, it will be deemed as unqualified. We set up six test groups and got the average relative error value of each group, the unit is millimeter, and the results are not more than 9 mm. Looking at the curve trend in the graph, we can find that the average relative error curve of facilities is below the fault tolerance curve. This means that the average relative error of all test groups is below 1%, which is within the qualified error range. Among them, the fifth test group has the highest error, which can reach 0.78%. The first test group has the lowest error, only 0.39%, as shown in Figure 3.

4.2.2. Monitoring Quality Evaluation. In this section, the main test system monitors the overall quality of the facility, for example, the accuracy of facility test results, the duration, and delay of use. Six kinds of gymnastics facilities that can be monitored are selected, numbered A~F. According to the curve trend in the figure, we can find that the monitoring time of the system is between 5 s and 10 s, and the overall time delay is less than 1.5 s. In terms of accuracy, the results of facilities E and F are all over 90%. Except for facility B, the accuracy is 77.80%, and the test results of other facilities A, C, and D are all between 80% and 90%. In addition, in order to evaluate and monitor sports facilities more professionally and comprehensively, three experts and scholars in related sports fields were invited to conduct a systematic satisfaction evaluation. It can be found that the satisfactory results are between 70% and 90%, and the overall effect is good. However, the monitoring results of A, B, and C facilities are 76.70%, 70.10%, and 78.45%, respectively. Experts think that these three gymnastics facilities still need to be improved as shown in Figure 4.

4.2.3. Evaluation of Monitoring Results. Usually, the temperature of gymnastics training venues is 22–23 degrees, and the humidity index is 22–38. Generally, it can be fine-tuned according to the actual weather conditions of the day. It is necessary to keep the indoor air of the site fresh and free from harmful gases or special gases causing human discomfort. We monitored the sports facilities of gymnastics

FIGURE 4: Overview of system quality.

venues 1 to 5 and summarized the following results as shown in Table 2.

Subsequently, through the monitoring of wearable intelligent devices, this paper counts the sports injury data of athletes under different gymnastics movements. Need to declare one point is because the gymnastics movement selected in this experiment belongs to more professional and difficult items, the data will be biased, resulting in a higher injury tendency. Let 7 athletes numbered A to G perform 6 gymnastics exercises on sports facilities. The controlled room temperature is 22 degrees, the air wettability is 35 degrees, the gas quality is good, the facility pressure detection and physiological signal detection devices can operate normally, and the energy consumption is in a general state. After testing, the system analyzes the possibility of damage according to the detected data. According to the curve, we find that the actual injury rate of athletes with an injury tendency between 70% and 100% is 100%, which proves the accuracy and effectiveness of monitoring and predicting effects as shown in Figure 5.

4.3. Results and Evaluation of Intelligent Layout Optimization

4.3.1. General Situation of Venue Facilities Selection Location. After selecting the appropriate gymnastics site, the system optimizes the distribution of the facilities intelligently. In this section, the final results are evaluated for three rounds. Score the site location evaluation, overall use efficiency, coverage demand points, layout cost, area utilization rate, and layout comfort and professional qualification. We can find that the location of the venue chosen in this paper is convenient and superior and can cover more demand points, and the use benefit can reach 74%. After optimizing the layout of facilities in the site, the distribution of facilities is more reasonable, with a professionalism of 100%, and both the area utilization rate and comfort are higher than 85% as shown in Figure 6.

4.3.2. Comparison of PSO Optimization Algorithms. In this paper, according to the global optimization, the PSO algorithm is used to plan and integrate all the internal resources or equipment in a given limited stadium to solve the

problem of site distribution. We add the FACOPT algorithm and genetic algorithm to compare the layout results. It can be found that the proposed method can obtain the optimal fitness value under the lower iteration times, and the shortest time is about 3.83 s as shown in Figure 7.

4.3.3. *Optimization Results of Continuous Spatial Distribution.* When optimizing the space of the site, there are usually many design schemes. In order to improve the

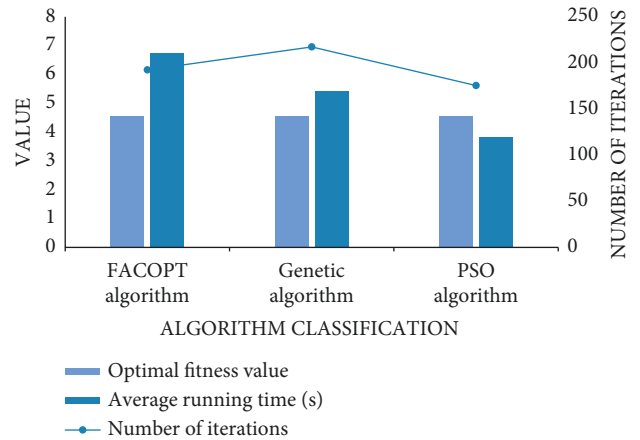

FIGURE 7: Comparison of different algorithms.

FIGURE 8: PSO optimization process of different schemes.

credibility and reliability of the results, we will go through 500 iterations of different schemes and observe their average fitness values. According to the curve in the figure, we can

know that with the increase in iteration times, the average fitness values of the three schemes also increase. Among them, the effect and advantage of scheme 3 are the most obvious as shown in Figure 8.

5. Conclusion

In this paper, flexible pressure, temperature, physiological signals, and other sensors are used to intelligently collect sports equipment data; wavelet transform and random forest algorithm are used to intelligently monitor gymnastics activities; ArcGIS system and particle swarm algorithm are used to optimize the layout of facilities. The final experimental results show that the application of GIS technology promotes the results of site selection and layout, and the model solution is efficient. Through the sensor data monitoring system, the equipment, environment, and athletes can be detected in real time. The Internet of Things can better improve the management efficiency of facilities and venues for China's sports industry and help to improve the overall level of competition. Although this paper has obtained good experimental data and research results but is affected by various factors and conditions, the research on this subject should be refined, further adjust the system environment and work, and put forward more stringent new requirements. The location of the venue selected in this paper is convenient and superior, which can cover more demand points, and the use efficiency can reach 74%. After optimizing the layout of facilities in the site, the distribution of facilities is more reasonable, the professionalism reaches 100%, and the area utilization rate and comfort are higher than 85%. FACOPT algorithm and genetic algorithm are to compare the layout results. The results show that the method can obtain the optimal fitness value with a low number of iterations, and the shortest time is about 3.83 s.

In the future, the following issues should also be considered: exploring cheap and effective sensor materials to reduce the use cost of Internet of Things technology, coordinating government departments to transform gymnastics venues, planning and construction from a more reasonable point of view; dynamically analyzing the optimal layout of gymnastics venues, site selection should be considered more thoroughly, facility types should be adapted to local conditions, and the layout should be clear according to the user groups and scale; smart wearable devices should be used together with smart devices of monitoring facilities to unify data specifications; learn from advanced technology and experience to further optimize the model algorithm, reduce a large number of complex calculation steps in training and testing, reduce the amount of calculation, and improve the calculation speed.

Schizophrenia (SZ) is a severe and prolonged disorder of the human brain where people interpret reality in an abnormal way. Traditional methods of SZ detection are based on handcrafted feature extraction methods (manual process), which are tedious and unsophisticated, and also limited in their ability to balance efficiency and accuracy. To solve this issue, this study designed a deep learning-based feature extraction scheme involving the GoogLeNet model called “SchizoGoogLeNet” that can efficiently and automatically distinguish schizophrenic patients from healthy control (HC) subjects using electroencephalogram (EEG) signals with improved performance. The proposed framework involves multiple stages of EEG data processing. First, this study employs the average filtering method to remove noise and artifacts from the raw EEG signals to improve the signal-to-noise ratio. After that, a GoogLeNet model is designed to discover significant hidden features from denoised signals to identify schizophrenic patients from HC subjects. Finally, the obtained deep feature set is evaluated by the GoogLeNet classifier and also some renowned machine learning classifiers to find a sustainable classification method for the obtained deep feature set. Experimental results show that the proposed deep feature extraction model with a support vector machine performs the best, producing a 99.02% correct classification rate for SZ, with an overall accuracy of 98.84%. Furthermore, our proposed model outperforms other existing methods. The proposed design is able to accurately discriminate SZ from HC, and it will be useful for developing a diagnostic tool for SZ detection.

1. Introduction

Schizophrenia (SZ) is a devastating mental disorder and a progressive neurological disease that causes a significant impact on the quality of life of patients and their families, social environments, and healthcare systems [1]. This disorder affects a person’s perception of reality, social interactions, thought processes, and cognitive ability. Symptoms of SZ include hallucinations (hearing voices or seeing things that are not there), delusions (fixed, false beliefs), and thought disorders (unusual ways of thinking), as well as reduced expressions of emotions, reduced motivations to accomplish goals, difficulty in social relationships, motor impairments, and cognitive impairments

[2, 3]. SZ affects every 1 in 100 Australians and approximately 21 million people worldwide [4, 5]. It is associated with increased morbidity and mortality, and is the cause of disability and health costs worldwide [6]. SZ is treatable, but its treatment involves long-term medications, causing an extreme burden on healthcare systems and families. If the patients are not treated, SZ symptoms may be persistent which makes them disabled after a period of time. If early detection is possible, then patients can get timely treatments that can help those affected individuals and their families improve their lives [7]. Hence, there is a growing demand to develop an efficient and automatic diagnostic technique for the early detection of SZ patients from healthy control (HC) people.

Traditionally, the diagnosis of SZ is mainly performed through solely interviews and observations of patient behavior by a trained psychiatrist [8]. This diagnosis is a manual process that is time-consuming, burdensome, and subject to human errors and bias. Instead of this, recently, some imaging techniques, such as magnetic resonance imaging, computed tomography, positron emission tomography, and electroencephalography (EEG) have been introduced to diagnose SZ. Among these imaging techniques, currently, EEG has emerged as the reference standard for diagnosing SZ due to its high temporal resolution, noninvasiveness, and relatively low financial cost compared to other tests [2, 9]. EEG signals describe the electrical activity of the human brain recorded from the scalp via a set of electrodes. EEG recording generates a huge volume of data. Generally, this massive amount of data is analysed by visual inspection, which is time-consuming, error-prone, and reduces decision-making reliability. Thus, a computer-aided automatic data analysis system is required to make an accurate and reliable decision for the diagnosis of SZ.

1.1. Related Works. In recent years, many researchers have attempted to identify SZ from EEG data [10–18], but no efficient and reliable system has been developed yet for the reliable detection of SZ patients. Much research has been performed based on traditional handcrafted feature extraction methods, but they were inadequate in their ability to generate suitable performance for real-time applications. For example, Sabeti et al. [10] used autoregressive (AR) model coefficients, band power, and fractal dimension-based features for identifying SZ subjects. These features were fed to linear discriminant analysis (LDA), multiLDA, and adaptive boosting (AdaBoost) classifiers. An empirical mode decomposition (EMD) technique was introduced in [2] for the diagnosis of SZ from EEG signals to handle the behavior of nonstationary and nonlinear EEG signals. In [11], Ramos et al. employed power spectral density-based features in the maximum likelihood theory for classifying SZ and HC subjects.

Kaplan et al. [12] used spectral features, and the obtained features were classified using the “Kora-N” algorithm. A fast Fourier transformation (FFT)-based feature extraction process was reported by Buettner et al. in [13]. Finally, those features were used as input to a random forest (RF) classification method for identifying SZ and non-SZ. Approximate entropy, Shannon entropy, Kolmogorov complexity, and Lempel-Ziv complexity methods were proposed by Akar et al. in [14] for extracting features from EEG signals for identifying SZ. In their another work, Akar et al. [15] computed features using wavelet transformation (WT) and Welch power spectral density (PSD) methods for the detection of schizophrenia from EEG data. In [16], Li et al. used functional EEG networks to extract the inherent spatial pattern of the network (SPN) feature for brain states. The combined SPN features of the rest and task networks were used as the input to LDA and the support vector machine (SVM) to recognize SZ.

Only a few studies have been performed on deep learning for the detection of SZ using EEG data. In deep

learning, both the feature extraction and classification processes are conducted automatically, while traditional techniques require features to be extracted manually. Phang et al. [17] proposed a deep convolutional neural network (CNN) framework for the classification of SZ. In that model, the authors integrated the features from various domains and dimensions using different fusion strategies, and the model achieved 93.06% accuracy. An eleven-layered CNN model was introduced by Oh et al. in [18] to analyse the EEG signals for the diagnosis of schizophrenia. The model generated a classification accuracy of 81.26% for subject-based testing.

1.2. Motivations. Most of the existing research studies for SZ detection employ handcrafted feature extraction methods (e.g., WT, FFT, EMD, PSD, and entropy) before classification [10–16]. These feature extraction methods are manually chosen based on researchers’ expertise. The obtained performances of those methods are not satisfactory. The handcrafted feature extraction methods cannot form intellectual high levels of representations of EEG signals to discover deep concealed characteristics from data that can achieve better performance. This manual feature extraction process is time-consuming, labor-intensive, and has bias. Furthermore, if sizes of data are large, the method may not run properly and sometimes underperform.

As mentioned before, very few studies used deep learning methods for the detection of schizophrenia from EEG [17, 18]. The significant characteristic of deep learning is that the model can automatically extract effective features, which has certain advantages for large-scale data. The developed deep learning-based SZ detection methods are still limited in their ability to balance efficiency and accuracy. Hence, this study is motivated to introduce a new deep learning-based feature extraction scheme for automatic and efficient identification of SZ patients using EEG.

1.3. Objectives of This Study. The key objective of this study is to introduce a deep learning-based feature extraction scheme involving the GoogLeNet model called “SchizoGoogLeNet” for automatically and efficiently distinguishing schizophrenic patients from HC subjects using EEG data with improved performance. The reason for considering the GoogLeNet model in this study is that the GoogLeNet architecture has the ability to produce better performance than other deep learning models as it is designed to be a powerhouse with increased computational efficiency. This model trains faster than other network methods (e.g., AlexNet and VGGNet) and has fewer parameters and lower computational complexity than other models [19, 20]. Also, it has a relatively lower error rate than other deep learning methods.

To our knowledge, for the first time, GoogLeNet was introduced in SZ detection using EEG signals in this study. Our proposed “SchizoGoogLeNet” framework consists of several steps. First, this study employs an average filtering method to remove noise and artifacts from the raw EEG signals. Second, significant hidden features are extracted from EEG signals to identify schizophrenia patients from

HC subjects. Finally, a sustainable classification method for the obtained deep GoogLeNet features is explored. At this stage, deep learning and machine learning methods are tested for the obtained deep feature set. The performance of the proposed framework was tested using a publicly available EEG dataset.

1.4. Our Contributions. The main contributions of this work are summarized as follows: (1) For the first time, we introduce a GoogLeNet-based deep feature extraction scheme for automatic detection of SZ using EEG signals; (2) we investigate the impact of balance and unbalanced datasets on the proposed SZ detection model; (3) we discover a sustainable classifier for the obtained GoogLeNet deep feature set in a deep learning and machine learning environment; (4) we explore the performances of the deep feature set with a GoogLeNet classifier and several machine learning methods; (5) we achieve improved performances for our proposed model compared to those of the existing methods.

The rest of this paper is arranged as follows: The proposed methodology is described in Section 2. This section also provides the description of the data that is used in this study. Section 3 provides the experimental setup and the results with their corresponding discussions, followed by the conclusion in Section 4.

2. Proposed Methodology

This study proposes a GoogLeNet-based deep feature extraction scheme, “SchizoGoogLeNet,” for detecting SZ from EEG data automatically. Figure 1 graphically presents the general architecture of the proposed strategy. The proposed scheme involves four stages, such as data acquisition, removing noise and artifacts using average filtering, discovering deep features using GoogLeNet, and exploring sustainable classifiers for the obtained features. A detailed description of these steps is provided below.

2.1. Data Acquisition. This study used EEG data collected from 81 subjects, including 49 schizophrenia patients and 32 normal control persons, from the Kaggle data source. These data consist of EEG recordings of 14 female and 67 male subjects. The average age is 39 years, and the average education level is 14.5 years. The EEG data were recorded from 64 scalp sites and 8 external sites using a BioSemi active two system (<http://www.biosemi.com>). The data were continuously digitized at 1024 Hz and referenced offline to averaged earlobe electrodes. The details of the dataset can be seen online at <https://www.kaggle.com/broach/button-tone-sz> [21]. The description of the data is also available in [22].

2.2. Removing Noise and Artifacts Using Average Filtering. This section aims to introduce a technique for reducing noise and artifacts of EEG signals and improving the signal-to-noise-ratio (SNR) as the signal data are very noisy and often affected by artifacts. Due to noise, EEG signals have a low SNR that may lead to incorrect conclusions. The noise-

removing processes improve the data quality to create an appropriate model. In this study, we employ an average filter (AF) technique for removing noise and artifacts from EEG signals [23]. The reason for using this filtering is that it is simple, intuitive, and easy to implement for smoothing the signals and for dropping the amount of intensity variations that can reduce undesirable information from the signals.

In this study, we reduced noise smoothing of each signal (Sg) by the AF technique with a kernel size of $KS = 12$, and then, we sampled the smoothed signal considering an interval length $IL = KS = 12$ which is denoted as $\hat{S}g$. We selected the values of KS and IL using a trial and error procedure to make the final matrix with a size of around 200. After the filtering, the raw signal data become the input matrix in the feature extraction stage of the GoogLeNet model (discussed in the next step). Figure 2 shows an example of the pattern of a raw EEG signal and a filtered EEG signal. It is apparent from Figure 2 that the shape of the filtered signal is the same as that of the raw signal. As can be seen in Figure 2, the number of data points has been reduced while still keeping the shape of the original curve of the EEG signal.

$$\overline{Sg}(t) = \frac{1}{KS} \sum_{i=t-KS/2}^{t+KS/2} Sg(i). \quad (1)$$

$$\hat{S}g(t) = \sum_{i=0}^L \delta(i - t \cdot IL) \cdot \overline{Sg}(i). \quad (2)$$

2.3. Discovering Deep Features Using GoogLeNet. Technically, a feature represents a distinguishing property, a recognizable measurement, and a functional component obtained from a segment of a pattern [24]. Extracted features convey the most important information for the classification stage. Sometimes, traditional handcrafted features cannot convey meaningful information about the SZ detection due to manual choice of methods and also cannot handle big sizes of data. This section’s goal is to discover the significant feature set from EEG signals using the deep learning method that empowers efficiently the recognition of SZ from HC subjects. For this purpose, this study introduces the deep GoogLeNet-based architecture to extract representative features for identifying SZ from the denoised EEG signals automatically. To our knowledge, for the first time, GoogLeNet is employed in this study for the detection of SZ from EEG signals. GoogLeNet is a convolutional neural network (CNN)-based architecture designed by researchers at Google. It was the winner of ImageNet 2014, where it proved to be a powerful model.

The main objective of the GoogLeNet architecture is to achieve high accuracy with a reduced computational cost [19, 20]. The GoogLeNet model is constructed based on the inception architecture that introduced the new concept of the inception block in CNN, whereby it incorporates multiscale convolutional transformations using split, transform, and merge ideas [20]. A general strategy of the inception block is illustrated in Figure 3. The inception

FIGURE 1: The overall architecture of the proposed “SchizoGoogLeNet” framework for automatic identification of SZ from EEG signals.

FIGURE 2: An illustration of the pattern of a raw EEG and filtered EEG signal.

module is different from other deep learning architectures where there is a fixed convolution size for each layer. In the inception module, 1×1 , 3×3 , and 5×5 convolutions and 3×3 max pooling perform in a parallel way at the input, and the output of these is stacked together to generate the final output. In the GoogLeNet model, conventional convolutional layers are replaced with small blocks. These blocks condense filters of different sizes (e.g., 1×1 , 3×3 , and 5×5) to capture spatial information at different scales, including both fine and coarse grain levels [19, 20]. As shown in Figure 3, multiple convolutions, with 1×1 filters, 3×3 filters, and 5×5 filters, and 3×3 max-pooling layers are organised in the GoogLeNet model.

The GoogLeNet model regulates the computations by adding a bottleneck layer of 1×1 convolutional filters before employing large-size kernels. 1×1 convolution is used to decrease the number of parameters (weights and biases) of the architecture. Furthermore, it uses sparse connections (not all the output feature maps are connected to all the input feature maps) to overcome the problem of redundant information and reduced costs by omitting feature maps that are not relevant [20]. Additionally, connection density is reduced by using global average pooling at the last layer

FIGURE 3: General architecture of the inception block.

instead of using a fully connected layer. These parameter tunings cause a significant decrease in the number of parameters [25].

In this study, we designed the structure of the GoogLeNet model for implementation of the SZ EEG database as illustrated in Table 1. This table presents layer-by-layer architectural details of the GoogLeNet model. “ 1×1 # 3×3 # 5×5 ” refers to various convolution filters used within the inception module. “ 3×3 reduce” and “ 5×5 reduce” symbolize the number of 1×1 filters in the reduction layer used before related convolution layers. The number of 1×1 filters in the projection layer after the built-in maximum pooling is shown in the “pool projection” column (denoted as “Pool proj”). “Max pool” stands for the maximum number of pooling layers. The purpose of these max-pooling layers is to downsample the input as it is fed forward through the network. All the convolution, reduction, and projection layers inside this architecture use rectified linear units (ReLUs) as their activation functions. This architecture is 22 layers deep without pooling (or 27 layers when we count pooling) [19, 20].

2.4. Exploring Sustainable Classification Method for Identifying Schizophrenia. This section’s aim is to discover a sustainable classifier for the obtained deep feature set to classify SZ and HC subjects and improve its performance. Unlike other deep learning models, GoogLeNet does not use fully connected (fc) layers for the final result of classification. Instead, the last convolutional map is subjected to channel-wise global average pooling, and the average activation values of each of the channels are used as the feature vector of the input image.

TABLE 1: Model architecture of GoogLeNet used in this study.

Layer	Patch size/stride	Depth	#1 × 1	#3 × 3 reduce	#3 × 3	#5 × 5 reduce	#5 × 5	Pool proj	Output size

Fc		1							1 × 1 × 2
Softmax		0							1 × 1 × 2
Classification output									1 × 1 × 2

As can be seen in Table 1, the last four layers of our proposed architecture are as follows: a dropout layer set with a probability of 40% dropout, a fully connected (fc) layer, a softmax layer, and a classification output layer. The softmax layer is a final layer of the model that uses the softmax function, and an activation function is used to derive the probability distribution of a set of numbers within an input vector. The output of a softmax activation function is a vector in which its set of values represents the probability of a class or an event occurrence. The classification output layer is set to have the same size as the number of classes in the new dataset, which was two (e.g., SZ and HC) in our case. Before training GoogLeNet, training parameters were set after empirical evaluation. In our experiments, two parameters were used to access the performance of the networks: maximum epochs and batch size.

To determine an appropriate classifier for the obtained deep GoogLeNet feature set, this study also tested four machine learning classification methods: SVM, k-nearest neighbour (KNN), decision tree (DT), and linear discriminant analysis (LDA) for identifying SZ from HC subjects. The reason for the choice of these classifiers in this study is due to their popularity, simplicity, and effectiveness in implementation. They are also very powerful and fast learning algorithms that examine all their training inputs for classification. The description of these methods is available in [26–30].

2.5. Performance Evaluation Parameters. To fairly assess the performance of the proposed models, we computed all standard measurement parameters including the accuracy, sensitivity, specificity, positive predictive value, false alarm rate, F1-score, and the receiver operating characteristic curve (ROC) in this study. The descriptions of the mentioned measurements are available in [28, 31–35].

3. Experiments and Results

3.1. Experimental Setting. In this study, we performed all the experiments in MATLAB (2018b) on a PC with a six-core Intel i7 processor and 32 GB of memory. The server was equipped with an NVIDIA RTX 2060 GPU with 6 GB of memory. We run the GoogLeNet model in the MATLAB deep learning toolbox for our proposed design. As stated before, the dataset includes a total of 81 subjects, where 32 cases are normal control (with 3108 trials; 3072 samples per trial; 70 channels) and 49 cases are schizophrenia patients (with 4608 trials; 3072 samples per trial; 70 channels). In this study, we used all 70 channels' data for the proposed design. Here, we provide an example how we processed the raw EEG signal data of each subject and transformed the processed dataset for implementation in the experiments in this study. For example, for Subject 1, we had a dataset: 887808 × 70 (samples × channels), and we converted this dataset to a matrix sized 70 × 3072 × 289 (channels × window length × epoch) using the transpose process. Here, we obtained epoch = 289 dividing samples by window length (887808/3072). After the average filtering, the raw signal data matrix 70 × 3072 × 289 was moved to a reduced matrix size of 70 × 256 × 289. Afterward, the 70 × 256 × 289 matrix was resized to 224 × 224 × 3 × 289 to be compatible with the deep GoogLeNet input size for subject 1.

Following a similar process, for a total of 81 subjects, the whole dataset was transformed into an image matrix with a size of 224 × 224 × 3 × 23201 (height × weight × 3 symbolize color layer × image samples). The sizes of data for SZ and HC are 224 × 224 × 3 × 13975 and 224 × 224 × 3 × 9226, respectively, which shows that the sample points of SZ and the HC groups are not equal. Thus, we divided the dataset into two groups: balanced and unbalanced datasets to test the effect of equal and unequal sizes of sample points in SZ and HC categories. A balanced dataset is one that has the same

number of observations for each class in a classification dataset. An unbalanced dataset has the different number of observations for each class. Both SZ and HC categories in this study's balanced dataset have the same number of sample points; however, both categories in the unbalanced dataset have an unequal number of sample points. As seen in Table 2, the balanced dataset consists of 9226 sample points in each category of SZ and HC (including training, validation, and testing data), and total sample points for both categories are 18,452.

In the unbalanced dataset, the SZ category has 13,975 sample points and the HC category has 9,226 sample points (including training, validation, and testing data). The total sample point size for the unbalanced data is 23,201. Please note that the unbalanced dataset is the original dataset after data preprocessing. Thus, the balanced data size is $224 \times 224 \times 3 \times 18452$ (height \times weight \times 3 symbolize color layer \times image samples), and the unbalanced data size is $224 \times 224 \times 3 \times 23201$ (height \times weight \times 3 symbolize color layer \times image samples). Then, both datasets are divided into three parts: training, validation, and testing with a ratio of 70%, 10%, and 20%, respectively. The sizes of different parts of data are given in Table 2. In this study, the training dataset was used for the learning process in the proposed model, and the validation dataset was regarded as a part of the training set to tune the model. The validation set was used for tuning the parameters of the model and also for avoiding overfitting. Generally, the validation dataset helps provide an unbiased evaluation of the model's fitness. The testing dataset was used for the performance evaluation.

3.2. Feature Extraction Process and Hyperparameter Setting.

This section presents the process of how the features are extracted using the GoogLeNet model for the balanced and unbalanced datasets. Figure 4 shows the feature extraction process in the GoogLeNet model for the balanced dataset and unbalanced dataset. As seen in Figure 4, the proposed GoogLeNet model yields a deep feature set with a size of 18452×2 for the balanced dataset and 23201×2 for the unbalanced dataset. It means that two deep features are generated, including 18,452 sample points for the balanced dataset and 23,201 for the unbalanced dataset. In both datasets, two deep features are called deep feature1 and deep feature 2.

Figures 5 and 6 present the patterns of the distribution of the obtained two deep features (deep feature 1 and deep feature 2) for the balanced and unbalanced datasets through boxplots, respectively. As can be seen in both figures, the shape of the distribution in both schizophrenia and control groups are symmetrical and there are some outliers in each diagram. In both figures, it is observed that there is a significant difference between the central value of schizophrenia and control groups in both feature sets. The boxplot figures clearly demonstrate that there is a clear and significant difference in the values of the feature set in two groups that help in the efficient classification of schizophrenia and control.

To find the best model, the hyperparameters (e.g., the number of hidden units, the number of epochs, and the batch size) of the GoogLeNet model are optimized (tuned) by the training process. We run the data through the operations of the model, compare the resulting prediction with the actual value for each data instance, evaluate the accuracy, and adjust until we find the best values. We performed an extensive number of experiments to find appropriate values for different parameters. The configuration of hyperparameters of the proposed model is provided in Table 1. The table illustrates the layer-by-layer structural details of the proposed "SchizoGoogLeNet" model.

In this study, the SVM classifier with a linear kernel was used as an optimal kernel function after testing all the kernels (e.g., linear, polynomial, and radial basis kernels) because this kernel produced a better performance compared to others. The KNN classifier used the default distance metric "Euclidean distance" for the distance measure and $K=1$ in the model after several experimental evaluations. For DT and LDA classifiers, the parameter values are considered which have been used in MATLAB default parameter settings as there are no specific guidelines for setting the values of the parameters for these classifiers.

3.3. Results and Discussion. This section provides the experimental results that are achieved using 10-fold cross-validation through MATLAB. For both balanced and unbalanced datasets, we used the obtained deep feature set as an input to the softmax classifier of GoogLeNet (deep learning (DL) classifier) and also four popular machine learning (ML) classifiers (SVM, KNN, DT, and LDA), separately, to find an optimal classifier. Tables 3 and 4 present the overall performance results for our proposed approaches in terms of the sensitivity (SEN), specificity (SPE), accuracy (ACC), positive predictive value (PPV), and $F1$ -score for the balanced and unbalanced datasets, respectively.

As can be seen in Table 3, for the balanced dataset, the SVM classifier achieves the highest performances such as ACC (98.30%), SPE (98.27%), PPV (98.27%), and $F1$ -score (98.30%), and the LDA classifier produces the highest sensitivity value (98.53%). The lowest performances (e.g., ACC (94.28%), SEN (92.15%), SPC (96.42%), PPV (96.26%), and $F1$ -score (94.16%)) are obtained by the GoogLeNet classifier (DL classifier). For the unbalanced dataset, Table 4 reports that among the reported classifiers, the highest classification performances are attained by the SVM classifiers, which are 98.84% of ACC, 99.02% of SEN, 98.58% of SPE, 99.06% of PPV, and 99.04% of $F1$ -score. On the other hand, the lowest performance (e.g., ACC (95.09%), SEN (93.81%), SPC (97.02%), (PPV 97.95%), and $F1$ -score (95.83%)) are obtained by the GoogLeNet classifier like the balanced dataset.

In order to further assess, we also computed the false alarm rate (FAR) of the proposed classification models for the balanced and unbalanced datasets as shown in Figure 7. This figure also demonstrates that the SVM classifier produces better performance (a lower FAR indicates better

TABLE 2: The sizes of different parts of data.

Data	Category	Training data	Validation data	Testing data
Balanced	HC	$224 \times 224 \times 3 \times 6458$	$224 \times 224 \times 3 \times 922$	$224 \times 224 \times 3 \times 1846$
	SZ	$224 \times 224 \times 3 \times 6458$	$224 \times 224 \times 3 \times 922$	$224 \times 224 \times 3 \times 1846$
	Total	$224 \times 224 \times 3 \times 12916$	$224 \times 224 \times 3 \times 1844$	$224 \times 224 \times 3 \times 3692$
Unbalanced	HC	$224 \times 224 \times 3 \times 6458$	$224 \times 224 \times 3 \times 922$	$224 \times 224 \times 3 \times 1846$
	SZ	$224 \times 224 \times 3 \times 9782$	$224 \times 224 \times 3 \times 1397$	$224 \times 224 \times 3 \times 2796$
	Total	$224 \times 224 \times 3 \times 16240$	$224 \times 224 \times 3 \times 2319$	$224 \times 224 \times 3 \times 4642$

SZ = schizophrenia; HC = healthy control.

FIGURE 4: Feature extraction process in the proposed “SchizoGoogLeNet” model for the balanced and unbalanced dataset.

performance) with the obtained feature set than the GoogLeNet classifier (a higher FAR indicates lower performance). From Tables 3 and 4 and Figure 7, it is clearly apparent that the obtained feature set yields higher performance with ML classifiers than the DL classifier (e.g., GoogLeNet) for both balanced and unbalanced datasets. In both datasets, the SVM classifier is superior for the obtained deep feature set compared to other reported classifiers, and the GoogLeNet classifier with the same feature set achieved the worst performance.

Figure 8 and also Figure 7 show a comparison of the performances (in terms of ACC, SEN, SPE, and FAR) between the balanced and unbalanced datasets. The figures demonstrate that the performances of all classifiers are higher for the unbalanced dataset than those for the balanced dataset. The overall accuracy is increased by 3.75% for the unbalanced data and 4.02% for the balanced data for the ML-based classifier compared to the DL scheme. The

unbalanced dataset’s improved performance may be due to the fact that it is the original dataset, which includes all of the subjects’ data points. On the other hand, the balanced dataset was produced from the unbalanced dataset by eliminating some subjects. The performance was lower for the balanced dataset because some subjects’ data points had been eliminated. From the results, it can be considered that the obtained deep feature set with an SVM classifier is exceptional for the identification of SZ EEG signals from HC.

Figures 9(a) and 9(b) display an illustration of training and validation accuracy patterns for the deep GoogLeNet model in different iterations of the balanced and unbalanced datasets, respectively. For both datasets, the training accuracy and validation accuracy increase with the increase in the iteration numbers. It is notable that the accuracy of the training set does not deviate substantially from that of the validation set as observed in Figures 9(a) and 9(b). In the

FIGURE 9: (a) Patterns of the training and validation accuracy of the GoogLeNet-based model for the balanced dataset. (b). Patterns of the training and validation accuracy of GoogLeNet-based model for the unbalanced dataset.

FIGURE 10: (a) Patterns of the training and validation loss information of the GoogLeNet-based model for the balanced dataset. (b). Patterns of the training and validation loss information of the GoogLeNet-based model for the unbalanced dataset.

training stage, the learning rate was set at 0.0001 and the batch number was one sample each time. The number of filters and kernel size was determined via the brute force technique.

The loss information of the training set and validation set with respect to different iterations is displayed in Figures 10(a) and 10(b) for the balanced dataset and unbalanced dataset, respectively. For both datasets, it is observed that the training loss and the validation loss decrease with the increase in the iteration numbers. The performance of the training set does not significantly diverge from that of the validation set, as shown in Figures 10(a) and 10(b).

To further assess the effectiveness of the GoogLeNet-based model, the ROC curves are drawn for different SZ detection models, where the input data were the deep feature set shown in Figures 11(a) and 11(b) for the balanced and unbalanced datasets, respectively. The corresponding performance measurements in every condition are shown in Table 5. Table 5 reports the area values under the ROC curve (AUC) for the reported classifiers. The AUC is the value of the area under the ROC curve that belongs to a value between 0 and 1 (a larger area indicates a better performance of the classifier). As can be seen in Table 5, the highest AUC is obtained by the SVM classifier, which is 0.9984 (close to 1) for the unbalanced dataset and 0.9973 for the balanced dataset. The KNN model produces the lowest AUC for both the balanced (0.9728) and the unbalanced (0.9795) datasets. Like the previous results, the results also indicate that the SVM classifier with the obtained deep feature set works better than other reported classifiers.

3.4. Comparative Analysis Report for Our Proposed Method with Existing State-of-the-Art Methods. A comparison of the prior EEG-based techniques used for SZ detection with our proposed model has been provided in Table 6. Until now, we found seven articles [2, 28, 35–39] in the literature for the

same database that we have used in this study. Table 6 shows the performance comparison of the proposed method with these published methods [2, 28, 35–39]. Kahre et al. [35] reported a method based on empirical wavelet transformation and SVM for the detection of SZ from EEG signals. Their method achieved an ACC of 88.70%, SEN of 91.13%, and SPE of 89.29. In [2], Siuly et al. introduced empirical mode decomposition (EMD)-based features with an ensemble bagged tree (EBT) for the detection of SZ using EEG signals. The ACC, SEN, and SPE scores of their method were 89.59%, 89.76%, and 89.32%, respectively. Guo et al. [38] reported a random forest (RF)-based machine learning algorithm for identifying schizophrenia patients from healthy control subjects using EEG signal data. In the designed plan, the author considered a number of features such as gender, age, education, and event-related potential (ERP) and the combination of the features.

RF yielded an accuracy of 81.1%. Khare et al. [36] introduced an automatic approach based on flexible tunable Q wavelet transform (F-TQWT) and a flexible least square support vector machine (F-LSSVM) classifier for the detection of SZ from EEG signals. The authors used the “Fisher score” method for the selection of the most discriminant channels. Their proposed method generated 91.39% accuracy, 92.65% sensitivity, and 93.22% specificity. In [37], Guo et al. proposed a scheme based on convolutional neural networks (CNNs) to characterize the difference in the distributed structure of data for identifying SZ from EEG. Their method achieved an accuracy of 92%. Khare et al. [38] designed a model involving a robust variational mode decomposition (RVMD) and an optimized extreme learning machine (OELM) algorithm. The experiment results reveal that the third mode’s chaotic features are responsible for generating the best performance (overall ACC of 92.30%). In [39], a time-frequency analysis-based convolutional neural network (CNN) model was proposed for identifying SZ from EEG signals by Khare and Bajaj. The authors used

continuous wavelet transform, short-time Fourier transform, and smoothed pseudo Wigner–Ville distribution (SPWVD) techniques to obtain scalogram, spectrogram, and SPWVD-based time-frequency representation (TFR) plots for SZ detection. Their method achieved an overall accuracy of 93.36% using the SPWVD-based TFR and CNN model.

It is apparent from Table 6 that our proposed model yielded the highest performance scores with an accuracy of

98.84%, sensitivity of 99.02%, and specificity of 98.58%, compared to performance scores of the other existing methods. The achieved accuracy improvement of our proposed model is 17.74% better than the accuracy score of Zhang [28] and 10.14% better than the accuracy score of Khare et al. [35]. In the end, it can be concluded based on the experimental results that deep GoogleNet features of EEG signals with an SVM classifier could serve as an applicable

measurement to correctly discriminate between schizophrenics and HC subjects. [40].

4. Concluding Remarks

In this study, a GoogLeNet-based feature extraction scheme, called “SchizoGoogLeNet” is developed to efficiently identify SZ patients from HC subjects using EEG signal data. The proposed GoogLeNet model automatically extracted important hidden features which are advantageous for large-scale data. The obtained deep feature set was verified by the GoogLeNet classifier (DL classifier) and also four popular ML classifiers (e.g., SVM, KNN, DT, and LDA), separately. The performance of the proposed framework was evaluated on the benchmark SZ EEG database from Kaggle through extensive experimental evaluation. To check the effect of equal and unequal sample points in SZ and HC groups, we divided the dataset into two groups: balanced (the same number of sample points in SZ and HC) and unbalanced dataset (unequal sample points in SZ and HC) (original dataset). The experimental results show that the unbalanced set produces better performance compared to the balanced dataset. Among the reported classifiers, the SVM classifier with the obtained deep feature set yielded the highest performance (e.g., ACC 98.84%, SEN 99.02%, SPE 98.58%, PPV 99.06%, and F1-score 99.04%), while the lowest performances were obtained by the GoogLeNet classifier (e.g., ACC 95.09%, SEN 93.81%, SPC 97.02%, PPV 97.95%, and F1-score 95.83%). Moreover, our proposed model outperforms the existing methods. The findings of this study indicate that the obtained deep GoogLeNet features perform better with the SVM classifier in the SZ detection than the DL classifier (GoogLeNet classifier).

This study has some limitations, such as the fact that the study only considers two-class classification problems (SZ versus HC), while we intend to expand the application of the suggested approach to multiclass scenarios soon. Another flaw is that this study used a small SZ-based EEG dataset (81 total subjects: 49 schizophrenia (SZ) patients and 32 healthy control (HC) people). In the near future, we will broaden our method’s application to include huge clinical datasets.

Data Availability

The data can be obtained from the Kaggle website: <https://www.kaggle.com/broach/button-tone-sz>.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors would like to thank Kaggle EEG data collection team for the dataset: “EEG data from basic sensory task in Schizophrenia.” Funding for the data collection was supported by National Institute of Mental Health (Project Number: 5R01MH058262-16).

Aiming at the problem that online video learning resources of business English are scattered and the learners are inefficient in acquiring learning resources, this paper designed a business English learning system based on the EDIPT model. In addition, aiming at the problem of multifeature fusion between low-level features and high-level semantic features in video scenes, this paper proposes a multi-modal video scene segmentation algorithm based on a deep network. By minimizing the square sum of distances in the time period, the shots are clustered, and finally, the semantic scene is obtained. The experimental results show that the algorithm has good performance in classification accuracy and can effectively segment video scenes, which is helpful for users to improve their comprehensive business English skills.

1. Introduction

Education makes human knowledge and civilization spread, and it is an important force to promote the development of human knowledge and civilization. With the development of science and technology and the increase of knowledge, the society needs more advanced and effective means of education. Using the network to spread knowledge is an effective way to spread knowledge. Among them, business English is an application-oriented major that teachers need to pay attention to the exercise of students' English, especially oral communication, so it is very important to build a good English learning environment [1, 2]. However, many colleges and universities are lack of a good business English learning environment, resulting in students cannot get effective English training. Normally, business English students in the development of oral practice are carried out in the simulation of business activities, the lack of daily teaching of business English oral exercise, so that students' oral English level cannot be effectively exercised and then affect the students' English level.

In the teaching design, the EDIPT design thinking model is widely recognized in the field of education from the

perspective of students. It is used to guide teaching practice and is conducive to the development of students' innovation ability and design thinking. Through the implementation of the design thinking process, Lin changed the current situation of single information technology works of junior high school students and provided a teaching model and activity design suitable for junior high school [3]. Yu introduced a foreign typical EDIPT design thinking model into a scratch classroom in primary school, guided scratch teaching according to the operation process of the EDIPT design thinking model, and designed learning activities to improve students' design thinking ability [4]. Design thinking is not only used to guide classroom teaching but also applied to practical teaching by many educational institutions outside school.

In addition, online video learning is an effective means for students to exercise their business English application ability. But at present, the retrieval of teaching video still relies on the TBVR form, which has the following problems [5, 6]. Firstly, the manual annotation only represents the staff's personal views on the video, which is too subjective and difficult to cover each person's grasp of the different focuses of the video; secondly, manual tagging requires staff

to make a brief summary after watching the video, but in the face of the explosive growth of massive video data, the time and labor cost of tagging are difficult to estimate; thirdly, the content in the video is abundant, so it is difficult to summarize it with simple words or phrases. For the above-given reasons, TBVR is not conducive to users to quickly find their interesting teaching video clips and knowledge points, and it is difficult to meet the needs of users. The semantic information based on a single modal analysis is always limited. While combining two or more modes for multimodal feature semantic analysis can obtain more abundant video semantic information, which is an effective method to extract video content.

Multimodal theory refers to the phenomenon that various senses interact with each other through language, image, sound, animation, and other elements [7]. However, multimodality can strengthen the communication of verbal meaning, and learners can effectively understand multiple knowledge signals. Cross thought that video information can promote the understanding of business English materials [8]. In particular, multimodal theory video resources are represented by images, sounds, and languages. Compared with single-mode learning resources, audio-visual learning resources can reduce the difficulty of business English learning. Most of the users' information comes from reading, listening, and writing in a business environment. A Révalo found that multimodal guidance can better promote learners' understanding of business English. Business English learning emphasizes scenario simulation and pays attention to the cultivation of communicative competence. In addition, the introduction of multimodal theory has a certain theoretical basis for the integration of business English videos [9].

Therefore, this paper extracts and analyzes the video learning resources of business English, introduces the EDIPT thinking model, and designs a business English learning system integrating multimodal information such as text, graphics, audio-visual, animation, and so on, so as to improve the comprehensive business English skills of users with different learning styles.

2. Design of Business English Learning System Based on EDIPT

2.1. EDIPT Design Thinking. The EDIPT design thinking model consists of five stages that can jump through the cycle: empathy, problem definition, conception, prototyping, and testing, as shown in Figure 1. Each stage includes stage objectives, implementation principles, specific methods, and tools. The specific stages and implementation process are as follows [10, 11].

The specific implementation process of the empathy stage: learners use What? How? Why? Empathy map, situational story method, and other tools, in-depth understanding of the user's environment, in-depth mining of the user's inner activities, to provide a foundation for targeted solutions. The specific implementation process of defining stage: learners use the POV problem definition method to state factual problems as operational problems, using the method of "how might we," we can ask questions in an open

way, decompose and think about the problems, and focus on innovative problems. In the stage of ideating, we can use the scaffold table to think about problems from the seven directions provided in the scamper table or from some selected directions and initially form the problem solution. The realization methods of the prototype stage include sketch drawing, pattern making, and demo design. The specific implementation process: learners can use the simplest tools such as paper and pen to draw sketches, show their own or group ideas, and achieve the goal of expressing ideas, presenting solutions, and quickly realizing creativity. The specific implementation process of the test: learners can use the "feedback capture grid graph" tool to collect and integrate user feedback information, sort out the highlights and problems of the prototype from the collected information, obtain constructive suggestions and further improvement ideas, so as to promote the generation of the best solution.

2.2. Teaching Model Design. The whole teaching model includes teaching process design, teaching evaluation design, teaching evaluation design, and teaching feedback design.

The learning mechanism is linear; learners need to complete all learning tasks, and then they can unlock the next video learning. Taking single video teaching as a cycle, the teaching process of this system belongs to cyclic teaching. In addition, learners complete the business English learning module in turn according to the set task objectives. In a single learning cycle, learners acquire business knowledge, improve oral communication, and strengthen other comprehensive business English skills. Video teaching is divided into seven indicators, namely, visual, listening, reading, speaking, testing, translation, and writing, to assess the teaching results. While each teaching task is set with a corresponding score.

2.3. Functional Design. By integrating high-quality business English video learning resources, users can improve the efficiency of acquiring learning resources, improve the learners' comprehensive learning ability of business English, create a microbusiness communication platform, and create a business communication circle. The business logic function of the system is divided into three functional modules: basic learning function, learning the main function, and learning auxiliary function. The main function of learning runs through the whole process of video learning and is the core function of the small program. The specific function design is shown in Figure 2.

2.3.1. Basic Learning Function. The basic learning functions include learning check-in, learning review, learning forwarding, video collection, and video like. Check-in design is a basic function commonly used by users, where learners get bonus points for daily check-in, and the points obtained by check-in are converted into scores in equal quantities. Users judge their current learning needs through video reviews, and their diagnostic learning evaluation strengthens their reflection on video learning.

FIGURE 1: EDIPT design thinking model.

FIGURE 2: System function design.

2.3.2. *Learning Main Function.* The main functions of learning include audio-visual task function, scene following function, oral recording function, practice feedback function, text translation function, and learning note taking function. In the whole learning process, the task-driven teaching method promotes learners to complete video learning. For the key parts of the video content, blank out randomly and fill in the blanks with words. Subtitles are not set in the audio-visual task link. Text translation is attached in the learning link, and the learning note function is added.

2.3.3. *Learning Auxiliary Function.* The learning assistance function includes two parts: one is to help customs clearance with points and the other is to help the business microgroup to socialize. Redeem the points, add the points to the score, regenerate the score report, view the rating level, help the customs clearance, and unlock the next video learning. The score values of different task modules are recorded in the score report, and the video learning score must be greater than or equal to 90 points to pass the test.

2.4. *Design of Data Flow.* Because the system mainly uses user data and video data, the whole process includes three kinds of data flow. The first is that the user sends the behavior request to the system, and the system returns the processing results in the small control layer. The second way is to get the current data information, but it does not involve the change of database information, so it needs to access the

background server, where the user sends the access request to the client. After receiving the request, the client realizes C/S communication with the server. Finally, the server returns the business logic processing results to the client, and the client presents it to the user in the form of a page. The third one involves updating the data table information, where the user requests to update or query the data, and the client sends the event request to the server. During the process, the database server program will listen to the network request events, realize the communication between the model layer and the server by passing parameters, and update the information after data proofreading and validation, as shown in Figure 3.

3. Multimodal Video Scene Segmentation Algorithm

3.1. *Overall Design.* Because the above-given system is aimed at video learning resources, the semantic information based on single modal analysis is always limited. While combining two modes or more to carry out multimodal feature semantic analysis can obtain more abundant video semantic information, which is an effective method to extract video content. Therefore, the multimodal deep network method is adopted, where the video scene segmentation task is treated as a supervised time constrained clustering problem. Firstly, rich underlying features and semantic features are extracted from each shot; secondly, in order to obtain the similarity measure between shot features, these features are embedded

FIGURE 3: Design of data flow.

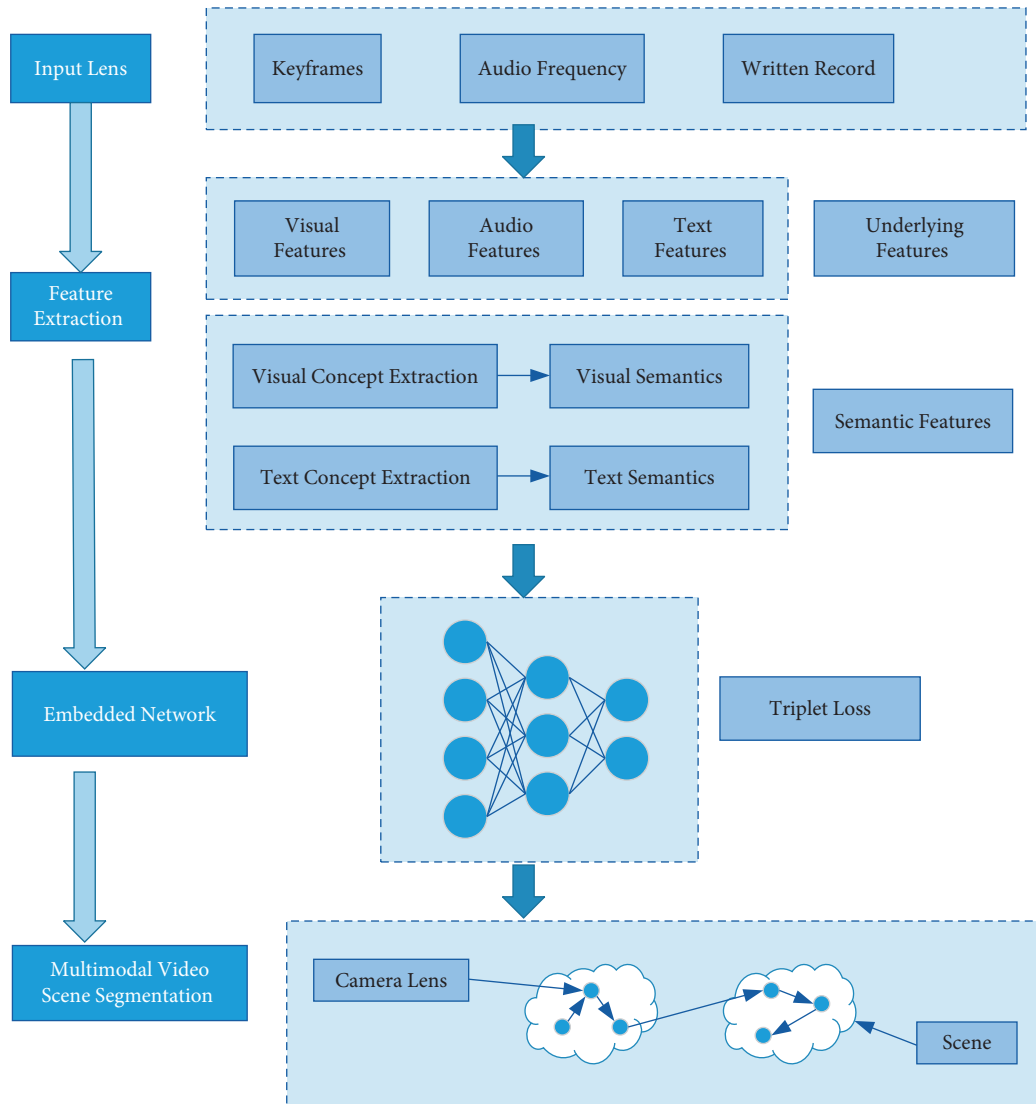

FIGURE 4: Overall algorithm framework.

in Euclidean space; finally, the optimal scene boundary is detected by minimizing the sum of squares of distances in the time period and use a penalty to automatically select the number of scenes. The overall framework is shown in Figure 4.

3.2. *Embed Deep Networks.* Considering that the shots in the same scene usually have the same content in the video stream, the scene segmentation problem is also considered as the problem of grouping adjacent shots together, which is to maximize the semantic consistency of similar shots. In

order to reflect the semantic similarity, it is necessary to calculate the distance between lens feature vectors X , so an embedding function $\varphi(X)$ is constructed, which can map a lens feature vector to the space where Euclidean distance has the required semantic properties. The distance matrix is

$$\left[\varphi(X_i) - \varphi(X_j) \right]^2 = [1 - \alpha_{i,j}], \quad (1)$$

where $\alpha_{i,j}$ is a binary function, indicating whether the scene X_i and X_j belong to the same scene, $i, j = 1, 2, \dots, N$.

The embedded function $\varphi(\cdot)$ makes the shots of a particular scene X_i closer to all shots of the same scene X_i^+ , rather than any other shots of any other scene X_i^- , so that the constraint can be carried out.

$$\varphi(X_i) - \varphi(X_i^+) < \varphi(X_i) - \varphi(X_i^-). \quad (2)$$

In order to improve the embedding ability, a triple depth network is designed, which is composed of three basic networks, where the same parameters are shared, and each parameter takes the scene descriptor as the input and calculates the required embedding function. Train the network loss of Triplet (X_i, X_i^+, X_i^-) through the Triplet loss function, and Hinge loss of Triplet is defined as follows:

$$L_i(w, \theta) = m(0, \varphi(X_i) - \varphi(X_i^+)^2 + (1 - \varphi(X_i) - \varphi(X_i^-))^2), \quad (3)$$

where w is the network weight; θ is the deviation. The total loss of N triples is given by the average loss of each triplet plus the L_2 regular term of the network weight to reduce overcompensation.

Therefore, the total loss of N triples can be defined as follows:

$$L(w, \theta) = \frac{5 \times 10^{-5}}{2} \|w\|^2 + \frac{1}{N} \sum_{i=1}^N L_i(w, \theta). \quad (4)$$

3.3. Multimodal Scene Segmentation. Because scenes need to be continuous in time, scenes with similar semantic content but far away in time should be distinguished. The task of video scene segmentation is treated as a supervised time constrained clustering problem; secondly, in order to obtain the similarity measure between shot features, these features are embedded in Euclidean space; finally, the optimal scene boundary is detected by minimizing the sum of squares of distances in the time period, and a penalty term is used to automatically select the number of scenes.

In order to obtain scene segmentation of video, shots are required to be as semantically consistent as possible. Inspired by K-means, cluster homogeneity can be described by the sum of square distances between cluster elements and their centroids, which is called within cells sum of squares (WSS) [12]. Therefore, the reasonable goal is to minimize the sum of squares within a group, that is, the sum of all WSS. While only minimizing the sum of squares within a group will lead to a trivial solution of only one scene in each sequence. Therefore, it is necessary to add penalty terms to

avoid over segmentation. Therefore, Formula (5) needs to be solved.

$$\min_{M, t_m} \sum_{m=0}^M WSS_{t_m, t_{m+1}} + C \cdot g(M, N), \quad (5)$$

where M is the number of change points of input video segmentation; t_m is the position of the m -th change point. t_0 and t_{M+1} are the beginning and end of the video respectively; $WSS_{t_m, t_{m+1}}$ is the sum of squares within the group of the m -th segment in the embedded space. $g(M, N) = M(\ln(N/M) + 1)$ is the standard punishment of Bayesian information, which is parameterized by the number of clips M and the number of scenes N in the videos. The C parameter is used to adjust the relative importance of the penalty. A higher penalty value of C would cause too many segments, so the choice of C value depends on the video. Adjust the C value by using a step size of 0.001, until the number of clusters is less than the number of scenes in the video.

The sum of the square distances between a set of points and its mean can be expressed as a function of the paired square distances between individual points. Therefore, the sum of squares within a group can be represented as scene segmentation.

$$WSS_{t_m, t_{m+1}} \triangleq \sum_{t=t_m}^{t_{m+1}-1} \varphi(X_t) - \mu_m^2 \quad (6)$$

$$= \frac{1}{2(t_{m+1} - t_m)} \sum_{i,j=t_m}^{t_{m+1}-1} \varphi(X_i) - \varphi(X_j)^2.$$

Among them, μ_m is the average value of each scene shot feature.

$$\mu_m = \frac{1}{2(t_{m+1} - t_m)} \sum_{t=t_m}^{t_{m+1}-1} \varphi(X_t). \quad (7)$$

In this way, clustering targets can be minimized using dynamic programming methods. First, $WSS_{r,r+d}$ is calculated for the starting point r and the duration d of each segment. Secondly, the optimal target values of $j \in [1, N]$ lenses and $M \in [0, N-1]$ change points are calculated iteratively to minimize the target, as shown in equation (8), where $D_{0,j} = WSS_{0,j}$. In the end, the optimal number of variation points was chosen as $M^* = M^* = \arg \min D_{M,N} + C \times g(M, N)$, and the optimal scene segmentation was reconstructed.

$$D_{M,j} = \min_{r=M, M+1, \dots, j-1} (D_{M-1,r} + WSS_{r,j}). \quad (8)$$

In the video scene segmentation algorithm, the input is the scene video stream, where the total number of video shots is N and the overall feature vector of the shot is X . The output is the scene boundary (lens number is S_i). The specific algorithm steps are as follows:

- (1) The input video frequency stream is segmented into shots, and the key frame of the shot is identified by calculating the average distance of all frames within

TABLE 1: Parameters of model training.

Training set	Epoch	Batch-size	Loss function	Number of iterations	Learning framework
8000	2	32	Cross entropy	2000	Keras

the shot. All shots and key frames after segmentation are numbered, namely, S_i and S_f .

- (2) According to Formulas (1) and (2), the visual concept feature vector $v(s)$ and text concept feature vector $t(s)$ of the lens are extracted respectively. Then, all of its features are connected in series to obtain its global eigenvector X .
- (3) Adopt a deep network to learn an embedding function $\varphi(X)$, embed video shot features in Euclidean space, and calculate the pair distance matrix between shots to get the similarity measure between shot features, and then get the semantic similarity between shots.
- (4) For each segment starting point r and segment duration d , calculate $WSS_{r,r+d}$.
- (5) Let $j \in [1, N]$, $M \in [0, N - 1]$, calculate an optimal target value containing j lenses and M change points to minimize the target $D_{M,j}$. If $r < N$, continue to Step (5). While if $r \dots N$, go to Step (6).
- (6) The optimal number of change points M^* is selected by calculation, and the lens number S_i of the corresponding scene boundary is output according to the location of the segmentation points, and the segmentation result of the video scene is finally obtained.

4. Experiment and Analysis

4.1. Model Training. The gradient descent method is used to optimize the algorithm, and the learning rate is taken as the default value of 0.01. Table 1 shows the specific parameter configuration of network training.

Figure 5 shows the influence of the number of iterations on the final experimental results. It can be seen that when the number of iterations is small, the number of learning is not enough, so the accuracy of the final result is insufficient. However, because the visual features are only one part of the basis of video scene segmentation, the results still have a certain accuracy. Then, with the increase of iterations, the value of F increases, and after 2 000 iterations, it is stable.

4.2. Analysis of Model Validity. In order to verify the effectiveness of the proposed algorithm for video scene segmentation, five kinds of standard teaching videos are selected from the school online (<https://www.icourse163.org/>). The total length of the video is 128'19", with 2760 lenses and 98 scenes. The details of the experiment are shown in Table 2.

Recall, Precision, and F were used to evaluate the performance of the algorithm; the calculation formula of them are as follows:

FIGURE 5: Results of model training.

$$\text{Recall} = \frac{n_c}{n_c + n_m} \times 100\% = \frac{n_c}{n_a} \times 100\%,$$

$$\text{Precision} = \frac{n_c}{n_c + n_f} \times 100\% = \frac{n_c}{n_d} \times 100\%, \quad (9)$$

$$F = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \times 100\%,$$

where n_c is the total number of correct detected scenes; n_m is the total number of undetected scenarios; n_f is the total number of scenarios detected by errors; n_a is the total number of actual scenarios; n_d is the total number of detected scenarios. The proposed algorithm is compared with the NW algorithm [13] and STG algorithm [14], and the experimental results are shown in Figures 6 and 7.

From the data in the figure, we can see that the algorithm can construct video scene correctly. Compared with the NW algorithm and STG algorithm, the recall, precision, and F value of our algorithm are greatly improved. This is mainly because modesty only considers the combination of video underlying color features and NW algorithm, and the latter only integrates various visual and audio features in STG, the characteristics of temporal association and symbiosis between multiple modes in video data are not fully considered. We proposed a deep learning framework, where different low-level features from videos are extracted, and semantic concept features are combined with multi-modal semantic embedding space through triple deep network learning to segment videos into coherent scenes, thus effectively reducing the distance between low-level features and high-level semantics. Therefore, the scene segmentation effect achieved by our algorithm is better, and the algorithm is more universal for different types of videos.

4.3. System Testing. The response time of the system refers to the time spent by users when using the system. For the

TABLE 2: The details of the experiment.

Video clip	Duration	Number of lenses	Number of scenes
V1 Discovering business opportunities and establishment of a business	29'13"	390	23
V2 organizational structure & recruiting and training employees	292'21"	436	20
V3 employee motivation and corporate culture	30'06"	587	16
V4 production, product and marketing	27'19"	633	14
V5 financial management and financing	31'47"	714	25
Total	128'19"	2760	98

FIGURE 6: Comparison of scene construction.

FIGURE 7: Comparison of model evaluation.

FIGURE 8: Response time of the system.

system, the response time is the time interval from clicking a page to displaying the page completely in the browser, which is divided into three parts, server response time, network response time, and client response time, respectively. The smaller the response time is, the faster the processing speed of the system is, and the shorter the waiting time of user operation is. Therefore, this paper tests the response time of the system, and the results are shown in Figure 8.

When users get a response between 2 and 5 seconds, the response speed of the system is considered to be good. When users get the response within 5 ~ 8 seconds, the response speed of the system is considered to be very slow, but it is still acceptable. It can be seen from Figure 8 that the peak value of the maximum response time curve of the system is about 3 seconds, indicating that the response time of the platform is very fast. In addition, the peak value of the minimum response time curve is only 1.5 seconds, and the response time of the platform is better. The peak value of the average response time curve of the system is about 2.5 seconds, and the average response time of the system is less than 3 seconds, which meets the actual needs.

5. Conclusion

This paper realizes the characteristic application of EDIPT design thinking and business English in the crossing field. With business English video learning resources as the carrier, a business English learning system is constructed, which solves the problem of learning integration of business English learning groups and opens the exploration mode of design thinking in the field of education. In addition, aiming at the multimodal video scene segmentation algorithm based on a deep network, this paper extracts rich underlying features and semantic concept features from each lens, which realizes fast segmentation of video scene and achieves good experimental results. Moreover, it solves the problem

of the “semantic gap” between video low-level e features and high-level semantics by multimodal feature fusion, making video scene segmentation more accurate and universal. In the following work, we will pay more attention to the functional test of the system, such as taking the form of the questionnaire.

Scientific and objective book quality evaluation and research on the value of books in the smart library are conducive to improving the reading needs of readers. However, it is difficult to obtain the important coefficient of the subjective and objective weight of the personalized information service index of the smart library at present, which has the problem of poor system performance. Therefore, a personalized information service system of the smart library based on multimedia network technology is designed. In multimedia network technology, the data collector module, data retriever module, and data memory module of the system hardware are designed. The Ethernet interface is connected through three buses to ensure the efficient operation of the system; according to the hardware, the software flow is introduced, which is divided into UI layer, logical business layer, and data access layer. On this basis, the application program is designed, all operation instructions follow the association rules, and the single-chip microcomputer is connected with the voice chip through the SPI serial port, so as to complete the design of the personalized information service system of the smart library. The experimental results show that the average absolute deviation of the designed system is small, the comprehensive performance is strong, and the update delay is kept within 0.6 s, which can improve the work efficiency.

1. Introduction

With the continuous development of society in recent years, the smart library, as the “concentration place” of books, is also the best place for readers to acquire knowledge and information in depth [1, 2]. Books make an important contribution to society and people’s acquisition of cultural knowledge and are also an important product of human civilization and development [3, 4]. Titles were there was a substantial growth in recent years, at the same time there were many behind the rapid growth of performance driven by economic interests of hidden trouble, the main performance for the quality of books has plummeted, and similar content in the books published, and follow the repeat publishing phenomenon everywhere so that the books are of variable quality [5]. Due to the continuous development of information and communication technology and the wide application of the Internet, the personalized information service system management of books in smart libraries has

become one of the main themes of the current library management reform and development [6, 7]. In this case, it is necessary to effectively design the personalized information service system in the smart library and establish a complete and scientific book quality evaluation index system in the smart library to identify the book quality in the smart library, so that more excellent books can stand out [8, 9].

Because the design method of the personalized information service system of the smart library has far-reaching development significance, it has also become a hot topic studied by experts and scholars, and has attracted extensive attention. Reference [10] proposes the role of media resource center in bringing novelty and creativity to Nigerian school library services. This article reveals the novelty of the functions of the center, especially in training qualified personnel to serve as librarians, media experts, reading teachers, and other school media personnel in Nigeria’s preschool, primary, and postprimary education institutions, as well as organizing programmes related to children’s

reading and library use in Nigeria. Reference [11] proposes to evaluate the impact of traditional and digital marketing practices on university library services and resources. Determine how digital and traditional marketing methods can raise awareness among users and make better use of library services and resources. Understand the role of library staff in university library marketing practice and technology in digital and traditional ways. Based on quantitative research methods, cross-sectional survey research methods were used for data collection.

Although the above methods have made some progress, the application of multimedia network technology is not particularly sufficient, so the design of the intelligent library personalized information service system is based on multimedia network technology. Multimedia network technology refers to the text-based data communication and the text-based communication technology, including file transfer, e-mail, remote login, network news, and e-commerce. The technology is a comprehensive, interdisciplinary technology. It integrates the computer technology, network technology, communication technology, and a variety of information science technology achievements and has become the world's fastest developing and the most dynamic high-tech. In multimedia network technology, the data collector module, the data retrieval module, and the data storage module of the system hardware are designed, and the Ethernet interface is connected by three buses to ensure the efficient operation of the system. According to the hardware analysis software process, it is divided into UI layer, logical business layer, and data access layer. On this basis, the application program is designed, all operation instructions follow association rules, and the MCU is connected with the voice chip through the SPI serial port, thus the personalized information service system of the smart library is designed. The application in the personalized information service system of the intelligent library has remarkable effects, and the designed system has high performance.

2. Personalized Information Service System of Smart Library under Multimedia Network Technology

In multimedia network technology, the data collector module, data retrieval module, and data memory module of the system hardware are mainly designed, and the Ethernet interface is connected through three buses to ensure the efficient operation of the system; according to the hardware, the software process is introduced, which is divided into UI layer, logic business layer, and data access layer; on this basis, the application program is designed, all operation instructions follow the association rules, and the single-chip microcomputer and the voice chip are connected through the SPI serial port, thus completing the design of the personalized information service system of the smart library.

2.1. Hardware Design of the Personalized Information Service System of Smart Library. The basic components of multimedia network technology are: CD-ROM with optical drive,

which is an important symbol of multimedia network technology system; It has the functions of A/D analog-to-digital conversion and D/A digital analog conversion, which can convert the analog signal and digital signal of voice to each other, so that the multimedia network technology has high-quality digital voice function; display with high definition [12, 13]. Under the multimedia network technology, the establishment of the personalized information service system of the smart library is the basis to ensure better service of resources. It can truly provide resources according to users' needs and enable users to obtain the richest resources, if allowed [14, 15]. The hardware function of the designed intelligent library personalized information service system is to use the client to feed back the data resources that customers need to retrieve and use the data collector module to collect library resources, and the data integrator will integrate and process the collected resources. The data searcher module will check and search the integrated data resources and finally feedback to the user by the data memory module [16]. The hardware structure of the personalized information service system of the smart library is shown in Figure 1.

The system hardware in Figure 1 applies multimedia network technology to share the resources of Smart Library. The system hardware adds a large number of embedded products to support various cloud classroom systems, improve teaching quality, and ensure students' learning efficiency [17].

2.1.1. Data Collector Module. The personalized information service system of the smart library designed in this paper can realize high-quality positioning collection, and compress the collected audio and video to meet the low-power requirements of the system [18, 19]. The internal chip of the collector is the GD32F103RCT6 chip, which was launched by Shenzhen Zhuocun Electronic Technology Co., Ltd. and has the characteristics of multifunctional multimedia application, which is convenient for collection, compression, and transportation [20, 21]. The GD32F103RCT6 chip consumes very low power. Generally, the chip can maintain normal acquisition work above 5V voltage. The acquisition speed under low voltage can also reach 10000 MIPS, and the acquisition speed under high voltage is higher [22, 23]. The acquisition capability fully meets the acquisition requirements of large-scale library digital resources, and the acquisition accuracy is much higher than that of other chips, with an accuracy of 10 bits or even more [24]. The power supply mode of the data collector module is dual power supply of internal and external interfaces, and the internal interface is connected to the external interface to ensure the continuous input of voltage [25]. The collector is automatically connected to the wireless network. After signal coding and synthesis, it is transmitted to the wireless network data terminal, stored in the terminal, and recorded on the hard disk. The collector structure is shown in Figure 2.

When collecting video signals, the collector in Figure 2 selects SCLK as the clock to record all signals, and the input video is one video. When collecting GPS signals, data

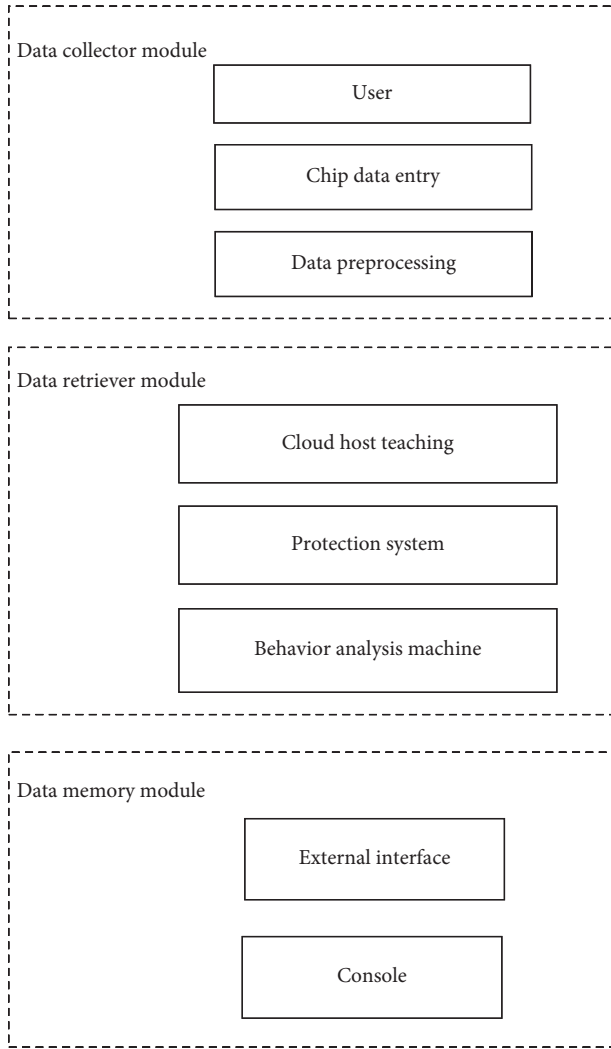

FIGURE 1: Hardware structure of the personalized information service system of smart library.

FIGURE 2: Collector structure.

transmission signals, RX data reception signals, and asynchronous signal interfaces are used as power interfaces, and the maximum baud rate supported is 2.56 Mbyte/s. When collecting, it is necessary to connect and receive personalized information service system signals. The positioning accuracy of GPS signals is very strong, and the error rate is less than 4 m, which can locate high-speed mobile signals [26, 27]. The signal collector is connected by PCI and HPI, and the bus interface is an Ethernet interface. The transceiver can send and receive 10 M~100 M personalized information service

data. In order to realize the simultaneous transmission of service data network, a wireless module is added in the system.

2.1.2. Data Retriever Module. The data searcher module is the core part of the hardware of the personalized information service system of the whole Smart Library. The searcher adopts the high-precision BAM6 chip developed by TRM Company in Norway. TRM fully analyzed the shortcomings and advantages of the previous two generations of BAM5 and BAM4 when developing the BAM6 chip. Therefore, this chip is significantly better than the previous two generations of chips in working time and retrieval efficiency [28]. The working delay time of the BAM6 chip is very short, only 10 minutes μ s. The rapid mode is used to control the retrieval speed, so the speed is very high. There are many retrieval interfaces inside. When the searcher runs, the interfaces will be connected together and work at the same time, which greatly reduces the working time, strengthens the retrieval ability, and retrieves more library digital resources [29]. The BAM6 chip requires the working voltage to be above 20 V and the data packet length of the chip is 45 B. It works under the multimedia network technology and the data retrieval rate is 80 Mb/s. However, in the low-voltage state, the chip will enter the automatic sleep mode and cannot start working.

2.1.3. Data Memory Module. In order to improve the storage efficiency of the hardware memory of the personalized information service system of the smart library, a flash memory with large storage range and low manufacturing cost is selected. A single-chip microcomputer is added to the memory to increase the storage capacity and reduce the floor area. The memory structure is shown in Figure 3.

There are three buses outside the memory, each bus is connected with an Ethernet interface, and different interfaces are connected with different signals [30]. The three wire buses are as follows:

Bus 1: connect signals in I/O mode, input and output in two-way way, and realize two-way exchange of data. The remark mode is I/O.

Bus 2: connect the signal in OUT mode, output the signal in one-way, and control the signal to enter.

Bus 3: connect the signal in BUSY mode, and the input mode is busy signal input.

2.2. Software Design of the Personalized Information Service System of Smart Library. In order to realize the software design of the intelligent library personalized information service system and complete the data receiving and processing, it communicates with the system terminal host computer through the wireless sensor network RS232 serial communication protocol of multimedia network technology. The gateway of the intelligent library personalized information service system uses socket process communication combined with a multithreading

FIGURE 3: Memory structure.

mechanism to complete the communication with the intelligent library personalized information service system terminal host computer [31]. The software structure of the personalized information service system of the smart library is shown in Figure 4.

As shown in Figure 4, the specific contents of the system software are as follows:

- (1) The UI layer of the intelligent library personalized information service system based on multimedia network technology, that is, the user interface of the intelligent library personalized information service system, is mainly used to realize the organic interaction between the intelligent library personalized information service system and readers, including the design of book borrowing, return, query interaction, reader information management, user interface attribute configuration, and so on. The UI layer is connected with the logical business layer (UI layer service providing layer). The UI layer of the intelligent library personalized information service system based on multimedia network technology designed in this paper includes two parts: RFID tag reading and writing component and user page component using the ISO/IEC14443 protocol. The RFID tag reading and writing component using the ISO/IEC14443 protocol is essentially the interface part between the PC and the RFID RF terminal to realize the data reading and writing function of the RFID RF terminal. The design of UI layer interface components mainly includes the book borrowing management module, reader information management module, book ID information management module, and system parameter attribute setting [32].
- (2) The logical business layer of the intelligent library personalized information service system based on multimedia network technology: the main function is all logical operation and processing of readers and managers.
- (3) Data access layer of the intelligent library personalized information service system based on multimedia network technology: it provides services for all

logical operation and processing processes of readers and managers, and is mainly responsible for data access of the intelligent library personalized information service system database.

2.3. Application Design. The personalized information service system of the smart library connects the single-chip microcomputer with the voice chip through an SPI serial port, and all operation instructions must follow the association rules [33, 34]. All serial data transmission must be kept at a low level, and a high level should be used between two instructions. In order to ensure system security, a user authentication stage should be added in the process of application programming, and the system reminder function can be realized only through authorization.

In the implementation process, the layer-by-layer search iterative method is used to control the reminder function by calculating the confidence of association rules. The specific calculation contents are as follows:

$$D_{abc} = A_a \times B_b \times C_c. \quad (1)$$

In formula (1), A_a represents the total amount of all data in the personalized information service data item set, B_b represents the total amount of all data in the item set contained in the smart library database, and C_c represents the total amount of support corresponding to each subservers.

In the application structure, the storage and playback of reminder instructions are controlled by pressing the key to realize the reminder function. Therefore, the elimination of key jitter and key response are introduced [35, 36]. The key jitter time is determined by the equipment performance. The software delay is used to detect whether the key is really pressed, which effectively avoids the key jitter time.

In order to reduce the error, set F to represent the end value of the counter, so as to obtain the key cycle as follows:

$$Y_H = (F - C_s) \times T_z. \quad (2)$$

In formula (2), C_s represents the initial value of counting and T_z represents the clock cycle of a single-chip microcomputer. According to the key cycle shown in formula (2), the reminder time can be accurately mastered to avoid the delay problem of traditional system reminder.

When the system is started, the relevant reminder information is displayed on the display screen, and the pre-stored information is selected through the relevant keys of the keyboard. Under the multimedia network technology, the reminder instruction can be issued through the single-chip microcomputer controller of the hardware module to complete the design of the application program of the personalized information service system of the smart library.

3. Experimental Study

In order to test the actual working effect of the personalized information service system of the smart library based on multimedia network technology, an experiment is designed. The experimental environment is Intel(R) Pentium(R) 4, the

FIGURE 4: Software design of the personalized information service system of smart library.

CPU is 2.40 GHz, the memory is 1024 MB, and the operating system is Microsoft Windows XP SP3. Other experimental parameters are shown in Table 1.

According to the contents of Table 1, this paper uses the system in this paper, the system in reference [10] and the system in reference [11], respectively, to carry out the comparative experiment of intelligent library personalized information service system design. Three different methods are used to compare the accuracy of the personalized information service of the smart library. The average value of absolute deviation P_{JC} is used as the evaluation index of the accuracy of the personalized information service system. The average value of absolute deviation, i.e. the average deviation, refers to the average value of the absolute deviation of each measured value. The smaller the value, the better the effect of the personalized information service of the smart library. The calculation method is shown in

$$P_{JC} = \frac{\sum_{i \in S} |U_i - W_i|}{|S|} \quad (3)$$

In formula (3), $|S|$ represents the book quality evaluation data set, U_i represents the actual scoring value of readers on item i Book personalized information service scheme in the book quality evaluation data set, and W_i represents the predicted scoring value of readers on item i scheme given by the book personalized information service system. Compare the average absolute deviation (%) of three different methods for personalized information service of the smart library, and the results are shown in Figure 5.

Through the analysis of Figure 5, it can be seen that the average absolute deviation of the personalized information service of the smart library using the system in this paper is lower than that of reference [10] system and reference [11] system. This is mainly because in the process of designing the personalized information service system of the smart library using the system in this paper, high-quality positioning acquisition can be realized, and the collected audio and video can be compressed. Get the important coefficient of subjective and objective weight of each evaluation index of the personalized information service in the smart library, so that the average absolute error of the personalized information service in the smart library using this system is low.

In order to further verify the effectiveness of the designed system, it is necessary to comprehensively analyze the effects of different performance of the system, and compare and analyze the storage performance, operation difficulty coefficient, expansion performance, security performance, and integration performance, respectively. The comparison results are shown in Table 2.

It can be seen from Table 2 that the storage performance of the system in this paper is good, the operation difficulty coefficient is small, the expansion performance and security performance are good, and it has the ability of data sharing and integration at the same time. While the storage performance of reference [10] system is general, the operation difficulty coefficient is large, the expansion performance is good, but the security performance is poor, it does not have data sharing, and the integration ability is also poor. Reference [11] system has general storage performance, large

TABLE 1: Experimental parameter setting table.

Serial number	Entry name	Parameter content
1	Transmission signal	Audio signal, video signal, and GPS signal
2	Data line distance	1500 m
3	Input interface	TUB interface
4	Output interface	VUTR interface
5	Resolving power	One hundred and sixty \times 128 dpi
6	Operating hours	Usually 24 h
7	Power consumption	<1 W

FIGURE 5: Comparison results of average absolute deviation of personalized information service of smart library under different methods.

operation difficulty coefficient, and poor expansion performance, but it has good security, data sharing, and general integration ability. Based on the traditional system, the designed system improves the storage performance of the system to make the storage performance of the designed system better.

Continue to explore the effects of the personalized information service system of the smart library based on multimedia network technology. The working frequency of the system is detected every 60 s, and there is no waiting time when readers query relevant book information. The time difference between the actual database update frequency and the corresponding book information update frequency of the designed system is defined as the update delay (s). The comparison results are shown in Figure 6.

According to Figure 6, compared with reference [10] system and reference [11] system, the book information refresh frequency of the personalized information service system of the smart library based on multimedia network technology designed in this paper can meet the practical requirements of the smart library. The system update delay is kept within 0.6 s, which can effectively realize multiple links such as on-board book inventory, return to the shelf, and query circulation, and greatly improve the work efficiency of the system.

To sum up, the designed system has good performance and realizes the intelligent inventory function and personalized service of personalized information service of the University Smart Library. With the help of the application of the personalized information service system of the University Smart Library, the work progress of the library and the work efficiency of librarians are greatly improved, which can better serve readers.

4. Discussion and Analysis

In terms of multimedia network technology, aiming at the development of personalized information service of the smart library, the countermeasures are as follows:

4.1. Improving the Management Mechanism of Personalized Information Service. Due to the lack of a macro-control mechanism in China's libraries, in order to coordinate and develop libraries and realize the common knowledge and sharing of information resources, China's higher education document guarantee system has been established. Strengthen the cooperation between the system and its member museums, improve the service level of higher education, and give full play to the maximum social and economic benefits. Strengthening the service consciousness and management means alone cannot meet the requirements of improving the service quality of the library. The cooperation between departments, the adjustment of structure, and the unification of the evaluation system are indispensable. Master the information needs of users, track and evaluate the service quality, pay attention to the feedback of user satisfaction, adopt incentive mechanism to stimulate the initiative of service personnel, and provide users with comprehensive and high-quality personalized information services. To develop the library personalized information service, the improvement of library personalized information service mechanism plays a very important role in the development of the smart library.

4.2. Strengthening the Construction of Information Service Resources

4.2.1. Strengthening the Content Construction of Information Resources. Establish a professional navigation database and a characteristic database. In order to cope with the rapid expansion and disorder of network information resources, the smart library should collect, sort, and classify the

TABLE 2: Comparison of different performance of different platforms.

Performance	Paper system	Reference [10] system	Reference [11] system
Storage performance	Preferably	Commonly	Commonly
Operation difficulty coefficient	Less	More	More
Extended performance	Preferably	Good	Poor
Safety performance	Preferably	Difference	Preferably
Data sharing	Have	No	Have
Integration performance	Preferably	Poor	Commonly

FIGURE 6: Book information update delay of the personalized information service system of smart library.

network information resources according to the specialty according to the characteristics of teachers and students, for the purpose of meeting users' learning and scientific research, highlight the professionalism of subject navigation, and establish professional navigation links. For the construction of information resources, the smart library is based on the careful investigation of databases at home and abroad. According to the professional setting of the university, the focus of scientific research and the information needs of users, combined with the library's collection resources, the smart library establishes a characteristic database according to a certain discipline, specialty, or local characteristics.

4.2.2. Strengthening the Organization and Integration of Information Resources. Resource integration and service integration are the main contents of information resource integration. Resource integration refers to the integrated information system formed by classifying and sorting the existing information resources. Service integration needs to build a personal information database, which includes the basic information of users and feedback information of users on services. Compared with traditional information services, in the organization of information resources, the new requirements of personalized information services are: the content should be targeted, clear, easy to understand, open, and flexible; in the navigation system, the classification should be detailed and reasonable; the user interface should be friendly; the evaluation ability and information navigation should be strong; and the cross-platform seamless

connection of information resource content should be realized. The library needs to sort out and classify the discrete electronic resources and establish a professional navigation database with a friendly interface, powerful functions, and comprehensive according to the needs of users.

4.2.3. Strengthening the Co-Construction and Sharing of Information Resources. In the school, each department will establish its own library reference room according to its own situation, which overlaps with the resource construction of the library, resulting in a low utilization rate and a waste of material and human resources. Therefore, strengthening the cooperation between reference room and library and jointly building and sharing information resources in the school is the main measure of information co-construction and sharing. Smart libraries can give full play to their respective advantages of document resources, which not only avoids the repeated construction of resources but also enriches the acquisition of users' information resources.

4.3. Changing the Service Concept and Improving the Quality of Service Personnel. The establishment of a humanistic care service concept of "people-oriented, user-first" is very beneficial to the active and effective development of personalized information services in the library. "People-oriented and service-oriented" refers to putting the needs of users in the first place, taking the completion of this goal as the fundamental purpose of the work, all for the sake of users and convenience, and providing users with maximized and optimized services. To meet the service needs of users, service personnel should have strong information analysis ability and language ability to answer various questions for users; we should broaden the scope of knowledge and strengthen learning, especially the relevant knowledge of library and information; master skilled information skills; be able to analyze, integrate, and summarize information; and master the sources and retrieval methods of various types of information. Only with these can service personnel improve the service level and provide users with obvious personalized information services. "Subject Librarian" is a kind of special personalized information service talent arising from the problems of low technical level, single knowledge, and poor information analysis ability of library service personnel. Subject librarian refers to the person that the library sets up to establish contact with a certain department or discipline specialty as the counterpart unit, build a bridge between the department, discipline specialty, and the library, communicate with each other, and actively collect and provide

document information services for users. This kind of service personnel needs to have a certain level of foreign language, be familiar with library business, be skilled in computer operation, have high educational background and professional title, profound cultural heritage and strong language ability, and be able to provide powerful help for teaching and scientific research.

4.4. Strengthening the Construction of Personalized Information Service Systems. To develop a personalized information service system, the library should have both rich system resources and rich system functions, and be able to provide comprehensive services. The designed system interface should be concise, intuitive, and clear-cut, and users should be able to make personalized customizations; it should be able to realize automatic integration with other resource systems, which not only saves users' time but also reduces users' use burden; and can protect user privacy. The measures to improve the personalized information service include the following: establishing a professional navigation system, building an effective information space, systematically organizing relevant information resources, providing users with a good retrieval interface, information customization, and information push. The system can provide users with selection services. Users can also select and manage information to realize their interactive functions. The problems encountered in use can be solved in time to improve the service quality.

To sum up, under the multimedia network technology, the smart library will encounter many problems in the process of building personalized information services. The smart library needs to improve its personalized service management mechanism, strengthen the construction of information resources, strengthen the construction of personalized information service system, and strengthen the research and training of user needs. While changing the service concept, library service personnel should also pay attention to the improvement of their own quality, improve the service quality, and make the library's personalized information service develop continuously.

5. Conclusions and Prospects

5.1. Conclusions

- (1) The average absolute deviation of the intelligent library personalized information service system based on multimedia network technology is lower than that of the reference system, which has a good effect. It can realize high-quality location collection and get the important coefficient of subjective and objective weight of each evaluation index of personalized information service a in smart library.
- (2) The system in this paper has good storage performance, low operation difficulty coefficient, good expansion performance, and security performance, as well as data sharing and integration ability.
- (3) The book information refresh frequency of the personalized information service system designed in this paper can meet the practical requirements of the smart library, and the system update delay is kept within 0.6 s, which effectively improves the working efficiency of the system. With the application of the personalized information service system of the university intelligent library, the progress of library work and the work efficiency of librarians have been greatly improved, and it can serve readers better.

5.2. Prospects. The personalized information service system of the smart library realizes the unattended of the library, uses the accurate positioning of multimedia network technology and the realization of self-help borrowing and returning books, reduces the labor intensity of the staff, and enables them to devote more energy to scientific research. However, in order to serve college teachers and students more perfectly, there are still a lot of problems to be solved in order to explore a more intelligent, personalized information service mode.

The further development of the personalized information service system of the smart library can use the mobile device library platform for subsequent docking on the basis of this information service system and realize a more efficient and intelligent library information service system through the construction of the mobile platform. For example, it can realize that the mobile device can receive an update of all library information, the system can automatically urge the return of books, etc. Interlibrary communication and information sharing can be achieved by relying on the mobile platform to improve the quality of interlibrary communication and information sharing. Relying on the advantages of multimedia network technology, we can popularize the installation and popularization scope of book borrowing and returning terminals, open library resources, break the constraints of time and space, and realize the possibility of systematic remote management and real-time circulation of books through the push of terminal points, so as to improve the circulation times in the book cycle.

The development of technology and the popularization of networks promote the development of library cause. In multimedia network technology, the personalized information service of the Smart Library continues to develop and progress with various changes. The specific contents are as follows:

- (1) Under the network environment, the information service of smart library is gradually open to the society from the closed state that only faces the teachers and students of the University. Each smart library will no longer "act in its own way," but build a network information platform and share information resources through networking.
- (2) The smart library is constantly changing its service mode due to the change of users' needs, changing from the traditional passive service mode to an active service, actively understanding the new trends of users, and adjusting the service content in time.

- (3) The service personnel of smart library are aware of the shortcomings of the traditional service concept, actively change their own service concept, and gradually establish a new concept of “people-oriented, user-first.”
- (4) The knowledge cultivation and ability of service personnel in Smart Library are constantly improving to adapt to the continuous development of personalized information service. In particular, the establishment of “Subject Librarian” is a prominent embodiment of talent training in personalized information service.
- (5) The strengthening of the awareness of training users by the smart library enables more users to master the ways and means of obtaining information and master the retrieval skills and tools, which is conducive to users to make better use of various resources in the library and improve the utilization rate of library information resources.

It is a challenge for the current music teaching system to carry out teaching according to the difference of score difficulty and realize automatic grading. Therefore, identifying the difficulty of music score according to pitch is the key to individualize music teaching resources. This paper summarizes and analyzes the problem of pitch feature extraction in music teaching. In the pitch extraction, the audio signal is divided into frames, and the feature matching of high-pitched content in music teaching resources is realized by smoothing the pitch sequence. In addition, the pitch feature extraction algorithm in MIDI music score files is proposed, and the pitch feature matching model is constructed. Finally, a music tutoring system based on pitch feature matching is designed, including a music score learning tool, overall structure of system, and interaction between teachers and students. Tutoring strategies include three main functions: learning suggestions of knowledge points, skills in practice and training, and learning path adjustment. This study is helpful to further improve the music teaching model and realize intelligent and personalized music learning.

1. Introduction

With the rise of Internet teaching, the limitations of traditional teaching methods in time and space have been solved, and virtual teaching scenes and resources have been built by the network-based teaching platform, which makes the teaching behavior no longer confined to classrooms and classrooms. An intelligent learning guidance system uses artificial intelligence technology to simulate and learn the teaching methods of human teachers and furnishes them with customized learning ways and learning ideas as per the requirements of various students. In the educational experience, we can find out about their learning propensities and inclinations through language correspondence, conduct investigation, recreation, and so on and dynamically guide learners to master knowledge [1, 2]. In recent years, artificial intelligence (AI) technology has greatly promoted the development of intelligent tutoring system, formed a standardized structural framework, and produced many excellent products in computer foundation, language, medicine, mathematics, and other disciplines [3–5].

Musical Solfeggio is a course based on mastering the basic principles of music, which aims at cultivating students' abilities of reading music, singing music, memorizing music scores, recognizing music scores, and perceiving, analyzing, expressing, and imagining music. With the continuous development of the music education system, the teaching concepts of sight, singing, practice, and listening are constantly innovated. However, teaching and training in the classroom has been adopted for many years, which is not only wasteful, yet in addition, incredibly influences understudies' advantage in learning. Albeit increasingly more sight and sound apparatuses and showing programming are utilized in the study hall of solfeggio educating, they can help instructing, while the current internet-based courses and Internet learning stages just gives rich learning assets and different learning ways for students, and it can not meet the demand of intelligent teaching [6]. At the same time, the evaluation of students' ability and achievement is still done by teachers or experts, and the current scoring method can only evaluate the difference between singing performance and standard template. However, in the process of music

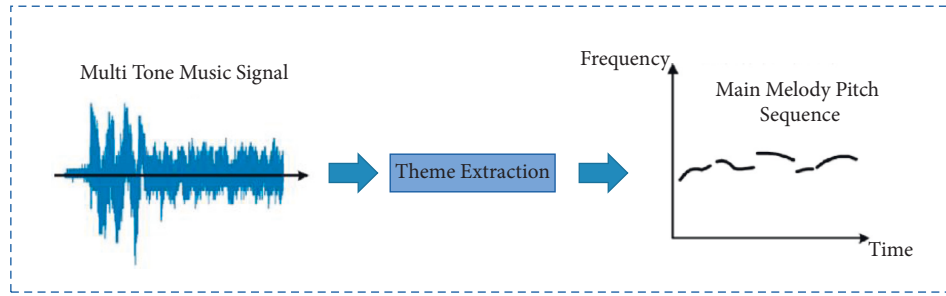

FIGURE 1: Pitch feature extraction process.

teaching, different music has different difficulty in singing, so there is a big error in the evaluation method that only considers the difference between template and performance [7]. In addition, the same problem as learning resources is that there is no uniform standard for the classification of music score difficulty level, and it depends on the subjective judgment of experts. In the evaluation of music teaching, the questions can only come from expert question banks or textbooks, while the individual inclination and expert level will influence the equilibrium of the trouble about the inquiries, which can not ensure the decency, exactness, and objectivity of the assessment [8, 9]. Therefore, it is also a challenge for the solfeggio teaching system to achieve automatic scoring according to the differences in score difficulty.

Therefore, this paper combines the characteristics of music, matches the characteristics of pitched content in music teaching resources, and designs an intelligent music tutorial system, which is helpful to further improve the music teaching model and realize intelligent and personalized music learning.

2. Research Basis of Pitch Feature Matching

2.1. Description of Pitch Features. Pitch is one of the most familiar note attributes, and intuitive understanding is the height of the note; as described in the previous chapter, the sound is composed of fundamental tone and overtone, and the part that determines the pitch of the sound is the fundamental tone. Physically, the vibration frequency, that is, Hertz, is used to describe the pitch of the sound. The pitch range recognized by human ears is about 20 to 20,000 Hz. Generally speaking, when people describe sounds, the higher the frequency, the higher the tone, which can be said to be a positive correlation [10].

According to the frequency, music can be divided into different pitches. The most commonly used method is the twelve-average law method, which divides an octave into twelve parts on average by a certain mathematical method of raising the power, which can improve the true performance of music and make the pitch reasonably distributed. In addition, the notation can be divided into numerical notation and alphabetic notation according to the different forms of notation symbols. The numeral notation uses numbers to indicate the pitch, and the short line under the numbers indicates the sound value, that is, the duration of notes; digital notation has the advantages of convenient

presentation and low learning difficulty. By using the law of twelve averages to divide the pitch, an octave can be divided into twelve points, each of which is called a semitone; similarly, an octave can be divided into six whole tones by the law of twelve averages.

2.2. Analysis of Pitch Feature Extraction. The research object of main melody extraction is polyphonic music composed of voice and one or more musical instruments. As shown in Figure 1, the target of main melody extraction is to extract the vocal pitch sequence defined as the main melody from such mixed audio signals.

Because the singing and accompanying note components have rich harmonic information, the harmonic characteristics of music signals can be fully utilized in the pitch estimation stage. When judging the pitch fundamental frequency, only the energy information of the fundamental frequency and its harmonic components plays a positive role, and other frequency energies are equivalent to noise here, which will interfere with the main melody extraction. However, due to the existence of harmonic characteristics, octave errors often appear in the main melody extraction results [11]. An octave error means that when the pitch is estimated, the pitch is mistakenly identified as one or more octaves different from the correct pitch, which makes it easy for people with healthy hearing to identify singing information from complex multisource music signals without being influenced by other accompaniments. However, it is extremely difficult to extract the main melody by computer, as shown in Figure 2, which is mainly caused by the following factors:

- (1) Multitone music signals are composed of the superposition of sound waveforms produced by all instruments in the recording. Many times these instruments are played at the same time. It is extremely difficult to separate the corresponding notes from different sound sources according to the frequency spectrum which is highly coupled and superimposed with the sound structure, and the later reverberation, echo, and other treatments will further increase the overlap of sound sources. Blurring the start and end time of the music signal makes spectrum separation more difficult.
- (2) Even if the fundamental frequency sequence of notes has been obtained, it is still necessary to judge which

FIGURE 2: Problem analysis of pitch feature extraction.

pitches belong to melody and which belong to accompaniment. When the melody is singing but there is background harmony, it is more difficult to detect.

- (3) Because of the existence of harmonic structure, it is easy to produce octave errors.

For the existing methods, most methods based on pitch saliency have an unavoidable problem, that is, due to the harmonic characteristics of music signals, the algorithm can easily output the fundamental frequency of an octave before and after the correct melody pitch, resulting in octave errors. While the method based on source separation is more dependent on singing energy, for strong accompaniment, it is difficult for the model to correctly separate melody and accompaniment.

Therefore, this paper combines the characteristics of music and matches the characteristics of high-pitched content in music teaching resources based on the deep learning.

3. Pitch Feature Matching Based on Deep Learning

3.1. Deep Learning Theory. The purpose of deep learning is to establish a learning model similar to a brain neural network, which is a branch of machine learning. For machine learning algorithms, there are only one or two nonlinear feature structures. However, on complex problems, such as speech signal and image processing, these shallow structures have their limitations, while deep learning builds deep nonlinear structures, which can express richer information [12, 13]. In this paper, a fully connected layer neural network is adopted, as shown in Figure 3, it is a feedforward neural network with two hidden layers.

In order to make the network learn nonlinear characteristics and increase the complexity of the model, there is usually a nonlinear activation function between each layer this paper adopts the LRelu function, as shown in formula (1), which is a variant of ReLu.

$$\text{LRelu}(x) = \begin{cases} x, & x \geq 0, \\ 0.01x, & x < 0. \end{cases} \quad (1)$$

FIGURE 3: Fully connected neural network model.

The main melody extraction in this paper is actually the task of classifying pitches. In a neural network, for binary logistic regression, the output layer can be activated by sigmoid, and the real number field can be mapped to $0 \sim 1$ Range, this is the output probability of normal class. For multiclassification problems, the output layer can be activated by softmax, and its formula is as follows:

$$S_i = \frac{e^{z_i}}{\sum_{n=1}^N e^{z_n}}. \quad (2)$$

The training process of the neural network is a process of gradient iterative updating. Usually, the gradient descent method is used to find the optimal solution of the objective function, which makes the loss function smaller and smaller and makes the model learn the information of deep features from a large amount of data.

3.2. Feature Extraction Algorithm. In this study, the evaluation of music is based on the MIDI music score file, while MIDI uses pitch value and duration to describe notes in a music score, so it is necessary to extract pitch features and duration of solfeggio audio. The feature vector of music is usually obtained by the main melody, and MIDI files usually include multi-track accompaniment. It is very important to extract the main melody that can represent complete music information from a multitrack MIDI melody, whose extraction steps are shown in Figure 4.

3.2.1. Build Feature Vectors. Each note in the main melody corresponds to a characteristic point, which is described as follows:

$$v = \langle \text{Pitch}, \text{Time} \rangle, \quad (3)$$

where Pitch is the value of pitch, and the note value is derived from $0 \sim 127$; Time is the improvement of MIDI time, which represents the information of duration. The feature quantity corresponding to the main melody note sequence can be expressed as follows:

$$V = \{v_1, v_2, \dots, v_n\}. \quad (4)$$

FIGURE 4: Steps of music feature extraction.

Among them, V is the sequence of note characteristic points of the whole music, n is the total number of notes.

Considering that there are phrases in music, the above vector can be further expressed as follows:

$$V = \{P_1, P_2, \dots, P_k\}. \quad (5)$$

Among them, V is the sequence of note characteristic points of the whole music, k is the total number of phrases.

$$P_i = \{v_{i1}, v_{i2}, \dots, v_{in}\}. \quad (6)$$

This feature vector can well express the melody and rhythm of the music.

3.2.2. Extraction of Pitch Pitch. The notes in each MIDI track are determined by two MIDI events: note on and note off. MIDI message: XX NN KK.XX represents the status byte, which determines 8 MIDI commands and 16 MIDI channels. The commonly used MIDI command 9x (X represents channel number) indicates that the note is on, and the data byte NN immediately following represents the pitch symbol (pitch), with a value of 1–127, and two consecutive notes are opened; the second note can be omitted to open the command 8x means off. KK means the key and release force (vel) value is 0~127. Command 9x followed by the key strength KK is 0, equivalent to note off. The Polyphony of music determines the simultaneous pronunciation of notes. In this paper, the value of the highest pitch note is selected according to the skyline algorithm, and the values of the remaining simultaneous notes are deleted.

According to the skyline algorithm, the notes with smaller pitch value can be removed and a MIDI event sequence can be obtained. The pitch stored in the MIDI file is expressed in hexadecimal. According to the MIDI note coding table, it is converted to a decimal system, and each value corresponds to the corresponding note. The pitch of a note is represented by the semitone value; the semitone and pitch frequency have the corresponding relationship expressed by the following formula:

$$\text{Pitch} = 69 + 12 * \log_2 \frac{f_0}{144}, \quad (7)$$

where 69 is the corresponding half-tone value of international standard A, f_0 represents the pitch frequency, and 144 is the frequency difference between two semitones.

3.2.3. Pitch Feature Matching. Assuming that each singer's goal is to sing the score accurately, the breaks should not last long and should be followed by a steady sub-sequence of pitches. In the pitch extraction, the audio signal is framed, and the pitch sequence obtained is also frame based. The breakpoint usually appears in the middle of two stationary signals, which only lasted 1–2 frames. Therefore, as shown in Figure 5, we can smooth the pitch sequence as follows:

- (1) The adjacent frames with equal pitch values in pitch sequence are regarded as a subsequence, and the number of frames is counted
- (2) After traversing the frame number of each pitch subsequence, the break point can be found where the frame number is between 1 and 2, and the pitch frame number before and after it is greater than 2
- (3) The pitch value corresponding to the breakpoint is set as the average pitch of the subsequences before and after the breakpoint
- (4) Median filter is used to optimize the pitch sequence

Assuming that the pitch sequences of the matching and template are respectively X and Y , where p represents pitch, t represents the number of frames, k is the number of subsequences with a continuous equal pitch in the sequence to be matched, and v is the number of notes in the template.

$$\begin{aligned} X & ((p_1, t_1), (p_2, t_2), (p_3, t_3), \dots, (p_k, t_k)), \\ Y & ((p_1, t_1), (p_2, t_2), (p_3, t_3), \dots, (p_v, t_v)). \end{aligned} \quad (8)$$

Replace frame matching with subsequence matching, then the calculation formula of distance is

FIGURE 5: Steps of pitch sequence smoothing.

$$\text{dist}(x_i, y_j) = \sqrt{(p_i \cdot t_i - p_j \cdot t_j)^2}. \quad (9)$$

The formula of pitch path matching is as follows:

$$w(x_i, y_j) = m \left(\begin{array}{l} w(x_{i-1}, y_j) + \text{dist}(x_{i-1}, y_j) \\ w(x_{i-1}, y_{j-1}) + \text{dist}(x_{i-1}, y_{j-1}) \end{array} \right). \quad (10)$$

4. Design of Music Tutorial System Based on Pitch Feature Matching

4.1. Input of Musical Score. This research will be applied as a learning tool, to achieve the function by expanding the components, the following part mainly introduces the spectrum component that is difficult to realize. Considering that only the notes appearing in the music score need to be input in solfeggio practice, in order to reduce the difficulty of input and improve the fluency, there are two input methods in this paper.

4.1.1. Selective Input. Selective input means that the notes contained in the music score are provided in the input interface. After the user selects the input position, the system pops up the note selection interface, and the corresponding notes can be written into the staff and displayed.

4.1.2. Input by MIDI Symbol. In the MIDI standard, the pitch and duration of notes are respectively expressed by numerical values, in which the pitch value corresponds to the keys of a piano, and the pitch within each 8 degree is, respectively, expressed by 12 numerical values according to the 12-tone law. Because the range of voices that people can sing is limited, only 0–8 sound zones are provided, and the duration of notes is set by the time slider.

4.2. Overall Structure of the System. The music learning tutoring system includes a storage layer, strategy layer, and interaction layer. The storage layer is responsible for providing the databases needed by the system operation, including learner model base, knowledge model base, and learning resource base. The strategy layer is used for systematic decision-making and data analysis, it carries out personalized services such as learning resource push, resource management, intelligent learning guidance, learning effect statistics, and ability evaluation, with the data support of the strategy layer. And, then it analyzes students' learning process in real time, so as to dynamically construct and update their learning models; the interaction layer is the man-machine interface of the system, including system management, evaluation results display, learning progress display, ability level visualization, and interaction of learning process. The overall structure of the system is shown in Figure 6.

The interaction layer only directly accesses the storage layer to obtain data during data retrieval, and other interactions need to analyze the requirements through the strategy layer and then return the results to the interaction layer after making a decision.

4.2.1. Storage Layer. Learner model base: learner model base stores data of the learner model, including basic information of learners, solfeggio ability level, knowledge mastery, and learning history. Which provides the decision-making layer with the raw data needed for learning and analysis.

Knowledge model base: the knowledge model base is based on the knowledge model of solfeggio, including the main basic knowledge entities, solfeggio knowledge entities, and music knowledge entities.

Learning Resource Library: the resource library stores the examples, practice scores, and training scores needed in the learning process and establishes an index table according to the structure defined in the resource model, which facilitates the sorting and retrieval of resources.

4.2.2. Strategy Level. Ability evaluation: ability evaluation consists of two parts: evaluation strategy and evaluation algorithm. The evaluation strategy is the solfeggio scoring index and ability level calculation method, and the evaluation algorithm is a solfeggio scoring algorithm based on pitch characteristics proposed in Chapter 3. This module is responsible for evaluating learners' performance in exercises and tests, then dynamically update the data of the submodel of ability level and knowledge mastery in the learner model.

Learning tutor strategy: learning tutor strategy includes three main functions: learning suggestions of knowledge points, skills in practice and training, and learning path adjustment. The learning suggestions of knowledge points come from the attribute fields in the knowledge model; skill information is used to make the analysis of the difficulties and error-prone points contained in the current learning resources and then gives learning suggestions in combination with specific teaching methods; learning path adjustment refers to the degree of difficulty of adjusting learning

FIGURE 6: Overall structure of music tutorial system.

FIGURE 7: Learner interface.

resources after dynamically analyzing learners' learning effects. For example, when learners learn a certain knowledge well for many times, the system will adjust the difficulty coefficient of the next learning resource recommendation.

Resource management: resource management consists of two main functions: resource import and resource sorting.

Resource import is to provide learners with the function of customizing external resource import and online resource download; resource collation is to analyze the knowledge points and extract the difficulty features of the own resources or the resources imported by users, and it is also responsible for checking the validity of resource files.

Model construction: model construction mainly includes the learner model, the rules of knowledge point model construction, and the rules editing interface. Among them, rule editing is an interface to provide modification for the optimization of algorithms and models in the later system when there are enough user data.

4.2.3. Interaction Layer. System management: system management is the common functional interface of the system, including user registration, login, information modification, system settings, and other functions.

Data visualization: data visualization is mainly the display and comparative analysis of data such as evaluation results, ability level, and learning progress, which consists of visualization components and data control. Visualization components are mainly various commonly used chart controls, such as graphs, radar charts, and data tables. Data control includes data request, data structure transformation, data update, report generation, and printing and is mainly responsible for data generation and output to be displayed.

4.3. Design of Interaction between Teachers and Students. The learner model is the data entity of learners in the intelligent tutoring system, which records all kinds of information related to learners and stores them in the database. In order to let learners know their learning status in real time, the system needs to provide a visual user interface to present the learner model, as shown in Figure 7.

There are two kinds of music score files in this system: pictures and MIDI, so there are two kinds of music score display modes in each learning resource, which can be switched freely. The title bar of the component displays music score information such as range, bar number, interval number, note number, chord number, and the playing button of music score audio. To meet the learning preferences of different learners, the system provides a variety of learning modes, some of which need the assistance of special tools, such as music score input tools in dictation and musical note playing tools in singing.

5. Conclusion

The recognition and distinction of music difficulty is the key to realize the individualization of music teaching resources. Only by accurately recommending teaching resources with difficulty and the ability for learners, can they make effective use of resources, quickly master the knowledge and avoid the loss of learning interest. Therefore, this paper summarizes and analyzes the problem of pitch feature extraction in music teaching. By combining with the characteristics of music pitch, the features of high-pitched content in music teaching resources are matched based on deep learning. Then, the algorithm of pitch feature extraction in MIDI music score files is put forward, and the pitch feature matching model is constructed. Finally, a music tutoring system based on pitch feature matching is designed, including the design of music score learning tools, the overall structure of the system, and the interaction between teachers

and students, which is helpful to realize the individualized teaching of music solfeggio, and further improve the music teaching model and realize intelligent and personalized music learning.

The study of enterprise management driven by accounting data has not only great strategic significance but also great practical value and distinctive characteristics of The Times. Although the macro evaluation of DCMM is strong, its objective operability is slightly weak. Therefore, based on the maturity model, this article establishes a three-level accounting data management (AAM) capability evaluation index system, divides the maturity level and key process domains, and constructs an AAM capability evaluation model. Through the evaluation of the accounting data management ability of the case enterprise, the evaluation value of the AAM ability is calculated, and the measurement of the AAM ability is completed, which is helpful to improve the data management ability of the enterprise scientifically and efficiently.

1. Introduction

At present, China's economic development has entered a "new normal," but economic development is closely related to the improvement of science and technology. With the nonstop improvement of science and innovation, information is a fundamental piece of it, which is rethinking the interaction and method of social administration and public key independent direction, an endeavor to board navigation, authoritative business cycle, and individual independent direction, and is becoming increasingly important for the development of modern enterprises and society [1]. Nowadays, accounting data is the top priority of data management and the huge commercial value, scientific research value, social management value, and the value of supporting scientific decision-making are being constantly recognized and developed. Scholars' research on AAM has gradually provided some improved overall ideas and strategies for optimizing AAM [2, 3]. However, at present, the domestic research is limited to a certain part of AAM or stays in the discussion of the relationship between the two, which cannot effectively combine the whole and part of AAM.

CMM (capability maturity model) refers to a staged description used by software development organizations to

define, implement, measure, control, and improve their software processes [4], which is divided into five grades to evaluate software contracting ability to improve software quality. In recent years, scholars have introduced the maturity model into data management for research, thereby forming a data management CMM. Literature [5] put forward the maturity model of enterprise information portals and evaluates the maturity of the case enterprise information portal. Literature [6] applied the maturity model to the measurement of the integration of industrialization and industrialization, which enriches the theoretical methods of evaluating the integration of industrialization and industrialization. Literature [7] applied the maturity model to the evaluation of multiproject management level of the construction unit. Literature [8] applied the maturity model to divide enterprise informatization maturity into five stages: informatization preparation, information system introduction, integration and sharing, enterprise extension, and decision support.

Although CMM has certain advantages compared with other data management capability models, it can be better applied to organizations in China. However, according to the published documents at present, DCMM (data capability maturity model) evaluation is strong in macro but slightly

weak in objective operability, and it does not classify the data. Moreover, there is no research on the combination of AAM and maturity in China at this stage. Therefore, aiming at the partial improvement of all aspects of AAM, this article establishes an evaluation model of AAM ability to promote the improvement of the overall ability, which has reference significance for the research of AAM among enterprises.

2. Theoretical Basis of Maturity Model

2.1. Overall Architecture. As shown in Figure 1, three capability domains of data capability maturity evaluation are defined: data strategy, data application, and data life cycle. The biggest difference between DCMM and other data management capability maturity models is that DCMM increases the data application capability domain. At the same time, data strategy and data life cycle are two indicators that run through the application.

2.2. Grading. Maturity is divided into five levels: initial level, managed level, steady level, quantitative management level, and optimization level [9, 10]. The positioning of each grade is shown in Figure 2:

Grade 1. Initial level: Organizations at this level are not aware of the importance of data to the organization, so they have not formed the consciousness of actively managing data. Data management within enterprises mainly runs through project management. No unified data management rules and procedures have been established within the enterprise, and the problems caused by the data lead to the low quality of customer service, which cost a lot of human resources to maintain the data.

Grade 2. Managed level: Organizations at this level realized the importance of data and began to manage data as an asset. Driven by the needs and strategies of the enterprise, the corresponding data management process was formulated, and the personnel within the organization were assigned to manage the data preliminarily, realizing and identifying the stakeholders of the data.

Grade 3. Robust level: Enterprises at this level regard data as an important asset that can improve performance. They have formulated organizational data management processes and policies to promote the standardization and standardization of data management. Data managers can manage across systems where the management of data can meet the requirements of the organization.

Grade 4. Quantitative management level: Enterprises at this level regard data as an important resource think that data management can enhance the competitiveness of enterprises and realize the promoting role of data in workflow and efficiency. All-round improvements have been made to the processes related to enterprise data management, performance indicators are set for relevant organizations, posts, personnel, etc., and they are regularly assessed so that the system and process can be

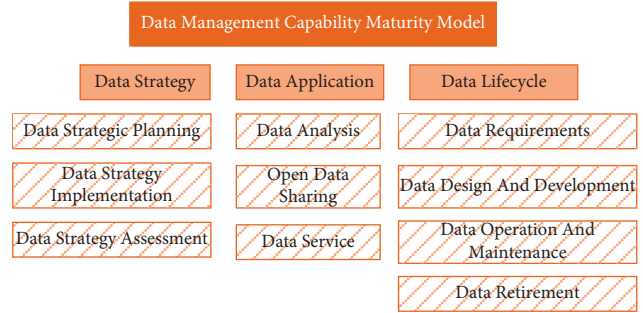

FIGURE 1: Architecture of DCMM.

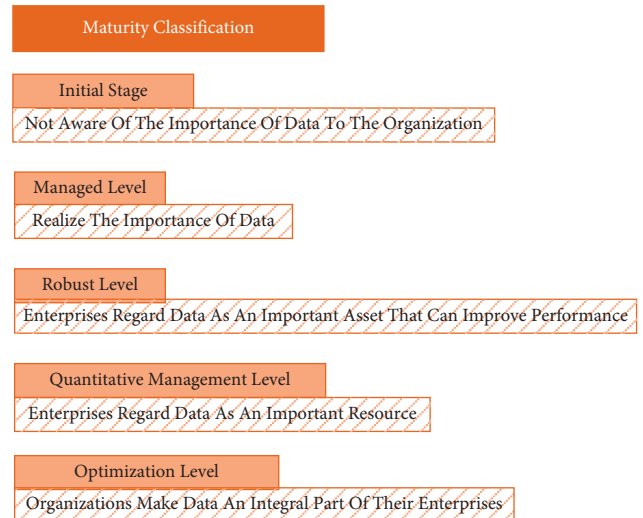

FIGURE 2: Grading of maturity.

optimized and improved according to the monitoring and analysis of data management, where data management is gradually becoming scientific and standardized.

Grade 5. Optimization grade: Organizations at this level regard data as an indispensable part of the enterprise. The policies and processes of AAM can be improved in real time according to the external environment and the current situation of the industry and are regarded as the benchmark of data management in the industry.

3. Enterprise AAM Evaluation Methods

3.1. Analytic Hierarchy Process. Analytic hierarchy process (AHP) is a multicriteria decision-making form combining quantitative and qualitative analysis. It is characterized in that based on analyzing the essence and internal relations of complex decision-making problems, a hierarchical structure model is constructed, and its process of complex problems is presented mathematically with less quantitative information. Through data to solve complex decision-making problems with multiobjectives, multicriteria, or no structural characteristics, the purpose of simplifying the decision-making scheme is achieved [11].

The general steps of AHP mainly include four steps. The first step is to build the hierarchical structure model; second,

construct the judgment matrix; third, obtain hierarchical single sorting and its consistency check; and finally implement hierarchical general ranking and its consistency check.

3.1.1. Establishment of a Hierarchical Structure Model.

The decision to solve the problem is divided into three levels, namely, the target level, the decision criterion level, and the decision scheme level. In the application of the AHP, the problem to be solved is to calculate the relative weight of the bottom layer to the top layer, so as to sort the schemes and measures at the bottom layer and choose the best scheme [12, 13].

3.1.2. Construction of a Comparative Judgment Matrix.

The construction of judgment matrix is to determine the weight of each criterion layer to the target layer by comparing each element with each other pairwise. The comparative judgment matrix of A is as follows:

$$A = (a_{ij})_{m \times n} = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{n1} & \cdots & \cdots & \cdots \end{pmatrix}, \quad (1)$$

where the elements in A should meet the following requirements: $a_{ij} > 0$; $a_{ij} = 1/a_{ji}$; $a_{ii} = 1$.

3.1.3. Hierarchical Single Sort. Hierarchical single sort refers to evaluating all elements in pairs for an element in the previous layer and arranging the important order. The concrete calculation can be carried out according to the judgment matrix A , and the calculation can ensure that it can meet the characteristic root and characteristic vector conditions of $AW = \lambda_{ax}W$, where the largest feature root of A is λ_{ax} , and the normalized feature vector corresponding to λ_{ax} is W , and W_i is a component of W , which refers to the weight, and corresponds to the single ordering of its corresponding elements. Use the judgment matrix to calculate the weight of each factor a_{ij} to the target layer.

The calculation steps of the weight vector (W) and the maximum feature (λ_{ax}) are as follows.

First of all, take the product of the row elements according to equation (2) and then raise it to the n th power:

$$\vec{W}_i = \sqrt[n]{\prod_{j=1}^n a_{ij}}, \quad i, j = 1, 2, \dots, n. \quad (2)$$

Then, it is normalized into a ranking weight vector by formula (3), which is denoted as W (the element of W is the ranking weight of the relative importance of the factor in the same level to a factor of the previous level), then $W = (W_1, W_2, \dots, W_n)^T$ is the result of judging the hierarchical single ranking of the matrix.

$$W_i = \sum_{i=1}^n W_i. \quad (3)$$

Finally, determine the maximum characteristic root of the matrix by the following formula:

$$\lambda_{\max} = \frac{1}{n} \sum_{i=1}^n AW_i. \quad (4)$$

3.1.4. Consistency Inspection and Hierarchical General Sorting. If the n -order judgment matrix is B , the maximum characteristic root λ_{ax} can be obtained by the following methods:

$$BW = \lambda W. \quad (5)$$

The following consistency index CI is taken to test the consistency index of judgment:

$$CI = \frac{\lambda_{\max} - n}{n - 1}. \quad (6)$$

$CI = 0$ means that the judgment matrix is completely consistent and the larger the CI , the more serious the inconsistency of the judgment matrix.

Assuming that A is the target layer, the weight coefficients of m total ranking of factor levels are as follows: a_1, a_2, \dots, a_m ; B is the middle layer, and the weight coefficients of n hierarchical single sort of factors are as follows: $b_1^1 \cdots b_n^m$; therefore, the total ranking of layer B is calculated according to the following formula:

$$b_i = \sum_{j=1}^m a_j b_{ij}. \quad (7)$$

Set the B layer B_1, B_2, \dots, B_n On the upper layer (A Layer), the hierarchical ranking consistency index of factors A_j ($j = 1, 2, \dots, m$) is CI_j , the random consistency index is RI_j , and the consistency ratio of the hierarchical total sort is as follows:

$$CR = \frac{a_1 CI_1 + a_2 CI_2 + \cdots + a_m CI_m}{a_1 RI_1 + a_2 RI_2 + \cdots + a_m RI_m} = \frac{\sum a_i CI_i}{\sum a_i RI_i} = \frac{CI}{RI}. \quad (8)$$

When < 0.1 , it is considered that the overall ranking of the hierarchy has passed the consistency test; otherwise, it is necessary to readjust the element values of the judgment matrix and make the final decision according to the overall ranking of the decision-making level.

3.2. Fuzzy Analytic Hierarchy Process. The fuzzy comprehensive evaluation method is an overall decision based on a single decision of all factors involved in things, which is a comprehensive evaluation affected by multiple factors. In contrast, the fuzzy analytic hierarchy process (FAHP) is an improved AHP, which combines the above AHP with the fuzzy comprehensive evaluation method. It is a comprehensive qualitative and quantitative evaluation model, which is suitable for dealing with uncertain problems. It is widely used in system evaluation, system optimization, efficiency evaluation, and so on.

Generally speaking, the first step is to use AHP to determine the weight of each index in the model index system, and the second step is to use the fuzzy comprehensive evaluation method to comprehensively evaluate the grade so

as to effectively combine the two methods and obtain a more scientific evaluation result. The FAHP adopted in this paper is useful for studying the management ability of accounting data, which is applicable to determine the index weight, evaluate the maturity level, and establish the evaluation model of AAM ability.

4. Evaluation Model of Enterprise AAM Based on Maturity Model

4.1. Setting of Index System. The index system of the AAM capability evaluation model consists of three levels of indicators, including three competence domains (first-level indicators), eight competence items (second-level indicators), and 24 subcompetence items (third-level indicators). The weights of all levels of indicators in the AAM capability evaluation model are determined by AHP, and consistency tests are carried out in turn. The distribution of each indicator is shown in Figure 3.

4.1.1. Accounting Data Strategy. Generally speaking, accounting strategy is to combine accounting data technology, concept, framework, and strategic management so as to build an accounting data analysis platform and enhance the overall core strength and environmental adaptability. There are three competency items under the accounting data strategy, which are accounting data strategy planning, accounting data strategy implementation, and accounting data strategy evaluation.

4.1.2. Accounting Data Application. The application of accounting data is the process of mining effective information from accounting data using the method of accounting data analysis, providing users with auxiliary decisions, providing accounting data services, and maximizing the value of accounting data. There are three competency items in accounting data application: accounting data analysis, accounting data open sharing, and accounting data service.

4.1.3. Accounting Data Life Cycle. The accounting data life cycle is the whole process of accounting data from design, development, creation, migration, application, archiving, recycling, reactivation, and withdrawal. There are four competency items in the accounting data life cycle: accounting data demand management, accounting data design and development, accounting data operation and maintenance, and accounting data retirement.

4.2. Maturity Level Setting. The maturity level of the AAM capability evaluation model is divided into five levels: initial level, repeatable level, defined level, managed level, and optimized level. Each maturity level has its own function. Except for the first stage, all the other stages are constructed according to the same internal structure. Different maturity levels reflect different levels of AAM capabilities.

4.2.1. Initial Level. The initial level is characterized by passive management, and there is no initiative in AAM. The organization is not aware of the importance of AAM, and it is chaotic and disorderly as a whole, whose specific performance is that no standardized AAM policies, documents, plans, and processes have been formed. There is no formal AAM organization at the organizational level. There is no clear goal and practice. Moreover, there are no key process areas and key practices in this stage.

4.2.2. Repeatable Level. The repeatable level is the second stage of the accounting data management ability assessment model. Organizations in this stage initially realize the importance of accounting data management and begin to manage accounting data, but the scope of accounting data management is relatively limited. The definition of repeatable level is shown in Figure 4.

4.2.3. Defined Levels. The third level of the AAM evaluation model is the defined level, which means that the key process areas of repeatable level have been realized, whose specific performance is as follows: the relevant system and process of AAM are more perfect and standardized; it is able to carry out comprehensive AAM within the organization; the role of AAM personnel has been enhanced. The specific distribution is shown in Figure 5.

4.2.4. Managed Level. The fourth level of the AAM capability evaluation model is the managed level, which means that the key process areas of the defined level have all been realized. Specifically, it can optimize and update the systems and processes related to AAM; AAM is more systematic and professional, and its application in organizations is more standardized; AAM supports the decision-making of the organization and has made great progress. The specific distribution is shown in Figure 6:

4.2.5. Optimized Level. The highest level of the accounting management capability evaluation model is the optimization level, which means that the key process areas of the managed level have all been realized. The concrete performance is as follows: all the basic construction, manpower reserve, material resources, and other aspects of support are ready; through the long-term practice of AAM, the organization has accumulated a lot of experience and can make timely adjustments to the changes of the internal and external environment; the AAM culture is formed. The specific distribution is shown in Figure 7:

4.3. Calculation of Maturity Level

4.3.1. Fuzzy Evaluation Matrix. Before the fuzzy comprehensive evaluation of AAM ability, the evaluated fuzzy relationship should be expressed as a fuzzy evaluation matrix and then determine the evaluation set $A = \{A_1, A_2, \dots, A_n\}$, in which A_n indicates the grade of the evaluated index. Because the maturity level is divided into five levels, in the

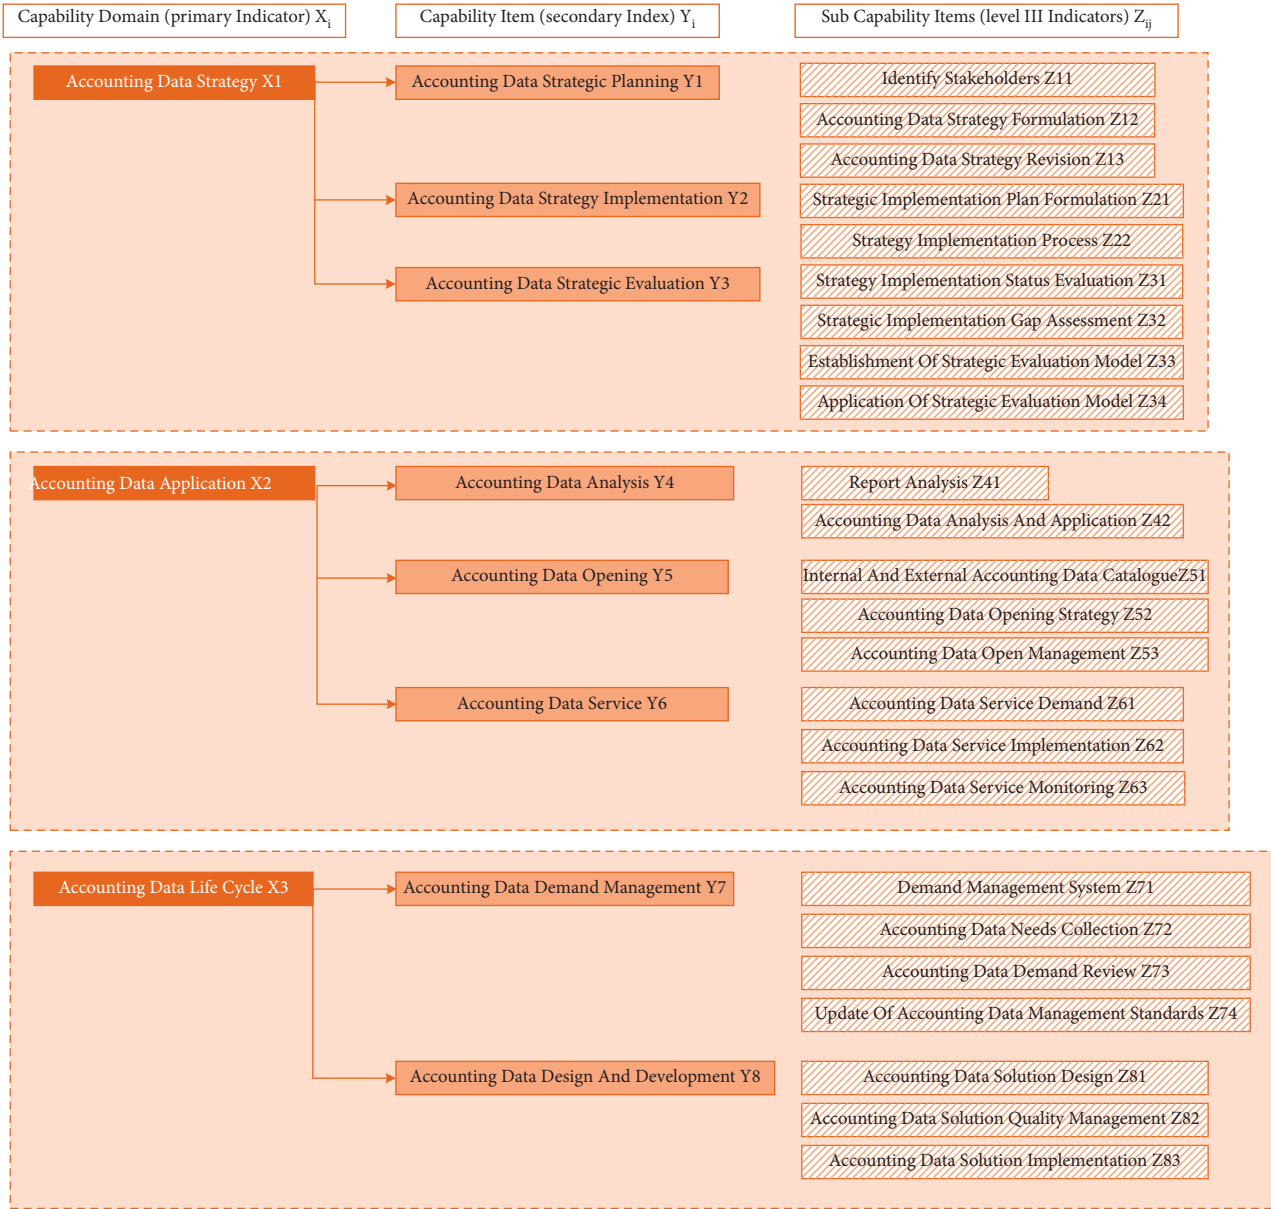

FIGURE 3: Distribution of index system.

evaluation set, $n = 5$, the fuzzy evaluation matrix with 5 columns is set as follows

$$P = \begin{pmatrix} P_{11} & P_{12} & P_{13} & P_{14} & P_{15} \\ P_{21} & P_{22} & P_{23} & P_{24} & P_{25} \\ \dots & \dots & \dots & \dots & \dots \\ P_{j1} & P_{j2} & P_{j3} & P_{j4} & P_{j5} \end{pmatrix}, \quad (9)$$

where element p_{jn} ($n = 1, 2, 3, 4, 5$) refers to the probability that all the three-level evaluation indexes Z_{ij} included by a certain second-level index Y_i get n -level times, respectively, in the scoring, namely, the membership degree p_{jn} of the measured index, which is expressed by the following formula:

$$p_{jn} = \frac{\text{The number of times the in dex } Z_{ij} \text{ was graded } n}{\text{Total grading times}}. \quad (10)$$

Note: the secondary indicators are the same in the same matrix Z_{ij} .

4.3.2. Fuzzy Evaluation Matrix. The weight matrix of all the three-level evaluation indexes Z_{ij} contained in a certain two-level index Y_i is set as $Z = (z_{i1}, z_{i2}, \dots, z_{ij})$, where Z_{ij} represents the weight of the corresponding three-level index Z_{ij} . Then, the fuzzy relationship evaluation matrix of indicators at all levels can be obtained by the calculation of the following formula:

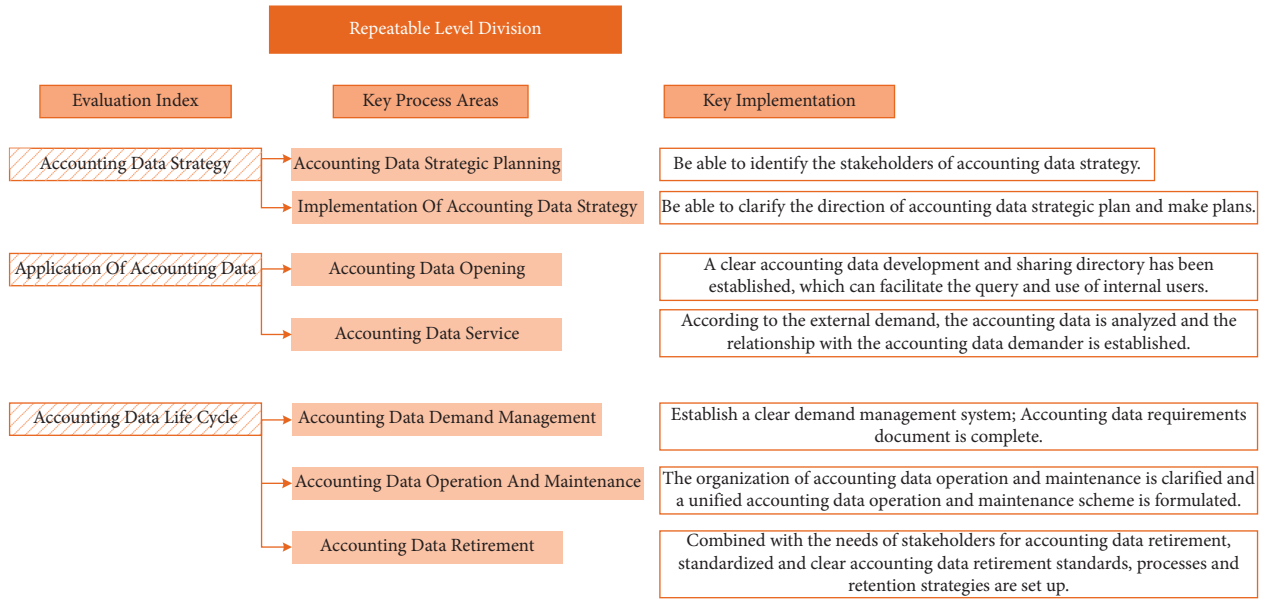

FIGURE 4: Division of repeatable level.

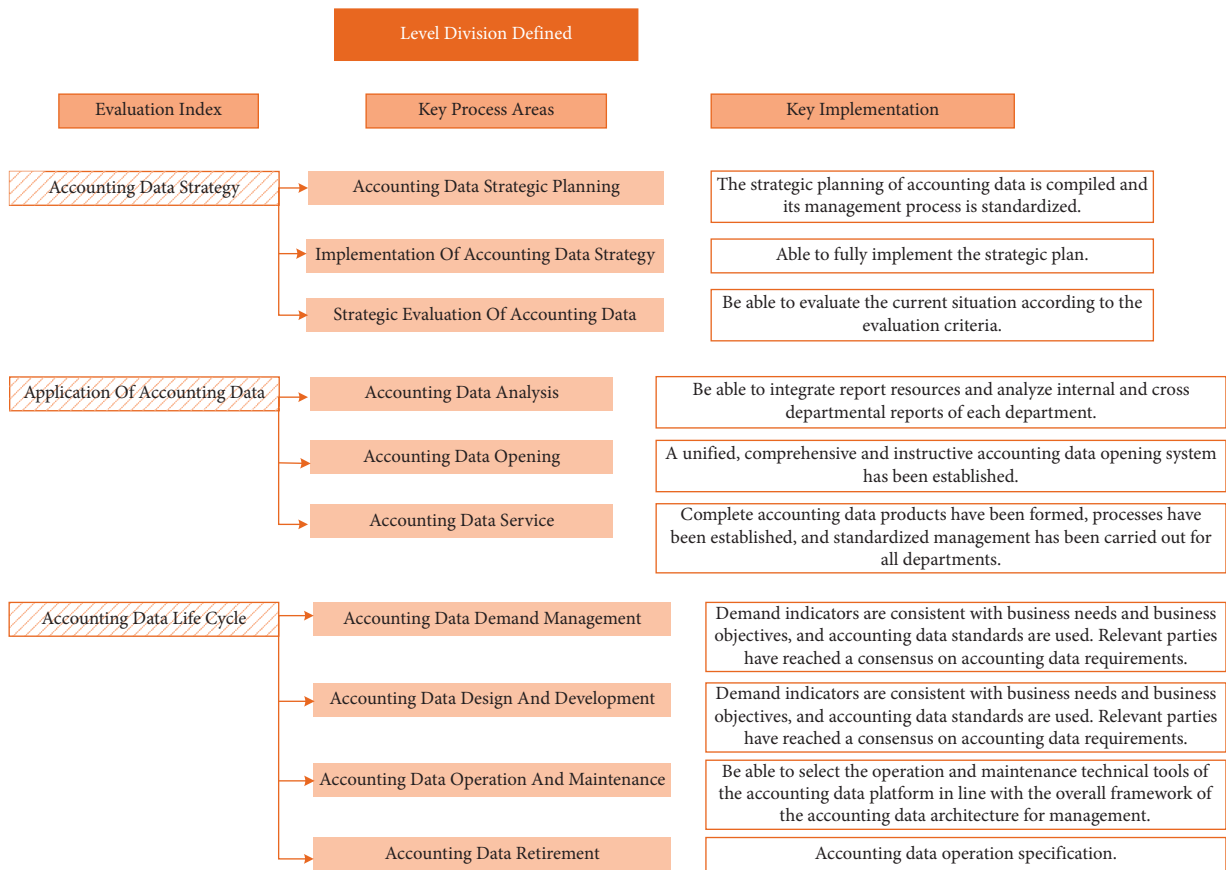

FIGURE 5: Division of defined level.

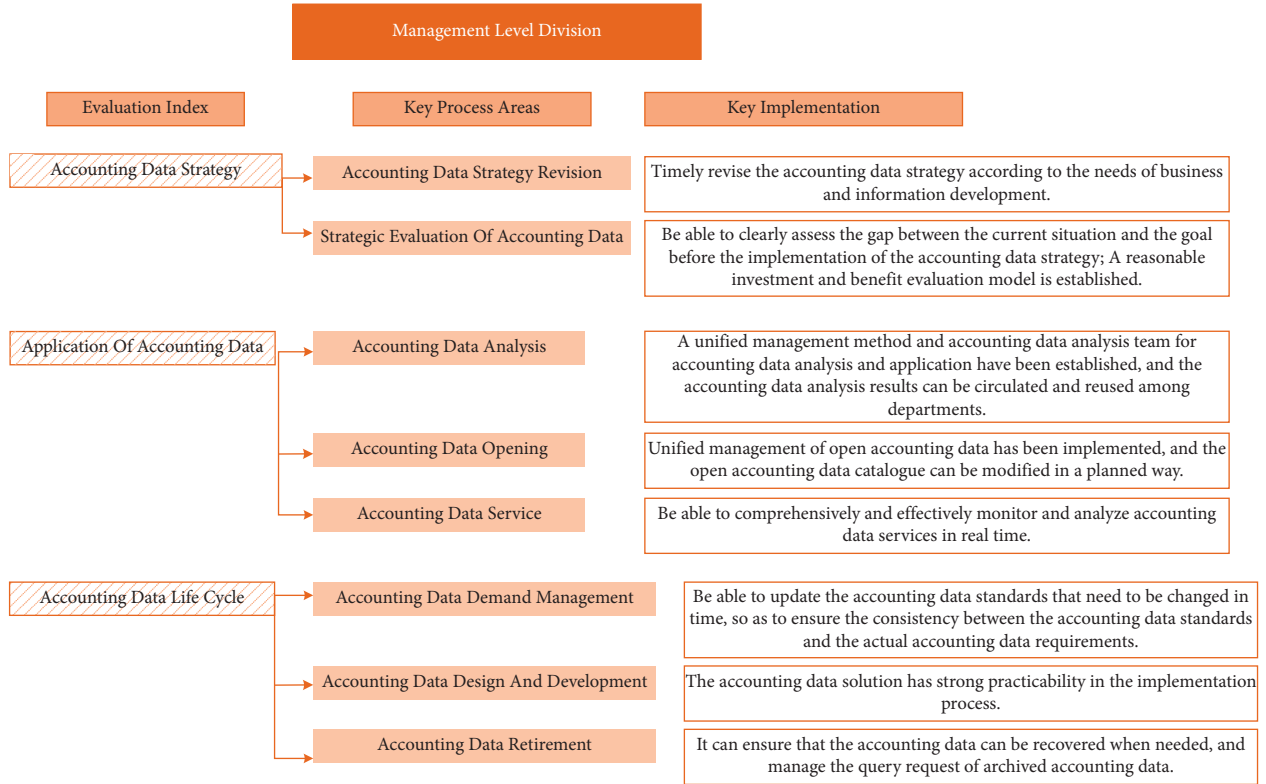

FIGURE 6: Division of managed level.

FIGURE 7: Division of optimized level.

$$M = (M_{ij})_{m \times n} = Z \times P. \quad (11)$$

4.3.3. *Determine the Maturity Level.* After the final fuzzy comprehensive evaluation result is obtained through the calculation in the previous section, the cascade of the enterprise's AAM ability can be calculated through the following formula:

$$L = M \times N. \quad (12)$$

Among them, $N = \{20, 40, 60, 80, 100\}$, $M = \{\text{Initial level, repeatable level, defined level, managed level, optimized level}\}$.

According to the calculation results of L , the maturity level of AAM ability to which each first-level index and the final result belong can be determined. At the same time, in the process of grade judgment, the maturity grade of AAM ability can be judged according to the principle of maximum membership degree, and the judgment result can be further proved.

5. Case Analysis

Through the evaluation of the accounting data management ability of the case enterprise, the evaluation value of the accounting data management ability is calculated, and the measurement of the accounting data management ability is completed, which is helpful in improving the data management ability of the enterprise scientifically and efficiently.

5.1. *Analysis of AAM.* The evaluation of Company A was conducted by questionnaire. The respondents are mainly stakeholders of AAM in enterprise A, including department heads, managers, experts, and AAM professionals. According to the scores of the respondents on the related indicators of Company A, the basic information of each capability domain of Company A can be obtained, and the results are shown in Tables 1–3.

According to the calculation formula mentioned above, it can be concluded that the fuzzy relation evaluation vector of each first-level index is as follows:

TABLE 1: Grading results of accounting data strategy.

First-level index	Second-level index	Third-level index	Grading				
			1	2	3	4	5
Accounting data strategy X1	Accounting data strategic plan Y1	Identify stakeholders Z11	1	5	11	13	0
		Strategy formulation Z12	0	3	12	14	1
		Revise strategy Z13	4	12	14	0	0
	Accounting data strategy implementation Y2	Implementation of strategic planning Z21	0	6	10	11	3
		Implementation process Z22	2	7	15	5	1
		Evaluation of strategic implementation status Z31	2	8	12	8	0
	Accounting strategy evaluation Y3	Implementation of strategic gap assessment Z32	0	7	9	12	2
		Establishment of strategic model Z33	6	15	7	2	0
		Evaluation model application Z34	5	16	7	2	0

TABLE 2: Grading results of accounting data application.

First-level index	Second-level index	Third-level index	Grading				
			1	2	3	4	1
Accounting data application X2	Accounting data analysis Y4	Analysis report Z41	0	0	10	15	5
		Analytical application Z42	0	1	9	11	9

	Accounting data service Y6	Service Z61	4	11	14	0	1
		Implement service Z62	3	10	15	2	0
		Service Z63 monitoring	6	7	11	5	1

TABLE 3: Grading results of accounting data life cycle.

First-level index	Second-level index	Third-level index	Grading				
			1	2	3	4	1
Accounting data life cycle X3	Accounting data demand management Y7	Demand management system Z71	0	4	11	14	1
		Collect demand Z72	1	5	17	7	0
		Review requirements Z73	5	11	10	4	0
		Management standard update Z74	4	6	20	0	0
	Accounting data design and development Y8	Solution design Z81	0	5	21	4	0
		Solution Quality Management Z82	1	2	18	8	1
		Solution implementation Z83	0	1	7	21	1

$$\begin{aligned}
M_{x1} &= (0.0524 \ 0.2467 \ 0.3703 \ 0.2972 \ 0.0334), \\
M_{x2} &= (0.0619 \ 0.1548 \ 0.3763 \ 0.2778 \ 0.1292), \\
M_{x3} &= (0.0488 \ 0.1331 \ 0.4602 \ 0.3108 \ 0.0471).
\end{aligned} \quad (13)$$

By multiplying the weight vector composed of the weights of the first-level indexes with the above-mentioned first-level fuzzy relation evaluation matrix to obtain the final fuzzy relation evaluation vector, the following vector is obtained:

$$M_x = (0.0503 \ 0.1517 \ 0.3807 \ 0.3320 \ 0.0853). \quad (14)$$

According to the principle of maximum membership degree, the maximum value in the vector is the third value, i.e., 0.3807, which can preliminarily determine that the AAM ability of Company A is defined.

5.2. Comprehensive Evaluation of AAM. Calculate the final evaluation score and grade of Company A's AAM ability, and the comprehensive evaluation results of enterprise AAM ability are shown in Figure 8:

The evaluation value of Company A's accounting data strategy is 60.25. Although the corresponding maturity level is the "defined level," it is just entering the defined level, and there is still a big gap from the next level (managed level). Company A has not revised the accounting data strategy in time according to business and information development needs and cannot optimize the accounting data strategy in time. Before implementing the accounting data strategy, the gap between the present situation and the target cannot be clearly assessed. In addition, a reasonable investment and benefit evaluation model has not been established.

FIGURE 8: A Comprehensive evaluation of Company A's AAM ability.

The evaluation value of Company A's accounting data application is 65.152. The corresponding maturity level is the "defined level," and it is in the transitional stage between the defined level and managed level. It has not yet established a unified management method and accounting data analysis team for the application of accounting data analysis, and the results of accounting data analysis have not been circulated and reused among departments. In addition, we implement unified management of accounting data that has not yet been opened, which is failure to conduct comprehensive and effective monitoring and real-time analysis of accounting data services.

The evaluation value of the accounting data life cycle of Company A is 63.486. From the evaluation value, the corresponding maturity level is the "defined level," and it is in the transitional stage between the defined and managed levels. Specifically, the demand indicators are consistent with the business needs and business objectives, accounting data standards are used, and relevant parties have reached a consensus on accounting data needs. Moreover, the solution meets the demand for accounting data, and the design content is complete; and the operation of accounting data retirement is standard.

6. Conclusion

Based on the maturity model, this article establishes a three-level evaluation index system of AAM ability, divides the maturity level and key process areas, and constructs the evaluation model of AAM. In addition, Company A, which has some experience in AAM, is selected to evaluate the effectiveness of the model. The evaluation values of accounting data strategy, accounting data application, and accounting data life cycle of Company A are 60.25, 65.152, and 63.486, respectively, and its AAM ability belongs to the "defined level." The evaluation model of AAM ability established in this article can provide support for the research of AAM ability and provide guidance for the development of AAM ability evaluation.

In order to improve the security and stability of data transmission in vehicle-road cooperative communication and reduce the error rate of data transmission, a fast data transmission method based on the clustering algorithm is proposed. First, the multisensor information acquisition method of the vehicle networking is used to realize data acquisition and data structure analysis of the vehicle-road cooperative communication, and a data transmission channel model for vehicle-road cooperative communication is constructed. The interference suppression in the data transmission process of the vehicle-road cooperative communication is realized by the matched filter detection algorithm. Then, according to the symbol characteristic distribution of the vehicle-road cooperative communication channel, the baud interval equalization method is used to realize the piecewise equalization adjustment of data transmission for the vehicle-road cooperative communication. With the adaptive error compensation and channel fading suppression, the K-means clustering algorithm is used to carry out the coordinated adjustment to data packets during the rapid data transmission of the vehicle-road cooperative communication. Finally, the adaptive control of data transmission for the vehicle-road cooperative communication is carried out according to the dynamic distribution characteristics of the clustering center so as to reduce the influence of channel fading and intersymbol interference caused by channel spread. The simulation results show that the bit error rate of this method is kept at about 0.05, and the data transmission rate continues to increase, most of which remain above 0.95. This method has strong anti-interference ability for the rapid data transmission of vehicle-road cooperative communication, with lower communication bit error rate, less end-to-end time delay, and higher stability and accuracy of data transmission.

1. Introduction

With the development of vehicle networking technology and vehicular ad hoc network (VANET), people attach great importance to the research on the security and stability of data transmission in vehicle-road collaborative communication. With the channel balance control of vehicle-road collaborative communication, a data transmission method with high stability and strong anti-interference is adopted to realize the optimal control of vehicle-road collaborative communication and improve the collaborative control ability for the vehicle-road collaborative communication in data transmission. It is of great significance to study the rapid data

transmission method of vehicle-road cooperative communication in the design of mobile ad hoc network (MANET) for vehicle-road cooperative control and vehicle networking [1].

The data transmission of vehicle-road cooperative communication has the characteristics of nonstationarity and multipath so that the fast data transmission of vehicle-road cooperative communication is affected by intersymbol interference and multipath, and the output stability is not good. Thus, it is necessary to design a data transmission control model for vehicle-road cooperative communication to improve the stability of fast data transmission of the vehicle-road cooperative communication with channel equalization adjustment. At present, the fast data

FIGURE 1: Structure model of data input and output of vehicle-road cooperative communication.

transmission methods of vehicle-road cooperative communication mainly include the data transmission control method of vehicle-road cooperative communication based on orthogonal frequency division multiplexing, the BPSK modulation method, the PSK modulation method, and so on [2–4]. Through time-frequency characteristic analysis and equalization control, the data transmission control of vehicle-road cooperative communication is realized. Reference [5] has proposed a method of vehicle-road cooperative communication and interference suppression based on the PTS-clipping algorithm. In the method, the piecewise fitting control method is used to design the channel equalization and suppress the intersymbol interference in the process of data transmission of vehicle-road cooperative communication, which improves the output signal-to-noise ratio and reduces the intersymbol interference, but the stability and real-time performance of this method are not good. Reference [6] has proposed a vehicle-road cooperative communication control method for the direct sequence spread spectrum. In this method, the direct sequence spread spectrum transmission method is used to transmit the data of vehicle-road cooperative communication in the spatial multipath channel, which reduces the output bit error rate, but the computational load is high. Reference [6] has proposed a vehicle-road cooperative communication control method based on matched filter detection. In this method, the interference suppression and filtering during data transmission of vehicle-road cooperative communication are analyzed by a matched filter detector, which improves the stability and real-time performance of data transmission of vehicle-road cooperative communication, together with error compensation, but the packet reception performance of this method is not good under the background of strong interference.

In view of the above problems, a fast data transmission method of vehicle-road cooperative communication based on clustering algorithm is proposed in this study. First, the multisensor information collection method of vehicle network is used to realize data acquisition and data structure analysis of vehicle-road cooperative communication. Then according to the symbol characteristic distribution of the vehicle-road cooperative communication channel, the baud interval equalization method is used to realize the piecewise equalization adjustment to data transmission for the vehicle-road cooperative communication. With the adaptive error compensation and channel fading suppression, the K-means clustering algorithm is used to carry out the coordinated adjustment of data packets during the rapid data transmission of the vehicle-road cooperative communication, and the Matlab simulation analysis method is used to realize

the fast data transmission of vehicle-road cooperative communication. The results demonstrate the superior performance of the proposed method in improving the control ability of vehicle-road cooperative communication.

2. Channel Model of Vehicle-Road Cooperative Communication and Signal Analysis

2.1. Channel Model. In order to realize fast data transmission and optimal control of vehicle-road cooperative communication based on the clustering algorithm, a channel model of vehicle-road cooperative communication is constructed based on routing protocol control and channel model equalization design of vehicle-road cooperative communication network. The single copy routing algorithm SimBet is used to reorganize the data transmission channel model of vehicle-road cooperative communication. With the passive time reversal mirror (PTRM) and BPSK modulation technology, the channel model of vehicle-road cooperative communication is established [6]. According to the attenuation of the data transmission bandwidth of the communication network, the weighted vector of the channel and the frequency component of the output signal are obtained. Through the convolution operation, the communication data transmission and equalization design are realized. The structure model of data input and output is shown in Figure 1.

According to the structure model of vehicle-road cooperative communication data input and output shown in Figure 1, the optimal distribution control of vehicle-road cooperative communication data time series is carried out based on the attenuation of communication network data transmission bandwidth. The vehicle network multisensor information collection method is used to realize the data acquisition and data structure analysis of vehicle-road cooperative communication. Assuming that the vehicle-road cooperative communication data signal is $p(t)$ and the cooperative communication data sequence of PS waiting for a period of time Tg to be transmitted is $S(t)$, the output processed by the reversal mirror is as follows after Wigner-Ville distribution detection and time reversal:

$$p_{ri}(t) = p(t) * h_i(t) + n_{pi}(t), \quad (1)$$

where $h_i(t)$ represents the attenuation coefficient of impulse response characteristic quantity $p(t)$ of vehicle-road cooperative communication data in the multipath channel. The channel equalization control of vehicle-road cooperative communication data transmission is carried out on a

continuous sliding window to obtain the symbol sequence of vehicle-road cooperative communication data $S_r(t)$ after matched filtering:

$$S_r(t) = S(t) * h(t) + n_s(t), \quad (2)$$

where $n_s(t)$ represents the interference noise on the data collection bandwidth of the vehicle-road collaborative communication, and the relevant matched filter detection output is obtained through a preprocessor $P_r(-t)$:

$$S_{r_i}(t) = S(t) * h'_i(t) + n_{si}(t), \quad (3)$$

where $h'_i(t)$ is the response function after filtering in $S(t)$, and the bandwidth of the data transmission array element sequence of vehicle-road cooperative communication is

$$\begin{aligned} r'_i(t) &= S_{r_i}(t) * p_{ri}(-t) \\ &= S(t) * p(-t) * h'_i(t) * h_i(-t) + n_{1i}(t), \end{aligned} \quad (4)$$

where $S(t)$ is the local signal, $S_{r_i}(t)$ is the multipath signal, $p_{ri}(-t)$ is power spectral density, and $n_{1i}(t)$ is the noise component. The signal component in the extended signal $r(t)$ of the vehicle-road cooperative communication in the spatial multipath channel is approximately the information signal waveform $S(t)$, and the output interference suppression component is

$$\begin{aligned} n_{1i}(t) &= S(t) * h'_i(t) * n_{pi}(-t) \\ &+ n_{si}(t) * p(-t) * h_i(-t) \\ &+ n_{si}(t) * n_{pi}(-t), \end{aligned} \quad (5)$$

where $n_{pi}(-t)$ represents the noise component on the p -th symbol sequence, and $n_{si}(t)$ represents the noise component on the s symbol sequences. According to the above processing, the data transmission channel model of vehicle-road cooperative communication is constructed, and the anti-interference design of signal transmission is realized by the matched filter detection algorithm.

2.2. Transmission Signal Analysis. In order to obtain the data transmission gain of vehicle-road cooperative communication, the subsection equalization adjustment of vehicle-road cooperative communication data transmission is realized. It is assumed that the vehicle-road cooperative communication data are transmitted to each node b_i , and the number of pulse frames for the impulse response of the channel is N_f , then the time required $T_{\text{spray}} = \max(t_i)$ for the diffusion stage is obtained by the auto-correlation matching filter detection. The extended signal of vehicle-road cooperative communication data output is

$$\begin{aligned} r(t) &= \sum_{i=1}^M r'_i(t) * p(t) \\ &= S(t) * p(t) * p(-t) * \sum_{i=1}^M h'_i(t) * h_i(-t) + \sum_{i=1}^M n_i(t), \end{aligned} \quad (6)$$

where $n_i(t)$ is also the noise interference term of the data transmission channel for vehicle-road cooperative

communication, $n_i(t) = n_{1i}(t) * p(t)$. The forwarding delay depends on the diffusion delay. Therefore, in the data transmission process of vehicle-road cooperative communication, the fuzzy function is introduced and the feature clustering algorithm is used. The clustering algorithm is a classic algorithm to solve the clustering problem, which is simple and fast. For dealing with large data sets, the algorithm maintains scalability and efficiency. When the cluster is close to Gaussian distribution, its effect is better. The fuzzy matching function of data transmission of vehicle-road cooperative communication is obtained as

$$\begin{aligned} H(t) &= \hat{h}(t) * p(t) * p(-t) \\ &= \left(\sum_{i=1}^M h'_i(t) * h_i(-t) \right) * p(t) * p(-t), \end{aligned} \quad (7)$$

where $\hat{h}(t)$ and $p(t) * p(-t)$ approximate the impulse response function $\delta(t)$; $p(t)$ and $p(-t)$ indicate the spectral components of the impulse response signal taken on the positive and negative sequences, respectively. $*$ is convolution operation. By the time-frequency analysis method and through calculation, $h'_i(t)$ is calculated through $h_i(t)$, and the signal components of the vehicle-road cooperative communication channel are processed by feature focusing, and the following result is obtained:

$$|s(f)| = A \sqrt{\frac{1}{2k} \{ [c(v_1) + c(v_2)]^2 + [s(v_1) + s(v_2)]^2 \}}, \quad (8)$$

where $A(t)$ is the amplitude of the vehicle-road cooperative communication signal, f_0 is the initial transmission frequency of the vehicle-road cooperative communication channel, $k = B/T$ is the BPSK modulation component of the vehicle-road cooperative communication, and B is the frequency modulation signal bandwidth. The spread spectrum algorithm is adopted to obtain the information flow of the output signal $a(t)$ in the delay time interval T_a . Accordingly, the data clustering algorithm is adopted to obtain the data transmission gain of the vehicle-road cooperative communication as follows:

$$E = \|x(t)\|^2 = \sum_j \sum_k |C_j(k)|^2 = \sum_j E_j, \quad (9)$$

where $x(t)$ is the time series of data transmission signal of vehicle-road cooperative communication, $C_j(k)$ is the data delivery delay, and E_j is the amplitude modulation parameter. According to the above channel and signal analysis, the baud interval equalization method is adopted to realize the piecewise equalization adjustment for data transmission of vehicle-road cooperative communication according to the symbol characteristic distribution of the vehicle-road cooperative communication channel [7].

3. Optimization of Fast Data Transmission in Vehicle-Road Collaborative Communication

3.1. Data Transmission Channel Equalization of Vehicle-Road Collaborative Communication. The channel equalization

model for vehicle-road cooperative communication is established by adaptive control of link forwarding protocol and baud interval equalization control [8]. In the process of forward and reverse driving, the time-frequency characteristic component of the vehicle-road cooperative communication signal received by the receiver is as follows:

$$s(t) = \cos[2\pi f_0 t + \pi\beta t^2 + \psi_0], \quad (10)$$

where f_0 and ψ_0 are the starting frequency and initial phase of the multipath channel of vehicle-road cooperative communication, respectively. The statistical characteristics of the units to be detected are estimated, and the spread spectrum allocation model of vehicle-road cooperative communication channel is constructed. The extended bandwidth loss is expressed as

$$X' = \sum_{v=1}^V b_v X_v, \quad (11)$$

where $\{b_v, v = 1, 2, \dots, V\}$ is the impulse weighting coefficient of the data transmission channel of vehicle-road cooperative communication and X_v represents the distance ambiguity parameter. $p(t)$ is introduced as the propagation attenuation coefficient. The multipath spectrum bandwidth of vehicle-road cooperative communication is W . By adopting the iterative learning and adaptive control methods, an equilibrium control mode for the multivehicle-road cooperative communication channel in multidimensional road network space is constructed [9], and the channel equilibrium adjustment output is as follows:

$$H(z) = Am \cdot \frac{1 + 2z^{-1} + z^{-2}}{(1 - \rho e^{j\phi} z^{-1})(1 - \rho e^{-j\phi} z^{-1})}, \quad (12)$$

where z is the transfer function of vehicle-road cooperative communication, A is the amplitude of path loss, and m is the intersymbol interference. Using pole estimation, the signal output $x(n)$ in the road network $\rho e^{\pm j\phi}$ is

$$x(n) = A \cos(0.3\pi n + \varphi) + v(n), \quad (13)$$

where φ is the output spread phase of vehicle-road cooperative communication and $v(n)$ is the intersymbol interference caused by path spread. By introducing the multiscale characteristics of channel transmission, data transmission control and adaptive adjustment are carried out based on man-machine interaction control [10].

3.2. Data Clustering of Vehicle-Road Collaborative Communication and Transmission Optimization. Based on data transmission channel equalization of vehicle-road cooperative communication, data clustering is carried out to vehicle-road cooperative communication, and the specific flow chart is shown in Figure 2.

With the adaptive error compensation and channel fading suppression, the K-means clustering algorithm is used to carry out coordinated adjustment to data packets during the rapid data transmission of the vehicle-road cooperative communication. The K-means clustering

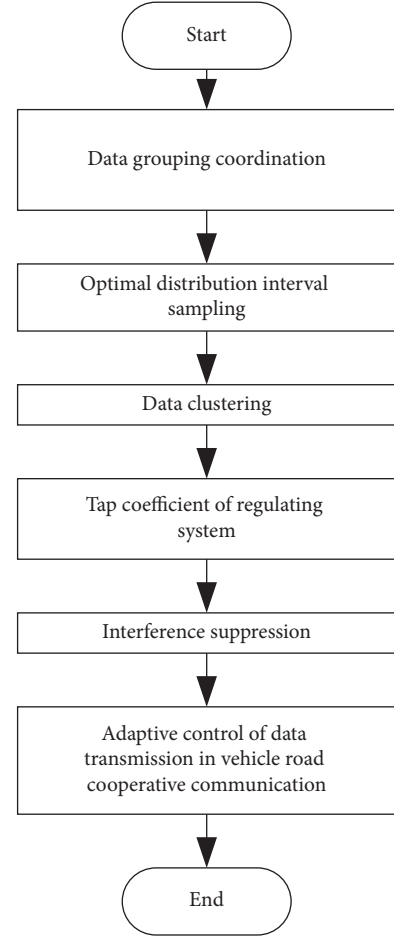

FIGURE 2: Flow chart.

algorithm is an iterative clustering analysis algorithm. This step is to divide the data into k groups, randomly select k objects as the initial clustering center, then calculate the distance between each object and each subclustering center, and assign each object to the nearest clustering center. According to the attenuation of communication network data transmission bandwidth, the optimal distribution interval sampling of vehicle-road cooperative communication data time series is carried out [11], and the clustering function is obtained as follows:

$$s(t) = \sum_i b_j \sum_{j=0}^{N_f-1} p(t - iT_s - jT_f - c_j T_c), \quad (14)$$

where b_j is the interference item of the vehicle-road cooperative communication data, T_s is the time sampling interval, and c_j is the transmission bandwidth of the vehicle-road cooperative communication data. Assuming that the similarity of the vehicle-road cooperative communication data is $h(n)$, the nonlinear equilibrium parameter is $n(n)$, the time domain loss is $\gamma(n)$, and the intersymbol interference is $\tilde{x}(n)$, then under the limited symbol rate, the channel aliasing and superposition are carried out by convolution $h'_i(t) * h_i(-t)$, and the data clustering is realized by the data K-means cluster shown in Figure 3.

FIGURE 3: K-means clustering of data.

With the clustering result of vehicle-road cooperative communication data in Figure 3 as the output, the spectral component of communication data output is as follows:

$$\begin{aligned} S(n_j) &= (E_{\text{elec}} + E_{DF})l\delta + E_{Tx}(l, d_j) \\ &= (E_{\text{elec}} + E_{DF})l\delta + lE_{\text{elec}} + l\varepsilon_{fs}d_j^2 \quad (15) \\ &= [(E_{\text{elec}} + E_{DF})\delta + E_{\text{elec}} + \varepsilon_{fs}d_j^2]l, \end{aligned}$$

where E_{elec} is the superposition component of vehicle-road cooperative communication at the same time in the same phase, E_{DF} is the attenuation loss of multipath spread of vehicle-road cooperative communication, $E_{Tx}(l, d_j)$ is the channel impulse characteristic quantity of vehicle-road cooperative communication transmission, ε_{fs} is the frequency spectrum parameter, l is fuzzy information sequence, and d_j is the multipath component of detection signal. The tap coefficient of vehicle-road cooperative communication data transmission is adjusted, and the blind equalization method is adopted to suppress interference. The adaptive control of data transmission in vehicle-road cooperative communication is carried out according to the dynamic distribution characteristics of clustering centers so as to reduce the effects of channel fading and intersymbol interference caused by the channel spread spectrum [12].

4. Simulation Experiment

In the experiment, the distance between vehicles in the motorcade was kept at 24–100 m, and the upper speed line v_{max} was 120 km/h. RFID was used as the sensor in the motorcade, and 100 receiving array elements were set to form the transmission array of vehicle-road cooperative communication. The independent variable X of data transmission in vehicle-road cooperative communication indicated the distance between two nodes in the link establishment time. The vehicle driving can be divided into two situations: forward driving and reverse driving. The

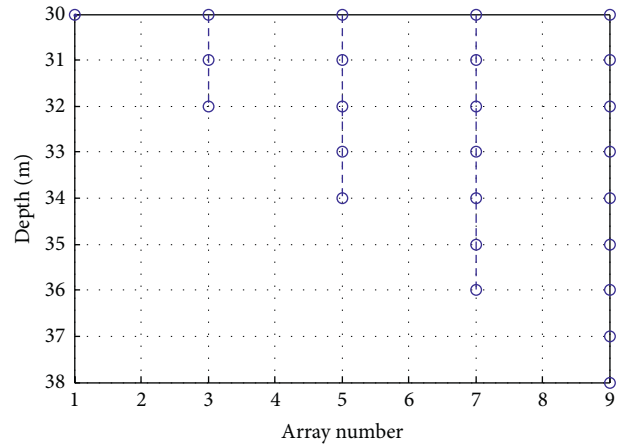

FIGURE 4: Distribution of transmission elements in vehicle-road cooperative communication.

communication range was $[0, 300)$, satisfying $0 \leq X < 300$. In vehicle-road cooperative communication, the symbol transmission rate was set at 1 k Baud. The maximum data transmission delay was set at 25 ms; the symbol distance was 100 m; the waiting time of vehicle-road cooperative communication data was $Tg = 100\text{ms}$; the signal-noise ratio was fixed at 10 dB; the number of snapshots was changed from 200 to 2000. According to the above simulation environment and parameter settings, the data transmission optimization simulation analysis of vehicle-road cooperative communication was carried out, and the distribution of transmission array elements of vehicle-road cooperative communication is shown in Figure 4.

According to the array element distribution in Figure 4, the signal transmission model for vehicle-road cooperative communication was constructed, and the output time series of vehicle-road cooperative communication data was obtained by taking the input signal-to-noise ratio of -10 dB , -5 dB , and 0 dB , respectively, as shown in Figure 5.

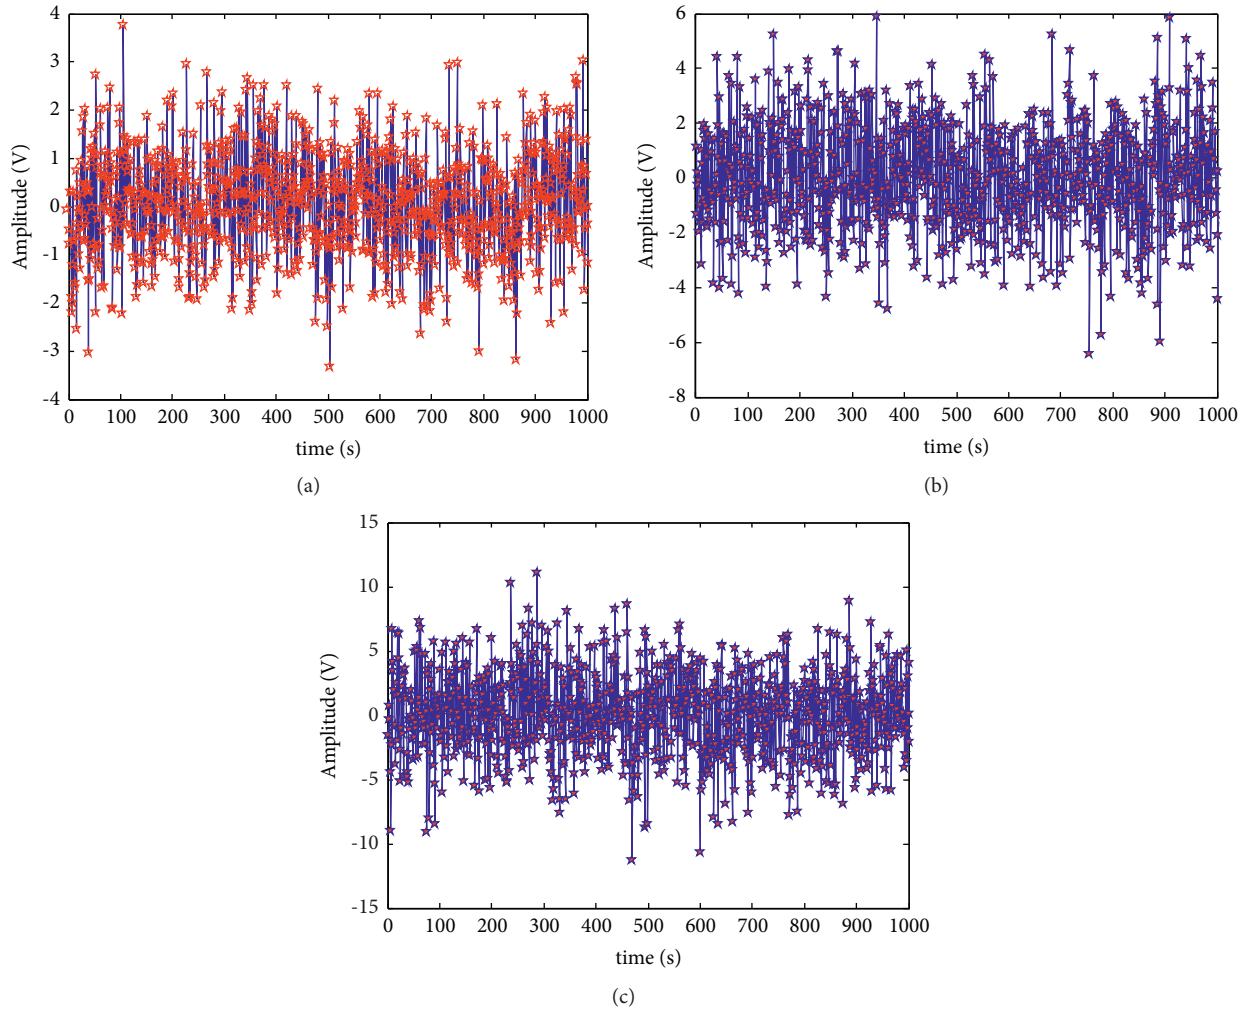

FIGURE 5: Output time series of vehicle-road cooperative communication data. (a) Transmission data sample 1 (SNR=0 dB). (b) Transmission data sample 2 (SNR=-5 dB). (c) Transmission data sample 3 (SNR=-10 dB).

FIGURE 6: Data clustering results.

With the output time series of vehicle-road cooperative communication data shown in Figure 5 as a sample, the data were clustered. The clustering results are shown in Figure 6.

According to analysis of Figure 6, the method proposed in this paper has good clustering and strong segmentation detection ability. On this basis, the data transmission is realized, and the data transmission rate and bit error rate are tested. Data transfer rate is one of the important technical indicators to describe the data transmission system. It refers to the speed of information transmission on the communication line and the number of bits transmitted in unit time (usually one second). Ser (symbol error rate) is an index to measure the accuracy of data transmission within a specified time. $Ser = \text{error code in transmission} / \text{total number of transmitted codes} * 100\%$ [1]. If there is bit error, there is bit error rate. In addition, the bit error rate is also defined as the frequency used to measure the occurrence of errors. The research of bit error rate under specific conditions is of great

FIGURE 7: Bit error rate comparison.

FIGURE 8: Comparison of data transmission rate.

significance to enhance the performance of wireless communication system and improve the quality of data transmission. The comparison results are shown in Figures 7 and 8. Through the analysis of the results in Figures 7 and 8, the bit error rate of the method proposed in this paper is maintained at about 0.05, the data transmission rate is above 0.8, and the data transmission rate continues to improve, most of which remain above 0.95. The bit error rate of BPSK and PTRM methods is above 0.1, and the data transmission rate of PTRM method is below 0.7. The results show that this method has strong anti-interference ability for the data transmission of vehicle-road cooperative communication, with low communication bit error rate, small end-to-end delay, high data transmission rate, high stability, and high accuracy.

5. Conclusion

The data transmission control model for vehicle-road cooperative communication is designed, which is used to improve the stability of fast data transmission of vehicle-road cooperative communication based on channel equalization adjustment. Accordingly, a fast data transmission method of vehicle-road cooperative communication based on the clustering algorithm is proposed in this paper. The single copy routing algorithm SimBet is used to reorganize the data transmission channel model for vehicle-road cooperative communication, and the data transmission channel model is thus constructed. The matched filter detection algorithm is used to realize the anti-interference design of signal transmission. According to the symbol characteristic distribution of the vehicle-road cooperative communication channel, the band interval equalization method is used to realize the segmented equalization control of the vehicle-road cooperative communication data transmission, and the channel equalization model is designed. The K-means clustering algorithm is used to carry out the coordinated adjustment to data packets during the rapid data transmission of the vehicle-road cooperative communication. According to the attenuation of communication network data transmission bandwidth, the optimal distribution interval sampling of vehicle-road cooperative communication data time series is carried out so as to improve the stability of data transmission. The test shows that the method proposed in this paper has a low bit error rate, with bit error rate kept at about 0.05, and has high data transmission rate and good stability [13].

With the establishment and perfection of social market economy, China has made changes to the disadvantages of farmers' vocational education system, such as singleness, backward educational means, and backward levels. Compared to traditional forms of farming, problems related to lack of farming expertise, poor scientific and technological awareness, and weak labor skills are analyzed by applying big data mining technology to retrieve key issues in order to establish a professional education system. Data mining can meet the needs of farming knowledge and rapidly develop into an automatic information farming model, which is an effective way to maximize and enhance professional knowledge. The establishment of a professional education system will train most scientific research members and further enhance diversified labor productivity. The experimental summary of this paper is as follows: (1) the relevant data need to be predicted before and after, the predicted experimental data will effectively improve students' grades, which is beneficial to the development of practical teaching, and the pretreatment stage plays a substantial role. (2) Among the three algorithms, the adaptive function of genetic clustering algorithm is obviously better than the other two algorithms, and the adaptive curve is relatively stable. (3) The comprehensive assessment of the course divides students into three categories: poor students, medium students, and excellent students, among which poor students account for 30%, medium students account for 50%, and excellent students account for 20%. (4) The standardization of the education system has brought users a good learning mechanism, in which the teaching resources have been strengthened, and users have very high satisfaction with the evaluation of the whole system.

1. Introduction

Farmers' vocational education system is established on the level of economic system, which adapts to the development of market economy and will improve agricultural development economy. Adapt to the basic conditions of taking rural areas as the primary industry, and extend the professional technology to ideological education. The Internet plays a key and substantive role, and will adopt diversified educational models to teach farmers about planting methods. Because the allocation of teaching time in the whole period needs to be detailed, it is necessary to avoid the confusion of relevant information, which is a kind of

development and utilization of resources. Big data mining technology will retrieve and reserve the knowledge of farmers' professional education cognition, professional knowledge, technical training, and other personnel engaged in agricultural activities. School-running modes and means should be diversified, and school-enterprise cooperation, rural service, and other educational concepts serving the people should be implemented to run schools. This paper summarizes the innovation status of the pilot counties of new professional farmers and puts forward the theory of establishing and perfecting the policy system and giving full play to the role of the market [1]. In view of the confusion of the concept of new professional farmers, this paper re-

examines the basic concept and connotation of the times of new professional farmers [2]. This paper expounds the connotation and realistic needs of new-type professional farmers and the cultivation experience of foreign professional farmers, and puts forward some supporting policies and measures for perfecting the cultivation of new-type professional farmers [3]. Strengthen the policy orientation of cultivating new professional farmers, and construct a new professional farmer cultivation system that embodies the concept of lifelong learning [4]. The meaning of professional farmers: New professional farmers have a broad and narrow distinction, and have a more conscious sense of responsibility and broader responsibility requirements [5]. On the issue of cultivating new professional farmers, we can learn from the practice of the USA and introduce practical laws and regulations [6]. Vigorously strengthen system construction, promote the integration of industrial chain, and strengthen the education and training of agricultural practitioners [7]. Construct flexible practical curriculum system, implement flexible talent training scheme, and explore practical teaching assessment methods with vocational education characteristics [8]. This paper discusses the characteristics of vocational education with multiple purposes and comprehensive contents, and cultivates new teaching forms [9]. A practical teaching system suitable for agriculture and forestry majors has been established, which enriches and expands students' practical skills [10]. Based on the analysis of China's modern agricultural development perspective, this paper puts forward some suggestions on how to build a platform and other aspects of the reform of the training mode of agriculture-related professionals in secondary vocational schools [11]. This paper expounds how the experimental teaching demonstration center can better serve the experimental teaching and the cultivation of innovative talents, and give full play to the radiation role of the experimental teaching demonstration center [12]. In-depth thinking on the curriculum of agriculture-related majors provides scientific ideas for the development of rural secondary vocational education [13]. To better cultivate students' practical ability and innovative and entrepreneurial ability, we should carry out practical teaching reform from the aspects of teaching mode and teaching team [14]. Taking individualized experimental teaching as the content, the practical teaching system of microbiology is constructed to meet the individualized needs of different individuals [15].

2. Theoretical Overview of Big Data Mining Technology

Big data mining technology extracts useful information from data sets and makes use of it, which is expressed in the form of rules, concepts, laws, and patterns. It can effectively help decision-makers to analyze the current situation, find hidden relationships, and then predict possible behaviors. The basic process is shown in Figure 1.

The whole process is a continuous feedback process. For example, if a bad extraction is found in the process, or the expected results are not achieved, it is necessary to start over.

There are two influencing factors in quality selection: first, whether the effectiveness of its products can be brought into play in this process, whether key factors can be extracted, and whether it can be applied in the actual situation; second, if there are errors or improper options, the conversion is unsuccessful, which will depend on the goodness of the extraction results.

2.1. A Survey of Clustering Algorithms. Clustering is an easy-to-understand way to gather related activities. Through the research and analysis of things, people can recognize related laws. There are also small classifications in clustering projects. Classification is to classify the regular characteristics known in advance, and other categories are the results of human analysis and research. In biology, cluster analysis can be used to deduce the related habits of plants and animals, analyze genes, and obtain inherent survival rules. Correlation calculation can be roughly divided into three categories: classification of fuzzy relation, fuzzy algorithm of objective function, and fuzzy algorithm based on neural network.

Partition clustering refers to dividing related combined data sets into n groups, which makes the objective function partition level smaller. Hierarchy refers to merging or splitting related passing objects until all conditions are met. Strictly implement the conditions of partition, people can grasp the key points when dealing with problems, and each can reflect the actual problems, thus becoming the mainstream research of cluster analysis and making use of it.

2.1.1. K-Means Clustering Algorithm. K-means is the most classical clustering algorithm. Firstly, K objects are randomly selected, and each object represents a core. According to the distance between cores, similar type characteristics are assigned to one class for each subject. They are summarized as follows.

Nonlinear programming problem [16]: The classification algorithm is as follows:

$$\begin{aligned} \min J(W, P) &= \sum_{i=1}^k \sum_{j=1}^n d^2(x_j, p_i), \\ \text{s.t. } \omega_{ij} &\in \{0, 1\}, 1 \ll i \ll k, 1 \ll j \ll n. \end{aligned} \quad (1)$$

Among them,

$$W = [\omega_{ij}]_{k \times n}. \quad (2)$$

W is the partition matrix, which indicates that J samples belong to and do not belong to Class I , P is the cluster center, and D is the adaptation degree. The specific process is as follows:

Input: The number of clusters contains n object data sets.

Output: The value of the cluster.

The algorithm has good extensibility, and the difficulty of the algorithm can calculate the core quality results according

FIGURE 1: Basic process of data mining.

to the number of clusters generated in advance. His shortcomings are that we must realize the results of understanding spherical clusters, but also consider the choice of initialization, so as to achieve the optimal processing. Secondly, the sensitive response of noise to the algorithm is very strong.

2.1.2. Fuzzy C-Means Clustering. Fuzzy C-means (FCM) algorithm is an optimization algorithm based on K-means algorithm by introducing fuzzy matrix and dividing it. The objects considered in practice have not strict attributes, so they must be in the classification algorithm of fuzzy clustering. The algorithm is described as follows:

Mathematical programming problem [17] formula is as follows:

$$\begin{aligned} \min J(W, P) &= \sum_{i=1}^k \sum_{j=1}^k (\omega_{ij})^m, d^2(x_j, p_i), \\ \text{s.t: } \omega_{ij} &= \epsilon [0, 1], 1 \leq i \leq k, 1 \leq j \leq n, \\ \sum_{i=1}^k \omega_{ij} &= 1, 1 \leq j \leq n, \\ 0 < \sum_{i=1}^k \omega_{ij} &\leq n, 1 \leq j \leq n, \end{aligned} \quad (3)$$

where m represents the weighting index, and the algorithm is to find the fitness degree d of clustering center. Euclidean distance [18] formula is

$$d^2(x_j, p_i) = \left(\sum_{s=1}^l x_j(s) - p_i(s) \right)^{1/2}. \quad (4)$$

In order to realize the clustering center P of the minimum membership matrix of the objective function $J(W, P)$, it is necessary to cluster the fuzzy C of the mean value. The optimal solution of the objective function is the solution of the minimum value; that is, the center and membership degree are updated as follows:

$$\begin{aligned} \omega_{ij} &= \frac{1}{\sum_{c=1}^k (d_{ij}/d_{cj})^{2/(m-1)}}, \\ p_i &= \frac{\sum_{j=1}^n \omega_{ij}^m x_j}{\sum_{j=1}^n \omega_{ij}^m}. \end{aligned} \quad (5)$$

According to the above conditions, C-means can be modified repeatedly to achieve central clustering and

membership matrix. The specific algorithm flow is as follows in Figure 2.

Fuzzy C-means algorithm is a popular algorithm nowadays, which is not only simple, but also fast, because it has a fairly perfect theoretical system; secondly, it can be applied in many wide fields as a simple practical tool. However, there are still some shortcomings, such as sensitivity to initial points and local optimal clustering results, and improved points can be divided into any point and any class of different degrees of clustering.

2.2. Genetic Algorithm. Genetic algorithm is a search method with self-adaptation and organization ability, which draws lessons from the principles of natural evolution and development of biology. Its principle is that each individual has its corresponding fitness value, which can be used to measure the quality of an individual. By imitating the principle of survival of the fittest of animals and plants in nature, the classification is carried out according to the fitness value. Individual crossover operation is to form new individuals through the combination of individuals, so as to form excellent individuals, which is similar to the process of gene selection.

The general working steps are as follows:

- (1) The input parameter set is transformed into bit string structure.
- (2) Defining fitness function.
- (3) Confirming genetic strategy.
- (4) Calculating fitness value.
- (5) Optimize the operation to generate the next stage group.
- (6) Output decoding and return to optimization operation again; in order to understand the unique deterministic index of individual survival chance selection of population, its fitness value is non-negative, and the larger the result, the better. For a given optimization problem, the evaluation of the objective function is also non-negative, and the transformed coordinate direction is a positive correlation direction. This shows that the encoding of the initial population has a direction, different individual spaces have their own patterns, and its theory is rotation and gambling selection.

2.2.1. Genetic Clustering Algorithm. Genetic clustering algorithm divides all data elements corresponding to sample codes into a category, and this function is defined as

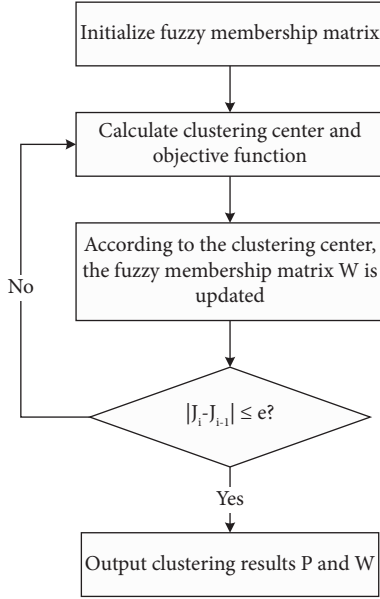

FIGURE 2: Basic flow of fuzzy C-means algorithm.

Euclidean distance, which can be randomly generated and obtained. Genetic operation can find the global optimal solution without the influence of outliers, which requires large data, more classifications, faster convergence, and stronger practicability. Its function expression is as follows: Adaptation function [19] is

$$\begin{aligned} \min J(W, P) &= \sum_{i=1}^k \sum_{j=1}^k (\omega_{ij})^m, \\ \text{s.t. } \omega_{ij} &\in [0, 1], \\ \sum_{i=1}^k \omega_{ij} &= 1, \\ 0 < \sum_{i=1}^k \omega_{ij} &\leq n, \end{aligned} \quad (6)$$

Through the definition of objective function, the minimum value is transformed into the maximum value. That is, the formula is

$$f = \frac{1}{J(W, P)}. \quad (7)$$

It needs to expand the coding form, and real coding is to directly define animal and plant genes through parameter problems. The clustering problem directly defines the center code.

Clustering center [20] expression is

$$P = (p_1, p_2, \dots, p_k)^T. \quad (8)$$

P represents a one-dimensional vector.

Gene string [21] expression is

$$I = \{p_{11}, p_{12}, \dots, p_{1m}, \dots, p_{k1}, p_{k2}, \dots, p_{km}\}. \quad (9)$$

Next, the genetic strategy is implemented, which includes selection operator, crossover operator, and mutation operator. The Group X for which the size is defined is

$$X = \{x_1, x_2, \dots, x_n\}. \quad (10)$$

Selection probability [22] is

$$p_s = \frac{f(x_i)}{\sum_{i=1}^n f(x_i)}, i = 1, 2, \dots, n. \quad (11)$$

Individual cumulative probability [23] is

$$p_s(x_i) = \sum_{j=1}^i p_s(x_j), i = 1, 2, \dots, n, j = 1, 2, \dots, i. \quad (12)$$

When selecting, the interval is $[0, 1]$, which obeys uniform distribution. When the individual x_i with cumulative probability p_s is selected to enter the classification center, the judgment result of random number $rand$ is as follows:

$$rand \leq p_s(x_i). \quad (13)$$

This means that the operator is selected. At present, the crossover operator has the mating forms of one-point crossover, uniform crossover, and multi-point crossover. When it obeys the uniform distribution, it can choose a crossover position, and the expression result is as follows:

$$a \in \{1, 2, \dots, m-1\}. \quad (14)$$

The exchange of gene strings at this position is as follows:

$$\begin{aligned} x_1 &= \{x_{11}, x_{12}, \dots, x_{1a}, x_{2(a+1)}, \dots, x_{2(m-1)}, x_{2m}\}, \\ x_2 &= \{x_{21}, x_{22}, \dots, x_{2a}, x_{1(a+1)}, \dots, x_{1(m-1)}, x_{1m}\}, \end{aligned} \quad (15)$$

In this way, the information exchange process between genes is completed, and new gene combinations are produced.

The validity function of clustering: the main requirement of analysis is that the similarity of categories is higher and there are more categories, so it can be measured from the compactness and separation of clustering.

Compactness definition [24] is

$$comp = \frac{1}{n} \sum_{i=1}^k \sum_{j=1}^n (\omega_{ij})^2 \cdot d^2(x_j, p_i). \quad (16)$$

Definition of separability [25] is

$$sep = (d_{\min})^2 = \min \|p_i - p_j\|^2. \quad (17)$$

The validity of clustering is directly proportional to compactness and conversely inversely proportional to separability. The greater the compactness value, the higher the classification similarity and the better the effect. On the contrary, the smaller the separation value, the better the clustering effect. Therefore, the validity function is defined as

$$S = \frac{\text{comp}}{\text{sep}} = \frac{\sum_{i=1}^k \sum_{j=1}^n (\omega_{ij})^2 \cdot d^2(x_j, p_i)}{n \min \|p_i - p_j\|^2}. \quad (18)$$

As a result, it is obvious that the maximized effectiveness S corresponds to the minimized comp, and the summary is the minimized objective function J . The requirement of analysis effectiveness is that the interior of classification is as similar as possible, and its exterior needs differentiation, which is to realize effective analysis of results by measuring the size of index.

3. Application of Algorithm Feature Module

Through the previous algorithm analysis, according to the strategy of genetic algorithm: selection, crossover, mutation, and a series of operations to produce new individuals, and then use fuzzy C-means for local optimization to speed up the algorithm. Its basic idea is as follows: firstly, encoding is done from randomly generated classification centers, and secondly, judging the termination condition: whether the maximum evolutionary algebra is reached. Otherwise, it is necessary to continue iteration, so that the maximum number of possible clusters can be judged, and then the transformation can be carried out. The application steps of adaptation are as follows in Figure 3.

The goal of feature analysis module is to group individuals into each group of features. Using the adaptive algorithm of this module to do system analysis can effectively reduce the irrationality of the initial cluster number, realize the evaluation and classification of individual overall features, and optimize the global parallelism of the system.

3.1. Data Collection and Preprocessing

3.1.1. Collect Data. Collect relevant useful data according to the experimental requirements, including the original historical data. For example, the curriculum content, basic information, education system, and teaching tasks included in this experiment are all original data.

3.1.2. Data Preprocessing

(1) Remove irrelevant items

If the basic features of the original data have no intuitive effect on this experimental analysis, they can be removed.

(2) Merging similar items

The practice of vocational education has relatively more performance assessment, which can be replaced by average performance in this system. There are still more practical training and theoretical study that can be comprehensively considered and merged.

(3) Numeralization

Convert the hierarchy of excellent, good, medium, and poor into 90, 75, 60, and 50 of the percentile system.

(4) Standardization

Through the unified processing in the preprocessing stage, the standard required by the data is adopted. If the corresponding table is used to express the students' course scores, the conclusions that are beneficial to the strategy analysis will be output.

3.2. Setting of Algorithm Parameters. Aiming at the problem of constructing the practical teaching system of vocational education in this paper, the clustering method is used to summarize and analyze, and the adaptive algorithm, fuzzy C-means algorithm, and genetic learning algorithm are provided. In order to reduce the workload and loss of classification and achieve global optimization, setting parameters have great influence on operation efficiency, which must be carefully considered. The setting parameters are as follows:

- (1) The maximum possible classification of data sets should not be less than 2 groups, and the best group number should be found between 2 and parameters.
- (2) The improvement of error accuracy is 0.01 by default.
- (3) Reducing the number of cycles of the algorithm and properly increasing the accuracy of parameters are helpful to improve the excellent classification.
- (4) Control the fuzzy degree of clustering process, too much classification is poor, and too little algorithm degenerates.

After setting the parameters, the system will automatically display the classification results and output relevant useful information. Set the unique parameters of genetic algorithm.

3.3. Clustering Analysis and Data Output. After clustering and parameters are set, you can view the proportion of various samples, the total scheme and variance of samples, the mean value of various types, standardization, and experimental results.

- (1) Sample ratio: Histogram, pie chart, and line chart can be used.
- (2) All kinds of variances of the total number of samples: histogram representation.
- (3) All kinds of mean values: rectangular coordinates represent abscissa courses and ordinate mean values.
- (4) The development of standardized curriculum implementation, expressed by curve.
- (5) Output the clustering results of each sample.

The output of effective function value avoids the oscillation phenomenon of genetic classification and analyzes the scores, preferred courses, and other related information of each educated person. On the one hand, the application of teaching system solves the arrangement of daily educational administration; on the other hand, it explores the effective use of clustering algorithm in student feature mining and gets good feedback.

FIGURE 3: Flowchart of adaptive fuzzy C-means clustering algorithm.

4. Construction of Farmers' Practical Teaching System in Vocational Education

4.1. Comparative Analysis of Professional Farmers' Teaching Achievements before and after Data Preprocessing. According to the educational needs of farmers, the practical courses must be carried out, and the teaching tasks related to the needs must be conducive to the absorption of knowledge. Its technical economy, marketing, rural finance, etc., are all professional courses, and the efficiency and necessity of learning are analyzed before and after the prediction of achievement data sets. The results of the combination of theory and training are shown in Figure 4.

From the results in the figure, we can know that the results of relevant data preprocessing have been significantly improved, except for the course of marketing; accounting

course is the largest increase of 12% after prediction processing, which shows that this course has increased by 10 points, which is the effective improvement of data quality and the importance of preprocessing.

4.1.1. Output the Standardized Mean Value of Practical Courses. After the end of the semester, the practical course is to judge the student's learning situation. The practical course may be agricultural experiment, the development of planting technology and sowing, which all reflect the significance of the course arrangement. The arrangement of teaching tasks is judged by the number of course sections. C1, C2, and C3 represent the three dimensions of the evaluation criteria, and the standard results under the dimensions are as follows in Figure 5.

It can be seen from the results in the figure that the standard values of dimension C1 are all greater than 0, the standard results of C2 fluctuate around 0, and the evaluation results of dimension C3 are all less than 0, indicating that there are obvious differences in the evaluation results under the three dimensions. When the evaluation system is realized, the accuracy of the evaluation index is increased, the complicated work is reduced, and the learning efficiency is improved.

4.2. The Value of Educational Curriculum Adaptation Function of Related Algorithms. From the students' adaptation to the curriculum, we can get the degree of people's love for the curriculum and the rationality analysis of the number of school years. The previous three algorithms classify similar courses for better difference and plan the teaching arrangement for the next academic year from the students' adaptation. The experimental results are as follows in Figure 6.

From the numerical curve of fitness function, it can be clearly seen that genetic clustering algorithm is obviously superior to fuzzy C-means and K-means clustering algorithm, and has strong stationarity, while the other two kinds of algorithms have oscillation phenomenon. Genetic algorithm effectively avoids the fluctuation of average grades caused by the increase of the number of courses with the increase of evolutionary algebra, which will have a good preparation for teaching arrangement.

4.2.1. All Kinds of Mean Curves after Teaching Standardization. After the standardization of the teaching system, the work will be carried out efficiently with this system, which greatly improves the teaching quality and reduces the time for students to adapt to teachers' teaching habits. The 20-session cycle course of the semester is a standardized time, which can complete the work tasks of the whole semester. The following results in Figure 7 are obtained by analyzing the scores of three types of students.

Class I belongs to the overall level of poor, accounting for 30% of the total number, and the results are not idealized; Class II belongs to the medium level of learning, which has a certain mastery of basic knowledge and needs to strengthen learning, accounting for 50% of the total number; Class III belongs to top students, with excellent grades, accurate

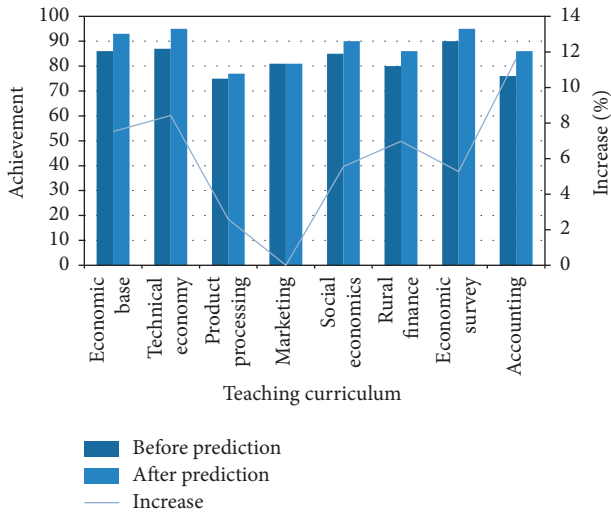

FIGURE 4: Comparative analysis of agricultural professional achievements before and after pretreatment.

FIGURE 5: Average results of curriculum standardization.

mastery of knowledge and utilization, accounting for 20% of the total. Therefore, when carrying out professional skills training, we can strengthen innovative education and make technical ability develop in a balanced way.

4.3. Construction of Farmers' Practical Teaching System Based on Genetic Algorithm. Among the above three algorithms, genetic clustering algorithm is the best judgment for students to adapt to teaching, so according to the above results, it is determined to build a system with this algorithm. Teachers and students will have relevant key problems in the whole professional practice process, so this paper discusses the system evaluation. The experimental results are as follows in Figure 8.

It can be seen from the figure that the time spent on becoming a talent is the longest 8 ms in the whole test, because becoming a talent is a stage process that cannot be judged in a hurry, and difficult analysis is only a problem

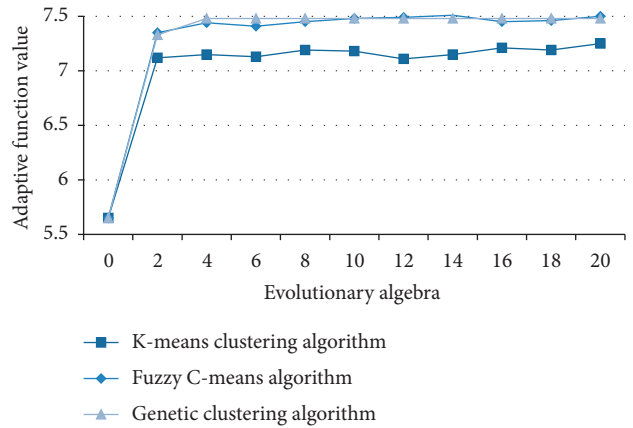

FIGURE 6: Evolutionary fitness curves of three clustering algorithms.

FIGURE 7: Average score curves of various algorithms.

FIGURE 8: Experimental results of genetic algorithm.

concept, so it takes relatively little time. The accuracy measurement under the whole algorithm mechanism is relatively stable without large fluctuation. However, the prediction accuracy needs to be improved.

FIGURE 9: Questionnaire on the construction of teaching system.

4.4. Application of Vocational Teaching System. Promoting the professional agricultural teaching system will provide farmers with a good way to know the blind spots; instead of blindly judging by previous planting experience, it now relies on standardized planting techniques. Enhance people's learning efficiency and train a large number of comprehensive talents. The survey results of user use are as follows in Figure 9.

Taking the algorithm as the theoretical basis of the whole system, through the investigation of users' reliability, satisfaction, and feedback, it is known that the feedback degree of users to the situation of UGC is the lowest 68%, which shows that the rich cultural heritage under the system lies in it. However, there are also problems that the security system has not been satisfied by users, and it needs to be optimized and improved.

5. Conclusion

Farmers' vocational education system is a complete system, which needs comprehensive analysis from all aspects and multi-angle consideration of the synergy of the whole system factors. In building a feasible education system, we should establish relevant infrastructure conditions to teach professional education for every educated person. This paper uses big data mining technology to construct the whole system, database retrieval, and the rapid construction of the whole educational administration system and applies it to educators. The dissemination of agricultural knowledge through professional education has made obvious changes in planting skills, increased income, and diversified planting. Big data mining technology has greatly improved the way of education, provided a solid theory for professional education reform, and effectively analyzed the reform system. The experimental conclusions of this paper are as follows: (1) for the introduction of educational curriculum information, fuzzy mean is introduced through clustering algorithm to optimize the processing, which overcomes the slow running

problem of educational administration system. (2) The integration of peasant education in developing courses is studied, and data mining is used to analyze the influence of various educators' courses. (3) Explore the possible difficulties and conquering points in the whole learning process, so that people can understand knowledge more clearly. (4) Through comprehensive score prediction and analysis, the loopholes and optimization points in the education system are known, and the big data model is used as the basic theory to establish and optimize the system.

Experiments and Prospects: (1) The sparsity of data quantity and the authenticity of data will affect the accuracy of its results, and the quality of data sets should be greatly improved. (2) Because of the cultivation of professional knowledge in vocational education, more teachers and students resources should be mobilized to make use of. (3) With the continuous exploration of scientific research achievements, new teaching modes will inevitably appear, which is also the premise of promoting the reform of vocational education, and the continuous optimization of its system is also the basic work in the future. (4) To adapt to the specialized education mode, farmers should be regarded as the primary productive forces, but they should also learn modern mechanical work to adapt to the progress of the times.

In order to improve the defect that the quality of English flipped classroom teaching cannot be quantitatively evaluated, an English flipped classroom teaching model based on big data learning analysis is proposed. In the English flipped classroom teaching mode, which applies the flipped classroom teaching mode, the classroom teaching links are changed, the preview feedback, joint answer and question between teachers and students, classroom teaching, and teachers' questions are taken as the key links of classroom teaching, and the teacher education and school management system are improved, so as to complete the reform of English flipped classroom teaching mode. The convolution neural network is used to extract the evaluation text features, mine the association rules of massive evaluation text data through the Apriori algorithm, determine the evaluation index of English flipped classroom teaching quality, and complete the evaluation of English flipped classroom teaching quality by using the decision tree method in big data analysis. The experimental results show that the proposed method can quantitatively evaluate the quality of English flipped classroom teaching by using the evaluation text, and the evaluation accuracy and recall rate are higher than 98%, which can realize the objective evaluation of English flipped classroom teaching quality.

1. Introduction

At present, many international conferences are communicated in English [1], and many materials are published in English. Even many letters and even broadcasts are inseparable from English. It can be seen that English is widely used [2, 3]. Therefore, in the new era of social development, English has gradually become the focus of attention and one of the important indicators of talent training in colleges and universities. In the information age, with the rapid development of information technology, on the one hand, it has brought new opportunities for college English teaching. On the other hand, it also makes college English teaching face new challenges. Therefore, it is a problem faced by major colleges and universities to establish an English flipped classroom teaching model in line with the development of the times under the background of informatization [4, 5].

Reference [6] uses the comparative method to analyze the two types of assessment: formative assessment and

summative assessment. The results show that the characteristics of formative evaluation include teachers' adaptability to the classroom and immediate feedback to teachers. As a high-risk evaluation, summative evaluation needs high standard control and safety to ensure its reliability and effectiveness. In [7], through one-on-one cooperation with speech and language therapy students, children participated in weekly activities aiming at promoting receptive and productive knowledge of 20 target words in secondary vocabulary categories. Reference [8] adopts an online format and carries out digital access through the school-oriented learning management system. Upon completion, teachers will receive a personalized report on their ability to assess teaching skills in nonuniversity teaching.

Considering that, at present, the evaluation of English flipped classroom teaching quality is mainly achieved through a small amount of data, and the evaluation results under the condition of small sample data have high limitations and one sidedness. Big data technology can

effectively improve this defect. Big data technology has transformed from sampling evaluation of English flipped classroom teaching quality to full data evaluation of English flipped classroom teaching quality. Mining teaching quality related information from massive data to improve the diversity of English classroom teaching quality evaluation [9]. Therefore, on the basis of clarifying the English flipped classroom teaching mode, this paper uses big data technology to evaluate the teaching quality of English flipped classroom.

2. Reform of English Flipped Classroom Teaching Mode

2.1. Changing Classroom Teaching Links. Under the traditional teaching mode, the low efficiency of traditional classroom teaching restricts the improvement of classroom teaching quality. At the same time, some students have relatively weak basic knowledge, weak learning ability, and low learning enthusiasm [10, 11]. In order to effectively improve classroom efficiency and improve students' knowledge level, it is urgent to reform classroom teaching. Therefore, we should change the traditional classroom teaching links. It is transformed into a teaching link of preview feedback, joint answer and question between teachers and students, classroom teaching, teachers' questions, students' oral training, classroom summary, and reflection, as shown in Figure 1.

Through preview feedback, teachers can quickly grasp the learning situation of students and help teachers explain in class. The main contents contained in preview feedback are shown in Figure 2.

First, the teacher organizes the students to have a group discussion [12], the team leader writes down the questions, and then the team leader asks the teachers. Through the above methods, the teachers can understand the students' learning situation and can also use these questions as a reference for subsequent classroom questioning and teaching. In the preview process, it is difficult for students to grasp the overall knowledge and logic, and it is inevitable that they will not fully understand the knowledge points and key points. Therefore, teachers need to check the lack of formulas, ask questions to students, make students' thinking active, and stimulate students' learning enthusiasm at the same time.

2.2. Improve Teacher Education and School Management System. The traditional teaching mode is that teachers teach according to textbooks. In the information age, teachers' teaching ability needs to be improved. At the same time, the traditional school management system is mainly managed by the school. Under the flipped classroom teaching mode [13], it not only puts forward higher requirements for teachers' ability but also puts forward higher requirements for school management.

In terms of improving the teacher education system, teachers are required to turn from the person who prepares the teaching plan to the video producer, from the lecturer on

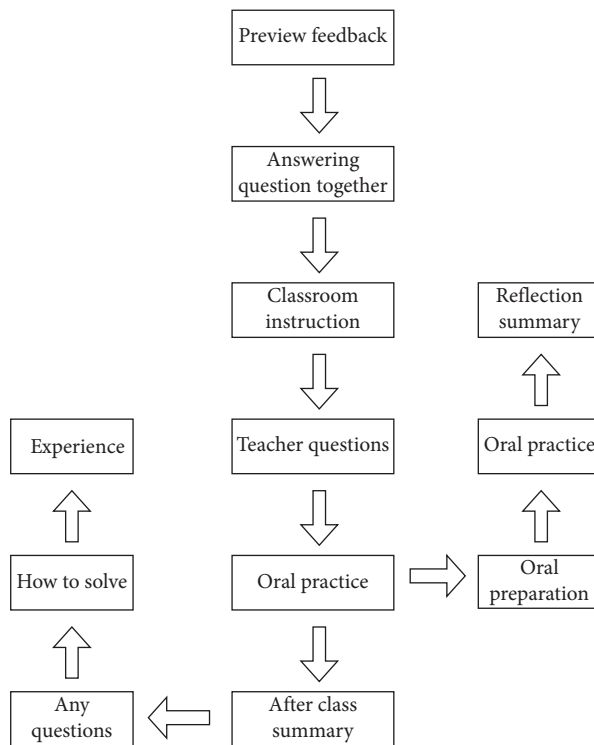

FIGURE 1: Process design of flipped classroom teaching.

the podium to the communicator among students, and from the outsider who internalizes students' knowledge to the guide in the classroom. The main teaching process of teachers in class is shown in Figure 3.

At the same time, the flipped classroom teaching mode pushes teachers and students to the front end of the network. Only by improving their ability in the information age can teachers better understand students and meet students' learning needs in the network environment [14, 15]. Through the above analysis, according to the requirements of English teaching, in order to improve the problem that the quality of English flipped classroom teaching cannot be quantitatively evaluated, the evaluation criteria of teachers' learning tasks are formulated according to Table 1.

Based on the analysis of the current school management system, parents are more dependent on the school management system. Because their right to participate in school management is limited, they will not take the initiative to fulfill their obligations to students' learning. The emergence of flipped classroom teaching mode divides the traditional teaching process into two parts, in class and after class [16, 17]; that is, the right to guide students' learning is pushed to parents. In order to better promote flipped classroom in China, innovate at the level of the school management system, tap the role of parents in the process of education and teaching, enable parents to give full play to their talents in the process of school running, and jointly promote the growth of students, so as to promote the application of flipped classroom teaching mode from the level of school management system.

3. Evaluation of English Flipped Classroom Teaching Quality Based on Big Data Technology

3.1. Evaluation Text Feature Extraction. The convolution neural network method is selected to extract the text features of English flipped classroom teaching quality evaluation. The convolution neural network automatically learns the input data features through convolution layer and pool layer. The training set is established by using the evaluation text, and all samples in the training set are marked by tags. After inputting the test dataset, the trained neural network is used to obtain the classification label of new samples [18]. Convolution neural network method not only has the characteristics of analyzing the context semantics of comment text and feature learning but also has the advantages of high noise resistance and high classification degree.

The feature structure of the evaluation text is extracted by convolution neural network, as shown in Figure 4.

As can be seen from Figure 4, the convolution neural network extraction and evaluation of text features mainly includes the following steps.

3.1.1. Data Preprocessing. Through data preprocessing, the useless comments of English flipped classroom teaching quality evaluation text are filtered, and the filtered evaluation text is divided into short sentences. Through data filtering, we can avoid noise interference in the process of evaluating the quality of English flipped classroom teaching. When using convolution neural network to classify text evaluation, it is necessary to deal with comments composed of many short essays.

3.1.2. Word Vector Training. Quantitatively transform the evaluation text, use the distribution formula word vector to represent the evaluation text, select a large-scale unsupervised method to train the distribution formula word vector so that the text that completes the quantitative transformation can reflect more grammatical information and semantics [19], and use the filtered evaluation text to realize the word vector training.

3.1.3. Model Training and Testing. Extract part of the data and set it as the training set to complete the classification training. Mark the added labels through the model, compare the labels marked by the model with the existing labels, and adjust the model parameters through the error of the comparison results.

3.1.4. Feature Extraction. The evaluation text represented by the word vector is input into the convolutional neural network, and the convolutional neural network outputs the corresponding label [20, 21]. Annotate the part of speech of the evaluation text, extract the nouns in the evaluation text, and obtain the feature word set. The tags forming the feature words are the same as those in the evaluation text.

3.2. Big Data Mining Technology. The same evaluation text contains multiple characteristic words, and the final evaluation index of English flipped classroom teaching quality needs to be determined by cluster analysis. Big data mining technology is to mine association rules with minimum confidence and minimum support in massive data [22]. Big data mining technology mining association rules mainly includes two parts: (1) mining frequent itemsets with minimum support in transaction database; (2) mining frequent itemsets used to generate association rules for English flipped classroom teaching quality evaluation. The Apriori algorithm is an important algorithm for mining frequent itemsets in data mining algorithms. This algorithm is used to obtain itemsets with support higher than the minimum support. The Apriori algorithm obtains $K+1$ itemsets by using K itemsets through a layer-by-layer search method.

B represents the transaction database, $I = \{I_1, I_2, \dots, I_m\}$ represents the itemset in the database, and I_i represents the elements in the itemset. $W = \{T_1, T_2, \dots, T_n\}$ and T_i , respectively, represent the transaction set and the elements contained therein and satisfy $T_i \subseteq T$. Identify all transactions T with separate labels. The length or dimension of itemset in massive data indicates the number of elements contained in the itemset. When the number of elements in the itemset is K , it indicates that the itemset is a K -itemset. Set up a random English flipped classroom teaching quality transaction database B and mine its frequent itemsets. The process is as follows:

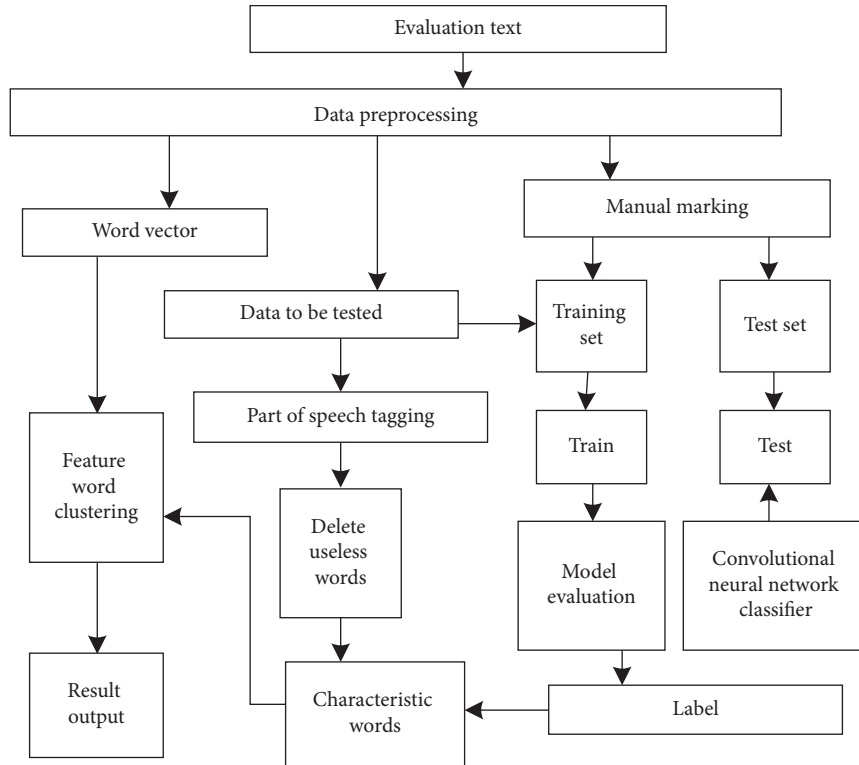

FIGURE 4: Structure diagram of evaluation text feature extraction.

- (1) Calculate all 1 itemsets, represented by C_1 , and search all common 1 itemsets greater than or equal to the set minimum support, represented by L_1 .
- (2) Use the common 1 itemset to obtain the candidate 2 itemsets, which are represented by C_2 . Search for all 2 itemsets greater than or equal to the set minimum support from the obtained 2 itemsets, which are represented by L_2 .
- (3) According to the above process, use the obtained common 2 itemsets to obtain the candidate 3 itemsets, which are represented by C_3 . Search for all three itemsets greater than or equal to the set minimum support from the obtained three itemsets, which are represented by L_3 .
- (4) Repeat the above process until higher dimensional frequent items cannot be obtained, and terminate the iteration.

It can be seen from the above process that the Apriori algorithm obtains the final frequent itemset through continuous iteration [23], and too many candidate sets are formed in the search process, which has high complexity and low operation efficiency. The Boolean matrix is introduced into the Apriori algorithm to make it suitable for massive big data mining. The massive database of big data is prone to excessive memory. The database needs to be segmented, and the segmented database will be scanned in segments. Suppose that there are N transaction databases that complete the

segmentation, which are represented by $\{B_1, B_2, \dots, B_N\}$. It can be seen that the number of Boolean matrices is N , which corresponds to the transaction database that completes the segmentation one by one. The process of obtaining frequent itemsets using the Apriori algorithm optimized by the Boolean matrix is as follows:

- (1) Set the number of copies of massive transaction database and determine the size of different copies. Initialize the loop variable to 1 and set the minimum support of the Apriori algorithm.
- (2) Read B_i in the transaction database and map it to the Boolean matrix R_i .
- (3) Calculate the local minimum support of R_i for B_i using formula (1):

$$\text{mins}_i = \min \frac{B_i}{|B|} \quad (1)$$

In formula (1), $|B_i|$ and $|B|$ represent the number of elements in the transaction database and the number of elements in the massive transaction database, respectively.

Obtain the corresponding row vector of the frequent itemset in B_i in the Boolean matrix R_i through the above formula, save the row vector obtained by searching, release the memory space of the Boolean matrix R_i update dataset, and obtain the updated matrix R_i .

- (4) Set $i = i + 1$, and when the $i \leq N$ condition is met, return to step (2) to repeat the iterative calculation. Otherwise, go to step (5).
- (5) Recombine the Boolean matrix R_i corresponding to all frequent itemsets in the transaction dataset B_i , and establish a new Boolean matrix, which is represented by $R = (R_1, R_2, \dots, R_N)^T$. Thirdly, search the minimum support of the new Boolean matrix, determine the corresponding row vector of the frequent itemset of the massive transaction database B , and obtain the frequent itemset that can finally evaluate the quality of English flipping classroom teaching.

3.3. *Realize the Evaluation of English Flipped Classroom Teaching Quality.* There are many commonly used algorithms for data mining, such as genetic algorithm, clustering algorithm, and Apriori algorithm [24]. Combined with the characteristics of English flipped classroom teaching quality evaluation, this paper uses the ID3 decision tree method to complete the data mining of teaching evaluation.

Decision trees can classify a large amount of data purposefully so as to obtain valuable potential information. The decision tree uses the sample attribute as the node, and the attribute value is the branch tree structure. The root node is the attribute with the largest amount of information in all samples, the middle node is the attribute with the largest amount of information in the root node, and the leaf node is the sample category value. In the ID3 algorithm [25], the entropy concept in information theory is applied to complete the selection of node attributes, and the decision tree is constructed through the attribute with maximum information gain, which ensures that the decision tree has the minimum number of branches and minimum redundancy.

The information entropy can be expressed as formula (2):

$$I(m) = \log_2 p(m_i). \quad (2)$$

In formula (2), $p(m_i)$ represents the proportion of samples with category m_i in the total samples. The information in the decision tree is binary coded [26], so the logarithm function is based on 2.

The conditional entropy of attribute A can be calculated by formula (3).

$$E(A) = p(m_i|v_j) \log_2 \left(\frac{1}{I(m)} \right). \quad (3)$$

In formula (3), $p(m_i|v_j)$ is the conditional probability of category m_i when the value of attribute A is v_j . The information gain of attribute A is calculated by formula (4):

$$\text{Gain}(A) = I(m)E(A). \quad (4)$$

In formula (4), $\text{Gain}(A)$ represents the coding information obtained from the branch of attribute A ; that is, the value of A causes the expected compression of information entropy.

To sum up, the ID3 algorithm realizes attribute selection through information gain. Therefore, the use of gain rate can be expressed as formula (5):

$$\text{Gain Ratio}(A) = \frac{\text{Gain}(A)}{\text{Split Info}(A)}. \quad (5)$$

Suppose D represents the training sample set, A represents an attribute in D , A contains n noncoincident values $\{v_1, v_2, \dots, v_n\}$, and D is divided into n subsets D_1, D_2, \dots, D_n ; then, the value of the training sample in D_i in A can be expressed as v_1 . The process of decision tree mining is to automatically construct a decision tree from the data of the training set through the above method and then judge any instance according to the obtained decision tree.

Taking the six evaluation contents in Table 1 as the sample data of evaluation indicators and training, the number of teachers participating in the evaluation is 1~6 to evaluate the quality of English flipped classroom teaching, and the results are divided into five grades as follows:

- (1) A: excellent, with a score of 90–100.
- (2) B: good, with a score of 80–89.
- (3) C: medium, with a score of 70–79.
- (4) D: pass, with a score of 60–69.
- (5) E: fail, score below 60.

The evaluation results of teachers are shown in Table 2.

It can be seen from Table 2 that the information entropy required by the sample can be expressed as formula (6):

$$I(S) = \frac{1}{6} \log_2 \left(\frac{1}{6} \right). \quad (6)$$

The information entropy of each attribute can be obtained through formula (6). The attribute with the largest information gain is taken as the node test attribute. The branch of the corresponding attribute value is constructed downward from the root node, and the ID3 decision tree algorithm is continued to be used for further division. If the path from the root node to the current node contains all attributes, the algorithm ends, and the whole process of comprehensive evaluation is completed.

4. Experimental Test

In order to verify the effectiveness of the designed English flipped classroom teaching quality evaluation model based on big data analysis, a teacher's English flipped classroom teaching course is selected as the test object, and the main data comes from the intelligent English flipped classroom teaching system. A total of 8795 people attended the English flipped classroom teaching. After the students completed the class, they did feedback on the evaluation text, deleted the useless evaluation text and garbage evaluation text, and collected a total of 8564 effective evaluation texts. The experimental tests were carried out by using the methods of papers [6, 7].

TABLE 2: Teacher evaluation results.

Number	Q11	Q21	Q31	Q41	Q42	Q43	Total
1	B	B	A	B	A	B	Good
2	B	A	B	B	B	A	Good
3	B	B	B	B	B	B	Good
4	C	B	C	C	C	C	Secondary
5	B	C	C	C	B	B	Secondary
6	A	A	A	B	A	A	Excellent

4.1. Model Inspection. The grid search method is selected to determine the hyperparameters. The results of the determined convolution neural network hyperparameters for extracting and evaluating text features are shown in Table 3.

According to the parameters determined in Table 3, the convolutional neural network is trained and tested by the tenfold cross-validation method. The convergence of the convolutional neural network is shown in Figure 5.

As can be seen from the experimental results in Figure 5, the convolutional neural network is used to extract the features contained in the evaluation text in this method, and the rapid convergence can be achieved only after about 15 times of network training. It shows that the convolutional neural network selected in this method has a high convergence speed and can improve the operational performance of the English flipped classroom teaching quality evaluation model.

4.2. Algorithm Performance Test. In order to make the comparative data more accurate, the comprehensive evaluation value given by several teaching supervision experts in many lectures is used as the verification basis of the accuracy of this method. The comparison data between the evaluation results obtained by using this method and the comprehensive evaluation results of several expert groups are shown in Table 4.

From the data in Table 4, it can be concluded that the evaluation results given by this method are close to those of the expert group. Therefore, it can be seen that the system is a feasible and reasonable teaching quality evaluation system.

The expert evaluation method is used as the standard to evaluate the quality of English flipped classroom teaching. This method is used to evaluate the evaluation accuracy and recall rate of English flipped classroom teaching quality in different evaluation text sizes. In order to intuitively show the evaluation effect of this method, this method is compared with the models in [6] and [7]. The comparison results are shown in Table 5.

From the data in Table 5, it can be concluded that using this method to evaluate the quality of English flipped classroom teaching has high evaluation accuracy and recall rate for different evaluation text sizes. Accuracy and recall rate are important evaluation indexes to evaluate the performance of machine learning methods. The evaluation accuracy and recall rate of this method are higher than 98%, which can meet the needs of big data English flipping classroom teaching quality evaluation. The evaluation accuracy and recall rate of the other two models decrease with

TABLE 3: Superparameter setting.

the increase of the number of evaluation texts, indicating that the other two methods cannot adapt to massive data processing, and the operation level decreases when the amount of data increases.

4.3. Actual Verification. In the evaluation, the designed model text scoring standard is adopted, and the full score is 25 points. One class is selected to apply the teaching mode of this paper, and the remaining two classes are selected to adopt the traditional teaching mode. The average composition score data of the three classes are shown in Table 6.

According to the average composition score data of the three classes in Table 6, the average composition score of the experimental class is significantly higher, the average composition score of the control class 2 is in the middle, and the average composition score of the control class 1 is the lowest. It shows that the designed flipped classroom teaching mode of English writing is the most effective and can improve students' composition scores.

The comparison results of students' inquiry ability after learning the three methods are shown in Figure 6.

It can be seen from Figure 6 that the students' inquiry ability improved more after applying the design teaching mode, which is better than that of the students applying the comparative method.

The comparison results of students' innovation ability with the three methods are shown in Figure 7.

It can be seen from the analysis of Figure 7 that the innovation ability of students applying the design teaching mode is much higher than that in the past because, under the

1000	98.76	98.45	88.75	85.75	86.63	84.72

TABLE 6: Average composition score data of three classes.

Composition	Average composition score		
	Experimental class	Control class 1	Control class 2
One	22	15	18
Two	23	16	17
Three	24	14	19
Four	22	15	18
Five	22	14	17

FIGURE 6: Comparison of students' inquiry ability.

FIGURE 7: Comparison of students' innovation ability.

FIGURE 8: Comparison of students' application ability.

design teaching mode, students can experiment by themselves and strengthen their communication with teachers, so as to improve students' innovation ability. After the application of comparative teaching mode, although the students' innovation ability has improved, the improvement in innovation ability is not high.

The comparison results of students' application ability after applying the three methods are shown in Figure 8.

It can be seen from Figure 8 that the application ability of students after applying the traditional two systems is improved less, while the application ability of students after

applying the system designed this time is improved higher, which shows that students have accumulated small phenomena related to English in life and can connect their learned knowledge with practice.

The comparison results of students' satisfaction after applying the three methods are shown in Figure 9.

As can be seen from Figure 9, students' satisfaction is greatly improved after applying the designed English flipped classroom teaching mode because, in the flipped classroom teaching mode, students become the leaders in the classroom and stimulate students' curiosity. Although the satisfaction

FIGURE 9: Comparison of students' satisfaction with teaching mode.

of students applying the comparative method has improved, it is lower than that of students applying the teaching mode designed this time.

Therefore, the above experiments can prove that the designed English flipped classroom teaching model can improve students' inquiry ability, innovation ability, and application ability, and students are more satisfied with the teaching model.

5. Conclusion

English flipped classroom teaching quality has high subjectivity, which is difficult to accurately quantify as a qualitative problem. The big data mining method is used to mine the massive data related to English flipped classroom teaching, determine the evaluation index of English flipped classroom teaching quality, and obtain the quantitative scoring results by using the determined evaluation index of English flipped classroom teaching quality. The use of big data technology provides theoretical support for the accurate evaluation of English flipped classroom teaching quality. Through the experimental verification, the evaluation accuracy and recall rate of the evaluation method studied are higher than 98%, which can realize the accurate evaluation of English flipped classroom teaching quality.

The detection and classification of histopathological cell images is a hot topic in current research. Medical images are an important research direction and are widely used in computer-aided diagnosis, biological research, and other fields. A neural network model based on deep learning is also common in medical image analysis and automatic detection and classification of tissue and cell images. Current medical cell detection methods generally do not consider that the yield is affected by other factors in the topological region, which leads to inevitable errors in the accuracy and generalization of the algorithm; at the same time, the current medical cell imaging methods are too simple to predict the classification markers, which affect the accuracy of cell image classification. This study introduces the concepts of two kinds of neural networks and then constructs a cell recognition model based on the convolution neural network principle and staining principle. In the experimental part, we developed three groups of experiments using the same equation as the experiment and tested the best cell recognition model proposed in this study.

1. Introduction

In this study, we propose a study to train neural network simulators using biosphere flux data collected by EURO-FLUX project to provide spatial and temporal estimates of European forest carbon flux on the continental scale. The novelty of this method is that the neural network structure is constrained and parameterized using traffic data, and a limited number of input driving variables are used [1]. In this study, a hybrid intelligent system based on past financial performance data is proposed, which combines a rough set method with neural network to predict enterprise failure. By comparing the traditional discriminant analysis and neural network method with our hybrid method, the effectiveness of this method is verified [2]. The artificial neural network method is used to predict short-term load of large-scale energy system. Different neuron combinations were used to test networks with one or two potential layers, and the prediction errors of the results were compared. When the neural network is divided into different load patterns, it can give a good load forecast [3]. The improved criteria of WG

and MPA are established and verified using the artificial neural network and traditional methods. A multicenter study was conducted on 240 WG patients and 78 MPA patients. Appropriately trained neural networks and CT can distinguish these diseases and perform better than LR [4]. The support vector machine (SVM) and artificial neural network (ANN) systems are applied to the drug/non-drug classification problem as an example of the binary decision-making problem in the early virtual compound filtering. The results show that compared with the artificial neural network, the solution obtained by support vector machine training has better robustness and smaller standard error [5]. In this study, a new method based on the artificial neural network is proposed to identify MHCII binding cores and binding affinities simultaneously. A new training algorithm is used for training, which allows the correction of deviations in training data caused by redundant binding kernel representations [6]. This study introduces the implementation of FANN, which is a fast artificial neural network library written by ANSIC. The results show that the speed of FAAN library is obviously faster than other libraries on the system

without floating-point processor, while the performance of FANN library on the system with floating-point processor is equivalent to other highly optimized libraries [7]. The purpose of this study was to determine whether circulating tumor cells were present in the blood of patients with large operable or locally advanced breast cancer before and after neoadjuvant chemotherapy and before and after preoperative neoadjuvant chemotherapy. After research, we concluded that in patients receiving neoadjuvant chemotherapy, CELLSEARCH system can detect circulating tumor cells in a low truncation range of 1 cell. Detection of circulating tumor cells is not associated with primary tumor response, but is an independent prognostic factor for early recurrence [8]. The pathological TNM stage is the best factor to judge the prognosis of non-small cell lung cancer. After isolating NSCLC patients by the size of epithelial tumor cells, cytological analysis was used to evaluate the presence of CTC in surgical patients [9]. In this study, a microbial electronic manipulation and detection lab-on-a-chip based on a closed dielectrophoresis cage combined with impedance sensing is proposed. This method is suitable for implementation in integrated circuit technology, which can not only operate and detect a single unit but also reduce the scale of the system [10]. Circulating tumor cells have long been considered to reflect the invasiveness of tumors. Therefore, many people have tried to develop analytical methods to reliably detect and enumerate CTCs, but such analytical methods have not been available until recently. This article reviews CTCs, especially the technical problems of its detection, the clinical results obtained so far, and the future prospects [11]. To determine the clinical application of immunoglobulin heavy chain gene rearrangement identification in multiple myeloma tumor cell detection, we investigated 36 consecutive newly diagnosed patients intending to receive high-dose chemotherapy in a research program. There is no consistent relationship between bone marrow MRD status and clinical course, and patients with negative PCR also have early recurrence [12]. Using yeast cells as a model system, a piezoelectric lead zirconate titanate-stainless steel cantilever beam was studied as a real-time cell detector in water. Under the experimental conditions, when the cell diffusion distance is less than the linear size of the adsorption area, the resonance frequency shift rate has a linear relationship with the cell concentration, and the resonance frequency shift rate can be used to quantify the cell concentration [13]. Although optical cell counting and flow cytometry devices have been widely reported, there is usually a lack of sensitive and effective nonoptical methods to detect and quantify large surface area cells attached to micro-devices. We describe an electrical method based on measuring cell count changes in the conductivity of the surrounding medium due to ions released by immobilized cells on the inner surface of the microfluidic channel [14]. Background of the diagnostic value and prognostic significance of circulating tumor cell detection in bladder cancer are still controversial. We conducted a meta-analysis to consolidate the current evidence of using CTC detection methods to diagnose bladder and other urothelial cancers and the association between CTC-positive and advanced and

remote diseases. Conclusion of CTC evaluation can confirm the diagnosis and differential diagnosis of bladder cancer [15].

2. Artificial Neural Network

2.1. RBF Neural Network. RBF neural network belongs to a kind of radial neural network. When there are enough nerve cells in the hidden layer, it can be designed as any continuous function infinitely. Local approximation, classification, and pattern recognition are all very good, and the learning and teaching time of the algorithm is very short. The mapping relation in RBF neural network is expressed as $f(x): R_n \rightarrow R_o$, as shown as follows:

$$y = f(x) = \sum_{i=1}^c \omega_i \varphi(\|x - c_i\|, \sigma_i) = \sum_{i=1}^c \omega_i \exp\left(-\frac{\|x - c_i\|^2}{2\sigma_i^2}\right), \quad (1)$$

where C is the number of neurons in the potential layer of the network, c_i is the center of radial basis function of each potential layer, the width is σ_i , and ω_i is the i th activation function and exit neuron. The neural network of RBF must be trained and learned to determine the radial basis center c_i , width σ_i , and weight ω_i between the potential layer and the output layer of neurons in each potential layer, to determine the mapping relationship between inputs.

To ensure that each activation function is not peaceful or too sharp, the activation function of latent neurons is regarded as a fixed radial basis function, and the center c_i of latent radial basis function is randomly selected from training. The radial basis function is defined as follows:

$$\varphi(x, c_i) = \exp\left(-\frac{k}{d_{\max}} \|x - c_i\|^2\right), \quad (2)$$

where K represents the number of neurons in the hidden layer and d_{\max} is the maximum distance between the two centers, and this formula shows that the width of neurons in the hidden layer is constant.

2.2. BP Neural Network. BP neural network is a multilayer feedback neural network with inverse error transmission. The learning process can be divided into signal transmission and error reverse transmission. A schematic diagram of BP neural network reverse transmission algorithm is shown in Figure 1.

From this, it can be deduced that the weight correction values are shown as follows:

$$\Delta\omega_{ji}(n) = \eta \times \delta_j(n) y_i(n), \quad (3)$$

$$\delta_j(n) = (d_j(n) - y_j(n)) \varphi_j \left(\sum_{i=0}^m \omega_{ji}(n) y_i(n) \right), \quad (4)$$

where M represents all the inputs that affect neuron J , η is the inverse error rate of learning, $\delta_j(n)$ is the local gradient, $y_i(n)$ is the output of neuron I , and Ψ is the activation function.

FIGURE 1: Schematic diagram of BP neural network reverse algorithm.

3. Research on Cell Image Detection

3.1. Construction of Cell Image Detection Network Model

3.1.1. Principle of Convolution Neural Network. The convolution neural network is based on the mathematical mapping in this study. It can learn the same mapping ability as this expression independently. It specializes in learning that needs to be practiced in a specific space, so this training can make it learn the mapping relationship between input and output. The process is shown as follows:

$$y = g(x; w_1, \dots, w_L),$$

$$= g_L(\cdot; w_L) \circ g_{L-1}(\cdot; w_{L-1}) \circ \dots \circ g_2(\cdot; w_2) \circ g_1(x; w_1), \quad (5)$$

where y represents output vector, x represents input vector, g represents CNN, g_L represents layer 1 CNN, w_L represents layer 1 g_L weight and bias vector, and \circ represents convolution operation.

A convolution neural network is usually composed of the following types (as shown in Figure 2). The convolution layer is used to separate important functions, the pooling layer is used to reduce the number of parameters and excessive matching, and the complete combination layer is usually used for network output after all convolution operations.

Input Layer: This layer is used to input data. In multi-dimensional data processing, because the input data are usually images, this study mainly introduces the input layer of objects placed in images. First, the image information is converted into function data and input into convolution neural network. The image structure is the embodiment of image information. In analysis, the CNN input layer keeps its original data when processing image information. Images are usually divided into black and white images and color images. When CNN analyzes different types of images, the inputs are different.

Convolution Layer: the convolution layer first detects each feature of the image locally and then performs local expansion processing at a higher level to obtain global information. The core of convolution operation is a mathematical operation, which usually represents discrete

convolution in convolution neural network. The convolution formula is as follows:

$$x_i^l = f\left(\sum_i w_{i,j}^{l-1,l} \circ x_i^{l-1} + b_j^l\right), \quad (6)$$

where x_i^l represents the i -level image of the i level, x_i^{l-1} represents the first to i -level images, \circ is the convolution operator, $w_{i,j}^{l-1,l}$ is the first to i -level images and $l-1$, b_j^l represents the offset of the j th feature corresponding to the l level, and F represents the activation function. The most common of these activation functions is the relay-type activation function, whose principle is shown as follows:

$$\text{Relu} = \max(0, x) = \begin{cases} x, & x \geq 0, \\ 0, & x < 0. \end{cases} \quad (7)$$

Pooling Layer: pooling layer is usually combined with the convolution layer, which is mainly used to reduce function scale, compare data, reduce the number of network parameters, reduce overmatching, and improve the tolerance of fault model. **Complete Combination Layer:** after processing several convolution layers and a pooling layer, the convolution neural network will be combined with the complete combination layer. **Output Layer:** the focus of the output layer of convolution neural network is to produce the desired results according to the situation. After calculation, different probability values are obtained from input to output.

3.1.2. Proposition and Construction of Cell Image Detection Model. Assuming that the time domain remains constant, Ω is defined as the state region of output Y , which is based on the finite state of the model. Suppose that the spatial constrained regression model g is used to test the known and has $y = g(\Omega; s(x))$ form, where $s(x)$ is an unknown parameter vector, and the result of the last layer of ordinary CNN is shown as follows:

$$y = f_L(x_{L-1}; w_L), \quad (8)$$

where x_{L-1} is the output of the network $(L-1)$ layer in the neural network and w_L is the weight of the last layer, which is output under the mapping of f_L . Based on the theoretical analysis of space constraints in this study, we need to extend the standard CNN to estimate $s(x)$ so that the last two layers (f_{L-1}, f_L) of the network are defined as follows:

$$s(x) = f_{L-1}(x_{L-2}; w_{L-1}), \quad (9)$$

$$y = f_L(\Omega; s(x)) = g(\Omega; s(x)), \quad (10)$$

where x_{L-2} is the output of the network $(L-2)$ layer and Formula (9) is the parameter estimation layer. According to the weight w_{L-1} , printing the image to obtain a parameter vector; Formula (10) is the spatial constraint layer, which belongs to the parameter vector in the regression model.

At the beginning of kernel image recognition, image plane $x \in R^{H \times W \times D}$, height H , width W , and feature number

FIGURE 2: Basic structure diagram of convolution neural network.

D are given, and the goal is to detect the center point X of each kernel.

In this study, the Euclidean distance from the pixel to the core, i.e., $\|Z_j - Z_m^0\|_2$, is obtained when the core is detected, where Z_j and Z_m^0 represent the coordinates of y_j and the center coordinates of the m th core, respectively. The weight is reduced, i.e., normalized, and the regularized formula is shown as follows:

$$d = \frac{1}{2} \|Z_j - Z_m^0\|_2^2. \quad (11)$$

Let $\Omega = \{1, \dots, H'\} * \{1, \dots, w'\}$, and y is the spatial region. The j -th element is $j = 1, \dots, |\Omega|$. Equation (12) is defined as follows:

$$y_j = \begin{cases} 1 & \text{if } \forall m \neq m', \|Z_j - Z_m^0\|_2 \leq \|Z_j - Z_{m'}^0\|_2 \leq d, \\ \frac{1}{1 + \left(\|Z_j - Z_m^0\|_2^2 / d^2\right)} & \text{otherwise,} \end{cases} \quad (12)$$

where Z_j and Z_m^0 represent the coordinates of y_j and the center coordinate of the m th core of D , respectively, and Ω is a constant radius. It can be seen from the figure that the probability graph defined by Equation (12) has a maximum value near the center of each core Z_m^0 , and other places are

flat. Next, a prediction output \hat{y} generated from a space-constrained layer of the network is determined. Based on the known structure of the motion result probability graph described in Equation (12), we define the predicted output as Equation (13) of the J th element.

$$\hat{y}_j = g\left(Z_j; \hat{Z}_1^0, \dots, \hat{Z}_M^0, h_1, \dots, h_M\right), \quad (13)$$

$$= \begin{cases} 1 & \text{if } \forall m \neq m', \|Z_j - \hat{Z}_m^0\|_2 \leq \|Z_j - \hat{Z}_{m'}^0\|_2 \leq d, \\ \frac{1}{1 + \left(\|Z_j - \hat{Z}_m^0\|_2^2 / d^2\right)} & \text{otherwise,} \end{cases}$$

where $\hat{Z}_m^0 \in \Omega$ represents the center of the formula estimate, $h_M \in [0, 1]$ represents the height of the m th variable, and M represents the maximum number on \hat{y} . Because of the redundancy provided by $h_M = 0$ or $\hat{Z}_m^0 = \hat{Z}_{m'}^0, m \neq m'$, \hat{y} defined in this way will occur to allow the number of prediction cores to change from 0 to M . In the experiment, D in Formula (12) and Formula (13) is set to 4 pixels to provide sufficient support area for the probability mask.

Parameters $\hat{Z}_m^0 = (u_m, v_m)$ and h_m are estimated in a parameter estimation layer. X_{L-2} is made the output of the $(L-2)$ layer of the network. u_m, v_m, h_m are defined as follows:

$$u_m = (H' - 1) * \text{sigm}(W_{L-1, u_m} * X_{L-2} + b_{u_m}) + 1, \quad (14)$$

$$v_m = (W' - 1) * \text{sigm}(W_{L-1, v_m} * X_{L-2} + b_{v_m}) + 1, \quad (15)$$

$$h_m = \text{sigm}(W_{L-1, h_m} * X_{L-2} + b_{h_m}). \quad (16)$$

The purpose of formulas (14) and (15) is to show that the corresponding weights and deviations are output to the previous layer, then normalized, and then combined with the previous predictions to obtain a parameter estimate.

The importance of Formula (16) is that it is useful for the upper exit. After the corresponding weights and deviations are given, normalization is carried out to obtain the

estimated height of M variable, which fully integrates the spatial area position data. When $b_{u_m}, b_{v_m}, b_{h_m}$ and $W_{L-1,u_m}, W_{L-1,v_m}, W_{L-1,h_m}$ are vectors, the former represents deviation, the latter represents weighting, and $\text{sigm}(\cdot)$ represents the sigmoid function commonly used in convolution neural networks, which is often used to hide the output of neurons, and its value range is $(0, 1)$. It can specify a real number between $(0, 1)$; that is, it is used for normalization. The principle is shown as follows:

$$S(x) = \frac{1}{1 + e^x}, \quad (17)$$

where X represents the data after zero mean processing and $S(x)$ represents the data after normalization processing, and the learning method should use a loss function, as shown as follows:

$$l(y, \hat{y}) = \sum (y_j + \varepsilon)H(y_j, \hat{y}_j), \quad (18)$$

where ε is a small constant, which represents the ratio of nonzero probability pixels to the total number of zero probability pixels in the training input, and $H(y_j, \hat{y}_j)$ is the cross-entropy loss, which is specifically defined as follows:

$$H(y_j, \hat{y}_j) = -[y_j \log(\hat{y}_j) - (1 - y_j) \log(1 - \hat{y}_j)]. \quad (19)$$

Among them, when the actual values are $y_j = 1$ and $H(y_j, \hat{y}_j) = -\log(\hat{y}_j)$, when the predicted value of \hat{y}_j is closer to 1, $\log(\hat{y}_j)$ is closer to the maximum value of 1, and the minus sign indicates the minimum error value. When the predicted value of \hat{y}_j is closer to zero, $\log(\hat{y}_j)$ is closer to the negative. An infinite addition and subtraction sign indicates the maximum error value. When the actual values are $y_j = 0$ and $H(y_j, \hat{y}_j) = -\log(1 - \hat{y}_j)$, when the predicted value \hat{y}_j is closer to zero, $\log(\hat{y}_j)$ is closer to the maximum value 1, and the minus sign indicates the minimum error value, while when the predicted value \hat{y}_j is closer to 1, $\log(\hat{y}_j)$ is closer to the negative infinite addition and subtraction sign, which represents the maximum error value.

The detailed parameters of each convolution are shown in Table 1.

In Table 1, you can see that the input is an input attribute with a size of 27×27 , and the output attribute after the final network frame is 11×11 . To extract and merge all function information, the scroll window increment is always set to 1, and the trigger function uses relay-type trigger function evenly.

The network model structure mentioned in this article is shown in Figure 3.

F is the full interconnection layer, and these neurons in the full interconnection layer represent medical image information without spatial information; $S1$ is a new parameter estimation layer, and these neurons in the parameter estimation layer represent the estimated position information; $S2$ is the spatial constraint layer, L is the total number of layers in the network, and each neuron represents the medical image information with state parameter information.

3.2. Nuclear Image Preprocessing

3.2.1. *Coloring Principle of Stain.* The color deconvolution method is mainly based on the orthogonal transformation of the original RGB image, and according to the Beer-Lambert law, it is expressed as the relationship between the light intensity of the histological cell image and the staining matrix, as shown as follows:

$$I_C = I_{O,C} \exp(-Q * C_C), \quad (20)$$

where $I_{O,C}$ is the intensity of incident light radiated from the tissue cell image, I_C is the intensity of light passing through the tissue cell image, subscript C is the RGB three-channel identifier, Q is the dye color matrix, and C is the dye absorbance. It can be seen from Equation (10) that the intensity of transmitted light and dye content is relatively complex nonlinear relations. In the RGB color model, the light intensity of each pixel in the camera is I_R , I_G , and I_B , respectively. The optical density (OD) expression of each pixel is shown as follows:

$$\text{OD}_C = -\log_{10}\left(\frac{I_C}{I_{O,C}}\right) = Q * C_C. \quad (21)$$

It can be seen from Equation (21) that the optical density of each channel has a linear relationship with the absorption of light absorbent, so the optical density of each channel can be used to distinguish the color rendering effect of several dyes. The color effect of each point can be quantified by a 3×1 RGB three-channel optical density matrix. Using simple hematoxylin staining, the absorbance of R, G, and B channels was 0.18, 0.20, and 0.18, respectively. The size of the color matrix Q is related to the type of point, and each element of the matrix is proportional to the absorbance of each channel. For the three dyes R, G, B, the three-channel color system is defined as follows:

$$\begin{bmatrix} Y_{11} & Y_{12} & Y_{13} \\ Y_{21} & Y_{22} & Y_{23} \\ Y_{31} & Y_{32} & Y_{33} \end{bmatrix}. \quad (22)$$

Each row represents a dot, and each column represents the absorbance values of R, G, and B channels. In this data set, only two dyes are used for staining, and the corresponding chromosome systems of R, G, and B channels are shown as follows:

$$\begin{bmatrix} Y_{11} & Y_{12} & Y_{13} \\ Y_{21} & Y_{22} & Y_{23} \end{bmatrix}. \quad (23)$$

In the dyeing experiment, one dye was used to obtain the absorbance values of three RGB channels after dyeing with each dye. The dyeing formula for hematoxylin and eosin multiple dyeing is as follows:

$$\begin{bmatrix} 0.18 & 0.20 & 0.18 \\ 0.01 & 0.13 & 0.01 \end{bmatrix}. \quad (24)$$

TABLE 1: Design of parameter table of nuclear detection model based on spatial information.

Number of layers	Category	Filter size	Input/output dimensions
0	Input		$27 \times 27 \times 1$
1	conv1	$4 \times 4 \times 1 \times 36$	$24 \times 24 \times 36$
2	pooling1	2×2	$12 \times 12 \times 36$
3	conv2	$3 \times 3 \times 36 \times 48$	$10 \times 10 \times 48$
4	pooling2	2×2	$5 \times 5 \times 48$
5	Fully-connected1	$5 \times 5 \times 48 \times 512$	1×512
6	Fully-connected2	$1 \times 1 \times 512 \times 512$	1×512

3.2.2. Color Deconvolution. To make the color effect of each color in multicolor image stand out, RGB information must be transformed orthogonally. The purpose of orthogonal transformation is to make the color effect of each color independent of each other, to obtain the color effect of a dye. The transformed matrix must be normalized, and the normalization process for each dye is shown as follows:

$$\hat{Y}_{11} = \frac{Y_{11}}{\sqrt{Y_{11}^2 + Y_{12}^2 + Y_{13}^2}}, \quad (25)$$

$$\hat{Y}_{21} = \frac{Y_{21}}{\sqrt{Y_{21}^2 + Y_{22}^2 + Y_{23}^2}}. \quad (26)$$

The normalized optical density matrix A is shown as follows:

$$\begin{bmatrix} \hat{Y}_{11} & \hat{Y}_{12} & \hat{Y}_{13} \\ \hat{Y}_{21} & \hat{Y}_{22} & \hat{Y}_{23} \end{bmatrix}. \quad (27)$$

The $N \times 2$ matrix C is used to describe the color effect of two dyes on a pixel, and then, the optical density matrix $Y = AC$ of the image collected from the pixel is obtained. $C = A^{-1} Y$, and the color convolution matrix is then a pixel hint. Individual color effects can be determined according to the optical density and color moment of the image. The inverse of matrix $D = A^{-1}$ is obtained.

The color deconvolution matrix of the above H&E coloring method is shown as follows:

$$\begin{bmatrix} 1.88 & -0.07 & -0.60 \\ -1.02 & 1.13 & -0.48 \end{bmatrix}. \quad (28)$$

Multiple color images are separated by color deconvolution theory, and the separated images can be used for density and texture analysis.

The cell sample images were experimented according to H&E staining mode, and the experimental results are shown in Figures 4–6.

In the image of the isolated hematoxylin-stained component, the nucleus is blue, while in the image of the eosin-stained component, the cytoplasm and cytoplasm are pink. After color inversion of the pathological picture of this material, the separation result of nucleus and cytoplasm is very good. As shown in the above figure, the color deconvolution method can be used as an image preprocessing method in this study.

4. Comparative Experiment and Analysis

4.1. Comparative Experiment and Analysis of Cell Detection. In this section, we designed the same control group as the experimental group, tested SCNN and SR-CNNSSAE models, respectively, and tested the parameters according to the detection performance of CRCStoPhenotypes data set.

This section selects 100 cell images from the test data set and stores the accuracy, recovery rate, and F1 scores of the three experimental models when testing the images. Tables 2–4 compare the differences in the three experimental systems in three evaluation indexes in detail.

Table 2 shows that the maximum recovery rate of SCNN is 0.9076, which is 0.0546 and 0.2146 higher than SR-CNN and SSAE, respectively, same but improved compared with 0.16 SSAE; on average, SCNN still leads SR-CNN and SSAE. SCNN through the maximum recovery rate, minimum recovery rate, and average recovery rate of comparative analysis shows that the detection accuracy has been greatly improved. However, the mean square error of SCNN is larger than that of SR-CNN and SSAE, which shows that the stability is not as good as that of SR-CNN and SSAE, but the difference is very small, only 0.01, which is within the range of acceptable area.

It can be seen from Table 3 that in terms of accuracy, the highest accuracy of SCNN is 0.8883, and SR-CNN and SSAE are 0.0503 and 0.2163, respectively; SCNN has a minimum

FIGURE 4: Sample image of H&E staining.

FIGURE 6: Eosin staining component image.

FIGURE 5: Images of hematoxylin staining components.

accuracy of 0.7002. In SR-CNN and SSAE, the minimum values are 0.6801 and 0.5141, respectively; in terms of average accuracy, SCNN and SR-CNN are basically the same, only 0.002 behind, which belongs to the normal statistical range and is obviously ahead of SSAE. The above three groups of comparative data show that SCNN has an excellent performance in accuracy. In terms of stability, the three experimental systems are basically the same, and they are all relatively stable.

It can be seen from Table 4 that the maximum F1 of SCNN is 0.836947, which is 0.009 and 0.173 higher than SR-CNN and SSAE, respectively. Based on SR-CNN, the

TABLE 2: Quantitative table of detection and evaluation indexes.

	SCNN	SR-CNN	SSAE
Maximum value	0.9076	0.8531	0.6932
Minimum value	0.7011	0.7011	0.5411
Mean value	0.8234	0.8039	0.6439
Mean square error	0.0363	0.0264	0.0264

TABLE 3: Quantitative table of detection and evaluation indexes.

	SCNN	SR-CNN	SSAE
Maximum value	0.8823	0.8321	0.6662
Minimum value	0.7002	0.6801	0.5141
Mean value	0.7811	0.7829	0.6169
Mean square error	0.0285	0.0264	0.0264

TABLE 4: Quantitative table of detection and evaluation indexes.

	SCNN	SR-CNN	SSAE
Maximum value	0.8369	0.8276	0.6638
Minimum value	0.7006	0.7102	0.5688
Mean value	0.8007	0.7929	0.6296
Mean square error	0.0159	0.0208	0.0194

TABLE 5: Experimental comparison results.

Method	Precision	Recall	F1 score
SCNN	0.781	0.823	0.802
SR-CNN	0.782	0.804	0.793
SSAE	0.617	0.644	0.63

minimum F1 of SCNN is 0.70065. On the basis of SSAE, it decreased by 0.009 and increased by 0.132. For average, F1 of SCNN improved by 0.008 on SR-CNN but significantly surpassed SSAE. The above three sets of comparative data

FIGURE 7: F1 scores were obtained by classifying different types of nuclei by three methods.

show that SCNN performed very well at F1. In terms of stability, the F1 score of SCNN in SR-CNN system is less than 0.005 and that in SSAE system is 0.001, which shows that this system is more stable.

The above analysis compares the detection performance differences in multiple cell images in detail from three indexes. Table 5 analyzes and compares the total indexes of the three experimental systems.

Table 5 shows that SCNN has better performance than SR-CNN and SSAE in terms of recovery rate and F1 score. Although it lags behind SR-CNN in accuracy, the difference is very small, which indicates that the experimental performance can be relied on.

Summarizing the above experimental results and comparative analysis, this section shows that the SCNN cell recognition model proposed in this study has better detection accuracy and stronger generalization ability, which shows that it is very important to add spatial information to the designed convolution neural network model.

4.2. Comparative Experiment and Analysis of Cell Classification. This section contains three sets of comparative experiments with the same experimental settings, which are designed to test the classification ability of the kernel classification model, the kernel classification model, and the kernel classification model proposed in this paper for the CRCHistoPhenotypes dataset. The parameters of the comparative test are the same as those of the classification test in Chapter 3.

The F1 scores in different core classifications are compared, and the reference methods are CRImage method and superpixel imaging method. The exact F1 score is shown in Figure 7.

As can be seen from Figure 7, the F1 score of the classification method based on adjacent set prediction proposed in this study is higher than that of the other two methods in the four categories, and the curve is more stable, indicating the best performance. See Table 6 for a detailed comparison.

TABLE 6: Quantitative table of F1 fraction of different nuclear classifications by three methods.

	Softmax CNN + ASP	Super-pixel descriptor	CRImage
Maximum value	0.875	0.817	0.672
Minimum value	0.538	0.395	0.156
Mean value	0.7342	0.625	0.427
Mean square error	0.1692	0.177	0.216

FIGURE 8: AUC values of four types of nuclear classification by three methods.

It can be seen from Table 6 that in terms of average F1, this method is obviously ahead of CRImage method in the super-pixel imaging method. The above three groups of comparative data show that the classification model based on adjacent set prediction in this study performs very well for F1 scores. In terms of stability, this method is 0.047 smaller than CRImage method, which shows that this model is more stable. In the same experimental environment, we combine SoftmaxCNN with a group of adjacent prediction methods, use CRImage method and superpixel imaging method to detect four different nuclei, and get the AUC values of different nuclei. See Figure 8 for details.

Figure 8 analyzes and compares the present model, the CRImage super-pixel imaging model, and the AUC metrics. Comparing these three curves, we can see that the model in this study has better AUC performance than the other two methods in the classification of four types of kernels. Table 7 compares the differences in AUC statistical data of the three experimental schemes in detail.

As can be seen from Table 7, the AUC of prediction-based adjacent set classification model for four different core types is 0.059 and 0.217 higher than that of super-pixel imaging method and CRImage method, respectively, the minimum value is 0.099 and 0.295 higher, and the average value is higher, more than 0.071 and 0.2435. The performance of this model is better, and the mean square error is less than 0.0208 and 0.0346, which shows that the model in this study is more stable in classifying cell images. After comparing the F1 fraction and AUC values obtained from

TABLE 7: Quantification table of AUC values of four nuclear classifications by three methods.

	Softmax CNN + ASP	Super-pixel descriptor	CRImage
Maximum value	0.946	0.887	0.729
Minimum value	0.836	0.737	0.541
Mean value	0.901	0.831	0.657
Mean square error	0.047	0.068	0.081

TABLE 8: Comparison of nuclear classification results of three methods.

Method	F1 score	Multi-class AUC value
Softmax CNN + ASP	0.784	0.917
Super-pixel descriptor	0.687	0.853
CRImage	0.488	0.684

different types of nuclei, the weighted integration of F1 fraction and AUC values was carried out and a detailed comparison was made. The specific numerical equations are shown in Table 8.

Table 8 shows that the combination of SoftmaxCNN and AdjacentSetPrediction is used to classify the kernel used in this study, which is nearly 1 percentage point higher than the F1 score of the other two kernel classification methods, which is more. It shows the superiority of the proposed model in nuclear classification of cell histology image classification based on adjacent set prediction. The multi-class AUC is at least 0.6 percentage points higher than that of SuperpixelDescripto method and 2 percentage points higher than that of CRImage method. The combination of SoftmaxCNN and adjacent force prediction is more than 90% in multiclass. The comparison results of AUC values show that the proposed method has better classification ability and stability in nuclear classification.

Based on the above experimental results and comparative analysis, this section demonstrates that the proposed nuclear classification model based on adjacent set prediction has better classification ability and stronger stability and proves that convolution neural network combined with adjacent set prediction model is effective.

5. Concluding Remarks

In this study, we propose a method to detect nuclei by combining spatial data. This method aims at detecting nuclei in histological cell images and constructing a spatial model of cell image detection, to solve the problem of missing topological input in the current model. Aiming at the problem of how to classify the nuclei in the enlarged image of human cells, a prediction mechanism based on adjacent sets is proposed, and a large classification model of human cell images is constructed by combining the convolution neural network system of linear regression. In recent years, the deep learning method is widely used, which provides a

theoretical basis for human cell image detection and classification combined with neural network model.

For the problems of unreasonable computation offloading and uneven resource allocation in Mobile Edge Computing (MEC), this paper proposes a task offloading and resource allocation strategy based on deep learning for MEC. Firstly, in the multiuser multiserver MEC environment, a new objective function is designed by combining calculation model and communication model in the system, which can shorten the completion time of all computing tasks and minimize the energy consumption of all terminal devices under delay constraints. Then, based on the multiagent reinforcement learning system, system benefits and resource consumption are designed as rewards and losses in deep reinforcement learning. Dueling-DQN algorithm is used to solve the system problem model for obtaining resource allocation method with the highest reward. Finally, the experimental results show that when the learning rate is 0.001 and discount factor is 0.90, the performance of proposed strategy is the best. Furthermore, the proportions of reducing energy consumption and shortening completion time are 52.18% and 34.72%, respectively, which are better than other comparison strategies in terms of calculation amount and energy saving.

1. Introduction

With the rise of computing-intensive applications and explosive growth of data traffic, users' requirements for the computing power and service quality of mobile devices are also increasing [1]. At present, cloud computing also faces many problems and challenges. Due to its resource-intensive architecture, mobile cloud computing imposes a huge additional load on the backhaul link of mobile networks [2, 3]. Thus, Mobile Edge Computing (MEC) technology is proposed, which physically integrates computing and storage resources into the edge of mobile network architecture [4, 5]. This not only effectively reduces the transmission delay but also solves the problems of high load and high delay caused by mobile cloud computing [6]. At the same time, MEC has the characteristics of distributed architecture, being at the edge of network, low latency, user location awareness, and network status awareness [7, 8]. However, deploying a large number of computing and storage devices at the edge of network for users

to choose and accessing neighboring service providers for edge computing will bring a series of complexities such as access and resource allocation strategy selection, user mobility management, and computing task migration problems [9].

In order to achieve the goal of short completion time and lower terminal energy consumption under delay constraint, this paper proposes a task offloading and resource allocation strategy based on deep learning for MEC. In order to shorten the completion time of computing tasks and minimize the energy consumption of all terminal devices while satisfying delay constraints, the proposed strategy is designed in a multiuser multiserver MEC environment, combined with computing model and communication model in system. Moreover, a new objective function is designed, which uses objective optimization to further reduce energy consumption and time delay. It uses Dueling-DQN algorithm to solve the optimization model to shorten completion time and minimize energy consumption of all terminal devices while meeting the delay constraints.

The remaining chapters of this paper are arranged as follows: Section 2 introduces the relevant research work on mobile task unloading. Section 3 introduces the system model. Section 4 introduces the new computing offload method based on improved DQN. In Section 5, simulation experiments are designed to verify the performance of the proposed model. Section 6 is the conclusion.

2. Related Work

In MEC network, computation offloading may occur in three types: full offloading, partial offloading, and local processing [10]. An important research hotspot in the field of computation offloading is computation offloading decisions. Generally speaking, the offloading goal mainly focuses on minimizing the overall delay or minimizing energy consumption for user devices while meeting the minimum delay requirements [11]. Reference [12] proposed a distributed task offloading strategy for low-load base station groups in MEC environment. It selects the best MEC node offloading amount by game equation on the basis of quantifying offloading cost and delay. But it is not suitable for high-load application environments. In reference to the problem of unbalanced computing resources on the edge server in vehicle edge computing network, [13] proposed a load balancing task offloading scheme based on software-defined network. This solution can effectively reduce delay and improve the efficiency of task offloading processing. However, the processing method used has poor performance, which affects the distribution efficiency. Reference [14] used greedy selection to design a maximum energy-saving priority algorithm to achieve optimal offloading of computing tasks on mobile devices, but it does not consider the delay constraints of task offloading. Reference [15] combined long short-term memory (LSTM) and candidate network set to improve the deep reinforcement learning algorithm and used this algorithm to solve the problem of offloading dependency of multinode and mobile tasks in large-scale heterogeneous MEC. But they ignore the optimal allocation problem of computing resources.

Similar to computation offloading, resource allocation is also one of the core issues in MEC [16]. In MEC network, technologies such as content caching and ultradense deployment are introduced, and multiple resources are deployed to mobile network edge according to the specific needs of users. This can further ensure the quality of service and greatly increase system capacity [17]. However, due to objective reasons such as physical volume and power consumption, the mobile network edge has limited computing resources, storage cache capacity, and spectrum resources. How to allocate multiple resources and improve the system service efficiency has a huge effect on the improvement of MEC network system performance [18]. Reference [19] proposed a time average computation rate maximization (TACRM) algorithm, which allows joint allocation of radio resources and calculation resources. However, the overall performance and task requirements of devices were not considered comprehensively in the allocation process, and the allocation efficiency still needs to be improved. Reference

FIGURE 1: System model diagram.

[20] comprehensively considered factors such as CPU, hard disk space, and required time and distance and proposed a comprehensive utility function for MEC resource allocation to achieve the optimal allocation of resources in MEC and cloud computing. However, this function considers many factors, which will seriously affect the efficiency of allocation in real applications. Reference [21] designed a two-layer optimization method for MEC, which uses pruning candidate modes to reduce the number of unfeasible offloading decisions. Through ant colony algorithm to achieve the upper-level optimization, the resource allocation effect is better. However, the server computing resource constraints and task delay constraints are not considered, and the overall timeliness is not good. Reference [22] constructed a low-complexity advanced branch model, which can be used for resource scheduling in large-scale MEC scenarios.

Due to the lack of powerful processing algorithms, the overall efficiency and performance are not ideal. To this end, comprehensively considering the task offloading and resource allocation problem, a deep learning-based MEC task offloading and resource allocation strategy is proposed to coordinate and optimize the allocation and offloading between computing resources and computing tasks, which improves the comprehensive computing efficiency of MEC.

3. System Model

The system model is a multiuser multiserver application scenario, in which there are N terminal devices and M MEC servers. The base station is used to provide communication resources for user equipment. Each base station is connected to an edge computing server through optical fiber, through the wireless communication link to connect to MEC server to calculate task data of offloading terminal devices, as shown in Figure 1. It is assumed that each terminal device can perform offloading computations or local calculations for its own execution tasks. And when offloading, the task can only be offloaded to one MEC server for calculation, and each terminal device is within the range of wireless

connection. However, the computing power of each MEC server is limited; it cannot accept the offloading request of each terminal at the same time.

The collection of terminal devices is $U = \{1, 2, \dots, n, \dots, N\}$, the collection of MEC server is $H = \{1, 2, \dots, m, \dots, M\}$, and the collection of all tasks is G . Each terminal device n has a calculation-intensive task G_n to be processed, which specifically includes the data D_n (code and parameters) required for computing task G_n , the CPU workload ϕ_n required for computing task G_n , and the completion time of task G_n . The extension constraint is τ_n , namely, $G_n \cong (D_n, \phi_n, \tau_n)$. The set of offloading decisions for each G_n is $X = [x_1, x_2, \dots, x_n, \dots, x_N]$.

When $x_n = \{0, 1, \dots, m, \dots, M\}$, and $x_n = 0$ is local offloading, the rest means offloading G_n to m MEC servers.

3.1. Communication Model. In the computation offloading problem, two links are mainly studied: wireless link from terminal devices to MEC and the wired link from MEC to cloud in the core network. In the wireless link, Finite-State Markov Channel (FSMC) model based on fading characteristics is used. FSMC model has a wide range of applications in wireless networks [23, 24].

The channel is divided into nonoverlapping intervals through the division of channel-related parameter ranges, and each interval of selected parameters represents a state in FSMC model. The relevant parameter used in FSMC may be Signal-to-Noise Ratio (SNR) amplitude of received signal at the receiving end or collected energy. SNR can be selected as a parameter that composes SNR model [25]. The SNR of receiving end is divided into K levels, and each level is associated with a state of Markov chain. The block fading channel is considered to be that the SNR of receiving end is a constant within a period of time but will change according to Markov transition probability between different periods. Assume that random variable γ is the SNR of receiving end of terminal device n . That is, γ can be improved according to Markov chain of finite states, and all its states can be expressed as $\kappa = \{1, 2, \dots, K\}$. The realization of random variable γ of terminal device n in the time period t is represented as $\Gamma(t)$, specifically expressed as

$$\Gamma_n(t) = k, \text{ if } \gamma_n(t) \in [h^{i-1}, h^k), \quad (1)$$

where $k \in \kappa = \{1, 2, \dots, K\}$ and $h^0 = 0 < h^1 < h^2 < \dots$. Let $\rho_{s'_n, s''_n}(t)$ denote the probability of state $\Gamma_n(t)$ transitioning from state s'_n to state s''_n in the time period t . The $K \times K$ channel state transition probability matrix of terminal device n is denoted as $\Phi_n(t) = [\rho_{s'_n, s''_n}(t)]_{K \times K}$, where $\rho_{s'_n, s''_n}(t) = \Pr(\Gamma_n(t+1) = s''_n | \Gamma_n(t) = s'_n)$, $s'_n, s''_n \in \kappa$.

In practical applications, the transfer matrix can be observed and measured from wireless environment in the past. In addition, it is considered that $\{\Gamma_n(t), 1 \leq t \leq T\}$ exists independently for terminal device n . Based on FSMC channel model, $\Gamma_{n,m}$ is used here to represent SNR between terminal device n and MEC server m . Since there is no interference between terminal devices, its channel efficiency can be expressed as $\vartheta_{n,m} = \log_2(1 + \Gamma_{n,m})$. Considering that the bandwidth W_m of MEC server m is divided into W_m/B_m ,

the bandwidth of each channel is B_m . Assuming that each user is allocated at most one channel, the transmission rate from terminal device n to MEC server m can be expressed as

$$v_{n,m}(t) = B_m \vartheta_{n,m}(t). \quad (2)$$

The subchannel owned by MEC server m has certain restrictions on receiving W_m/B_m ; that is, the bandwidth allocated by MEC server m to all connected users cannot exceed the total bandwidth of MEC server m . Besides, MEC server is limited by cache and computing capacity. On the one hand, MEC server can only handle a limited number of tasks; on the other hand, the load that MEC server can handle is also limited (such as the number of computing tasks). Therefore, some tasks will be further offloaded to the core network to be processed by the core network. Use $g_u(t) \in \{0, 1\}$ to represent the computation offloading decision indicator, which is used to indicate the way the server provides services. Among them, $g_n(t) = 0$ means that the terminal device n is processed by connected MEC server for computing tasks. And $g_n(t) = 1$ indicates that the task will be further offloaded to core network for processing by connected MEC server.

In order to further offload tasks to cloud, the wired backhaul link from MEC server to core network is considered. Assuming that the backhaul link capacity of network is Z (in bits per second), the backhaul link capacity allocated by MEC server m is Z_m . Then, the following restrictions must be met:

$$\begin{aligned} \sum_{n=1}^N g_n(t) \theta_{n,m}(t) \bar{\omega}_{n,m}(t) &\leq Z_m, \\ \sum_{m=1}^M \sum_{n=1}^N g_n(t) \theta_{n,m}(t) \bar{\omega}_{n,m}(t) &\leq Z, \end{aligned} \quad (3)$$

where $\theta_{n,m}$ is the connection between terminal device n and MEC server m and $\bar{\omega}_{n,m}$ is the transmission rate between terminal device n and MEC server m .

The sum of the rates of offloading computation tasks to the terminal device of core network by MEC server m cannot exceed the backhaul capacity of MEC server m . And the sum of speeds of all terminal devices processing computing tasks in the cloud cannot exceed the total backhaul capacity of system.

3.2. Calculation Model. If G_n is processed locally, use T_n^L to represent the time when G_n is executed locally, which is specifically defined as

$$T_n^L = \frac{\phi_n}{f_n^L}, \quad (4)$$

where workload ϕ_n is the total number of CPU cycles required to complete G_n and f_n^L is the local computing power of terminal device n (i.e., the number of CPU cycles executed per second).

Use E_n^L to represent the energy consumption of devices executed locally by G_n , which is defined as follows:

$$E_n^L = \phi_n \times e_n, \quad (5)$$

where e_n is terminal device n to calculate the energy consumption per unit of CPU cycle, $e_n = (f_n^L)^2 \times 10^{-27}$.

If G_n is processed at the edge, delay T_n^O and device energy consumption E_n^O under G_n edge execution should be calculated from three parts: data upload, data processing, and data return [26]. The specific calculation is as follows.

First, terminal device n uploads data G_n to the corresponding MEC server by wireless channel. Let T_n^I be the time when device n uploads G_n data, which is defined as

$$T_n^I = \frac{D_n}{v'}, \quad (6)$$

where D_n is the data size of G_n and v' is data upload rate in the system model (i.e., the amount of data uploaded per second).

Then, the energy consumption E_n^I of terminal device n uploading data is

$$E_n^I = T_n^I \times P', \quad (7)$$

where P' is the uplink transmission power of terminal device n .

Then, MEC allocates computing resources for calculation after receiving processed data. Use T_n'' to represent the time when the offloading data is calculated in MEC server, which is defined as

$$T_n'' = \frac{\phi_n}{f_{nm}^O}, \quad (8)$$

where f_{nm}^O are the computing resources allocated by m MEC servers for G_n offload execution (i.e., the number of CPU cycles executed per second). When G_n is unloaded to the local or other MEC server, f_{ij}^O is zero and serves as a constraint in the model, namely,

$$f_{nm}^O = 0, x_n \neq m. \quad (9)$$

At this time, terminal device n has no computing task and is in a waiting state and generates idle energy consumption. Suppose P_n^I is the idle power of terminal device n , then the idle energy consumption E_n'' of terminal device n under offloading computation is

$$E_n'' = T_n'' \times P_n^I. \quad (10)$$

Finally, MEC server returns the calculation result to terminal device n . The calculation result during backhaul is small and downlink rate is high, so the time delay and energy consumption when terminal device is received are ignored. Therefore, delay T_n^O under G_n edge execution is the sum of transmission delay T_n^I and the calculation delay T_n'' of MEC server, namely,

$$T_n^O = T_n^I + T_n''. \quad (11)$$

The device energy consumption E_n^O under G_n edge execution is the sum of upload energy consumption E_n^I of device n and the idle energy consumption E_n'' of device n waiting for G_n to complete calculation on MEC server, namely,

$$E_n^O = E_n^I + E_n''. \quad (12)$$

In summary, the time delay T_n and energy consumption E_n of the entire calculation process of task G_n in terminal device n are

$$T_n = \begin{cases} T_n^L, & x_n = 0, \\ T_n^O, & x_n \neq 0, \end{cases} \quad (13)$$

$$E_n = \begin{cases} E_n^L, & x_n = 0, \\ E_n^O, & x_n \neq 0. \end{cases}$$

Note that T_n and f_{nm}^O should meet the following restrictions:

$$T_n \leq \eta_n, \quad (14)$$

$$T_n \leq \eta_n.$$

The time delay constraint η_n of G_n is that computing power is twice 1.4GHz. F_m is the overall computing resources of MEC server m ; that is, the sum of computing resources allocated by each G_n that is offloaded to MEC server m should not exceed F_m .

3.3. Problem Model. The purpose of this paper is to jointly optimize offloading decision-making and resource allocation scheme in the multiuser multi-MEC server scenario, considering the limited computing resources and time delay constraint of computing tasks. This allows all computing tasks to shorten the completion time and minimize energy consumption of all terminal devices while meeting the delay constraints and extend the use time of terminal devices [27, 28]. Thus, the system objective function Ψ is defined as

$$\Psi = \sum_{n=1}^N E_n + 10 \times \sum_{n=1}^N \frac{T_n}{\eta_n}. \quad (15)$$

(T_n/η_n) is the ratio of completion time G_n to the delay constraints. According to the calculation results of simulation experiment, the difference between $\sum_{n=1}^N E_n$ and $\sum_{n=1}^N (T_n/\eta_n)$ is a decimal order of magnitude. Therefore, to ensure that the two are of the same order of magnitude and optimized together, $\sum_{n=1}^N (T_n/\eta_n)$ is multiplied by a factor of 10. The objective function Ψ minimizes the ratio of overall energy consumption of terminal devices to the task execution time and delay constraints by solving the optimal offloading decision and resource allocation plan to achieve research purpose. The overall problem model is as follows:

$$\begin{aligned}
 & \min_{x,f} (\Psi), \\
 & X = [x_1, x_2, \dots, x_n, \dots, x_N], \\
 & X = [x_1, x_2, \dots, x_n, \dots, x_N], \\
 & y_n = \begin{cases} f_n^L, x_n = 0, \\ f_{nm}^O, x_n = m, \end{cases} \\
 & \text{s.t.} \\
 & C_1: x_n \in \{0, 1, \dots, m, \dots, M\}, \forall n \in U, \\
 & C_2: y_n > 0, \forall n \in U, \\
 & C_3: f_{nm}^O = 0, x_n \neq m, \\
 & C_4: T_n \leq \eta_n, \forall n \in U, \\
 & C_5: \sum_{n=1}^N f_{nm}^O \leq F_m, \forall m \in H, \\
 & C_6: \begin{cases} \sum_{n=1}^N g_n(t) \theta_{n,m}(t) \omega_{n,m}(t) \leq Z_m, \\ \sum_{m=1}^M \sum_{n=1}^N g_n(t) \theta_{n,m}(t) \omega_{n,m}(t) \leq Z, \end{cases}
 \end{aligned} \tag{16}$$

where X is the task offloading decision amount and Y is the calculation resource allocation amount. Constraints C_1 , C_2 , and C_3 indicate that each task G_n can only be offloaded to the local or one of MEC servers for calculation. C_4 represents the constraint of task completion delay, and C_5 and C_6 represent the constraint that allocated computing resources should meet.

4. New Computation Offloading Method Based on Improved DQN

4.1. Multiagent Reinforcement Learning Algorithm. The multiagent reinforcement learning system is shown in Figure 2, where multiple agents act at the same time. Under the joint action, the entire system will be transferred, and each agent will be rewarded immediately [29, 30].

For multiagent reinforcement learning, it is first necessary to establish a Markov game model. Markov game can be described by a multigroup $(n, S, A_1, \dots, A_n, R_1, \dots, R_n)$. Among them,

- (1) n is the number of agents; that is, N is the number of terminal devices. S is the system state, which generally refers to the joint state of multiple agents, that is, the joint state of each agent. The terminal device shares the current load status of edge computing servers, which can be expressed as

$$LD(t) = [LD_1(t), LD_2(t), \dots, LD_m(t)], \tag{17}$$

where LD_m is the load of MEC.

- (2) R_i is the instant reward function of each agent. That is, in current state s , after joint action (A_1, \dots, A_n) taken by multiple agents, the reward is obtained in the next system state \hat{s} .

FIGURE 2: Multiagent reinforcement learning system.

The reward function completely describes the relationship between multiple agents. When the reward function of each agent is the same, that is, $R_1 = R_2 = \dots = R_n$, it means that the agent is a complete cooperative relationship. When there are only two agents and reward function is opposite, that is, $R_1 = -R_2$, it means that the agents are in perfect competition. When the return function is between the two, it is a mixed relationship between competition and cooperation.

4.2. Problem Description and Modeling

4.2.1. Network Status. $S = \{s(t)\}$ represents the network state space, where $s(t)$ represents the network state at time period t , and improvements are made in the entire time period T . The network status consists of SNR of each terminal device and cache status of each MEC server. $s(t)$ can be defined as

$$\begin{aligned}
 s(t) = & (\Gamma_1(t), \dots, \Gamma_n(t), \dots, \Gamma_N(t), \\
 & \psi_1(t), \dots, \psi_m(t), \dots, \psi_M(t)),
 \end{aligned} \tag{18}$$

where $\Gamma_n = \{\Gamma_{n,m}, m \in M\}$ represents SNR between user terminal device n and all MECs. $\psi_m(t) = \{\varphi_{k,m}, k \in K\}$ represents the cache status of MEC servers.

4.2.2. Network Behavior. The intelligent agent needs to determine the attachment relationship between the terminal device and MEC server in each time period. That is the determination of the terminal device's computing offload, the allocation of computing resources, and the service cache policy of each MEC server. Thus, each executable action of terminal devices in the time period t can be defined as follows:

$$\begin{aligned}
 a(t) = & (A_1(t), \dots, A_n(t), \dots, A_N(t), \\
 & G_1(t), \dots, G_n(t), \dots, G_N(t), \\
 & \psi_1(t), \dots, \psi_m(t), \dots, \psi_M(t)),
 \end{aligned} \tag{19}$$

where $A_n(t) = \{a_{n,m}(t), m \in M\}$ represents the attachment indicator of terminal device n and $G_n(t)$ represents the calculation and offloading decision of terminal device n .

4.2.3. Reward Function. The goal is to maximize total benefit of system, but the reward function should be set to current benefit of system. First calculate the system leased spectrum and backhaul resources and allocate them to terminal devices part of the revenue. The unit price of spectrum leased from MEC server m is set to δ_m per Hz, and the unit price of backhaul link from MEC server m to core network is set to σ_m per bps. Corresponding to this, the calculation data is transmitted to MEC server corresponding to terminal device n and backhaul link from MEC server to the core network is used for charging. The unit price is defined as α_n per Hz and β_n per bps. Therefore, by summarizing this part of the income and expenditure, part of income for leased spectrum and backhaul resources obtained by terminal device n can be obtained:

$$R'_n(t) = \alpha_n \sum_{m=1}^M a_{n,m}(t) B_m + \beta_n g_n(t) \sum_{m=1}^M a_{n,m}(t) R_{n,m}(t) - \sum_{m=1}^M \delta_m a_{n,m}(t) B_m - g_n(t) \sum_{m=1}^M \sigma_m a_{n,m}(t) R_{n,m}(t). \quad (20)$$

Then, calculate the profit obtained by terminal devices from allocating computing resources. On the one hand, when MEC side performs computing tasks, it needs to pay communication company for the loss of processing computing tasks and define the unit price of MEC server m energy consumption as χ_m . On the other hand, the terminal device needs to pay a certain price for the server on MEC side, and computing resource allocated for each unit computing task is set to ζ_n . Therefore, the benefit obtained by allocating computing resources to terminal device n can be calculated as

$$R''_n(t) = (1 - d_n(t)) \sum_{m=1}^M \alpha_{n,m} \frac{\zeta_n F_{n,m}(t)}{L_{u_n} - \chi_m E_{n,m}^{MEC,e}(t)}. \quad (21)$$

The amount of computing resources allocated to each unit computing task by the above formula has a very important impact on the completion time of computing task. Thus, the service cache cost mainly includes two parts: the cost of replacing type of cache supported on MEC side, and the cost of caching specific services on MEC server. Define the unit price of replacing cache type on MEC server m as ξ_m for each service type, and the unit price for caching services on MEC server is ξ_m per storage space. In order to increase the benefits of cache, the business type is quantified by weak backhaul from MEC server to the core network, which will be used to measure the cost of users. The benefits obtained by executing the cache service on MEC server m can be expressed as

$$R''_m(t) = \sum_{n=1}^N \beta_n (1 - g_n(t)) R_{n,m}(t) - \xi_m |I[\psi_m(t) - \psi_m(t-1)] - c_m \kappa |\psi_m(t)|, \quad (22)$$

where $|\psi_m(t)|$ represents the number of nonzero elements, $I[\cdot]$ is an auxiliary function, and when $x > 0$, $I(x) = 1$;

otherwise, $I(x) = 0$. The instant reward is designed as the total income of MVNO of all current users of system during the time period t , namely,

$$r(t) = \sum_{n=1}^N (R_n(t) + R''_n(t)) + \sum_{m=1}^M R''_m(t). \quad (23)$$

Here the long-term return $\mathfrak{R}(t)$ is expressed as

$$\mathfrak{R}(t) = \sum_{t=1}^T \epsilon r(t), \quad (24)$$

where $\epsilon \in [0, 1)$ is the discount rate of future earnings weights. When ϵ approaches 1, the system will pay more attention to long-term benefits, and when ϵ approaches 0, the system will pay more attention to short-term benefits.

4.3. Dueling-DQN. DQN is an effective reinforcement learning algorithm, which can make the agent learn good experience from the interaction with environments [31–33]. At the same time, according to DQN learning mechanism, there are improvements to DQN algorithm in different aspects. In DQN, due to the error in the Q estimated value itself, $\max_a Q$ process can be seen according to the expression. It is equivalent to putting forward the largest error, which also leads to the problem of overestimation. Double-DQN is an effective improved algorithm for this problem. In Double-DQN algorithm, the update form of $\hat{Q}(S)$ is changed to

$$\hat{Q}(s) = R(s) + \lambda \cdot \hat{Q}\left(\hat{s}, \max_a Q_{\text{eval}}(\hat{s}, a; \alpha); \alpha^-\right), \quad (25)$$

where λ is the discount factor.

The Double-DQN algorithm takes advantage of double neural network and uses two neural networks to learn at the same time, effectively avoiding the overestimation problem caused by error amplification.

Dueling-DQN is also an improvement to DQN algorithm. Compared with previous algorithms, Dueling-DQN algorithm learns faster and has better results. Compared with DQN algorithm, Dueling-DQN retains most of the learning mechanism, and the only difference is the improvement of neural network, as shown in Figure 3.

In the traditional DQN algorithm, the output result is Q value corresponding to each action. In Dueling-DQN algorithm, the output is expressed as a combination of two parts: the value function and advantage function [34]. Among them, value function refers to the value of a certain state, and advantage function refers to the advantage obtained by each action on the state. Therefore, in Dueling-DQN algorithm, Q value problem in DQN can be reexpressed as the following form:

$$Q(s, a; \alpha, \omega_1, \omega_2) = V(s; \omega, \omega_2) + \ell(s, a; \omega, \omega_1) - \frac{1}{|\mathcal{L}|} \sum_{a'} \ell(s, a'; \omega, \omega_1), \quad (26)$$

where $V(\cdot)$ and $\ell(\cdot)$ are the value function and advantage function, respectively, and ω is the parameter of neural

FIGURE 3: Comparison between DQN algorithm and Dueling-DQN algorithm. (a) DQN. (b) Dueling-DQN.

FIGURE 4: Convergence of the proposed algorithm under different learning rates.

network convolutional layer. ω_1, ω_2 are the parameters of two control flow layers, respectively. The latter item of the plus sign centralizes the advantage function in order to solve the uniqueness problem of Q value.

5. Experimental Results and Analysis

The specific simulation parameters are as follows.

Assume that the computing power of each device n is 1.5 GHz, the uplink transmission power is 800 mW, the idle power is 100 mW, and the upload rate is 2.5 Mb/s. $M = 4$ and overall computing capacity of each MEC server is 6 GHz, 5 GHz, 3 GHz, and 1 GHz, respectively. The data D_n in task G_n obeys uniform distribution of (600, 1200), and the unit is k bits. The workload ϕ_n obeys uniform distribution of (1000, 1500), and the unit is Megacycles.

For the parameters of Dueling-DQN algorithm, set the learning rate ϵ to 0.001 and discount coefficient λ to 0.90. The

FIGURE 5: System long-term rewards with different discount rates.

size of experience replay set is 3000, and the number of randomly sampled samples is 40.

5.1. Parameter Analysis

5.1.1. Learning Rate Analysis. The learning rate of the algorithm will have a great impact on the performance of the proposed strategy. Therefore, three different learning rates ϵ of 0.01, 0.001, and 0.0001 are selected to compare the convergence of improved DQN algorithm, as shown in Figure 4.

5.1.2. Discount Factors Analysis. Similarly, the influence of discount factor on improved DQN algorithm is shown in Figure 5, where the discount factor takes values 0.8, 0.9, and 0.95.

It can be seen from Figure 5 that as the discount factor increases, the long-term reward is continuously increasing. When λ is 0.95, the long-term reward is 3700 when it is

stable. Because the discount factor will affect behavior selection strategy, that is to say, a larger discount factor will cause system to pay more attention to long-term benefits, and a lower discount factor will cause system to pay more attention to current benefits, a higher discount factor will often lead to greater long-term benefits. However, in actual use, using an overly high discount factor does not have corresponding benefits. This is because the system in reality is more changeable, and too much emphasis on future benefits will lead to excessive calculations and excessive losses in the system, which often requires a trade-off.

5.2. Optimization Comparison under Different Objective Functions. For multiobjective optimization problems that reduce time delay and energy consumption, the weighted sum of task execution time delay and terminal execution energy consumption is usually used as the objective function to solve problem, and the calculation is as follows:

$$\Psi' = \frac{\sum_{n=1}^N (\omega_t \times T_n + (1 - \omega_t) \times E_n)}{N}, \quad (27)$$

where ω_t is the weight coefficient of execution delay and $1 - \omega_t$ is the weight coefficient of execution energy.

Comparing (22) with the proposed objective function (13) to optimize the delay and energy consumption, the number of terminal devices is 12. Considering that the goal of the proposed strategy is to shorten time delay and reduce energy consumption while satisfying the time delay constraints, therefore, the values of ω_t are, respectively, 0.8, 0.6, and 0.4, and the joint experiments of Energy Reduced Scale (ERS) and Time Reduced Scale (TRS) are carried out, as shown in Table 1.

It can be seen from Table 1 that when ω_t is 0.8 and 0.6, the control strategy pays more attention to the optimization of time delay, and when ω_t is 0.4, optimization results pay more attention to the optimization of energy consumption. However, the optimization result of the proposed objective function is the best, and ERS and TRS are 52.18% and 34.72%, respectively, which can shorten time delay and reduce energy consumption under the time delay constraints.

When computing task is 150, comparing control strategies under the four objective functions with the random offloading strategy, the results of ratio of the time delay and energy consumption reduction are shown in Table 2.

It can be seen from Table 2 that delay and energy consumption optimization effect of the proposed optimization target is better, and the reduction ratio of delay and energy consumption is 2.58% and 30.67%, respectively, because the optimization objective of the proposed strategy comprehensively considers the offloading decision and resource allocation plan of joint optimization system when the computing resources are limited and computing tasks have time delay constraints. This allows all computing tasks to shorten completion time and minimize the energy consumption of all terminal devices while meeting the delay constraints. This demonstrates the effectiveness of the proposed objective function.

TABLE 1: Comparison results of optimization for different objective functions.

Objective function	ERS (%)	TRS (%)
$\omega_t = 0.4$	48.71	27.96
$\omega_t = 0.6$	41.85	31.38
$\omega_t = 0.8$	31.03	32.56
Formula (13)	52.18	34.72

TABLE 2: Comparison results of optimization for four objective functions.

Objective function	Delay reduction ratio (%)	Energy consumption reduction ratio (%)
$\omega_t = 0.4$	1.25	23.29
$\omega_t = 0.6$	1.97	21.16
$\omega_t = 0.8$	2.03	19.98
Formula (13)	2.58	30.67

5.3. Performance Comparison with Other Algorithms. In order to demonstrate the performance of the proposed strategy, compare it with [12], [19], and [14] in terms of objective function value, calculation amount, and time saving. Li and Jiang [12] proposed a distributed task offloading strategy, which selects the best MEC node offloading amount by game equation on the basis of quantifying offloading cost and delay. Reference [14] used the greedy selection algorithm to design the maximum energy-saving priority algorithm and energy priority strategy to achieve optimal offloading of computing tasks on mobile devices. Reference [19] used the time average calculation rate maximization algorithm to jointly and efficiently allocate radio resources and computing resources.

5.3.1. Algorithm Comparison under Different Cumulative Tasks. In the experiment, objective function value results of the four strategies are shown in Figure 6 for different accumulations of computing tasks.

It can be seen from Figure 6 that the value of objective function is gradually increasing with the increase of cumulative number of tasks for the four offloading strategies. However, the proposed strategy has a relatively lower objective function value than other strategies. That is, the energy consumption and delay are relatively small. For example, when the number of tasks is 180, the objective function value is only 298. Since the proposed strategy considers computation offloading and resource allocation comprehensively, improved deep learning algorithm is used for optimization, and delay and energy consumption are minimized. Reference [19] only matched computing resources but did not rationally optimize the task offloading scheme and computing resource allocation scheme, resulting in high task execution time delay and energy consumption. References [12] and [14] both used corresponding algorithms for optimization to achieve better resource allocation and task offloading. But their analysis of time delay is less, so the performance needs to be strengthened.

FIGURE 6: Comparison results of offloading strategies under different cumulative number of tasks.

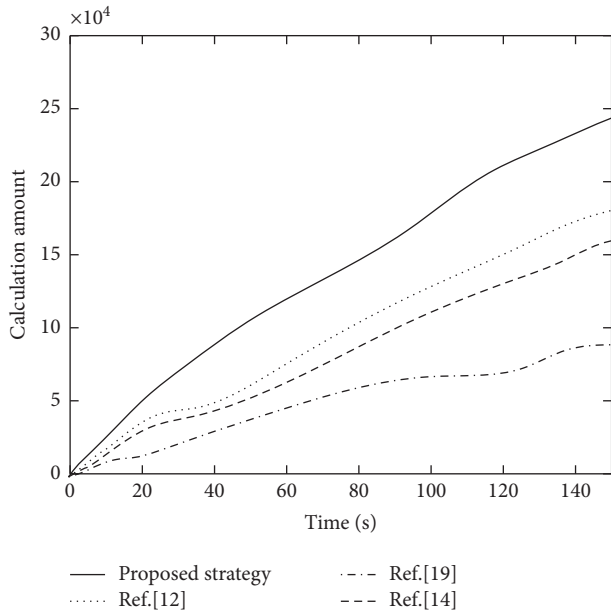

FIGURE 7: Comparison results of the computation number of offloading tasks under different offloading strategies.

5.3.2. Computation Number Comparison of Offloading Tasks under Different Offloading Strategies. Under four different computation offloading strategies, the comparison results of the computing number of offloading tasks on terminal device side are shown in Figure 7. Vertical axis represents the total calculation number of tasks performed by all terminal devices to perform calculation and offloading. The calculation number of tasks is used to represent the amount of calculation services provided by MEC server. Therefore,

FIGURE 8: Comparison results of energy saving per unit terminal device under different offloading strategies.

the evaluation indicators in the figure also represent the benefits of computing terminal devices in the offloading mode.

It can be seen from Figure 7 that as time increases, computing tasks continue to increase, and the amount of task calculations also increases. However, the calculation amount of the proposed strategy is significantly better than other comparison strategies. Taking the simulation time of 140 s as an example, compared with [12], [19], and [14], the proposed strategy has increased by 11.54%, 20.83%, and 152.72%, respectively. It can be argued that the proposed strategy is the best compared to task offloading. It uses Dueling-DQN algorithm to process task offloading and resource allocation models, and its optimization performance is better than the greedy selection algorithm in [14] and the game equation model in [12].

5.3.3. Energy-Saving Comparison of per Unit Terminal Devices. Under four different computation offloading strategies, the comparison of energy consumption saved by each terminal device by computation offloading on average is shown in Figure 8. In the local calculation model, all energy consumption is generated by local calculations. In the computation offloading mode, the energy consumption is communication energy consumption caused by upload tasks. For the task of performing computation offloading, the difference between the two is energy saving.

It can be seen from Figure 8 that, compared with other comparison strategies, the proposed strategy has the largest energy-saving rate, which is close to 10×10^4 J; this also means the least energy consumption. Aiming at the over-estimation problem in DQN, the proposed strategy uses Dueling-DQN algorithm for optimization. And it designs the system benefits and resource consumption as rewards and

losses, which improves the efficiency and rationality of task offloading and resource allocation by optimizing problem solution. Reference [19] only used the time average calculation rate maximization algorithm to efficiently allocate computing resources. The optimization algorithm is more traditional and has poor performance. Thus, the overall energy saving is not high. Reference [12] used the game equation model to optimize task offloading strategy but does not realize the rationalization of resource allocation. Therefore, the maximum energy saving is 710×10^4 J. Reference [14] used greedy selection algorithm to design an optimal energy-saving strategy but did not consider server computing resource constraints and task delay constraints. Therefore, the overall performance is not as good as the proposed strategy.

6. Conclusion

MEC server has limited computing resources and computing task has delay constraint. How to shorten completion time and reduce terminal energy consumption under the delay constraints becomes an important research issue. To solve this problem, this paper proposes a task offloading and resource allocation strategy based on deep learning for MEC. In the multiuser multiserver MEC environment, a new objective function is designed to construct mathematical model. In combination with deep reinforcement learning, the partially improved Dueling-DQN algorithm is used to solve the optimization problem model, which can reduce the completion time of computing tasks and minimize energy consumption of all terminal devices under the delay constraints. The proposed strategy is demonstrated by experiments based on Python platform. The experimental results show that when learning rate is 0.001 and discount factor is 0.90, the energy saving is close to 10×10^4 J, which is better than other comparison strategies. In terms of calculation amount, it increased by 11.54%, 20.83%, and 152.72%, respectively.

In practice, different users have different concerns about service quality. Therefore, we can refer to the different needs of users when making computation and offloading decisions in the following research. It can assign a certain weight to the factors affecting the quality of service and combine the task priority for scheduling.

In the context of global science and technology, all countries pay more and more attention to the text analysis of emotional intonation, and the emotional intonation text analysis and policy orientation of enterprise management in major international and domestic enterprises have also changed from shallow to deep. In the twenty-first century, with the rapid development of human society, people's demand for living standards and material needs increases rapidly, and employees' awareness and needs for work are constantly changing. At present, there is the problem of emotional intonation text analysis error in the management of the enterprise, and the task and emotional transmission command are not clear and thorough. It is necessary to reasonably use deep-learning-related algorithms, especially convolutional neural network and other algorithms, to study the emotional intonation text analysis and policy guidance of the enterprise management. Aiming at the forefront of deep learning development, the latest deep learning technologies are constantly introduced. The research field of emotional intonation text analysis and policy orientation of enterprise management is focused. Through simulation experiment, the characteristics of emotional intonation text analysis and policy orientation research of different enterprise management are compared and analyzed, so as to further improve the emotional intonation text analysis and policy orientation of deep learning for enterprise management.

1. Introduction

Can Chinese capital market investors understand the management's "commitment"? This paper uses LSM deep learning technology to analyze the management response in the annual performance briefing of Chinese listed companies and discusses the actual semantics of management. The results show that investors can understand the true semantics of management, and the capital market gives a positive response to the positive semantics and gives a more timely and meaningful negative response to the negative semantics. Starting from a three-factor model, we further investigate whether management semantics is a factor in the investor stock trading strategy, but there is no evidence that investors use management semantics as a factor in the trading strategy. On the one hand, this study shows that nonfinancial disclosure channels such as performance briefing are valuable, verifying the perspective theory of

behavioral economics; on the other hand, it is worth extending to other areas of text analysis for future application of [1]. With the development of deep learning, more and more neural network-based algorithms are used for classifying text sensation, and the accuracy of classification is constantly improved. If we blindly pursue accuracy and go deep into the network level, it will bring huge obstacles to the reaction performance in real application scenarios. By studying techniques such as integrated representation of texts, we can further grasp the main features of the text in the classification logic based on the current FastText models. A novel weight-based WDFM model is presented for classifying lighter text immunity, achieving high accuracy while ensuring the simplicity of the model and better solving the classification task of text immunity. To solve the problem of employee behavior analysis in key positions, a video-based behavior analysis method is proposed. Multipostural sampling employee behavior records were created, formed by

the YOLOv3 network, yielding a behavior detection model [2]. The proposed behavior analysis algorithm is combined with the behavior detection model. Based on the behavior analysis algorithm and the similarity and brightness characteristics of the image, the evaluation results of mobile phone shutdown, sleep, and game events are presented. The experimental results show that the product data group has high recognition accuracy in identifying employee behavior and behavior analysis, which can handle in real time [3].

Emotional text analysis mainly uses text extraction technology to analyze emotional processing, and identifying the tendency of subjective text is a positive, negative, and neutral process. This classification of text emotion particles is insufficient, incomplete, too rigid, and violent, which not only effectively reflects the intensity and size of different emotion particles in the text but also requires extensive manual annotation. We verify the effectiveness of emotion word carrier and improve the accuracy of text emotion classification [4]. Through a sample survey of nonfinancial enterprises that issued bonds in China's stock market in 2017, this paper studies the influence of accounting text intonation on bond communication, establishes an emotional dictionary for China's financial market, and quantifies the direction intonation by using text extraction technology. The study shows that management's positive tone can significantly reduce the credit spread of bonds. The management tone has a less negative relationship with the bond interest rate difference. In addition, the bond market is more sensitive to the tone of state-owned and small-business management [5]. Selecting listed companies from 2008 to 2019, through management analysis and discussion text analysis, this paper studies the constraints and impact mechanism of management emotional voice signals on corporate financing; the results show that management of positive net tone may have signal conduction effect, alleviate enterprise financing constraints, by expanding equity financing channels to achieve this effect, attract the attention of investors, is the management emotional influence to financing bottleneck mechanism. The results of the heterogeneous effects of speech tampering strategies show that investors cannot effectively identify text readability strategies and positive speech bias strategies, while speech splitting strategies are fully understood by investors, leading to differences in the emotional voices of people at different levels of management in reducing financial constraints. Expand the voice. This paper confirms that management can effectively use the emotional sound in the text to exert the signal transmission effect and guide the market to achieve its ideal goal [6].

If the hardware is the body of the company, the software is the blood of the company; the invisible emotion and emotion cannot be touched but really exist in the company that is the "gas" of the company. On the contrary, mismanaged corporate emotions and emotions, creating a healthy entrepreneurial spirit, and psychological and emotional air are major issues that managers cannot face up to and think about. Traditional management theory holds that human feelings have an influence on the realization of organizational goals in [7]. The development and evolution of

network public opinion between the COM incident on June 6 and the Hyderabad incident were compared, and the ways of emotional development of netizens were revealed through the collection and analysis of microblog data, especially the emotional analysis of microblog text. Comparing the gains and losses of the two online incidents to deal with these events, we summarize the strategy of enterprises to effectively deal with the network public opinion, which will help enterprises to deal with the public opinion crisis online [8].

In the 1980s, emotion management as a management model was proposed by many experts and scholars. In the twenty-first century, with the rapid development of human society, people's demand for living standards and material needs increases rapidly, and employees' awareness and needs for work are constantly changing. This paper briefly introduces the concept and significance of emotion management, summarizes the main factors affecting employees "emotions, analyzes the current situation of employees" emotions in the chemical industry, and puts forward some suggestions for emotion management [9]. Based on the on-site interviews and two questionnaires of 28 middle and senior managers, as well as the analysis of exploratory factors and confirmed factors, this paper formulated the scale to measure the emotional connection of managers in the transformation process of local enterprises in China. The results show that managers' emotional attachment consists of three factors: attachment to life, attachment to work and situation, and attachment to life that are positively related to attachment to work. They also have a positive relationship with context-binding. The research content not only illuminates the emotional culture of the organization but also provides a new way to promote the transformation of enterprises through emotional strategies [10].

Structural and functional analysis of managers' trust found that managers need to handle three trust relationships in their careers: subordinate trust, supervisor trust, and colleague trust. These three trusts lead to superior support, subordination, and peer cooperation, which is conducive to improving the personal performance of business operators. In modern enterprise management, the emotional contribution of employees to enterprise development is very important. This paper discusses the concept of emotion management and its role and position in human resource management [11]. By utilizing the "emotional talent" of employees, we can grasp the emotional management method in management practice, promote the emotional investment of employees, and ensure the continuous success of [12]. With the increasing popularity of online review and suggestion systems, emotion analysis has gradually become an important academic research task that has attracted the attention of many scholars in recent years. The traditional method to solve the problem of text emotion analysis is mainly based on the emotional dictionary or shallow knowledge, and the feature extraction and classification are conducted through regression and classification schemes. However, due to the short and clear features of the annotated text, a large number of unknown words make these methods have data scarce and ignore the problem of word tracking. Starting from these methods, deep learning methods are

used to analyze the mood of comment text, and we can find a deep understanding of human emotional expression mode through comparative combination experience [13].

In recent years, public opinion sentiment analysis has become one of the most popular topics in the NLP space. The sentiment analysis and emotional trend assessment of these public opinion data provide important support for the company government to make strategic decisions. At present, the supervised plane automatic learning algorithm model is widely used in emotion analysis research. The manual annotation process is lengthy, and the annotation results often do not reflect the real situation of the data. This paper expounds on the current situation of emotional word analysis, discusses the emotional analysis of public opinion data by using deep learning and fusion methods, summarizes the shortcomings and challenges of Chinese emotional analysis, and looks forward to the future [14]. Some scientists say that deep learning algorithms are a gem in the crown of artificial intelligence. By applying deep neural network (DNN) models, deep learning has become the closest intelligent learning method to the human brain. Not only Google, Baidu, and other companies participate in the application research of in-depth learning but also e-commerce giants such as Jingdong and Ali join the competition. This paper introduces the in-depth study of e-commerce in China [15].

2. Deep-Learning-Related Algorithms

2.1. Artificial Neural Network. Artificial neural networks are the foundation of deep learning, simulating human brain models. Neuron is the basic computational unit of deep learning model [16]. The neuron output formula is

$$y = f\left(\sum_{i=1}^n w_i x_i - \theta\right), \quad (1)$$

where f represents the activation function. Commonly used activation functions are the Sigmoid activation function, the Tanh activation function, and the ReLU activation function. The respective representation formulas are as follows:

$$\begin{aligned} f(z) &= \frac{1}{1 + \exp(-z)}, \\ f(z) &= \frac{e^z - e^{-z}}{e^z + e^{-z}}, \\ f(z) &= \max(0, z). \end{aligned} \quad (2)$$

2.2. Circular Neural Network and Long-and Short-Term Memory Network. The recurrent neural network can handle the time-series data well. The simplest recurrent neural network formula is as follows:

$$\begin{aligned} o_t &= g(V \bullet S_t), \\ S_t &= f(U \bullet X_t + W \bullet S_{t-1}). \end{aligned} \quad (3)$$

However, as the input increases, the standard RNN decreases the perception ability of the data nodes, resulting in the gradient disappearance and gradient dispersion phenomenon. To address this problem, the transformation function is defined as follows:

$$\begin{aligned} i_{(t)} &= \sigma(W_{xi}^T \cdot x_{(t)} + W_{hi}^T \cdot h_{(t-1)} + b_i), \\ g_{(t)} &= \tanh(W_{xg}^T \cdot x_{(t)} + W_{hg}^T \cdot h_{(t-1)} + b_g), \\ f_{(t)} &= \sigma(W_{xg}^T \cdot x_{(t)} + W_{hf}^T \cdot h_{(t-1)} + b_f), \\ c_{(t)} &= i_{(t)} \otimes g_{(t)} + f_{(t)} \otimes c_{(t-1)}, \\ o_{(t)} &= \sigma(W_{xo}^T \cdot x_{(t)} + W_{ho}^T \cdot h_{(t-1)} + b_o), \\ h_{(t)} &= o_{(t)} \otimes \tanh(c_{(t)}), \end{aligned} \quad (4)$$

where σ is the sigmoid activation function.

2.3. Support Vector Machine. The core idea of the SVM algorithm that is fast and reliable is to find an optimal classification hyperplane [17] in high-dimensional space. In linearly separable samples, the formula for defining the hyperplane is

$$w^T x + b = 0. \quad (5)$$

The distance from any point in the sample to the optimal plane is

$$r = y_0 \left(\frac{w}{\|w\|} x_0 + \frac{b}{\|w\|} \right). \quad (6)$$

Any training data satisfies the following formula:

$$y_0 (w^T x_0 + b) \geq 1. \quad (7)$$

So the SVM solves the constrained optimization problem as follows:

$$\begin{aligned} \min_{w,b} & \frac{1}{2} \|w\|^2, \\ \text{s.t.} & y_i (w^T x_i + b - 1) \geq 0 \quad i = 1, 2, \dots, N. \end{aligned} \quad (8)$$

Cross-validation methods and prior knowledge can be used to select the kernel functions that meet the data distribution. The following are the four common kernel functions:

$$\begin{aligned} (1) \text{ Linear kernel function} \\ K(x, x_i) &= x \cdot x_i. \end{aligned} \quad (9)$$

$$\begin{aligned} (2) \text{ Polynomial kernel function} \\ K(x, x_i) &= ((x \cdot x_i) + b)^d. \end{aligned} \quad (10)$$

$$\begin{aligned} (3) \text{ Gaussian kernel function} \\ K(x, x_i) &= \exp\left(-\gamma \|x - x_i\|^2\right). \end{aligned} \quad (11)$$

$$(4) \text{ Sigmoid kernel function}$$

$$K(x, x_i) = \tanh(\gamma x \cdot x_i + b). \quad (12)$$

2.4. Logical Regression. The logic regression algorithm is very simple and practical, belongs to the generalized linear regression model, and is often used to solve the binary classification problem [18]. The basic mathematical formula is as follows:

$$g(x) = \frac{1}{1 + e^{-x}}. \quad (13)$$

Mathematical expression model of logistic regression is as follows:

$$h_{\theta}(x) = g(\theta^T x) = \frac{1}{1 + e^{-\theta^T x}}. \quad (14)$$

For binary classification problems, the logistic regression formula can be simplified as follows:

$$p(y = 1|x; \theta) = \frac{1}{1 + e^{-\theta^T x}}, \quad (15)$$

$$p(y = 0|x; \theta) = 1 - \frac{1}{1 + e^{-\theta^T x}}.$$

For a single sample, the model assumes a unity of

$$P(y|x; \theta) = \left(\frac{1}{1 + e^{-\theta^T x}} \right)^y \left(1 - \frac{1}{1 + e^{-\theta^T x}} \right)^{1-y}, \quad (16)$$

where $y \in \{0, 1\}$.

3. Text Analysis of Emotional Intonation

Text emotion analysis is one of the studies of natural language processing. Pang et al., in 2002, has been widely studied and applied in data exploration, information search, text search, and other fields. As textual emotion analysis plays an important role in society and the economy, it transforms into an interdisciplinary research topic. In recent years, high-level academic conferences at home and abroad have produced many excellent research results. In China, Internet companies such as Baidu and Ali have provided users with a text sentiment analysis API to help users quickly deploy online applications and reduce development costs. Lip, in 2012, introduced the emotional analysis in detail. According to the research method, the text emotion analysis method can be divided into supervised and unsupervised methods. In foreign countries, the research of English text emotional analysis is gradually mature. The main methods of text sentiment analysis can be divided into sentiment dictionary based sentiment analysis method, sentiment analysis method based on traditional machine learning and sentiment analysis method based on deep learning. The method uses processed and labeled data to form a classifier and then uses a classifier to assess the emotional trend [19] of unlabeled data.

The emotional dictionary mainly consists of emotional polarity or emotional intensity. There are three common methods to create emotional dictionaries: methods based on

manual annotation, methods based on existing dictionaries, and methods [20] based on body statistics. The research on the construction of emotion dictionaries abroad started earlier, among which SentiWordNet is the most seriously affected English emotion dictionary. In China, the research on the Chinese emotion dictionary started relatively late. Founded by Dong Zhendong and Dong Qiang, HowNet was a widely used emotional dictionary in early China. Manual creating emotional dictionaries requires a lot of manpower and material resources, and their effects vary by field, so researchers tend to create emotional dictionaries automatically. Hu cites emotionally inclined words as opening phrases and generates a general emotional dictionary through constant iterations. Emotional polarity reverses only when words change. Huang et al. first mark the emotional polarity of high-frequency words in the main text of a specific domain and then use connectors to evaluate the emotional polarity between words to generate a domain-specific emotion dictionary. Due to the few Chinese knowledge bases, most domestic scholars will combine different methods of [21] when automatically compiling the Chinese sentiment dictionary. Zhou Yongmei adopted the Chinese-English translation method, searched for the English words translated by the HowNet dictionary in the SentiWordNet dictionary, calculated the average emotional intensity of all the words, and finally generated the Chinese emotional dictionary. Wang Changhou et al. used the model-based paddle method to extract emotional words, through which they collected a large number of words not included in the traditional emotional dictionary.

This is a popular research method that applies traditional machine learning methods to text emotion analysis. It can learn training data sets to extract functions and generate a text emotion analysis model [22]. Experience has shown that analyzing text sensation using SVMs is effective. Zhang adopted the Bayesian algorithm weighted SME TF-DF own value, applied it to the emotional analysis of the course evaluation text, and achieved good results. Chiong et al. analyzed the text sense of new finance using an SVM-based approach and used a particle test optimization algorithm to optimize the parameters. Huang et al. used the Stanford method to support the voice-dependent support vector machine to analyze financial information, with good results. Liu Siye et al. introduced the keywords of facial expression to expand the text characteristics of tourists' microblog and adopted the maximum entropy model to achieve good results.

In the early 1990s, the development of scientific and industrial deep learning was directly suspended due to the problem of gradient disappearance in the BP algorithm. Until 2006, Hinton, the father of deep learning, has always proposed the weight initialization scheme through the fine adjustment of unsupervised training and supervised training, thus solving the problem of gradient disappearance in the process of deep network formation. The emotional dictionary method and traditional machine learning method have produced many excellent research results in the research of emotional text analysis, but a large labor cost of [23] is needed early in the data processing process.

Deep learning is a machine learning technique based on a set of self-learning algorithms and deep neural networks. In recent years, with the rapid development of technology, the research and application of in-depth learning have also undergone great changes. Compared with traditional machine learning methods, deep learning reduces artificial factors, has deeper model depth, mimics the mechanism by which the human brain processes data, and is able to deeply extract data features. A convolutional neural network is a special neural network that has achieved very good [24] in the field of computer vision. The convolutional layer of the convolutional neural network can extract the local features very well. Six sets of data were used for experimental comparison, demonstrating that TextCNN is effective for some simple text classification tasks. Yu et al. have studied the problem of cross-domain sentence fitting analysis, designing a model involving two distinct networks of convolutional neurons that learn two hidden feature representations from labeled and unlabeled data. The emotional classification, using low-monitoring convolutional neural networks, was performed by Guan et al. The framework consists of two stages: the first is to learn the representation of a sentence, which is not adequately monitored, and the second is to perfect the sentences with labels. Zhao et al. proposed a text sentiment classification method by using the underlying contextual semantic relations and statistical features of co-occurring words on Twitter, combined with a powerful neural network.

Long-term memory networks contribute to natural language modeling, which is important for computer processing and computer processing natural language, deep into the semantic comprehension level [25]. Twitter emotions were classified using long, short-term memory networks. Huang et al. suggest encoding syntactic knowledge into long- and short-term tree memory networks to improve the expression of sentences and phrases. Learning emotion intensity using long- and short-term bidirectional memory networks. Long- and short-term memory networks of language regulation for textual emotion analysis were proposed by Qian et al. This model combines emotional dictionaries, negative words, and intensity words and more accurately captures feelings in sentences. Fu et al. introduced a dictionary-modified LSM model that uses the emotion dictionary to train a word sense classifier to maintain the emotional integration of each word and address the problem that word integration contains more semantic information than emotional information. Lu et al. used the word integration model CBOW to capture word semantic features in microblog text sentiment analysis and extract deep sequence word vector features using stacking BiLSTM.

4. Example Analysis

4.1. Experimental Preparation. Based on the experiment designed for the emotion intonation analysis of enterprise management based on deep learning, we should first collect and classify the emotion tendency data and then analyze it. The experimental environment and configuration adopted in this article are shown in the following Table 1.

TABLE 1: Experimental environment and configuration.

Experimental environment	Configuration information
Operating system	Windows10 (64 bit)
Processor	Intel® Core™ i7-4790, 3.6 GHz
Internal storage	16 GB
Programming language	Python 3.6
Deep learning framework	TensorFlow 1.13
Partition tool	Jieba, PkuSeg

Based on the management staff, a comprehensive happiness questionnaire was specially designed as the measurement questionnaire of this study, and the emotional text analysis of the enterprise management personnel was used in two modules and nine dimensions. It is shown in Figure 1 and Table 2.

Descriptive statistics, factor analysis, correlation analysis, and regression analysis were used in this study. With the enterprise managers, the enterprise managers of all levels in Chengdu, Shenzhen, Xiamen, and Wuhan were investigated. The enterprises mainly include finance, logistics, construction, and other aspects. The sample was selected in April 2022. A total of 300 questionnaires were distributed through the Internet, and 237 valid questionnaires were collected. The sample is provided in Table 2.

4.2. Statistical Results of the Scale. In the general happiness questionnaire, the happiness index scores ranged between 4.91 and 1.628, with the highest proportion being “mean” (see Figure 2). The lowest scores were negative emotions (2.42, 0.96), and the highest scores were self-worth (5.25, 68.4). Besides negative emotions, other dimensions were scored between 3.91 and 5.68 (see Figure 2).

Figure 3 shows that the values for all well-being dimensions are type V, and the lowest point is negative effect. Understandably, Figure 4 respondents’ happiness, Figure 5, in all aspects are positive and high.

4.3. Analysis and Comparison of Experimental Results

4.3.1. Mean Comparison of Each Dimension

- (1) According to the survey results of the psychological authorization scale, the average of the four dimensions of psychological authorization is shown in Figure 4, where the autonomy dimension has the highest score of $4.42 + 0.79$; self-efficacy and work impact are the lowest, 3.71 ± 0.76 and 3.71 ± 0.90 , respectively. It can be seen that the mean for each dimension is between “uncertain” and “very consistent.”
- (2) According to the survey results of the integrity management scale, the average score of the five dimensions of integrity management is shown in Figure 5. We can see that integrity and selflessness have the highest score of $5.17 + 0.91$, while subordinates have the lowest score of $4.59 + 0.93$. The various dimensions of integrity management were scored between 4.59 ± 0.93 and 5.17 ± 0.91 , namely between “slightly consistent” and “fully consistent.”

4.4. Experimental Summary

4.4.1. Innovation of This Experiment

- (1) As a questionnaire compiled by domestic scholars, the comprehensive happiness questionnaire has high

reliability and validity and has been verified in different groups. However, the questionnaire was not applied to business managers prior to this study. In this study, the volume was used for the first time for business managers to conduct qualitative and quantitative analysis, resulting in good credit validity

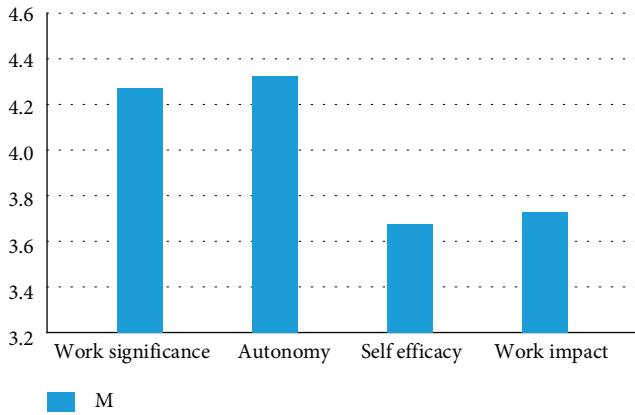

FIGURE 4: Bar chart of the average value of all dimensions of psychological authorization.

FIGURE 5: Bar chart of the mean of each dimension.

and expanding the scope of the comprehensive well-being questionnaire.

- (2) According to the results of this study, the purpose is to adjust the psychological empowerment of management, improve the well-being of enterprise managers, and stimulate their potential through the intermediary variables of well-being. In order to improve the manager’s ability of honesty management and manage the enterprise and staff better, the theory of honesty management and the theory of humanistic management are expanded.

4.4.2. Limitations of This Experiment

- (1) Due to time, resources, and financial constraints, the sampling range of this paper is very limited, and the representativeness of the sample data needs to be further tested by more researchers. Because the mechanisms of happiness are very complex and the

influencing factors are also very complex, they are greatly influenced by regional and economic conditions. Therefore, it is suggested that future studies can expand the regional range of the sample and increase the volume.

- (2) This study focuses on model building and the surface analysis of demographic variables. Furthermore, this study only collected and analyzed data on demographic variables from four aspects: gender, education, years of work, and position. Other demographic variables may differ significantly. No more research was done in this paper due to energy and condition limitations, which require further discussion by later researchers.

5. Conclusion

In view of the emotional intonation text analysis and policy orientation of enterprise management, the technical methods of the deep learning are preliminarily introduced, but more in-depth research is still needed. The application of deep learning method, especially the network neural method; has just started in the field of emotional intonation text analysis and policy orientation of enterprise management; and faces many uncertainties and challenges, but the application prospect is broad.

- (1) Aiming at the forefront of deep learning development, the latest deep learning technologies are constantly introduced. The research field of emotional intonation text analysis and policy orientation of enterprise management is focused. Through simulation experiment, the characteristics of emotional intonation text analysis and policy orientation research of different enterprise management are compared and analyzed, so as to further improve the emotional intonation text analysis and policy orientation of deep learning for enterprise management.
- (2) In the face of doubts about emotional intonation text analysis and policy-oriented research, conduct the interpretability research of deep learning. Based on domain knowledge, an interpretable deep learning model is established to promote the development of crossover research between emotional intonation text analysis and policy-oriented research in the field and the field of deep learning research.
- (3) Enterprise management can not only improve the enthusiasm of enterprise management but also bring positive impact on the health of employees by using emotional tone text analysis and policy-oriented research and analysis to select the optimal scheme.

With the promotion and application of information technology, smart cities based on artificial intelligence have become the best choice for the government to solve urban problems, connect urban citizens, and provide quality public services. From the initial information city and digital city to the current smart city, the construction of smart cities has undergone profound changes with five major characteristics: big data, intelligence, innovation, interaction, and integration, and Internet giants have emerged in the field of public services in smart cities. Internet giants are emerging in the construction of public service platforms for smart cities, and traditional smart city construction enterprises are also expanding various forms of urban operation services through the form of “Internet+”. Nevertheless, there is still a gap between the quantity and quality of China’s smart cities compared with developed countries, and there is a need to build a number of pilot smart cities characterized by the linkage of artificial intelligence technology and public services, easy to promote, and sustainable development. The smart city construction model with public services as the core has research value and has the possibility of becoming the mainstream development in the future. Therefore, exploring the organic combination of AI technology and urban public services is the key to answer whether AI technology can promote the improvement of urban public services.

1. Introduction

China’s urbanization process is accelerating, the level of economic development is rapidly increasing, the urban population is constantly coming in and expanding, and residents’ requirements for daily life and public services are also increasing [1]. Under such circumstances, the traditional public service model is increasingly unable to adapt to these changes [2]. In the face of the growing population size and the increasing requirements for living experience, the contradiction between insufficient urban carrying capacity and low level of public services has forced the need for rapid transformation in the construction of urban public service facilities. Smart cities are undoubtedly a powerful means to break this bottleneck [3]. SmartCity is an intelligent self-awareness, self-adaptation, and self-optimization based on comprehensive perception and interconnection of ubiquitous information using new-generation information technology to achieve

seamless connection and cooperative linkage among people, things, and urban functional systems, so as to make intelligent responses to urban service demands, such as people’s livelihood, environmental protection, public safety, urban functions and business activities, and form a safe, convenient, efficient, and green city with sustainable endogenous power. It can form a safe, convenient, efficient, and green city form with sustainable endogenous power [4]. It can make the services and facilities in the city make intelligent and rapid responses to better perform their functions and guarantee the development of people’s livelihood [5]. Public service facilities, which are the concrete manifestation of the city’s services for its residents, are the means of expression of all aspects of the city’s functions [6]. Whether they are truly organically combined with modern information means, scientific planning and innovation, and ultimately meet the requirements of intelligent services, is the biggest criterion to measure whether a smart city is truly built.

For the construction of urban public service facilities, the main issues to be considered are the rational allocation of space and the correspondence between functions and needs, so when using the theory of smart cities for construction, these issues should also be considered, and on this basis, a more “intelligent” model and thinking should be used to deal with problems, introduce new technologies, and bring wisdom into play [7]. After setting this basic direction, it is necessary to consider various factors, such as input, efficiency, effectiveness and balance. For example, when planning the space, it is necessary to ensure the maximum representation of functions, but also to take care not to take resources from other areas and to ensure the overall coordination and science of urban planning. When designing the specific locations and configurations of various service facilities, the degree of residents’ demand for different services should be actually investigated so that the response speed and priority of the service facilities meet the actual needs, such as appropriately increasing the number and density of some services with high pedestrian flow and urgent demand [8]. In addition, when designing and planning, it is also necessary to apply a developmental perspective as much as possible and introduce innovative means and technologies so that traditional public service facilities can be infused with new vitality, keep up with the times, and strive to meet the gradually growing individualized needs of residents. In this way, it is also expected to enhance the residents’ sense of identity and life experience in the city, pull the development of the city, and improve the overall development level and comprehensive strength of the city.

The construction of smart cities is also inseparable from the application of big data. Through data collection and macro analysis of city residents, we can summarize the demand and intensity of various public service facilities and residents’ tendency to choose them to help make more reasonable planning and settings [9]. By applying various perception-based technologies and location identification systems to draw precise point-to-point planning maps and incorporate detailed information of residents in real time, we can gain a deeper and more comprehensive understanding of residents’ daily needs and living habits and improve the efficiency of public service facilities in a targeted manner.

At present, the construction and development of smart cities suffer from the lack of regional characteristics, insufficient development planning, unbalanced construction and application, imitation over R&D, and difficulty in integrating resources, while the research on smart cities emphasizes technology over application, the disconnection between high-tech and application services, and the deviation between concept and practice. How to plan urban public service facilities scientifically and effectively, and how to apply wisdom technology to public services in combination with social needs are the key points and difficulties of smart city construction, which is also the main theme of this paper.

2. Related Work

Since the theory of “smart city” was proposed, it has been discussed and analyzed by various parties, and the

theoretical system is becoming more and more enriched and mature, and the basic connotation is changing [10, 11]. At present, the discussions and concerns about smart cities are mainly focused on the technical level and the policy level: at the technical level, the concern is about the technology to be introduced and its feasibility; at the policy level, the discussion is about the government’s attitude and guidance, and the presence of democratic forces is considered [12]. In addition, many scholars in China have been committed to constructing and filling the basic framework of smart city theory, trying to explore deeper connotations, combining local characteristics or even local features, and constructing a comprehensive and detailed theory from which all places can learn and form a system that truly fits our national conditions [13].

Technology has always been the focus of attention, and although the combination of information technology and urban construction is not a new concept, how to use it skillfully and rationally needs to be explored in depth [14]. At present, smart cities are applied to a variety of technical means, of which the supporting technologies mainly include cloud computing, information collection and integration, artificial intelligence identification, etc. And with the continuous development of information technology and frequent results, more new technologies are bound to be applied to the construction of smart cities [15]. At present, several cities in China have incorporated the construction of smart cities into their development plans, and the applicable technologies will be different for these cities with different development directions and human geographic connotations [16]. How to use the technology comprehensively according to their own characteristics and realize the maximum value of the technology is also a problem that needs to be faced directly [17].

The smooth construction and development of smart cities cannot be achieved without the support and guidance of policies [18]. In this regard, relevant departments and experts have studied and discussed the policies. Smart cities involve economy, people’s livelihood, humanities, environment, etc., which cannot be favored over others, otherwise, it will easily cause unbalanced and unstable conditions, which is the reason why policy forces are needed to intervene. The policy research should start from the position of each resident, close to the people’s life, and try to achieve real benefit to the people.

In the context of artificial intelligence, it is of great importance how to better recommend and apply public services in smart cities, in which effective intelligent recommendation algorithms are necessarily needed. The basic idea of recommendation system, as a tool to facilitate people to quickly and accurately locate the items they are interested in among a large number of item choices in the era of big data, is to extract the characteristics of users and items from their historical data by building a model, and to recommend items to users in a targeted manner using the trained model [19]. Research on applying reinforcement learning to recommender systems has received increasing attention. The first exploratory model that applies deep reinforcement

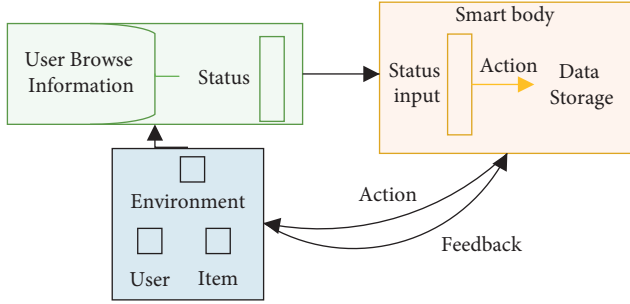

FIGURE 1: Schematic diagram of deep reinforcement learning-based recommendation system.

learning to recommender systems is DRN [20], which constructs a basic framework for recommender systems, and the block diagram is shown in Figure 1.

In such a reinforcement learning framework, the learning process of the model can be iterated continuously, and the iterative process has the following main steps.

- (1) Initialize the recommendation system (intelligent body)
- (2) The recommendation system performs news ranking (action) based on the current collected data (state) and pushes it to the website or app (environment)
- (3) The user receives a list of recommendations and clicks or ignores (feedback) a recommendation result
- (4) The recommendation system receives the feedback and updates the current state or updates the model-by-model training
- (5) Repeat step 2

There have been many research results about deep reinforcement learning-based recommender systems, such as

the literature [21] and others applied DQN to social networks. Applied DQN to a trust recommendation system based on social networks, applied to an intelligent body to learn the dynamic representation of trust between users and recommend users based on that trust value; literature [22] applied DDQN to recommendation suggestions, solving the problems of low recommendation accuracy, slow speed, and cold start; literature [23] applied DDPG algorithm to stored recommendations, solving the problem of sparse user data. The literature [24] applied the Actor-Critic algorithm to list-based recommendation, solving the problem that the traditional recommendation model can only model the recommendation process as a static process. The above research results and the numerous studies not listed above use the nature of reinforcement learning itself to solve the recommendation problem, and rarely consider the problem from the recommendation perspective.

3. Practical Scheme

By dividing the basic public service items, the dimensions of measuring the level of public services in smart cities were classified as public education (PE), social security (SC), medical health (MHC), housing security (HC), public culture (PC), and social services (SS). The smart city pilot started in 2013, so the panel data of 31 provinces (regions and cities) in China from 2014 to 2018 were selected for the empirical study. The data were obtained from China Statistical Yearbook, China Science and Technology Statistical Yearbook, and National Housing Fund Report from 2014 to 2018. In order to exclude the influence of factors, such as interaction terms and reveal the relationship between AI technology and public service level, control factors are added and a panel data model is constructed:

$$\begin{aligned}
 PE_{ti} &= \alpha_0 + \beta_1 DI_{ti} + \beta_2 DO_{ti} + \beta_3 GDP_{ti} + \beta_4 FDI_{ti} + \beta_5 INF_{ti} + \beta_6 PS_{ti} + \epsilon_{ti}, \\
 SC_{ti} &= \alpha_0 + \beta_1 DI_{ti} + \beta_2 DO_{ti} + \beta_3 GDP_{ti} + \beta_4 FDI_{ti} + \beta_5 INF_{ti} + \beta_6 PS_{ti} + \epsilon_{ti}, \\
 MHC_{ti} &= \alpha_0 + \beta_1 DI_{ti} + \beta_2 DO_{ti} + \beta_3 GDP_{ti} + \beta_4 FDI_{ti} + \beta_5 INF_{ti} + \beta_6 PS_{ti} + \epsilon_{ti}, \\
 HC_{ti} &= \alpha_0 + \beta_1 DI_{ti} + \beta_2 DO_{ti} + \beta_3 GDP_{ti} + \beta_4 FDI_{ti} + \beta_5 INF_{ti} + \beta_6 PS_{ti} + \epsilon_{ti}, \\
 PC_{ti} &= \alpha_0 + \beta_1 DI_{ti} + \beta_2 DO_{ti} + \beta_3 GDP_{ti} + \beta_4 FDI_{ti} + \beta_5 INF_{ti} + \beta_6 PS_{ti} + \epsilon_{ti},
 \end{aligned} \tag{1}$$

$$\frac{1}{n} \sum_{i=1}^n \text{Ave_Reward}_i, n,$$

where PE_{ti} denotes the level of public education in city i ($i = 1, 2, \dots, n$) in year t , SC_{ti} denotes the level of social security in city i in year t , MHC_{ti} denotes the level of health care in city i in year t , HC_{ti} denotes the level of housing security in city i in year t , PC_{ti} denotes the level of public culture in city i in year t , SS_{ti} denotes the level of social services in city i in year t , DI_{ti} denotes the AI technology input of city i in year t , DO_{ti} denotes

the AI technology output of city i in year t , GDP_{ti} denotes the economic level of city i in year t , FDI_{ti} denotes the openness level of city i in year t , INF_{ti} denotes the infrastructure level of city i in year t , PS_{ti} denotes the population size of city i in year t , and ϵ_{ti} is a random disturbance term.

Public education (PE) is measured by the pupil–teacher ratio in elementary schools. With the popularization of

TABLE 1: Descriptive statistics of each variable.

Variable name	Sample size	Mean value	Standard error	Min	Maximum value
PE	155	16.187	2.35	12.13	18.99
SC	155	3.197	0.65	1.32	4.51
MHC	155	8.933	2.06	5.39	18.21
HC	155	545.798	445.21	42.12	2293.69
PC	155	0.699	0.55	0.28	3.28
SS	155	28.798	10.05	8.31	65.21
DI	155	0.245	0.21	0	1.00
DO	155	0.205	0.23	0	1.00
GDP	155	0.279	0.19	0	1.00
FDI	155	0.152	0.21	0	1.00
INF	155	0.556	0.23	0	1.00
PS	155	0.387	0.28	0	1.00

quality education, the teacher–student ratio has become an important criterion for the improvement of educational strength. Social Security (SC) is measured by the urban registered unemployment rate. With the development of the economy, the role of unemployment insurance in preventing unemployment and promoting employment is becoming more and more important, and has become a booster and safety valve for economic development and social stability. Medical Health Care (MHC) is measured by the number of beds in medical and health institutions per 1,000 people. With the development of modern economy, the residents’ demand for medical and health resources allocation is getting higher and higher, and the number of medical and health institution beds in a region represents the intensity of medical and health security in that region. Housing security (HC) is measured by the amount of CPF contributions. The value-added income of the CPF provides a source of funds for the construction of low-cost housing and supports low-income families in solving their housing problems, reflecting the special function of housing security. Public culture (PC) is measured by the number of books per capita in public libraries. In terms of equalization, standardization, digitalization, and socialization, libraries have always led the development of public cultural services. Social services (SS) are measured by the number of elderly beds per 1,000 elderly people. “The 13th Five-Year Plan points out that the number of social service beds for the elderly can be used as the basis for judging the assistance and welfare subsidies for the elderly.

Artificial intelligence investments are based on trading logic and mathematical models given to computers by computer programmers. Computers are programmed to capture investment opportunities across the market and put them into practice, and all trading moves are made based on models, algorithms, and logic that can overcome human weaknesses, such as greed, fear, and fluke. Investment in artificial intelligence (DI) is measured by the intensity of investment in research and experimental development (R&D) in each region. Capital is the blood of innovation activities and is an important link to continuously support the development of innovation in the digital economy. R&D investment intensity can better measure the R&D capital investment in digital information technology. Artificial intelligence technology output (DO) is measured by the number

FIGURE 2: Sketch of state generation.

of patent applications per 10,000 people in each region. Patent data can better reflect technological innovation and better demonstrate the level of AI technology in cities.

Economic level (GDP), measured by per capita gross regional product; openness level (FDI), measured by foreign fixed asset investment; infrastructure (INF), measured by per capita urban road area; and population size (PS), measured by the number of population at the end of each year, are given in Tables 1–3.

This section introduces the proposed model for Smart City Recommendation (SCR), which uses user interests as the states seen by the intelligences in deep reinforcement learning as a way to accomplish the intelligent recommendation task. To capture the long-term interest of users, this paper uses a long- and short-term memory network (LSTM) with state enhancement units to learn the browsing records of users over a longer period of time, and retention ratios in the network through three gating units.

We use the attention mechanism as the base model for extracting users’ short-term interests. It is assumed that the user’s short-term interest can be extracted from three consecutive browsing records (item1, item2, and item3), which are coded to form vector γ . After that, the three vectors are calculated as respective Queries vector, Keys vector, and Values vector according to different parameters W_{Qi}, W_{Ki}, W_{Vi} ($i = 1, 2, 3$) and combined into a matrix form, and then the following formula is used to calculate the self-attentive value of each record is calculated by the following formula.

$$Z * = \text{softmax}\left(\frac{Q \times K^T}{\sqrt{d_k}}\right), \quad (2)$$

FIGURE 3: Ave_Reward trend graph.

 FIGURE 4: Trend of total_ave_reward value for different values of γ .

where Q, K, V are the matrices based on X_1, X_2, X_3 vectors combined as Queries vector, Keys vector, and Values vector, respectively, and d_k is the length of a browsing record. Z^* is the matrix of the final calculated vector of short-term interests of the user reflected by each item.

The final short-term interest of the user is achieved by directly summing the user short-term interest vectors reflected by each item, i.e.,

$$\text{shortinterest} = Z_1 + Z_2 + Z_3 + \dots + Z_n. \quad (3)$$

The Z_i in the equation represents the user's short-term interest reflected by the i th browsing record. i has a temporal characteristic, i.e., the larger i is, the closer it is to the current moment, and Z_i the closer the interest expressed is to the user's current interest. Careful consideration reveals that when multiple Z_i 's are superimposed, the trend of current user short-term interest is diluted as Z_i 's are superimposed. To solve this problem, this paper improves short interest by

adding weights to the short-term interests expressed by each browsing record in order, and the more backward the time, the greater the weight assigned to the user's short-term interests, as expressed by the formula

$$\text{shortinterest} = \frac{1}{n}Z_1 + \frac{2}{n}Z_2 + \frac{3}{n}Z_3 + \dots + Z_n. \quad (4)$$

The final model is called T -self-attention, and the weight of the interest vector in the short-term interest composition is assigned in time sequence. By embedding the long and short-term interest extraction module into the Actor network of the DDPG algorithm, the purpose of updating the parameters of the long- and short-term interest extraction module network while training the Actor network is achieved, and an improvement of the Actor network is shown next. The pseudocode of the algorithm of SCR is given in Algorithm 1.

Input: user history browsing records
Random initialization of Critic network $Q(s, a \theta^Q)$ and Actor network $\mu(s \theta^\mu)$
Network parameters θ^Q, θ^μ
Initialize the network parameters $\theta^{Q'} \leftarrow \theta^Q, \theta^{\mu'} \leftarrow \theta^\mu$ for the target network Boo Q', μ' .
Initialize the LSTM network parameters
Initialize the T -self-attention network parameters
Initialize the T -self-attention network parameters
For episode = 1, Mdo for action exploration initialization
Random process N
Randomly select user u
Get the current browsing history of user u and the browsing history of the next moment
For $t = 1$ to T do
Based on the current browsing record R_c , the current moment status s_t is generated by Algorithm 2
Based on the next browsing record R_n , the next moment s_{t+1} is generated by Algorithm
Generate action based on Evaluation-Actor and noise $a_t = \mu(s_t \theta^\mu) + N_t$
Execute the action a_t Get the return r_t
Calculating TD-error target values $y_t = r_t + \gamma Q'(s_{t+1}, \mu'(s_{t+1} \theta^{\mu'})) \theta^{Q'}$
Based on loss $L = 1/n \sum_i (y_i - Q(s_i, a_i \theta^Q))^2$
Update Critic Network
Update actor policy with sampling policy gradient: $\nabla_{\theta'} J \approx 1/N \sum_i \nabla_a Q(s, a \theta^Q) _{s=s_i, a=\mu(s_i)} \nabla_{\theta'} \mu(s \theta^\mu) _{s=s_i}$
Update the target network parameters by soft copy. $\theta^{Q'} \leftarrow \tau \theta^Q + (1 - \tau) \theta^{Q'}$
$\theta^{\mu'} \leftarrow \tau \theta^\mu + (1 - \tau) \theta^{\mu'}$
Output: predicted ratings

4. Case Study

In order to prove the effectiveness of our scheme, we have experimented and analyzed it on a dataset. In this paper, the following rules are followed in both training and testing phases: the user browsing sequence is denoted as: $S_u = (I_1, I_2, I_3, \dots, I_{|S_u|})$, where I_i denotes the i -th record of the item viewed by the user. The first $0.8 * |S_u|$ of each user's browsing records are used as the training set, and the remaining data are used as the test data. During training, the browsing records in the training set are input into the model in order of users, and for each record, the model predicts the rating of the recommendations contained in the record, and

the reward value is calculated based on the difference between the real rating and the predicted rating and fed back to the intelligence, and the algorithm optimizes the model based on the reward value. The operations during testing are similar to those during training, but there is no model optimization operation.

- (1) Action space: in this paper, the original scores are normalized to map the range of values to the interval $[0, 1]$, which becomes $(0, 0.25, 0.5, 0.75, 1)$. Meanwhile, the results are mapped to the $[0, 1]$ interval using the sigmoid activation function at the fully connected layer of the algorithm using the

floating-point data with continuity generated each time as the action, i.e., the predicted recommendation scores. Therefore, the action space of this model is a continuous space in the interval of $[0, 1]$.

- (2) State space: the user browsing records are treated as an observation, and the extracted interests are used as states after interest extraction by the long-term interest and short-term interest extraction modules in chronological order. The brief process is shown in Figure 2.
- (3) Reward function: when designing the reward function, this paper uses the difference between the predicted score and the real score as the criterion to guide the optimization direction of the intelligent body. The specific design approach is as follows:

$$\text{Reward} = e^{-(\text{abs}(\text{pre_score} - \text{real_score}))}, \quad (5)$$

where pre_score indicates the predicted score, real_score indicates the real score, and abs indicates that the absolute value sign is taken. The reward function can be interpreted as follows: the larger the gap between the predicted score and the real score, the smaller the reward obtained by the intelligence, and the smaller the gap the larger the reward obtained.

In this paper, the performance of the algorithm is observed mainly through the trend of the rewards obtained by the intelligences to observe whether the algorithm eventually converges. In testing the convergence of the algorithm, because the test results of a single user are contingent and do not reflect the overall performance of the algorithm, this paper collects the rewards obtained by the intelligences of each record of each user during the test and reflects the convergence of the algorithm by calculating the mean value of the collected data. Thus, the final rewards used for testing take the form of

$$\text{Ave_reward} = \frac{\sum_i \sum_j r_{ij}}{N}. \quad (6)$$

The effectiveness of the algorithm is tested using the root mean square error (RMSE) and the mean absolute error (MAE), which are common test metrics for rating classification algorithms. The RMSE and MAE are expressed as

$$\text{RMSE} = \sqrt{\frac{1}{m} \sum_{i=1}^m (y_i - \hat{y}_i)^2}, \quad (7)$$

$$\text{MAE} = \frac{1}{m} \sum_{i=1}^m |y_i - \hat{y}_i|.$$

4.1. Experimental Results and Analysis

4.1.1. Overall Performance Comparison. Therefore, after the analysis of Tables 4–6, the performance of the deep reinforcement learning algorithm based on the extraction of public service infrastructure. The specific results are given in Tables 4–6.

4.1.2. Analysis of Algorithm Convergence. This part of the experiment mainly collects the Reward value Reward that the intelligent body can obtain after each prediction recommendation score when the algorithm is tested, as well as the RMSE and MAE values that can be obtained for each round of prediction, and analyzes the convergence of the algorithm by observing the trend of the values of these evaluation indexes. Also, in order to evaluate the convergence of the algorithm as a whole, this paper analyzes the algorithm by observing the trend of the average return Ave_Reward in each round. Figure 3 shows the trend graph of the Ave_Reward values of the DDPG-LA algorithm and the combined algorithm of each module with increasing number of training sessions on both data sets.

From Figure 3, it can be seen that the overall results of all algorithms tested on the dataset are better.

4.1.3. *Comparative Analysis of Discount Factor γ* . In the experimental process to get the best experimental results, this paper tries various different discount factor values and visualizes the effect of each discount factor through the final results. And by comparing the height of the curves, it is found that the height of the curve changes with the value of γ from small to large, and the trend of this correlation is shown in Figure 4.

The Total_Ave_Reward value represents the average of the average Reward for each round of testing at different γ values, i.e.,

$$\frac{1}{n} \sum_{i=1}^n \text{Ave_Reward}_i, \quad (8)$$

where n denotes the number of test rounds. Figure 4 shows that different discount factors have an effect on the final convergence of the algorithm and are positively correlated.

5. Conclusion

The needs of social development, the support of national policies, and the support of information technology have created a very favorable environment for the development of smart cities and become a strong impetus for the smooth development of smart cities. In practice, construction planners tend to pay too much attention to the input of technology and its effect to meet expectations, while ignoring the inner needs of thousands of city dwellers, that is, ignoring the essence of "service." Before making a decision, a comprehensive and large-scale survey should be conducted to identify the needs of the residents, and on this basis, a plan should be designed to make the city a livable place that is recognized by the people through artificial intelligence-based methods, rather than operating according to the criteria that the decision makers have in mind. The concept of smart cities continues to rise in popularity, with more and more voices participating in the discussion, and it is normal for misconceptions and deviations to occur, but as decision makers and builders, it is important to clearly understand

where the original intention of developing smart cities lies, to think about its essence and connotation in an environment where the heat remains high, and to make decisions that are truly relevant.

Among the many service industries, e-commerce, which is based on the Internet and relies mainly on platforms and third-party transaction models, has developed rapidly. All localities have actively deployed their regional e-commerce development strategies to improve the core competitiveness of the regional economy. The rapid development of e-commerce provides a favorable development environment and construction environment for the spatial agglomeration of e-commerce service industry. We use the intelligent computing method to calculate the e-commerce service degree prediction experimental results that show that according to the curves of the three algorithms, we can also see that the curve values of the intelligent computing and fuzzy statistical algorithm models are very stable and the experimental results are also very stable. It shows that the performance of the intelligent computing algorithm is the most superior; the second-level indicators are the after-sales service of the merchant, the popularity of the merchant, and the attitude of the merchant's customer service; in the establishment of the logistic satisfaction evaluation index system, we found that the logistic satisfaction is the first-level indicator; the secondary indicators are the speed of logistics, the safety of logistics, the service attitude of logistics, and the price of logistics; after running on the test set, the model accuracy rate of the fuzzy statistical algorithm is 89.12%, and the accuracy rate can reach 89.56%. The accuracy rate of the intelligent algorithm can reach 92.46%, and the accuracy rate can reach 93.27%, which is the one with the highest index value among the three experimental models. Among the many service industries, e-commerce, which is based on the Internet and relies on platforms and third-party transaction models, is developing rapidly. All localities have actively deployed their regional e-commerce development strategies to improve the core competitiveness of the regional economy. The rapid development of e-commerce provides a favorable development environment and construction environment for the spatial agglomeration of e-commerce service industry.

1. Introduction

While users are using such huge multimedia data more and more, more and more people are using cloud computing technology. It is necessary to effectively manage big data and consider the transmission efficiency of multimedia data of different qualities. A variable allocation algorithm is required for this. This study proposes a method to design a MapReduce scheme applying the FP-growth algorithm, which is a data mining method based on the IaaS (infrastructure as a service) stage of the Hadoop platform, including CPU, network, and storage. The method is then used to allocate resources using this scheme [1]. This study is

devoted to applying evolutionary algorithms, gradient methods, and artificial neural networks to the problem of mechanical structure recognition. A dedicated intelligent computing technology (ICT) for global optimization is proposed. ICT is based on a two-phase strategy. The first stage adopts an evolutionary algorithm as a global optimization method. The second stage adopts a special local method combining gradient method and artificial neural network. The proposed technique has many advantages. The key issue of the proposed method is the application of artificial neural networks to compute sensitivity analysis [2]. This study proposes to use the quality prediction method to develop a cloud computing-based intelligent manufacturing

scheduling system. A CBIMS continuously builds a variety of different production line layout modes. We use a cloud database for data decentralization and storage, and the scheduling engine contains a sequence scoring system for products, an optimized layout system, and a monitoring system for all available resources [3]. Big data fusion intelligence is the core issue of data science and engineering. This study will first analyze the connotation of big data fusion from the perspective of complex systems. The new research perspective of deep learning technology and the new technology trend of granular processing in data fusion are analyzed, and finally, the architecture of particle computing and processing used to build an intelligent big data integration model for complex system intelligence research is discussed. The research of this subject is a meaningful research and development method in system management and control [4]. According to previous studies, robot walking can only be achieved in prespecified spaces and prespecified actions. In this study, a walking system for a bipedal robot uses fuzzy systems and neural networks to overcome these limitations. The system enables bipedal walking in a variety of environments and more complex obstacles. To do this, a walking robot should recognize its surroundings and determine its movements. In the proposed system, the robot uses neural networks to dynamically generate the walking path of each of its joints as it encounters new obstacles, such as stairs, and maintains walking stability thanks to the control system. The walking stability is maintained by controlling the closed-loop fuzzy control system of the lumbar joint [5]. This article was prepared with financial support from the UK Government's Department for International Development, funding a B2B e-commerce research project in developing countries. The authors draw on comments from Robin Mansell, John Humphrey, and Hubert Schmitz in previous publications in which they collaborated on this research project. Any errors or omissions are the sole responsibility of the authors [6]. We recommend designing an intelligent agent to improve the accessibility of e-commerce applications and websites for the visually impaired. An important feature of this design is the use of information presentation techniques, especially conceptual structures that accurately capture and represent the navigational semantics of each document. It allows users to express high-level navigation destinations using design techniques to achieve these goals. In practice, complex parts of HTML documents are traversed by proxy servers on behalf of visually impaired users [5]. As an emerging network technology, cloud computing provides new methods and means for the construction of e-commerce service system. The author discusses the operation mechanism of the service platform from four aspects: the distributed storage of resources, the coordination of service subjects, and the multiparty interaction between services and security, aiming to promote the rapid development of e-commerce in the cloud computing environment [7]. This study firstly extends log4j and then applies the log file distribution function of log4j to the e-commerce service system. In this way, all log information can be avoided centrally interspersed in a single log file, and log information of different

concerns can be effectively dispersed, which is convenient for monitoring and analyzing the running status of the e-commerce service system [8]. Whereas traditional marketing is product-centric, e-commerce marketplaces focus exclusively on customers. The challenge of e-commerce is to really capture the interest of the Internet user and tailor the answer to his requirements that helps the business to target the right customer with the right product or service. To address these issues, the system analyzes the property marketing of online businesses to connect advertisements to target customer groups. Through an agent-based architecture and obfuscation techniques, the system provides simple support for e-commerce market intermediaries [9]. First, a multinomial logit (MNL) model was constructed to reveal the influence of individual attributes, family attributes, and safety hazards on residents' travel satisfaction and to clarify the influencing factors. Then, with significant factors as independent variables, a tourism satisfaction evaluation model based on support vector machine is constructed. The results show that the following factors have a significant impact on residents' travel satisfaction: age, work, education level, number of cars, income, living area, and hidden safety hazards of people, vehicles, roads, and environment [10]. This article conducts a comprehensive and effective survey and data collection on the current situation of geriatric nursing with questionnaires and establishes an evaluation index system that influences the satisfaction of geriatric nursing services with the SERVQUAL model. Based on this, this article analyzes one-dimensional data into two-dimensional data, uses extensive computer vision research, and then uses the educated online model as an effective analysis tool to provide possible predictive outcomes to improve the health care of proposed retirees [11]. Even if neural language models encode these constraints, we design an extensible test suite to address different aspects of utterance and dialogue coherence. Unlike most previous coherence assessment studies, we address language-specific devices beyond sentence order perturbations, allowing for a more fine-grained analysis of what constitutes coherence and what neural models trained on language modeling goals actually encode. This paradigm is equally applicable to assessing the quality of language that contributes to the concept of coherence [12]. The job responsibilities of teachers have changed significantly in recent years, and now more than ever, there is an urgent need for high-quality teachers to achieve the goals of ESD, especially in developing countries. This timely study examined professional and nonprofessional teachers' assessment competencies and their satisfaction [13]. Job satisfaction is one of the most important variables in student standards. We compare, but are not limited to, a number of employee-related variables, including performance, organizational commitment, and core concepts. The results provide documentation of the structural impact and identify two-thirds. The unique effect was found to be the strongest predictor of job satisfaction, despite the use of the satisfaction measure. Further developments are needed to structure the impact, knowledge, and components of these factors and evaluations of job satisfaction predictions [14].

2. Research on e-Commerce Services

2.1. Deep Docking between e-Commerce Services and Individual Consumers. e-commerce relies on online system platforms to provide users with services of different types and natures. Whether it is purchasing physical products, recharging games in virtual space, or even making lists for fans on specialized service websites, they can all be regarded as the category of e-commerce services. In the era of big data, people in the industry need to expand their management concepts, should not focus on traditional commodities, logistics, and other services, and should summarize all transaction behaviors based on the Internet platform into the e-commerce service system. In the future, enterprises should deeply infiltrate e-commerce into individual consumers, emphasizing individualized services for consumers. Every ordinary consumer is the service object of e-commerce enterprises. Organizations must provide accurate and proactive customer service through scientific analysis of big data. Organizations must also innovate and improve service models in daily consumption and self-satisfaction, such as when consumers buy clothes. They only enjoy the personalized service of premium members; that is, online or offline designers can provide consumers with unique clothing designs. It cannot only enrich the service content but also bring users the ultimate enjoyment and service, so that they can feel the respect and attention from the enterprise. The groups of e-commerce services are shown in Figure 1. The scope of sub-business is very wide and generally can be divided into business-to-business, or business-to-consumer, or two. There is also a consumer-to-consumer model that is growing in stride. As the number of Internet users in China grows, the method of using the Internet to purchase and pay with a debit card is becoming increasingly popular. Market share is also growing rapidly. e-commerce sites are slowly evolving. The most common security mechanisms for e-commerce are SSL (secure socket layer) and SET (secure electronic transaction protocol).

2.2. Innovation Strategy of the e-Commerce Service Model. Today, the Internet provides global connectivity. Through the network, customers can bypass distance restrictions and provide consulting and consumption services to global merchants at any time. Despite the growing share of the e-commerce market, the influx of anonymous users has created many problems for the company. With the development of data technology, marketers can accurately identify anonymous shoppers and recommend products that satisfy customers' purchasing power by examining their attention and enthusiasm for purchasing. This not only saves consumer consultation time but also helps merchants avoid the cost of moving unnecessary merchandise. Based on this, providing these services is not enough—e-commerce companies need to improve service specifications and find market gaps from data analysis to service development.

As the online shopping model becomes more and more popular, e-commerce models such as Taobao, Pinduoduo, and Tmall Suning Tesco have shown positive growth. People have a wider choice of shopping routes, and the logistic requirements for these online shopping businesses are also

greater. E-commerce businesses not only need to serve customers and recommend products but also need to enhance transportation and logistics. For example, consumers may want to buy their favorite fruit online, but the delivery time is too long and they miss the coldest moment, which naturally makes customers happy. Therefore, enterprises need to evaluate the nature of products purchased by consumers; data technology is used to select the most suitable transportation method to effectively improve logistic efficiency.

Due to the unstable market, e-commerce companies should not copy others' words along the way, and if they see an advantage over other companies, they do not copy them. You will only look ridiculous and never go the way of a market economy. Electronics companies not only focus on this fact in business operations but also make similar mistakes in the field of services. In the era of big data, e-commerce companies can use real-time market analysis to predict future market trends and fine-tune their service models. The e-commerce innovation strategy is shown in Figure 2.

2.3. Suggestions for Improving e-Commerce Services

2.3.1. Building a Multilingual Service Platform. Intensification and integration are the focus of cross-border e-commerce service innovation. Cross-border transfers include multilingual communication and customs documentation to complete logistics and distribution; multiple currency changes and multilingual payment instructions are required. A multilingual service platform is established to solve language translation problems.

2.3.2. Providing Full Logistic Services. Cross-border logistic services can improve cross-border e-commerce, making it easier for local consumers to search for information in other countries and buy high-quality, affordable products. Logistic services are provided throughout the process, greatly enhancing cross-border e-commerce opportunities. For example, overseas warehousing and logistic providers bear development costs; speed will combine various transportation methods to meet the needs of different suppliers, including security and after-sales service. The delivery and delivery time of all logistic service products are shortened, and customers with a one-stop solution are provided. It includes product tracking service. Cargo visibility service is a local and international logistic information platform that connects importing companies to provide real-time cargo information. The service aims to accurately understand market demand, help cross-border e-commerce companies to accurately locate goods, and distribute popular science vehicles to increase capacity.

2.3.3. Strengthening Omni-Channel Management. Massive mobile Internet applications have created multi-channel channels in the network, expanding the scope of no application boundaries, integrating online and offline, and taking multichannel channels as the development goal. Overseas "tentacles" (such as opening foreign experience stores and opening foreign warehouses through display

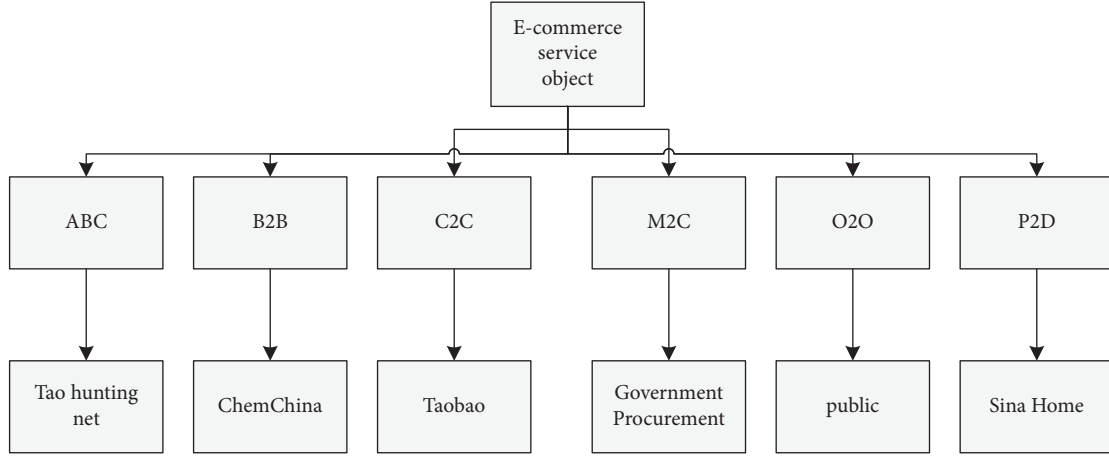

FIGURE 1: e-commerce service groups.

FIGURE 2: e-commerce innovation strategy.

business) are created to shorten the distance with customers; experience services combined with online product information are provided; customer trust, discounts, and promotions are built; and it is inspiring. Consumption provides value-added services for enterprises. The proposed model of e-commerce service is shown in Figure 3.

3. Intelligent Computing Algorithm

3.1. Federated Average Algorithm. In traditional machine learning methods, feature extraction needs to capture unique features based on images and unique detection purposes, such as HOG features that emphasize the outline of objects and Haar features that focus on light and dark contrast. After the features are described, they are sent to the machine learning algorithm for classification, such as SVM and AdaBoost, and then determine the classification of objects. The image detection and recognition tasks are completed by performing the sliding frame operation on the image or substituting the above process into the preprocessed ROI frame.

Centralized learning algorithm, distributed learning across devices, learns local model updates and occasionally interacts with a central server to coordinate global learning objectives. Unlike traditional machine learning methods, blended learning requires training models to be centralized on a computer or data center so that each client device can use a local training dataset to update the model. Federated learning is defined as solving the minimization of the objective loss function according to equation (1), where K is the

FIGURE 3: e-commerce service suggestion.

total number of client devices and n_k is the number of samples in the dataset on the client device k . The combinatorial learning algorithm uses the shared dataset as $n = \sum_k n_k$ and $p_k = n_k/n$. It is expressed as the proportion of the total set of algorithm training data for each device k .

The data of horizontal federated learning are divided horizontally, and the data schemas of the participants are consistent and have the same characteristics. This is the most mature direction of federated learning at present. The federated learning first proposed and implemented by Google can be regarded as horizontal federated learning, except that the participants are its APP clients.

$$\min f(\omega) = \frac{1}{n} \sum_{k=1}^K n_k F_k(\omega) = \sum_{k=1}^K p_k(\omega). \quad (1)$$

The local prediction loss function trained by the model parameters for each client device k is $F_k(\omega)$, as shown in equation (2). By computing multiple local optima, it is aggregated to achieve global learning loss minimization.

Centralized learning algorithm, distributed learning across devices, learns local model updates and occasionally interacts with a central server to coordinate global learning objectives. Unlike traditional machine learning methods, federated learning requires training models to be centralized in a data center on a machine or computer, allowing each client device to use a local training dataset for model updates. Federated learning is defined to solve the objective loss function minimization.

$$F_k(\omega) = \frac{1}{n_k} \sum_{i \in n_k} f(x_k, \omega). \quad (2)$$

This will improve common patterns in connected learning systems. To solve the objective equation (1), FedAvg first randomly selects k units from a subset of system units at each computation iteration and then uses a combined FedSGD optimization method to globally implement each selected unit, computing the sum of the global state and local data.

$$\begin{aligned} g_k &= \Delta F_k(\omega_k), \\ \forall k, \omega_{t+1}^k &\leftarrow \omega_t - \eta g_k. \end{aligned} \quad (3)$$

In each round of the update round, the server collects training data from all devices participating in that training round of the pattern and calculates the weighted average system update pattern according to equation (4), where η represents the training learning rate.

$$\omega_{t+1} \leftarrow \omega_t \eta \sum_{k=1}^k 1. \quad (4)$$

The number of elements in the FedAvg algorithm plays a crucial role in the speed of convergence and the accuracy of predictions. Some people suggest adding the stack size to some value to approximate disk. When installing a large compressed package, each device can speed up the calculation of the same amount of data, improve the convergence speed of the system, reduce the number of iterations, and keep the training of the system at a high enough level of accuracy.

3.2. Balanced Optimization Algorithm. In the equilibrium optimization algorithm, two points P_1 and P_2 are used within a hypersphere of radius of 1 for local development and global exploration, respectively. The search radius δ_1 based on point P_1 will become smaller and smaller, which has the meaning of shrinking inward, corresponding to the yin, while the search radius δ_2 based on the point P_2 will become larger and larger. It has a sense of outward expansion, which is consistent with any Yang pair. In an intelligent optimization algorithm, local development and global exploration are both complementary and competitive, corresponding to yin-yang mutual root and yin-yang opposition, respectively. In the calculation process, the local search and global search based on points P_1 and P_2 are continuously strengthened, which corresponds to both yin and yang. If point P_2 is better than point P_1 , then these two points are exchanged, and the

sympathetic algorithm corresponding to yin and yang is repeated based on points P_1 and P_1 . The optimization search of P_2 is expected to achieve a balance between local development and global search, corresponding to the balance of yin and yang. In the specific implementation, the yin-yang balance optimization algorithm mainly includes two stages: the solution update based on the archive set and the solution update based on the hypersphere. The main contents of these two stages are given below. The search radius δ_1 and δ_2 are updated, and the calculation method is as follows:

$$\begin{aligned} \delta_1 &= \delta_1 - \left(\frac{\delta_1}{\alpha}\right), \\ \delta_2 &= \delta_2 + \left(\frac{\delta_2}{\alpha}\right), \end{aligned} \quad (5)$$

where α represents the scaling factor. In this stage, P_1 is the center, δ_1 is the radius, P_2 is the center, and δ_2 is the radius to perform local search and global search in the hypersphere. According to the algorithm design, these two searches use the same solution update equation. For the convenience of expression, let P and δ denote the search center and radius. Before updating the solution, firstly 2D identical points P are generated, denoted by $NP_1, NP_2, \dots, NP_{2D}$, respectively, and then the update operation on these 2D points is performed. In the algorithm, one component or all components of a point can be updated. A component update equation for a point is as follows:

$$\begin{aligned} NP &= P^j + \delta \times \frac{r}{\sqrt{2}}, \\ NP &= P^j + \delta \times \frac{r}{\sqrt{2}}, k = D + 1, D + 2, 2D. \end{aligned} \quad (6)$$

Among them, NP represents the NP component of point j ; P^j represents the P component of point r ; and r represents the random number between 0 and 1. When updating all components of the point, $2D \times D$ is also used. Binary matrix B requires each binary string of the matrix to be unique, and the updated equation for all components of points is as follows:

$$\begin{aligned} NP_k &= P^j + \delta \times r, B_k^j = 1, \\ NP &= P^j - \delta \times r, B_k^j = 0, \end{aligned} \quad (7)$$

where B_k^j represents the matrix element at row k and column j . In the algorithm, one of the above two update methods is selected with a probability of 50%. It has the characteristics of strong fine-tuning ability and applies wavelet to the learning of these elite solutions. Let X be an elite solution in the file set, and the new solution after learning through the wavelet elite solution is X^* . The specific method is as follows:

$$X^* = \gamma X + r(L + U). \quad (8)$$

Among them, γ is the wavelet function value; r is a random number between 0 and 1; and U and L are the upper and lower bounds of the variable X . Because the Morlet wavelet has excellent time-frequency characteristics and

dynamic characteristics, it is a typical representative of the dynamic change space of wavelet function, this study will use the Morlet wavelet in the calculation of equation (8), and its calculation method is as follows:

$$\begin{aligned} \gamma &= \frac{1}{\sqrt{a}} \exp\left(1\left(\frac{\Phi}{2}\right)^2\right) \cos\left(5\left(\frac{\Phi}{2}\right)\right), \\ a &= \exp\left(-\ln g \times \left(1 - \frac{t}{T}\right)^\xi\right) + \ln g. \end{aligned} \quad (9)$$

Among them, g represents the upper bound of a ; t represents the current number of iterations of the algorithm; T represents the maximum number of iterations; ξ represents the shape parameter. In the algorithm, the elite solution retained in the archives is compared with the new solution learned by adopting the wavelet elite solution, and the best two solutions to P_1 and P_2 are assigned, respectively. In addition, if these elite solutions are local optimal solutions, the learning of these solutions can also jump out of the local extreme points to avoid premature convergence of the algorithm.

g represents the upper bound of a ; t represents the current number of iterations of the algorithm; T represents the maximum number of iterations; ξ represents the shape parameter. In the algorithm, the elite solution retained in the archives with the new solution learned by adopting the wavelet elite solution is compared, and the best two solutions to P_1 and P_2 , respectively, are assigned.

3.3. Lightweight MobileNet-SSD Model Construction. To adapt to the computing power limitation of embedded devices, this study constructs the MobileNet-SSD network, adopts the lightweight MobileNet feature extraction network, combines it with the SSD detection network, and replaces the backbone network VGG-16 in the SSD with MobileNet, which greatly reduces the memory usage. Then, patches of different scales and aspect ratios are placed a priori on the feature maps of different scales, and the predicted boundary patches are based on the previous patch. The size of the previous image depends on the scale and aspect ratio. The rules for scaling the previous frame in different target maps are as follows:

$$S_k = S_{\min} + \frac{S_{\max} - S_{\min}}{M - 1} (k - 1), \quad k \in [1, m]. \quad (10)$$

In the formula, the K th feature map of S_k shows the relationship between the size of the previous frame and the feature map; S_{\min} and S_{\max} represent the maximum and minimum values, respectively; m represents the number of map features. From equation (10), it can be seen that as the map feature size decreases, the scale of the previous field increases linearly. This article predefines the aspect ratio of the box according to the prior configuration rules of the SSD box:

$$a_r \in \left\{1, 2, 3, \frac{1}{2}, \frac{1}{3}\right\}. \quad (11)$$

In the formula, a_r is the aspect ratio of the prior frame. According to the aspect ratio and the scale of the a priori

frame, the width and height of the prior frame are calculated, and the calculation formula is as follows:

$$\begin{aligned} w_k^a &= s_k \sqrt{a_r}, \\ h_k^2 &= \frac{s_k}{\sqrt{a_r}}, \end{aligned} \quad (12)$$

where w_k^a and h_k^2 are the width and height of the prior frame, respectively. The loss of the whole process is divided into two parts, the weighted sum of the position loss and the confidence loss, that is, the loss function. The input sample x is defined, and then, the loss function is defined as follows:

$$L(x, c, l, g) = \frac{1}{n} (L_{\text{conf}}(x, c)) + \alpha L_{\text{conf}}(x, c, l, g), \quad (13)$$

$$Pe(Q(K + 1)) = S_i Q(k) = s_j.$$

In the formula, c is the trust value of the trust class; l is the predicted value of the associated box position corresponding to the previous box; g is the position parameter of the actual object; and N is the number of positive samples in the previous field. Finally, non-maximum suppression (NMS) is used to reduce the number of negative samples. Since multiple multiscale feature maps will generate a large number of prior frames, which contain a large number of redundant and overlapping samples, resulting in redundant computation, NMS can be used to perform iterations the traversal-elimination process filters the a priori boxes, which can effectively improve the network performance.

4. Prediction and Evaluation of e-Commerce Services

4.1. e-Commerce Service Evaluation Index of Intelligent Computing. We summarized the questions in the questionnaire and came up with 10 secondary indicators. These include the secondary indicators of the customer service index system, the popularity and satisfaction of customer service attitudes, the speed, safety, attitude, price, and other indicators of secondary logistic services. By analyzing the indicator system, we are satisfied with the logistics of Shentong. Some categories are listed in Tables 1 and 2.

Among them, in the establishment of the merchant satisfaction evaluation index system, the first-level index is the merchant's satisfaction, and the second-level indicators are the merchant's after-sales service, the merchant's reputation, and the attitude of the merchant's customer service; in the establishment of the logistic satisfaction evaluation index system, we found that the satisfaction of logistics is the first-level indicator, and the second-level indicators are the speed of logistics, the safety of logistics, the service attitude of logistics, and the price of logistics.

When establishing an index system to measure seller satisfaction, the survey questions are summarized into first-level indicators, and the second-level indicators are salesperson service, salesperson popularity, and salesperson attitude. Dealer customer service: when establishing the logistic satisfaction index system, we found that logistic

TABLE 1: Establishment of the evaluation index system of merchant satisfaction.

First-level indicator	Secondary indicators	Symbol
Merchant satisfaction	After-sales service	H1
	Reputation	H2
	Customer service attitude	H3

TABLE 2: Establishment of the evaluation index system of logistic satisfaction.

First-level indicator	Secondary indicators	Symbol
Logistic satisfaction	Logistic speed	T1
	Safety	T2
	Service attitude	T3
	Logistic price	T4

satisfaction is the first-level indicator, and the second-level indicators are logistic speed, logistic safety, service logistic ratio, and logistic price. The data collected can be used to assess customer satisfaction with services, popularity, customer service, logistic speed, security, and service and trade logistic prices. “Very satisfied” represents 5 points, “satisfied” represents 4 points, “generally satisfied” represents 3 points, “dissatisfied” represents 2 points, and “very dissatisfied” represents 1 point; the 5-year total score of each indicator is calculated on the basis of annual satisfaction. By calculation, we get Figure 4.

Through the analysis of Figure 4, we find that the membership degree also increases with the increase in the year, which indicates that the evaluation of the e-commerce service is getting better and better each year. Through the increase in the year, we also find that the weighted average satisfaction has been increasing the rate of increase and membership increase in 2019–2020 is the fastest, indicating the highest e-commerce satisfaction in this year.

4.2. Prediction of e-Commerce Service Satisfaction Based on Intelligent Computing. It can be seen from the following figure that there is not much difference between the predicted value and the actual value, indicating that the e-commerce service satisfaction prediction is effective. In 2018, the actual comprehensive score of service satisfaction was 2.8, the prediction of polynomial fitting was 2.9, and the prediction of Gaussian curve fitting was 2.98; in 2019, the actual comprehensive score of service satisfaction was 3.2, the prediction of polynomial fitting was 3.26, and the prediction of Gaussian curve fitting was 3.2. The forecast is 3.3; the actual comprehensive score of service satisfaction in 2020 is 3.9, the polynomial fitting forecast is 3.81, and the Gaussian curve fitting forecast is 3.86; in 2021, the actual comprehensive score of service satisfaction is 4.5, and the polynomial fitting forecast is 4.56. Gaussian curve fit predicts 4.44, as shown in Figure 5.

The model can help e-commerce service platforms to quickly judge the indicators that affect satisfaction. Through the gradual regression results of the satisfaction prediction model, the improvement of indicators such as after-sales service, customer service attitude, and logistic speed, safety,

FIGURE 4: Weighted average satisfaction.

FIGURE 5: Fitting comparison between actual and predicted values of e-commerce service satisfaction.

service attitude, and logistic price can be obtained. It can improve service satisfaction. The fitting result of stepwise regression analysis is $R^2 = 0.9996$, indicating that the model has a high degree of fit, as shown in Table 3.

4.3. Comparison of Service Accuracy under Intelligent Computing. In this article, we use the intelligent computing method to calculate the e-commerce service satisfaction evaluation, which improves the accuracy of the effect evaluation. In order to obtain the evaluation of e-commerce service satisfaction under intelligent computing, the intelligent computing method is compared with other computing methods in accuracy. We conducted a comparison test, and the comparison results are shown in Figure 6:

According to the experimental data of the figure, we can know that the evaluation accuracy of the algorithm after intelligent calculation is the highest among the three methods. When the number of times reaches 40, the evaluation accuracy of the intelligent algorithm can reach about 0.9, and when the number of times reaches 30, in the three methods the accuracy of the algorithm is the closest to around 0.5.

4.4. Performance Test. The performance advantages of the intelligent algorithm technology model proposed in the article are tested. The test will test the models of the three algorithms proposed in the article. The smart algorithm is an

TABLE 4: Performance of each model on the test set.

Model	Accuracy (%)	Accuracy (%)	Score (%)
Fuzzy statistical algorithm model	89.12	89.56	90.48
Intelligent algorithm model	92.46	93.27	93.45
Artificial algorithm model	85.45	85.43	86.18

ambiguous statistical algorithm and the pseudo-algorithm model runs on a test suite and an integrated test suite, respectively. The test suite is used to evaluate the general capabilities of the final model. A set of hybrid tests is used to tune the model's hyperparameters, and initially, the model's capabilities are evaluated. The results of the tests are recorded to verify the validity of the three sample ratings. A curve according to the test results is drawn.

According to the data in the table and graph, we can conclude that after running on the test set, the model accuracy rate of the fuzzy statistical algorithm can reach 89.12%, the accuracy rate can reach 89.56%, the accuracy rate of the intelligent algorithm can reach 92.46%, and the accuracy rate can reach 92.46%. It reaches 93.27%, which is the highest index value among the three experimental models. The accuracy of the artificial model is 75.14%, which is the lowest among the three systems, and the fuzzy statistical

FIGURE 7: Curve of the test set.

TABLE 5: Performance of each algorithm on the mixed test set.

Model	Accuracy (%)	Accuracy (%)	Score (%)
Fuzzy statistical algorithm model	87.88	87.12	88.96
Intelligent algorithm model	90.12	90.24	90.29
Artificial algorithm model	82.14	82.47	82.64

FIGURE 8: Performance on the mixed test set.

model is in the middle state. According to the curves of the three algorithms, we can also see that the curve values of the intelligent computing and fuzzy statistical algorithm models are very stable, and the experimental results also show that the performance of the intelligent computing algorithm is the best, as shown in Table 4 and Figure 7.

According to the data in Table 5 and Figure 8, after running the hybrid test package, the performance of the three models decreases somewhat, but the performance of the smart computer model is still high. In three models, the accuracy rate of the fuzzy statistical algorithm is 87.25%, and the accuracy rate of the intelligent computer algorithm is 90.12%. According to the performance of the three algorithms, it can be seen that the intelligent computer algorithm is very stable and always at 0.95, whether it is a test set or a mixed test set. The experimental results also show that the model validation accuracy of the intelligent computing algorithm is very high.

5. Conclusion

Through the comparison of algorithms and experiments, we can conclude that the current e-commerce services are facing severe postgraduate entrance examinations, and more and more e-commerce platforms are facing the risk of bankruptcy. In the face of these risks, government departments should introduce corresponding measures, such as introducing corresponding policies to reduce the taxation of merchants; the government should relax the corresponding import and export of goods. Our experiments in the fourth part can be concluded that, after running on the test set, the model accuracy rate of the fuzzy statistical algorithm can reach 89.12%, the accuracy rate can reach 89.56%, the accuracy rate of the intelligent algorithm can reach 92.46%, and the accuracy rate can reach 93.27%, which is one of the highest index values in the experimental model.

In the field of mechanical and electrical equipment, the motor rolling bearing is a workpiece that is extremely prone to damage and failure. However, the traditional fault diagnosis methods cannot keep up with the development pace of the times because they need complex manual pretreatment or the support of specific expert experience and knowledge. As a rising star, the data-driven fault diagnosis methods are increasingly favored by scholars and experts at home and abroad. The convolutional neural network has been widely used because of its powerful feature extraction ability for all kinds of complex information and its outstanding research results in image processing, target tracking, target diagnosis, time-frequency analysis, and other scenes. Therefore, this paper introduces a convolutional neural network and applies it to motor-bearing fault diagnosis. Aiming at the shortcomings of fault signal and convolutional neural network, a large-scale maximum pooling strategy is proposed and optimized by wavelet transform to improve the fault diagnosis efficiency of motor bearing under high-voltage operation. Compared with other machine learning algorithms, the convolution neural network fault diagnosis model constructed in this paper not only has high accuracy (up to 0.9871) and low error (only 0.032) but also is simple to use. It provides a new way for motor bearing fault diagnosis and has very important economic and social value.

1. Introduction

With the development of the economy, mechanical equipment is developing towards large-scale and integration, and the structure is becoming more and more complex, such as high-speed railway, aviation aircraft, nuclear power plant, and so on. These equipment put forward high requirements for reliability. If mechanical faults cannot be diagnosed in time, it may lead to machine shutdown, economic losses, and even accidents [1, 2]. Therefore, the research on mechanical fault diagnosis is of great significance.

Rolling bearing is an important part of rotating machinery. It plays an important role in supporting the high-precision rotation of the mechanical rotating body. It is a key component prone to damage [3]. Different electric rotating machinery and equipment often work in various complex working environments, and the uncertain change of working environment can easily lead to different types of damage to rolling bearing, such as high temperature, high heat, high

speed, overload load, and so on. If these factors are not controlled in time, they will greatly affect the working life of bearing [4]. As the key parts of most rotating machinery and equipment, once the rolling bearing fails, the replacement of maintenance goods is not timely, which is likely to lead to the paralysis of the whole power unit and even the scrapping of the equipment, resulting in major accident casualties and huge loss of economic property [5, 6].

In recent years, with the rise of computer technology, in order to more accurately and quantitatively describe the performance indexes of electromechanical equipment, many scholars are committed to the research of information diagnosis technology of motor bearing fault. By introducing dyadic discrete wavelet transform, Chen et al. realized the automatic selection of weight factors in the network and then realized the automatic acquisition of bearing fault characteristics [7]. Tan et al. used the public data set of bearing fault of Case Western Reserve University in the United States for diagnosis. The final results showed that this

method performed significantly better than the traditional BP neural network [8–10]. Li et al. proposed a bearing fault diagnosis technology combining CNN and wavelet time-frequency map by using a convolution network for excellent feature extraction and generalization performance of data. Relevant experiments were carried out using fault data sets. The results show that this method can effectively classify bearing fault types [11–13]. Han et al. developed a bearing fault classification model based on a deep neural network (DNN). The feature of this method is to directly extract the features of the original fault data and use it as the feature input of the deep neural network model to realize the diagnosis of fault data [14, 15]. Aiming at the problem of manual acquisition of fault characteristics in traditional fault diagnosis, Lu et al. proposed a bearing fault diagnosis method based on a deep self-coding network and carried out experiments under the network model. The results show that this method can effectively diagnose the fault data [16–18]. David et al. proposed a novel network model LAMSTAR and then used the proposed lamstar model to classify the bearing fault signals. Under this method, the equipment is tested at different speeds, and finally, the fault identification accuracy is more than 96% [19–23].

It can be seen from the above research that at present, the CNN fault diagnosis model has been widely used in motor bearing fault diagnosis, and the accuracy of bearing fault diagnosis has gradually improved with the deepening of research. However, many studies also found that when the machine works, because the load often changes greatly and the speed will change within a certain range, it is difficult for the conventional method to be robust to the load and speed at the same time. In addition, the acquisition of training samples is very difficult, and the weak generalization ability in the case of small samples also limits the development of these fault diagnosis methods. The strategy of weight summation and large-scale maximum pooling is proposed to solve the translation invariance of features and enhance the generalization ability of small samples. Improve the practical application ability of the CNN motor bearing fault diagnosis model in bearing fault diagnosis.

2. Basic Theory of CNN

2.1. Basic Structure of CNN. The CNN is generally composed of three neural network layers: convolutional layer, pooling layer, and fully connected layer, as well as an output layer (softmax and other classifiers). Its essence is a multilayer perceptron (MLP) neural network. Each layer is composed of multiple two-dimensional plane blocks, and each plane block is composed of multiple independent neural elements, as shown in Figure 1.

2.1.1. Convolutional Layer. The convolutional layer is partially connected with the neurons of the upper layer through the local receptive field. The neurons in the same local receptive field are associated with the corresponding pixels in the image area with fixed two-dimensional plane coding information, forcing the neurons to extract local features.

Many groups of different neurons are distributed at each position of each layer, and each group of neurons has a set of input weights. These weights are associated with the neurons in the rectangular block of the previous neural network, that is, shared weights, which reduces the number of weights and the complexity of the network model. Convolutional layer plays an important role in feature extraction in CNN. The observation features obtained by the local sensing domain method are independent of translation, scaling, and rotation. Its weight-sharing structure reduces the number of weights and further reduces the complexity of the network model.

2.1.2. Pooling Layer. The pooling layer is a feature mapping layer. Different continuous ranges in the convolution feature map are selected as the pooling area, and then the maximum or average value of the feature is taken as the feature of the pooling area, so as to reduce the dimension of the feature vector, realize the local average and sampling, and reduce the sensitivity of the feature mapping output to translation, rotation, scaling, and other forms of transformation. The pooling layer usually follows the convolutional layer, which forms a structure of twice feature extraction, so that the network has good distortion tolerance in the identification of input samples.

2.1.3. Fully Connected Layer. The fully connected layer is a structure in which the neurons in this layer and the neurons in the upper layer are connected in pairs, but the neurons in this layer are not connected. It is equivalent to the hidden layer in the multilayer perceptron (MLP). The local feature information is used as the input of the output layer (softmax and other classifiers), and then the convolutional layer is no longer connected. Because after passing through the fully connected layer, the image feature has been reduced from two-dimensional information to one-dimensional information, and the two-dimensional convolution operation cannot be carried out.

2.1.4. Output Layer (Softmax Classifier). Softmax classifier is the generalization of the logistic regression model in multicategory classification. It can predict the possibility (the number of types of sample labels), but here, it is required that the label of each sample must be unique. If it is a multilabel sample, the softmax model is not applicable. Assuming that the input feature is marked as $x^{(i)}$ and the sample label is marked as $y^{(i)}$, which constitutes the training set $S = \{(x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \dots, (x^{(m)}, y^{(m)})\}$ of supervised learning at the classification level, the forms of hypothesis function $h_{\theta}(x)$ and logistic regression cost function are as follows:

$$h_{\theta}(x) = \frac{1}{\sum_{j=1}^k e^{\theta_j^T x^{(i)}}} \begin{bmatrix} e^{\theta_1^T x^{(i)}} \\ e^{\theta_2^T x^{(i)}} \\ \vdots \\ e^{\theta_k^T x^{(i)}} \end{bmatrix}, \quad (1)$$

FIGURE 1: Classic structure of CNN.

where $\theta_1, \theta_2, \dots, \theta_k$ is the learnable parameter of the model and $1/\sum_{j=1}^k e^{\theta_j^T x^{(i)}}$ is the normalized term.

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m \sum_{j=1}^k 1\{y^{(i)} = j\} \ln \frac{e^{\theta_j^T x^{(i)}}}{\sum_{l=1}^k e^{\theta_l^T x^{(i)}}} \right], \quad (2)$$

where $1\{\cdot\}$ is an indicative function, that is, when the value in braces is true, the result of the function is 1; otherwise, the result is 0.

The optimal solution of softmax's cost function is usually solved by iterative algorithms such as random gradient descent method (SGD), Newton method, and quasi-Newton method (L-BFGS).

2.2. Error Propagation of CNN. The convolution neural network adopts error backpropagation and then is optimized by gradient descent method (or conjugate gradient method, L-BFGS method). Residual δ is defined as the influence of the node on the error of the final output value, so residual δL of output layer L is

$$\delta^L = f'(z^L) \odot (y^n - \sigma^n), \quad (3)$$

where \odot represents point-by-point product. Therefore, the weight and bias gradient of the output layer, respectively, are

$$\begin{cases} \frac{\partial E}{\partial \mathbf{W}^L} = \mathbf{x}^{L-1} (\delta^L)^T, \\ \frac{\partial E}{\partial \mathbf{b}} = \delta^L. \end{cases} \quad (4)$$

The convolutional layer is followed by a lower sampling layer, so the upper sampling is required first when calculating its residual.

$$\delta_j^l = \beta_j^{l+1} (f'(z_j^l) \odot \text{up}(\delta_j^{l+1})), \quad (5)$$

where $\text{up}(\cdot)$ indicates upsampling operation. For maximum pooling, copy the residual in layer $l+1$ to the position corresponding to the maximum in layer l and fill the positions of other elements with zero. Summing all elements in the error signal δ_j^l is the gradient of bias in the convolutional layer.

$$\frac{\partial E}{\partial b_j} = \sum_u (\delta_j^l)_u. \quad (6)$$

Considering that the convolution kernel k_{ij}^l is connected with many shared weights, the region corresponding to the convolution kernel k_{ij}^l in the convolution process needs to be considered when calculating its gradient through backpropagation.

$$\frac{\partial E}{\partial k_{ij}^l} = \sum_u (\delta_j^l)_u (p_i^{l-1})_u, \quad (7)$$

where $(p_i^{l-1})_u$ represents the area multiplied by convolution kernel k_{ij}^l in the convolution process in layer x_i^{l-1} .

For the lower sampling layer where the next layer is connected with the convolutional layer, the shared weight needs to be considered when calculating the residual.

$$\delta_j^l = \sum_u (\delta_j^{l-1})_u (q_i^{l-1})_u, \quad (8)$$

where $(q_i^{l-1})_u$ represents the weight in the corresponding convolution kernel k_{ij}^l .

After the gradient is calculated by the above method, the convolution kernel, bias, and the fully connected parameters of the last layer are updated to realize the automatic learning of the convolution kernel, so as to complete the expression and recognition of the signal.

3. CNN Fault Diagnosis Model

3.1. Basic Model of CNN Fault Diagnosis. The idea of the basic model structure of CNN in this paper is shown in Figure 2.

3.2. Basic Idea of CNN Fault Diagnosis. The idea of bearing fault diagnosis in this paper is shown in Figure 3.

3.3. CNN Fault Diagnosis Model Optimization. CNN's unique topology makes it invariant to feature translation and scaling although CNN has been proved to have good application effects in many fields, such as digital recognition, face recognition, voice recognition, pedestrian diagnosis, and so on. However, there are great differences between motor bearing fault diagnosis and the above problems, and the traditional CNN model is difficult to be effectively applied. Therefore, in the application of motor bearing fault diagnosis, in order to accurately diagnose the rolling bearing fault and reduce the impact of rolling bearing fault on equipment operation, the combination of wavelet packet transform analysis and convolutional neural

FIGURE 2: Basic model structure of CNN.

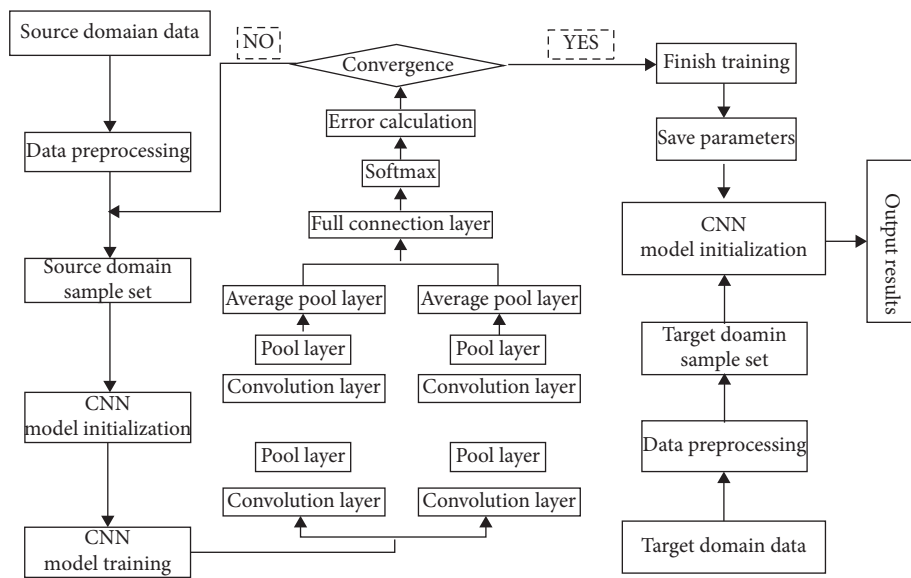

FIGURE 3: CNN bearing fault diagnosis idea.

network is proposed to optimize the motor rolling bearing fault diagnosis model. The optimization steps are as follows:

Step 1. Denoise the bearing vibration signal through wavelet packet transform and analyze the signal in the time domain and the frequency domain by wavelet packet analysis method. The three-layer decomposition process of the wavelet packet is shown in Figure 4.

Step 2. Extract the eigenvalues of the denoised signal with the eight characteristics of the signal as indicators and diagnose the bearing fault a priori through the time domain and frequency domain information map.

Step 3. Taking the extracted eigenvalues as samples, the bearing fault category is classified and diagnosed by a convolution neural network model.

FIGURE 4: Tree structure of wavelet packet decomposition.

4. Experimental Process

The vibration signal of the rolling bearing is collected through the rolling bearing fault simulation test bed. Firstly, the collected signal is processed by wavelet packet transform, and the noise signal is eliminated to facilitate

FIGURE 5: Fault diagnosis flow chart after wavelet transform.

the subsequent diagnosis. Then extract the fault feature information, input the obtained feature vector into CNN for training and testing, and finally diagnose the fault category through CNN. The specific process is shown in Figure 5.

4.1. Data Acquisition. The experimental data come from the comprehensive mechanical fault simulation experimental platform. The experimental platform is shown in the first figure of Figure 5. The platform mainly includes five parts: engine, governor, rotor, shaft, and rolling bearing. The rolling bearing with a fault diameter of 0.3 mm is selected as the experimental object, and the sensor is arranged at the end of the fault bearing.

The experiment collects a variety of fault data at 10 Hz, 20 Hz, and 40 Hz. The data types include the faults of the outer ring, the inner ring, and rolling element and the data of normal bearing. Set the sampling frequency to 1 kHz, take the sampling time for 3 min, and finally pass the data collected by the sensor through MATLAB 2016b[®] (The MathWorks, Inc, Natick, MA, USA) software conversion to save the mat file. After that, the signal is effectively cut. According to the sampling frequency, every 1,024 sampling points are selected as a whole fault sample. The four data types under each working condition are 100 samples, except for 300 normal signal samples. Finally, the sum of the four fault type sample data under each working condition is 600. Then the data is preprocessed and divided into two groups: one is used for model training, which is called the training set, and the other group is used for model testing, which is called the test set.

4.2. Data Preprocessing. The data preprocessing process mainly is as follows: using data window shift technology to enhance the original time-domain vibration signal and generating training and test sample sets. The “single heat” coding method is used to label the fault type, and then all the data in the training and test set are standardized.

4.2.1. Data Enhancement. To realize the high recognition rate of deep learning fault diagnosis, a large number of data samples are needed as support, and the correlation between the fault vibration signal of the rolling bearing cage and the

FIGURE 6: Overlapping sample segmentation.

adjacent time series signal is retained. In this paper, a data window shift technique is proposed to segment overlapping samples to achieve data enhancement. The division method is shown in Figure 6. This method can preserve the continuity and periodicity between time series signals, avoid the problem that equal distance sampling is difficult to express all the information characteristics of signals, greatly increase the total number of samples input to network training, and give full play to the powerful learning ability of the model.

As can be seen from Figure 6, if the total length of vibration signal data in fault state is L , the length of the sample is l , and the vibration signal is divided by a certain offset m , the data length of the overlapping part is $l - m$.

- (1) Number of divisible samples under current signal length D :

$$D = \left\lfloor \frac{L - l}{m} + 1 \right\rfloor, \quad (9)$$

where $\lfloor \cdot \rfloor$ is the downward rounding operator.

Expansion multiple of the sample set after data enhancement β :

$$\beta = \frac{l(L - l + m)}{Lm}. \quad (10)$$

- (2) Position x_i of the i segmented sample in the vibration signal data.

$$x_i = L[(i - 1) \times m + 1] : (i - 1) \times m + l, i \in [1, D], \quad (11)$$

where B is the split sample, and sample data sets of different sizes can be obtained by setting the corresponding offset M .

4.2.2. Data Standardization. In order to improve the convergence speed and accuracy of the model in deep learning, the sample set is usually standardized and preprocessed. The standardized formula is as follows:

$$\bar{x} = \frac{x - x_{\text{mean}}}{x_{\text{std}}} \quad (12)$$

Where x_{mean} is the mean value of sample data, x_{std} is the standard deviation of sample data, and x is the result after standardization.

At present, formula (12) is one of the most commonly used methods in big data normalization processing. Compared with other data normalization processing formulas, this formula has a better processing effect. Using this formula can also greatly improve the convergence speed and accuracy of the model.

After data standardization, the gradient explosion during model training can be prevented, and the reliability of the results can be guaranteed.

4.2.3. Time-Frequency Analysis Based on Wavelet Transform.

In the time-frequency analysis of unstable signals, a wide window is needed to analyze the low-frequency signals in the low-frequency region. On the contrary, a narrow window is needed in the high-frequency region to obtain high-precision amplitude information. However, in the fast Fourier transform, the shape of the window function is fixed. When analyzing the nonstationary signal, there is no adaptability for the signals with different time intervals. Therefore, the fast Fourier transform has some limitations. In order to solve this limitation, the Morlet mother wavelet is introduced into the time-frequency analysis in this paper. Its window area is fixed. It can change the length and height of its window according to the high- and low-frequency characteristics of the signal to adapt to the signal characteristics and ensure the accuracy of time-frequency analysis, its unique multi-resolution characteristics, and the advantages of time-frequency localization, which can well meet the needs of practical engineering. The time-frequency analysis results of the Morlet wavelet are shown in Figure 7. It can be seen from the figure that the Morlet wavelet has a relatively concentrated energy distribution of signal, better frequency resolution at high frequency, more accurate time positioning, and slightly better time-frequency focusing. When this kind of time-frequency analysis method is applied, it not only can reduce the burden of time-frequency analysis but also can effectively improve the learning efficiency and diagnosis accuracy of convolutional neural networks.

4.3. Establishment of CNN Model Based on Bearing Fault Detection in This Paper. The convolutional layer is a supervised deep learning network, which can extract the fault features in the rolling bearing signal by scanning the

convolution kernel on the axis of the image. Usually, a convolutional layer has one or more convolutional nuclei. The neurons of two adjacent convolutional layers are connected with each other. The number of connected neurons is related to the size of the convolution nucleus. By scanning the features, the convolution kernel can take the input data as a matrix, multiply and sum the values in the matrix, and finally superimpose all deviations as follows:

$$\begin{aligned} Z^{l+1}(i, j) &= [Z^l \omega^{l+1}](i, j) + b \\ &= \sum_{k=1}^{K_l} \sum_{x=1}^f \sum_{y=1}^f [Z_k^l(s_0 i + x, s_0 j + y) \omega_k^{l+1}(x, y)] + b, \\ &\cdot (i, j) \in \{0, 1, \dots, L_{l+1}\} = \frac{L_l + 2p_0 - f}{s_0} + 1, \end{aligned} \quad (13)$$

where b is the deviation in neurons; Z^l and Z^{l+1} are the input part and the output part of layer $l + 1$ convolutional layer, respectively; L_{l+1} is the size of the output part Z^{l+1} ; $Z(i, j)$ is the pixel of time-frequency spectrum after wavelet transform; K is the number of channels of the map (the time-frequency map used in this paper is an RGB image, and the number of channels is 3); f , s_0 , and p_0 are the parameters of convolution neural network layer, where f is the size of convolution kernel, s_0 is the step size of convolution operation, and p_0 is the size of padding pixels.

Among them, the activation function used by each convolutional layer is ReLU activation function, and its expression and function image are shown in Figure 8.

After extracting fault features in the convolutional layer, a pooling layer is often needed to filter the extracted fault information and the useless features. The pooling function of the pooling layer is usually preset, which can reduce the dimension of the output of the convolutional layer and make the data compact. This paper selects the maximum pooling layer in the pooling layer, which is used to reduce the estimation mean deviation caused by errors in the training process of the convolutional layer. Generally, the maximum pooling layer is set after the convolutional layer, and the output characteristics of the convolutional layer are maximized by obtaining the maximum value of the feature points. Mathematically, the l -th feature map y_n^l of the n -th pooling layer can be expressed as follows:

$$y_n^l = \text{pool}(y_n^l, p, s), \quad (14)$$

where y_n^l is the n -th input mapping, that is, the n -th input mapping of the previous convolutional layer; $\text{pool}()$ is the maximum pool equation; p is the maximum pool size; and s is the step size of the maximum pool.

The CNN architecture constructed in this paper is shown in Figure 9. In the proposed CNN model, four different convolution paths are used to learn the representation from the input sensor data. Each convolution module is composed of two parts: two-dimensional convolutional layer and maximum pooling layer. These convolutional layers and maximum pooling layers are arranged in parallel, and four

FIGURE 7: Morlet mother wavelet transform.

FIGURE 8: ReLU activation function.

FIGURE 9: CNN model framework.

different convolution kernel sizes are used to extract the fault features at different speeds. In feature learning, there is no interaction between the four convolution paths, and the fault information is extracted independently from the convolutional layers with different convolution kernel sizes, so as to

ensure the integrity of feature extraction. In addition to using different convolution kernel sizes, the four convolution paths are the same in network structure. Each convolution path is constructed by stacking one convolutional layer plus one maximum pooling layer five times. After each

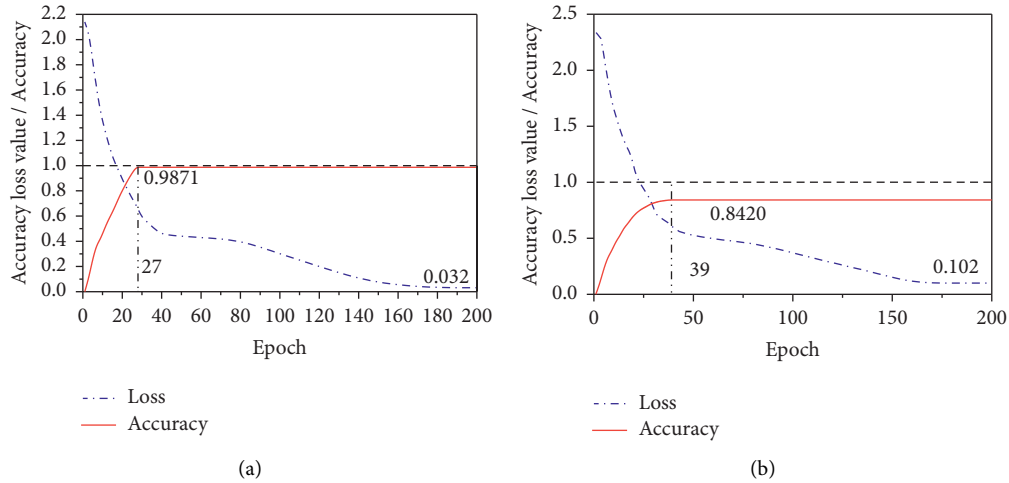

FIGURE 10: CNN training convergence curve: (a) CNN after wavelet transform and (b) CNN.

convolution path, an attention module is added to learn the weight of each channel, suppress useless feature information, emphasize fault-related information, and then flatten these learned features into a one-dimensional vector through the flatten layer. Finally, the four vectors are combined and input into the classification module for classification.

5. Analysis of Experimental Results

5.1. Performance Evaluation of Wavelet Transform. After the network is constructed, the classification prediction results are obtained after 200 times of iterative training, as shown in Figure 10. Figure 10(a) shows the training convergence curve of the CNN after wavelet transform, and Figure 10(b) shows the training convergence curve of the CNN without wavelet transform. Comparing the two figures, it can be found that the network errors of the two models gradually decrease with the increase of epoch. After 27 iterations of the CNN through wavelet transform, the network fully converges. At this time, the network accuracy reaches the best accuracy of 98.71%, and the loss is only 0.032. However, the CNN without wavelet transform needs 40 iterations to converge. At this time, the network accuracy is only 0.8420, but the error is 0.102. It can be seen that compared with the traditional CNN fault detection model, the result of training the network by preprocessing the data through wavelet transform converges faster, and the accuracy is greater than that of training the network without wavelet transform. It shows that the nonstationary original data can be processed through wavelet transform, which reduces the time of network feature extraction and improves the network accuracy.

5.2. Model Generalization and Robustness Verification. It can be seen from Section 4.1 that the CNN model optimized by wavelet transform has high accuracy in detecting the original test set. In order to further verify the generalization ability of the model, build a new test set, input it into the CNN model

and count its classification results to obtain the confusion matrix of the test data, and use column summary and row summary to display the accuracy and recall of each class. The results are shown in Figure 11. It can be seen that the CNN model optimized by wavelet transform has a strong generalization ability, and the deep features of the whole original signal can be obtained through less sample learning.

In order to verify the feature extraction ability of the method proposed in this paper, t-SNE dimensionality reduction technology is used to visualize the image features extracted from the traditional CNN model and the last hidden layer of the optimized CNN model proposed in this paper, as shown in Figure 12. The left figure is the CNN fault data feature visualization image after wavelet optimization, and the right figure is the fault data visualization image of the traditional CNN model. It can be seen from Figure 12 that both methods have efficient feature extraction performance for image data, and the fault features representing each fault type have obvious separability in space. However, in terms of spatial clustering, CNN optimized by wavelet transform is obviously better than the traditional CNN model. For example, the features representing the slight damage of the inner ring are distributed in different spatial positions in the feature space of the traditional CNN model, while they are distributed in similar spatial positions in the feature space of the optimized CNN model. The characteristics representing the severe damage of the inner ring also show more dense clustering in the feature space of the optimized CNN model. It further verifies the detection accuracy of the model proposed in this paper for the fault category of rolling bearing.

Because the above verification only tests a group of fault data and cannot represent the detection accuracy of all faults, in order to further verify the feasibility of the method proposed in this paper, the vibration signals and normal vibration signals of 10 different fault positions and different fault degrees at different bearing positions with the measurement speed of 1,797 r/min and the sampling frequency of 12 kHz are selected as the research object. The collected experimental sample data are shown in Table 1.

FIGURE 11: CNN training convergence curve: (a) CNN after wavelet transform and (b) CNN.

FIGURE 12: Features visualization for faulty data.

TABLE 1: Experimental sample data.

Test number	Detection position	Damage diameter (mm)	Training/validation samples	Test sample
1	Inner	0.3105	1,600/400	400
2	Outer	0.2987	1,600/400	400
3	Roller	0.4136	1,600/400	400
4	Roller	0.2254	1,600/400	400
5	Normal	0.0000	1,600/400	400
6	Roller	0.3512	1,600/400	400
7	Inner	0.3528	1,600/400	400
8	Normal	0.0000	1,600/400	400
9	Outer	0.2911	1,600/400	400
10	Outer	0.3019	1,600/400	400

Figure 13 intuitively shows the fault detection accuracy of the two models in 10 tests. From Figure 10, it can be seen that the CNN algorithm applied to wavelet optimization proposed in this paper has the highest detection accuracy of

bearing fault, the smallest numerical fluctuation, and the best stability, which is basically more than 0.95, while the detection accuracy of bearing fault applied to traditional CNN model algorithm is not only lower than that of the

FIGURE 13: Recognition accuracy of different models.

optimized model but also fluctuates greatly, and the lowest accuracy is only 0.63, The highest is only 0.85, but the accuracy difference between the two is 34.92%. Thus, the reliability of the optimized CNN model in bearing fault detection is verified again.

6. Conclusion

Aiming at the problem that the bearing fault information is difficult to extract completely and the label data samples are insufficient under variable working conditions, this paper proposes a fault detection method based on a convolutional neural network combining wavelet transform and maximum pooling strategy. In this method, the bearing signals at different speeds are used as the input of the fault diagnosis network to integrate the complete fault information. Firstly, the optimized CNN model is constructed by four parallel convolutional neural networks combined with a wavelet transform. Then, after the original data is processed by data enhancement, the time-domain signal is transformed by wavelet transform to obtain the two-dimensional time-frequency spectrum of the fault signal, which is used as the input of the network. Finally, the learned model is used to diagnose and identify the test data. Using the bearing fault data at different speeds to verify the proposed optimized CNN model, it can be concluded that this method has the following advantages:

- (1) Wavelet transform preprocessing of fault data can reduce the influence of redundant background noise in the data, and when the one-dimensional fault time-domain signal is converted into a two-dimensional fault, the frequency energy spectrum can give better play to the feature extraction function of convolutional neural network.
- (2) The optimized convolution neural network can select different convolution parameters according to different frequency conversions to extract more complete fault features and highlight fault information.

The convolution neural network fault diagnosis model constructed in this paper not only has high accuracy (up to 0.9871) and low error (only 0.032) but also is simple to use, providing a new way for motor bearing fault diagnosis.

- (3) The data enhancement method can effectively expand the data set and can effectively improve the convergence speed and accuracy of the network while expanding the data set.

Data Availability

The experimental data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Authors' Contributions

Shuiqin Zhou and Xiaochun Lou conceived the idea of this manuscript. And Shuiqin Zhou and Lepeng Lin developed this theory and performed the computations. Shuiqin Zhou, Chu Chen, and Wenbin Pan verified the results and completed the written work. All the authors read and approved this final manuscript.

In order to improve the Resource Recommendation and sharing ability of mobile library, an intelligent optimization model of Mobile Library Resource Recommendation Service Based on digital twin technology is proposed. Build the association rule feature distribution set of mobile library resource recommendation service, carry out text information retrieval in the process of Mobile Library Resource Recommendation and sharing, carry out semantic correlation feature registration according to the retrieval preference of mobile library reading user object, establish the association rule data set of mobile library reading user object preference for mobile library Resource Recommendation and sharing, carry out feature block processing, and analyze the library reader preference. Complete the collaborative filtering recommendation of Mobile Library Resource Recommendation sharing. The simulation results show that the collaborative recommendation under the intelligent optimization mode of mobile library resource recommendation service using this method has high accuracy and good confidence level, which improves the intelligent level of Mobile Library Resource Recommendation and user satisfaction.

1. Introduction

As a place with strong professional scholarship and comprehensive scientific research, mobile library has provided a huge development space for discipline teaching, cultural exchange, scientific research and application technology in Colleges and universities [1, 2]. In order to enable the library to play a greater social role, improve its social value of information services and the quality of information service products, considering how to improve the sociality of services is also an important opportunity for the quality improvement and career development of library staff [3, 4]. The research on Collaborative Recommendation Algorithm under the intelligent optimization model of mobile library resource recommendation service is of great significance in the construction of digital library. The related research on intelligent optimization model and fusion scheduling algorithm of mobile library resource recommendation service has attracted great attention.

Reference [5] takes the public library in Matara District of Sri Lanka as an example, and puts forward the research on mobile library services of public libraries. The main purpose of this research is to investigate the application, practice, and challenges of mobile library services provided by public libraries. The survey method is used as the data collection method. The library does not collect books separately for the mobile library service, and the mobile library has fewer books. The mobile library identifies school-age children as its target audience, and most people use the vehicles of management institutions to transport books and provide services. Research shows that no library provides this service to people in hospitals and prisons, and the vehicles allocated to mobile libraries lack the necessary facilities. Increasing financial support, the number of books collected, publicity plans, and improving transportation facilities can be used as suggestions. Reference [6] proposes a mobile library Resource Recommendation Algorithm Based on data mining, which uses block fusion clustering analysis and data mining

algorithm combined with particle swarm optimization to analyze the personalized demand feature categories of users for mobile library resources, and realizes mobile library resource recommendation according to the identification of typed parameters. This method has poor recommendation performance in complex environments.

In view of the above problems, this paper proposes an intelligent optimization model of Mobile Library Resource Recommendation Service Based on digital twin technology. Combined with the filter detection method, it realizes the analysis of Library Readers' preference, realizes the collaborative matching of Mobile Library Resource Recommendation sharing and reading user object preference, and completes the collaborative filtering recommendation of Mobile Library Resource Recommendation sharing. Finally, simulation experiments are carried out to show the superior performance of this method in improving the collaborative recommendation ability under the intelligent optimization model of mobile library resource recommendation service.

2. Theoretical Method of Digital Twinning Technology

Digital twin technology is an integrated system composed of data, models, and analysis tools. It can not only describe the state of aircraft fuselage in the whole life cycle but also make operation and maintenance decisions (including real-time diagnosis and future prediction) for the whole fleet and single fuselage based on uncertain information [7, 8].

Digital twinning is a virtual entity that creates physical entities digitally. It makes full use of data such as physical model, sensor update and operation history [9, 10], integrates multi-disciplinary, multi-physical, multi-scale and multi-probability simulation processes, and completes mapping in virtual space, thus reflecting the whole life cycle process of the corresponding physical equipment [11, 12]. By digitizing all elements of the physical world, such as people, things, and events, a corresponding "virtual world" will be recreated in cyberspace, forming a pattern of coexistence of physical world and digital world in the information dimension [13, 14]. The dynamics of the physical world are fed back to the digital world accurately and in real time through sensors [15]. Digitization and networking can realize the goal of turning reality into reality, networking and intelligence can realize the goal of turning reality into reality, and through virtual-real interaction and continuous iteration, the best and orderly operation of the physical world can be realized. It is the core element of digital twinning. It originates from physical entities, virtual models, and service systems, and at the same time, it is integrated into each part after integration, which promotes the operation of each part [16–18]. Therefore, data acquisition is the basis of digital twinning. To read the equipment data from the control system, it is necessary to clean the native data through data format analysis, data structure redefinition, data logic redefinition, etc., and then extract the key and effective parts from the data and output them. Twin data include data related to physical entities, virtual models, service systems, domain knowledge, and their fusion data, and is constantly

updated and optimized with the production of real-time data. Twin data are the core driver of digital twin operation. The above four parts are connected pairwise to enable effective real-time data transmission, thus realizing real-time interaction to ensure consistency and iterative optimization among the parts. Digital twinning technology supports the open communication standard OPCUA and API custom protocol access, which can ensure the stability of data transmission, reduce the delay of data transmission, realize the high speed, high reliability, and high adaptability of edge data acquisition, and provide an important foundation for subsequent digital twinning applications. The digital function architecture is shown in Figure 1.

It can be seen from Figure 1 that the digital twin functional architecture is a simulation process that makes full use of the physical world, information dimensions and other information to map and feedback each other, integrates multi-disciplinary, multi-physical quantities, multi-scale and multi-probability, and completes the mapping in the virtual space, so as to reflect the whole life cycle process of the corresponding real equipment. Digital twinning is a concept that transcends reality and can be regarded as a digital mapping system of one or more important and interdependent equipment systems.

3. Information Retrieval and Information Extraction of Mobile Library Resource Recommendation

3.1. Overall Structure and Information Retrieval of Mobile Library Resource Recommendation. In order to realize the optimization design of intelligent optimization model of mobile library resource recommendation service based on digital twin technology, firstly, the information retrieval model of mobile library resource recommendation sharing is constructed, and the personalized preference judgment model of mobile library resource recommendation is established. This paper analyzes the local relationship between users and the library, and then explores the diversity of users' preferences. Hidden factor analysis is a model-based collaborative filtering method, which defines the recommendation problem as the behavior matrix between sparse users and libraries. Assuming the low-rank matrix, the low-rank approximation of the matrix is performed to realize the learning task of implicit representation [19]. The hidden factor analysis method based on matrix approximation can effectively estimate the global structure of users' personalized preference judgment. Split the original behavior matrix into multiple sub-matrices, where each sub-matrix contains the relevance of users, projects, and ratings. The recommended method expression based on matrix approximation is

$$V_m = \frac{C_m \times \chi}{\rho}. \quad (1)$$

In formula (1), C_m represents the set of fitting real score items, χ represents the number of users, and ρ represents the parameter of loss items. Implicit representation of user preference diversity by low-rank matrix approximation:

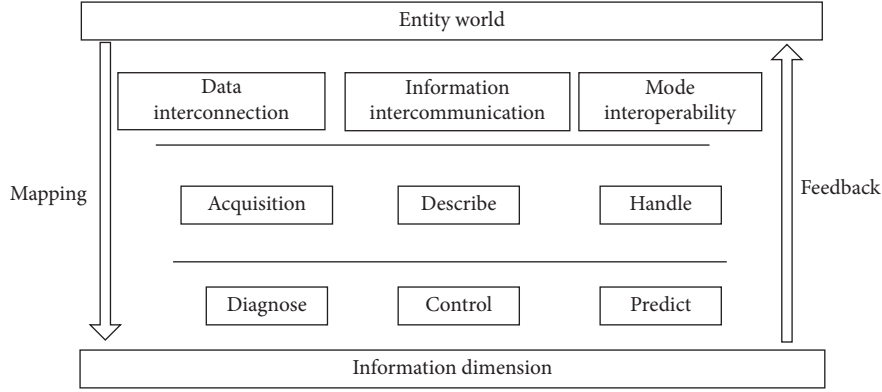

FIGURE 1: Digital twin functional architecture.

$$Q = \sum V_m \times g \times (1 - j). \quad (2)$$

In formula (2), g represents the preference weight of the user, and j represents the option of fitting the scoring items. Two-stage separated local low-rank matrix approximation is used to weight the results of user preference diversity:

$$H_i = \frac{[Z(x_i) - Z(x_i + h)]^2}{Q}. \quad (3)$$

In formula (3), Z represents the superposition of non-linear fitting functions, x_i represents the item score of the i -th user, and h represents the dependence of missing data. The global low-rank matrix approximation method can effectively obtain the overall characteristics of user preference diversity. According to the correlation analysis of users, items, and ratings, the model factors of personalized distribution of mobile library resources are established, and the tag form of mobile library resource recommendation is obtained: $G = (V, E, C)$. Where V represents the nearest neighbor set of graph model nodes recommended by mobile library resources, and the RFID tag of each node represents the number of items of mobile library resources; E represents the edge set of the distribution domain of mobile library resources, and represents the distribution sequence of user parameters of mobile library resources; Indicates the user's interest in different mobile library resources. Using the method of knowledge map modeling analysis, combined with personalized feature preferences, this paper establishes the user preference typing parameters of mobile library resource recommendation, analyzes the click and collection distribution characteristics of mobile library resource user U in a period of time, optimizes the collection management of library resources by combining video monitoring equipment, realizes the integration and information transmission of library resource information in the network layer, and constructs the library information management database in the application layer. SQL database is used to build the local database of library resource information management, artificial intelligence algorithm is used to manage and optimize the scheduling of information, and man-machine interaction is carried out in the application layer to realize the information retrieval and intelligent service of mobile library resource recommendation and sharing [20]. The

information retrieval and intelligent service mode of mobile library resource recommendation and sharing designed in this paper is shown in Figure 2.

According to the distribution structure model of mobile library resources recommendation and sharing resources shown in Figure 2, the phase space reconstruction method is adopted to reconstruct and extract the features of library resources under the intelligent service mode. Phase space reconstruction is a method to recover and describe the motive power system from the known time series. Using takens' delay embedding theorem, the infinite and noiseless dimension factors are embedded into the phase space. Multi-dimensional phase space vector is constructed by different delay times of one-dimensional time series. Reconstruct a phase space from one-dimensional chaotic time series, which is the same as the power system in topological sense, and judge, analyze, and predict the chaotic time series in the phase space. The recommendation module is established by using typed parameter analysis and category similarity feature analysis, and the workflow of mobile library resource recommendation based on digital twin technology is shown in Figure 3.

According to the distributed structure model of mobile library resource recommendation and sharing resources shown in Figure 3, the phase space reconstruction method is used to reconstruct and extract the features of library resources under the intelligent service mode, and the recommendation module is established by using the typed parameter analysis and category similarity feature analysis [21]. The workflow of mobile library resource recommendation based on digital twin technology is shown in Figure 4.

Establish the resource distribution attribute set $i \in S_s$ under the intelligent optimization model of mobile library resource recommendation service, and use semantic extraction method to retrieve the information of mobile library resource recommendation sharing. The semantic feature distribution mapping satisfies

$$\alpha^T Q \alpha = \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j Q_{ij} \geq 0. \quad (4)$$

In formula (4), α_i is the satisfaction parameter of mobile library resource recommendation, α_j is the reliability parameter of mobile library resource recommendation, Q_{ij} is

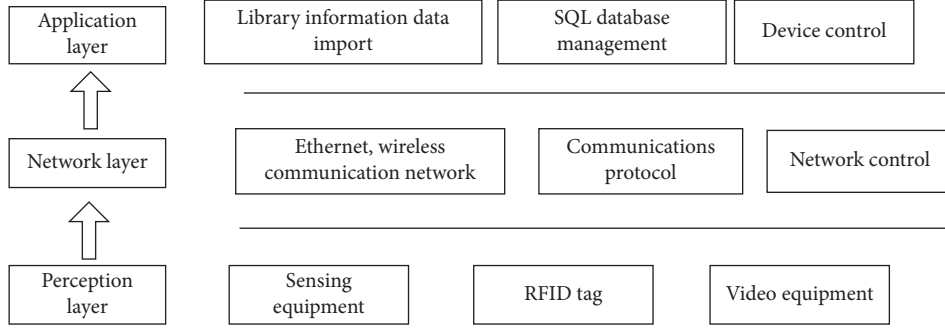

FIGURE 2: Information retrieval and intelligent service structure system of resource recommendation and sharing in mobile library.

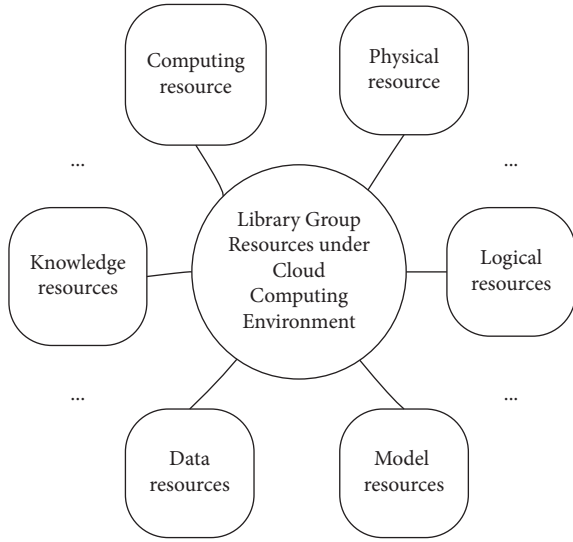

FIGURE 3: Resource distribution structure model of resource recommendation and sharing in mobile library.

the personalized feature matching parameter, and the trust relationship of library resources under the intelligent service mode is expressed $A \rightarrow B$ and $B \rightarrow C$. According to the above analysis, the semantic extraction method is used to search the information of mobile library resource recommendation and share, extract the semantic correlation features of mobile library resource recommendation, and filter and recommend the information of mobile library resource recommendation and share.

3.2. Semantic Relevance Feature Extraction. The semantic extraction method to retrieve information of mobile library resource recommendation and sharing is used, semantic correlation features of mobile library resource recommendation is extracted, a big data statistical analysis model of mobile library resource recommendation and sharing is constructed [22]. The specific process is shown in Figure 5.

Association rules under the intelligent optimization model of mobile library resource recommendation service is scheduled according to the attribute features of library resources, analyzes the distribution feature values of multi-source data recommended by mobile library resources [23], and it makes fuzzy matching according to user preference

scores in the recommended cache area, The details are shown in Table 1:

The tag category parameters are established, and the personalized features of mobile library resources are mined by using the feature registration algorithm, and the iterative formula of semantic correlation feature reconstruction of mobile library resources recommendation and sharing is obtained as follows:

$$x_i^{(k+1)} = (1 - \omega)x_i^{(k)} + \frac{\omega}{a_{ni}} \left(b_i - \sum_{j=1}^{i-1} a_{ij}x_j^{(k+1)} - \sum_{j=i+1}^n a_{ij}x_j^{(k)} \right), \quad (5)$$

$$i = 1, 2, \dots, n,$$

$$k = 1, 2, \dots, n.$$

In formula (5), ω is a weighted learning parameter, $x_i^{(k)}$ and $x_j^{(k)}$ represent personalized knowledge map and project distribution parameters of mobile library resources, respectively, and a_{ij} is a fuzzy matching degree. According to the part-of-speech tagging and part-of-speech filtering results of book information, the discrete scheduling feature distribution set of collaborative filtering of library resources is established as follows:

$$S_b = \sum_{i=1}^c p_i (\vec{m}_i - \vec{m}) (\vec{m}_i - \vec{m})^T. \quad (6)$$

In formula (6), $\vec{m} = \sum_{i=1}^c p_i \vec{m}_i$ is the difference between positive samples and negative samples, p_i is the recommended reliability probability magic parameter, and fuzzy clustering is carried out according to the matching results of semantic features of library resources under the intelligent service mode. The semantic ontology concept set of library resources under the intelligent service mode is as follows:

$$J(\vec{X}_j) = \frac{y_j^T S_b y_j}{\lambda_j}, \quad j = 1, 2, \dots, l. \quad (7)$$

In formula (7), y_j is the correlation entropy, λ_j is the recommended reliability characteristic value, and S_b is the similarity between recommended combinations. Using

FIGURE 5: Process of building model.

TABLE 1: Resource recommendation label attribute allocation matrix of mobile library.

Item	Attribute 1	Attribute 2	Attribute j	Attribute m
Item 1	LI ₁₁	LI ₁₂	LI _{1j}	LI _{1m}
Item 2	LI ₂₁	LI ₂₂	LI _{2j}	LI _{2m}
.....
Item i	LI _{i1}	LI _{i2}	LI _{ij}	LI _{im}
.....
Item n	LI _{n1}	LI _{n2}	LI _{nj}	LI _{nm}

$$W_k = [w_{0k}, w_{1k}, \dots, w_{lk}]^T. \quad (11)$$

In formula (11), w_{0k} is the weighting coefficient of the k th node under the joint constraint of user set and item set, w_{1k} is the weighting coefficient of the next node, and w_{lk} is the weighting coefficient of terminal i at time t .

The mining results of reading user object preference information of mobile library in the process of resource recommendation and sharing of mobile library are as follows:

$$\text{Recall}(X, Y) = \frac{P(X \cap Y)}{P(X) + P(Y) - P(X \cap Y)}, \quad (12)$$

$$\text{Overload}(X, Y) = \frac{P(X \cap Y)}{\min(P(X), P(Y))}, \quad (13)$$

$$\text{Time}(X, Y) = \frac{2P(X \cap Y)}{P(X) + P(Y)}. \quad (14)$$

In formulas (12)–(14), $P(X)$ and $P(Y)$ represent the probability density function of the fusion of library information resource recommendation and mobile library reading user object preference under the intelligent service mode, X and Y are the concept sets of library information resource distribution, and $P(X \cap Y)$ is the joint cross distribution set. According to the above analysis, the object preference information mining and text information retrieval of mobile library readers are realized, and the resource recommendation and sharing collaborative filtering recommendation design of mobile library is carried out according to the matching results of the two features.

4.2. Mobile Library Resource Recommendation and Sharing Optimization. Establish a data set of association rules for reading users' preferences of mobile library resources recommendation and sharing [26], and use digital twin matching method to block features [27]. The association rules structure model of mobile library resources recommendation and sharing is as follows:

$$X = [s_1, s_2, \dots, s_K] = \begin{bmatrix} x_1 & x_2 & \dots & x_K \\ x_{1+\tau} & x_{2+\tau} & \dots & x_{K+\tau} \\ \dots & \dots & \dots & \dots \\ x_{1+(m-1)\tau} & x_{2+(m-1)\tau} & \dots & x_{M+(m-1)\tau} \end{bmatrix}. \quad (15)$$

In formula (15), $K = N - (m - 1)\tau$ represents the embedding dimension of mobile library resources search, τ is the time delay, m is the number of layers of semantic relations of mobile library resources, and $s_i = (x_i, x_{i+\tau}, \dots, x_{i+(m-1)\tau})^T$ is called the semantic ontology feature sequence of mobile library resources. The project scoring item $v \in N_u$ is introduced. According to the scoring distribution of mobile library resource users' items, the classification distribution law of mobile library resource labels is as follows:

$$\bar{R}_{ik} = \sum_{j \in N_u} C_{i,j}^* R_{jk}. \quad (16)$$

In formula (16), \bar{R}_{ik} represents the evaluation value of user u_i 's satisfaction with the recommended mobile library resources. The credibility level of R_{jk} library readers u_j to recommended mobile library resources is indicated. Combined with K-means clustering method, library readers'

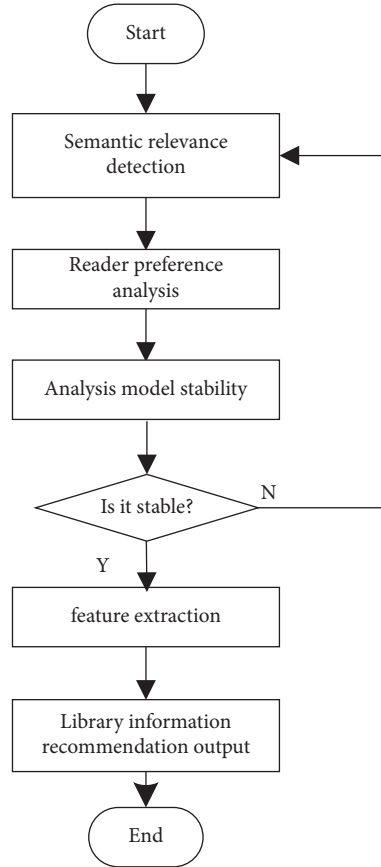

FIGURE 6: Implementation process of the algorithm.

TABLE 2: Fuzzy decision parameters of resource recommendation and sharing in mobile library.

X Value	Y Value	Fuzzy closeness vector Q_1, Q_2, Q_3, Q_4, Q_5	Priority order of recommendation and sharing of mobile library resources
821.404	417.343	0.334	$Q_4 > Q_1 > Q_3 > Q_2 > Q_5$

519.723	150.878	0.810	$Q_4 > Q_1 > Q_3 > Q_2 > Q_5$

preference analysis is realized, and the trust value of library resource recommendation under intelligent service mode is obtained:

$$ITrust_{a \rightarrow c} = \frac{\sum_{b \in adj(a,c)} DTrust_{a \rightarrow c} \times (DTrust_{a \rightarrow c} \times \beta_d)}{\sum_{b \in adj(a,c)} DTrust_{a \rightarrow b}} \quad (17)$$

In formula (17), $Trust_{a \rightarrow b}$ represents the trust degree of recommended choices A to B , and has a similar concept. $Trust_{b \rightarrow c}$ is the domain ontology parameter. According to the scoring results of N mobile library resource users, the typed list parameter analysis is adopted. The digital twin matching method is used to block the features, and the K-means clustering method is used to realize the library reader preference analysis, so as to realize the collaborative matching of mobile library resource

recommendation sharing and reading user object preference, and complete the collaborative filtering recommendation of mobile library resource recommendation sharing. The iterative formula of collaborative filtering recommendation of library resources under intelligent service mode is obtained as follows:

$$x_i(k+1) = x_i(k) + s \left(\frac{x_j(k) - x_i(k)}{\|x_j(k) - x_i(k)\|} \right) \quad (18)$$

In formula (18), $\|\vec{x}\|$ represents the norm of \vec{x} , the preference feature of reading user objects in mobile library is $P_{ij}^{best}(k)$, and the iteration step is S . To sum up, the collaborative filtering recommendation of resource recommendation and sharing of mobile library is realized, and the intelligent optimization model of resource recommendation service of mobile library is optimized according to the

TABLE 3: User parameter configuration.

User list	Preference level	Contribution degree	Similarity level
1	0.166	0.166	5.3428
2	0.167	0.204	7.4065
3	0.169	0.146	4.8596
4	0.177	0.161	1.0726
5	0.171	0.187	1.5970
6	0.176	0.174	7.9761
7	0.171	0.187	1.6630
8	0.176	0.177	6.2025

optimization design of fusion scheduling algorithm. The implementation process is shown in Figure 6.

5. Simulation and Result Analysis

In order to test the application performance of this method in collaborative filtering recommendation of mobile library

resource recommendation sharing, an experimental analysis was carried out, and a simulation test was carried out by combining Matlab and C++ programming software. The sample size of information sampling of library resources in intelligent service mode is 2000, the test set size of reading user's preference information distribution in mobile library is 400, and the initial statistic value of intelligent optimization

FIGURE 8: Comparative test of resource satisfaction of mobile library.

model of mobile library resource recommendation service is $\hat{\delta}_0 = -15$. The number of users is set to 20,000, and 1,500 users are randomly generated as the test set and 200 users as the training set. The recommended parameters $\lambda_1 = 1, \lambda_2 = 1, c_1 = 2, c_2 = 2$ are adaptively and collaboratively filtered, and the distribution of fuzzy decision parameters for resource recommendation and sharing of mobile library is shown in Table 2. See Table 3 for user parameter configuration.

According to the above parameter design results, the collaborative filtering recommendation of mobile library resource recommendation sharing is carried out, and the semantic relevance feature registration is carried out according to the retrieval preference of reading user objects in mobile library, and the user object preference association rule data set pushed by mobile library resources is established. The confidence level distribution weight is set to 1.25, and the mean square error is set to 0.031. The satisfaction level distribution of the recommendation is shown in Figure 7.

According to the analysis of Figure 7, the satisfaction level of mobile library resource recommendation by this method is high, among which the average satisfaction level of recommendation in the optimal state is 95.1%, and the recommendation satisfaction level is higher in the confidence range of $P < 0.01$. The reason is that this method extracts semantic correlation features, which is conducive to improving the satisfaction of mobile library resource recommendation.

The resource holding level of mobile library resources recommended by different methods is tested, and the comparison results are shown in Figure 8.

After analyzing Figure 8, it is found that the adaptability and preference satisfaction level of mobile library resources recommended by this method are high, which improves the user's satisfaction level with mobile library resources. Because of the small number of iteration steps, it can be seen that this method has a good optimization management ability. The

reason is that this method is conducive to improving the adaptability and preference satisfaction of mobile library reading user object preference information mining and text information retrieval in the research process.

To sum up, using the intelligent optimization method of Mobile Library Resource Recommendation Service Based on digital twin technology to recommend mobile library resources has a high level of satisfaction, and the average satisfaction of recommendation in the optimal state is 95.1%; It can improve users' satisfaction with mobile library resources and has better optimization management ability.

6. Conclusion and Prospect

6.1. Conclusion. This paper proposes an intelligent optimization model of Mobile Library Resource Recommendation Service Based on digital twin technology. To realize the collaborative matching between the recommendation and sharing of mobile library resources and the preferences of reading users, the following conclusions are obtained through the research:

- (1) The method in this paper has good registration for Mobile Library Resource Recommendation and sharing
- (2) Using this method to recommend mobile library resources has a high level of satisfaction
- (3) Using this method to recommend mobile library resources has a high level of adaptability and preference satisfaction

6.2. Prospect. Further research is still needed for the next step:

- (1) Each mobile library has its own characteristics, and does not fully use all the models and mechanisms of library resource aggregation and services. Only by properly improving and perfecting the methods and technologies of resource aggregation in combination with the characteristics, advantages and disadvantages of specific libraries, can we realize the deep aggregation and innovative services of mobile library resources on the basis of reflecting the characteristics of the library.
- (2) The lack of systematic understanding of mobile library resource aggregation and innovative services, the combination of resource aggregation and innovative services, enhances the integrity and systematicness of the research itself in the process of research from a certain angle, thus strengthening the service effect of resource aggregation and innovative services on user resource retrieval and knowledge acquisition, which needs to be further studied in the future.

As a decentralized, distributed system between functional and benefit management functions, blockchain is effective for financial transaction data security, data tracking and antitampering, product tracking, and access control. In this context, we have conducted experimental research on the blockchain product traceability trusted data analysis consensus mechanism and reached the following conclusions. (1) There are decentralization, irreversible tampering, traceability, and openness through the blockchain's own information and other functions so that a series of processes from raw material production, transportation, and logistics sales are well documented. (2) Under the same network environment, if the number of matches in the system increases, the average matching time consumed by the original engine is greater than the average matching time on the optimized engine. For example, taking 10% of Byzantine nodes in the system, the number of consensus increases, the average ITPBFT consensus time is about 5.74 s, and the average consensus time of the PBFT consensus mechanism is about 6.13 s. As a decentralized distributed data management system through nodes, blockchain is widely used in financial transactions, copyright protection, and product areas such as tracking and access control. In this regard, we conducted an experimental study of the consensus mechanism to analyze reliable data on the traceability of blockchain products and came to the conclusion of the experiment.

1. Introduction

Driven by the recent surge in interest in blockchains, it was investigated whether they would be ideal for the Internet of Things (IoT). Blockchain supports networks where untrusted participants communicate together in a verifiable manner without a trusted broker. We study the operation of this mechanism and evaluate smart contract scenarios which are in the blockchain and allow you to automate multistage processes. Then, we move into the IoT field and describe how the combination of blockchain and IoT can facilitate sharing of services and resources and create a market for interoperable services [1]. The performance of a probabilistic proof-of-work- (PoW-) based consensus structure, also known as a blockchain, is not a major concern. It is a success story despite its consensus latency of around hours, and the theoretical maximum throughput is only 7 transactions per second. The current situation is very different and the poor performance scalability of the initial PoW blocks no longer makes sense. In particular, platform trends support the

implementation of randomly distributed applications across block structures, and the need for better performance has entered the realm of database replication protocols [2]. Blockchain is a distributed transaction and information management technology first developed for the Bitcoin cryptocurrency. Interest in blockchain technology has grown since the idea was proposed in 2008. Interest in blockchain lies in the fact that its key features ensure security, anonymity, and data integrity without third-party control. This makes it an interesting area of research, especially in terms of technical issues and limitations [3]. Block chains are a new cryptographic and IT application to solve an old financial reporting problem and can lead to extensive changes in corporate governance. Many major financial players have already started investing in the new technology, with exchanges proposing the use of block chain as a new way to trade in company shares and track ownership. The effects of these changes on directors, institutional investors, minority shareholders, auditors, and other parts of the corporate governance system are reviewed. The lower costs,

higher liquidity, more detailed information, and ownership transparency offered by blockchain can significantly improve the balance of power between these groups [4]. The main advantages of blockchain are decentralization, time series data, shared services, programmability, and security, making it particularly suitable for building programmable monetary systems, financial systems, and even macrosocial systems. The basic model of the blockchain system is proposed, and the principles, technologies, methods, and applications of the blockchain and related Bitcoin systems are discussed. We also discuss smart contracts and their applications and show future trends in a blockchain parallel society. It provides useful guidance and reference for future research work [5]. At present, several Chinese departments have invested a lot of money and effort in setting up proper food control systems. As a research team that has developed and applied traceability systems for several years, this article presents methods to achieve effective traceability and highlights the importance of traceability systems. The scientific elements of the proposed traceability system will be used to explore the usefulness of analytical data and the development of a food safety assessment system. The above methods can be used to produce useful and effective information to improve corporate governance [6]. Logistics helps companies optimize the entire enterprise supply chain from one source to another to achieve their strategic goals. Traceability has become one of the integrated components of supply chain management, supply chain monitoring, and data monitoring at various points at the beginning and end of a product. Depending on their role, all participants in the supply chain have different goals for implementing monitoring solutions [7]. Blockchain technology is a distributed ledger that allows you to transfer data seamlessly, securely, and reliably. The benefits of introducing blockchain technology to manage and control PSA products in the supply chain include decentralized management, security, tracking capabilities, and verified operational planning [8]. Elaborated through the required performance analysis with data traceability. The implementation of the proposed EWRDN service for sexual functionality is the main contribution of this work. A trusted authoritative service coordination is also introduced to operate the proposed service. The results show that the proposed service synergy can provide the traceability function of data and experimentally defends against most experienced data security threats. Additionally, the EWRDN service has been shown to provide two different data compression qualities as a differentiated quality service. It has been shown that in EWRDN coordination, a fixed compression recovery rate has been achieved [9]. There is a traceability link between each new requirement and the objects predicted to change in the design object model. When asked, they claimed they were confident that the correct number of objects would be changed, but they were less sure what was needed number of hours worked. Analysis of impact analysis shows that predictions for individual objects are often nearly correct, but the number of objects actually changed is often larger than the number of objects predicted [10]. The multiterminal controllable security intelligent system not only adopts the proprietary protocol to

fight against wireless network intrusion and system vulnerability mining program to realize the secure encrypted transmission of multiterminal data exchange but also establishes a consensus environment and uses the consensus mechanism to record and verify the security status of the access device to ensure the security of the system. The system reduces the cost of establishing a security architecture and the requirements for computing power and can better cope with the frequent occurrence of security incidents [11]. The current architecture of the risk scoring system is highly centralized, which can lead to issues such as data loss, bias, and decentralization. Along with blockchain technology, it has the features of decentralization, security and reliability, integrated service, and consistency. A new architecture of a blockchain-based risk assessment system and an enhanced DPOS-based consensus mechanism algorithm is proposed [12]. Strengthening the management and support of non-consensus basic research is conducive to promoting the original innovation of basic research, and local science and technology departments are increasingly interested in exploring the management mechanism of nonconsensus basic research. Combined with management experience, policy recommendations are put forward from two aspects: the establishment of nonconsensus basic research special funds and the design of nonconsensus project selection mechanism, to provide certain theoretical guidance for the management practice of nonconsensus basic research in the future [13]. The blockchain and D-IoT equivalent architectures are based on a master-slave multichain. The integrated equivalent architecture provides key applications of blockchain technology as a unified mechanism and smart contract in D-IoT. The broad perspective for blockchain deployment in D-IoT is explored [14]. There are several general consensus algorithms in blockchain technology. They differ in the complexity of calculating fault tolerance and fault tolerance. The implementation, consistency, scalability, and efficiency of blockchain consensus mechanisms require further refinement and improvement. Mechanisms for code approval and implementation of Bitcoin, Ethereum, and Hyperledger are reviewed, discussed, and proposed in [15].

2. Trusted Data Analysis of Product Traceability of Blockchain

2.1. Blockchain Technology

- (1) Decentralization: the blockchain uses peer-to-peer technology to store data, using distributed accounting and storage. All nodes have equal rights and obligations
- (2) Security: information security cannot be tampered with
- (3) History: any transaction records will be stored in the database
- (4) Collective maintenance: in an open system, private information in transactions is encrypted, and all nodes with maintenance functions are jointly maintained. Anyone can query each blockchain data

through an open interface, so the entire system information is highly transparent

Blockchain technology is considered the key technology most likely to power the fifth wave of disruption. It is a distributed ledger technology consisting of distributed databases, encryption algorithms, consensus mechanisms, and smart protocols. Based on the characteristics of openness, transparency, decentralization, and nontampering of blockchain data, it has received more and more attention, and it has gradually become materialized from the concept, from the initial application of financial currency to applications in various fields.

Encryption Algorithm. The encryption algorithm is the cornerstone of the blockchain. Blockchain uses hash algorithms and asymmetric encryption technology to ensure the irreversibility and security of blockchain technology. Hash algorithms, also known as secure hash algorithms, are widely used in many encryption technologies, including blockchain technology. It maps data of any length to a fixed-length hash queue according to certain rules. Algorithms, the most common being the SHA-1, SHA-2, and SHA-3 families, MD5, etc.

Consensus Mechanism. The consensus mechanism is the key blockchain mechanism. The blockchain consensus mechanism introduces Basic Certificate (PoW), Proof of Contribution (POS), Delegated Proof of Contribution (DPOS), Practical Byzantine Error Resistance (PBFT), etc. to adapt to the consensus system of each platform. The consensus mechanism is used to solve the consensus problem of distributed systems. It first appeared in 1975, and the blockchain consensus mechanism was the proof-of-work mechanism proposed by Satoshi Nakamoto in Bitcoin core.

Smart Contract. A smart contract is essentially a computer protocol that allows the blockchain application platform to operate automatically and unconditionally according to the proposed contract terms, thereby replacing the uncertainty of manual calculations and operations used in traditional business practices to perform contracts. It greatly improves the interaction and circulation of information nodes. Smart contracts have a certain ability for independent judgment and self-execution. Because they are based on programming languages, they do not need to rely on third parties or centralized institutions and cannot be intervened by humans, so they have high efficiency and accurate and strong execution capabilities. The technical types of blockchain are shown in Figure 1.

2.2. Blockchain Product Traceability. With the continuous improvement of material living standards, product updates and iterations have become more and more frequent, resulting in the emergence of many electronic foundry companies, small workshops, etc., which have threatened the safety of electronic use. The trust mechanism between consumers and consumers has not been perfected. The main raw materials, parts, production, processing, assembly, supply,

FIGURE 1: Blockchain technology.

and all aspects of logistics involved in the production of products will involve many supply chains, distributors, software and hardware companies, and so on. The traceability of the product cannot be fully maintained and guaranteed at all. A series of processes that make products from raw material production, transportation, and logistics sales are well documented. Compared with other traditional traceability methods, the advantages of blockchain traceability can be roughly summarized into the following three basic aspects:

- (1) **Multiparty confirmation:** use blockchain features such as decentralization, irreversibility, and traceability to support product trust, encourage more participants in the supply chain to jointly collect and maintain product information, and increase system trust.
- (2) **Traceability and accountability:** the blockchain adopts distributed ledger technology to ensure that data records cannot be tampered with, making commodity information and transaction information transparent, authentic, and traceable. Consumers can view product information and eliminate the problem of fake and inferior products. Enterprises can effectively and quickly trace the cause and source of electronic product problems and quickly recall all problematic products to reduce financial losses.
- (3) **Hacker data warehouse of all parties:** when these data are packaged and stored in blocks, supply chain participants jointly maintain their own data sources, which can realize information disclosure. All parties can query the process information through the system to ensure that all participants find out the problems in their operation in time, which helps to improve the management efficiency of the entire supply chain. The advantages of blockchain product traceability are shown in Figure 2.

2.3. Product Traceability Method. The blockchain approach to product tracking involves each merchant and consumer registering an address before using the system. More event information for this address is as follows. When selling an item, the seller must provide the system with information about the transaction. When consumers buy a product, they can verify the product through the QR code in the system before purchasing. The first level of the system is Consumer, Outstanding Supplier, and Production Log in to create a public/private key pair and use the revocation script and personal information to register and authenticate to the

FIGURE 2: The advantages of blockchain traceability.

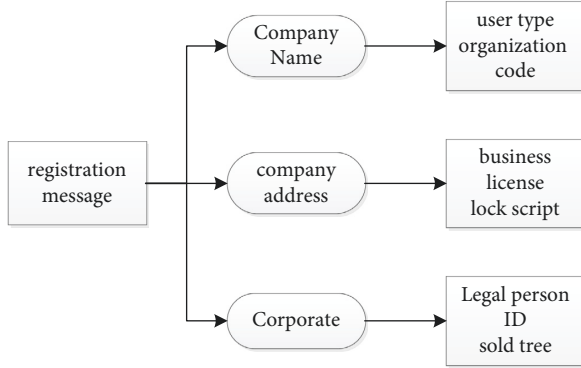

FIGURE 3: Registration information data structure.

system, as shown in Figure 3 to add information to the registration: company name, address, corporate legal entity, etc. The registration node sends registration information, and other nodes cache the registration information after receiving the message, making a smart trade. Registration information is collected in blocks awaiting approval if the message conforms to all terms of the smart agreement. If the message does not meet all the requirements of the smart contract, the message is removed from the cache. Review intelligence logs to ensure that information provided by controllers is the property of individuals and to prevent attackers from maliciously recording information about others. Check the contents of the “Authentication Information” field of the registration information. Registration information performs three functions: first, to inform consumers of the legitimacy of transactions, second, to trace incidents involving commodities, and third, to prevent manufacturers from releasing counterfeit products. It returns success if all conditions are true and returns an error if any test fails.

3. Blockchain Algorithms

3.1. Adaptive PoW Algorithm

- (1) The node monitors the data records of the entire network, and the data records that pass the basic legality verification will be temporarily stored.
- (2) After finding a reasonable random number, generate block information, first enter the block header information, and then the data record information.
- (3) The newly generated block is broadcasted to the outside after receiving the order. After other nodes

have passed the verification, they will be connected to the blockchain, and the height of the main chain will be increased by one. Then, all nodes will switch to the new block and continue to perform workload proof and block. Production.

To improve the efficiency of end node transactions on the local network, end nodes use a handshake protocol called an adaptive handshake algorithm. The algorithm dynamically adjusts the complexity of implementing the PoW algorithm according to the behavior of end nodes. At the same time, the security risk in the local network is reduced by reducing the complexity of the PoW algorithm. The correct operation of the A-PoW algorithm depends on the results of the local network node edge verification mechanism checks. The following describes how the node bounds checking mechanism works. We describe how edge nodes calculate the contribution of the corresponding node based on the behavior of the node under test. We create nodes in a variety of ways and ultimately ensure that the node’s input value calculation formula effectively and accurately represents the node’s contribution to the input blockchain. We calculate node contribution using the following formula:

$$C_i = \lambda_1 C_i^P + \lambda_2 C_i^N. \quad (1)$$

To study the influence of different types of transactions on the contribution amount, C_i^N represents the influence of malicious behavior on the contribution value, λ_1 and λ_2 represent the weight of these two effects, and the formula can be expressed as

$$C_i^P = \sum_{k=1}^n T_1(t) * a(b). \quad (2)$$

Among them, n is the number of events published by the entire node in unit time, $T_1(t)$ is a function of time damping, its value gradually decreases with time, and when the importance is greater, $T_1(t)$ can be expressed as

$$T_1(t) = N_0 e^{-a(t+1)}, \quad (3)$$

$$a = \frac{1}{m} \ln \left(\frac{N_{\text{INIT}}}{N_{\text{FINISH}}} \right), \quad (4)$$

$$l = \frac{1}{a} \ln \left(\frac{N_0}{N_{\text{init}}} \right), \quad (5)$$

N_0 in formula (3) is the initial value of the function, a is called an exponential decay variable, and l is the inversion to the left, so the value of $T_1(t)$ can be calculated from any position instead of N_0 . According to equations (4) and (5), the decay function of N_{init} begins to decrease and decreases to N_{finish} after m unit time. $A(b)$ represents the actual impact on the payment amount. When the host requests authentication, if there are pending events, $a(b)$ has the value N ; otherwise, $a(b)$ has the value $-N$. Therefore, the payment calculation formula encourages nodes to actively look at these “pending” events. The impact factor of the detected harmful payment behavior can be expressed as

$$C_I^N = \sum_{k=1}^n T_2(i) * \beta(b). \quad (6)$$

The system assumes relatively no malicious activity. Harmful activity detected during this check affects not only the number of attachments calculated at this time but also the number of attachments in the future. As shown in the formula, $T_2(i)$ is a function of temporary damping, which can be written as

$$T_2(i) = 0.8^i, \quad (7)$$

where $B(b)$ in the C_I^N calculation formula represents the degree of damage caused by malicious behavior. Assuming that in the current system, the threshold for publishing transactions through terminal nodes is M , and the number of transactions performed during this analysis T period is N , then $\beta(b)$ can be expressed as

$$\beta(b) = \begin{cases} 0, & N < M, \\ K * (N - M), & N > M. \end{cases} \quad (8)$$

If the number of errors is below the threshold, there is no penalty. If the trading volume exceeds 10%, the value of k is relatively large. If the additional transaction volume does not exceed 10%, the edge node considers this to be an acceptable margin of error. Therefore, the value of k is relatively small. Meanwhile, $T_2(t)$ is a function that is repeatedly decomposed in control events. Formula (1) is the number of breakpoints between the malicious activity's breakpoint and the current breakpoint.

3.2. Affinity Propagation Clustering Algorithm. Since the number of game participants and the number of solutions have a great influence on the complexity of the game, in order to solve this problem, this paper firstly organizes the data and regards the clustering of the game as a category of participants, which not only simplifies the game process. At the same time, the original structure and function of the data are preserved. If participants rely on clusters, they will not be penalized if the number falls below a threshold. When the trading volume exceeds 10%, the value of k is relatively large. If the number of transactions exceeds 10%, the edge node is considered to have an error range. So, the value of k is relatively small. Meanwhile, $T_2(t)$ is a function that is repeatedly decomposed in checkpoint events. The i formula represents the breakpoint between the malicious behavior and the current breakpoint (the number of breakpoints between intervals). That is, the longer the malicious behavior is, the lower the $T_2(t)$ is. The result is to observe the data characteristics of each cluster and further analyze a specific set of clusters to make decisions. The silhouette factor provides a nice scoring function to determine the best score. The silhouette coefficient is one of the commonly used performance metrics to evaluate cluster cohesion and separation, defined as follows:

$$s(i) = \frac{b(i) - a(i)}{\max\{b(i) - a(i)\}}. \quad (9)$$

The higher the silhouette factor, the better the clustering effect. The quality of the grouping is evaluated by silhouette

coefficients corresponding to different reference values. We choose a Nash equilibrium solution and find the best path. This paper captures the best idea of finding the optimal solution, uses the advanced particle swarm algorithm to achieve the optimal global resource allocation, and develops and solves the Nash equilibrium solution for various industries. The position of each particle in the algorithm represents the situation of an investment company. Using this algorithm, we display the origin of all particles in $[0, 1]$ and determine the origin of the particle.

$$N_{X,Y} = \frac{N_{\max} - N_{\min}}{O_{\max} - O_{\min}} \times (O_{x,y} - O_{\min}) + N_{\min}. \quad (10)$$

The optimal idea is used to find the optimal solution, the improved particle clustering algorithm is used to obtain the overall optimal distribution of resources, and the Nash equilibrium solution is designed and opened for each type of industry. The position of each particle in the algorithm represents the situation in which the investment company operates. The starting positions of all particles in the algorithm are plotted on $[0, 1]$, and the initial positions of the particles are determined.

In the game situation, the strategy selected by the player optimally matches the strategies of other players. In the game scenario, the strategy selected by the player corresponds well with the strategies of other players. Therefore, the particle in the optimal state is the Nash equilibrium in the game, according to the definition and properties of N_{ash} equilibrium. The game strategic planning based on n -person limited refusal to cooperate is as follows:

$$u_i = \max\{\text{sreg}_i - (E(x) - E_{\text{avg}}), 0\}. \quad (11)$$

If the mixed situation according to equation (11) is a Nash equilibrium solution, u_i can obtain the minimum value of 0, and when the mixed situation is a non-Nash equilibrium solution, u_i can obtain a larger value. In order to evaluate the Nash equilibrium solution and obtain an approximate Nash equilibrium solution, this article will develop the fitness function in the investment board game scenario:

$$f(x) = \min u_i, \quad i \in (1, 2, \dots, n). \quad (12)$$

In the game strategy combination space, the smaller the condition of $f(x)$ is, the closer the enterprise profit is to the equilibrium value. The compaction rate method selects the global optimal position and guides the particles to search the sparse area, so that it does not fall into the local optimum, improves the understanding of variability, and finally adheres to the game balance for adaptation. This method takes time. As the data accumulates or the complexity increases on a large scale, the performance of the algorithm degrades. In intelligent algorithms, the data processing capacity is limited and the accuracy is insufficient. In this paper, the gravity search algorithm is used to improve the particle flow algorithm to improve the overall optimization ability. GSA is a new heuristic method. The motion of particles follows the laws of dynamics. Particles move toward particles with higher mass, and particles with higher mass are in the best

position to obtain the optimal solution to the problem. Learning the value of the particle state function determines each particle's mass and force, calculates acceleration, and updates velocity and position. The steps to calculate these parameters are as follows:

$$m_i(t) = \frac{\text{fit}_i(t) - \text{worst}(t)}{\text{best}(t) - \text{worst}(t)},$$

$$M_i(t) = \frac{m_i(t)}{\sum_{l=1}^N m_l(t)}. \quad (13)$$

Calculate gravity. The gravitational force of particle j on particle i is

$$F_{ij}(t) = G(t) \frac{M_{pi}(t) \times M_{aj}(t)}{R_{ij}(t) + \varepsilon} (x_j(t) - x_i(t)). \quad (14)$$

The gravity detection algorithm is used to improve the particle swarm algorithm to improve global optimization capabilities. GSA is a new research method. The movement of particles obeys the laws of kinetics. Particles move in the direction of the particles with the greatest force, and the most powerful particles are in the best position to obtain the best solution to the problem. By evaluating the value of the particle's fitness function, the force and strength of each particle are determined, the acceleration is calculated, and the speed and position are updated.

In the formula, $G(t)$ represents the value of the gravitational constant, $M_{pi}(t)$ represents the inertial mass of the acted particle i , M_{aj} represents the inertial mass of the acting particle j , and ε is a small constant to avoid the denominator being 0. The net force is then applied to part i .

$$F_I(t) = \sum_{j=1}^N \text{rand} \times F_{ij}(t), \quad (15)$$

where rand is the reference value for calculating acceleration. According to the law, the acceleration of particle i is

$$a_i(t) = \frac{F_I(t)}{M_i(t)}. \quad (16)$$

In this paper, the particle swarm algorithm is used to solve the Nash equilibrium solution, and the clustering distance calculation method is used to control the particle search process.

3.3. Homomorphic Encryption Algorithm. Encryption algorithms can achieve additive homomorphic properties, which can meet the needs of many privacy-preserving applications. In particular, the Payet encryption algorithm can be composed of three parts, namely, key generation, data encryption, and data decryption. Generate the key: according to the specified security parameter k , first select two sufficiently large prime numbers, where the sum of these two prime numbers is k , and then calculate the RSA modulus N . Define a function.

$$L(\mu) = \frac{\mu - 1}{N}. \quad (17)$$

Then, choose a suitable generator, and use the above parameters to calculate. Finally, the formula in the Payet encryption algorithm is obtained. $p_k = (N, g)$, and its corresponding formula $m \in Z_N$. Data encryption: according to the given message $m \in Z_N$, choose a random number $r \in Z_N^*$, so the file can be calculated by the following formula:

$$c = E(M) = g^m \cdot r^n \text{mod} N^2. \quad (18)$$

Data decryption: according to the ciphertext $C \in Z_N^*$ calculated above, the corresponding ciphertext m before encryption can be calculated by the following formula:

$$m = D(C) = L\left(C^{\text{mod} N^2}\right). \quad (19)$$

It should be noted that the Payet encryption algorithm is semantically secure and can resist multiple plaintext attacks, and its accuracy and security can be verified.

4. Research on Consensus Mechanism of Product Traceability Trusted Data Analysis of Blockchain

4.1. Analysis of Product Traceability under Different Blockchain Algorithms. This paper examines the time between transaction validation and block generation and compares the PoVT proposed in CDBFT to the PBFT used in Hyperledger Fabric. The initial total number of nodes in the system is fixed at 10, and the number of transfers per block is 1 to 500. It is shown in Table 1.

In Figure 4, the required time is shown as a function of the number of events in the block. The comparison shows that for multiple simultaneous 100 events, PBFT lasts 200 ms, CDBFT lasts 120 ms, and PoVT lasts 80 ms. Correspondingly, for 30 events, the PBFT gain time is 600 ms, the CDBFT is 350 ms, and the PoVT is about 210 ms. As the number of simultaneous events increases, so does the confirmation time for all three. However, the computation time oT is higher than PBT and CDBFT.

Figure 5 compares the time required to complete a transaction under two different scenario changes. The horizontal axis represents the number of events in each block and the number of participants in the corresponding consensus. In the consensus algorithm proposed in this paper, each session has 20 consensus nodes and 100 events. PBFT acceptance time increases significantly (200 ms), CDBFT takes 100 ms, and PoVT takes only 80 ms. From the analysis point of view, PoVT takes less time to complete the transaction. PBFT reaches consensus through a full three-step broadcast, while the CDBFT system takes a long time to calculate voting fees, fines, and the credit evaluation process. If 100% of the nodes participate in the consensus process, the time required will gradually increase. The solution proposed in this paper is to achieve consensus by selecting multiple nodes and reducing the amount of communication, which can effectively reduce the communication cost.

TABLE 1: Number of block products under different algorithms.

Number of product transactions	0	100	200	300	400	500
PBFT	0	200	300	550	800	1000
CDBF	0	80	90	150	280	390
PoVT	0	90	145	300	400	550

FIGURE 4: Time changes of PoVT algorithm when the node is fixed.

FIGURE 5: Time changes of PoVT algorithm when the number of nodes and transactions is variable.

In Figure 6, we see the importance of ensuring the performance required to achieve optimal transaction rates, as consensus must be formed when a particular block is delivered. Bandwidth requirements are measured by varying the number of simultaneous events per second and the number of participating nodes. Bandwidth requirements increase with the number of simultaneous events, not directly with the number of IoT nodes. In traditional blockchains, this demand is quasi-linear and proportional to the increase in transaction volume.

4.2. *Product Traceability Trusted Data Analysis.* We can conclude that the method in this article analyzes the reliable data of product traceability, and the accuracy of the effect evaluation is high. The experiment also conducts a reliability test of the method presented in the article and compares it with the statistically ambiguous method and the digital game method. The results are shown in Figure 7.

From the experimental data in Figure 7, we can know that the reliability of reliable traceability tracking is highest among the three methods. The number of iterations can be up to 50, the confidence level can be up to 1, and the number

FIGURE 6: Changes in bandwidth demand as the number of concurrent transactions increases.

FIGURE 7: Credibility comparison test.

of iterations of obscure statistical methods with quantitative estimates can be up to 80. Up to 90 repetitions of game mods, reliability can reach 1.

4.3. Research on Consensus Mechanism of Blockchain Product Traceability. The security of blockchain consensus protocols is often related to feasibility. The security evaluation of the consensus protocol proposed in this paper is carried out in terms of durability and performance.

It can be seen from Table 2 that the selection times of each node are not related to each other, the maximum error rate can be allowed in the design, and the selection times of each node are roughly the same, which are all possible events. That is, all nodes are selected approximately the same number of times in each cycle. Also, the maximum number of selection errors does not depend on the total number of nodes. In terms of consensus effectiveness, the experiment

TABLE 2: Statistical table of data related to node election in four cases.

Number of elections	Trend line function	Maximum number of errors	Maximum error rate (%)	R.R
10000	$Y = 400$	13	3.35	0.0078
10000	$Y = 200$	11	5.50	0.0015
10000	$Y = 133.3$	9.3	6.97	0.0026
10000	$Y = 100$	6	6	0.0017

mainly estimates and evaluates the average consensus time of these two mechanisms, and the average consensus time is shorter and the consensus efficiency is higher. The test graph environment selects 10%, 20%, and 30% of Byzantine nodes in the network. The number of system nodes n is 52, the number of hits is increased to 2000, and the corresponding number t is 1500. Under certain conditions, the number of

FIGURE 8: Average consensus time when the number of consensus increases.

FIGURE 9: Average consensus time when nodes are incremented.

TABLE 3: Average consensus schedule with increasing consensus times.

Mechanism	1000	1500	2000
PBFT	6.3	6.5	6.8
ITPBFT	2.4	4	6.2

TABLE 4: Average consensus time when nodes are incremented.

Mechanism	40	70	100
PBFT	6.3	6.9	7.7
ITPBFT	5.4	6.2	7

system nodes increases to 100. We compare the consensus performance of the two mechanisms under different conditions, check the consensus number, the number of nodes, and other factors, repeat the experiment 100 times, and run the average test results. The results are shown in Figures 8 and 9.

In Tables 3 and 4, the following are experimental results for network environments with 10%, 20%, and 30% Byzantine nodes. According to the test results, the average consensus time of the main mechanism under the same network environment is higher than the average consensus time of the optimized mechanism in the system. For example, the number of Byzantine nodes in the system has increased by 10%, and the average repair time of ITPBFT is about 5.74 seconds. The average fitting time of the PBFT consensus engine is about 6.13 seconds; in addition, as the number of nodes in the system increases, the average consensus time used by the original engine is also higher than that of the optimized engine. The consensus efficiency of the optimized engine has been significantly improved compared to the original engine. For example, by using 10% of Byzantine nodes in the system, the optimization engine can increase consensus efficiency by about 4.7%. With the gradual growth of Byzantine Online, the improvement of consensus performance has become more and more obvious. There are 30% Byzantine nodes in the system. By increasing the consensus, the optimization engine can improve

the consensus efficiency by about 18.5%; as the number of nodes increases, the optimization engine can improve by nearly 16% compared to the original engine. The test results show that although the approval efficiency of the two mechanisms decreases with the increase of the number of approvals and the number of nodes, the optimization engine can improve the approval efficiency and reduce the approval time.

5. Conclusion

As a distributed information system supported by nodes, blockchain is widely used in the fields of transaction, copyright protection, product control, and access control. The emergence of platforms such as Ethereum and Hyperledger has promoted the rapid development of blockchain technology. Although blockchain technology is popular, high-power consumption and poor performance also affect the development of blockchain. The consensus mechanism is the core of blockchain technology: it is the basic mechanism for nodes to sequence events during model implementation, ensuring that nodes reach a consistent and secure network during delivery.

Web content mining describes the classification, clustering, and attribute analysis of a large number of text documents and multimedia files on the web. Special tasks include retrieval of data from the Internet search engine tool W; structured processing and analysis of web data. Today's blog analysis has security concerns. We do experiments to investigate its safety. Through experiments, we draw the following conclusions: (1) Web log extraction can use efficient data mining algorithms to systematically extract logs from web servers, then determine the main access types or interests of users, and then to a certain extent, based on the discovered user patterns, analyze the user's access settings and behavior. (2) No matter in the test set or the mixed test set, the curve value of deep mining is very stable, the curve value has been kept at 0.95, and the curve value of fuzzy statistics method and quantitative statistics method is stable within the interval of 0.90–0.95. The results also show that the data mining method has the highest identification accuracy and the best security performance. (3) Web usage analysis requires data abstraction for pattern discovery. This data abstraction can be achieved through data preprocessing, which introduces different formats of web server log files and how web server log data is preprocessed for web usage analysis. One of the most critical parts of the web mining field is web log mining. Web log mining can use powerful data mining algorithms to systematically mine the logs in the web server and then learn the user's access or preferred interests and then conduct a certain degree of user preferences and behavior patterns according to the discovered user patterns. Based on the above analysis, the current web log analysis is faced with security problems. We conduct experiments to study to verify the security performance of web logs and draw conclusions through experiments.

1. Introduction

Methods developed since the 1970s to represent, process, and extract knowledge for a variety of applications from the ever-increasing accumulation of data have made the pervasiveness of computing possible, perhaps inevitable, and have built a system for examining and a general framework for classification methods. Provide simple examples to demonstrate the nature of representative feature selection methods, compare them using datasets with a combination of intrinsic properties according to the goal of selecting features, propose guidelines for using different methods in various situations, and identify areas of research new challenge venue. There is a reference for researchers in

machine learning, data mining, knowledge discovery, or databases [1]. As the ability to track and collect large amounts of data using current hardware technologies continues to improve, there is a lot of interest in developing data mining algorithms that protect users. Recently proposed approaches have addressed data protection issues by aggregating data and restoring aggregation level distributions for data mining. This technology protects the confidentiality of the information contained in the original mark. Of course, rebuilding a distribution will result in an acceptable loss of information in many real situations. The algorithm is better in terms of data loss levels than currently available methods. In particular, the EM algorithm has been shown to satisfy the maximum likelihood method of the

initial distribution in noise-based estimation. When large amounts of data are available, the EM algorithm provides a reliable estimate of the raw data [2]. Interest in mining time series data has exploded over the past decade. In this work, the following claims are made. Much of the utility of this work is small, because the amount of improvement provided by the contributions is entirely the variance that can be observed by testing on many real-world datasets or by changing minor implementation details. To illustrate this point, the most exhaustive time series experiment ever performed has been reimplemented [3]. The Bayesian network is a graphical model that encodes probability relationships between variables of interest. When used in statistical methods, the model has many advantages in data modeling because it encodes relationships between all variables, facilitates the processing of missing data, and can be used to understand problems and predict results. This article describes the construction of the Bayesian network based on historical data and summarizes Bayesian statistical methods for using the data to improve these models [4]. The use of soft-computing provides an overview of the available data mining literature. Classifications were made based on the various software computing tools used and the data mining activities they performed, as well as the data mining activities performed and the preference criteria selected of the model. The utility of various soft computation methods is emphasized. In general, fuzzy sets are useful for solving problems related to image comprehension, mixed-media information, and human interaction and can provide approximate solutions more quickly. Genetic algorithms provide efficient search algorithms for selecting models from mixed-media data, pointing out specific problems for data mining, and applications of soft-computing techniques are presented in extensive bibliography [5]. Access blogs through business services and academic research are usually limited to the content of web posts. In this paper we provide a large-scale study of blogging and its relationship to posts. Using a large-scale comment corpus, we estimate the large number of comments in the blogosphere; analyze the relationship between blog popularity and comment patterns; and measure the contribution of comment content to various aspects of our blog visits [6]. Several systems have been developed to provide statistical analysis of World Wide Web usage logs. These programs typically report the number of files used and the number of times the site was used by the site, and some programs even provide time-of-request analysis. However, these programs are not interactive and cannot see the local database. The Internet is designed to provide database administrators and designers with graphical representations and templates for accessing local databases. In other words, by incorporating the network path paradigm into interactive software, users can not only view documents in the database, but also contact users by requesting documents from the database [7]. It presents the methods and analysis used in the ongoing, three-year Excite research project, which aims to examine the search nature of major Internet search engines. This article starts with general information about the web, unique and attractive views of users searching the web, and the impact of the web. The main

content of this article discusses the structures and methods used so far in material analysis and concludes with conclusions and expectations for future network research [8]. Web usage analysis or web usage analysis or web log extraction or clickthrough rate analysis is the process of extracting useful information from web server logs, database logs, user requests, client-side cookies, and user profiles to test the performance of web users. Internet usage analysis requires data abstraction to find patterns. This data abstraction can be achieved by data preprocessing, which adopts different web server log file formats and how the web server log data is preprocessed to analyze network usage [9]. Log files are maintained in communication between web browsers and web servers generated by real users accessing content associated with dynamic hyperlinks. These log files represent past user access to content and are used to generate web crawler access. This approach allows crawlers to accurately simulate real users, leading to the ability of legacy bots to automatically access everything a real user can access [10]. A method of evaluating an organization's information security policies and practices, including identifying risks associated with information security policies and practices, collecting information about information security policies and practices, using a security due date assessment matrix, generating ratings from the collected information, and correlating information with information risks associated with security policies and exercises, is to use ratings to generate a list of corrective actions, execute the list of corrective actions to create new security information policies and exercises, and monitor new security information policies and exercises [11]. Ecological security is a challenging issue for human survival and development. Cities are efficient and interactive human activities, resource shortages prevent further urban development, and ecological refugees and environmental health issues affect human survival. Urban ecological security is threatening the sustainable development of cities. There is an urgent need to appreciate urban sustainability. There is an urgent need to appreciate that urban ecological security and urban ecological security assessment are the most important issues. Through the assessment, decision makers can obtain more information about the current status of urban ecological security so that they can issue rational strategies to solve the problem. People can obtain information in time and then take decisive action to protect themselves [12]. Security analysis is a complex system development. The latest security scanning tools are only used to scan and detect vulnerabilities in network systems. Systems engineering thinking and techniques are applied to a comprehensive cybersecurity analysis. An artificial neural network model for safety analysis has been proposed, and computer simulation experiments have been carried out. The results show that the model can be effectively used to comprehensively evaluate the network security level. The overall assessment of the security status of computer networks provides new ideas and methods [13]. Security assessment is a complex system engineering. Through the hierarchical analysis process, various factors affecting network security are deeply studied, and a comprehensive network security ranking index system is

established. A security assessment is proposed, which provides a new idea and method for the overall assessment of computer network security status [14]. Network security analysis is a complex system design. The latest security analysis tools are only used to scan and detect security vulnerabilities in network systems. Comprehensive analysis of system design and techniques applied to cybersecurity is done. Build a comprehensive evaluation index system for network security. An artificial neural network model for safety assessment is proposed, and computer simulation experiments are carried out. The results show that the model can be effectively used to comprehensively evaluate the network security level. The overall assessment of the security status of computer networks provides new ideas and methods [15].

2. Web Log Analysis under Data Mining

2.1. Overview of Web Log Mining. Web mining is one of the most important components of the web mining industry. The web systematically extracts logs from web servers using powerful data mining algorithms to obtain information about user availability or priority of interest and is based in part on detected user patterns. Evaluate your website, adjust its topology, improve system performance, improve your website experience, provide intelligent personalization, and increase user loyalty. Internet communication is usually done through a web server architecture. The server for each site generates logs, the web client generates log files for clients accessing multiple sites, the proxy server generates log files for multiple users accessing multiple sites through a proxy, and the web server generates journal log files. Log files for multiple users using the site. Therefore, recording user habits can also capture user habits from three perspectives: network client, proxy server, and web server. Since the log information of the three nodes is different, the available user information is also different. Currently, two main aspects of the weblog algorithm are being analyzed, pattern sequence analysis algorithms and clustering algorithms. Customer usage patterns and agency buying should start online. Periodic pattern analysis algorithms are usually chosen to analyze the user's desired path, capture the content of interest to the user, and use an intelligent search engine to improve performance. Server-side clustering algorithms are commonly used to aggregate log data generated by all users visiting a website and create blogs that evaluate user behavior based on the clustering results. Finally, in this article, we will look at campus website logs to determine patterns of visitors. Therefore, it was decided to use a clustering algorithm to extract server-side access patterns.

2.2. Web Log Mining Process. In general, the journal launch process is divided into four steps: collecting journals, defining journals, defining templates, and modifying templates. (1) This article also uses this type of logs to review work, and there are ways to collect logs using

JavaScript scripts on our web page. (2) Log preprocessing phase after the general data exploration phase; initial data preprocessing will be performed in this phase. The log data source is irregular, impure, invalid data. Raw logs are used to cover data processing. It is converted into a format suitable for intelligence assessment, stored in a single format, and then continuously assessed. (3) Use a variety of data mining algorithms according to other business needs, mainly covering cluster analysis, association recommendation, path and intelligent sequence data analysis, etc. (4) Model analysis step: This step is the process of defining and analyzing data mining, which makes the generated model easy to understand. In the case of solving fundamental problems, theoretical theory is based on the definition of strategies. The web log mining process is shown in Figure 1.

2.3. Web Data Mining Classification and Development Design Focus. Web content mining involves classifying, grouping, and analyzing connections between multiple text and multimedia files on the Internet. Specific tasks include retrieving information from W search engines on the Internet; structuring and analyzing network data; page content analysis based on HTML technical standards and efficient data analysis. The implementation methods of web content extraction are mainly divided into direct document content decompression object; search engine query data retrieval object. According to different data mining objects, online content decompression includes two categories: online document decompression and media decompression. Web analysis is basically the process of searching and refining information about the structure and informational associations of pages on the World Wide Web. Its traditional implementation is as follows: First, the topology structure of the World Wide Web is analyzed using graph theory and transformed into a directed graph model. Each web page acts as a structural cue for a directed graph, with each edge of the graph representing links between different web pages. Examining the network structure can capture the necessary elements of directed graphs transformed from the World Wide Web to objects and extract valuable information from them. The purpose of a preliminary analysis of the site structure is to support search engines and provide users with valid information on the man pages. The object of web data mining research is shown in Figure 2.

Web content mining refers to the classification, clustering, and association analysis of a large number of text documents and multimedia files on the web. The specific tasks include extracting data information from the W search engine tool in the Internet; performing structured processing and analysis on network information; analyzing the page content based on HTML technical standards and mining the effective data information.

Pure log mining analysis extracts the access records stored by the server when users access network resources. The information stored in the web log includes the user's access method, access date and time, user query, user's

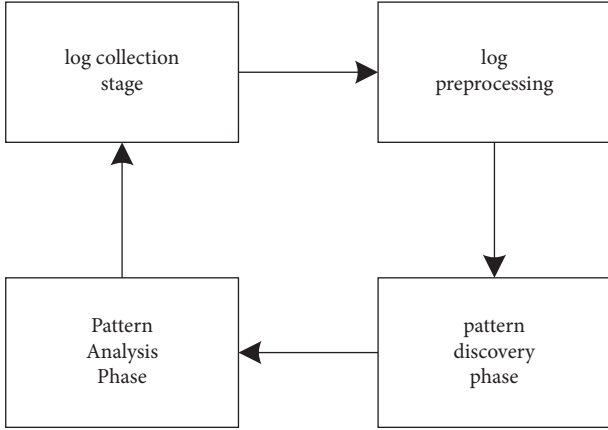

FIGURE 1: Web log mining process.

FIGURE 2: Web data mining research objects.

smart address, etc. Statistical analysis of this information allows us to examine the relationship between this information so that we can still find some key characteristics of user behavior. The key points of the development and design of network log extraction technology are as follows: (1) Before data mining, the target data must be pre-processed to meet the requirements of data mining and retrieval and to improve the level of efficient use of data. (2) OLAP can be used to perform multilevel analysis on the web log database to determine the N most popular web pages that will be opened when N users open web pages, so that users can understand their usage preferences and lay a foundation for this, so as to tap potential demand and market development.

3. Web Log Analysis under Data Mining Algorithm

3.1. Data-Based Mining Model. When performing data analysis based on historical data, data analysis can be carried out from a mathematical point of view and in accordance with the idea of time series analysis. When analyzing historical data, the algorithm used in this paper is support vector machine. Define a training set (X_i, Y_i) of number n and a nonlinear map $\psi(X)$ as

$$\{(X_i, Y_i) | i = 1, 2, \dots, n\},$$

$$\psi(X) = (\varphi(x_1), \varphi(x_2), \dots, \varphi(x_n)). \quad (1)$$

The two complete the mapping from the sample input space to high-dimensional features by a linear regression function:

$$f(x_t) = \omega^T \varphi(x_t) + b. \quad (2)$$

Among them, ω is the weight vector in the high-dimensional space, and b is the bias of the model. The ultimate goal of the SVM algorithm is to minimize the structural risk, that is, to find the optimal ω and b . During the calculation of model parameters, SVM is usually based on the principle of structural risk minimization:

$$\min J = \frac{1}{2} \omega^2 + c \sum_{i=1}^n (\xi_i + \xi_l) \quad (3)$$

$$s.t \{ y_i - \omega^T \varphi(x_i) - b \leq \varepsilon + \xi_i.$$

Among them, c is the regularization coefficient in the optimization process, and ξ_i, ξ_l is the relaxation factor to adjust the structural risk. When solving the optimization problem, this paper uses the Lagrange function, and its basic process is as follows:

$$L = \frac{1}{2} \omega^2 + c \sum_{i=1}^n (\xi_i + \xi_l) - \sum_{i=1}^n \bar{\alpha}_i. \quad (4)$$

According to the optimization algorithm there are

$$\frac{\partial L}{\partial \omega} = 0 \longrightarrow \omega = \sum_{i=1}^n (\alpha_l - \alpha_i) \varphi(x_i). \quad (5)$$

At this point, the kernel function that defines the heap function used in the optimization process is

$$k(x_i, x_j) = \varphi(x_i)^T \varphi(x_j). \quad (6)$$

Finally, the prediction formula of the model can be obtained:

$$f(x) = \sum_{i=1}^n (\alpha_l - \alpha_i) K(x_i, x_j) + b. \quad (7)$$

Among them, $k(x_i, x_j)$ is the radial basis function used in the model prediction, and its form is as follows:

$$k(x_i, x_j) = \exp \left[\frac{-x_i - x_j}{2\sigma^2} \right]. \quad (8)$$

3.2. Realize Intelligent Data Mining. Use neural network technology, an important branch of artificial intelligence technology, to achieve the goal of big data mining in the Internet of Things. A BP neural network with a three-layer transmission structure is used as the main structure, and normalized data is inputted into the neural network. Due to the peculiarities of the structure of the neural network, to replace the weight of the connection between the input and intermediate layers of the network W , the average information-information entropy E is used. The formula for calculating the weight:

$$\omega = \frac{1 - H_i}{\sum_{i=1}^E H_i}. \quad (9)$$

In the formula, the calculation result of the connection weight of the neural network is obtained through the entropy value of the i -th dimension attribute of the data. A genetic learning step is added to design a classifier with the network nonlinear classification ability and network structure as the core. Through the optimization of the genetic learning algorithm, the data that meets the mining requirements is output. The improvement of this artificial intelligence technology method, while ensuring the nonlinear ability, is connected with the previous processing method to ensure the accuracy of data mining. The genetic algorithm is integrated in the data mining process, and it is necessary to complete the modification of the hybridization operator and the mutation operator on the data input to the neural network. The calculation of the hybridization operator is expressed as a linear combination, expressed as:

$$\begin{aligned} \theta_1 &= u\theta_1 + (1-u)\theta_2, \\ \theta_2 &= u\theta_2 + (1-u)\theta_1. \end{aligned} \quad (10)$$

In the formula, θ_1 and θ_2 are the two data pieces of linear combination, and the value range of the constant U is between 0 and 1, and the value range is narrowed according to the actual situation. When the constant value is in a fixed state, it means that the hybridization operator in the calculation process is inconsistent. When the constant value changes with the number of iterations, the average performance of the hybridization operator can be improved, so that the IoT big data can be gradually mixed. In the modification of mutation operator in data mining, each random data C may have a certain probability of mutation, and the value V_k after one mutation of the data is randomly expressed as

$$v_k = v_k + \Delta(t, v_k - LB). \quad (11)$$

Generate data variation values based on the left and right neighbors LB and UB of variable k and the return value of the function. The value of data variation tends to be infinitely close to 0 as the algebraic t increases. Based on the above operations, the overall search of the operator in the data set is completed, and the IoT data information that meets the data mining requirements is output. Through all the above processing steps, the design of the IoT big data mining algorithm based on artificial intelligence technology is realized.

3.3. Data Mining Based on Influencing Factors. In the data analysis based on influencing factors, this paper introduces the Gray Wolf Optimal Algorithm (GWO) in the field of data mining. The GWO algorithm is an optimization algorithm based on the gray wolf population hierarchy and

group predation behavior. The principle is described in mathematical language as follows: For a gray wolf population, its number is M , and the search space is k , and for the gray wolf individual numbered i , its position can be described as

$$x_i = (x_1, x_2, \dots, x_k), \quad (12)$$

(13) and (14) give the process of wolves surrounding their prey:

$$D = |C \cdot x_p(t) - x(t)|, \quad (13)$$

$$x(t+1) = x_p(t) - A \times D. \quad (14)$$

Among them, D is the distance between the wolf and the prey in the wolf pack, $x(t)$ is the individual position of the gray wolf after iteration, and A and C are the parameter vectors of the model. The calculation method is as follows:

$$\begin{aligned} A &= 2ar_1 - a, \\ c &= 2r_2. \end{aligned} \quad (15)$$

When rank α, β, δ is close to the prey in the gray wolf group, the position of the prey can be estimated at this time, and the gray wolf group will iteratively update the position according to α, β, δ . Combined with the application scenarios in this paper, the common gray wolf optimization algorithm has a local optimum in the iterative process. Therefore, dynamic evolution operators and nonlinear convergence factors are introduced into the traditional gray wolf algorithm to improve the performance of the algorithm. After introducing the dynamic evolution operator, the wolf population combines the position of α, β, δ to update the position. At this point, the location update method can be rewritten as

$$\alpha = 2 - (e^{1/t} - 1) \cdot \frac{2}{(e - 1)}. \quad (16)$$

Differential evolution algorithm is used in this paper when making evolution improvements to the improved gray wolf algorithm. The algorithm includes three steps of mutation, crossover, and selection. First, the population is initialized:

$$x_{ij}(0) = x_{ij}^L + \text{rand}(0, 1)(x_{ij}^U - x_{ij}^L). \quad (17)$$

Mutate N initial populations on a random search space:

$$V_i(t+1) = x_{r_1}(t) + F[x_{r_2}(t) - x_{r_3}(t)]. \quad (18)$$

Then perform a crossover operation to improve the diversity of the population:

$$U_{ij}(t+1) = X_{ij}(t+1). \quad (19)$$

Based on the greedy algorithm, the individual with better evolution is selected as the new generation individual:

$$X_{ij}(t+1) = U_i(t+1), f[U_i(t)] \leq f[X_i(t)]. \quad (20)$$

TABLE 1: Web log security assessment.

Log model	Coverage (%)	Accuracy (%)	Recall (%)	Safety score (%)
Web log	81	93	44	94
Normal log	70	83	57	82

4. Web Log Analysis and Security Assessment under Data Mining

4.1. *Web Log Security Assessment.* In order to test the security performance of web logs, we collected the following data to evaluate the data coverage, accuracy, and recall to obtain the experimental results. The experimental results are shown in Table 1 and Figure 3.

According to the experimental data in the above chart, we can conclude that the accuracy rate and security score of web logs have reached more than 90%, and the coverage rate has reached 81%, and the recall rate is only 44%, while the accuracy rate and security score of ordinary logs have only reached about 80%, and the coverage rate is only 70%, and the recall rate reaches 57%. Through comparative experiments, we can see that web logs are more stable than ordinary logs in terms of coverage accuracy and security score.

4.2. *Overview of Web Log Hotspots and Trend Analysis.* We have made comprehensive statistics on the hot issues mentioned in the web logs and counted the overall traffic, monthly hot spots, and the highest visiting days and traffic. The data obtained are shown in Table 2 and Figure 4.

As can be seen from the above figure, the number of visits was the highest in the fifth week, and the number of visits this week reached 99,473. The least week was the first week, with 87,655 visits. From the trend point of view, the fluctuation of the number of visits is dominated by a continuous upward trend, with a slight increase in the number of abnormal weekly visits.

4.2.1. *Web Log Hotspot Query Type.* As shown in Figure 5 above, the largest query type was sales, which accounted for 33% of the total; by contrast, intermediaries had the lowest share, accounting for less than 20% of the total. This is followed by Ajax pages at 17% to 29%, followed by Ajax pages at 18% to 22%. In terms of trends, the sales page has maintained a high level of attention for a long time, while the data on the intermediate pages is scattered and incomplete, making it difficult to build a stable trend.

4.2.2. *Visits of Web Logs during Hot Spots.* As can be seen from Figure 6 above, the hot spots browsed by users are all concentrated in the noon and June period, the frequency of visits reaches the highest and its proportion reaches about 15%, and the time period with the lowest visit frequency is 3. During the month, it accounted for about 7%. From the above figure, we can see that the time period of hotspot access is always fluctuating, and there is no stable trend.

FIGURE 3: Web log security assessment.

TABLE 2: Weekly visits.

	First	second	Third	Fourth	Fifth
Weekly visits	87655	87898	88242	89883	99473

FIGURE 4: Week visits.

FIGURE 5: Hotspot query types.

FIGURE 6: Visits during hotspots.

4.3. *Data Mining Accuracy Comparison.* According to the experimental results, we can conclude that the data mining method used in this paper is relatively high in terms of experimental results and accuracy. The statistical method was compared, and the comparison results are shown in Figure 7.

According to the experimental data of the graph, we can know that the evaluation accuracy of the data mining method is the highest among the three methods. When the number of iterations reaches 50, the evaluation accuracy can reach 1, and when the number of iterations of the fuzzy statistical method is 80. When the number of iterations of the game method is 90, the evaluation accuracy can reach 1.

FIGURE 7: Evaluation accuracy comparison test.

4.4. *Performance Test and Safety Evaluation Test.* In order to test the superiority of the performance based on the data mining technology proposed in the paper, after the model proposed in the paper is improved, the fuzzy statistics method and the quantitative statistics method are, respectively, run on the test set and the mixed test set. The test set is used to evaluate the generalization ability of the final model, and the mixed test set is used to tune the model’s hyperparameters and to make an initial evaluation of the model’s ability. Record the experimental results to verify the advantages of the three methods, and draw graphs based on the experimental results. The experimental data of different models on the test set and the mixed test set are shown in Table 3 and 4.

According to the data in the table and Figure 8, we can conclude that, after running on the test set, the accuracy rate of quantitative statistics method can reach 89%, the accuracy rate can reach 91%, and the accuracy rate through data mining technology can reach 92.%. The accuracy rate can reach 93%, which is the highest index value among the three experimental models. The accuracy rate of fuzzy statistics method is 85%, which is the lowest among the three models. According to the curves of the three models, we can also see that the curve values of the data mining technology are very stable, the curve value of the quantitative statistics method is kept at about 0.90, and the curve value of the data mining method is also always kept at 0.97. The curve value of the statistical method is lower, and the experimental results also

TABLE 3: The performance of each model on the test set.

Method	Accuracy (%)	Accuracy (%)	Score (%)
Data mining	92	93	95
Fuzzy statistics	85	82	83
Quantitative statistics	89	91	90

show that the performance of the data mining technology is the best and the security performance is also the best.

According to the data in Table 4 and Figure 9, we can conclude that, after running on the mixed test set, the performance of the three models has decreased to a certain extent, but the data mining method proposed in the article is still the highest among the three methods. One, the accuracy rate of quantitative statistics method is 87%, and the accuracy rate of fuzzy statistics method is 90%. According to the curves of the three algorithms, we can also see that the curve value of deep mining is very stable, whether in the test set or the mixed test set, the curve value has been kept at 0.95, and the curve of the fuzzy statistical method and the quantitative statistical method values stabilized within the range 0.90–0.95. The experimental results also show that the data mining method has the highest recognition accuracy and the best security performance.

TABLE 4: The performance of each method on the mixed test set.

Method	Accuracy (%)	Accuracy (%)	Score (%)
Quantitative statistics	87	88	90
Data mining	90	92	95
Fuzzy statistics	82	81	85

FIGURE 8: Curves on the test set.

FIGURE 9: Curves on the mixed test set.

5. Conclusion

One of the most important parts of the web indexing arena is the indexing of your blog. Web log extraction can use powerful data mining algorithms to systematically manage our logs on web servers and then learn accessibility or user preferences, in part based on settings and usage patterns. Website analytics and interactive website experience will be enhanced, and intelligent personalization will be provided to increase user loyalty. Through the analysis of the web log of data mining, we can also find that the curve value of deep mining is very stable no matter in the test set or the mixed test set, the curve value has been kept at 0.95, the curve value of fuzzy statistics method and quantitative statistics method is stable within the range of 0.90–0.95. The experimental results also show that the data mining method has the highest recognition accuracy and the best security performance.

As one of the three main courses from primary school to senior high school, improving the quality of English teaching in and out of class has become the top priority of colleges and universities. English knowledge points are complex, and domestic scholars have studied vocabulary knowledge and grammatical awareness from various perspectives, but there is still a lack of research on the correlation between vocabulary knowledge, grammatical awareness, and cloze test scores of senior high school students. Therefore, this paper carries out empirical research from the depth of English vocabulary, English grammar, reading comprehension, cloze test, and composition, aiming at exploring the relationship between teaching quality and English knowledge points. Classroom teaching quality evaluation is the basic content of education quality evaluation, which not only needs to evaluate the effect of class hours but also needs a student's long-term learning effect. In order to improve the quality of classroom English teaching, enrich the content of classroom English, and ultimately make the quality of students' learning to a higher level, the combination model of the teaching quality evaluation index is established by combining the decision tree with the knowledge point rule association method and the evaluation results are verified by association rule analysis. This paper selects the effective indicators that affect the evaluation of English teaching quality, determines the weight of the indicators by using the analytic hierarchy process, effectively constructs the combination model of the decision tree and rule association method, and establishes the evaluation model of students' English learning ability in the classroom. Taking students as the main object and combining them with the requirements of digital teaching, the evaluation index system is formed, the index weight is determined by using the analytic hierarchy process, and the classroom teaching quality evaluation model based on the decision tree and English knowledge point correlation analysis is constructed to truly reflect the teaching level of teachers, and the correlation analysis is carried out between English teachers' own quality and students' learning effects and knowledge points. By testing the model performance of English vocabulary depth, reading comprehension, grammar, writing, and other knowledge points, we can well evaluate and analyze students' mastery of English learning and the correlation of English knowledge points.

1. Introduction

English is the most common language in the world, and its importance goes without saying. In order to evaluate the quality of English teaching in schools and study the correlation between teaching quality and English knowledge points, we have constructed a combined evaluation system of the decision tree and rule association analysis of knowledge points. This paper expounds that this method is efficient in detecting large error data in fringe images [1] and uses artificial intelligence technology to evaluate the quality of surgery in medicine [2]. It expounds the anatomical analysis

of the components of kidney stones by the deep learning method [3]. In order for the leaders of colleges and universities to do a better job in teaching management and reduce unnecessary management problems, literature [4] fully demonstrates the effectiveness of teaching evaluation for students in colleges and universities under the background of intelligent computing. Using big data related knowledge to study the evaluation system of college physical education can not only promote the implementation of college physical education evaluation but also effectively improve the quality of college physical education [5]. It takes the quality of graduates as the core content, establishes a result-oriented

evaluation system of teaching quality in colleges and universities, and finds that the academic level and the level of competition in choosing jobs are two quantitative levels reflecting the quality of graduates [6]. It mainly puts forward some measures to construct the evaluation system of college English teaching from the key point of constructing the evaluation system of junior and senior high school English teaching based on online learning platform [7]. Through a scientific and complete teaching evaluation system, we can optimize the physical education teaching process to a certain extent, promote the effective realization of physical education teaching objectives, and improve the quality and efficiency of physical education in colleges and universities [8]. It expounds the development of task-based learning as the center of the English teaching evaluation model and cultivates the English writing ability and creative thinking of Thai sixth grade students [9]. It mainly explores the multidimensional teaching evaluation system of local universities under the background of transformation [10]. It discusses how higher education institutions apply the questionnaires used in our research to diversity management [11]. It implements gauge teaching evaluation from the perspective of students and teachers [12]. There are considerable problems in the hypothesis of students' evaluation to measure the teaching effect, especially in the system where problem-based learning is the main teaching idea. It determines a working hypothesis; that is, students do not use teaching ideas as the main motivation to evaluate employees, which leads to an abnormal incentive [13]. This study assessed the effectiveness of focused educational practice designed for teachers in multiple professional departments, which have a large number of elderly patients, and became a geriatrics-based teacher development plan [14]. This paper explores the diversity of evaluation methods and exerts the positive functions of evaluation, detection, stimulation, and development. By expanding evaluation ideas, emphasizing performance evaluation, realizing immediate evaluation, and carrying out special evaluation, the evaluation function can be repositioned [15]. The paper verifies the effectiveness and practicability of our method through an intuitive multimedia teaching evaluation example [16]. The analysis results of this paper may provide some theoretical basis and reference for the research of history teaching methods and also provide relevant information for overseas Chinese modern history research institutions to understand the learning situation of Chinese history in this period [17]. On the basis of continuous development and improvement of teaching evaluation, this paper explores the refined management of undergraduate teaching [18]. Teaching evaluation is an important part of curriculum teaching, which is beneficial for teachers to get feedback, improve the teaching quality, and maintain the teaching foundation. It is an effective measure for students to find the most suitable learning method, correct learning habits, and improve learning efficiency [19]. The fuzzy comprehensive evaluation of the cloud system is studied, and finally the experimental verification is carried out by an example [20]. The purpose of this study is to analyze the relationship between learning styles and academic achievements of accounting science students combined with teachers' evaluation [21]. It examines the evaluation degree of

teachers' own teaching behavior management practice, as measured by the evaluation system of classroom learning strategies [22]. The teaching evaluation method proposed in this study is helpful to fully reflect the quality of classroom teaching and guide students' professional development [23]. In this paper, we propose two vocabulary-based methods, especially knowledge-based and machine learning-based methods, to automatically extract opinions from short comments [24]. This structured process produces an evidence-based and systematically developed EM teacher evaluation tool, which can provide teachers with real-time operational feedback and support improved clinical teaching [25].

2. Construction of the Index System of the English Teaching Quality Evaluation Model

2.1. Indicator Construction. The evaluation of English teaching quality from primary school to senior high school is a nonstatic process involving many variables and influencing factors. The evaluation system of English teachers' classroom teaching quality needs to reflect and exclude teachers' own influencing factors, such as teachers' teaching concepts, teaching attitudes, teaching methods, and educational effects. It is also necessary to take into account the factors of students who directly participate in teaching. Students can directly feel teachers' own teaching quality and students' learning effects during the whole feeling process of participating in classroom teaching. The innovation and diversification of information-based foreign language teaching methods require the cultivation of students' intrinsic motivation and self-efficacy and the effective integration of information technology and foreign language teaching. Finally, it establishes the initial index content composed of four most important indexes and fifteen more important indexes: "curriculum goal, classroom teaching, teaching effect, and teaching expansion."

- (1) The index of "curriculum goal" is the direction and soul of the curriculum, which determines the overall quality of personnel training. It aims to reflect the applicability of teaching content and cultivates the matching degree of knowledge and skills that students need to achieve through curriculum study.
- (2) The index of "classroom teaching" reflects the main forms and key links of English teaching from primary school to senior high school, including the effectiveness of English classroom teaching activities in cultivating knowledge depth and learning ability, the rationality of classroom teaching time and content arrangement, and the breadth and depth of information resources use under the background and environment of the digital age.
- (3) The "Teaching effect" reflects the effectiveness measurement index after the teaching process, especially reflects the advancement of foreign language teaching supported by information technology and its promotion to the teaching effect.

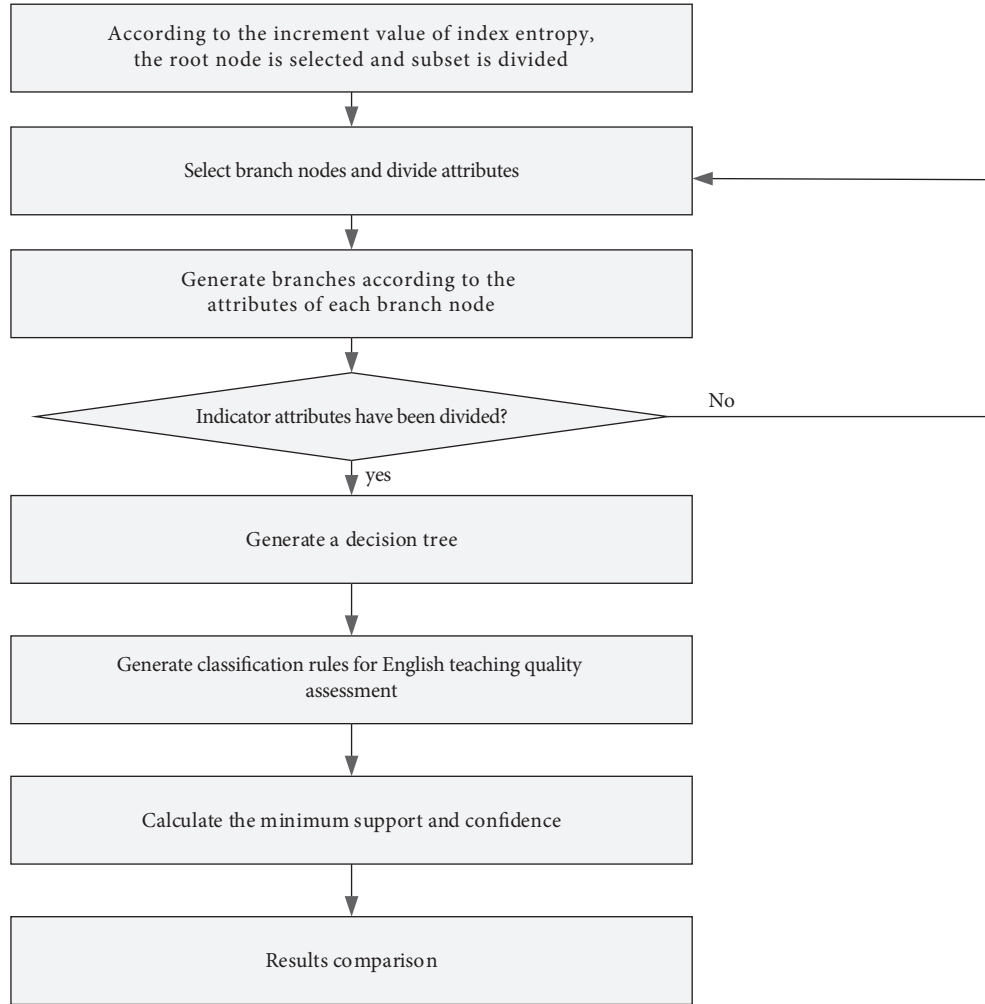

FIGURE 1: Evaluation process.

- (4) “Teaching expansion” refers to the teaching methods outside the classroom, which are carried out around the curriculum objectives under the support of information technology. The design and effect evaluation of extracurricular learning content to assist classroom teaching and enrich related courses, including the diversification of extracurricular learning resources and assessment contents and methods, the abundance of resources provided online and offline, and the effectiveness of promoting college English learning.

2.2. Teaching Evaluation Process. The evaluation process is the selection of teaching quality and teachers’ own quality evaluation indicators from two aspects; one is the relevant data of teachers, and the other is the related factors of teaching schedule and teaching links. Obtain the English teaching evaluation data package from the educational administration platform, initialize the data according to indicators, generate samples to be evaluated, calculate entropy increment values of all indicators to generate a decision tree, and verify the classification rules of English teaching quality

evaluation generated by the decision tree by the association rules method. In this, the specific steps for verifying the decision tree and association rule combination model are shown in Figure 1.

3. Description of the Algorithm

3.1. Decision Tree and Knowledge Point Association. The decision tree is mainly composed of roots, branches, and leaves. The calculation method of expected entropy is as follows:

$$I(s_1, s_2, s_3, \dots, s_m) = - \sum_{i=1}^m \frac{s_i}{s} \log_2 \frac{s_i}{s}. \quad (1)$$

Let the expected expression of an attribute A of the sample be

$$E(A) = \sum_{j=1}^m \frac{s_{ij} + s_{2j} + \dots + s_{mj}}{s} I(s_{ij}, s_{2j} + \dots + s_{mj}). \quad (2)$$

For the subset Is_j is defined as follows:

$$I(s_{ij}, s_{2j} + \dots + s_{mj}) = - \sum_{i=1}^m \frac{s_{ij}}{s_j} \log_2 \frac{s_{ij}}{s_j}. \quad (3)$$

Expected Entropy Gain of A to S is

$$\text{Gain}(A) = I(s_{ij}, s_{2j} + \dots + s_{mj}) - E(A). \quad (4)$$

The gain rate is expressed as

$$\text{Gain}(A) = \frac{\text{Gain}(A)}{\text{splitinfo}(s)}, \quad (5)$$

$$\text{splitinfo}(s) = \sum_{i=1}^m \frac{s_i}{|s|} \times \log_2 \frac{s_i}{|s|}.$$

3.2. Correlation Analysis of Knowledge Points. Suppose that the number of items in all sets D is D , X is an item set in D , and the number of item sets in D is count, then the support degree of X is

$$\text{support}(X) = \frac{\text{count}(X \subseteq D)}{|D|}. \quad (6)$$

Let any two item sets X and Y in D satisfy the condition $X \subset D$, $Y \subset D$, they are independent of each other, and the probability that they appear at the same time in D can also be expressed by support:

$$\text{support}(X \Rightarrow Y) = \frac{\text{count}(X \cap Y)}{|D|}. \quad (7)$$

In addition to calculating support, reliability can also be used to measure the relationship between X and Y :

$$\text{confidence}(X \Rightarrow Y) = \frac{\text{support}(X \Rightarrow Y)}{\text{support}(X)}. \quad (8)$$

It can also be measured by the degree of improvement:

$$\text{lift}(X \Rightarrow Y) = \frac{\text{confidence}(X \Rightarrow Y)}{\text{support}(X)}. \quad (9)$$

3.3. RCNet Model. RCNet consists of four parts, namely, the output layer, bidirectional GRU layer, attention layer, and prediction layer. In this, GRU is selected to learn the calculation formula of remote dependency of the whole input sequence as follows:

$$\begin{aligned} z_n &= \sigma_g(w_z x_n + u_z h_{n-1} + b_z), \\ r_n &= \sigma_g(w_r x_n + u_r h_{n-1} + b_r), \\ \hat{h}_n &= \varnothing_h(w_h x_n + u_h (r_n * h_{n-1} + b_h), \end{aligned} \quad (10)$$

$$\text{GRU}(h_{n-1}, x_n) = (1 - z_n) * h_{t-1} + z_n * \hat{h}_n.$$

The hidden layer vector of the bidirectional GRU is calculated as follows:

TABLE 1: Quantitative statistics of text length.

Statistical parameters	Quantity
Content and text length of English test questions	53003
Length of English text	11393
Length of question text	3291
Length of option text	9132

FIGURE 2: Difficulty distribution of test questions.

FIGURE 3: Scatter plot of English learning quality and vocabulary breadth knowledge level.

$$\begin{aligned} \vec{h}_n &= \text{GRU}(\vec{h}_{n-1}, x_n), \\ \overleftarrow{h}_n &= \text{GRU}(\overleftarrow{h}_{n-1}, x_n), \\ h_n &= [\vec{h}_n, \overleftarrow{h}_n]. \end{aligned} \quad (11)$$

The N word vectors are fused into

TABLE 2: The actual value and evaluation value of teaching quality evaluation.

Weight	Evaluation value	Actual value
K11	0.78	0.69
K12	0.82	0.80
K32	0.81	0.83
K31	0.79	0.87
K35	0.88	0.89
K41	0.83	0.88
K43	0.91	0.90

FIGURE 4: Comparison between the actual value and the evaluation value.

$$\bar{Q}_i = \text{avg}(h_1, h_2, \dots, h_N) \in R^{2u}. \quad (12)$$

In the further calculation, the influence of TC and TQ tail is eliminated by the mask method, namely,

$$G(i, j) = \begin{cases} H_C(i)^T H_Q(j), & i < |TC|, < |TQ| \\ 0, & i \geq |TC| \text{ or } j \geq |TQ|. \end{cases} \quad (13)$$

After obtaining the paired matching matrix, the attention layer applies the softmax function to each column in G to obtain the probability distribution of each column, wherein when considering a single test word, each column in the matrix represents a separate text-level attention, the text-level attention of the n th word is as follows:

$$a(n) = \text{soft max}(G(1, n), \dots, G(|TC|, n)). \quad (14)$$

Calculate reverse attention; that is, for words in the n th chapter, calculate the importance distribution of test words to indicate which test words are more important for individual words in the chapter. The attention mechanism will gradually implement the softmax function and apply it to each pair of matching matrices to obtain the attention of English test questions with different difficulties:

$$\beta(n) = \text{soft max}(G(n, 1), \dots, G(n, |TQ|)). \quad (15)$$

Get the average attention at the test level as follows:

$$\beta = \frac{1}{|TC|} \sum_{N=1}^{|TC|} \beta(n). \quad (16)$$

Explicitly understand the contribution of each test word, vote according to the importance of each test word, and output the final text-level attention weight as the text-level attention vector as follows:

$$CA_i = a^T \beta. \quad (17)$$

The expression for predicting the difficulty of English test questions is as follows:

$$\tilde{P} = \text{Sigmoid}(W_2 \cdot o_i + b_2). \quad (18)$$

Training model expression is as follows:

$$J(\theta) = \sum_{T_i, Q_i, Q_j} ((P_i^t - P_j^t) - (\tilde{P}_i^t - \tilde{P}_j^t))^2 + \lambda_\theta \theta_M^2,$$

$$\text{RMSE} = \sqrt{\frac{1}{m_i} \sum_{j=1}^{m_i} (P_{ij} - \bar{R}_{ij})^2}, \quad (19)$$

$$R^2 = 1 - \frac{\sum_{j=1}^{m_i} (P_{ij} - \bar{R}_{ij})^2}{\sum_{j=1}^{m_i} (R_i - \bar{R}_{ij})^2}.$$

4. Experiment

4.1. Simulation Experiment

4.1.1. Data Set Introduction. The sample data set adopted in this experiment is the English test results and answer records

from many middle schools in China from 2014 to 2021. Each data include five fields: English test content, question, correct option, wrong option, and test difficulty. The statistical results are shown in Table 1.

The difficulty of the experimental data set is tested, and the uniformity of the difficulty distribution of the test

FIGURE 7: Comparison chart of reading comprehension teaching quality.

FIGURE 8: Comparison of cloze teaching quality.

questions is distributed by the classical measurement theory difficulty of 0–1, as shown in Figure 2.

4.2. *Experimental Research.* The correlation between the quality of English teaching and the breadth and depth of vocabulary is analyzed. This question verifies the correlation between English teaching quality, vocabulary breadth knowledge, and vocabulary depth knowledge. It is necessary to check whether there are singular values in the whole data so as to analyze whether there is a curve relationship between the data. Therefore, before testing the correlation coefficient,

we draw scatter charts on the relationship between the teaching quality of English learning and vocabulary breadth knowledge and vocabulary depth knowledge as shown in Figure 3.

The effectiveness of the index system of the traditional English classroom teaching quality evaluation model is to ensure students’ trust in the evaluation results of college English classroom teaching quality. The purpose of training the students before the evaluation is to let them know the purpose and significance of the evaluation and to guide students to deepen their familiarity with the indicators and grading standards. Finally, the scoring results are collected,

FIGURE 9: Comparison of English writing teaching quality.

Writing	0.887	0.871	0.838	0.856	0.887

FIGURE 10: Comparison between teaching quality and English knowledge points.

and according to the students' scoring data, the actual scores of teaching quality evaluation are calculated. The results are shown in Table 2.

The above data are counted into tables as shown in Figure 4.

4.3. Model Comparison. For English learning vocabulary depth, grammar, reading comprehension, cloze, writing, and other knowledge points, student-centered teaching quality evaluation uses their mastery to evaluate teachers' English teaching quality. Based on the above index standards, we use the decision tree method under deep learning to study and evaluate English teaching quality evaluation. The experimental data are given in Table 3.

Three senior high school students were selected to evaluate the teaching ability, teaching attitude, teaching content, teaching methods, and teaching effect of English teachers as the quality indicators of English classroom teaching and to evaluate the quality of each English learning knowledge point.

The combination model of the decision tree and knowledge point association rule mining is used to evaluate the teaching quality of English vocabulary depth, as shown in Figure 5.

The combination model of the decision tree and knowledge point association rule mining is used to evaluate the teaching quality of English grammar, as shown in Figure 6.

The combination model of the decision tree and knowledge point association rule mining is used to evaluate the teaching quality of English reading comprehension, as shown in Figure 7.

The combination model of the decision tree and knowledge point association rule mining is used to evaluate the teaching quality of the English cloze test, as shown in Figure 8.

The combination model of the decision tree and knowledge point association rule mining is used to evaluate the teaching quality of English writing ability as shown in Figure 9.

4.4. Contrast Experiment. The decision tree model and rule mining association combination model proposed in this paper are tested in terms of model performance, and different English knowledge points are compared, as shown in Table 4.

The comparison table between teaching quality and English knowledge points is counted into a bar chart, as shown in Figure 10.

5. Conclusion

We analyze the relationship between the effective evaluation of teaching quality in the college English classroom and knowledge points and propose a combined model based on the decision tree and rule association analysis of English knowledge points to evaluate teaching quality in English classrooms. Through the combination model of the two

methods to evaluate the teaching quality in the classroom, the evaluation results of teaching quality after evaluation are obtained, which shows that this method is effective and has strong applicable value for the evaluation of English teaching quality in the classroom. The results are as follows:

- (1) In the difficulty test of English, the difficulty distribution of test questions is relatively uniform. In the difficulty interval of classical measurement theory from 0 to 1, the proportion of test questions in each difficulty interval with a difficulty interval of 0.1 is about 10%.
- (2) By comparing the actual values of different weights of English teaching indicators with the evaluation values, we can see that the evaluation performance of this model is good.
- (3) The limitations of the decision tree model combined with rule association analysis can greatly improve the evaluation level of English teaching quality inside and outside the classroom and study and analyze the relevance of English knowledge points.

In view of the inability to accurately analyze the application of deep learning in college physical education teaching design from the perspective of flipping classroom, this paper puts forward an improved deep learning method based on the integration of flipping classroom vision and deep learning, which can reduce the design ability of physical education teaching design in college physical education teaching design and improve the level of college physical education teaching design. Firstly, the initial data set is established by using the theory of flipping classroom horizon, so that the data meet the requirements of normal distribution and reduce the differences between teaching data; Then, the physical education teaching design is divided into different subdesigns by using the theory of flipping classroom horizon. Find the best design result in this domain in each subinstructional design; Finally, under the guidance of the theory of flipping classroom horizon, each subdesign realizes the optimal allocation of teaching resources. MATLAB simulation shows that under the conditions of initial design scheme and teaching resources setting, the improved deep learning method can improve the accuracy of physical education teaching design and shorten the convergence time of design, which is superior to the original deep learning method. Therefore, the deep learning method is used to analyze the instructional design of college physical education, which has a good design effect and is suitable for the instructional design of college physical education.

1. Introduction

With the continuous improvement of physical education teaching level, the requirements of instructional design are becoming more and more strict, and it presents a complicated direction of development Yu, and Zhu [1], so it is particularly important to study physical education instructional design under complex conditions. The key to the allocation of teaching resources in physical education teaching design is to judge the types of resources and design requirements Yin [2]. The theory of flipping classroom horizon can not only adjust the dynamic relationship between teaching content and resources but also solve the selection of physical education teaching design under multiple horizons, which is the main theory of physical education teaching design at present Xiao et al. [3]. Flipping the classroom horizon can make teachers realize the significance of preview and its importance to physical education. Flipping classroom

takes students as the main core, which can give full play to students' initiative and change the center of traditional teaching. Relatively speaking, flipping the classroom can distinguish the primary and secondary of teaching, so that students can study deeply according to their own interests. Therefore, flipping classroom plays a very important role in physical education teaching design. Literature research shows that the theory of flipping classroom horizon classifies physical education teaching design, shortens the design time and improves the overall level of design. However, in the process of design classification by flipping classroom horizon theory, the complexity of design will affect the judgment of conditions and the final design result Webb et al. [4]. Some scholars have put forward the deep learning method. Although the deep learning method can realize the selection of design schemes, it is suitable for the conditions with less design requirements. Although there are many researches on flipping classroom by scholars at home and abroad, there are

TABLE 1: Complexity of physical education teaching design requirements from the perspective of flipping classroom.

Classification	Instructional design in colleges and universities		Physical education teaching design

few researches on other methods from the perspective of flipping classroom, and deep learning methods can better promote the improvement of physical education teaching design level. At present, scholars at home and abroad have little research on deep learning from the perspective of flipped classroom, especially the actual case analysis. Under changeable and complex conditions, the overall design ability of the design scheme is greatly reduced Wang and Wang [5]. Therefore, some scholars put forward the theory of flipping classroom horizon and improving deep learning, as shown in Table 1.

It can be seen from Table 1 that the complexity of college physical education teaching design is high from the perspective of flipping classroom. However, to a certain extent, it also shows the need of intelligent algorithm for college physical education teaching design. Among them, shooting, martial arts, 100 meters, and high jump need intelligent algorithms to achieve intelligent management and analysis. At the same time, some scholars have studied the integration of deep learning method and flipped classroom horizon theory, and found that the flipped classroom horizon theory can reduce the complex design requirements and improve the reliability of physical education teaching design Umezawa et al. [6]. Based on this, this paper puts forward an improved deep learning method based on the integration of deep learning and flipping classroom horizon theory, designs physical education under complex conditions, and verifies the effectiveness of the design. At present, there is a dynamic relationship between design difficulty and standard in college physical education teaching design, as shown in Figure 1.

As can be seen from Figure 1, there is a positive correlation between physical education teaching design and standards, so it is necessary to strengthen the difficulty analysis of physical education teaching design to meet the design standards and requirements Trpkovska et al. [7].

To sum up, there are many researches on flipping classroom horizon, which can provide support for deep learning and better promote the improvement of college physical education teaching design level. At the same time, the integration of deep learning and physical education teaching design requires more reasonable adjustment. Flipping the classroom

FIGURE 1: Relationship between difficulty and standard in physical education teaching.

can provide preview in the early stage and discussion in the later stage, and realize a series of teaching optimization. At present, the research of physical education teaching design is developing in the direction of intelligence, and turning over the classroom horizon lays the foundation for this development, which is also the focus of future research.

2. Related Concepts

2.1. Flip the Classroom Horizon Theory. The theory of flipping classroom horizon was first put forward by Eric Mazur in 1990s, which is based on peer teaching method. Compared with the traditional teaching mode, the theory of flipping classroom horizon not only pays attention to information transmission, but also deepens the understanding of knowledge Tang, and Wang [8]. The theory of flipping classroom horizon requires students to teach themselves the course content after class and interact in the form of “asking questions-thinking-answering” in class. According to the

proportion of students' correct answers, teachers should adjust their teaching contents J. Song, and Kapur [9], so as to deepen students' understanding of knowledge and make them understand the key points and difficulties of teaching. However, flipping classroom is the best combination put forward from the perspectives of teachers, teaching, and students, which has the characteristics of sparsity and integration, and can be designed dynamically in physical education. The theory of flipping classroom horizon needs to construct core functions and analyze the experience and requirements in physical education teaching design in order to improve the accuracy of the design scheme Soler et al. [10].

Theorem 1. *Assuming a collection of physical education instructional design schemes, $T = (\{d_i \forall b_i, i = any\})$ arbitrary physical education instructional design $q_i \in [-\infty, +\infty]$, innovative instructional design $b_i \in [1, 100]$, and adopted design methods $K(d_i \Rightarrow q_i \Leftarrow b_i)$. The resource allocation function matches the teaching resources with the educational requirements $L(x_i \Leftrightarrow y_i \Leftarrow z_i)$, and the sports design scheme makes the scheme optimal Y_f . The calculation is shown in formula.*

$$Y_f = w \times f(d_i \Rightarrow q_i \Leftarrow b_i) \Leftarrow \lambda. \quad (1)$$

Among them, w is the allocation condition of different resources and λ is the teaching resource. When $\sum Y_f \approx \infty$, the number of physical education teaching design classifications was the largest, the classification interval was the largest, and the design was more difficult; when $w=1$, the design was the most innovative.

Theorem 2. *If the deviation of physical education teaching design ξ_i is between $[-1, 1]$, it means that physical education teaching design is reasonably optimized, otherwise, it should be re-optimized, and the optimal scheme Y_f calculation is shown in formula.*

$$\begin{cases} \min Y_f = w \cdot K(d_i, q_i, b_i) \quad \forall C \sum \xi_i, \\ w \cdot K(d_i, q_i, b_i) \approx 1. \end{cases} \quad (2)$$

Among them, C is deviation, which reflects the deviation between physical education teaching design and design conditions Sofya, and Sahara [11].

Theorem 3. *If the resource allocation function $K(d_i \Rightarrow q_i \Leftarrow b_i) = \sum \varphi(d_i) \Leftrightarrow \sum \varphi(q_i)$, the matching function $L(x_i, y_i, z_i)$ is calculated as shown in the following formula:*

$$\begin{cases} \max L(a) = \sum a_i \Leftrightarrow \sum a_{ij} q_{ij}, \\ \sum a_i = dx_i \Leftrightarrow q_i. \end{cases} \quad (3)$$

Among them, flipping the deviation coefficient C in the theory of classroom horizon is the key to the implementation of deep learning method Shim et al. [12].

2.2. Improve the Deep Learning Method

2.2.1. Deep Learning Can Realize the Optimization of Large-Scale Physical Education Teaching Design by Simulating Artificial Behavior, Including Leading, Assisting, and Adjusting. During initialization, the number of PE instructional design and instructional design innovation schemes is the same, and the matching of different PE instructional designs represents the optimal solution. Firstly, the initialization of physical education teaching design and physical education teaching design are randomly generated, and the physical education teaching design is judged near the scheme with better fitness scheme Luo and Zhu [13], and the "poor" scheme is eliminated by comparison, about 1/2 of the number; Then, the auxiliary scheme uses roulette strategy to judge the best scheme, gives corresponding weights, and carries out greedy judgment around the optimal scheme to generate a 1/2 scheme. Finally, the physical education teaching design that does not conform to the teaching resources needs to be abandoned, and the physical education teaching design should be judged in other directions [14].

Assuming that the initial number of physical education teaching design and innovative schemes is n , and the random matching of physical education teaching design is $L = (x_i, y_i, z_i)$, x_i, y_i represent plane coordinates and z_i represents difficulty, then the initial matching calculation of physical education teaching design is shown in formula:

$$L_i(x_i, y_i, z_i) = w \cdot K(d_i \Rightarrow q_i \Leftarrow b_i) K \left\{ (x_{j \max}, y_{j \min}, z_{j \min}) \rightarrow L(0, 1) \right\} \quad (4)$$

where, x_i, y_i , and z_i are any matching resources $x_{j \max}$ is the scheme with the greatest complexity, $y_{j \min}$ and $z_{j \min}$ the sum is the scheme with the smallest complexity. $L(0, 1)$ is a random number in the range of $[0, 1]$.

The improvement scheme is to randomly allocate physical education teaching resources and make cross judgment among resources to realize the renewal of physical education teaching design. Under the constraint of fitness, the optimal resource matching is obtained by using the most complex conditions, and the calculation is shown in formula:

$$\Delta L_i(x_i, y_i, z_i) = w \cdot K(d_i, q_i, b_i) \Leftrightarrow \int \varphi_{ijz} \frac{(\Delta x_{io} \Rightarrow \Delta y_{io} \Leftarrow \Delta z_{io})}{\sum \lambda \cdot K(d_i \Rightarrow q_i \Leftarrow b_i)} \quad (5)$$

Among them, $o, i \in [0, n]$, $\varphi_{ijz} \in (-2, 1)$.

The auxiliary scheme p_i is to adjust the physical education teaching design by probability method, and judge the neighborhood of the better physical education teaching design to obtain the optimal design result, which is calculated as shown in formula:

$$p_i = \frac{K(b_i)}{\sum_{i,j,k}^n [K(\Delta d_{io} \Rightarrow \Delta q_{io} \Leftarrow \Delta b_i)]} \quad (6)$$

Among them, $F(\cdot)$ is a moderate function with different complexity.

If the physical education teaching design has not got the optimal solution after circular adjustment, the complexity will be reduced, and then the physical education teaching design will be judged.

2.2.2. Dynamic Optimization of Physical Education Teaching Design.

In the preliminary analysis, physical education teaching design can not guarantee the whole design, which may increase the subjectivity of the design and reduce the overall effect of the design. Therefore, in the process of physical education teaching design, we should try our best to expand the use of teaching resources and constantly adjust teaching resources. Some scholars adjust teaching resources ρ linearly to reduce the randomness in the selection of teaching resources, but there is still “partial subjectivity” in the selection of teaching resources. In order to make up for the above shortcomings, the adjustment factor ν is introduced in this paper, and the calculation is as shown in formula:

$$\rho = \min \sum \Delta \nu_i \Rightarrow \log e^{-F(x_i, y_i, z_i) / \sum F(x_i, y_i, z_i)}. \quad (7)$$

Among them, $\Delta \nu_i$ is i times dynamic adjustment and $F(x_i \Rightarrow y_i \Leftarrow z_i)$ is i times update function Gayef [15]. The matching function between teaching resources and teaching design can be obtained from formulas (6) and (7), and the calculation is shown in formula

$$\Delta L(x_i, y_i, z_i) = w \cdot K(d_i, q_i, b_i) + \nu_{ijz} K(\Delta d_{ik}, \Delta q_{ik}, \Delta b_{ik}). \quad (8)$$

It can be seen from formula (8) that the complexity of $(F(x_i, y_i, z_i) / \sum F(x_i, y_i, z_i)) = 1$ and $\nu = 1$ is the smallest and the complexity of time and time is the largest in preliminary analysis. In order to reduce the “subjectivity” in instructional design, we should keep the diversity of teaching resources. In the final judgment of instructional design $(F(x_i, y_i, z_i) / \sum F(x_i, y_i, z_i)) = 1$, ν harmony plays an important role, which can not only reduce the complexity of design but also improve the processing ability of design resources and play the role of deep learning method. The result is shown in Figure 2.

As can be seen from Figure 2, the dynamic adjustment of physical education teaching design can accurately carry out the overall design, and the teaching design and teaching resources can be matched. This shows that the dynamic adjustment of physical education teaching design can meet different complexities and improve the effect of teaching design Fang and Jiang [16]. At the same time, the number of physical education teaching designs is relatively uniform, and the adjustment degree is relatively average, which shows that deep learning can achieve the balance of physical education teaching design. Under the condition of ensuring the requirements of physical education teaching design, the analysis of physical education teaching should be carried out to the greatest extent, and the adjustment level of teaching design should be ensured.

2.2.3. Introduction of Flip Classroom Horizon Factor.

When a certain physical education teaching design has been adjusted many times and meets the best standard, leading to flip the classroom horizon factor can make the teaching design more in line with “asking-thinking-answering” and get a new solution. Because of the randomness of deep learning method, “subjectivity” has great influence, which will reduce the objectivity of design and do not meet the relevant requirements. In order to reduce the probability of “subjectivity” in physical education teaching design and meet the requirements of different complexities. The “flip class horizon factor” can be introduced by probability density calculation, which is shown in formula:

$$L(x_i) = \frac{\lim_{\delta x \rightarrow 0} (F(x_i, y_i, z_i) / \sum F(x_i \Rightarrow y_i \Leftarrow z_i))}{\pi \sum_{i,k=1}^{+\infty} |K(\Delta x_{ik} \Rightarrow \Delta y_{ik} \Leftarrow \Delta z_{ik})|^2}. \quad (9)$$

If the educational design meets the sum of $\lim_{x \rightarrow 0} (F(x_i, y_i, z_i) / \sum F(x_i, y_i, z_i)) \approx 1$ and $F(x_i \Rightarrow y_i \Leftarrow z_i) = 1$ it shows that the physical education teaching design is the best, otherwise the design does not meet the requirements Fan, and Meng [17].

2.3. Analysis of Physical Education Teaching Design from the Perspective of Flipping Classroom

2.3.1. Optimization Model of Physical Education Teaching Design from the Perspective of Flipping Classroom.

Rationality judgment of physical education teaching design from the perspective of flipping classroom Collins [18], it is the main index to measure the deep learning method. From formula (8), it can be seen that in the early stage of physical education teaching design, great attention is paid to the overall utilization of teaching resources, and in the later stage of design, attention is paid to the utilization of local teaching resources, so different design strategies should be adopted in different stages of physical education teaching design. At present, besides the improved deep learning method proposed in this paper, there are other dynamic optimization models.

- (1) The adjustment strategy of specific instructional design is calculated as shown in formula:

$$\Delta L_i(x_i) = \sum_t \Delta L_{i-1}(x_i \Rightarrow y_i \Leftarrow z_{i-1}) \forall [p \cdot K(\Delta d_{ik}, \Delta q_{ik}, \Delta b_{i-1k})]. \quad (10)$$

- (2) The adjustment strategy of the whole instructional design is calculated as shown in formula:

$$\Delta L_i(x_i) = \sum_t \Delta L_{i-1}(x_{i-1} \longrightarrow y_{i-1} \Leftarrow z_{i-1}) \forall [g \cdot \max K(\Delta d_{i-1k}, \Delta q_{i-1k}, \Delta b_{i-1k})]. \quad (11)$$

- (3) The adjustment strategy of teaching resources is calculated as shown in formula:

FIGURE 2: Dynamic adjustment results of physical education teaching resources.

$$\Delta L_i(x_i) = \sum_{i=1, t}^{n/2} \Delta L_{i-1}(x_i \Rightarrow y_i \Leftarrow z_{i-1}) \forall [\max K(g) \quad \forall \max K(p)]. \quad (12)$$

- (4) The adjustment strategy of multiview instructional design is calculated as shown in formula:

$$\Delta L_i(x_i) = \sum_t \Delta L_{i-1}(x_{i-1} \longrightarrow y_{i-1} \Leftarrow z_{i-1}) \cdot F(x_{i-1}, y_{i-1}, z_{i-1}) \forall K(\Delta d_{i-1k} \longrightarrow \Delta q_{i-1k} \Leftarrow \Delta b_{i-1k}). \quad (13)$$

Among them, T is the time designed for physical education.

In this paper, the deep learning method is improved in two aspects: on the one hand, the physical education teaching design is constantly adjusted. Under the constraint of weight and threshold, we choose randomly from five strategies and complete many adjustments of physical education teaching design. In the later period of physical education teaching design, the use of physical education teaching resources is gradually reduced, and small-scale design adjustment is carried out to keep the diversity of design and improve the overall design ability. On the other hand, we should balance the relationship between physical education teaching design and resources, and integrate renewal coefficient, Δv_i moderate function $F(x_i, y_i, z_i)$ and Lagrangian multiplier function to carry out physical education teaching design more quickly.

2.3.2. Complexity Adjustment of Physical Education Teaching Design from the Perspective of Flipping Classroom. The complexity of physical education teaching design is the key to realize dynamic optimization. This paper based on the complexity optimization of physical education teaching design from the perspective of flipped classroom can further improve the design effect. Different physical education teaching design complexities adopt different optimization strategies. The physical education teaching design is randomly divided into five subclasses, each subclass represents the scope of physical education teaching design in No. 1 Middle School. In each iteration process, different schemes will be randomly selected from subclasses. After each subclass is adjusted, the fitness and resource utilization of physical education teaching design in different sub-classes is compared, and the overall optimal matching design is recorded; other subclasses gather to the optimal matching design to improve the level of the optimal physical education teaching design.

2.4. Flip the Steps of Physical Education Teaching Design from the Perspective of Classroom. The basic idea of deep learning method from the perspective of flipping classroom is to use various strategies to optimize physical education teaching design, improve the utilization rate of teaching resources, obtain the overall optimal design scheme, and meet the requirements of design complexity. The implementation steps of physical education teaching design from the perspective of flipping classroom in this paper are shown in the Figure 3:

FIGURE 3: Implementation flow of improved deep learning method.

Step 1: Determine the structure and complexity of physical education teaching design. According to the actual design requirements, determine the steps of physical education teaching design, generally speaking, the complexity of physical education teaching design.

Step 2: Initialize the physical education teaching design. According to the relevant instructional design

parameters, the physical education instructional design is initialized. The number of physical education teaching designs $n = 120$, and the number of iterations $m = 100$.

Step 3: Determine the fitness function. Using the theory of flipping classroom horizon, the physical education teaching design scheme is randomly produced, and

TABLE 2: Results of different test functions.

Function	Method	Minimum value	Maximum value	SD	Global optimal design	Local optimal design
Utilization rate of teaching resources	Deep learning method	38.14	48.45	3.72E-05	97.94	1
	Improve deep learning methods	35.05	46.39	5.18E-05	96.91	3
Student satisfaction rate	Deep learning method	47.42	45.36	4.73E-05	96.91	2
	Improve deep learning methods	40.21	55.67	5.07E-05	97.94	1
Feedback rate of teaching	Deep learning method	47.42	51.55	4.17E-05	97.94	2
	Improve deep learning methods	31.96	50.52	3.94E-05	98.97	3
Students' thinking situation	Deep learning method	40.21	50.52	4.39E-05	97.94	1
	Improve deep learning methods	45.36	56.70	4.28E-05	98.97	2

combined with teaching materials, the initial weight w and complexity λ are obtained, that is $w = 0.32$, $\lambda = 0.62$. Through formulas (3)–(7), the physical education teaching design is improved, and the fitness scheme of each physical education teaching design is obtained.

Step 4: The whole and local optimal matching of instructional design. The initial physical education teaching design is divided into five subclasses, and the fitness degree is obtained, and the corresponding local matching and overall optimal matching are calculated.

Step 5: Update iteration of physical education teaching design. According to the requirements of physical education teaching design, the five subclasses dynamically adjust the flipping classroom horizon factor, randomly select strategies from the five subclasses, and integrate the flipping classroom horizon factor C according to formulas (2) and (7).

Step 6: Dynamic optimization of each subclass. After optimizing the local physical education instructional design, the overall optimal design is selected, and the instructional design is shared with other subclasses, and the neighborhood optimal instructional design scheme is adjusted.

Step 7: Judge whether the physical education teaching design reaches the maximum iteration value M . If it is not reached, repeat steps 1–5, otherwise stop iterative calculation and return to the best physical education teaching design and complexity.

3. Empirical Case Analysis

3.1. Model Performance Analysis. In order to further judge and improve the deep learning method, four tests were conducted, namely, the utilization rate of teaching resources, the satisfaction rate of students, the feedback rate of teaching, and the thinking situation of students. The test process is as follows.

- (a) The utilization function of teaching resources is calculated as shown in formula:

$$f(x) = \sum_{i=1}^n \frac{x_i^2}{10} \cdot \cos(2\pi x_i) + \xi' \quad (14)$$

- (b) The student satisfaction rate function is calculated as shown in formula:

$$f(x) = \left| \sum_{i=1}^n x_i^2 \right| \quad (15)$$

- (c) The feedback rate function of teaching is calculated as shown in formula:

$$f(x) = \left\{ e^{(1/n) \sum_{i=1}^n \cos(2\pi x_i)}, 1 - \lim_{x \rightarrow 0} e^{(x_i/5)\sqrt{1/n}} \right\} \quad (16)$$

- (d) The student's thinking function is calculated as shown in formula:

$$f(x) = \sum_{i=1}^n \frac{x_i^2}{100} \pm \prod_{i=1}^n \left| \cos\left(\frac{x_i}{\sqrt{i}}\right) \right| \quad (17)$$

In this paper, the parameters of physical education teaching design are set: the total number of physical education teaching resources is 50, the iteration times are 120, and each teaching design is analyzed independently. The results of the four test functions are shown in Table 2.

It can be seen from Table 2 that the improved deep learning method is superior to the deep learning method, and its overall optimal design and theoretical optimal design Chew et al. [19]. The maximum value of improved deep learning is less than deep learning, while the minimum value is greater than deep learning, and the global design value of improved deep learning is greater than deep learning, so the improved deep learning method is better, the overall result is more reasonable, and it can promote the development of physical education teaching design. Moreover, the analysis scope, resource matching rate and analysis error of the improved deep learning method are smaller than those of the deep learning method. In order to reflect the test results of the test function in 4 more intuitively, the following convergence curves are given, as shown in Figure 4.

FIGURE 4: Convergence curve of the best scheme for selecting the test function of teaching resource utilization rate.

FIGURE 5: Satisfaction rate test of improved deep learning methods.

It can be seen from Figure 4 that the resource utilization rate of the improved deep learning method is higher than that of the deep learning method, and the change range is relatively large, which makes the processing more difficult. In Figure 4, the number of inflection points of improving deep learning is less than that of deep learning, and the method of improving deep learning is more stable, which makes the college physical education teaching design more scientific and can comprehensively improve the level of physical education teaching design. The result is shown in Figure 5.

It can be seen from Figure 5 that the design satisfaction rate of the improved deep learning method is concentrated

between 40% and 90%, which shows that the overall effect of the satisfaction rate is high and meets the requirements of physical education teaching design.

The data in Figure 5 are scattered, but the overall distribution is relatively concentrated. Therefore, improving deep learning can optimize the physical education teaching design, and the optimization effect is relatively stable. In the optimization process, the results show scattered distribution, which meets the requirements of objective normal distribution. The result is shown in Figure 6.

It can be seen from Figure 6 that the feedback rate of the improved deep learning method is significantly higher than that of the deep learning method, which shows that flipping the classroom horizon can improve the feedback rate of students and the level of physical education teaching design. The result is shown in Figure 7.

It can be seen from Figures 4–7 that the improved deep learning method has faster calculation speed and better stability, which is superior to the deep learning method. Therefore, the improved deep learning method is suitable for the analysis of college physical education teaching design, and the design process is more stable.

3.2. Design and Treatment of Actual Cases. In this paper, football, tennis, swimming, high jump, and other types are selected as research objects, and the collection time was from January 2021 to January 2022. A total of 402 lesson plans were collected, and the class hours were 1023 hours. According to the requirements of the Ministry of Education for physical education, the above-mentioned physical

FIGURE 6: feedback rate test of teaching with different functions.

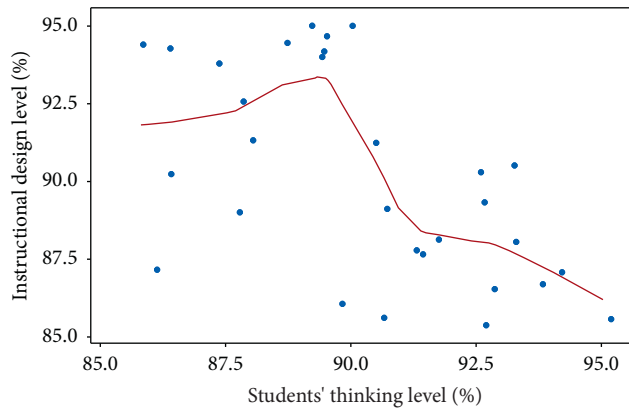

FIGURE 7: Students' thinking levels of different functions.

TABLE 3: Types and proportion of physical education teaching design.

Design type	Quantity of physical education teaching design (pieces)	Proportion (%)
Ask questions-think	99	24.63
Ask-think-answer	110	27.36
Ask-think-answer	91	22.64
Ask-think-answer-feedback	102	25.37

education design is divided into four categories: question-thinking, thinking-answering, question-thinking-answering, question-thinking-answering-feedback. The results are shown in Table 3. This paper verifies the accuracy of the analysis results according to theoretical judgment and actual detection methods. In order to avoid too many subjective factors in physical education teaching design, DETEL function is called to eliminate the design, which makes the physical education teaching design meet the relevant conditions. The results are shown in Table 3.

The physical education teaching design is trained by dichotomy, the first half is the research object, the second half is the analysis object, and the overall results are compared.

3.3. *Final Research Results.* According to the research conditions of physical education teaching design, the structure of physical education teaching design collection is determined as: structural design-semi-structural design-non-structural design, which meets the analysis

FIGURE 8: Classification results of complex physical education teaching design.

Different algorithms

- ◆ Flip classroom method
- ◆ Deep learning method
- ◆ General instructional design method
- ◆ Improve deep learning methods

FIGURE 9: Comparison of overall accuracy of different methods.

TABLE 4: Overall accuracy of different design types.

Design type	Improve deep learning methods	Deep learning method	Flip classroom method	General instructional design method
Ask questions-think	93.94	91.97	91.97	91.90
Ask-think-answer	97.91	96.90	92.91	91.91
Ask-think-answer	98.92	98.92	92.97	91.92
Ask-think-answer-feedback	98.93	97.93	97.92	92.91

requirements of improving deep learning methods. In this paper, the classification results of physical education teaching design by improving deep learning method are proposed, as shown in Figure 8.

Through comparative analysis, we can see that the classification of the improved deep learning method is discrete, which is closer to the actual situation, while the classification of the deep learning method is concentrated and cannot meet the needs of actual classification. In addition, the classification of improved deep learning method is not affected by complexity, while the classification of deep learning method is obviously affected by complexity, and becomes more concentrated with the increase in complexity.

The reason is that the improvement of deep learning method adds the theory of changing classroom horizon, and establishes a mapping among questioning, thinking, answering, and feedback, which makes the physical education teaching design more in line with the requirements. At the same time, fitness function is used to adjust physical education teaching design. In order to further prove the effectiveness of the model proposed in this paper, other comparative models are introduced for comparative analysis, and the results are shown in Figure 9.

It can be seen from the above figure that the fitness value of the improved deep learning method is the highest and reaches the limit at the earliest. Under the same complexity, the improved deep learning method has higher stability; The second is the deep learning method. The reason is that the theory of flipping classroom horizon reduces the influence of complexity on physical education teaching design; Different optimization strategies improve the accuracy of design, which is consistent with related research [19]. From the aspect of physical education teaching design types, this paper analyzes the accuracy of different deep learning methods, and the results are shown in Table 4.

It can be seen from the above table that improving the deep learning method can not only improve the efficiency of physical education teaching design but also keep the accuracy unchanged with the change of design type. The main reason is that the dynamic analysis of physical education teaching design from the perspective of classroom makes the time of physical education teaching design shorter and more flexible. Therefore, flipping the classroom horizon theory can not only reduce the impact of complexity on the results but also meet the requirements of different design types.

4. Conclusion

This paper puts forward an improved deep learning method based on the theory of flipping classroom horizon, which optimizes the physical education teaching design by setting teaching resources, weights, and designing strategies. The improved deep learning method constructed in this paper can classify the physical education teaching design discretely which makes the physical education teaching design more in line with the actual requirements. MATLAB simulation

results show that the deep learning method constructed in this paper has high design accuracy, the accuracy is concentrated in 90~98%, the single design quantity is relatively stable, accounting for about 3~4% of the total, the overall convergence is relatively short, and the convergence is carried out between 10 and 20 iterations, which can deal with physical education teaching design with complexity less than 45%, and the global optimal value is 2~3, the results are consistent with related studies. However, in the analysis of complexity, there are still deficiencies, future research in-depth analysis, to further improve the requirements of college physical education teaching design.

Sports dance is a competition project and a kind of sports, with the characteristics of being smooth, generous, leisurely, and comfortable, dance steps, smooth movements, and flowing clouds, and it can give full play to the indoor space. In the light of the new era, sports dance is also playing an increasingly important role. Through the time series data and feature analysis of dance sports movements through machine learning, the internal information is mined to find the trends and laws. Machine learning in the era of big data is widely used in research as the main tool for data analysis and mining. The key difficulty of data mining has always been time series data. Machine learning refers to a method of using the resulting data in a computer to derive a certain model and then using this model to make predictions. The core is “using algorithms to parse data, learn from it, and then make decisions or predictions about new data.”

1. Introduction

This paper is based on how machine learning analyzes the time series data prediction and characteristics of dance sport movements. The process of machine learning is similar to the learning process of human beings, such as people learning mathematical theoretical models to establish logical thinking skills, analyzing and predicting things [1]. For example, chatbots—chatbots is one of the earliest forms of learning that allows humans and machines to communicate and dialogue, from which to fill the communication gap between humans and technology. For example, machines can act according to human demands or requirements [2]. The earliest is to write scripts, put the script in the machine to compile and run so that these machines have a chat function, and the script code run by the machine will make the machine recognize and let the machine according to what keywords to take what action. But there is another member of the AI family, the acceptance of machines and the use of language recognition (NLP) [3]. Let us take the interactivity and productivity generated by chatting with machines to the next level [4]. The new generation of

chatbots can more effectively handle the needs of users and move forward like human-to-human communication [5]. Machine learning’s algorithms are used in a wide variety of digital assistants, and this technology can be applied to the new B2C and C2C to find ways to update the traditional way of chatting with robots [6]. Communicating with robots is one of the most widely used machine learning applications in the commercial world [7]. Some AI assistant scripting languages can analyze when relevant questions need to be asked and when to ask questions and demands from humans identification classification [8]; multimedia live platform chatbots can satisfy users’ use, search, and pass good music to friends and family, and at the same time, they can also enjoy the relevant music recommended by AI robots according to their personal preferences for us to enjoy [9]; during the rush hour of traffic jam, we need to take a taxi. Then you can take a taxi online through the relevant software, use the relevant software or other platforms or related request services, and receive the basic information of the driver and related vehicles that come to pick us up, such as the license plate number, color, and model of the vehicle [10]. Machine learning is also used in organizational

structures, and sophisticated learning and neural networks help them analyze images [11]. Machine learning-related technologies like this which have a high breadth of applications in social media sites want to put signs on photos of other media sites, as well as road cameras and store monitoring [12]. Groups that maintain safety such as Sky Eye conduct real-time monitoring, detection, and identification of criminal behavior; later, driverless cars are driven on smooth and wide roads. Retail investors also have many applications in various aspects such as the classification of images and the recognition and analysis of images. For example, install cameras in warehouses, connect the cameras to the computer, use the computer's visual system and the self-learning system to scan the relevant items on the current shelves, and identify and determine whether there are items that are misplaced, random, or out of stock; you can also use the scanner to scan the goods taken out of the shopping cart using image recognition technology to make the goods be identified one by one. This reduces the loss of sales formed in an unintentional state; it can also be used to use image recognition in the computer through cameras, surveillance, sky eyes, and other devices to analyze whether there is suspicious activity or illegal and criminal behavior (such as smoking on high-speed rail or carrying unauthorized dangerous goods or equipment) [13]. Although most of the machine learning is highly specialized for a certain need, most merchants still try the highly specialized technology of machine learning to shorten the business process, making it easy and fast to optimize the process of collaborative processing of daily business, especially financial transactions and software development such as banks, securities companies, and other related financial transactions [14]. From the early days to the present, the most widely used applications are in the financial organization, IM, and companies' business processes, as well as software development and testing. Most departments, such as VCs and operations, are using machine learning techniques to improve the efficiency of their own departments, thereby creating more value for the company [15]. Because human energy is always limited, machine learning techniques can be used to reduce work cycles, reduce errors, and speed up work efficiency. In machine learning, we can give it a time to form a cycle according to the time we set, automatically troubleshoot errors, detect problems, and give problems to the relevant technicians in a cycle, so that we can reduce the effort on it, thereby reducing unexpected problems and interference caused by unplanned work [16]. In addition, in software testing, machine learning techniques can be added to black and white box testing and automated testing, which greatly improves the speed of software testing so that software development is faster and cheaper. Sometimes we need to extract structured critical data in documents that cannot be extracted directly, because not all data is structured and stored in unstructured and semistructured formats; that is, we need to apply NLP's machine learning technology to help us extract key structured data in related documents [17]. Experts say applying machine learning-related techniques to understand documents is a great opportunity for all aspects of life. Companies can do this, from tax returns to invoices to

statutory contracts, all of which can improve efficiency and accuracy and free the work force [18] from positions that are seen as day-to-day work. Most of the smartphone's capabilities also come from machine learning. For example, voice assistants, from setting alarm clocks to finding language assistants in restaurants to decoding facial recognition phones, Apple's Siri, Xiaomi's Little Love, and Google Assistant, establish a dance sport movement time series data prediction and feature analysis based on machine learning to explore the characteristics of them for overall development.

2. Machine Learning for Sports Dance Movement Cognition

2.1. Obtain Sports Dance Movement Data. From the appearance of people, it is composed of several parts: head, neck, body, limbs, and so forth, of which the skin is on the surface of the body, and the subcutaneous tissue, muscles, and bones are below the skin. Composed of 206 bones, it can complete a variety of types, as well as uses of complex shapes; based on this physical test structure, people can complete a variety of actions; through the brain's thinking coordination, the human body in the completion of different movements reflects a strong coordination, so the study of sports dance is to make the AI system like a person have the abilities of learning, reasoning, and thinking; according to the content learned, knowledge judges what is actually going on online and predicts what will happen, hence the research on sports dance movements and intelligent control, human-computer interaction, AI, and other fields of research hotspots [19]. The capture of dances in sport includes contact and no contact in equipment, electromagnetic, inertial, machine, and optical terms, which record the movements through specific man-machine instruments, and the noncontact type includes a monocular RGB-D camera or a monocular RGB camera and a depth camera.

2.2. Dance Sport Movement Data Files. The dance sport movement acquisition system stores the acquired data to capture the movements in a file as BVH, which is parsed out after the action capture, which is the general format of the animation characteristic file through the human body function. It is well supported on many well-known animation software programs (flash, TV Painter, Blender3D) [20]. The representation of the human body therein is the skeleton model in the picture above, which is then expressed through the structure of the tree. BVH contains data on the movement of limb joints of characters performing dance sport movements.

3. Machine Learning Time Series Data Prediction Algorithm Implementation

3.1. Wavelet Transform. The basic solution of the wavelet transform (WT) is to represent the action signal as a set of wavelets, which can obtain information about the time and frequency domain of the action signal. The two most commonly used types of wavelet transform in WT include

FIGURE 1: Disassembly and reconstruction of discrete wavelet transforms.

the continuous wavelet transform (CWT) and the discrete wavelet transform (DWT) [21].

Continuous wavelet transforms are expressed as follows:

$$W_{s,\tau}(t) = \int_{-\infty}^{\infty} f(t) \psi_{s,\tau}^*(t) dt, \quad (1)$$

$$\psi_{s,\tau}(t) = \frac{1}{\sqrt{|s|}} \psi\left(\frac{t-\tau}{s}\right). \quad (2)$$

$\psi_{s,\tau}^*(t)$ is called a base wavelet or a mother wavelet; it is called a scaling factor (or scale); τ is the $\psi_{s,\tau}^*(t)$ conjugate of the translation factor. When the harmony can be continuously changed, the wavelet change at this time is called the continuous wavelet transform $\psi_{s,\tau}(t)st$ CWT. Due to the complexity of the calculation of the continuous wavelet transform and the high degree of redundancy, it is not suitable for practical applications. Therefore [22], the DWT is obtained by discretizing the scaling factor in the CWT. Bring it in (2) ($s = s_0^m \tau = n^{\tau_0 s_0^m} m, n \in \mathbb{Z}$) to get discrete wavelets:

$$\psi_{m,n}(t) = \frac{1}{\sqrt{|s_0^m|}} \psi(s_0^m t - nb_0), \quad m, n \in \mathbb{Z}. \quad (3)$$

The discrete wavelet transform is

$$W_{s,\tau}(t) = \int_{-\infty}^{\infty} f(t) \psi_{s,\tau}^*(t) dt = \frac{1}{\sqrt{|s_0^{-m}|}} \int_{-\infty}^{\infty} f(t) \psi^*(s_0^{-m} t - nb_0) dt. \quad (4)$$

The decomposition process of DWT is equivalent to going through a high-pass filter and a low-pass filter, followed by using a binary decimation algorithm for downsampling. The DWT decomposition and reconstruction process is shown in Figure 1. H and L are decomposition filters, where H is a high-pass filter and L is a low-pass filter; after decomposition, a downsampling operation is required. H' , L' is a reconstruction filter; likewise, H' is a high-pass filter and L' is a low-pass filter.

3.2. Static Wavelet Transform. Since the discrete wavelet decomposition uses a binary decimation algorithm to downsample the action, the wavelet coefficient will be reduced by one-half after each decomposition, so the details of the original action will be lost in each decomposition. The stationary wavelet transform (SWT) that removes the

downsampling and upsamples the filter solves this problem. The SWT decomposition reconstruction process is shown in Figure 2, in which the output components of the high-pass filter and the low-pass filter are no longer downsampled, but the upper filter is upsampled to obtain a decomposition of the high-pass filter and low-pass filter in each step [23]. The detail and approximate components after each decomposition of the static wavelet are the same as the length of the original action signal, which ensures that the characteristics of the movement are preserved to the greatest extent possible and are also conducive to the analysis and study of sports dance movements.

The single-step multiscale static wavelet decomposition process of the action signal is similar to the single-step multiscale discrete wavelet decomposition process, as shown in Figure 3.

3.3. ERD Models. The ERD model was proposed by Frigidaria [24]. It is an encoder-loop unit-decoder (ERD) model used to identify and predict human posture in video and motion capture [25]. The main way it runs is to obtain a new prediction frame by continuously putting the prediction frame of the previous step into the model, so as to achieve the effect of multiframe prediction; the specific method he achieves is to encode the human action data through the fully connected network and put it into the recurrent neural network to predict the next action state according to the memory information of the previous time, and then the obtained data vector is decoded through the corresponding full connection layer, obtain the action data, and reconstruct the action through a certain reconstruction method to obtain the prediction result. Its main structure is shown in Figure 4.

3.4. Conversion between Dance Sport Movement Data and Trainable Data. Since the sports dance action data recorded in the dataset is in the form of quaternions, the rotation amplitude of one of the movements consists of four numbers between -1 and 1 , and the continuity in the number value is not strong, so the original movement data needs to be processed to a certain extent.

That is, it proposes exponential mapping of raw data, which can effectively avoid data discontinuities and Vientiane knot locks [26]. The process is as follows:

$$\theta = r_2,$$

$$r'x = \begin{bmatrix} 0 & -r'[2] & r'[1] \\ 0 & 0 & -r'[0] \\ 0 & 0 & 0 \end{bmatrix},$$

$$r'x = r'x - r'X^T, \quad (5)$$

$$\text{rotationmat} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} + \sin \theta * r'x$$

$$+ (1 - \cos(\theta)) * r'x \cdot (r'x).$$

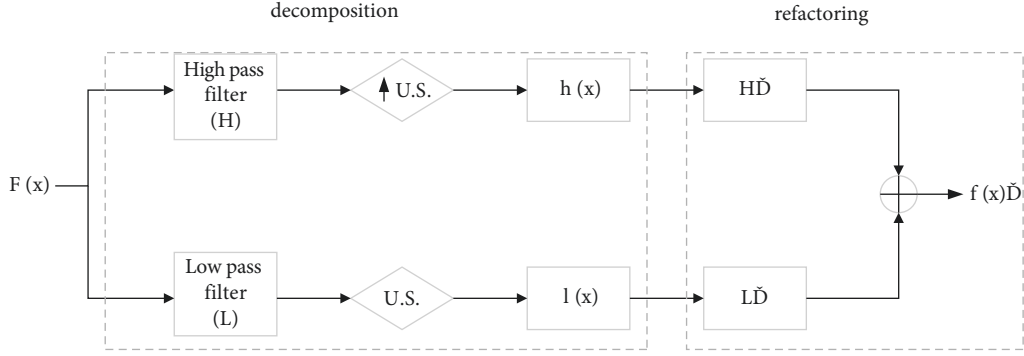

FIGURE 2: Static wavelet decomposition reconstruction.

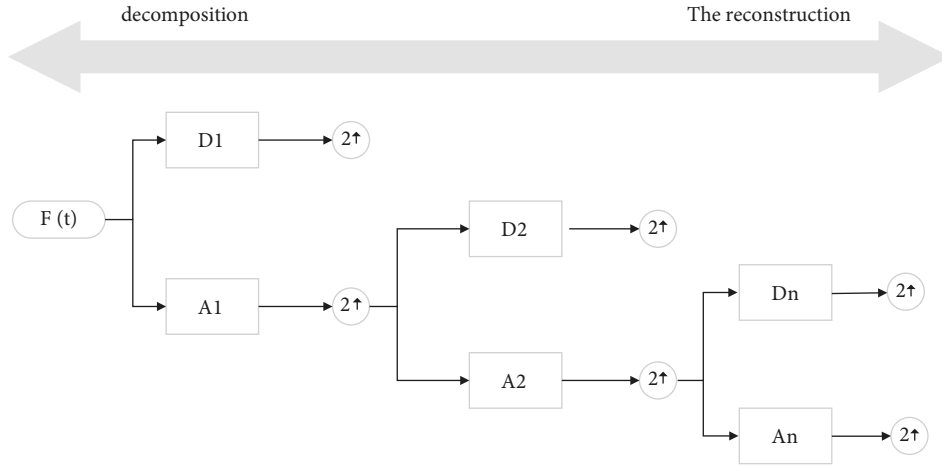

FIGURE 3: Single-step multiscale SWT decomposition process.

To find the rotation matrix rotationmat , where rotationmat is the original exponential mapping matrix, according to the rotation r matrix to find the rotation quaternion, the process is as follows:

$$\text{rotdiff} = R - R^T,$$

$$r0 = [-\text{rotdiff}[1, 2] \text{rotdiff}[0, 2] \text{rotdiff}[0, 1]],$$

$$\sin \theta = r_2,$$

$$r0 = \frac{r}{r_2},$$

$$\cos \theta = \frac{\text{trace}(R) - 1}{2}, \quad (6)$$

$$\theta = \arctan\left(\frac{\sin \theta}{\cos \theta}\right),$$

$$\begin{aligned} \text{quaternion} = & \left[\cos\left(\frac{\theta}{2}\right) r0[0] * \sin\left(\frac{\theta}{2}\right) r0[1] \right. \\ & \left. * \sin\left(\frac{\theta}{2}\right) r0[2] * \sin\left(\frac{\theta}{2}\right) \right] \end{aligned}$$

In the above equation, R is the rotation matrix, which eventually yields quaternion.

Due to the particularity of the heel node, if it controls the rotation mode and angle of the entire human body, we hope that the human body can have a certain stability, so the human root node is unchanged for the translation of the ground plane and for the rotation of gravity perpendicular to the ground (assuming that the ground surface is horizontal).

4. Case Studies

4.1. Comparative Experiments. The experiment selected 30 personnel for dance steps, outer dance steps, preparatory outside dance steps, reflexive movements, reflexive action positions, lifting, swinging, and other 7 kinds of sports dance movements in the same time and place to complete the experiment; the experiment does not constrain the behavior habits of the testers; participating students who take the test only need to complete the experiment in their own way. In this comparative experiment, the first adopts the traditional human movement pattern information collection method, and the second adopts the motion pattern recognition method of the accelerator and the sensor. There is a sports dance movement A, a dance step T, an outer dance step N, a preparatory outer dance step W, and a reflexive movement A. The experimental results of the reflexive action position of F lifting and descending to H and swinging to M are shown in Tables 1 and 2.

According to Tables 1 and 2, we can conclude that the difference between the dance steps and several other

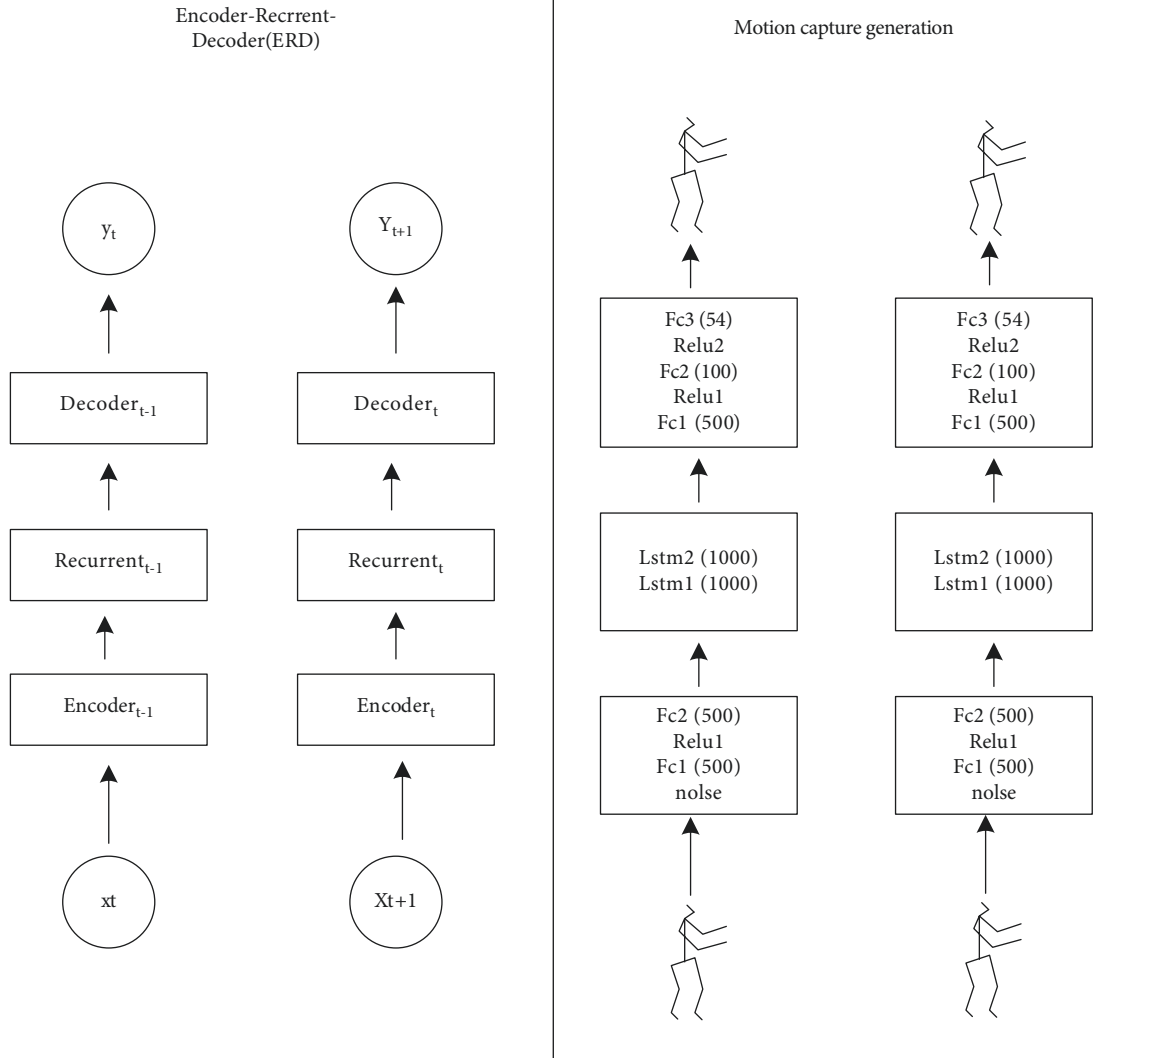

FIGURE 4: ERD model.

TABLE 1: Confusion matrix of the first set of dance sport movements.

A	T	N	W	U	F	H	M
T	190	4	2	1	2	1	0
N	1	180	7	5	7	0	0
W	0	7	81	5	6	0	1

F	2	6	3	2	87	0	0
H	5	0	0	0	3	92	0
M	5	1	0	1	0	0	93

movements is very high, so the recognition is 100%; the difference between the reflex and reflexive action positions is very small, so its recognition is very low. Specific parameters are identified as shown in Table 3.

As can be seen from Figure 5, traditional recognition technology can identify a variety of action patterns, and its recognition accuracy is balanced at 90.1%. The recognition of reflexive action and reflexive action position is low. When integrated with the accelerometer, its recognition accuracy can be balanced to 94.3%. Compared with the

previous recognition accuracy, its recognition accuracy is balanced upward by 4.2 percentage points, and the result is better.

FIGURE 5: Statistical chart of recognition results.

TABLE 4: Student physical condition statistics.

	General groups	Training group	<i>P</i> value	<i>T</i> value
Height (cm)	175 2.00 ±	175 1.41 ±	1.100	-0.150
Weight (kg)	70.10 2.61 ±	70.10 2.17 ±	0.978	-0.087
Age	16.6 0.51 ±	17 0.00 ±	0.701	-2.049

40 students were selected to test the standard degree of sports dance movements, and they were divided into two groups; that is, the regular group completed the experiment according to their own behavior, and the training group conducted sports dance movement analysis and teaching. The two sets of results are then compared and analyzed. Because the height, weight, and age of the students participating in the test are basically the same, the *P* value is greater than 0.06, so the elements related to the body will not affect the experimental results. Their situation is shown in Table 4.

From Table 5 and Figure 6, it can be seen that the indicators of the conventional group and the training group are basically the same, and after the *t*-test is carried out on both groups, *P* is above 0.05, which depends on the initial situation of the two groups.

From Table 6 and Figure 7, it can be seen that, under the same initial conditions, the sports dance indicators of the trained students can be improved.

Throughout the dance movements, the angle and speed of each movement change periodically. After making appropriate modifications to the movement predictions of the time series data, the comparison curve of the angle and speed of the movements during the process of performing the dance sport movements is shown in Figure 8.

4.2. Data Processing. The experiments set the mean and variance of the prediction accuracy as *p* and $p(1-p)$, respectively. Due to different experiments, the prediction reversibility of the algorithm is now statistically zero, so the correct random variable with a mean of *p* is *f*, and its variance decreases as $p(1-p)/N$ with the increase of the repeated simulation experiment coefficient *N*, and when $N > 100$, it is close to the normal distribution. This makes it possible to construct a positive-tyrannous random variable:

$$\frac{f - p}{\sqrt{p(1-p)/N}} \quad (7)$$

The following equation is then passed with the confidence level *c* determined:

$$P \left[-z < \frac{f - p}{\sqrt{p(1-p)/N}} < z \right] = 2 * (1 - c). \quad (8)$$

z values can be extrapolated from a probability table. The true value *p* can be obtained using the calculation method of probability theory, with the interval boundary value *c* of the probability approaching *f*.

$$p = \frac{\left(f + z^2/2N \pm \sqrt{f/N - f^2/N + z^2/4N^2} \right)}{(1 + z^2/N)}. \quad (9)$$

± gives two values, the upper and lower bounds of the confidence.

When collecting data, the duration of each action is relatively short, and it cannot correspond well to the data

obtained individually, so, by obtaining several pieces of action cycle data, clustering is divided, and the results and data are analyzed by curve comparison to determine the

action period to which the data belongs. As shown in Figures 9 and 10, the clustering results correspond to the two-dimensional three-point plot of the action.

Real class	Action (T)	Right (affirmatively)	Error (negation)
	Stationary (F)	Error (affirmation)	Right (negative)

TABLE 8: Three types of projected cost matrices.

		Prediction class		
		a	b	c
Real class	a	0	1	1
	b	1	0	1
	c	1	1	0

Table 1 shows the type II prediction confusion matrix. For one class, for example, the “Dance Sport” class in Table7, set to T the correct class, and the other is the negative class F, so that the true positive (TP), true negative (TN), false positive (FP), and false negative (FN) are verified. So, the correct rate of classification of an action is

FIGURE 11: Assuming an ascending chart.

FIGURE 12: The effect of probability classification on sports movements of the sample class.

$$\text{Kappa} = \frac{TP + TN}{TP + TN + FP + FN} \tag{10}$$

The maximum value is 1, and the action is the best.

Table 8 shows the cost matrix of the three classification projections. The cost matrix represents the cost caused by prediction error and correctness, the correct cost is 0 and the cost of error is 1, so the cost of the resulting statistical error is the number of errors, as shown in Table 8.

The first thing we need to consider for different movement performances is the rising chart, which represents the total number of students testing SCORP movements and the proportion of students practicing SCORP, and the vertical axis represents the correct prediction rate, as shown in Figure 11.

The cost curve is an action corresponding to a straight line, the purpose of which is that the action changes with the distribution of the class, as shown in Figure 12; the horizontal axis represents the probability of a certain class of samples in the training sample, and the vertical axis represents the expected error. Predictions made for only one of these types are represented by two diagonal lines, decisions are always erroneously represented by horizontal dotted lines, and horizontal lines indicate that predictions are always correct.

TABLE 9: Numerical projection indicators.

Performance measurement	Formula
Mean square error	$(p_1 - a_1)^2 + \dots + (p_n - a_n)^2/n$
Root mean square error	$\sqrt{(p_1 - a_1)^2 + \dots + (p_n - a_n)^2/n}$
Average absolute error	$ p_1 - a_1 + \dots + p_n - a_n /n$
Relative square error	$(p_1 - a_1)^2 + \dots + (p_n - a_n)^2 / (a_1 - \sigma)^2 + \dots + (a_n - \sigma)^2$
Relative square root error	$\sqrt{(p_1 - a_1)^2 + \dots + (p_n - a_n)^2 / (a_1 - \sigma)^2 + \dots + (a_n - \sigma)^2}$
Relative absolute error	$ p_1 - a_1 + \dots + p_n - a_n / a_1 - \sigma + \dots + a_n - \sigma $

P is the predicted value and a is the true value: $\sigma + 1/n \sum_i a_i$

TABLE 10: Action comparison indicators.

Index	Definition	Significance
Kappa statistic	—	Close to 100% is best
TP rate	Correct proportions	Close to 1 is best
Accuracy rate precision	$TP/TP + FP * 100\%$	Close to 1 is best
Feedback rate recall	TP	Close to 1 is best
F-measure	$2 * TP/2 * TP + FP + FN$	Close to 1 is best
ROC area	—	Close to 1 is best

FIGURE 13: Dance sport movement model recognition accuracy.

Weka simulation analysis will also use the working metrics in numerical forecasting to identify and propose each indicator, as shown in Tables 9 and 10.

4.3. Data Results Analysis. According to the experiment, the model of the article is compared with the performance of the support vector machine and the decision tree motion analysis model, and the results of three different models are observed from different aspects of accuracy and page response, and the specific experimental data are shown in Table 11.

As shown in Table 11, 8 images were taken at different distances on the same circuit board; the closest one was set as the template, and the remaining 7 groups of different images were tested to calculate the matching accuracy of various models. The method of detecting the response time of different models is to increase the number of tests and observe the average response time of different models.

As can be seen from Figure 13, among the 8 image samples used in our experiment, the multisensor motion analysis model has the highest accuracy, followed by the vector machine motion analysis model and the decision tree motion analysis model.

5. Conclusion

This paper mainly studies the use of machine learning to predict the timing data of sports dance movements and applies wavelet deformation and static wavelet variation based on the characteristics of time series data in the implementation of the algorithm. Through the implementation of the algorithm of time series data prediction, and then through the acquisition of the action data analysis model, the acquired data is transformed, and then the characteristics of the action are learned, including the encoder-loop unit-decoder (ERD) model. Then, a comparative experiment was conducted to verify this method, and the data collected were analyzed and processed to obtain the advantages of time series data prediction and feature analysis of dances in sport based on machine learning. That is, the action time series data prediction of machine learning is suitable for sports dance moves. However, due to the fact that the structure used does not have a higher level of supervision, the effect is not ideal in some aspects, although some results have been achieved here, but further research can be carried out, for example,

- (1) studying using seq2seq structure;
- (2) a combination of time and space studied using structure-run, a corresponding spatial attention model;
- (3) deeper use of Python and Unity3D for research.

In logistics industry of 12 provinces along China's new western land-sea corridor from 2010 to 2019, this research employed three-stage SBM model that considers undesirable output to measure logistics industrial efficiency and the panel Tobit model to investigate variables impacting logistics efficiency. The study found that after controlling for environmental variables and statistical noise, the logistics industrial efficiency in China's new western land-sea corridor has improved, and the logistics sector efficiency of each province has spatial variability. Generally speaking, the south part goes up and the north part goes down; industrial structure, logistics transportation intensity, and economic development have a favorable influence on logistics sector efficiency. The urbanization rate, government support level, level of infrastructure, and degree of openness all have a negative influence on efficiency. Finally, relevant policy considerations such as logistics transport intensity, pure technical efficiency, scale efficiency, and external environment are proposed.

1. Introduction

From the mid-1990s to the present, as the economy develops, the logistics industry has developed rapidly. Logistics is an important strategic sector whose development is inseparable from the dynamics of other businesses. Despite China's logistics industry has developed rapidly, due to the continuous improvement of distribution capabilities, the proportion of total social logistics costs as a percentage of GDP has dropped from 18.0% in 1991 to 14.6% in 2017, the proportion remains significantly higher than in industrialized nations like Europe and the United States. The current situation is still a real problem for China's trade [1]. Most earlier studies on the relationship between logistics and economic returns produced biased results regardless of social and environmental concerns. However, the spatial temporal variations in China logistics efficiency are examined with undesired outcomes as well as the impact of other external factors, and the results show that the China's logistics is less efficient but will only improve over time [2].

The growth of the logistics industry of China's new western land-sea corridor will benefit the economy of western China and its surrounding countries, and the new western land-sea corridor may have fostered trade partnerships with other countries, boosting regional growth in western China and Southeast Asia [3]. Therefore, following a comprehensive assessment by a multisector computer model, this paper aims to evaluate system efficiency of the sustainable logistics industry based on combining inputs and desired and undesired outputs.

2. Literature Review

In regional logistics industry efficiency measurement methods, Data Envelope Analysis (DEA) has become the main method, which does not require to define certain production functions and process measurement data, nor specify the weights of the input-output indicators. Markovits-Somogyi and Bokor used the new DEA-PC method (pairwise comparison) to assess logistics efficiency in 29 European nations, and the results were analyzed by

using Logistics Performance Index (LPI) [4]. Zahran et al. evaluated the efficiency of port taxation by using DEA and assessed their income generation mechanisms in terms of efficiency [5]. Lei et al. used the DEA-Malmquist approach to conduct an empirical research of the technical growth of 49 Chinese listed logistics enterprises from 2008 to 2017 [6]. Fried et al. proposed a three-stage DEA to reduce the impact of environment and statistical noise on decision-making units, with the positive objective of reflecting efficiency measurement result [7]. Qin used a three-stage DEA to quantify logistics efficiency in the 9 + 2 urban agglomeration of Guangdong, Hong Kong, and Macao from 2012 to 2018 and concluded that the impact of logistics sector fixed asset investment and the transportation network density on efficiency is extremely important [8].

In order to overcome the bias caused by the radial DEA, slack based measure (SBM) is presented, which considers not only slack variables but also desirable and undesirable outputs to improve efficiency measurement accuracy [9]. Wang and Liu used panel data from the Yangtze River Economic Zone logistics industry between 2005 and 2014 to quantify logistics sector efficiency with the Super-SBM accounting for undesirable output, and the results indicate that measuring logistics efficiency with undesirable output is close to the real distribution process [10]. Feng et al. used panel data of 17 Chinese port listed companies between 2010 and 2015, an empirical analysis is conducted with the SBM model, and conclusions were drawn on their overall operational efficiency [11]. Liu and Sun used the panel data from China's logistics sector between 2004 and 2014 to calculate the Super-SBM and Malmquist models with undesired output and concluded that the total factor productivity with undesired output is more realistic [12]. Ma et al. utilized a three-stage SBM to examine the logistics sector efficiency in Northeast China and six provinces in the "Yangtze River Delta" area from 2011 to 2015, which revealed that the logistics industry's technological efficiency and scale efficiency are higher in the "Yangtze River Delta" area than in the Northeast, and the small size of the logistics industry in the Northeast causes poor efficiency [13].

Some researchers have conducted relevant studies on the elements impacting logistics sector efficiency, and the research methods are mainly divided into three categories: (1) combine DEA and Tobit models to examine specific aspects of logistics efficiency. Zhou et al. analyzed Chinese 3PL enterprises efficiency using DEA and used multiple regression analysis to investigate the factors influencing 3PL efficiency [14]. Wang et al. analyzed China's road logistics efficiency and the elements that influence it and found that the central region has the highest road logistics efficiency and the western region has the lowest, but some western provinces have higher road logistics efficiency, and the level of regional informatization and road logistics resource utilization have the greatest influence on China's road logistics efficiency [15]. Gong et al. examined the effectiveness of China's logistics sector in 2017 and concluded that while there are significant disparities in logistics efficiency among areas, the amount of regional economic growth has minimal

impact on logistics efficiency [16]. (2) Combine three-stage DEA and Tobit model to assess various aspects affecting logistics efficiency. Wong et al. utilized three-stage DEA to examine the efficiency of 77 logistics companies in Singapore and Malaysia between 2012 and 2013, and the Tobit model to examine the elements that impact logistics efficiency [17]. Zhang et al. analyzed the logistics sector efficiency of 19 provinces in the Yangtze River Reserve from 2013 to 2017, concluding that scale efficiency is a key factor influencing total efficiency [18]. (3) Combine SBM and Tobit model to examine the specific aspects affecting influencing logistics efficiency. Tian et al. studied the efficiency and its influencing factors of 90 fresh produce e-commerce enterprises in China from 2016 to 2017 and found that the overall technical efficiency of fresh produce e-commerce enterprises was low, and there was a significant positive effect of IT talent share structure, relationship with partners and logistics infrastructure level on the technical efficiency of fresh produce e-commerce enterprises, while there was a significant negative effect of information technology level [19]. Cao and Deng conducted an empirical analysis on the Yangtze River Economic Zone's logistics efficiency between 2007 and 2016 and analyzed the factors affecting logistics efficiency [20].

Therefore, previous research mostly focuses on the radial DEA or nonradial SBM for assessing the efficiency of logistics industry, without taking into account the influence of environment and statistical noise. Although the three-stage DEA reduces the influence of environmental factors and statistical noise, it ignores undesirable output and cannot guarantee the objectivity of efficiency measurement results. In addition, few studies have been conducted to systematically assess the logistics sector efficiency in China's new western land-sea corridor as the research topic. On this basis, this paper is extended as follows: (1) in the research method, considering the undesirable results, a three-stage SBM model is developed to calculate the logistics sector efficiency, and a panel Tobit model can be used to discuss the main influences elements on logistics sector efficiency. (2) In the research content, from 2010 to 2019, the panel data of logistics industry input-output indicators from 7 provinces, 4 autonomous regions, 1 municipality (henceforth referred to as 12 provinces) along China's new western land-sea corridor are selected for empirical analysis to identify the important influencing factors.

3. Research Design

3.1. Measure Model

3.1.1. Three-Stage SBM Model. The first stage: slack-based measure (SBM) considering undesirable output.

Suppose there are n decision making units (DMU), each unit has x input indicators, y^g desirable output indicators, and y^b undesirable output indicators, assuming matrices $X = [x_1, \dots, x_n] \in R^{m \times n}$, $Y^g = [y_1^g, \dots, y_n^g] \in R^{s_1 \times n}$, $Y^b = [y_1^b, \dots, y_n^b] \in R^{s_2 \times n}$, and $X > 0$, $y^g > 0$ and $y^b > 0$. The equation is as follows:

$$\rho = \min \frac{1 - 1/m \sum_{i=1}^m s_i^- / x_{i0}}{1 + 1/s_1 + s_2 (\sum_{r=1}^{s_1} s_r^g / y_{r0}^g + \sum_{r=1}^{s_2} s_r^b / y_{r0}^b)}$$

$$\text{subject to } \begin{cases} x_0 = X\lambda + s^- \\ y_0^g = Y^g\lambda - s^g \\ y_0^b = Y^b\lambda + s^b \\ s^- \geq 0, s^g \geq 0, s^b \geq 0, \lambda \geq 0. \end{cases} \quad (1)$$

In the above formula: ρ is the efficiency, and $0 \leq \rho \leq 1$; $s^- \in R^m$ is the input slack variable; $s^g \in R^{s_1}$ is the desirable output slack variable; $s^b \in R^{s_2}$ is the undesirable output slack variable; $\lambda \in R^n$ is the weight variable.

The second stage: stochastic frontier analysis(SFA)

The equation is measured as follows by using SFA:

$$s_{ni} = f^n(z_i; \beta^n) + v_{ni} + \mu_{ni}, n = 1, \dots, N, i = 1, \dots, I. \quad (2)$$

Among them, s_{ni} is the slack variable of item n of the i DMU's input; $f^n(z_i; \beta^n)$ is the influence of environmental variables on s_{ni} ; $z_i = (z_{1i}, z_{2i}, \dots, z_{ki})$ is the k environmental variables; β^n is the environmental variables coefficient; v_{ni} is the statistical noise; μ_{ni} is the managerial inefficiency.

Using the results of SFA to alter the input variables, all decision-making units are modified to the similar situations, the equation is as follows:

$$x_{ni}^A = x_{ni} + [\max(f(z_i; \hat{\beta}^n)) - f(z_i; \tilde{\beta}^n)] + [\max(\hat{v}_{ni}) - \tilde{v}_{ni}], n = 1, \dots, N, i = 1, \dots, I, \quad (3)$$

where: x_{ni}^A is the modified input variable, x_{ni} is the original input variable before modification. $[\max(f(z_i; \hat{\beta}^n)) - f(z_i; \tilde{\beta}^n)]$ represents the adjustment for external environmental influences, and $[\max(\hat{v}_{ni}) - \tilde{v}_{ni}]$ represents the adjustment for statistical noise.

The third stage: after adjusting the input variables, carry out the SBM model analysis.

The adjusted input variable x_{ni}^A obtained by formula (3) is used to replace the original input x_{ni} before adjustment, and the first-stage SBM is proposed again to assess the efficiency to obtain the real efficiency after excluding external environmental influences and statistical noise.

3.1.2. Panel Tobit Model. Since the logistics sector efficiency assessed by the SBM in the third stage is in the $[0,1]$ interval, which is not a normal distribution, it does not meet the assumption requirements of OLS for the normal distribution of the explained variables. Therefore, taking the logistics industry efficiency calculated by three-stage SBM model as the dependent variable, and various impacting factors on the logistics industry efficiency are used as independent variables, the equation is as follows:

$$y_i = \begin{cases} y_i^* = X_i' \beta + u_i, & y_i^* > 0, \\ 0, & y_i^* \leq 0, \end{cases} \quad (4)$$

where y_i is the efficiency; y_i^* is the potential dependent variable; X_i' is the independent variable; β is the coefficient; u_i is the statistical noise, $u_i \sim (0, \sigma^2)$

Substitute the variables in Table 1 into formula (4) to construct a panel Tobit model:

$$y_{it} = \beta_0 + \beta_1 X1_{it} + \beta_2 X2_{it} + \beta_3 X3_{it} + \beta_4 X4_{it} + \beta_5 X5_{it} + \beta_6 X6_{it} + \beta_7 X7_{it} + u_{it}. \quad (5)$$

Among them, y_{it} is the logistics industry efficiency; β_0 is a constant term; $\beta_1, \beta_2, \dots, \beta_7$ is the regression coefficient; u_{it} is the statistical noise; $X1_{it}$ is the urbanization rate; $X2_{it}$ is the government support level; $X3_{it}$ is the infrastructure level; $X4_{it}$ is the industrial structure; $X5_{it}$ is the degree of openness; $X6_{it}$ is the logistics transportation intensity; $X7_{it}$ is the economic development; i is the province; t is the time.

3.2. Indicator System. This paper selects indicators of the logistics industry and provides a suite of research indicator systems to assess the efficiency and influencing factors of the logistics sector in China's new western land-sea corridor, as indicated in Table 1.

3.2.1. Input Indicator. Use labor force, capital, and energy as input indicators.

The work force is calculated by adding the total population employed in urban logistics units, urban private logistics firms, and individual logistics sector employees.

The capital stock formula is as follows:

$$K_{it} = K_{it-1} \times (1 - \delta) + \frac{I_{it}}{P_{it}}. \quad (6)$$

Among them, K_{it} and K_{it-1} represent the logistics industry's capital stock in i province in period t and $t - 1$, respectively; K_{i0} represents the logistics industry's capital stock in i province in its base period, divided by 10% of the fixed asset investment in 2010(2010 as the base period); δ represents the capital depreciation rate, which is taken as 9.6% [21]; I_{it} represents the fixed asset investment amount of t period of i province; P_{it} represents the price index of fixed asset investment of t period of i province.

The formula for calculating energy is as follows:

$$E = \sum_{i=1}^{11} (M_i \times P_i). \quad (7)$$

Among them, E represents the total energy consumption of energy after the conversion to standard coal of various types of energy; M_i is the various types of energy involved in the logistics industry; P_i is the reference coefficient for the conversion to standard coal of the i energy.

TABLE 1: Efficiency measurement and influencing factor index system of logistics industry.

Indicator type	Metric name	Metric definitions	Unit
Input	Labor force	People employed in urban units in the logistics industry	10,000 people
	Capital	Logistics industry total social fixed asset investment	100 million yuan
	Energy	Logistics industry energy consumption	10,000 tons of standard coal
Desirable output	Value added	Logistics industry value added	100 million yuan
Undesirable output	CO ₂ emissions	CO ₂ emissions from the logistics industry	10,000 tons
Environmental variables	Economic condition	Gross domestic product (GDP)	100 million yuan
	Computerization development level	The mobile phone users at the end of the year	10,000 households
	Industrial market structure	The amount of registered legal entities in the logistics sector	Piece
	Import and export	Total import and export	Billion dollars
Influencing factors	Urbanization rate	Urban population/total population	%
	Government support level	Financial expenditure of the logistics industry/fiscal general budget expenditure	%
	Infrastructure level	Length of transportation route/land area	km/km ²
	Industrial structure	Added value of tertiary industry/GDP	%
	Degree of openness	Total import and export/GDP	%
	Logistics transportation intensity	Total turnover of the logistics industry/GDP	Tons of km/yuan
	Economic development	Real GDP per capita	Chinese yuan/person

3.2.2. *Output Indicator.* Value added and carbon dioxide emissions are used as output indicators. Value added represents the desirable output and is processed by using the GDP deflator (2010 as the base period). Carbon dioxide emissions represent undesirable output and are computed as the sum of the logistics industry's energy consumption with the emission factors provided by IPCC 2006 Guidelines.

3.2.3. *Environmental Variables.* Complex environmental factors affect the efficiency of the logistics industry, but they are independent of the logistics industry itself. Four indicators are selected as environmental variables: economic condition, computerization development level, industrial market structure, import and export. Considering the availability of relevant indicators and the requirements of indicator selection, GDP is selected as the surrogate variable for economic condition, the mobile phone users at the end of the year is selected as the surrogate variable for computerization development level, the amount of registered legal entities in the logistics sector is selected as the surrogate variable for industrial market structure, and total import and export is selected as the surrogate variable for import and export.

3.2.4. *Influencing Factors.* Seven factors influencing logistics sector efficiency are selected: urbanization rate, government support level, infrastructure level, industrial structure, logistics transportation intensity, degree of openness, and economic development.

- (1) Urbanization rate (X1): with the development of spatial structure and economic structure, the strong agglomeration of industries and population in the

urbanization process and the change in distribution cost of logistics industry will affect the agglomeration of logistics industry. This paper describes the urbanization rate in terms of the share of urban population to overall population in each province.

- (2) Government support level (X2): the government can improve logistics infrastructure by providing effective logistics development strategies and financial support. At the same time, ineffective government intervention has also delayed the improvement of logistics competitiveness to a certain extent. This article reflects the level of government support through the ratio of logistics industry fiscal expenditure to the general budget expenditure of each province.
- (3) Infrastructure level (X3): the construction of transportation infrastructure network can improve the service capacity of the logistics sector. The ratio of the sum of railroad mileage, inland waterway mileage, and road mileage of each province to the area of each province is chosen to reflect the degree of infrastructure in each province.
- (4) Industrial structure (X4): the service demand for logistics industry in the tertiary industry exceeds that in the secondary sector, and the logistics sector demand composition is constantly changing. This paper selects the proportion of tertiary sector added value to GDP in each province to represent the industrial structure.
- (5) Degree of openness (X5): the expansion of the degree of openness can improve the level of local logistics technology and management, which in turn affects the logistics industry efficiency. The ratio of total exports and imports to GDP in each province is selected to represent the level of openness.

- (6) Logistics transportation intensity (X6): this paper selects the ratio of the total logistics turnover to the GDP of each province to represent the logistics transportation intensity.
- (7) Economic development (X7): the development of regional economy can provide relevant supporting facilities, human resources, scientific and technological foundation for the logistics industry, which in turn effects the logistics sector efficiency. This study utilizes real GDP per capita to assess the economic progress of each province.

3.3. Data Analysis. This paper selects the transportation, warehousing, and postal industries of 12 provinces along China's new western land-sea corridor between 2010 and 2019 as the research object to study the logistics industry. Tibet is excluded from the research scope owing to lack of statistics data. All research data came from the National Bureau of Statistics' website and the China Energy Statistical Yearbook (see Table 2 for details).

The correlation test of input and output indicators of logistics industry was carried out by stata16, the correlation coefficients are positive and pass the test at 1% significance level, which indicates that the indicators are reasonably chosen. Table 3 displays the results.

4. Three-Stage SBM Model Results and Analysis

4.1. The First Stage. Based on the input-oriented SBM, MaxDEA Pro8 is used to assess the logistics sector efficiency in China's new western land-sea corridor between 2010 and 2019, as shown in Table 4. Technological efficiency, pure technological efficiency, and scale efficiency have averages of 0.71, 0.84, and 0.85, respectively, all of which do not reach DEA effectiveness. By province, the logistics industry's uneven development is more prominent, and its efficiency level varies greatly. The top three logistics industry efficiency averages are Ningxia, Inner Mongolia, and Shaanxi, all above 0.9, close to the frontier of efficiency levels. The bottom three logistics industry efficiency averages are Hainan, Qinghai, and Sichuan, which are all below 0.6. Among them, the explanation for Sichuan and Qinghai's poor average technical efficiency is low scale efficiency, while the low technical efficiency in Hainan is due to the low pure technical efficiency. Only five provinces have an average technical efficiency of more than 0.71, namely Ningxia, Inner Mongolia, Shaanxi, Gansu, and Guizhou, most of which are located in the northern portion of the new western land-sea corridor.

4.2. The Second Stage. Based on the SFA, the explained variables are the input slack variables collected in the first stage, as well as four environmental elements, namely, GDP, the mobile phone users at the end of the year, the amount of registered legal entities in the logistics sector, and total import and export are used as explanatory variables, and the frontier4.1 is used to examine whether environmental factors have a considerable influence on input slack variables. Table 5 displays the results.

From Table 5, it can be concluded that:

Economic condition: the economic condition represented by GDP is negatively associated with all three slack factors and passes the significance test. It shows that improving economic conditions can minimize input redundancy of capital stock, employees, and energy consumption, and reasonable deploy of resources to increase the overall logistics business efficiency.

Computerization development level: the level of computerization represented by the mobile phone users at the end of the year is positively correlated with the slack variables "fixed assets" and "energy consumption," and negatively correlated with the slack variable "employees," all of which pass the test at the 1% statistical significance. It demonstrates that an increase in phone users at year end can result in increase in input redundancy of capital stock and energy consumption, resulting in inefficient allocation of capital and energy, while reducing the redundancy of employee input and making the employee input more reasonable.

Industrial market structure: the industrial market structure, represented by the amount of registered legal entities in the logistics sector, is positively correlated with the slack variable of energy consumption and negatively correlated with the slack variable of capital stock, both of which pass the test at the 1% significance level. There is no significant relationship with the slack variable of employees. This shows that the increase in the number of registered legal entities in the logistics sector may lead to inefficient energy consumption and more rational allocation of capital.

Import and export: total imports and exports is positively correlated with the slack variable of employees and energy consumption, and they pass the 1% significance test. It indicates that increasing import and export can lead to redundancy of employees and energy consumption, resulting in unreasonable input of employees and inefficient use of energy in the logistics industry.

4.3. The Third Stage. The second stage's modified input variables and the first stage's initial outputs are fed to the SBM of the first stage for calculation and give the real logistics industry efficiency. Table 6 displays the results.

The third-stage logistics industry efficiency in different provinces is shown in Figure 1:

By province, there are obvious disparities in the logistics sector efficiency before and after the adjustment of each province. Inner Mongolia and Shaanxi's logistics sector efficiency always remains at the forefront. The technical efficiency in Ningxia, Hainan, Qinghai, Gansu, and Guizhou declines, and the technical efficiency of Chongqing, Guangxi, Sichuan, Yunnan, and Xinjiang improves. This shows that the first-stage SBM does not consider the impact of environmental factors and statistical noise; it is

TABLE 2: Descriptive statistics of the efficiency measurement and influencing factors.

Indicator type	Metric name	Sample size	Average value	Standard deviation	Minimum	Maximum
Input	Labor force (100 million yuan)	120	7893.05	5676.19	1188.36	29314.7

Log likelihood	34.2272			
Prob > chi2	0			

Note. *, **, *** indicate significant at 10%, 5%, and 1%, respectively.

The average technical efficiency in Guangxi has adjusted from 0.656 to 0.904, mainly due to pure technological efficiency improvement. Chongqing's average technological efficiency has increased from 0.685 to 0.917, mainly due to the improvements in both pure technological efficiency and scale efficiency. Qinghai and Ningxia's technological efficiency have decreased from 0.544 to 0.961 before adjustment to 0.259 and 0.697 after adjustment, respectively. The pure technical efficiency of the two provinces has been at the production frontier, so the reduction in technical efficiency is mostly related to the reduction in scale efficiency. The phenomenon of high technical efficiency in the first stage is partly due to external environmental variables. Hainan, Guizhou, Gansu, and Xinjiang have improved their pure technological efficiency, while their scale efficiency has declined, leading to a slight drop in logistics industry efficiency, showing that external environmental variables have not significantly driven the logistics sector development. The average technical efficiency of 6 provinces of Inner Mongolia, Shaanxi, Chongqing, Guangxi, Yunnan, and Sichuan exceeds 0.734, most of which are located in the southern half of the new western land-sea corridor.

5. Analysis of Influencing Factors

Panel Tobit model regression is performed by Stata16, and the results are shown in Table 7.

- (1) The effect of urbanization rate: the urbanization rate has significantly negatively correlated with the logistics sector efficiency. If the proportion of urban population to the total population in each province increases by 1 unit, the efficiency of the logistics sector will decrease by 3.5985, which means that the logistics industry's efficiency cannot be significantly improved as the urban population grows. Although the provinces of the new western land-sea corridor are accelerating the process of new urbanization, it will take a long time to push the growth of regional large logistics hubs and intracity logistics systems.
- (2) The influence of government support level: the degree of government funding has no obvious negative impact on logistics business efficiency. If the share of fiscal expenditure on the logistics sector in the

general budget expenditure of each province increases by 1 unit, the efficiency of the logistics sector will decrease by 0.4964, indicating that there is no positive relationship between the government's fiscal expenditure on logistics industry and logistics business efficiency. Despite significant investments in logistics infrastructure by local governments, the logistics business in various provinces remains unequal.

- (3) The impact of infrastructure level: the transportation infrastructure network has a considerable negative impact on the logistics sector efficiency. If the share of the length of transport lines to the national territory in each province increases by 1 unit, the logistics sector efficiency will decrease by 0.3267. It shows that the increase in infrastructure construction cannot considerably enhance logistics sector efficiency. The convenient transport infrastructure network can help the logistics sector more efficient, but the redundant construction of the transport infrastructure will waste logistics resources.
- (4) The effect of industrial structure: the impact of industrial structure on logistics sector efficiency is not significant. If the share of value added in the services sector to GDP in each province increases by 1 unit, the efficiency of logistics industry will increase by 0.5721. This suggests that the industrial structure will lead to an increase in the efficiency, but the impact is not prominent. The development of the service sector contributes to service innovation in the logistics sector, the continuous satisfaction of different logistics services needs, and the continuous optimization of the resource allocation.
- (5) The impact of the degree of openness: the degree of openness has a considerable adverse influence on the logistics sector efficiency. If the share of total import and export to GDP of each province increases by 1 unit, the logistics sector efficiency will decrease by 0.5664. The majority of new western land-sea corridor is located in China's interior and its openness to the outside world is not high, which affects the flow of production factors and leads to the decrease of logistics sector efficiency.

- (6) The impact of logistics transportation intensity: logistics transportation intensity has a strong positive influence on logistics sector efficiency, when the ratio of total logistics turnover to GDP in each province increases by 1 unit, logistics sector efficiency increases by 1.0097. It indicates that the growth of logistics sector along the new western land-sea corridor should increase the value added while decreasing energy consumption of logistics industry by improving transportation intensity.
- (7) The influence of economic development: the economic development of each province has a substantial positive impact on the logistics sector efficiency, when each province's GDP per capita increases by 1%, the logistics sector efficiency increases by 0.5113%, implying that economic development leads to the improvement of logistics efficiency. Provinces with high level of economic development have a stable industrial base and sound industrial structure, which in turn promote the improvement of logistics industry efficiency.

6. Conclusion and Suggestion

Based on the growth of the logistics sector in 12 provinces of China's new western land-sea corridor from 2010 to 2019, this paper has introduced a three-stage SBM model considering nonradial, nonoriented, and undesirable output to make quantitative analysis of logistics efficiency and analyzes the influencing factors of logistics efficiency by using panel Tobin model and gets the following conclusions:

First, there are spatial variability of the logistics industry efficiency among provinces. From 2010 to 2019, except for Inner Mongolia, where the logistics sector's adjusted efficiency was at the production frontier. The logistics sector's efficiency in other provinces was uneven. The adjusted logistics sector efficiency of Shaanxi and Chongqing remains stable, while the logistics sector efficiency of Qinghai, Xinjiang, and Hainan was weak.

Second, the influence of environmental variables on logistics sector efficiency is diverse. Economic condition, computerization development level, industrial market structure, and import and export have a significant influence on logistics sector efficiency. There seem to be significant differences in logistics sector efficiency before and after adjustment.

Third, the panel Tobit model regression results indicate that industrial structure, logistics transportation intensity and economic development have positive effects on logistics sector efficiency, while urbanization rate, government support, infrastructure level, and degree of openness have negative effects on logistics business efficiency. Urbanization rate, infrastructure level, degree of openness, logistics transportation intensity, and economic development have significant effects on logistics industry efficiency, while government support and industrial structure have little effects on logistics industry efficiency.

In light of the findings, the following proposals are made in this paper:

The first is to improve current logistics transportation intensity of China's new western land-sea corridor. Promote the development of multimodal transit and land-sea intermodal transportation by railroad, highway, and waterway; support inland transport to speed up the adjustment of the transport structure; and increase the proportion of railway and waterway cargo transportation to the total freight volume. Rail and river transport for bulk transport has significantly reduces the cost of transporting raw materials, freight, and port transportation promote and facilitates the development of railway container distribution centers through rail-sea combined transportation and international trains, and strengthen intracorridor and cross-corridor cooperation. Ensure the smooth flow of the Southbound international railway and sea transport; promote the development of ports; improve the service level; formulate practical customs policies; and improve the comfort of pass customs.

The second is to improve the pure technological efficiency and scale efficiency of the logistics sector in the new western land-sea corridor. Make full use of the opportunity of creating "new infrastructure"; implement digital and intelligent logistics systems; expand the scope of information exchange; and improve the capabilities of logistics enterprises. Establish intelligent logistics industrial park; combine logistics with production factor policies; and develop the scale and benefits of logistics industrial parks.

Third, create a good external environment for logistics development in China's new western land-sea corridor. Considering the heterogeneity among environmental variables in different provinces, the change of environmental variables leads to significant changes in logistics efficiency in different provinces. All provinces should combine their own advantages, take enterprises as the main body under the leadership of the state, plan and standardize logistics industry growth, formulate and improve the logistics sector strategy, and promote the growth and introduction of green technology.

Data Availability

The experimental data used to support the findings of this study are available from the corresponding author upon request.

The business model of traditional market is declining day by day, and people's consumption cognition has risen to a new level with the leap in science and technology. Enterprises need to adjust and optimize their marketing strategies in time according to the new consumption characteristics, so as to smoothly adapt to the environmental changes in the Internet age. This paper briefly analyzes the relationship between sales development and psychology and constructs a fusion model that can predict preferences with the help of neural network structure of the deep learning method. Describe user portraits and characteristics, analyze users' purchasing behavior and credit literacy, and push related products combined with a hash algorithm to achieve accurate e-commerce marketing purposes. The results show that (1) the model constructed in this paper and five different models are used for multi-modal recognition analysis: the accuracy is 79.56%, the recall rate is 77.43%, F1 is 0.785, and the error value can be reduced to about 0.18 by epoch iteration; the model is superior and has great use value. (2) Using the model to extract user attribute features and predict certain preferences, 13 topics and weight ratios are obtained for users of a certain platform, and the portrait model of each user is constructed. (3) According to the portrait optimization, 8 different marketing strategies are obtained, and the marketing effect is remarkable, fluctuating between 69% and 82%, and the income situation is also satisfactory. The final model design is reasonable and the data performance is good, which provides an intelligent and efficient dynamic strategy service for enterprises.

1. Introduction

In the era of information explosion, the way of computer communication technology has changed, and people can complete the whole process of challenging, pricing goods or services without going out on the material platform and interconnected financial service. It is also a big challenge for each attempt to move the market. Consumers have more information channels. They no longer pay more attention to the sales promotion of merchants but pay more attention to the sexual price and sufficient demand for goods themselves. They also tend to pursue new things and expect 24-hour all-round service. Due to the shift of the focus of purchasing characteristics, which drives the shift of marketing focus, enterprises need to cater to the psychology of users and formulate different strategies for different users. However, relying solely on the strength of enterprise decision-making

and marketing personnel cannot cope with the massive user data, and it is easy to miss the market outlet and lose the opportunity to expand the reputation and influence of enterprises. Therefore, adhering to the concept of innovation and development, we collect relevant information for reference.

Design a multi-level network structure model, according to the data-driven and key characteristics of the development of gas station marketing strategy, and forecast oil sales [1]. Using the PaaS platform of Kubernetes container to construct TensorFlow container, unified resource scheduling management, and API access control service architecture [2]. Using stuttering word segmentation algorithm, SIFT method, PGBN deep learning model, and Gibbs up-down sampling method, an accurate marketing push is realized [3]. DCNN is used to extract feature vectors, regression analysis method is used to evaluate face value, and personalized products and services are output [4]. Based on the deep

learning of Maker Space as the carrier, the marketing major designs experimental teaching [5]. This paper studies the formation mechanism of marketing dynamic capability of international enterprises from the perspective of knowledge [6]. Combined with the characteristics and teaching experience of marketing specialty, this paper explores [7]. Neural marketing based on brain waves, combined with five 3D CNN and multi-layer LSTM prediction models, predicts consumers' preference for products [8]. By establishing a fusion model, artificial feature screening, and tree model for various machine learning algorithms, new ideas are provided for judging users' financial consumption behavior [9]. Test the combination form and effectiveness of graphic information, and explore the influence of consumer behavior and brand relationship [10]. Provide personalized recommendation service for consumers through multi-source big data recommendation system [11]. Using DCNN to learn binary hash coding, large-scale image retrieval is completed in low-dimensional Hamming space [12]. Logistic equations and particle swarm optimization algorithms are introduced to evolve and predict the time series of Internet communication behavior [13]. Based on the three mobile Internet portals of WeChat, Weibo, and APP, this paper studies the optimization of marketing strategy on railway lines [14]. CiteSpace software analyzes business intelligence at home and abroad, and measures management decisions and technology applications [15].

Based on the description of the above literature, this topic has a large number of theoretical basis and experimental ideas that can be used for reference. Change the marketing strategy into online mode, read the text, images, audio, and other contents of the network, and deal with the relevance of dynamic data with the help of business characteristics and users' consumption habits. Describe the user consumption portrait, and build a prediction model with mixed DCNN and LSTM neural network structure. In addition, a recommendation framework based on deep hash is introduced as a supplement, hoping to bring users a better experience and achieve more accurate marketing methods than traditional methods.

2. Theoretical Basis

2.1. Marketing Strategy. Marketing Strategy [16]; this kind of enterprise activity is mainly organized and operated in a planned way for the market, and obtains sales volume, purchasing power information, and industry prestige value according to various needs and past experience of certain target customers, including comprehensive strategies such as price, promotion, channel, and public relations. Marketing is a means that people, who receive news accept and appreciate the products, services, and benefits introduced and promoted by enterprises. Its main purpose is to make products accepted by consumers, provide customers with satisfactory goods or required services, improve the purchase and use effect, and at the same time establish a brand effect. Because this is a dynamic and changing process, decision-makers need to adjust, create and make plans repeatedly with the changes in the market. Use the 4P principle [17]; according

to the actual situation, we should optimize the strategic policy, selectively capture the target market, enhance the competitiveness, and strive to obtain the best economic results with the least input cost in the big environment. Focusing on the seven characteristics of marketing, such as purpose, foresight, uncertainty, systematicness, creativity, debugging, and dynamics, we can carry out effective marketing according to the types and characteristics of different markets.

2.2. Overview of Deep Learning. The realization of AI is inseparable from the application of deep learning (DL), which belongs to the extension of machine learning (ML) in AI field. It comes from researchers' exploration of ANN, that is, simulating and approximating biological neural networks. DL can be simply understood as feature learning or representation learning. Through multi-level processing, DL represents features from low level to the high level and completes complex learning tasks such as classification and recognition. Taking the deep learning structure of multi-layer perceptron as an example, it is composed of multiple hidden layers, which can solve the problem of linear indivisibility of a single layer. DL [18] is a general name for a class of pattern analysis methods; it mainly involves CNN [19], Autoencoder [20], and DBN [21]. In recent years, in order to have a deeper understanding of the characteristics and practical applications of DL, researchers have chosen to combine the three methods, which not only increase the parameters but also increase the training difficulty of the model. However, compared with the traditional models, these new fusion models have achieved excellent performance. This paper trains the hybrid network model of DCNN and LSTM to deal with complex transactions.

2.3. Deep Convolution Neural Network. Convolution neural network is a kind of feedforward neural network [22]. It is a hierarchical structure, and each convolution layer contains a certain number of convolution kernels. When the convolution layer and the pooling layer interact with each other, the features of the entered data are extracted, the data features are mapped and the output dimension size is reduced. Scholars represented by LeCun designed and trained the classical LeNet-5 model based on the principle of neural cognitive machine and BP algorithm. As the most classical CNN structure, many subsequent works need to improve this model to achieve. Using DCNN of VGGnet series and using multiple nonlinear feature extraction stages to automatically learn hierarchical representation, the computation can be greatly reduced. The operation process of convolution layer convolution is as follows:

$$y_n^l = f \left(\sum_{\forall m} (y_m^{l-1} * c_{n,m}^l) + b_n^l \right). \quad (1)$$

After complex neuron calculation, DCNN needs to be judged by activation and function, and then can output recognition results, which can improve the recognition ability of neural network. Therefore, our formulas (2)–(4),

respectively, introduce the three commonly used activation functions of Sigmoid, ReLu, and tanh, which can solve the problem of gradient disappearance.

$$f(x) = \frac{1}{1 + e^{-x}}, \quad (2)$$

$$\text{ReLu}(x) = \max(0, x), \quad (3)$$

$$f(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}. \quad (4)$$

The calculation form of convolution layer is introduced.

$$\begin{aligned} y_j^l &= f(z_j^l), \\ z_j^l &= \sum_{vm} y_i^{l-1} * c_{ij}^l + b_j^l. \end{aligned} \quad (5)$$

Weights [23] and thresholds [24] are obtained by random gradient descent method.

$$c_{ij}^l = c_{ij}^l + \alpha \frac{\partial L(c_{ij}^l)}{\partial c_{ij}^l}, \quad (6)$$

$$b_j^l = b_j^l + \alpha \frac{\partial L(b_j^l)}{\partial b_j^l}.$$

2.4. Long-Term and Short-Term Memory Neural Network. LSTM model is a special RNN [25]. It makes some changes in the neuron structure of RNN and introduces memory units to solve the problem of gradient explosion and disappearance that traditional RNN cannot avoid. Gradient learning algorithm is introduced into the network structure of LSTM, and a processor is added to judge whether information is useful or not, which includes three gates: input, forgetting, and output. In addition, it also has a memory unit that can improve the ability to process long sequence data. First of all, LSTM needs to decide the information to be discarded in the cell state, and view $h_{t-1}x_t$ through the forgetting gate to output the 0–1 vector, as shown in Formula (7). Then the information of the cell state is updated by the input gate and tanh to obtain Formulas (8) and (9). After updating the new unit information C_t , the output state characteristics are judged, and the vectors between $[-1, 1]$ are obtained by sigmoid and tanh. Finally, the RNN unit is output, and the vector is multiplied by the judgment condition to obtain a Formulas (12) and (11).

$$f_t = \sigma(W_f \bullet [h_{t-1}, x_t] + b_f), \quad (7)$$

$$i_t = \sigma(W_i \bullet [h_{t-1}, x_t] + b_i), \quad (8)$$

$$C_t = \tanh(W_c \bullet [h_{t-1}, x_t] + b_c), \quad (9)$$

$$o_t = \sigma(W_o [h_{t-1}, x_t] + b_o), \quad (10)$$

$$h_t = o_t * \tanh(C_t). \quad (11)$$

Attention mechanism can solve the capacity problem and long-term dependence problem of coding vector, effectively shorten the distance of information transmission and reduce unnecessary steps. So, the LSTM model is optimized. After input $x = \{x_1, x_2, \dots, x_n\}$, the attention mechanism is introduced when the hidden layer outputs vector h . According to the encoder output and attention probability, the average value is calculated after addition. Where A_i stands for the probability of attention; matrix parameters are represented by w, W, U ; b is the biased vector; tanh is a hyperbolic tangent function.

After introducing the attention mechanism, the related calculations are as follows:

$$A_i = \frac{\exp(f(\bar{h}, h_i))}{\sum_j \exp(f(\bar{h}, h_j))},$$

$$f(\bar{h}, h_i) = w^T \tanh(W\bar{h} + Uh_i + b), \quad (12)$$

$$V = \sum_{i=0}^t A_i h_i.$$

2.5. Binary Hash Algorithm. A binary hash layer is introduced to construct an independent hash function. When the feature passes through this layer, the hash code can be obtained. Then, the hash code passes through the loss layer to obtain the optimized parameters calculated by the loss function. Hash codes can be expressed as

$$(h_1, h_2, \dots, h_q)^T = (\text{sign}(Wx))^T. \quad (13)$$

Sub features that can enter the full connection layer are obtained from the slice layer.

$$f_i(x^{(i)}) = W_i x^{(i)}, i = 1, 2, \dots, q. \quad (14)$$

The activation layer maps the one-dimensional value output by each block.

$$\tanh(v^{(i)}) = \frac{1 - e^{\beta v^{(i)}}}{1 + e^{\beta v^{(i)}}}, i = 1, 2, \dots, q, \quad (15)$$

$$v^{(i)} = f_i(x^{(i)}).$$

Enter the merging layer and represent vectors.

$$s = (v^{(1)}, v^{(2)}, \dots, v^{(q)})^T. \quad (16)$$

Enter the thresholding layer.

$$g(s^{(i)}) = \begin{cases} 1, & s^{(i)} \geq 0, \\ -1, & s^{(i)} < 0. \end{cases} \quad (17)$$

The quantization error loss is added to the objective function.

$$L_q = \frac{1}{2} \|h - s\|_2^2. \quad (18)$$

Combined with SoftMax, the overall loss function is obtained.

$$L_T = L_s + \lambda L_q. \quad (19)$$

3. Design and Implementation of 3 System Model

3.1. User Portrait Model. The characteristics of the times make more and more people active on the Internet. People use but are not limited to words, pictures, videos, and other ways to record their lives and work in this online world and express their preferences freely and fully. Social activity data on the Internet will record a person's interests, behavior habits, psychological state, and other personal attributes. Major small and medium-sized enterprises should seize the opportunity, open up their thinking, and realize accurate marketing according to the distinctive personal characteristics of Internet users. Adjust the original strategy, carry out personalized analysis and feature optimization of products, and mine the value hidden in the data.

In view of the universality and practicability of the user portrait model, this paper also adds this mining method, which classifies users and labels them according to the features extracted from the DL model, so as to facilitate more detailed consumption analysis. First of all, we need to collect the user's basic data, and then preprocess the user's text data source and picture data source. Finally, the attributes are abstracted by a genetic algorithm, Bayesian algorithm, and neural network algorithm, and the useable user portrait is successfully established.

The hierarchical structure of portrait construction is as follows:

$$\left\{ \begin{array}{l} \Theta_j^{(T)} : \text{Gam} \left(r, \left(\frac{1}{c_j^{(T+1)}} \right) \right), \\ \Theta_j^{(T)} : \text{Gam} \left(\left[\begin{array}{l} \phi_w^{(t+1)} \phi_{w-j}^{(t+1)} \\ \phi_v^{(t+1)} \phi_{v-j}^{(t+1)} \end{array} \right], \left(\frac{1}{c_j^{(t+1)}} \right) \right), \\ \Theta_j^{(1)} : \text{Gam} \left(\left[\begin{array}{l} \phi_w^{(2)} \phi_{w-j}^{(2)} \\ \phi_v^{(2)} \phi_{v-j}^{(2)} \end{array} \right], \left(\frac{p_j^{(2)}}{(1 - p_j^{(2)})} \right) \right). \end{array} \right. \quad (20)$$

After simplification and derivation, we can get the following formula:

$$\left\{ \begin{array}{l} w_j^{(t)} : \text{Pois}(-\phi_w^{(t)} \theta_{w-j}^{(t)}, \ln(1 - p_j^{(t)})), \\ v_j^{(t)} : \text{Pois}(-\phi_v^{(t)} \theta_{v-j}^{(t)}, \ln(1 - p_j^{(t)})). \end{array} \right. \quad (21)$$

3.2. Preference Recommendation and Strategy Adjustment. Traditional marketing methods cannot meet the needs of Internet users, and cannot play a very good role in publicity,

but greatly increase costs, while achieving little effect. In order to improve the loyalty and satisfaction of users and achieve the predetermined sales volume and reputation, recommending the relevant preferences of users is the key. The preference here means that users have a good impression of specific goods or services, and are more inclined to buy trusted brands or trademark products when consuming, that is, consumption preference. Such users will buy repeatedly under the influence of subconscious habits. In addition, users are no longer limited to ordinary and popular standard goods after having a variety of choices. They are easily influenced by their own psychology, environment, and culture, and have a strong willingness to choose products that can satisfy their individualized pursuit. The previous experimental design has laid the foundation for our preference recommendation. We can analyze the user's love and habit of a certain kind of product or a certain kind of service, and turn this market information that can be mastered into the core of marketing strategy.

- (1) For consumers, who care about the price and practicality of goods or services, take affordable promotion as the marketing strategy, and push full reduction activities, coupons, and discounted goods for these people. They cannot control their desire to buy, and they cannot help buying more goods or services.
- (2) Not everyone measures the value of goods by cost performance, and there are also main buyers who, pay more attention to new things. They do not care about the amount of money, but pay attention to the trend of the times, the style and novelty of goods. They can pay generously for a service that has only become popular in society, just to satisfy the novelty of the moment; you can also snap up a small commodity because of its limited sales. Therefore, aiming at this part of consumers, we should constantly update and focus on the marketing of new models and early adopters.
- (3) For people, who go to work and study, due to the limitation of time and space, they cannot participate in offline shopping experience activities anytime and anywhere. They need convenient, fast and simple shopping choices, and can enjoy centralized customer service and after-sales service at any time.

3.3. Framework of Hybrid Model. The model of this paper is based on DCNN and LSTM neural network with an attention mechanism, which also introduces a binary hash layer so that the overall processing ability of the model is higher. According to the performance of users on the Internet, collect basic data, then preprocess the text and pictures, and transmit them to DCNN + LSTMATTENTION model to find various hidden user characteristics. According to the information characteristics of these users, the user portrait model is constructed, and the marketing strategy is optimized and adjusted. In order to better cater to consumers' ideas, analyze decision-making behavior, search

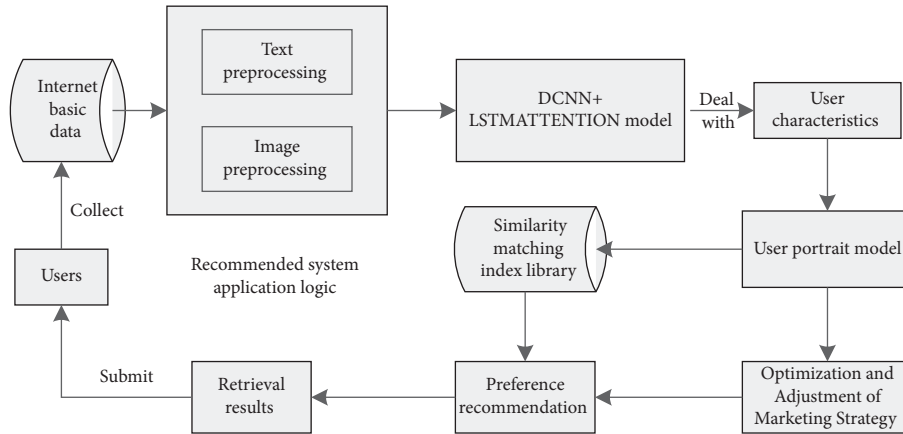

FIGURE 1: Schematic diagram of DL-based hybrid model.

FIGURE 2: Comparison of multi-modal recognition results.

the index database of similarity matching, recommend preferred products that meet consumers’ interests, and make the adjusted marketing strategy play a role. Finally, the retrieval results are submitted to users for use, which directly affects the transactions of consumer customers as shown in Figure 1.

4. Experimental Analysis

4.1. Performance Results of the Model. In this section of the experiment, we will explain the reasons for choosing the hybrid model. By identifying and detecting the graphic text of consumer shopping, we record the three indicators identified by multimodality respectively. In order to highlight the superiority of this model, CNN, LSTM, DCNN, LSTMATTENTION, basic hybrid model (DCNN + LSTMATTENTION), and mature hybrid model with hash

layer are compared. The recognition accuracy of CNN model is 68.42%, the recall rate is 71.08%, and the F1 score is about 0.701. LSTM and its value fluctuate between 1% and 2%, and their performance is roughly the same. The performance of DCNN and LSTMATTENTION models is slightly better than the first two models, with accuracy of 72.31% and 75.22%, respectively, and there is still room for optimization and improvement. The data of the common hybrid model performs well. After adding Hash, the accuracy of the fusion model is as high as 79.56%, the recall rate rises to 77.43%, and the equilibrium F score reaches 0.785. The larger the value, the better the model as shown in Figure 2.

After testing the above indexes, the error values of each model are analyzed. With the increase of the number of an epoch, the weight of the model is set to undergo repeated update iterative training. With the increase of epoch, their

FIGURE 3: Comparative analysis of errors.

FIGURE 4: Weight information for part of the topic.

diversity becomes stronger and stronger, and the curves transition from the initial nonfitting state to the fitting state. The method in this paper not only reduces the weight parameters but also reduces the prediction error of the model. After 50 updates, its error value can be reduced to about 0.18. Compared with other models, the error value of this model does not appear high or low, and its dynamic performance is obviously better than other basic network models. Finally, we can find that the performance of the model designed by this method is better than that of other single models and common mixed models, and the effect is satisfactory as shown in Figure 3.

4.2. Preference Prediction Analysis. First of all, we collect the basic data of users' Internet, and after processing the model, we can determine the topic content and its weight bias that

users prefer. Most subject words under each topic will have different characteristics, which are identifiable and unique, and can well distinguish the personal attributes of different users from their corresponding hobbies. Confirming these themes can better assist the construction of users' portraits and strive to create a database of one person and one portrait. A total of 1000 active users of a certain platform were randomly selected, the data containing text pictures were crawled as the original data, and 13 topics with a high topic degree were obtained, each topic had 20~70 subject words as shown in Figure 4.

Three users who volunteered to participate in the experimental test were selected, the training data set was processed and constructed, and their different preferences were predicted by portraits. It is obvious that they have different tendency distribution in theme preference, which proves that they pay close attention to and have a strong

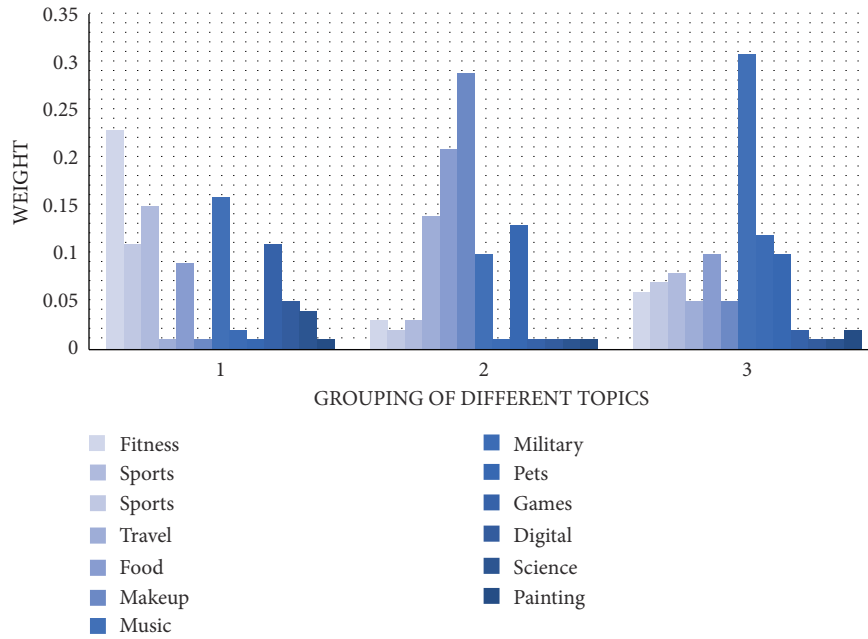

FIGURE 5: Preference prediction of user portrait.

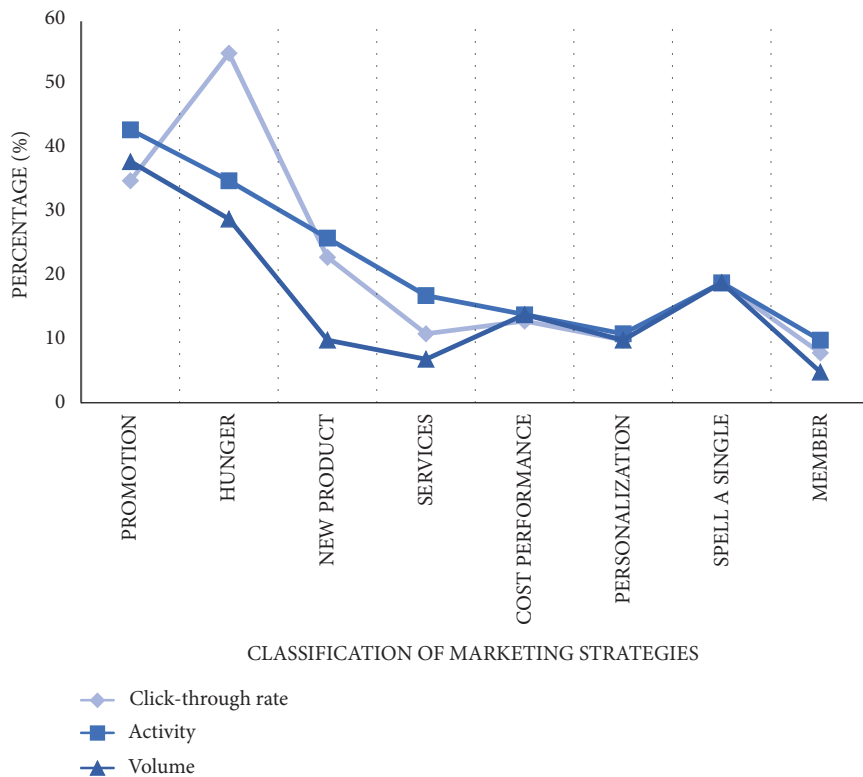

FIGURE 6: Marketing strategy optimization.

interest in a certain kind or several themes in daily life. We can clearly see that the first user prefers topics such as physical fitness, followed by music. The second user focused on travel, food, and beauty, and was interested in music and pets. The last user is interested in music, with a weight ratio as high as 31%, and pays attention to food, military affairs, and pets as shown in Figure 5.

4.3. Analysis of Marketing Strategy and Recommendation Effect. After using network and model to extract users' attributes effectively, enterprises can adjust different markets and optimize marketing strategies for different types of users. We analyzed and counted the increased percentage points of 8 adjusted marketing strategies, and compared the click-through rate, activity, and turnover of goods or services with

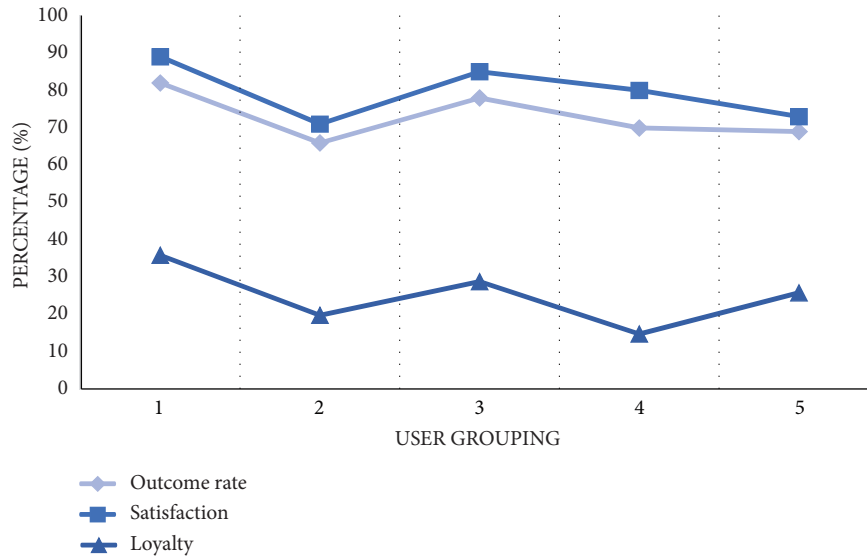

FIGURE 7: Recommended effect feedback.

the data of traditional marketing models. From the curve trend in the figure, we can find that preferential promotion and hunger marketing have the best effect, and the click-through rate and activity have increased by more than 20%. Secondly, the new product launch and group purchase/spelling strategy bring considerable benefits. Other strategies have increased to varying degrees, which proves that the adjusted and optimized model is very practical as shown in Figure 6.

After adjustment, this section also needs to evaluate the effect of the optimized strategy. Recycling five groups of users (10 people in each group) in the marketing achievement rate, consumer satisfaction, and brand loyalty of these three indicators of evaluation. According to these data, we can evaluate the actual effect and true value of the model after use, so as to carry out feedback and correction work. Because of different marketing strategies and individual differences, the index value of each group fluctuates to a certain extent. From the perspective of marketing results, the values of the five groups are between 69% and 82%, which has good results; consumer satisfaction is between 70% and 90%. However, brand loyalty needs long-term accumulation of word of mouth, so it is generally low, which needs further testing and research as shown in Figure 7.

5. Conclusion

Traditional marketing relies on the investment of manpower and capital and needs a large number of advertisements to put into the market, so as to arouse customers' desire to buy, establish the image of products, and make them deeply rooted in the hearts of the people. Customers can only choose the products and services provided by merchants or enterprises within a certain range, ignoring their different feelings. However, due to the rise of e-commerce, consumers are more willing to choose products with personality signs, low cost and good quality, and guaranteed after-sales service. Traditional marketing strategy in this online shopping trend does not have much effect, enterprises need an optimization

model that can constantly adjust marketing strategy. Based on this research background, the experiment in this paper takes the Internet as the basic business environment and enriches the field of personalized recommendation from all aspects and angles. Combining the purpose of the previous sale with the existing demand, we will promote e-commerce marketing that is accurate to everyone. Customers can enjoy high-quality services and fully meet individual needs. Enterprises also exceed their marketing objectives while expanding their influence, which has certain practical value. In this paper, combined with multi-modal data, the experiment based on a deep learning model can be done, and the completion and accuracy of the results are satisfactory. Because the research of deep learning is still in the development stage, there are many places that need to be further revised and improved in this experiment. In addition to the challenges faced by the fusion model algorithm, future research work should focus on the dynamic development process of marketing strategy facing the market. At present, the push function of marketing is relatively simple, which is only for the products that users are interested in. It can also appropriately enhance the broadcasting of online advertisements and send a variety of preferential policies for promotions and discounts to attract more customers. There is still a lack of inspection and analysis of overall operation defects, so as to ensure the normal operation of equipment in actual deployment. More data sets and features are still needed for testing, and the variability of parameters in different scenarios is worth exploring.

Data Availability

The experimental data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding this work.

With the wide application of artificial intelligence and big data technology in the medical field, the problems of high cost and low efficiency of traditional pharmacy management were becoming more and more obvious. Therefore, this paper proposed to use data mining technology to design and develop the dispensing process and equipment of intelligent pharmacy. Firstly, it summarized the existing data mining technology and association rule methods and expounded its application value in the related fields. Secondly, the data standard and integration platform of dispensing in intelligent pharmacy were established. Web service technology was used to design the interactive interface and call it to the intelligent device of pharmacy. Finally, an intelligent pharmacy management system based on association rule mining was constructed through the data mining of intelligent pharmacy equipment, in order to improve the intelligence and informatization of modern pharmacy management. For the emergency dispensing process of intelligent equipment failure, data mining was used to optimize the intelligent pharmacy equipment and dispensing process and change the pharmacy management from traditional prescription to patient drug treatment, so as to improve the dispensing efficiency of intelligent pharmacy equipment. Through the systematic test and analysis, the results showed that through the real-time risk prevention and control, the formula accuracy and operation speed of the intelligent dispensing machine were improved and the dispensing time was shortened. Through intelligent drug delivery, the unreasonable drug use of patients was reduced, the safety and effectiveness of clinical drug use were ensured, and the contradiction between doctors and patients was reduced. This study can not only optimize the medical experience of patients and provide patients with more high-quality and humanized pharmaceutical technical services but also provide some support for the intelligent management of modern hospitals.

1. Introduction

In recent years, with the rapid development of artificial intelligence and big data technology, the automation and intelligent management level of hospital pharmacies has been rising, and intelligent pharmacies have been used in some hospitals one after another. Compared with the traditional hospital pharmacy mode, the intelligent pharmacy service mode changes the traditional guarantee of drug supply into focusing on strengthening the pharmaceutical professional and technical services and participating in the dynamic management of clinical medication, so as to improve the management level of hospital pharmacy to a new level [1, 2]. In July 2018, the National Health Commission and the State Administration of Traditional Chinese

Medicine issued relevant documents and encouraged qualified medical institutions to promote the construction of smart pharmacy, so as to realize the seamless connection between prescription system and pharmacy dispensing system, so as to facilitate people to take medicine in time.

The construction of intelligent pharmacy mainly involves relevant intelligent equipment, database software, and interface technology. It needs to integrate different software and hardware technologies, which has the characteristics of diversity and cross platform [3]. In the construction planning of hospital information system, the business module of the hospital is generally considered, while the overall planning of medical industry information system is less. Due to the lack of effective top-level design and standard specification requirements, there are great differences in database

types and data formats involved in different information systems. At the same time, there are some problems in the construction of business information system of functional departments, such as insufficient function integration and different data interface standards, which leads to the widespread phenomenon of information island [4]. Traditional medicine management has seriously hindered the sharing of medical information and the improvement of medical service level, restricted the data sharing and resource utilization and allocation efficiency of intelligent pharmacy management information, and affected the time of taking and waiting for drugs and the quality of pharmaceutical care.

Research shows that some developed countries have effectively improved work efficiency and reduced deployment errors and labor intensity by realizing the automatic and intelligent management of pharmacies [5]. From the development trend of modern pharmaceutical industry, improving the overall application efficiency of intelligent pharmacy system and the accuracy of prescription review has become an inevitable trend of pharmacy management and development. At present, people have made a preliminary study on the intelligent efficiency of the same brand of equipment. Some people apply data mining to the market analysis, sales prediction, and intelligent drug preparation of automated pharmacies, which provides a basis for the establishment of the working mode of the automatic dispensing system of large-scale comprehensive outpatient pharmacies [6]. It is known from the existing research that the existing achievements have not conducted in-depth research on the unification of various intelligent device interfaces and data standards in the intelligent pharmacy, as well as the deployment and dispensing of various devices. Therefore, the existing intelligent drug management is still difficult to meet the needs of practical application. Therefore, this paper proposed to use data mining to study the deployment efficiency and intervention function of various intelligent devices in intelligent pharmacy, in order to provide theoretical reference for improving the modern management level and service function of intelligent pharmacy.

2. Related Works

With the gradual standardization of drug management under the situation of medical reform, in order to improve the capital turnover rate and reduce the cost, the hospital has adjusted the drug reserve of pharmacy accordingly. The hospital has optimized the types, quantity, and reserves of drugs, and tried to keep the balance of the use and management of drugs in stock. Through market analysis and sales forecast, some people use data mining to analyze drug sales data and inventory, and increase or decrease relevant drugs in real time, so as to maintain a dynamic balance of inventory [7, 8]. Through the given pharmacy inventory and sales data, the information is analyzed by using data mining technology, and the results are fed back to the drug warehouse, so as to effectively prevent the extrusion or shortage of drug inventory, which can not only meet the clinical needs, but also reduce the cost.

Outpatient medicine has a certain randomness. As a part of it, outpatient pharmacy should not only meet the needs of patients, but also ensure the standardized management of internal personnel. Some people use data mining technology to analyze the service information of outpatient pharmacy, and provide support for outpatient pharmacy service by evaluating the cost and risk of pharmacy. At the same time, according to the correlation degree of different links in the pharmacy service process, association rules are used to optimize relevant service matters, so as to reduce the waiting time of patients [9]. By optimizing the workflow of outpatient pharmacy, we can not only improve the allocation efficiency of drugs, but also reduce the waiting time of patients, so as to improve the service quality and level of pharmacy.

In modern intelligent pharmacy management, different types of drugs have certain differences in access efficiency. Generally, there may be some time differences when accessing the drugs in different storage locations [10]. Especially when the type and quantity of drugs change, the storage position of drugs needs to be adjusted. At the same time, the randomness of patients' demand for drugs should be fully considered in the design of pharmacy storage space. For example, patients may put forward the demand for different drugs. According to the dispensing characteristics of pharmacies, some scholars used data mining to analyze drug data and prescription information, and designed drug storage according to the batch number, distance, and relevance of drugs, and achieved certain results.

Data mining is widely used in the field of hospital pharmacy and its management [11, 12]. From the existing research results, compared with the traditional manual inference and experience, using data mining to manage the intelligent pharmacy is not only more efficient, but also more reliable. Intelligent pharmacies have high requirements for fine management and dispensing efficiency of drugs. The management of intelligent pharmacy needs the support of various intelligent devices [13]. For example, as a part of the dispensing machine, the intelligent medicine cabinet can effectively improve the efficiency and accuracy of drug dispensing only by tapping the design and functional potential of the medicine cabinet. The research shows that only by creating certain conditions for the use of intelligent medicine cabinet, can it give full play to its due effect. For example, intelligent medicine cabinet is not suitable for the storage of refrigerated drugs. Therefore, it is still difficult to obtain reliable results from drug data by using traditional data mining methods.

3. Data Mining Theory

3.1. Data Mining Method. According to the massive data provided by data warehouse and other data sources, data mining extracts the required relevant knowledge by means of mining calculation or knowledge discovery, so as to provide the basis for decision-making and analysis for relevant departments or personnel. For different research purposes, researchers' understanding of data mining may be different. Some scholars believe that the content or process

of data mining and database knowledge discovery (KDD) is similar, while others believe that data mining belongs to a stage of knowledge discovery, and there are obvious differences between data mining and knowledge discovery in related connotation. This paper mainly understands data mining from the broad concept and divides it into different stages, such as data acquisition, pro-processing, data analysis, and knowledge representation.

At present, the content of data mining generally includes descriptive objects or predictive objects. Descriptive objects mainly use certain data mining algorithms to explore the correlation between data. The results explored from descriptive information need to be further verified by relevant data. Predictive data is mainly used to predict possible future events based on known phenomena, which has strong purpose. It can be seen that the descriptive information reflects the hidden law within the data, while predictive data reflects the possible results in the future.

Different from the existing data analysis methods, data mining adopts automatic statistics and analysis methods, which can not only find out the valuable information inside the data, but also predict the future development trend or change law through the obtained useful information. Data mining can analyze the correlation of massive data, which is more efficient than the traditional analysis methods. At the same time, data mining can use clustering algorithm to realize the statistical analysis of discrete data and obtain the relationship between discrete information. In addition, data mining generally processes the relevant knowledge or information under unknown conditions and obtains the results, which is completely different from the traditional data analysis methods. With the development of related technology, the analysis object of data mining is no longer limited to structured data, but extended to almost any type of data processing, such as semi-structured or unstructured data information, which provides powerful conditions for making relevant decisions in different fields.

Fayyad model and CRISP-DM model are generally adopted in the process of data mining [14, 15]. Fayyad model is divided into nine different stages: data preparation and selection, data dimensionality reduction and transformation, knowledge evaluation, and so on. The model has no specific data source and result destination in the whole process from the beginning of data processing to the final result, so its application is not strong. Different from Fayyad model, CRISP-DM model combines the specific application environment. CRISP-DM model gives a more detailed description of the data to be processed, that is, data source and selection. At the same time, it also gives application reference for the output results of the model, so as to ensure the integrity of data source, data processing, and application results. As shown in Figure 1, the basic working process of data mining is described.

In the process of data mining, the tasks to be processed mainly include data classification analysis, cluster analysis, and association analysis. Data classification mainly analyzes and processes different data to obtain the common attribute information between data, and then attribute it to different classification models [16]. Clustering mainly adopts

unsupervised learning method, and uses the similarity of data to divide classes, and then classifies different data into different categories according to their attributes. Association mainly explores the internal relationship according to the attribute information between different data, so as to find the correlation between data. In practical application, parameters such as support and confidence are generally used to evaluate the correlation between different data.

3.2. Association Rule Mining. Association rule method is a part of data mining technology. This method is often used to deal with the internal relationship between things. It has certain stability and flexibility, and is not limited to the treatment of dependent variables. Therefore, it can provide effective support for the application of data mining in related fields [17, 18].

According to the existing research, the basic methods for association rules are as follows:

- (1) If P and Q are disjoint data item sets in database M , that is, $P, Q \subseteq M, P \cap Q = \Phi$, then association rules can be expressed as implication in the following form:

$$R: P \longrightarrow Q. \quad (1)$$

- (2) If the support of rule Q is expressed by S , S means that $S\%$ of transactions in M contain $P \cup Q$, and the support can be expressed by $Sup(R)$, which is as follows:

$$\begin{aligned} Sup(R) &= S \cdot M \cdot 100\%, \\ S &= Sup(R), P \cup Q \subseteq M. \end{aligned} \quad (2)$$

- (3) If the confidence of rule Q is represented by T , then T means that $T\%$ of the transactions in M and N that support P also support Q . The confidence can be expressed by $Con(R)$, which is defined based on conditional probability as follows:

$$Con(P \longrightarrow Q) = p\left(\frac{Q \subseteq N}{P \subseteq M}\right), \quad (3)$$

$$p\left(\frac{Q \subseteq N}{P \subseteq M}\right) = \frac{p(Q \subseteq N \cap P \subseteq N)}{p(P \subseteq N)}, \quad (4)$$

$$\frac{p(Q \subseteq N \cap P \subseteq N)}{p(P \subseteq N)} = \frac{Sup(P \cup Q)}{Sup(P)}. \quad (5)$$

According to the above equations (3) to (5), the following relationship can be obtained:

$$Con(P \longrightarrow Q) = \frac{Sup(P \cup Q)}{Sup(P)}. \quad (6)$$

If $MinSup$ represents the minimum support and $MinCon$ indicates the minimum confidence, when $Sup(R) \geq MinSup$ and $Con(R) \geq MinCon$, Q can be considered as a strong association rule. It can be described as follows:

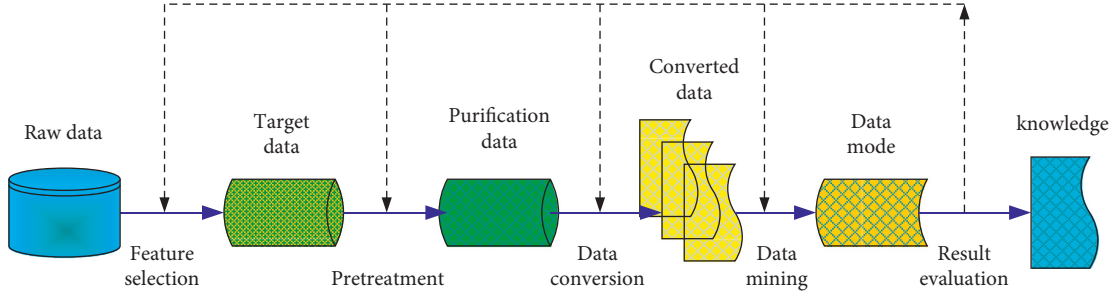

FIGURE 1: The basic working process of data mining.

$$R: P \Rightarrow Q. \quad (7)$$

Support is mainly used to reflect the effectiveness of association rules, while confidence is used to describe the credibility of association rules. Generally speaking, the mining of association rules should meet the minimum support threshold of user needs in order to reflect the minimum association between projects. At the same time, the confidence of mining rules should reach the lowest threshold, so that the reliability of mining rules should also reach the lowest. Therefore, the mining of association rules should reach the minimum support and minimum confidence, that is, the mining of association rules should meet the following conditions:

$$\begin{aligned} \text{Sup}(P \cup Q, M) &\geq \text{MinSup}, \\ \text{Con}(P \Rightarrow Q) &\geq \text{MinCon}. \end{aligned} \quad (8)$$

According to the existing research, item set refers to the set of items, and i -item set refers to the item set containing i items. The sum of the number of transactions that contain the item set is called the frequency of the item set, also known as the support rate of the item set. If the item set is greater than the minimum support, it can be called a frequent item set. D_i represents the sum of all frequent i -item sets.

Mining association rules mainly include finding frequent item sets and obtaining strong association rules through frequent item sets. When searching for frequent item sets, the frequency of item sets cannot be less than the minimum support. In order to obtain strong association rules, it is necessary to ensure that the rules are greater than the minimum support and minimum confidence.

Association rule mining methods can be classified from different angles. Firstly, in terms of the types of variables handled by association rules, association rule mining methods can be divided into Boolean and numerical types [19]. Boolean association rules mainly deal with discrete objects. This method only considers the existence of data items without knowing the number of data items. Numerical association rules mainly deal with the relationship between data items. The data item set processed by this method contains at least one data item belonging to numerical type. Secondly, from the data abstraction level processed by association rules, association rule mining methods can be divided into single-level association mining and multi-level association mining. The data items processed by the single-

level association mining method belong to the same level, while the data items processed by the multi-level association mining method may belong to different levels. In addition, according to the data dimension processed by association rules, association rule mining methods can be divided into single-dimensional association mining and multi-dimensional association mining. If the attribute of the processed data item is single, the association rule mining is single-dimensional association mining. If the attribute of the processed data item is multiple, the association rule mining is multi-dimensional association mining. The object processed by the single-dimensional association mining method is the relationship between single attributes, while the object processed by the multi-dimensional association mining method is the relationship between multiple attributes.

3.3. Association Rule Algorithm. Apriori algorithm can be used to get the required frequent item sets and obtain the corresponding association rules. Apriori algorithm mainly finds all frequent item sets through two different stages. Apriori algorithm forms the preliminary item set with the length of $i + 1$ from the frequent item set with the length of i through the layer-by-layer iterative method, and then forms the frequent item set with the length of $i + 1$, so as to obtain the corresponding association rules [20].

After setting the minimum support, start running the Apriori algorithm. First, calculate the support of each item one by one through scanning to form a frequent 1-item set, and then traverse i times until the obtained frequent item set is empty, and then stop the algorithm. The running process of Apriori algorithm is shown in Figure 2.

Apriori algorithm needs to scan the database many times in the process of data mining, which brings a large workload to the input and output of data. Moreover, Apriori algorithm may produce a large number of pre-selected item sets in the running process, which increases the running time and memory overhead of the algorithm to a certain extent. Therefore, FP-tree algorithm can be used, which can effectively obtain the association rules by generating frequent item sets [21, 22].

In order to improve the efficiency of obtaining the association rules, some people improve FP-tree algorithm and propose FP-growth algorithm. When using this algorithm, firstly, the database is scanned once, and the generated frequent item sets are added to the frequent pattern tree. Then, the association information between item sets remains

FIGURE 2: The running process of apriori algorithm.

unchanged. Then, the generated FP-growth is divided into different condition trees, and each condition tree corresponds to a frequent item set. Finally, the condition trees are mined in turn. FP-growth algorithm can be effectively applied to different rules, and it is better than the other algorithms in efficiency.

4. Deployment of Multiple Intelligent Devices in Intelligent Pharmacy

4.1. *Construction of the Data Integration Platform for the Intelligent Pharmacy System.* Web service is an Internet-based development model proposed by Microsoft [23]. It provides services for other applications through web communication protocol and open standards of information format (HTTP, XML, and soap). The integrated platform involves software suppliers such as his system (Beijing Donghua, cache database, and software architecture B/S), Tangshan automatic medicine dispenser system (Japan, SQL Server database, and software architecture C/S), medicine taking and reporting machine system (Great Wall, MySQL database, and software architecture C/S), Weilehitz whole box dispensing consis system (Shanghai, SQL database, software architecture is dbo), and Shenzhen weisi'an drug intelligent management system. The system interface technologies include Webservice, XML, Webservice + XML.

After data mining the information stored by various intelligent devices, the format and interactive content of

pharmacy data information can be further unified, and the corresponding interface program can be developed. Collect the interface documents of all intelligent devices and establish a unified pharmacy dispensing database. The main data tables are as follows:

- (1) *Basic Data Sheet of Drug Information.* This table mainly includes drug code, alias, trade name, English name, category, dosage form, specification, minimum specification, packaging unit, large packaging unit, packaging conversion factor, dose unit, minimum unit dose, dose conversion factor, drug price, manufacturer, manufacturer code, approval number/registration certificate number, storage conditions, storage type, and stop sign.
- (2) *Pharmacy Drug Storage Location Data Sheet.* This table mainly includes drug number, storage location information, drug batch, drug batch number, production date, expiration date, and storage location inventory quantity.
- (3) *Hospital Department Basic Data Sheet.* This table mainly includes department number, department name, and department category.
- (4) *Pharmacist Basic Information Data Sheet.* This table mainly includes pharmacist number, pharmacist job number, department number, pharmacist name, professional title, and job category.

- (5) *Prescription Information Data Sheet*. This table mainly includes prescription time, prescription number, patient name, medical card number, invoice number, patient type, patient birth date, patient gender, patient identity, medical insurance type, prescription attribute, prescription type, diagnostic information, prescription remarks, number of doses, expenses, paid in expenses, billing department number, billing department name, prescribing doctor, dispensing priority, drug name, drug specification, manufacturer number and manufacturer name, drug packaging specification, drug packaging unit, drug dose, dose unit, drug usage, drug dosage, supplementary usage, prescription details, and remarks.
- (6) *Prescription Window Information and Screen Call Information Data Sheet*. This table mainly includes dispensing window, dispensing time, dispensing man number, dispensing person's name, call number display information, drug return time, quantity, drug return person's name, and work number and other information.

In order to meet the various needs of pharmacies, intelligent pharmacy equipment and its control system can be used to improve the prescription allocation efficiency and information management level of modern hospitals. The intelligent pharmacy uses semi-automatic equipment to receive the electronic prescription provided by the hospital management system. Through data mining and information association processing, it compares the drug information stored in the upper computer, sends relevant instructions to the lower computer through the data bus, allocates the drugs required by the patients to the drug outlet, reminds relevant personnel to extract the corresponding drugs, and then transmits them to the patients from the drug distribution window after verification.

The intelligent pharmacy control system is mainly composed of upper computer control and lower computer control. Its control system and distribution are shown in Figure 3.

In the intelligent pharmacy control system, the upper computer system mainly receives and processes the prescription information from the hospital by using the data mining method, obtains the drug distribution in the dispensing prescription by associating the data, and then sends instructions to the lower computer system. Then, allocate the corresponding bin to the medicine outlet for relevant personnel to take medicine for dispensing, and receive the feedback message from the lower computer at the same time. When the drug treatment is finished, send the prescription to the window, and return the prescription to the patient after the relevant personnel check the dispensing prescription. The lower computer system mainly receives the instructions from the upper computer system and processes them through data mining. Then, send the instruction to the corresponding intelligent device, transfer the instruction to the drug outlet through the corresponding bin of the device, and display the corresponding instruction and drug

information on the man-machine interface board for the staff to take the medicine. When the above operations are completed, the results are transmitted to the upper computer system to feed back relevant information.

4.2. Intelligent Pharmacy Management System Based on Association Rule Mining. Association rule mining for medicine is mainly based on the prescription drug information provided by the hospital database to mine the information hidden between drugs with certain association. Because the hospital medical database stores a large amount of information occurring in the medical process, including clinical medical diagnosis information and medical management information, the medical data information has a wide range of sources and a large scale. Medical data information usually has certain characteristics. Medical data usually show some heterogeneity and complexity, and medical academic language is relatively rich, which brings some difficulties to the processing of medical information by data mining. Medical data has certain privacy, that is, the privacy of patients. In the process of data mining, we should not only protect the privacy of patients, but also ensure the security of relevant data. Medical data has certain diversity, that is, the establishment of medical database is based on medical experimental observation, doctor diagnosis, and communication between doctors and patients. Therefore, medical data have various forms, which is also the characteristic of medical data different from other types of data information. Medical data has certain relevance, that is, the data in cases may be related to each other. For example, there is often correlation between symptoms, therapies, prescriptions, and drugs, which can be explored by association rule mining. Medical data has certain repeatability, that is, the case data stored in the medical database will inevitably have some duplicate information. Association rule mining method can be used to find the hidden rules in the data. It can be seen that although a large number of medical data are diverse and complex intertwined, on the basis of data pre-processing, association rules can be used to mine the internal laws of medical data.

Considering that the purposes of data mining may be different in practical application fields, the process of data mining is related to specific application fields. For medical data mining, mainly according to the medical information resources stored in the hospital database, the data mining algorithm is used to mine the knowledge with certain correlation between the data. The specific mining process of medical data is as follows:

First of all, make relevant preparations and clarify the main objectives and work steps of medical data mining. On the basis of mastering the characteristics of medical data, pre-process the information stored in medical database with standardization and structure, so as to provide effective guarantee for the mining of association rules. Secondly, according to the goal of medical data mining, appropriate data mining algorithms are used to obtain the required information, and the mining results are analyzed and evaluated. Finally, test the results, decide whether to further

FIGURE 3: Structure and distribution diagram of the intelligent pharmacy control system.

mine the medical data according to the feedback results, and apply the final data mining results to the actual system.

As shown in Figure 4, it reflects the framework of intelligent pharmacy management system based on association rule mining.

4.3. Optimization of the Intelligent Pharmacy Management System. Based on the constructed data integration platform and intelligent pharmacy, the original dispensing process of pharmacy can be further optimized, and the integrated platform and unified data standard can be developed. At the same time, the dispensing process of outpatient prescriptions and emergency prescriptions can be improved by using the standard interface provided by intelligent devices, as shown in Figures 5 and 6.

Considering that various devices in the intelligent pharmacy may fail during use, the emergency dispensing process in case of failure of intelligent devices in the pharmacy is optimized through the construction of data integration platform.

5. System Test and Result Analysis

5.1. System Integration. In 2018, the outpatient pharmacy of our hospital carried out the transformation and construction of intelligent pharmacy, and introduced the first fully automatic integrated dispensing machine, intelligent medicine rack, transportation track, and other intelligent and automatic advanced equipment of pharmacy in Japan. The his system is connected with the pharmacist workstation, which realizes the preliminary intellectualization and automation of drug dispensing in the hospital, and changes the existing mode of manual dispensing and distribution of drugs in the hospital pharmacy. In 2021, weilehitz (Shanghai) was introduced to integrate intelligent equipment such as dispensing machine, and an integrated platform was built by using web service technology to integrate all kinds of servers, high-performance processors, and medical databases through the development and management environment system. According to the prescription data characteristics of various intelligent devices in intelligent pharmacy, data mining technology is used to analyze the relevant

FIGURE 4: The framework of intelligent pharmacy management system based on association rule mining.

information, so as to improve the intelligent degree, dispensing efficiency, dispensing speed, and quality of pharmacy.

5.2. Result Analysis

5.2.1. Comparative Analysis of Equipment Faults. The equipment failures and errors of the dispensing machine from July to September 2020 were statistically analyzed. The main problems occurred in the whole machine drug receiving basket, drug delivery, drug delivery receiving basket,

transmission process, drug lifting, machine restart, drug filling, and other links. In view of various problems, the replacement or transformation and upgrading of relevant equipment were carried out, and the faults and errors of the optimized intelligent pharmacy equipment were statistically analyzed from July to September 2021. The results showed that the failure rate of the system was reduced by 45.27% on average, which effectively improved the operation stability of intelligent pharmacy. The comparison results of faults and errors before and after optimization of intelligent pharmacy equipment are shown in Table 1.

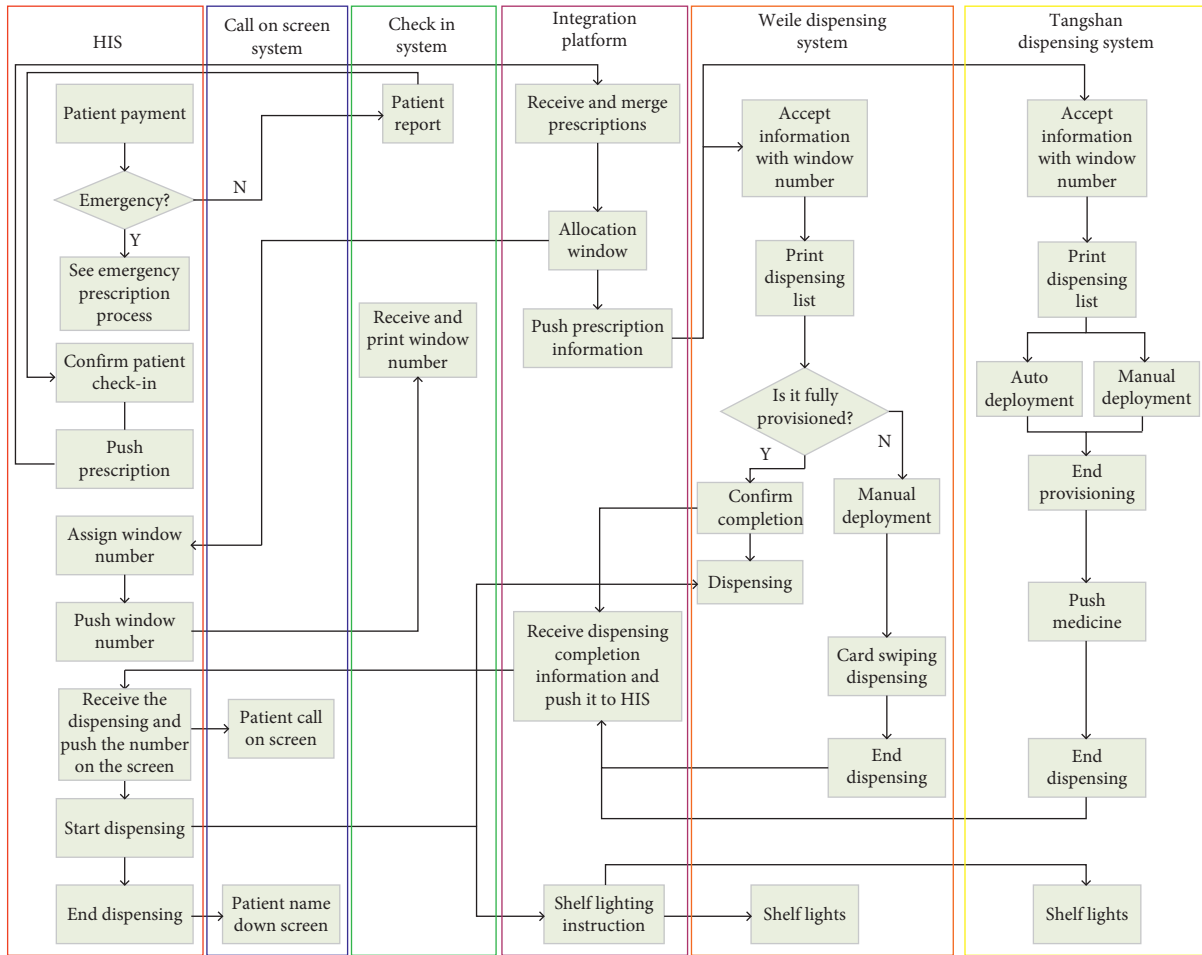

FIGURE 5: Outpatient prescription dispensing process after system optimization.

5.2.2. *Analysis of Allocation Efficiency.* From July to September 2020, the medical data sent by HIS system received by the dispenser every day were mined and analyzed, and the difference between the prescription payment time of patients in the outpatient department and the dispensing processing time of the dispenser was compared. As shown in Figure 7, it was the average waiting time of patients before building the data platform. Through data mining and association rule processing, the main reasons for the delay of dispensing machine were obtained. These factors mainly included the slow dispensing speed of the dispenser itself, the lack of drugs, the blockage of the dispensing basket due to the failure of the dispensing personnel to take drugs in time at the peak, and the blockage of the transportation of the medicine basket due to the failure of the dispensing personnel to take drugs in time. In addition, the deployment delay may also be caused by the networking delay of drug dispensers, drug errors, basket string, etc.

Aiming at the problem of dispensing delay of dispensing machine, this paper used data mining to analyze the prescription data of various intelligent devices in intelligent pharmacy, adopts data integration management, and optimized the dispensing machine and other intelligent devices in pharmacy. Then, the medical data were mined and analyzed from July to September 2021, and the waiting time of patients was compared. As shown in Figure 8, it was the average waiting time of patients after building the data platform. According to the comparison results of the average waiting time of patients before and after the construction of the data platform, it was known that the intelligent pharmacy after the construction of the data platform can significantly improve the dispensing efficiency, dispensing speed, and quality.

Through the construction of data integration platform and prescription data mining, the use of various intelligent devices in the pharmacy had been optimized, the dispensing

FIGURE 8: Average waiting time of patients after building the data platform.

efficiency of the pharmacy had been improved, and the waiting time of patients in peak hours had been shortened.

6. Conclusion

This paper studies the design and development of intelligent pharmacy, and establishes the dispensing data standard and integration platform of intelligent pharmacy. Web service technology is used to design the interactive interface, which can be called by various intelligent devices. It is also used to standardize the emergency dispensing process of various intelligent equipment failures, optimize the intelligent pharmacy equipment and dispensing process by using data mining, and improve the dispensing efficiency of intelligent pharmacy equipment. Through the data mining of intelligent pharmacy equipment, the intellectualization and informatization of modern pharmacy management are improved. Change the pharmacy management from traditional prescription based to patient-centered drug treatment. Through real-time risk prevention and control, the formula accuracy and operation speed of the intelligent dispensing

machine are improved, and the dispensing time is shortened. Through intelligent drug delivery, the unreasonable drug use of patients is reduced, the safety and effectiveness of clinical drug use are ensured, and the contradiction between doctors and patients is reduced. The research results obtained in this paper can not only reflect the professional technical value of pharmacists and change the pharmaceutical care mode, but also optimize the medical experience of patients, so as to provide patients with more high-quality and humanized pharmaceutical technical services. This study can provide some reference for modern hospital intelligent management and its economic and social benefits.

In the analysis of the teaching tactical characteristics of track and field sports training in colleges and universities, the teaching tactical characteristics are not quantified, which leads to the low key degree of determining the influencing factor indicators in colleges and universities, and the error in the evaluation of the teaching tactical characteristics of track and field sports training is large. Therefore, this paper designs a method to analyze the tactical characteristics of college track and field sports training teaching based on deep neural network. Firstly, by analyzing the current situation of track and field sports training teaching in colleges and universities, it determines the areas that need to be improved in teaching. Then, by determining the factors of teaching environment, the core competitiveness of track and field teams, and the teaching ability of track and field coaches, these factors are determined as the key characteristics, the data basis is analyzed, and the unified data quantitative processing is carried out to determine the key factor indexes affecting the analysis of tactical characteristics. Finally, the deep neural network is introduced to construct the evaluation model of the tactical characteristics of college track and field sports training teaching, and the characteristic analysis results are further modified with the help of cascade noise reduction self-encoder to complete the analysis of the tactical characteristics of college track and field sports training teaching. The experimental results show that the proposed method can effectively analyze the teaching tactical characteristics of track and field sports training in colleges and universities and improve the performance of the evaluation of the teaching tactical characteristics of track and field sports training.

1. Introduction

College track and field training is an important part of school physical education. Track and field is one of the key items of school physical education teaching and after-school training. It has the advantage of talent concentration and wide popularity [1, 2]. Track and field training is the basic training stage of track and field. It is the key stage to develop sports quality, learn and master track and field technology, and improve track and field ability. Paying attention to and strengthening track and field training is an important link to improve the overall training level of track and field [3]. Track and field sports play a positive role in realizing the knowledge, technology, and skills of sports in college physical education and improving students' physical and psychological quality and social adaptability. However, in

the process of deepening the reform of physical education teaching in colleges and universities, it is found that the number of students participating in track and field is becoming less and less, and the students' understanding of the value of participating in track and field is becoming less and less. The school also makes track and field teaching more and more marginalized because of the students' weak awareness of track and field teaching [4]. At the same time, track and field teaching pursues the integrity and systematization of competitive events too much and only pays attention to the teaching of technical actions in running, jumping, throwing, and other events, and the teaching means are single. It can not develop students' relevant physical quality around a certain event, so students' subjectivity and creativity are difficult to play. Only by making the track and field teaching concept clear and the goal clear and paying attention to a

series of problems such as teaching content, teaching methods, and textbook selection, can the track and field teaching reform in colleges and universities not be in a chaotic and fuzzy state and can a clear main line be provided for the reform and development of track and field teaching in colleges and universities [5, 6].

How to cultivate track and field sports talents who can shoulder the historical mission and have practical ability and innovation ability, constantly keep pace with the times, improve track and field sports training tactics, implement effective training tactics, and improve the quality of track and field training has become the top priority to be solved by China's colleges and universities of physical education [7]. Therefore, relevant researchers have made a lot of analysis on the tactical characteristics of track and field training in colleges and universities. Literature [8] designed a simulation training method and studied its application in track and field training tactics. In this technology, in order to ensure that athletes can play a better level in the competition, coaches should not only strengthen the training of their physical quality, but also let them fully master and use sports technology, which is a vital way and means in training. Once the psychological and special situation handling skills training is ignored, it will affect the normal competition of athletes and even lead to the loss of the competition. Therefore, this paper mainly analyzes the main advantages and characteristics of track and field simulation training and puts forward the specific application of simulation training method in track and field situation. It aims to promote athletes to have a good psychological and physical state in the process of competition, so as to give full play to their best potential and level and finally win the ideal results. This study pointed out the psychological characteristics and sports characteristics of training technology but did not effectively quantify the detailed tactical characteristics and indicators. Literature [9] analyzes the influencing factors of physical fitness training in track and field sprint events. Take this as the research basis to improve the quality of training tactics. This paper points out that, with the rapid development of track and field sprints in China, the requirements for sprinters' competition skills and tactical level are becoming higher and higher. How to improve the quality of track and field sprinters' training plan and how to quickly enhance the physical quality of track and field sprinters have become the most concerned topic in the field of track and field sprinters' training. Physical training is an important basis for all skill training. In order to make sprinters give full play to their potential and win the sprint competition, physical training is the most indispensable and important factor. This paper will deeply analyze and explore the influencing factors and related contents of physical fitness training in track and field sprint. However, this article is highly theoretical and needs to further expand the main technical characteristics of the research.

In view of the shortcomings in the above analysis of the teaching tactical characteristics of track and field sports training, this paper designs an analysis method of the teaching tactical characteristics of track and field sports training in colleges and universities based on the deep neural

network algorithm to complete the analysis of the teaching tactical characteristics of track and field sports training in colleges and universities. The main technical route of this paper is as follows:

Step 1: by analyzing the current situation of track and field sports training teaching in colleges and universities, determine what needs to be improved in teaching.

Step 2: by determining the factors of teaching environment, the core competitiveness of track and field teams, and the teaching ability of track and field coaches, these factors are determined as the key characteristics, the data basis is analyzed, and the unified data quantitative processing is carried out to determine the key factor indicators affecting the analysis of tactical characteristics.

Step 3: introduce the deep neural network to construct the evaluation model of the tactical characteristics of college track and field sports training teaching, and further modify the characteristic analysis results with the help of the cascade noise reduction self-encoder to complete the analysis of the tactical characteristics of college track and field sports training teaching.

Step 4: conduct experimental analysis. Taking a university as an example, the effectiveness of the proposed analysis method is verified.

2. Current Situation of Track and Field Physical Training Teaching in Colleges and Universities and the Determination of Influencing Factors and Indicators of Tactical Characteristics

2.1. Analysis on the Current Situation of Track and Field Physical Training Teaching in Colleges and Universities

2.1.1. *The Meaning of Track and Field Training Is Vague.* The goal of track and field teaching in colleges and universities is to enhance students' physical qualities, help students form good physical exercise habits, and establish correct health awareness. However, in the actual teaching and training, many teachers pay too much attention to the cultivation of students' track and field skills, and take the learning results of track and field skills as the standard to measure students, but they lack accurate positioning for the cultivation of students' fitness consciousness and exercise consciousness. Due to the overemphasis on the integrity and technicality of track and field events in teaching activities and the neglect of students' acceptance ability, students' interest in track and field training is not high [10].

2.1.2. *The School Pays Less Attention to the Teaching Value of Sports Track and Field.* As a special field, the school field is a space with its own logic and inevitability composed of various objective relations including organization and system. Its interior follows its own unique logic, operation rules, and development track and has a restrictive effect on the

survival and development of school leaders and track and field teachers in the field. School field is a realistic factor that affects the value orientation of track and field teaching in colleges and universities. It is mainly reflected in the fact that the school field has more and more successfully made people learn fast, learn more, and learn well, but it has caused the forgetting of the meaning of “learning,” which is not used by people, makes people subordinate to “learning,” is trapped by “learning,” and suppresses the perfection and harmonious generation of people. Track and field classroom teaching is based on rational knowledge. The real life, quality of life, and life value of teachers and students are usually ignored, forgetting the humanistic care for teachers and students and the improvement of human nature [11].

2.1.3. The Organization Form of Track and Field Teaching Is Single. The organizational form of track and field teaching in colleges and universities is relatively single. Teachers often do demonstration actions, then explain step by step, and learn to imitate and practice repeatedly. In this form of teaching organization, teachers are the main body of classroom teaching, and students can only passively accept teachers’ knowledge indoctrination, so students’ learning enthusiasm is greatly affected. In addition, many teachers only pay attention to how much they have taught but ignore how much students have learned. As long as their teaching tasks are completed, they think they have achieved the purpose of teaching.

2.1.4. The Influence of the Inertia of Power Field on the Occupation of Track and Field Teaching Skills. As an objective social existence, the behavior and thought of educators and other educational participants are affected by the right field, and anyone’s survival and development are in a certain right field. Zimmer, a famous sociologist, pointed out that, in any situation of social interaction, people may have the difference between superior position and inferior position. He called this form of social relations with the advantages and disadvantages of position and position as “domination”; that is, the dominant person has the ability and opportunity to influence, decide, and control the inferior person. Looking at the track and field teaching environment of physical education departments in colleges and universities from the field of power, as long as we understand the power of the “test baton,” we can understand why the first place of skills is virtual, and only the students’ track and field standard score is real [12].

2.2. Determination of Influencing Factors and Indexes of Teaching Tactics of Track and Field Sports Training in Colleges and Universities. In order to more effectively highlight the effectiveness of this analysis method, first quantify the data on track and field sports training teaching characteristics in colleges and universities, convert it into certain data, and more intuitively analyze the tactical characteristics of track and field sports training teaching in colleges and universities. In the teaching of track and field sports in colleges and

universities, the teaching environment is the key to the tactical characteristics of track and field sports training and teaching in colleges and universities. Therefore, this paper determines the important indicators affecting the track and field teaching environment in colleges and universities and effectively quantifies them [13].

Taking the element structure system of track and field teaching environment in colleges and universities as the basis, according to the establishment principles of the evaluation system and drawing on previous research experience, this paper summarizes, divides, and compares the important indicators affecting the track and field teaching environment in colleges and universities, forms the conceptual indicators of track and field teaching environment in colleges and universities, and finally constructs the evaluation index system of track and field teaching environment in colleges and universities. The specific contents are shown in Figure 1.

According to the abovementioned evaluation index system of track and field teaching environment in colleges and universities, this teaching strategy is quantitatively analyzed. Because the track and field teaching environment is the main influencing factor, it can not directly transform the data. Therefore, with the help of coefficient of variation, the influencing factors are studied quantitatively. The coefficient of variation is the ratio of the standard deviation of the index to the weighted average. If the coefficient of variation is small, it means that the expert evaluation results are not dispersed or the degree of dispersion is small [14]. Generally, the coefficient should be less than the standard of 0.25. If it is more than or equal to, it means that the index lacks coscheduling. The calculation formula of the influencing factor index is

$$R_r = \frac{A_i}{v_i}. \quad (1)$$

Among them, R_r represents the coefficient of variation of track and field teaching environment factors. The smaller the value, the higher the coordination degree of the teaching environment on tactics. A_i represents the standard deviation of teaching environment influencing factors, and v_i represents the arithmetic mean of environmental factors.

In order to minimize the influence of the teaching environment of university track and field on the teaching tactics, the coordination coefficient is introduced to balance it. The meaning of the coordination coefficient is whether there is a large difference between the recommendations in the expert group. The accounting of the coordination coefficient can obtain the degree of expert coordination of the index. The coordination coefficient is represented by W , and the value is between 0 and 1. Use consistency test; if $P > 0.05$, the evaluation made by experts does not have strong credibility and the result is invalid; if $P < 0.05$, it has certain credibility and can be used. The calculation formula is

$$P = \frac{W}{\sum R_r}. \quad (2)$$

FIGURE 1: Evaluation index system of track and field teaching environment in colleges and universities.

According to the above calculation, the influence degree of track and field teaching environmental factors in colleges and universities is determined, which is regarded as a key factor affecting the characteristics of sky landing teaching tactics. In addition, it also includes other influencing factors, which also need to be quantified one by one.

Core competitiveness is the integration of various advantageous resources that have been continuously optimized and improved to form their own unique and difficult to imitate form. Its core competitiveness is not only different from its general competitiveness, but also related. The core competitiveness of high-level track and field teams is finally formed in the general competitiveness. It goes beyond the general competitiveness [15], so that it can maintain a stable, leading position and advantage in the field of track and field competition for a long time. The biggest feature of this difference is that it is not easy to be imitated by competitors and can form its own unique competitive advantage. Therefore, to analyze the elements of the core competitiveness of high-level track and field teams, we should extract the most core factors from many “seemingly” general competitiveness elements, because these factors are most likely to play a vital and irreplaceable role in the formation of the core competitiveness of high-level track and field teams in colleges and universities [16]. The schematic diagram of competitive core strength of college track and field teams is shown in Figure 2.

By analyzing Figure 2, it can be found that the current model has the following important characteristics: first, integrity. The model reflects the main components of the core competitiveness of excellent high-level track and field teams, and the content system is relatively complete. The

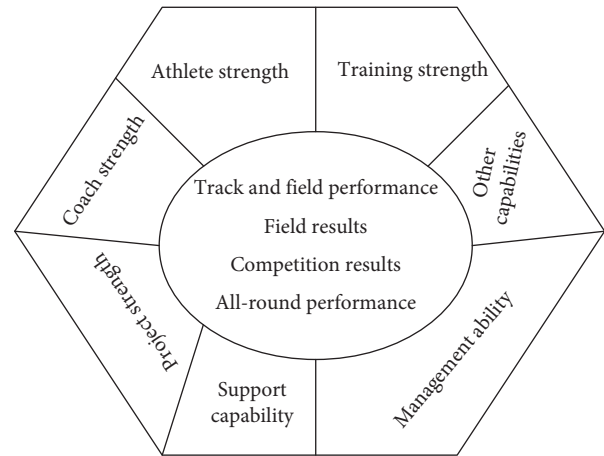

FIGURE 2: Schematic diagram of influencing factors of core competitiveness of college track and field teams.

second is scientific. The construction basis of this model is in line with the purpose and law of high-level track and field teams, the basic theory of core competitiveness construction, and the reality of running high-level track and field teams. It is highly scientific. The third is hierarchy, which is divided into three interrelated levels according to the relationship with competitive performance, reflecting the hierarchical principle of system theory, with rigorous logic and clear hierarchy. The fourth is the development and variability. This model expresses the meaning of the continuous operation of various elements of core competitiveness around the “expression of competitive achievements” and suggests that the composition of core competitiveness will change

with time and team running conditions. Only when the joint force of these elements can bring competitive advantages to the sports team, can the status of core competitiveness of various elements be stabilized; otherwise it may fall into the ranks of general competitiveness. Therefore, it has development and variability. In the quantification of the influencing factors, the importance of an aspect of the previous level is compared according to the factors in the same level, and the pairwise comparison judgment matrix is completed [17]. When the above layer factors are regarded as standards, the comparative standard b_{ij} can be adopted to represent the importance of competitiveness influencing factors. The judgment matrix composed is

$$B = \sum_{i=1, j=1} b_{ij}. \quad (3)$$

The constructed judgment matrix is tested, and the consistency and randomness of the matrix are tested. The following results are obtained:

$$C = \frac{c_i}{\eta_i}, \quad (4)$$

$$c_i = \frac{\lambda \max - k}{k - 1}, \quad (5)$$

where η_i represents the average random consistency criterion and c_i is a constant.

In the analysis of the tactical characteristics of track and field teaching in colleges and universities, the teaching ability of teachers, that is, coaches in track and field training, is also the key factor affecting the tactical characteristics. When evaluating the teaching ability of track and field coaches, we need to reflect their ability level through multiple indicators. The first step of this study is to classify the collected indicators. The second step is to screen and integrate the indicators with the same connotation and overlapping contents and rename them. On the basis of formulating the primary indicators, the Delphi method (the first round of expert questionnaire) is used to determine the candidate indicators of track and field coaches' teaching ability. Then make statistics of the feedback and further sort out and screen the corresponding indicators to determine the teaching ability index system of track and field coaches. The process is shown in Figure 3.

The contents of the teaching ability indicators of track and field coaches are shown in Table 1.

According to the abovementioned factors affecting the characteristics of track and field teaching tactics in colleges and universities, that is, the factors of teaching environment, the core competitiveness of track and field teams, and the teaching ability of track and field coaches, these factors are determined as the data basis of key characteristic analysis and unified data quantitative research [18]. The set of factors affecting the evaluation objectives is determined as follows:

$$E = \{e_1, e_2, \dots, e_n\}. \quad (6)$$

The comment set for establishing impact assessment objectives is

$$U = \{u_1, u_2, \dots, u_n\}. \quad (7)$$

Calculate the weight of each evaluation factor and the objective vector of impact assessment is

$$Q = \{q_1, q_2, \dots, q_n\}. \quad (8)$$

Using analytic hierarchy process to calculate the weight vector: carry out single factor fuzzy evaluation and determine the fuzzy relationship matrix; combined with the single factor evaluation vector of membership degree, complete the construction of multi-index comprehensive evaluation vector, and obtain

$$H_i = V \sum_{i=1}^n (E, U, Q). \quad (9)$$

According to formula (9), the results of fuzzy comprehensive evaluation are analyzed, and the quantitative influencing factors of track and field teaching tactical characteristics are taken as the key indicators of subsequent characteristic analysis. On this basis, the analysis of track and field teaching tactical characteristics in colleges and universities is improved.

3. Design of Evaluation Model of Teaching Tactics Characteristics of Track and Field Physical Training in Colleges and Universities Based on Deep Neural Network

3.1. Determination of Teaching Tactics Characteristics of Track and Field Physical Training in Colleges and Universities. Among the tactical characteristics of track and field teaching in colleges and universities, the characteristic of speed change is the external form of tactical application. The smooth implementation of tactics is reflected by athletes through the whole process of speed distribution and speed saving. Therefore, it can be said that the characteristics of speed change are the basis of tactical application. The main features are the following teaching tactics.

3.1.1. Leading Tactics. According to the different positions of athletes in the competition, the tactics can be divided into leading walking tactics and following walking tactics. The leading walking strategy refers to the strategy that athletes start walking at a faster speed at the beginning of the game, strike first, try their best to get rid of the opponent's follow, open the distance with the opponent, and lead all the way through the whole process [19]. The advantage of this tactic is that it can give full play to the physical, tactical, and psychological advantages of athletes without interference from opponents. It is suitable for athletes with good speed endurance, strong ability to walk at high speed for a long time, and special strength. The disadvantage is that the tactical speed changes greatly, the physical energy consumption is much, and the use is too risky. Therefore, it is not recommended to use it by ordinary athletes. If it is used blindly, it will often lead to the second half or final rush due to unreasonable physical distribution.

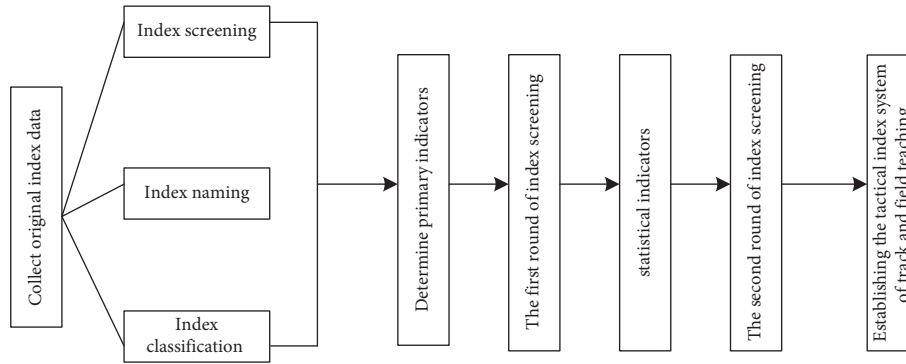

FIGURE 3: Process of teaching ability index system of track and field coaches.

TABLE 1: Contents of coaching ability indicators of track and field coaches.

Teaching ability	Content
Personal experience	Age, educational background, sports level, years, post training, etc.
Training ability	Diagnostic ability, prediction ability, designated plan ability, recovery ability, stimulation means, etc.
Teaching ability	Action modeling, explanation ability, sports equipment ability, learning ability
Competition guidance ability	Specify the program ability, organization and arrangement ability, and adjustment ability
Organization and management ability	Daily training and management, conflict resolution, etc.
Scientific research and innovation ability	Postgame summary, reflection ability, scientific research ability, etc.

In the stabbing stage, the physical strength is overdrawn, resulting in the situation of being surpassed by the opponent.

3.1.2. *Follow Tactics.* Following tactics refers to the tactics that athletes use faster speed to quickly seize a favorable position at the beginning of the competition, closely follow an athlete who is roughly consistent with their own rhythm and pace, and in the final sprint stage, attack later and surpass the follower or even the leader with the advantage of their own sprint ability. The advantage of using this tactic is that athletes only need to concentrate on following the followers, which not only reduces their psychological pressure, but also causes greater psychological pressure to the followers. In addition, from the perspective of hydrodynamics, compared with the follower, the follower resists certain air resistance because the follower leads in front, which makes the follower walk more labor-saving and less physical consumption. It is suitable for athletes with good speed and strong sprint ability, as well as competition in bad weather such as wind and rain [20]; its disadvantage is that the follower’s speed rhythm is easily disturbed by the follower. It is easy to put the follower in a passive position on the competition field.

3.1.3. *Uniform Velocity Tactics.* According to the speed changes of athletes in the competition, tactics can be divided into constant speed tactics and variable speed tactics. Uniform speed tactics refers to the tactics that athletes start and walk at a relatively uniform speed from the beginning of the game and maintain this speed to complete the whole process. The advantage of this tactic is that athletes can

determine the speed and rhythm according to their own competitive ability, and the physical consumption is small. It is suitable for athletes who create their best sports performance.

3.1.4. *Variable Speed Tactics.* Variable speed tactics refers to the tactics that athletes occupy a favorable position at a relatively fast speed at the beginning of the game, constantly adjust their physical fitness through speed control and rhythm changes, interfere with the opponent as much as possible, get rid of the opponent, and win the game. The advantage of this tactic is that it can not only disrupt the opponent’s speed change rhythm and break the functional balance of its internal organs and systems, but also cause greater psychological pressure on the opponent. It is suitable for athletes with high speed and endurance. Its disadvantage is that it consumes a lot of physical energy for athletes. If you cannot reasonably distribute your physical strength, it is easy to cause your own physical weakness.

3.2. *Evaluation Model of Teaching Tactics Characteristics of Track and Field Sports Training in Colleges and Universities.* According to the above extracted quantitative indicators of the influencing factors of the teaching tactical characteristics of college track and field sports training, in order to realize the analysis of the teaching tactical characteristics of college track and field sports training, this paper introduces the deep neural network algorithm [21] to construct the evaluation model of the teaching tactical characteristics of college track and field sports training and takes the quantitative indicators of the influencing factors of the teaching tactical

characteristics of college track and field sports training as the input data of the neural network, in order to complete the analysis of the teaching tactical characteristics of track and field sports training in colleges and universities.

3.2.1. Theoretical Basis of Deep Neural Network Algorithm. Deep neural network is an important branch of machine learning. Deep learning method has the ability to extract abstract features. Compared with machine learning, it does not need to extract features manually but automatically extracts basic features from samples. Then, some more advanced features are extracted layer by layer, such as lines, local structure, and so on. Finally, effective fitting results are obtained by updating model parameters similar to machine learning. The basic neural network structure is shown in Figure 4.

In Figure 4, the circle in the graph represents a neuron, x_i represents the i th input signal, z_{ij} represents the weight of the signal effect on the neuron j to simulate the strength of the synapses, μ_{ij} represents a threshold, and $y(x)$ represents the activation function after the neuron reaches the threshold, requiring that its nonlinearity is differentiable. The last current layer i th output signal t_i may be expressed as follows:

$$t_i = y\left(\sum_{i=1}^n z_{ij}x_i + \mu_{ij}\right). \quad (10)$$

The neural nodes in each layer of the traditional network model are connected with each other. As the learning task becomes more and more complex, the performance of hardware equipment shows a certain bottleneck. The amount of network parameters is limited, the neuron layer cannot be further deepened and widened, and the learning ability of the model is limited. In addition, in the field of computer vision, the fully connected network can not use the location information between pixels, which also limits the learning ability of the network to a certain extent. The emergence of deep neural network solves the above problems well [22].

3.2.2. Evaluation on Teaching Tactics of Track and Field Sports Training. With its excellent characteristic learning ability, deep neural network has become one of the most far-reaching achievements in the field of deep learning. For one of the neural network layers, the output characteristic formula is

$$x_j^l = f\left(\sum_{i=1}^n x_j^{l-1} \times w_{ij} + \beta_{ij}\right), \quad (11)$$

where w_{ij} represents the ensemble of neurons in the input layer, x_j^l represents the output of the i neuron, also the input in layer 1, and β_{ij} is the bias of the j input in layer 1.

Taking the tactical characteristic index data of track and field teaching in colleges and universities as the basic data of initial training in deep neural network, an appropriate loss function is determined to measure the error between the

FIGURE 4: Structure diagram of basic neural network.

output of deep neural network and the original data [23, 24], and the following results are obtained:

$$W = \sum \frac{1}{2} \|s_i - y\|_2^2, \quad (12)$$

where s_i represents the network output value, and y represents the sample label value. The network output with the sample labels was fitted by the algorithm to minimize the error.

The multilayer perceptron in the deep neural network further defines the error of the value of track and field teaching tactical characteristics output by the output layer as

$$\varphi_i = \frac{\partial w}{\partial s_i} H f'(s_i), \quad (13)$$

where φ_i represents the inactive output; H is the product of Hadama (Hadamard), and f' represents the derivative of the activation function, producing different types depending on the selected activation function.

Then, the gradient descent method [25] is used to update the result value of the tactical characteristics of track and field teaching in colleges and universities, and the following results are obtained:

$$\Delta\varphi_i = -\chi \frac{\partial w}{\partial s_i}, \quad (14)$$

where χ represents the learning rate. Through this method, the deep neural network parameters are iteratively updated to solve the target threshold, that is, the key value to determine the tactical characteristics of track and field teaching.

Because the characteristic of track and field teaching tactics is an abstract concept, it can not be output intuitively. Therefore, according to the output results of deep neural network, an unsupervised method is used to extract the key tactical characteristics from a large number of track and field tactical characteristics data. In this paper, the cascade noise reduction self-encoder is introduced to effectively extract the key features of the tactical characteristics of track and field teaching. The basic mode of the cascade noise reduction self-encoder [26] is shown in Figure 5.

Through cascade noise reduction, the input of the self-encoder network is the result of noise distortion of the original data. The training process does not need any manually labeled data labels, and the target label is the pure original data itself. The criterion of network training is to

FIGURE 5: Basic mode of stacked noise reduction self-encoder.

minimize the difference between the output of the network and the pure original data, that is, the reconstruction loss. Suppose that m track teaching tactical characteristics quantify the training sample data set $x = \{x^1, x^2, \dots, x^m\}$ as network input, where c represents a pure original sample, while x^n represents the noise distortion result of the original sample x^m . For a typical noise reduction autoencoder structure, the bottom-up process is usually called the encoding process, while the top-down process is known as the decoding process.

If d and d' represent the weight matrix of the uplink and downlink encoder, and b and b' represent the bias of the corresponding nodes, the objective function of the learned regularity term of a noise-reducing self-encoder is expressed as

$$\min \varepsilon = \eta \sum_{i=1}^m \|x^n - x^m\|_2^2 + \nu(d^2) + \|d'\|^2, \quad (15)$$

where ε represents the set of all parameters to be learned in the network; ν is a nonlinear excitation function, and η is the weight factor of the parametric regular term used to balance the reconstruction loss and the weight penalty.

According to the characteristic data of track and field teaching tactics after noise reduction self-encoder training, input it into the constructed depth neural network. When the number of samples is enough, these samples can really reflect the characteristics of track and field teaching tactics. The output results of the final track and field teaching tactics evaluation are as follows:

$$Y(x^n) = \sum_{i=1}^n r \delta_i (x^n - x^m). \quad (16)$$

Among them, $Y(x^n)$ represents the analysis result value, and δ_i represents the deviation coefficient of the output characteristics of teaching tactics.

4. Experimental Analysis

4.1. Experimental Scheme Design. In order to verify the effectiveness of the proposed method, an experimental analysis is carried out. In the experiment, the 20-kilometer walking race held by a university was taken as the research object, and 12 male athletes were selected as the research object. These 12 contestants were contestants in different classes of the same grade, aged between 18 and 19 years, and their physical qualities were relatively similar. In the 20-kilometer walking race, the characteristics of the speed change in the first and second half of the race are analyzed, and the feasibility of the analysis method in this paper is analyzed. Before the game, under the guidance of the coach, the training has been carried out for three months. The 12 people are divided into two groups. One group is the experimental group. Six players in this group compete in the tactics formulated by the coach, and the other group compete in accordance with their own training methods. Investigate the importance of the first and second half of the 20 km race walking race, as shown in Table 2.

According to the experimental scheme designed above, the effective analysis of the characteristics of teaching tactics is carried out. In the experiment, taking the analysis method of this paper, the method of [8], and the method of [9] for the 20 km race walking competition as the research object, analyze the error of different methods on the tactical analysis and the key degree of the influencing factors determined by the tactical characteristics as the experimental object, summarize the experimental data, and complete the experimental analysis.

4.2. Analysis of Experimental Results. In the experiment, firstly, the proposed method is analyzed. In the 20-kilometer race walking competition, the group using coach teaching tactics and the group without teaching tactics are used to determine the results of the 12 athletes. Among them, No. 1–6 are the athletes without coach teaching tactics, and 7–12 are the athletes under coach tactics. The 12 athletes complete the speed analysis of the 20-kilometer race walking competition. The results are shown in Table 4.

By analyzing the experimental results in Table 4, it can be seen that the shortest time spent by athletes No. 1–6 in the 20 km race walking competition is about 30.25 min, that of athletes No. 7–12 in the 20 km race walking competition is about 29.54 min, that of athletes No. 1–6 in the 20 km race walking competition is more than 30 min, and for athletes No. 7–12 in the 20 km race walking competition, two athletes spend less than 30 min, and the overall time is lower than that of athletes No. 1–6. It can be seen that the athletes using teacher tactics achieve better results, which verifies the feasibility of the proposed method.

The experiment further analyzes the error of the analysis method of this paper, the method of [8], and the method of [9] on the characteristics of teaching tactics in this race walking competition. The results are shown in Figure 6.

By analyzing the experimental results in Figure 6, it can be seen that there are some differences in the error of

TABLE 2: Investigation on the importance of the first and second half of the 20 km race walking race.

	The first-half result is even more important	The result in the second half is even more important	The first- and second-half results are equally important

FIGURE 7: Analysis of key degree results of influencing factors determined by teaching tactics characteristics of different analysis methods.

analyzing the characteristics of teaching tactics in this race walking competition by using the analysis methods of this paper, of [8], and of [9]. Among them, the analysis error of this method is low and is always lower than 1.8%, while the error of the two methods is high, which verifies the feasibility of the proposed method.

The experiment further analyzes the key degree of the analysis method of this paper, the method of [8], and the method of [9] on the influencing factors determined by the characteristics of teaching tactics in this race walking competition. The results are shown in Figure 7.

By analyzing the experimental results in Figure 7, it can be seen that the key degrees of the influencing factors determined by the analysis method of this paper, the method of [8], and the method of [9] in this race walking competition are different. With the change of the number of indicators, the curve trend of the three methods has changed to some extent. Among them, the key coefficient of the influencing factors determined by the teaching tactical characteristics of the proposed method is higher and always higher than 0.9. Compared with the other two methods, the key coefficient is lower, which verifies the feasibility of the proposed method.

5. Conclusion

This paper designs a method to analyze the tactical characteristics of college track and field sports training teaching based on deep neural network. By analyzing the current situation of track and field sports training teaching in colleges and universities, this paper determines the key characteristics of teaching tactics. By determining the factors of teaching environment, the core competitiveness of track and field teams, and the teaching ability of track and field coaches, these factors are determined as the key characteristics, the data basis is analyzed, and the unified data quantitative processing is carried out to determine the key factor indexes affecting the analysis of tactical characteristics. This paper introduces the deep neural network to

construct the evaluation model of the tactical characteristics of college track and field sports training teaching and further modifies the characteristic analysis results with the help of cascade noise reduction self-encoder to complete the analysis of the tactical characteristics of college track and field sports training teaching. The experimental results show that the proposed method can effectively analyze the teaching tactical characteristics of track and field sports training in colleges and universities and improve the performance of the evaluation of the teaching tactical characteristics of track and field sports training.

At this stage, in the research process of sports public service efficiency evaluation and analysis, due to the use of accurate data analysis methods, there are problems of low evaluation reliability and low analysis speed. Based on this, this paper studies the application of an information strategy based on the intuitionistic fuzzy data matching method in the evaluation and analysis of sports public service efficiency. The efficiency evaluation and analysis model of sports public service based on the intuitive fuzzy information algorithm is established. According to the characteristics of different types of sports public service, different types of data analysis methods are used to evaluate the efficiency, and the optimization of the efficiency analysis model of sports public service is realized according to the service demand and data type of different sports events. Finally, an experiment is designed to quantitatively evaluate the accuracy, stability, and reliability of the sports public service analysis model. The results show that the efficiency intelligent evaluation and analysis model based on the intuitive fuzzy information algorithm can effectively select the optimal sports public service evaluation countermeasures and rules according to the characteristics and data types of different sports events, realize the multi-dimensional accuracy classification of different types of sports events, and effectively improve the reliability of sports public service efficiency evaluation.

1. Introduction

Implementing the national strategy of nationwide fitness is the basic task of promoting healthy China to build a sports power. In order to optimize the transformation of government service functions, we will vigorously promote the development of public services for national fitness, so that the grass-roots people can enjoy the fruits of sports development and enhance their sense of gain and happiness. It is particularly important to improve the public sports service system and improve the efficiency of public sports service. Therefore, it is necessary to evaluate the efficiency of public sports services, explore the relevant influencing factors, solve the practical problems of the current reform and development of sports, and put forward effective paths for reference. The evaluation and analysis of sports public service efficiency has important practical significance for the improvement of

public service [1]. At this stage, due to different types of sports and different service contents, it is easy to have a variety of inefficient services, which will affect the experience of public users [2]. Although there are many researches on the efficiency evaluation of sports public service at this stage, there are still no good migration application research results, and many methods still need to be analyzed in combination with the problems existing in the public service of specific sports types [3]. Therefore, in order to better develop a more targeted evaluation system based on different types of sports public service strategies, it is necessary to combine the intuitive fuzzy information algorithm to realize high-quality analysis and customized evaluation of different sports events [4].

Based on this background, this paper studies the application of the intuitionistic fuzzy information algorithm in intelligent analysis of sports public service efficiency

evaluation, which is mainly divided into four chapters. The first chapter briefly introduces the application background of sports public service efficiency evaluation and intuitionistic fuzzy information algorithm and the chapter arrangement of this study. The second chapter introduces the research status of the efficiency evaluation model of sports public service and summarizes the shortcomings of the current research. The third chapter constructs the evaluation and analysis model of sports public service efficiency based on the intuitive fuzzy information algorithm. Through the disturbing intelligent analysis of different types of sports service data, it realizes the high-intensity representation of its internal relevance and carries out centralized control according to its internal error to improve the accuracy of the model. Chapter 4 tests the innovative characteristics of different types of data groups of the intelligent analysis sports public service efficiency evaluation model constructed in this paper and realizes the accuracy verification and analysis of the sports public service efficiency model by analyzing the error degree of the efficiency evaluation process of different types of sports public services. The experimental results show that compared with the traditional sports public service analysis and matching model of database modular analysis and processing, the sports public service efficiency evaluation and analysis model based on the intuitive fuzzy information algorithm proposed in this study has better use value and lower error rate.

The innovation of this paper is to propose an efficiency evaluation and analysis model of sports public service based on the intuitionistic fuzzy information algorithm. The model can evaluate the accuracy of different data groups according to the intelligent degree of sports public service efficiency evaluation types corresponding to different types of sports events and the efficiency analysis according to the intelligent classification effect of data, in order to improve its internal data accuracy.

2. State of the Art

At present, many mathematicians have carried out a lot of research according to the efficiency of sports public service, mainly focusing on service data group, innovative group analysis, and efficient intelligent matching and tracking [5]. Researchers Crothers and others adopted different matching strategies and data analysis stability thinking for different databases according to different types of sports, so as to realize intelligent and stable tracking of different data groups, and their internal data relevance has good analysis and fuzzy rules, so they can better complete the efficiency analysis of different sports public services. However, more parameters need to be checked [6]. Ni and other scholars adopted different types of data group classification ideas for different sports public service methods from the differences of service strategies and service methods of different types of sports, tree thinking strategy, and grid management thinking at marriage [7]. In the process of analyzing the efficiency evaluation of sports public service, Zhao and other scholars found that different types of sports have different sets of data centers, so they adopted a source efficient attack model to

realize targeted analysis and intelligent matching and tracking of data groups [8]. According to the characteristics of fuzzy information processing system, Rahimian and other scholars intelligently analyze different types of sports public service methods, classify different data, and use repair sparsity algorithm for in-depth analysis [9]. Simone and other scholars adopted an intelligent adaptive allocation strategy for sports events according to different types of sports service thinking. The experimental results show that this strategy can carry out feature recognition and intelligent analysis according to its internal differences and can be used for optimal matching analysis of different types of strategy groups [10]. Wu and other scholars conducted targeted analysis on the service efficiency of different sports events according to the differentiated characteristics of power points of sports events, discussed their internal relevance of sports events and evaluated their efficiency, and proposed a sports public service analysis model based on multi-dimensional innovation matching identification [11]. Relying on different types of high-end sports public service databases, Yang and other scholars classify the efficiency of sports public service for different types of sports events and put forward a sports public service analysis model that can match high-value data [12]. In the process of studying the efficiency evaluation of sports public service, Pradeep and other scholars found that different types of efficiency analysis problems need different methods for stability matching. Therefore, they proposed a high-intensity and multi type collaborative sports public service analysis and efficiency stability evaluation system. The system can effectively improve the service efficiency and data accuracy of different types [13].

To sum up, it can be seen that the current commonly used intelligent analysis models for sports public service efficiency evaluation cannot efficiently complete the quantitative analysis of high-precision data of sports events and need to classify and analyze the innovation of different model data. Therefore, there is the possibility of further research on the efficiency and stability of data analysis [14–16]. On the other hand, in the research on the differentiation of sports public service efficiency evaluation, there are few research results combined with the intuitive fuzzy information algorithm and few unified analysis combined with the fuzzy information strategy [17–19]. Therefore, it is of great significance to carry out the model analysis and research based on the fuzzy information algorithm applied to the efficiency evaluation of sports public service.

3. Methodology

3.1. Analysis of Intelligent Analysis Model for Efficiency Evaluation of Sports Public Service. Intuitionistic fuzzy information theory adopts the discrete processing technology of data group and multi-dimensional data matching and tracking strategy to realize data analysis and processing and intensity matching to varying degrees [20]. The current data analysis types have different degrees of error, which is because the parameters set by different data analysis types have many differences. Therefore, in the process of solving

specific problems, the differences of parameters are very different, which will affect the final data operation results [21]. Intuitionistic fuzzy information algorithm is mainly used to quantitatively analyze the targeted data of different sports public service efficiency and evaluation in solving the problem of sports public service efficiency evaluation. Through the value matching of different data groups, it can classify different types of data groups and then realize the high-accuracy analysis of different service efficiency [22]. The thinking process of data operation is shown in Figure 1. On the other hand, in the process of differential analysis of different types of sports public service projects, there will be great differences in their internal data matching degree and value analysis strategy, so there will be obvious differences in their internal data analysis intensity, and there is great uncertainty in their internal data accuracy [23]. In the process of adopting diversified data analysis dimension strategy for the data type of sports public service efficiency evaluation, the value degree will be matched according to its internal "Anjian performance," so as to realize the classification and quantitative research of the data group [24]. By using the intuitionistic fuzzy information algorithm and computer network analysis technology, the difference characteristics of its internal data types can be well analyzed, especially in value matching and stability strategy [25].

3.2. The Process of Establishing the Efficiency Evaluation Model of Sports Public Service. After the analysis and intelligent evaluation of different types of sports public service efficiency, high-precision quantitative analysis and stability solution can be realized according to its external relevance and internal matching. Usually, the quantitative analysis of sports public service mainly adopts common statistical analysis. However, it is difficult to obtain data related to sports public services or because they are often mixed with public services. Therefore, the relevant statistical analysis is difficult, even difficult to carry out. Compared with a large number of mathematical models and quantitative analysis methods and means in the fields of economy, management, education, and so on, it is not common to adopt similar methods in the field of sports public service.

Therefore, after the simulation analysis of different types of sports public service efficiency strategies combined with the fuzzy information classification algorithm, the data simulation analysis process based on computer intuitive fuzzy high latitude value analysis strategy is shown in Figure 2.

It can be seen from Figure 2 that for the sports public service efficiency evaluation data sets with different value analysis matching strategies, the evaluation scores of different types of sports public services are different because different types of fuzzy information data analysis networks and intuitive fuzzy algorithms are in the process of high-precision analysis of the data group. Eight dimensional matching classification will be carried out according to the accuracy of its data group to realize the classified processing of different service events, and then value analysis will be carried out according to its internal error, and its efficiency

will be evaluated. In this process, the corresponding evaluation function $P(x)$ and efficiency function $G(x)$ can be expressed as $h_c = 1/M \times N \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} \delta(f_{ij} - c)$.

$$P(x) = \frac{8 \sum_{i=1}^n (x_i^2 + x_{i-1}^2/2)}{3x_{i-1}^2 + 5x_{i-2}^2}, \quad (1)$$

$$G(x) = \frac{\sqrt{\sum_{i=1}^n (x_i^2 + x_{i-1}^2/2)/3x_{i-1}^2 + 4x_{i-2}^2}}{8\sqrt{x_i^2 + x_{i-2}^2}}. \quad (2)$$

The solution expression $L(x)$ of the eigenvector corresponding to different public sports service data groups is

$$L(x) = \sqrt{\frac{\lim_{x \rightarrow \infty} \sqrt{G(x)^2 + P(x)}}{\lim_{x \rightarrow 0} \sqrt{G(x)^2 + rP(x)}}}, \quad (3)$$

where r is the high-value response value of public service efficiency evaluation, which is converted into the classified value parameter of high latitude, then the corresponding discrete function $R(x)$ formula is expressed as

$$R(x) = \frac{\lim_{x \rightarrow \infty} G(x_k) + x_k}{L(x_k)}, \quad (4)$$

where x_k represents the low latitude parameter of public sports service. Complete different types of arrays and the corresponding combination strategy formula is

$$R(x_{k+1}) = \frac{\sqrt{R(x_k)^2 + L(x_k)^2}}{L(x_{k-1})}. \quad (5)$$

After discarding the correlation degree of its internal data type, with the help of the intuitive fuzzy strategy, its corresponding efficiency classification function is

$$U(x_k) = 8 \sqrt{\frac{\sqrt{R(x_k)^2 + L(x_k)^2}}{8R(x_k) + 3L(x_{k-1})}}, \quad (6)$$

where x is the high-intensity-type parameter group of the intuitionistic fuzzy classification. After completing this link, the corresponding high-value degree function analysis results are shown in Figure 3.

According to the results of Figure 3, after classifying the efficiency evaluation data of sports public service by using the intuitive fuzzy information algorithm, different types of arrays have great change intensity, and their efficiency is also different and multidimensional. In essence, public service efficiency is a production efficiency problem within the public service system. Most of the current research methods use the nonparametric method to determine the frontier production function, that is, the data envelopment analysis (DEA) method for research evaluation. It is a nonparametric linear mathematical programming method for convex efficient frontier estimation. At present, this method has been widely used in the efficiency evaluation and research of various industries and fields. This is because different types

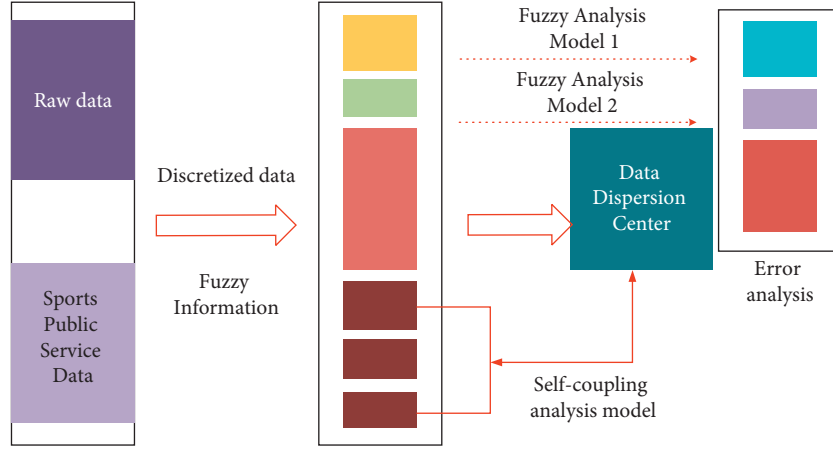

FIGURE 1: Data operation and processing process of intuitionistic fuzzy information algorithm.

FIGURE 2: Data simulation analysis process based on computer intuitive fuzzy high latitude value analysis strategy.

of fuzzy information analysis algorithms can realize high-dimensional classification and evaluation analysis of data according to super-precision function group. Then it realizes the quantitative representation and value matching analysis of the efficiency evaluation of sports public service.

Set the basic analysis value of the sports public service efficiency of the corresponding intuitive fuzzy information in this study as 0.1, and the simulation analysis results are shown in Figure 4.

It can be seen from Figure 4 that when characterizing and intensity matching analysis of sports public service efficiency evaluation data, the internal relevance data groups also have different types of value analysis strategies because different types of data groups need to carry out value matching and dimension correspondence in combination with the types of data groups in value analysis. At this time, the corresponding intuitionistic fuzzy information function can be expressed as

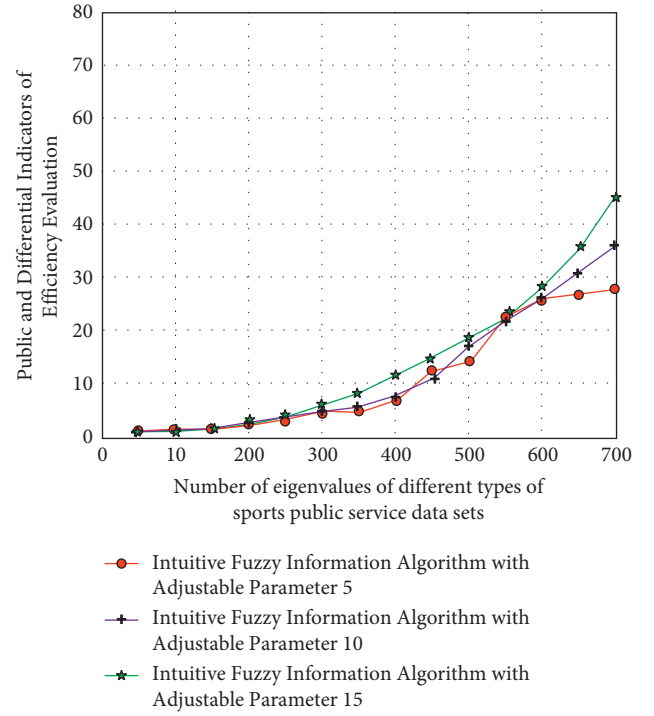

FIGURE 3: Analysis results of high-value function based on intuitive fuzzy evaluation algorithm.

$$r(x) = \sqrt{\frac{w\sqrt{x} + bx}{w + b}}. \quad (7)$$

The corresponding application restrictions are

$$\frac{x_i[h(x) + n]}{w\sqrt[3]{w} + r\sqrt[3]{b}} \geq \frac{x_i[h(x) - n(x)]}{w\sqrt[3]{w} + r\sqrt[3]{b}}. \quad (8)$$

Under the intuitionistic fuzzy analysis algorithm, the corresponding truth function is $T(x)$:

$$T(x) = \sum_{i=1}^n rx_i + b(x), \quad (9)$$

FIGURE 4: Simulation analysis results of sports public service efficiency indicators based on intuitionistic fuzzy information.

where $b(x)$ represents the truth value correspondence analysis function, w is the real array of sports public service efficiency evaluation, and b is the two-dimensional editing number of sports public service efficiency evaluation data group.

In order to improve the accuracy of its evaluation efficiency, it is also necessary to add the necessary conditions for significance classification:

$$\frac{x_i [h(x) + n] - x_{i-1}}{b\sqrt{x_i}} > b\sqrt{x_{i-1} + x_i}. \quad (10)$$

Under this significant condition, the formula corresponding to the collimation function $\beta(w, x)$ is

$$\beta(w, x) = \frac{\sqrt{\|w^2\|^3 + 2/3(K - x \sum_{i=1}^n x_i)}}{b(w, x)}, \quad (11)$$

where K represents the standard threshold function of intuitionistic ambiguity.

In order to further improve the standardization of fuzzy information, the gradient function $H'(x)$ of the judgment function in different dimensions is

$$H'(x) = \frac{\sqrt{|\sum_{i=1}^n a_i x_i (x_i \times x) + b(x_i \times x)|}}{H'(x-1)}, \quad (12)$$

$$H''(x) = \frac{\sqrt{|\sum_{i=1}^n a_i x_i (x_i \times x) + b(x_i \times x)|}}{H''(x-1)}, \quad (13)$$

$$H'''(x) = \frac{\sqrt{|\sum_{i=1}^n a_i x_i (x_i \times x) + b(x_i \times x)|}}{b(x_i)H''(x-1)}. \quad (14)$$

After quantitative evaluation, the corresponding public service efficiency analysis function is

$$Z(x_j, x_i) = \frac{\lim_{\delta x \rightarrow 0} \sqrt{|\sum_{i=1}^n a_i x_i (x_i \times x) + b(x_i \times x)|} / b(x_i) H''(x-1)}{|x_i - x_j|}, \quad (15)$$

where a_i represents data groups of different groups. At this time, the corresponding fuzzy information analysis results under different differentiation conditions are shown in Figure 5.

It can be seen from Figure 5 that when the efficiency evaluation of sports public service normalizes and analyzes different sports, the corresponding numerical changes are also quite different, but there are some regular and stable changes in local data. This is because the internal relevance is very different under the analysis of the intuitive fuzzy information algorithm. Therefore, the corresponding standardized single factor has good universality and stability.

4. Result Analysis and Discussion

4.1. Experimental Design of Sports Public Service Efficiency Evaluation Model Based on Intuitionistic Fuzzy Information Algorithm. During the experiment, in order to further confirm the credibility and feasibility of the sports public service efficiency evaluation model proposed in this study in dealing with unknown problems, it is necessary to carry out the authenticity data analysis experiment. The fuzzy evaluation analysis strategy used in this experiment is a multi-dimensional method combining fuzzy information processing and intelligent normalization strategy. In the process of analyzing different types of sports public service data groups, this method has high accuracy and periodicity in its internal relevance evaluation and value analysis. Specifically, the research selects quantifiable public service input and output variables. Generally speaking, to study the efficiency of public services between regions, we need to take all public services or some major public service projects provided by local governments as the research object to comprehensively investigate their efficiency. Here, we generally choose two main basic public service items, medical care and education, as samples for research. In terms of variable selection, in order to make the input-output data of various regions comparable, we all choose the per capita index for investigation. In terms of public service input variables, we select the per capita public service expenditure in each region, which represents the resources consumed by each region to provide public services. In terms of output variables, we selected three indicators from the fields of health care and education to reflect their comprehensive output.

Therefore, its internal data groups have good service characteristics and value types. Figure 6 is the preliminary experimental results based on the intuitive fuzzy information algorithm analysis model.

In the experimental results in Figure 6, it can be found that under the analysis of different types of intuitive fuzzy

FIGURE 5: The corresponding fuzzy information analysis results under different differentiation conditions.

FIGURE 6: Preliminary experiment results of computer chaos algorithm analysis model.

information algorithms, the internal differences in data reliability and stability of different sports public service data groups are obvious, and the results have high variability and consistency in the process of discretization of sports service behavior. This result is also in line with the experimental expectations. This is because under the intuitionistic fuzzy information analysis strategy, the data calculation efficiency of the corresponding sports public service efficiency evaluation model is improved, and its internal data group and reliability will also change, which leads to higher differences in its internal relevance and matching tracking rate.

4.2. Experimental Results and Analysis. This paper evaluates the residents' satisfaction with sports public service and constructs the evaluation index system. At present, the evaluation index of sports public service should be determined from the dimensions of the construction of national fitness facilities,

the construction of national fitness organizations, the development of national fitness activities, and the guidance service of national fitness. In the sports public service efficiency evaluation and analysis model based on fuzzy information processing algorithm proposed in this study, the commonly used evaluation index is used as the necessity reference strategy. If the error analysis is not carried out, the reliability of the results of the corresponding high-precision efficiency evaluation model will be reduced. Therefore, its internal relevance and data thinking coupling have different value analysis strategies, which will be directly related to the analysis accuracy of sports public service efficiency evaluation. The experimental analysis results are shown in Figure 7, in which the horizontal axis is the number of experimental analysis and the vertical axis is the quantitative characterization function value of the fuzzy evaluation index.

As can be seen from Figure 7, when analyzing different types of data groups, the experimental group using

FIGURE 7: Final experimental analysis results in computer monitoring mode.

intuitionistic fuzzy strategy has the lowest error degree of corresponding data results, and its corresponding efficiency evaluation parameters are also the highest. This is because after adopting the fuzzy information processing algorithm and intuitionistic fuzzy analysis strategy, the matching degree of the corresponding data analysis and the value degree of the disturbing error function will show the characteristics of strong pertinence and high efficiency. Therefore, when the difference of the corresponding different function types in the analysis process is large, the accuracy and value degree of the corresponding evaluation and analysis vector will have good reliability and stability, and its internal relevance vector group will also have a coupling effect with the internal matching degree of the value function, resulting in higher accuracy and value matching degree in its evaluation of the efficiency of sports public service. Therefore, its evaluation results can improve the accuracy by at least 33% and be more convincing.

5. Conclusion

This paper studies the application of information strategy based on the intuitionistic fuzzy data matching method in the evaluation and analysis of sports public service efficiency. An evaluation and analysis model of sports public service efficiency based on the intuitionistic fuzzy information algorithm is established. According to the characteristics of different types of sports public service, different types of data analysis methods are used to evaluate its efficiency, and according to the service needs and data types of different sports events, the optimization of the efficiency analysis model of sports public service is realized. Finally, an experiment is designed to quantitatively evaluate its accuracy, and the stability and reliability of the sports public service analysis model. The results show that the effectiveness intelligent evaluation analysis model based on the intuitionistic fuzzy information algorithm can effectively select the

optimal sports public service evaluation countermeasures and rules according to the characteristics and data types of different sports events, realize the multi-dimensional and accurate classification of different types of sports events, and effectively improve the reliability of sports public service efficiency evaluation.

However, this paper only focuses on the evaluation strategy of the efficiency of sports public service, so there is still room for improvement. We can conduct in-depth research on the scope of application and regional differences of the efficiency evaluation model of sports public service.

Bevel gears are widely used in aerospace transmission systems as well as modern mechanical equipment. In order to meet the needs and development of aerospace, high-speed dynamic vehicles, and various defense special equipment, higher and higher requirements are made for the high precision and stability of gear transmission systems, as well as the prediction and control of noise and vibration. Considering the nonlinear factors such as comprehensive gear error and tooth side clearance, a dynamic model of the three-stage gear transmission system is established. The relevant physical parameters, geometric parameters, and load parameters in the gear system are considered random variables to obtain the stochastic vibration model. When the random part of the random parameters is much smaller than the deterministic part, the vibration differential equation is expanded into a first-order term at the mean of the random parameter vector according to the Taylor series expansion theorem, and the ordering equation is solved numerically. Based on the improved stochastic regression method, the nonlinear dynamic response analysis of the three-stage gear train is carried out. This results in a relatively stable system when the dimensionless excitation frequency is in the range of 0.716 to 0.86 and the magnitude of the dimensionless integral meshing error is < 1.089 .

1. Introduction

Gearing systems are widely used in various types of machinery and equipment, and ensuring the smoothness and accuracy of the transmission process has always been the goal of industrial production [1]. With the development of wind turbine drive train power towards the megawatt level, the accuracy of the dynamic response analysis of the three-stage gearbox drive train model has been increasing. Therefore, the study of the coupled nonlinear dynamic characteristics of large generator gearboxes under variable loads, and then provide important theoretical value and practical engineering significance for the design of three-stage gearboxes [2]. In recent years, many domestic and foreign scholars have conducted in-depth studies on the performance research methods and dynamics models of three-stage gearbox drive systems, and have made certain achievements [3, 4, 5]. The coupled nonlinear dynamics model of the gear-rotor-bearing-box of a large three-stage gearbox with multi-stage planetary gearing was established

under the combined effect of internal and external load excitation, and the vibration response analysis of the three-stage gearbox was carried out by using the modal superposition method. Reference [6] accurately modeled the gearbox drive train of a large wind turbine and studied its drive train under variable wind loads. Reference [7] established a bending-torsion coupled dynamics model of a megawatt-class wind turbine gearbox drive train and calculated the structural sketch of the three-stage gearbox drive train using the fourth-order Runge-Kutta method.

Wind turbine gearboxes can be configured in different types, such as three-stage fixed shaft gear systems, planetary gear systems, and planetary and parallel shaft gear systems. The form of transmission mechanism used in the three-stage gearbox depends on the capacity requirements of the three-stage unit. The development of offshore three-stage technology and the need to reduce the cost of three-stage have strongly promoted the development of large single-capacity three-stage units. Three-stage planetary gearboxes are widely used in high-power double-fed three-stage gearboxes

because of their strong load-bearing capacity, large speed increase ratio, and compact structure. Compared with single-stage planetary gearboxes, three-stage planetary gearboxes are more susceptible to vibration and noise and failure due to interstage coupling and three-stage transmission of torque [8]. Therefore, it is important to analyze the dynamic characteristics of three-stage planetary gear trains. A series of research results have been obtained for the analysis of the dynamics of a three-stage planetary gear train in three-stage gearboxes.

The dynamics of a single pair of a gear pair system has been studied more systematically. In [8], a time-varying nonlinear dynamics model was established, and the effect of side clearance on the meshing state and its frequency response characteristics was considered [9]. The parameters of the single-stage spur gear system are studied in detail, and the effects of parameter variations on the dynamic characteristics are presented. In [10], an approximate analytical solution of the three-stage nonlinear gear train was carried out using the harmonic balance method, and the effect of the variation of key parameters on the system response was analyzed [11]. The dynamic simulation technique of a three-stage gear train considering only the time-varying meshing stiffness was studied [12]. The nonlinearities of the intermediate shaft system and the idler system with time-varying meshing stiffness are investigated, and the analytical and numerical solutions are compared. In [13], the dynamic characteristics of the three-stage idler system with nonlinear parameter excitation are presented, and the periodic steady-state solutions are obtained by both analytical and numerical methods.

Tooth surface errors are unavoidable in the gear manufacturing process. In this paper, a modified stochastic regression method is used to solve the system of vibration differential equations for a three-stage gear train, and the effects of the changes of the integrated dimensionless excitation frequency and the integrated meshing error on the dynamic response of the system are analyzed. It is found that the system is in a relatively stable state when the dimensionless excitation frequency is in the range of 0.716–0.86 and the magnitude of the integrated dimensionless meshing error is <1.089 .

2. Related Work

In order to meet the practical needs of low speed and a heavy load and a large transmission ratio, the study of the dynamics of the gear transmission system is becoming a hot spot for engineering applications and academic research. According to the research focus, [14] used the finite element method, the centralized parameter method, and the experimental modal analysis method, respectively. In [15], the finite element model and the centralized parametric model of the gear set were established, and the results of the two models were compared and analyzed, and the results of the two models were found to be consistent. In [16], the dynamic characteristics of the system under different fixation methods of the solar wheel were analyzed. In [17], the vibration model of the planetary gear was developed by the

centralized parameter method considering the meshing phase relationship, and the modalities and vibration modes of the system were calculated for different modalities. In terms of nonlinear dynamics of planetary gear sets, [18] analyzed the dynamics of planetary gears under changing meshing stiffness by using rectangular waves to represent the time-varying meshing stiffness of the gear teeth. In [19], the effect of manufacturing errors on the nonlinear dynamics of planetary gears were studied, and the differences in the dynamics of the system under normal conditions, in the presence of tooth profile errors, and when centrifugal forces were considered and compared. In [20], the dynamics of planetary gears under strong nonlinear factors with multiple clearances is considered, and it is important to note that the analytical solution of the system vibration differential equations is obtained by the harmonic balance method, which is a typical application of the approximate analytical solution method under strong nonlinear factors. The study of the concentrated mass model of planetary gear sets focuses on the pure torsional vibration model and the meshing coupling model. Theoretical tooth surface and real tooth surface STE are introduced into the dynamics model in the form of discrete points, and the effects of real tooth surface STE and theoretical tooth surface STE on the dynamics performance of the curved bevel gear pair are compared and analyzed.

3. Complex Modal Structural Systems

The basic equation for the vibration of a gear system and the complex modal forced vibration equation for an N -dimensional linear system can be expressed as

$$M\ddot{X} + C\dot{X} + KX = Q(t), \quad (1)$$

where M , C , and K denote the $N \times N$ order mass matrix, damping matrix, and stiffness matrix, respectively, X and $Q(t)$ denote the generalized displacement vector and external excitation, respectively, $M\dot{X}$ denotes the generalized velocity vector and $C\dot{X}$ denotes the generalized acceleration vector. The free vibration equation of the complex modal structural system can be expressed as

$$M\ddot{X} + C\dot{X} + KX = 0. \quad (2)$$

It may be assumed that, $X = xe^{\lambda t}$ by substituting into (2), the corresponding right eigenvalue problem is obtained as follows:

$$(M\lambda^2 + C\lambda + K)x = 0. \quad (3)$$

The corresponding concomitant eigenvalue problem is $(M\lambda^2 + C\lambda + K)^T y = 0$, and the left eigenvalue equation is obtained by transposing the concomitant eigenvalue equation as follows:

$$y^T (M\lambda^2 + C\lambda + K) = 0, \quad (4)$$

where the vectors x and y denote the right and left eigenvalues, respectively, and λ denotes the eigenvalue of the vibration equation.

To simplify the above representation, a right state vector u is introduced to replace x , satisfying $u = \lambda x / x = Tx$, where T is the state transition matrix and can be expressed as $T = \lambda I / I$. Similarly, another left state vector v is used instead of y , satisfying $V = \lambda Y / Y$. Thus, (3) and (4) can be rewritten as

$$\begin{aligned} (A\lambda + B)u &= 0, \\ v^T(A\lambda + B) &= 0. \end{aligned} \quad (5)$$

Among them

$$A = \begin{bmatrix} 0 & M \\ M & C \end{bmatrix}, B = \begin{bmatrix} -M & 0 \\ 0 & K \end{bmatrix}. \quad (6)$$

After the state transformation, (6) can be rewritten as

$$(A\lambda + B)u = 0. \quad (7)$$

$$v^T(A\lambda + B) = 0. \quad (8)$$

(7) and (8) have the same eigenvalues and can be derived from the following equation:

$$\det(A\lambda + B) = 0. \quad (9)$$

(8) is an algebraic equation with $2N$ eigenvalues in the complex domain, which can be expressed as $\lambda_i (i = 1, 2, \dots, N)$.

A and B can be expressed as

$$\begin{cases} A = A_0 + \varepsilon A_1, \\ B = B_0 + \varepsilon B_1. \end{cases} \quad (10)$$

4. Matrix Ingestion Method for Complex Modal Structural Vibrations

Since the non-diagonal of the consistent mass matrix contains non-zero elements, when vectorial finite elements are used for dynamic analysis, the consistent mass matrix is often replaced by the concentrated mass matrix in order to reduce computational effort and storage space. The most common method of constructing a centralized mass matrix is to distribute the mass of a cell equally among the connected nodes. When the mass of the unit or the internal nodes are not uniformly distributed, a higher-order difference function is used for mass distribution.

For the rod system structure, the elements on the main diagonal of each row of the centralized mass matrix element on each row of the consistent mass matrix is the sum of all elements in the corresponding row of the consistent mass matrix, i.e.,

$$M_1^c = \text{diag}(M_c^c \cdot J_n), \quad (11)$$

where $\frac{1}{M}$ is the concentrated mass matrix. $\frac{c}{M}$ is the consistent mass matrix. J_n is the n th-order square matrix composed of 1. Substituting equation (5) into (6) further simplification yields

$$M_1 = \left(\frac{1}{2}\right) \text{diag}(C^T \hat{m} C) \otimes I_3. \quad (12)$$

In practical engineering, the variation of structural parameters is reflected in the variation of the mass matrix. Considering the small perturbations of the parameters around their mean values, the mass matrix can be expressed as

$$\begin{aligned} \{M &= M_0 + \varepsilon M_1, \\ \{C &= C_0 + \varepsilon C_1 \\ K &= K_0 + \varepsilon K_1. \end{aligned} \quad (13)$$

According to the matrix regression method, the eigenvalues and eigenvectors of a complex modal structural vibration system can be expanded into the form of a regression series:

$$\begin{aligned} \{\lambda^i &= \lambda_0^i + \varepsilon \lambda_1^i + \varepsilon^2 \lambda_2^i + \dots u^i \\ &= u_0^i + \varepsilon u_1^i + \varepsilon^2 u_2^i + \dots \{v^i \\ &= v_0^i + \varepsilon v_1^i + \varepsilon^2 v_2^i + \dots x^i \\ &= x_0^i + \varepsilon x_1^i + \varepsilon^2 x_2^i + \dots y^i \\ &= y_0^i + \varepsilon y_1^i + \varepsilon^2 y_2^i + \dots \end{aligned} \quad (14)$$

Substituting (11) and (13) into (12), we get

$$\begin{aligned} (A_0 + \varepsilon A_1)(\lambda_0^i + \varepsilon \lambda_1^i + \varepsilon^2 \lambda_2^i + \dots) \\ + (B_0 + \varepsilon B_1)(u_0^i + \varepsilon u_1^i + \varepsilon^2 u_2^i + \dots) = 0. \end{aligned} \quad (15)$$

Similarly, substituting equations (12) and (13) into (14) gives

$$(v_0^i + \varepsilon v_1^i + \varepsilon^2 v_2^i + \dots)^T \left(\begin{matrix} (A_0 + \varepsilon A_1) \\ (\lambda_0^i + \varepsilon \lambda_1^i + \varepsilon^2 \lambda_2^i + \dots) \end{matrix} \right) + (B_0 + \varepsilon B_1) = 0. \quad (16)$$

Expanding (15) and ignoring the terms of $O(\varepsilon^2)$, comparing the coefficients of the same power of ε on the left and right sides of the equation yields

$$\begin{aligned} \varepsilon^0: (A_0 \lambda_0^i + B_0) u_0^i &= 0, \\ \varepsilon^1: (B_0 + \lambda_0^i A_0) u_1^i + B_1 u_0^i + \lambda_0^i A_1 u_0^i + \lambda_1^i A_0 u_0^i &= 0, \\ \varepsilon^2: (B_0 + \lambda_0^i A_0) u_2^i + (B_1 + \lambda_0^i A_1) u_1^i + \lambda_1^i A_0 u_1^i \\ &+ \lambda_1^i A_1 u_0^i + \lambda_2^i A_0 u_0^i &= 0, \end{aligned} \quad (17)$$

where ε is a small parameter and has $\varepsilon = 0$ for the original system; M_0, C_0, K_0 denotes the mean values; and $\varepsilon M_1, \varepsilon C_1, \varepsilon K_1$ denotes the first-order regression term of M_0, C_0, K_0 , respectively. Further, the same operation of (13) and (14) for (17) gives

$$\begin{aligned}
\varepsilon^0: \begin{pmatrix} A \\ 0 \end{pmatrix} + B_0 \Big) T v_0^i &= 0, \\
\varepsilon^1: \begin{pmatrix} B \\ 0 \end{pmatrix} + A_0 \Big) T v_1^i + \begin{pmatrix} B \\ 1 \end{pmatrix} + A_1 + A_0 \Big) T v_0^i &= 0, \\
\varepsilon^2: \begin{pmatrix} B \\ 0 \end{pmatrix} + A_0 \Big) T v_2^i + \begin{pmatrix} B \\ 1 \end{pmatrix} + A_1 \Big) T v_1^i + \lambda_1^i A_0^T v_1^i \\
+ \lambda_1^i A_1^T v_0^i + \lambda_2^i A_0^T v_0^i &= 0,
\end{aligned} \tag{18}$$

where λ_1^i and λ_2^i represent the first-order and second-order registers of the i th eigenvalue, respectively. In addition, the first-order and second-order registers of the left eigenvector and the first-order and second-order registers of the right eigenvector can also be found by (15).

Expanding u_1^i on the original right state eigenvector u_0^s yields

$$u_1^i = \sum_{s=1}^{2N} h_{is}^1 u_0^s. \tag{19}$$

Substituting (17) into (18) yields

$$(B_0 + \lambda_0^i A_0) \sum_{s=1}^{2N} h_{is}^1 u_0^s + (B_1 + \lambda_0^i A_1) u_0^i + \lambda_1^i A_0 u_0^i = 0. \tag{20}$$

The left multiplication of (19) by v_0^{sT} has

$$\begin{aligned}
v_0^{sT} (B_0 + \lambda_0^i A_0) \sum_{s=1}^{2N} h_{is}^1 u_0^s + v_0^{sT} (B_1 + \lambda_0^i A_1) \\
u_0^i + v_0^{sT} A_0 u_0^i \lambda_1^i = 0.
\end{aligned} \tag{21}$$

Considering the modal orthogonal normalization conditions expressed in (14) and (15), (20) can be reduced to

$$h_{is}^1 (\lambda_0^i - \lambda_0^s) + v_0^{sT} (B_1 + \lambda_0^i A_1) u_0^i + \lambda_1^i \delta_{is} = 0. \tag{22}$$

Only if $s = i$, then $\lambda_0^i = \lambda_0^s$ can be obtained from (22)

$$\lambda_1^i = -v_0^{iT} (B_1 + \lambda_0^i A_1) u_0^i. \tag{23}$$

(20) can be further rewritten as

$$\lambda_1^i = -y_0^{iT} \left((\lambda_0^i)^2 M_1 + \lambda_0^i C_1 + K_1 \right) x_0^i. \tag{24}$$

5. Uncertainty Propagation Analysis of Random Complex Eigenvalues

The mass matrix, damping matrix, and stiffness matrix of real engineering structures are generally considered as stochastic structural parameters due to the variation of raw material properties of gears, manufacturing errors, and loading environment. In this paper, the matrix regression method is introduced to the eigenvalue analysis of complex modal structures with stochastic parameters,

and also provides a basis for uncertainty propagation analysis of asymmetric systems. Considering the stochastic nature of the structural parameters, the stiffness matrix K , the mass matrix M , the damping matrix C , the complex eigenvalues λ_r , the left complex eigenvector y , and the right complex eigenvector x can be expressed in the following form:

$$\begin{cases} K = K_d + \varepsilon K_r, M = M_d + \varepsilon M_r, C = C_d + \varepsilon C_r, A = A_d + \varepsilon A_r, \\ B = B_d + \varepsilon B_r, \lambda^i = \lambda_d^i + \varepsilon \lambda_r^i, y^i = y_d^i + \varepsilon y_r^i, x^i = x_d^i + \varepsilon x_r^i, \end{cases} \tag{25}$$

where ε is a small parameter, $K_d, M_d, C_d, A_d, B_d, \lambda_d^i, y_d^i, x_d^i$ and $K_r, M_r, C_r, A_r, B_r, \lambda_r^i, y_r^i, x_r^i$ are the deterministic and random components of K, M, C , and $A, B, \lambda^i, y^i, x^i$, respectively. Also, it is assumed that the mean value of $K_r, M_r, C_r, A_r, B_r, \lambda_r^i, y_r^i, x_r^i$ is zero.

6. Numerical Solution of the Model

In this paper, we solve the differential equations of the system in terms of the magnitudes and vibrations, and briefly compare the results of the two numerical integration methods. Given the initial values of the system vibration, the first 800 transient response periods are omitted, and the dynamic response of the system is programmed in MATLAB to analyze the effect of the variation of excitation frequency, mesh damping ratio, and tooth side clearance on the bifurcation characteristics of the system. The basic parameters of the two-stage planetary gear train of the three-stage gearbox are as follows: rated power $P = 2500$ kW, normal speed range 16r/min~21r/min, transmission ratio $i_1 = 5.25$, $i_2 = 5.28$, number of teeth of the first stage $Z_s = 31$, $Z_{pi} = 47$, $Z_r = 125$, number of planetary wheels $N_1 = N_2 = 3$, and the basic parameters of each gear are shown in Table 1.

The presence of static transmission error can aggravate the meshing shock of the gear teeth and cause abnormal vibration of the system, therefore, this paper discusses the effect of the integrated meshing error on the bifurcation characteristics of the system.

The kinetic analysis of the solution results by the global bifurcation diagram and maximum Lyapunov exponent (LLE) is shown in Figures 1 and 2. Given the dimensionless excitation frequency $\Omega_m^1 = 0.86$, the mesh damping ratio $\xi = 0.07$ and the tooth side clearance $b = 1$, the effect of the integrated meshing error on the dynamic characteristics of the system is discussed with the dimensionless integrated meshing error magnitude E as the bifurcation parameter (for simplicity, the image coordinates $x_{spi}^{(1)}$ are denoted as $x_{spi}^{(1)}$ and $E_{spi}^{(1)}$ as E). According to Figure 1, the three-stage planetary gear system has a rich nonlinear dynamic behavior when the magnitude of the integrated dimensionless meshing error is used as the bifurcation parameter. Combined with Figure 2, it is found that the system is relatively stable at low values of the integrated meshing error, when LLE is negative, and it is clear that the system enters the chaotic response as a multiperiodic bifurcation.

TABLE 1: Basic parameters of a three-stage gear train.

	Planet carrier C	Sun wheel S	Planetary gear p	Inner ring gear r
<i>First stage planetary gear train</i> (number of planetary gears $N_1 = 3$)				
Radius of base circle R_b /(m)	0.471	0.196	0.243	0.683

FIGURE 1: System under the variation of the integrated meshing error.

The dynamics of the two-stage planetary gear and the one-stage parallel shaft gear system are further verified and analyzed by combining the phase trajectory diagram and the Poncelet cross section diagram with the aid of the time history diagram and the spectrum diagram, as shown in Figure 3. When the dimensionless integrated meshing error value $E_{spi}^{(1)} = 0.05$, the system is in a single-cycle motion state, the time history graph is close to a sinusoidal curve, the vibration amplitude between cycles is basically the same, the phase trajectory line is an elliptical closed curve, the Poincaré diagram is a single point and the fundamental frequency signal in the spectrum is very prominent at this time, indicating that the system is in a typical single-cycle state.

With the increase of the integrated meshing error, when 0.779, as shown in Figure 4, the time course diagram changes periodically with two amplitudes as one cycle, the phase trajectory line is concave from one elliptic curve to two elliptic curves, the Poincaré cross-sectional diagram splits from one single point to two single points, and the FFT spectrum is shown as octave components, indicating that the system is in a two-cycle motion state. Combining Figures 3 and 4, it can be found that the motion state of the system splits and changes from single-cycle to two-cycle and four-cycle with the increase of the magnitude of the integrated dimensionless mesh error. At the integrated dimensionless meshing

FIGURE 2: Plot of the maximum Lyapunov exponent of the system under the variation of the integrated error.

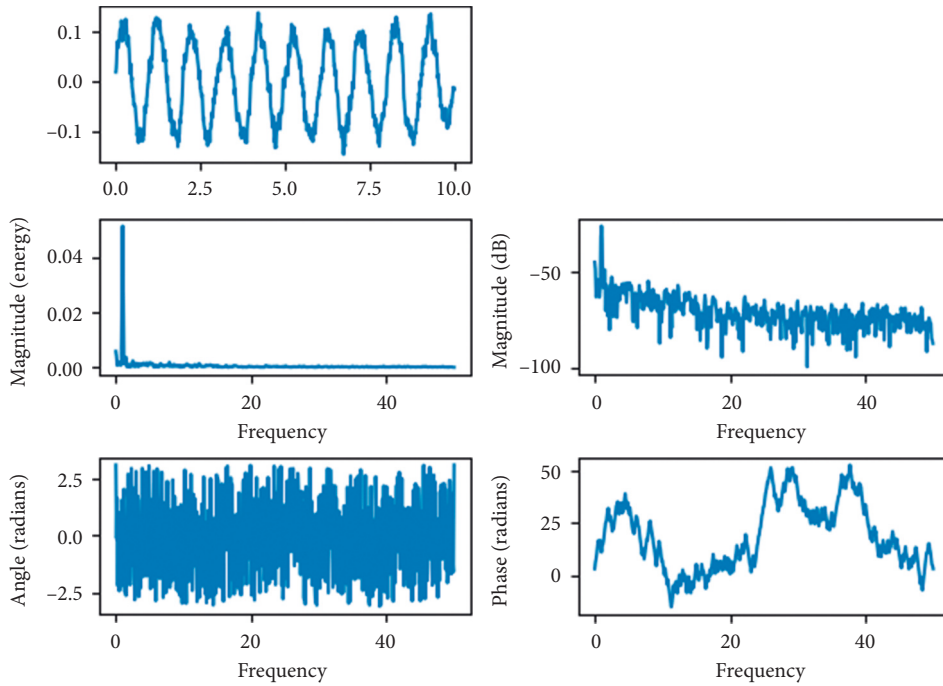

FIGURE 3: Dynamics of the system at $E = 0.05$.

error (1) $E_{spi}^{(1)} = 1.259$, strange attractors appear in the cross-sectional plot of Poincaré, indicating that the system enters the chaotic state through multi-cycle bifurcation at this time. When (1) $E_{spi}^{(1)}$ reaches 0.939, the system bifurcates from the two-cycle state to the two-

cycle state with an LLE value of -0.001713. Therefore, the “negative pole” that appears in the plot of the maximum Lyapunov exponent of the system under the change of the integrated mesh error can characterize the dynamics of the two-cycle bifurcation, as shown in Figure 5.

FIGURE 4: Dynamics of the system at $E = 0.779$.

FIGURE 5: Dynamics of the system at $E = 0.956$.

7. Conclusion

In this paper, a modified stochastic regression method is used to solve a system of vibration differential equations for a three-stage gear train, and the effects of changes in the integrated dimensionless excitation frequency and the integrated meshing error on the dynamic response of the system are analyzed. A new static no-load transmission error model is established, which has its unique advantages in the

fault diagnosis of gears. The model no longer requires tooth surface equations, avoiding the difficulty of merging tooth surface errors into tooth surface equations. The effect of the static unloaded transmission error of the real tooth surface on the dynamic characteristics of the bevel gear is analyzed. The model is also applicable to other types of gears. The global bifurcation diagram, Poincaré cross section diagram, and phase trajectory diagram are used as the main basis, and the time history diagram and the spectrum diagram are used

as auxiliary tools to determine the range of bifurcation parameters when the three-stage gearing system is in a relatively stable state. It is found that the system is in a relatively stable state when the dimensionless excitation frequency is in the range of 0.716–0.86 and the magnitude of the dimensionless integrated meshing error is < 1.089 .

The necessity of predicting and estimating river velocity motivates the development of a prediction method based on GAN image enhancement and multifeature fusion. In this method, in order to improve the image quality of river velocity, GAN network is used to enhance the image, so as to improve the integrity of image data set. In order to improve the accuracy of prediction, the image is extracted and fused with multiple features, and the extracted multiple features are taken as the input of CNN, so as to improve the prediction accuracy of convolution neural network. The results show that when the velocity is 0.25 m/s, 0.50 m/s, and 0.75 m/s, the accuracy of improved method can reach 85%, 90%, and 92%, which are higher than SVM, VGG-16, and BPNET algorithms. The above results indicate that the improvement has certain positive value and practical application value.

1. Related Work

China has abundant water resources, but it is also threatened by catastrophic flooding. However, due to the limitations of field environmental factors and the increase of data volume, using the traditional manual measurement for river velocity not only has great constraints, but also faces serious personnel threats. With the maturity of modern image acquisition technology and the wide application of artificial intelligence algorithm, how to use noncontact equipment for river monitoring has become the focus of current thinking and research.

It is found that the texture features of river channel image have a certain mapping relationship with the flow velocity, but the features are relatively single. If the traditional contact real-time monitoring is used, its accuracy will be greatly affected. To solve this problem, Tauro F et al. proposed a nonlinear learning fluid prediction method, so as to provide reference for fluid velocity prediction [1]. Ghoulami et al. [2] proposed a new CRBFNN model for the problem of river flow velocity. Through the model, the river flow velocity of 60° and 90° was predicted. The results showed

that the model was more suitable for the prediction of bend flow velocity of 60° [2]. Khuntia et al. [3] proposed to use multivariate regression to analyze and predict the river velocity and found that the machine learning algorithm performed better than the traditional Shiono and Knight methods [3]. Based on particle tracking velocimetry, Eltner et al. [4] collected and estimated River images. The results show that the deviation of this method is between 4% and 5% [4]; Zhang et al. [5] used the reflection technology of BeiDou system to inverse the river velocity and then obtained the river velocity with small error [5].

All the above studies focus on fluid velocity prediction, but its accuracy needs to be further improved. In view of the above problems, some scholars also proposed to process the collected water flow images. For example, Gulrajani et al. [6] proposed to introduce gradient punishment mechanism into the WGAN algorithm to better improve the WGAN algorithm [5]. David proposed an image processing technology based on the BEGAN algorithm to solve the contradiction between picture type and generation [6].

The above research shows that this paper proposes a flow image processing and velocity prediction method based on

GAN algorithm and CNN algorithm, which takes the Yellow River flow image as the object. Meanwhile, the feasibility of the construction method is verified.

2. The Basis of Convolutional Neural Network Algorithm

Convolutional neural network has been widely used in classification problems. The characteristics of the convolutional neural network are reflected in translation invariance, feature extraction, and so on. Moreover, it has the characteristics of weight sharing and local connection. The structure is divided into multiple layers, including input, output, and convolution layer. And each layer has different functions. In the different layer structure, the calculation methods are different to some extent. The basic structure of the network is shown in Figure 1.

The convolution layer needs to carry out convolution processing for the upper feature maps or input information. In this process, some learnable convolution kernel and activation function should be used to obtain the corresponding output results. The formula is shown below [7–9]:

$$\begin{aligned} x_j^l &= f(u_j^l), \\ u_j^l &= \sum_{i \in M_j} x_j^{l-1} * k_{ij}^l + b_j^l, \end{aligned} \quad (1)$$

where l represents the convolution layer; $f(\cdot)$ represents the activation function of l ; x_j^l represents the output of channel j in l ; u_j^l represents the net activation of channel j in l , and, specifically, it is obtained by the convolution layer $l-1$ of the output feature map with l convolution and then adding b_j^l . k_{ij}^l represents the convolution kernel weight matrix, whose size is generally $1 * 1$, $3 * 3$, $5 * 5$, etc. M_j represents the set of input feature maps.

The pooling layer is divided into two types: maximum pooling and average pooling, which is divided according to the input feature graph. Then, the dividing matrix block pixels are processed by sliding window. This layer is also called the downsampling layer, and the formula is shown as follows [10–12]:

$$\begin{aligned} x_j^l &= f(u_j^l), \\ u_j^l &= \beta_j^l \text{down}(x_j^{l-1}) + b_j^l. \end{aligned} \quad (2)$$

Here, $\text{down}(\cdot)$ represents the pooling function to realize the function of narrowing the input feature map; β represents the weight coefficient of pooling layer; u_j^l represents net activation, which means that it is necessary to combine the previous layer output feature map with the current layer pooling function, and then add b_j^l .

For convolutional neural network, the features of input information can be extracted in the execution, specifically using the convolution and pooling repeated superposition. The convolution is divided into two parts: high level and low level. The former mainly extracts image semantic information, and so on. The latter extracts details, such as image edge information. Combined with the previous analysis, it

can be seen that the characteristics of convolutional neural network include weight sharing and local connection, among which the weight sharing can effectively reduce the parameters, because the neurons weight on each feature mapping surface is consistent. The local connection means that the input of each neuron is connected with the local acceptance domain of the previous layer. In this way, the local features can be extracted. Meanwhile, the location relationship with other features can be clarified.

3. Flow Rate Classification Network Based on Multifeature Fusion

3.1. Multifeature Fusion. Traditional classification methods can achieve higher accuracy by deepening the network depth or broadening the network width of the classification model, namely, increasing the number of convolution layers or adding more feature map dimensions to the single convolution layer. However, the direct result of increasing the number of convolution layers is that the network parameters and computational complexity will greatly increase, and the training process will consume a lot of hardware and software resources. In addition, the increase of model layers can just improve the classification effect of the network within a certain range. When the number of layers increases to a certain depth, the gradient disappearance may occur during the backpropagation [13]. And the feedback information of shallow convolution cannot be obtained to adjust the weight size. Therefore, too deep structure will lead to performance degradation of the classification network. Taking the above considerations into account, this chapter proposes a multifeature fusion mechanism.

Figure 2 shows that, without increasing the network depth and spatial parameters, the learning robustness of the classification model for target data can be improved.

The feature maps of multiple convolution middle layers are fused. Under the normal use of data semantic information obtained by deep convolution, the local detail features reinforce information obtained by shallow convolution. The classification goal of higher accuracy can be achieved [14–17]. The calculation method is shown as follows:

$$L_n = \text{Concat}(L_k, L_p, L_q). \quad (3)$$

It can be seen from the formula that k , p , q represent the number of convolution layers of fusion output; L_n represents the output feature map of the convolution layer n . The output of each convolution layer is multichannel feature map, and the size is the same. But the size is directly related to the number of convolution layers, which are negatively correlated. In the multiscale fusion, the size of the feature map needs to be adjusted first, which means that the nearest neighbor interpolation method is used for upsampling, and then splicing. So, the multilevel feature map fusion can be achieved.

3.2. Classification Network Structure. As shown in Figure 3, VGG-16 is adjusted and applied to image recognition. The classification model consists of one input layer and five

FIGURE 1: Structure of CNN.

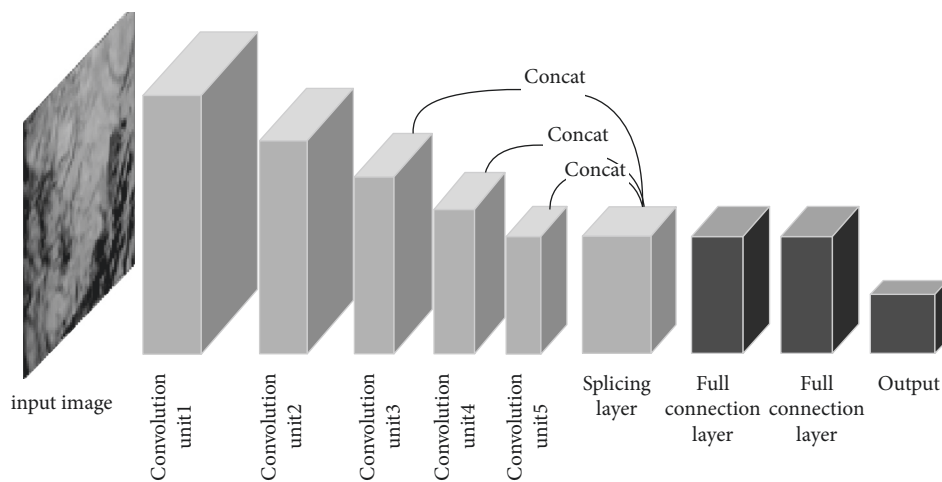

FIGURE 2: Diagram of multifeature fusion.

convolutional processing units. Each unit contains two to three unequal convolution layers, a single pooling layer, two full connection layers, a Dropout layer, and a feature fusion layer [18–22]. The feature fusion mechanism is introduced to upsample the flow feature map output from convolution C5_2 layer. Then fuse it with the feature map output from convolution C3_3 layer and convolution C4_3 layer to form the feature fusion layer. In this network, the 3×3 small convolution kernels are stacked to increase the depth of the model, and multiple Rectified Linear Units (ReLU) are added, which can reduce the computational complexity in the classification and recognition process. Apart from that, it can alleviate the overfitting problem to some extent. Before training the network, the multitype images generated by model learning in Chapter 2 and Chapter 3 are mixed with real samples. 70% of the data are randomly selected as the training set, and the rest as the test set. Dropout mechanism is added after the full connection layer of the classification network to alleviate the problem of overfitting during training.

The use of feature fusion mechanism has certain advantages, so that the underlying features on classification decision-making is strengthened. It is easy to identify the image with no significant difference in detail features. So, it has higher robustness. Even if the error between the training

set and the test set is large, the higher recognition accuracy can still be achieved.

4. Experiment and Analysis

4.1. Experimental Subjects. In this paper, a section of the Yellow River is analyzed as an example. The precipitation in this section basically stays within 1800 to 2000 mm, and there are significant changes. The precipitation is mainly concentrated in summer, and there are many rainstorms. It is easy to cause mountain floods and other disasters. Therefore, it is necessary to monitor and analyze the flow velocity of each tributary in this region which is as follows in Figure 4.

4.2. Flow Image Acquisition. The professional camera devices are set up on both sides of boundary card river to collect water images. And the collected images are transmitted through wireless equipment. Install cameras at an appropriate position in the building and set the frame rate to 60 fps at an appropriate spacing. In addition to capturing images of the river, information such as weather and velocity values should also be recorded. The specific solution is shown in Figure 5.

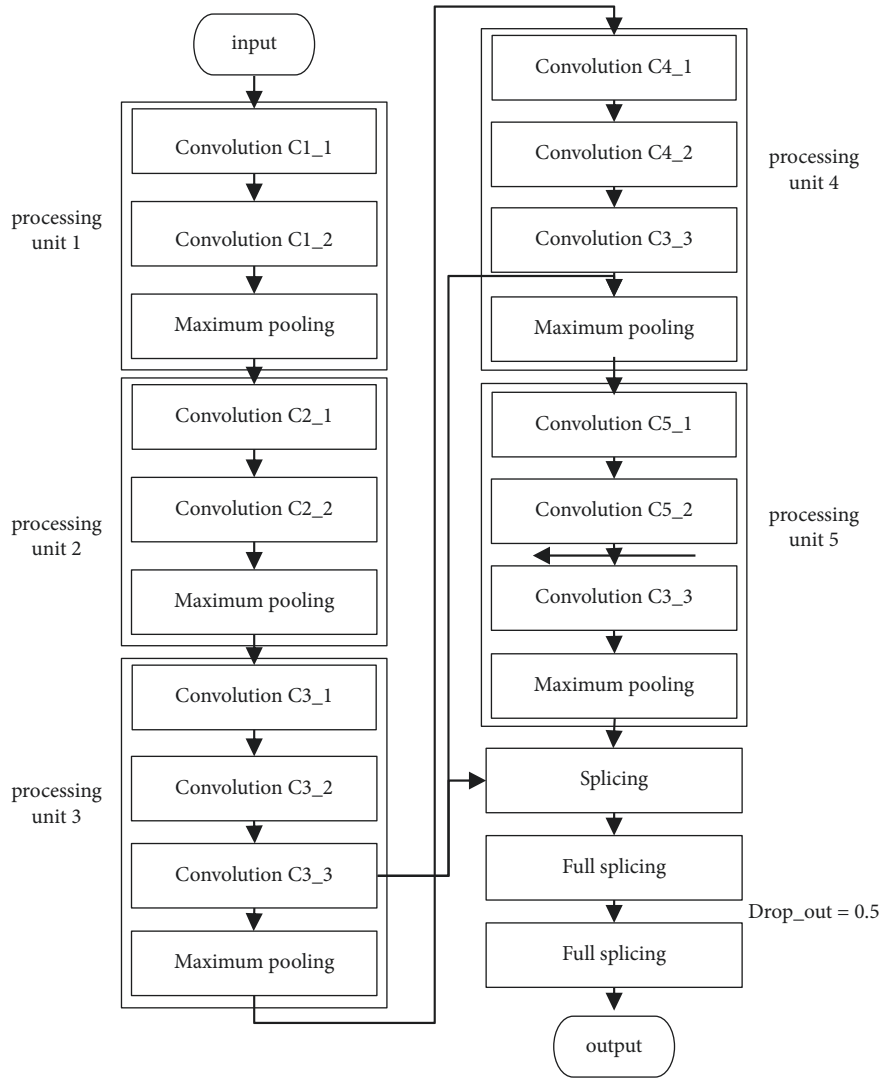

FIGURE 3: Classification network structure.

FIGURE 4: General River and tributary map.

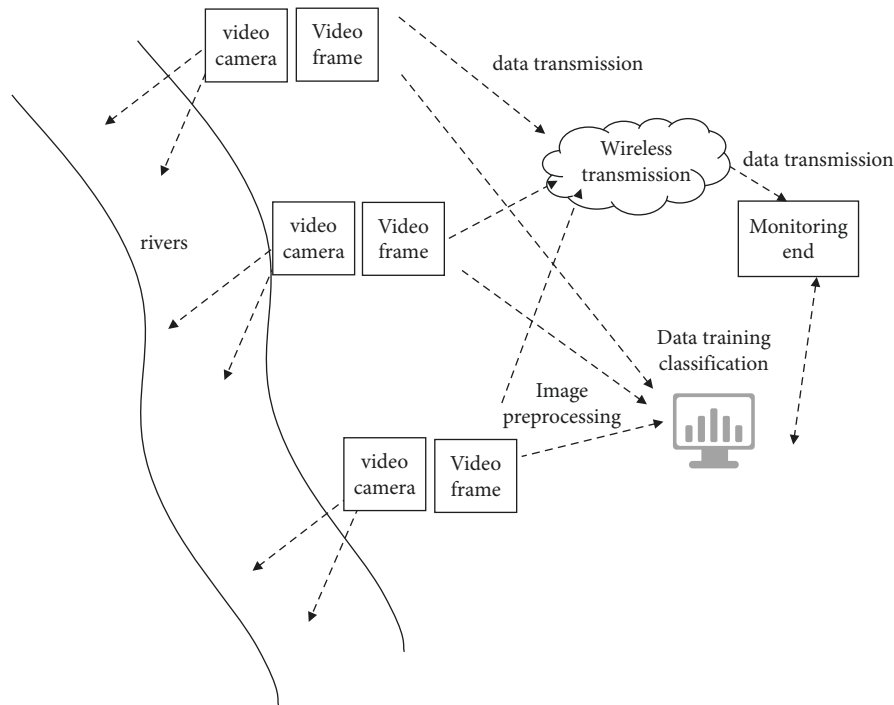

FIGURE 5: Water flow image acquisition scheme.

Many modules are involved in the river image acquisition, including video acquisition and wireless transmission module. The image acquisition and transmission functions are completed as a result of each module's effective cooperation. In the video acquisition module, the function camera with high performance is used to collect images according to the set parameters. The data transmission module realizes the video transmission function, which adopts the Unicom CDMA network. In addition to the above part, it also includes the central monitoring platform. The monitoring terminal can use different access methods. First is to automatically record and update the monitoring position of the image, and second is to query the current record of the image.

During image acquisition, not only the current average velocity is recorded, but also the velocity at both sides of the same time and middle positions is compared, so as to meet the requirements of hierarchical estimation. After the collection is completed, the professional software is used for video interception. So, the training sets can be obtained, totaling 8000 pieces, 1000 pieces for each power station. The classification interval is set, then the flow rate images were clipped. Therefore, the images with the same flow rate are classified based on the flow rate label. The flow rate resolution designed in this study is 0.5 m/s, which is totally divided into five flow rate intervals.

4.3. Experimental Platform Configuration. The experimental platform is set up, and the computing platform uses the Dawn W580-G20 server, Nvidia Tesla k8/0 computing card, dual processor architecture, and 480 GB/S video memory bandwidth. The computing performance is higher, which meets the requirements of this paper.

4.4. Image Processing. In order to enhance the completeness of data and improve the robustness of Figure 3 network, it is proposed to process the collected water flow image data before prediction. Based on GAN and current models, the relatively real pseudo samples can be obtained. But there are some problems with GAN. First, the diversity of sample generation cannot be guaranteed. Second, the training process is difficult [23, 24]. Third, the discriminator is stronger than the generator in the initial stage, so it is difficult for them to achieve a balance in the adversarial training. To solve the problem, David et al. designed a boundary-balanced generative adversarial network. In this network, a new loss function is set up and an autoencoder is introduced. Meanwhile, the GAN is able to learn the texture features directly from raw data, without modeling. Thus, it is consistent with the real data to the maximum extent available. However, as the BEGAN described earlier did not set generator constraints, the fitting effect is affected to some extent. In this study, the above problems are analyzed, and a method based on conditional boundary balance generative adversarial network is designed. Conditional label information has been added to this method to guide the direction in which the data flow is generated. At the same time, the reliability of the generated image is verified to ensure that the generated image meets the higher quality requirements.

4.4.1. Image Generation of Basic Label Information. To study the image generation strategy based on label information, firstly, the samples containing labels need to be extracted. Then, the conditional information is added in the boundary balance network to guide the image output based on

category information. In the design, the label information y is added to the input of the generator and spliced with the sampled noise z . So, the corresponding category's images are generated under guidance. The basic form of the objective function is shown below [25]:

$$\min_G \max_D V(D, G) = E_{x \sim p_{\text{dova}}}(x) [\log D(x|y)] + E_{z \sim p_z(z)} [\log(1 - D(G(z|y)))] \quad (4)$$

where $D(x|y)$ represents the probability of judging that the input image belongs to the real sample, while $D(G(x|y))$ represents the probability after the generator mapping. The loss function is as follows:

$$\text{Loss}(s) = |s - D(s)|^l, \quad l \in 1, 2. \quad (5)$$

In the formula, s represents the sample through autoencoder, and l represents the l_1 or l_2 norm.

In the algorithm, the discriminator and generator have different functions, which can minimize the reconstruction errors of real image and generated image, respectively. Bulldozer distance (EM) is introduced to fit the loss distribution of the autoencoder. The specific formula is as follows:

$$W(\mu_1, \mu_2) = \inf_{\gamma \in (\mu_1, \mu_2)} E_{(x_1, x_2) \sim \gamma} [\|x_1 - x_2\|], \quad (6)$$

Here, μ_1 and μ_2 represent the loss distribution of real data and generated data respectively, while $W(\mu_1, \mu_2)$ represents the set of all possible joint distributions of both of them.

4.4.2. Generate Image Verification Mechanism. This part designs a verification module, which is added into D to identify the extracted image features. The input data is processed based on the nonlinear method and inputs the results in Softmax layer, where the probability of the category can be calculated. The probability formula of an output sample belonging to category i is shown as follows:

$$y_i = \frac{e^{a_i}}{\sum_{k=1}^C e^{a_k}}, \quad \forall i \in 1, \dots, C. \quad (7)$$

It can be seen from the formula that C represents the number of categories to be predicted. The full connection layer output a_1, a_2, \dots, a_c can get the corresponding probability distribution by the Softmax layer processing. The loss function is cross entropy, and the specific formula is as follows:

$$\text{Loss} = - \sum_{k=1}^n \sum_{i=1}^C t_{ki} \log(y_{ki}). \quad (8)$$

The above formula revealed that n represents the number of samples; k stands for some sample; i stands for category; t_{ki} is the probability of k real categories; y_{ki} is the probability that the model pair k belongs to i .

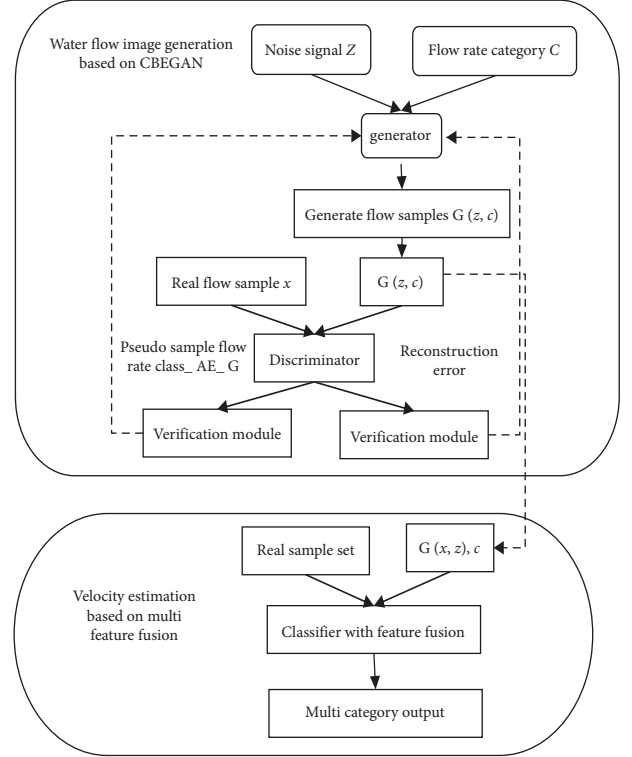

FIGURE 6: Proposed model based on GAN.

4.4.3. The Overall Model Construction. Combined with the above design, the flow velocity estimation model is constructed as shown in Figure 6.

where the whole model is divided into several parts, including three modules, namely, flow image generation, fogging, and velocity estimation. The design of each module is as follows:

Step 1: Collect the video of water flow in this area, which can be divided into two weather conditions. The first is fog blocking, and the second is no blocking, namely, normal illumination. During recording, it is necessary to record the velocity on both sides and in the center of the river, and the flow rate should be determined. Except for the above operations, the appropriate cropping and other operations are required to support the subsequent processing.

Step 2: First of all, the real sample is constructed, which means that the small flow data obtained in the previous step is corresponding to the flow velocity interval. Then, the discriminator and generator are constructed. Meanwhile, the uniform noise signals are input into the generator, and the mixed generated samples and real samples are input into the discriminator.

Step 3: To verify the reliability of the generated flow image, in this process, the classifier with the same structure as the discriminator is used to analyze the flow velocity category. Hence, the optimal model weight is determined on this basis.

Step 4: To generate the flow images, the key part of this step is the CBEGAN network.

Step 5: To generate the data set, normalize the generated samples in the fourth and sixth steps, mix the generated samples and original samples in a random way, and then divide them into training set and test set, which account for 70% and 30%, respectively.

Step 6: To build CNN, input the training set into the designed classification network. So, the recognized flow category can be obtained. Then the verification can be achieved through the test set. During the test, the input image is clipped with the same size, and the output results are weighted and averaged. Finally, the current time flow rate can be obtained.

4.5. Result Analysis

4.5.1. Image Generation Quality Verification

(1) *Verification Mechanism Results Analysis.* The results of verification mechanism are analyzed, and the accuracy curve and category label loss function are shown in Figures 7 and 8 respectively. According to the information in the figure, the quality stability of generated images in the initial stage of training is low, which is related to the training imbalance. And it corresponds to a higher loss function value. When the iterations increase, the adversarial network becomes stable, and the probability of accurate classification increases gradually. For the average accuracy of 0.95, the probability of generating the corresponding category flow image is significantly improved after adding the label information.

(2) *Image Generation Quality.* The results in Figure 9 show that the recognition accuracy of naive GAN and CGAN models is consistent, because the latter is the result of a slight improvement of the former. The classification accuracy obtained by the BEGAN model is significantly higher, because it improves the naive GAN greatly. However, the CBEGAN model designed a special validation module to constrain the flow of generated network data by the loss function. Thus, the higher accuracy is achieved relative to the BEGAN model.

It can be seen that CGAN is difficult to compute unlabeled data efficiently with unsupervised input. Compared with the naive GAN, the generation sample accuracy of BEGAN model is higher, which is related to the self-encoder that exists. The CBEGAN model designed in this study can transfer learning information to the model and then realize the adjustment of weight parameters.

Comparing the GAN network with conditional and unconditional input, it is found that the accuracy of the former generated sample is higher. It is mainly related to the mitigation of the freedom problem in training, which improves the quality of the generated sample.

(3) *Quality Analysis of Generated Image.* In image quality analysis, there are 5 different flow rate levels, namely, 0.5, 1, 1.5, 2, 2.5, and the unit is m/s. After the data set is

FIGURE 7: Accuracy of generated image.

FIGURE 8: Loss function value of generated image.

FIGURE 9: The effect of image generation under different models.

established, it is calculated by the SIM indicator. The formula is as follows:

$$SSIM(x, y) = I(x, y) * c(x, y) * s(x, y), \quad (9)$$

Here, x and y belong to two images, and $l(x, y)$, $s(x, y)$, and $c(x, y)$ are the brightness, structural similarity, and contrast of images in turn.

The above indexes can be used to analyze the image distortion. If the index is large, it means that the quality of the generated image is higher. The SSIM calculation results of different methods are shown in Figure 10.

The information above shows that, compared with GAN, CGAN, and BEGAN, the structural similarity of the algorithm was improved by 0.25, 0.14, and 0.05, respectively. So, the improvement effect was significant compared with the two front algorithms. Compared with the third model, the labeled mechanism can also improve the quality of the generated image, which proves the feasibility of the proposed algorithm.

Here are two images of three-channel X and Y . The size of them is $m * n$. The formula of MSE is as follows:

$$MSE = \frac{1}{m * n} \sum_k \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} (x(i, j, k) - y(i, j, k))^2. \quad (10)$$

In the formula, k represents the number of channels.

In this study, the peak signal-to-noise ratio (PSNR) index is also introduced for evaluation, and its formula is as follows:

$$PSNR = 10 * \lg \left(\frac{MAX^2}{MSE} \right). \quad (11)$$

The above formula shows that the MAX represents the maximum color value of image points, which is 255. Figure 11 lists the calculation results of each method.

The results show that the PSNR index of CGAN is significantly higher than that of GAN, which verifies the positive role of the labeled mechanism. Compared with CGAN, the PSNR of BEGAN is improved again, which verified that improving loss function can improve the image quality.

Compared with other methods, the algorithm designed in this paper has some advantages in the peak signal-to-noise ratio, but the overall PSNR is low. It is presumed to be related to the image compression caused by the autoencoder. The relevant studies are needed to further improve the quality of the generated image.

4.5.2. Analysis of Multifeature Fusion Effect. The adversarial network generated samples are mixed with the real samples. Then the VGG-16 model is adjusted using the transfer learning method. The unsampling and other processing are carried out for the obtained feature maps. After adjusting to a consistent size, the deep semantic and shallow detail information is fused and unified input to the full connection layer. After completing the above operations, the feature fusion network is compared with the untreated network. The training data are uniformly normalized, and the iterative recognition rate and other information are recorded. The final results are shown in Figures 12 and 13.

The information in Figure 11 shows that, compared with the unfused model, the fused model achieves higher

FIGURE 10: Comparison of different methods of SSIM.

FIGURE 11: Comparison of different methods of PSNR.

FIGURE 12: Recognition rate comparison of proposed model and VGG-16.

FIGURE 13: Loss function of proposed model and VGG-16.

FIGURE 14: Output of model in normal state.

recognition accuracy under the condition of the same iterations, which has basically converged around 800 times. Combined with the above analysis, it can be seen that the feature fusion method can be adopted for the feature recognition problem with insignificant difference, which is helpful to enhance the effect.

4.5.3. Flow Rate Estimation Analysis in Natural State. It is necessary to select appropriate test set data in natural state flow rate analysis. Here, the original A-E sample data are selected. In addition, the images without flow rate labels are used to uniformly input into the classification network for processing. The result is as shown in Figure 14. The information in the table shows that the predicted classification

FIGURE 15: Comparison of recognition rate in normal state.

results are basically consistent with the real flow rate levels, which verifies the validity of the model.

Here, when different images are input, the higher the network output result is, the higher the probability of the category is. For the images with different flow velocity intervals, the differentiation is different. The differentiation of B and C images is higher, and the degree of A and D images is lower. For E image, it is found that the category similarity has a certain influence on the discrimination.

The difference of recognition accuracy is analyzed based on different methods, as shown in Figure 15. The same data set is used in the verification, and the velocity resolution of multiple groups, respectively, is set as 0.25, 0.5 and 0.75, and the unit is m/s.

5. Conclusion

In summary, it can be seen that the prediction of river flow image velocity can be effectively realized through the enhancement of river image and multifeature fusion combined with convolutional neural network. The results show that the method has obvious advantages, which is not only in the accuracy of speed prediction, but also in the loss function of the algorithm itself. Through the research, the problem of single feature of river image and the problem of traditional manual real-time acquisition are changed, and the information ability of river disaster early warning is greatly improved.

Winter wheat is one of the most important food products. Increasing food demand and limited land resources have forced the development of agricultural production to be more refined and efficient. The most important part of agricultural production is sowing. With the promotion of precision agriculture, precision seeding has become the main component of modern agricultural seeding technology system, and the adoption of precision seeding technology is an important means of large-scale production and cost saving and efficiency enhancement. However, the current sowing technology and sowing equipment cannot meet the requirements of wheat sowing accuracy. In this context, a differential perturbation particle swarm optimization (DPPSO) algorithm is proposed by embedding differential perturbation into particle swarm optimization, which shows fast convergence speed and good global performance. After that the DPPSO is used to optimize the convolutional neural network (CNN) to build an optimized CNN (DPPSO-CNN) model and applied to the field of crops fine sowing. Finally, the experimental results show that the proposed method not only has a faster convergence rate but also achieves better wheat seeding performance. The research of this paper effectively improves the accuracy and uniformity of wheat seeding and lay a foundation for improving wheat yield per unit area and promotes the intelligent development of agriculture in the future.

1. Introduction

Food security is an important strategic issue concerning China's economic development and social stability. As a country with a large population in the world, China should attach great importance to food security at all times [1, 2]. Since the beginning of the new century, the central government has successively issued no. 1 documents, which have made great achievements in agriculture and rural areas. In 2020, China's grain and other agricultural products will have a bumper harvest, and the total grain output will reach 1,339 billion Jin. At the same time, it is very difficult for farmers to feed their families only by growing grain without relying on sideline work or migrant work, and a large number of agricultural labor force has flooded into the cities, and China's food security depends on the left-behind people who struggle to make a living by growing grain, and it is increasingly unsustainable [3, 4].

China is a big agricultural country, and wheat is one of the most important grain crops in China. The population whose staple food is wheat accounts for about 1/3 of the world's total population. Therefore, ensuring high and stable wheat yield is of great significance to food security. Agricultural production is a necessary condition for the survival and development of human society, closely related to social stability and economic development, and is the most important social production activities of human beings [5]. The development of wheat industry is directly related to food safety and social stability in China. The annual consumption of wheat products accounts for about 20% of the total food consumption in China [6].

As the key link of wheat production, sowing affects the growth and development of wheat, and ultimately affects the yield of wheat [7]. In the process of wheat production, there are mechanical drill sowing, broadcast sowing, and set sowing, etc. In the actual production, due to the contradiction between rice-wheat rotation system and wheat

seeding in South China, the production is mainly based on artificial broadcast sowing and extensive management, which increases the yield of wheat. Strengthening the research on new variety breeding and cultivation technology has a significant impact on the development of wheat productivity. The first is the success of wheat breeding, and the corresponding wheat breeding agronomy needs corresponding farming tools. Second, uniform plant distribution will increase the yield, which indicates the direction for the study of precision seeding in a plot. Precision sowing needs to be applied to the original seed quantity, quality, and other indicators to control, so as to complete the control of seeding quantity and quality to achieve the purpose of precision sowing [8]. Precision seeding device can complete the precise seeding process, but precision seeding is a complex organic combination, including the precise control of seeding depth and seeding position. Although the consistency of seeding depth can be achieved by seeding machine, the cost is too high. To sum up, precision sowing is the result of multiple factors, and a single analysis of seed metering device is not comprehensive. Therefore, it is necessary to combine machine-learning methods to increase the description of iodine excess in the sowing process, which is of great significance to promote precision sowing.

Compared with western developed countries, China's wheat production mode is relatively backward, mainly in the traditional way of planting, sowing, and fertilization according to artificial experience [9]. Planting closely can lead to crowding of crop seedlings and insufficient light, thus increasing the labor density. . Too little sowing will lead to inadequate land use and affect crop yield. Therefore, the realization of precision sowing and application of crops and the promotion of precision agriculture are not only of great significance to improve crop yield and reduce production costs, but also imperative. Precision agriculture is a modern agricultural production system based on modern information and space technology, which is based on remote sensing technology, geographic information system, and global positioning system to achieve precise agricultural operations [10, 11]. According to the specific conditions of each unit inside the farmland area, the soil nutrition information and the spatial status of productivity, the rational use of crop input determine the production target.

At present, the acquisition of crop growth information technology with high accuracy, high speed, high density, and low cost is still the biggest obstacle to the implementation of precision agriculture [12]. The traditional method of field sampling is to understand wheat-sowing situation, but due to the large manpower and material resources consumption of sampling and experiment, the amount of information collection and sampling cost is contradictory. Traditional precision agriculture variable implementation to obtain target data time-consuming, high cost, and time lag, cannot reflect the real-time sowing of wheat. Deep learning technology can provide timely information for agricultural production decision-making and management and provide new approaches and methods for crop growth, quality, and yield monitoring and regional management. Deep learning technology is an important means to collect physical and

chemical data of ground objects and their spatio-temporal change information [13, 14]. It has been widely used, especially with the development of hyperspectral remote sensing technology. Because it can measure the main information needed for wheat seeding and fully display its growth characteristics, it can obtain more abundant information than the conventional method, so as to realize the fine monitoring of wheat seeding. To sum up, wheat fine sowing benefits the country and the people, and the development of deep learning brings convenience to the evaluation and analysis of seeding effect. On this basis, it is of great significance to analyze wheat growth and spatial variation [15].

2. Related Work

The water consumption of wheat from sowing to overwintering was mainly distributed in the shallow soil layer of 60 cm. The water-consuming layer moved from shallow layer to deep layer as the temperature increased from rising stage to mature stage. The water use efficiency decreased with the increase of planting density. If the sowing rate is too high or too low, the soil water storage in the early stage will be overused and the water consumption of winter wheat will be reduced throughout the growth period [16, 17]. If the amount of sowing, the number of basic seedlings in the early stage, and the total tiller number and leaf area index were large too large, then all these factors lead to the decrease of leaf area in the middle and late stage than that in the low sowing. When the amount is small, the population per unit area is insufficient, resulting in low dry matter quality. The tillering capacity and material production capacity of wheat decreased when the amount of sowing was large, and finally the grain quality decreased [18].

With the increase of sowing amount, the number of grains per spike and 1000-grain weight of wheat decreased gradually over the small sowing amount, while the number of ears increased gradually with the sowing amount, and the number of ears was the highest under the large sowing amount. Under the condition of high sowing amount, the yield did not increase but decreased slightly with increasing sowing amount. The main effect of sowing rate on yield was panicle number, followed by grain number per panicle and 1000-grain weight. Increasing sowing amount could effectively increase panicle number, but grain number per panicle weight decreased, and the positive effect of increasing panicle number was greater than the negative effect of decreasing grain number per panicle weight. Nitrogen absorption efficiency and nitrogen production efficiency increased with the increase of sowing amount. With the increase of planting density, the assimilate transport decreased before anthesis, but the accumulation of assimilate and its contribution rate to grain increased after anthesis due to the influence of soil moisture and sunlight, and finally increased protein content. Medium and low sowing rate can not only increase the yield but also significantly increase the content of starch and protein in grain, so that the grain yield and quality can be improved synchronously. Suitable medium sowing amount could increase protein content at

maturity stage, and before the suitable sowing amount, protein content gradually increased with the increase of sowing amount and decreased when the suitable sowing amount exceeded [19, 20].

The appearance characteristics of granular fertilizer and wheat seed are similar, so the existing control system of granular fertilizer application amount has important reference significance to the research and development of wheat seeding amount control system. It can be seen from the current situation of foreign research that some seeding quantity control systems are still controlled by open-loop system, and even closed-loop system is controlled by indirect seeding quantity. In actual sowing operations, there is no breakthrough in the technology of accurate monitoring of large flow sowing quantity of wheat [21]. Therefore, in the process of literature research, there is no sowing quantity control system that can feedback the actual sowing quantity. Through the literature review, it can be seen that the domestic seeding quantity control system is mainly an open-loop system. If the friction between the seeding shaft and the machine and tools is large or there is an installation error, there is an error between the rotation speed of the seeding shaft and its theoretical value, and the rotation speed of the seeding shaft is not uniform within one week which will seriously affect the accuracy of seeding uniformity and seeding amount [22].

According to domestic and foreign practical experience, the advanced agricultural technology depends on the progress of agricultural production machinery. The current pattern of wheat precision sowing in China is also the most recognized by farmers [23, 24]. After that, the speed of seed wheel is controlled by the intelligent speed regulation system, so as to achieve uniform sowing of wheat seed. In this process, it is often necessary to have a fixed power source to provide power for the seed feeder, and the common power source is the ground wheel. However, due to the special properties of ground wheel drive, it has certain requirements on the size of seed besides the loss of seed and ridging, and only the wheat seeds that meet the requirements can be precisely sown. In particular, the poor stability of the power source has always limited the accuracy of seeding, so it is easy to form the instability of plant spacing, and serious shortcomings will also appear in ridging and lumps of seedlings. In the actual production process, due to the consideration of cost, the intelligent precision control system of this type of seeder is often missing, resulting in the adjustment of seeding quantity that is not accurate and cannot meet the most basic precision seeding requirements. At present, air-suction seeder is mainly oriented to large seeds, such as beans, cotton, which is generally economic crops and mainly applied to corn in the field of food crops [25, 26]. However, because wheat belongs to small seeds, air-suction seeder is not suitable for large seeds, and the existing small-seed seeder is mainly used for rapeseed, pepper, and other cash crops, so the type and number of air-suction seeder suitable for wheat are not very common.

The research on precision sowing in agricultural developed countries abroad is earlier, which can be traced back to the middle of the last century. Precision sowing can not

only save seeds but also improve the quality of sowing, thus playing an important role in improving crop yield. Therefore, precision sowing has become the development trend of the sowing industry once it came into being. The same type of precision planter is divided into different series to meet the requirements of different rows, spacing, and traction power. For example, the NC model of MONOSEM precision planter in the United States can realize 4–12 rows of simultaneous seeding. The spacing between rows is 35–80 cm and can realize the simultaneous sowing of 6–24 rows. The line spacing is 45–50 cm, and different types of fine seeding machine can meet the requirements of different ground conditions, soil conditions, and crops by replacing different structures or specifications of the working parts. Precision seeding is divided into mechanical type and pneumatic type. Compared with mechanical type, pneumatic type seed metering device pushes the seeds forward by the force of airflow [27, 28]. It has the advantages of fast seed dividing speed and noninjury and can realize the sowing of different seeds through the replacement of the seed metering plate, with high versatility. In the 1980s, the agricultural developed countries represented by the United States focused their attention on the research of pneumatic precision seeder, and it has been widely used. With the development of research, many modern technologies have been applied to precision seeding machines. In the 1990s, Japan developed a seeder that could be controlled by solenoid valve and developed an electronically controlled precision seeder. The precision seeder has high precision and can control the amount of seeding in real time, which greatly improves the sowing efficiency. This study not only broadens the research idea for the researchers of wheat fine seeding but also has great significance for the development of wheat industry, since the CNN model proposed in this paper is a typically deep learning model, and it can effectively deal with big data situations. The main contributions of this paper are the following:

- (1) DPPSO-CNN is applied in the field of fine sowing of crops for the first time in this paper.
- (2) The method in this paper not only has solid theoretical foundation but also has broad application prospect.

3. Optimized CNN for Fine Sowing of Crops

3.1. Deep CNN Model Introduction. In recent years, CNN model is often used to solve complex image recognition problems [29, 30]. Based on the traditional full-connection layer neural network, CNN adds convolution layer and pooling layer to form the deep CNN model, which is shown in Figure 1. As Figure 1 only shows the schematic diagram of CNN algorithm in this paper, it is impossible to know how many convolutional layers and pooling layers there are. In the algorithm of this paper, we set two layers of pooling layer and two layers of convolution layer, respectively.

The function of the convolution layer lies in the extraction of image features. The essence of the convolution kernel is a filter matrix, which can produce many different

FIGURE 1: The typical schematic diagram of CNN.

effects on the original image. The calculation process of convolution is as shown in equation (1):

$$\text{CONV}_{(ij)} = \sum_i^{m-1} \sum_j^{n-1} u_{ij} \times w + b \quad (1)$$

$$(i = 1, 2, \dots, m-1; j = 1, 2, \dots, n-1),$$

where, u_{ij} is the input image, m and n are the sizes of the input image, w is the size of the convolution kernel, and b is the bias constant of the convolution kernel. $\text{CONV}_{(ij)}$ is the characteristic graph output after convolution operation.

CNN adds an activation function layer to the network and analyzes the model better by adopting the feature mapping method of nonlinear function. Then, the mathematical expression of common activation function is introduced one by one. The mathematical expression of sigmoid function is

$$f(x) = \frac{1}{1 + e^{-x}}. \quad (2)$$

Since formula (1) is an almost function, the value range of its independent variables is the whole real number, and the range of its dependent variables is $[-1,1]$. The mathematical expression of tanh function is

$$f(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}. \quad (3)$$

The mathematical expression of ReLU function is

$$f(x) = \max(0, x). \quad (4)$$

The full name of ReLU function is rectified linear unit. The function is one of the commonly used activation functions, which are characterized by low-computational complexity and no exponential operation. However, it is worth explaining that ReLU function has certain defects in the calculation process. When the data passes through the negative range of ReLU function, the output value is equal to 0. The Leaky-ReLU function can solve the above problem.

$$f(x) = \begin{cases} x, & x \geq 0, \\ \alpha x, & x < 0. \end{cases} \quad (5)$$

Therefore, the efficiency of the entire network operation can be improved to a certain extent. The corresponding equations of Sig and Tanh are as follows:

$$\begin{cases} \text{sig}(x) = \frac{1}{1 + \exp(-x)}, \\ \text{tanh}(x) = \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)}, \end{cases} \quad (6)$$

$$h_{w,b}(x_i) = \begin{bmatrix} p(y_i = 1|x_i; w, b) \\ p(y_i = 2|x_i; w, b) \\ p(y_i = 3|x_i; w, b) \\ \dots \\ p(y_i = n|x_i; w, b) \end{bmatrix} \quad (7)$$

$$= \frac{1}{\sum_{j=1}^n e^{w_j x_i + b_j}} \begin{bmatrix} e^{w_1 x_i + b_1} \\ e^{w_2 x_i + b_2} \\ e^{w_3 x_i + b_3} \\ \dots \\ e^{w_n x_i + b_n} \end{bmatrix}.$$

The output layer adopts softmax function to normalize, and the probability value in the corresponding category is shown in equation (7). In the classification tasks, i is the cross entropy (CE) loss function that is often used to evaluate the gap between predicted value and true value. The CE formula is as follows:

$$\text{loss} = -\frac{1}{m} \sum_{j=1}^m \sum_{i=1}^n y_{ji} \log(\hat{y}_{ji}), \quad (8)$$

where \hat{y}_{ji} is the predicted value and y_{ji} is the real value. The error calculated from the CE function needs to be calculated by back propagation, so as to realize the newer back propagation of model parameters. The original form of the gradient descent method is shown in equation (9):

$$\theta := \theta - \alpha \frac{\partial}{\partial \theta} J(\theta). \quad (9)$$

In the experiments in the following sections, this paper also verifies that the use of Adam has faster convergence than SGD. The mathematical expression of a common Adam optimizer is given as follows:

$$\begin{aligned} m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_t, \\ v_t &= \beta_2 v_{t-1} + (1 - \beta_2) g_t^2. \end{aligned} \quad (10)$$

Therefore, the updating rule of gradient descent is as follows:

$$\theta_{t+1} = \theta_t - \frac{\alpha}{\sqrt{v_t + \epsilon}} m_t. \quad (11)$$

3.2. Optimized CNN Model. It is worth noting that differential perturbation is used in this paper to optimize the CNN model, but other optimization algorithms are feasible in this theory, but they are not optimal choices. Particle swarm optimization (PSO) is simple and easy to solve, but it is prone to local extreme points, low accuracy, slow convergence, and stagnation. In this section, the differential perturbation is introduced into the PSO to form the differential perturbation particle swarm optimization (DPPSO) algorithm, which makes use of the advantages of fast convergence speed and good global performance of difference, overcomes the shortcomings of low precision and local optimal caused by PSO, and builds an optimized CNN model. The multiobjective optimization model is

$$\begin{aligned} \min f_1(x_1, x_2), \\ \max f_2(x_1, x_2). \end{aligned} \quad (12)$$

s.t.

$$\begin{aligned} p_1 &< g_1(x_1, x_2) < q_1, \\ p_2 &< g_2(x_1, x_2) < q_2, \\ p_3 &< g_3(x_1, x_2) < q_3, \\ p_4 &< g_4(x_1, x_2) < q_4. \end{aligned} \quad (13)$$

and

$$\begin{aligned} 120 &< x_1 < 180, \\ 120 &< x_2 < 180, \end{aligned} \quad (14)$$

where f_1 represents energy consumption target, f_2 represents the output target $g_{\{1\}}, g_{\{2\}}, g_{\{3\}}, g_{\{4\}}$ $g_1(x_1, x_2), g_2(x_1, x_2), g_3(x_1, x_2), g_4(x_1, x_2)$ represent the packaging quality of four indicators: crushing strength, wear strength, drop strength, compressive strength, respectively. It is worth noting that the DPPSO algorithm used in this paper optimizes network parameters to obtain better model performance.

Based on the above discussions, the optimized deep neural network and its application in fine sowing of crops is shown in Figure 2. It mainly includes data preprocessing, CNN model training, and parameter optimization based on DPPSO model, and finally obtains the optimal model performance.

4. Experimental Results and Analysis

4.1. Experimental Data Introduction. This area belonged to semiarid and semihumid winter wheat growing. The experimental site was a hilly dry land with an average annual

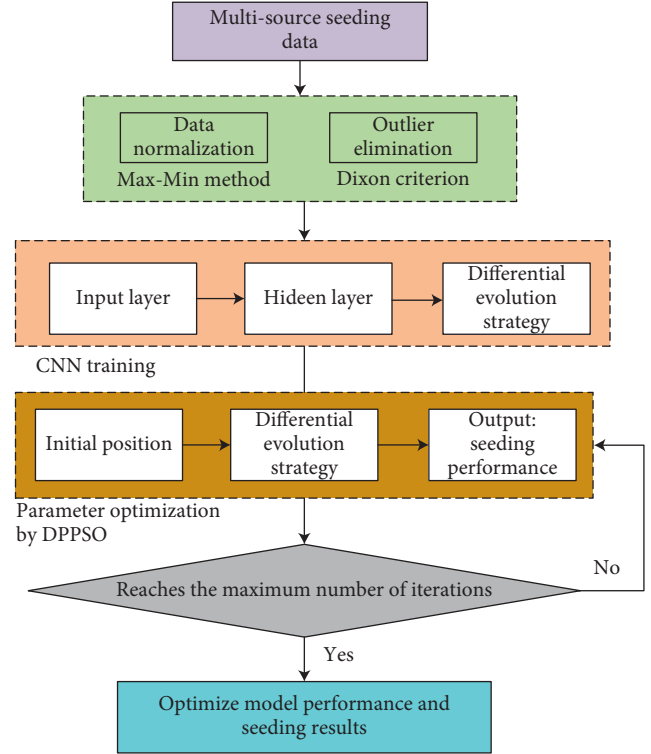

FIGURE 2: The framework of the proposed method in this paper.

rainfall of about 450 mm. The test field was flat and has one cropping system in a year, and the soil was medium alkaline clay loam. The water storage in the test area was mainly natural precipitation, which was concentrated in October and November of 2019. The experimental variety Linfeng no. 3 was provided by the County Agricultural Committee. The experiment used a two-factor experimental design. Furrow sowing (FS) was the main sowing area, and furrow sowing (FS), wide drilling sowing (WDS), and conventional drilling sowing (CDS) were the main sowing methods.

In addition, this study referred to the following data sources: China Rural Statistical Yearbook (1998–2019), China Statistical Yearbook (19982020), and National Agricultural Product Cost–Benefit Data Collection (1998–2020). Excel 2019 software and DPS7.05 software were used for statistical collation of data, Excel 2019 software was used for plotting, and least significant difference (LSD) method was used for significance test of difference, reaching significance level $\alpha = 0.05$.

4.2. Experimental Results Analysis. In order to demonstrate the universality of the proposed method, change curves of different activation functions of CNN model are presented in Figure 3. They all have the following common characteristics: (1) differentiability: this property is a prerequisite when using gradient-based optimization algorithms to optimize models. (2) Monotonicity: when the activation function meets the monotonicity, the single-layer network is guaranteed to be convex so that the subsequent convex optimization operations can be carried out. But in this case,

FIGURE 3: Different activation functions curves of CNN model.

the learning rate usually needs to be set to a small value, which inevitably increases the training time.

In order to verify the training performance of the model, different parameter updating methods are presented, as shown in Figure 4. The left is the batch gradient descent (BGD) algorithm, which refers to the calculation error every time, the gradient is obtained by the same batch as a whole, and the parameters are constantly updated until the error is zero or within the allowed range. The right is the stochastic gradient descent (SGD) algorithm, which means that the training of each sample is updated once, and the data order needs to be shuffled before each cycle. From Figure 4, we know that a big problem of BGD is that the whole data set needs to be scanned in each iteration of gradient calculation. Therefore, when the data volume is large, it inevitably leads to a large amount of calculation and low efficiency, while SGD only needs to take one sample point in each iteration of gradient calculation, so it has computational advantages. Second, since the gradient calculated by SGD is very different from the real negative gradient, it is not very stable, which also explains one of the advantages of SGD, which can jump out of the local optimal solution, so as to find the real global optimal solution. This is especially important in deep learning, where objective functions tend to be nonconvex. In conclusion, SGD model not only runs faster than BGD model in training time. In addition, SGD model solves the problem that BGD model can easily fall into local optimum. Hence, the SGD is used to update the model parameters in this paper.

In order to verify the effective control of the proposed method on wheat sowing range and sowing quantity, according to the determination method of seeding uniformity recorded in national standard GB/T 9478–2005, after the seeding operation is completed, a total of 30 sections of 10 cm were taken, and the number of seed particles in each section was counted, as shown in Figure 5. Sowing uniformity was calculated for each level of combination seeding operation. It can be seen from the

figure that the relative frequency distribution of wheat grain number in each subsection presents positive distribution. The experimental results were analyzed uniformly under the same theoretical sowing rate per hectare. Specifically, when the number of seeds is 50–60, both the sowing range and the sowing rate are the highest, so the result can be considered as the optimal sowing amount per unit area.

Figure 6 shows the computational efficiency and actual complexity of the proposed method. As can be seen from the figure, the computational complexity and efficiency of the proposed method increase first and then decrease with the increase of iterations. In other words, the computational efficiency of the method in this paper reaches the maximum after iteration at 1000 hours. Therefore, the proposed method has a large model fault tolerance rate, which can ensure good model performance within 1000 iterations. It also indirectly shows that the method proposed in this paper has good generalization and extensibility.

Because BP neural network is a shallow model, RNN is a classic deep learning model, and the method in this paper is based on CNN model. Hence, they are selected as the comparison algorithms and the simulation results are presented in Figure 7. As can be seen from the figure, the convergence rates of the four methods all were tended to increase first with the increase of data volume, but with the further increase of data volume, the convergence rate of BP neural network showed a downward trend, indicating that BP neural network is not suitable for processing a large amount of wheat sowing data in this paper. In contrast, the convergence rate of RNN and CNN models generally keeps increasing with the increase of data volume at any time. The main reason is that both methods are deep neural networks with the ability to process big data. However, the convergence rate of these two methods is still not as high as that of PSO-CNN in this paper, which shows the effectiveness and practicability of the method proposed in this paper.

Figure 8 shows the relationship between sowing accuracy and iteration times of different methods. We can figure out from the figure whether with the increase of iteration number, the sowing accuracy of the three methods shows an increasing trend. When the iteration number is 600, the three models all reach the highest classification accuracy, which is 81%, 87%, and 98%, respectively. Therefore, the PSO-CNN model in this paper achieves the highest classification accuracy. In addition, even when the number of iterations is small, the proposed method also has the best model performance and achieves the highest classification accuracy throughout the training process, which demonstrates the effectiveness of the proposed method in wheat seeding monitoring.

To better demonstrate the effectiveness of the proposed method, the monitoring results of CNN and PSO-CNN are shown in Figure 9. Specifically, it can be seen from Figure 9(b) that PSO-CNN method not only achieved the lowest omission ratio of 18.88% but also detected abnormal sowing at the 163rd sampling point with a detection delay of 2, while the corresponding delay numbers of CNN method

were 24, respectively. It shows that the method presented in this paper can detect the sowing error quickly. In addition, when the error is detected, the statistical curve corresponding to the PSO-CNN model rarely falls below the

threshold line, while the statistical curve corresponding to the CNN method always falls back to different degrees, resulting in a high failure rate, which further demonstrates the stability and persistence of the proposed method.

5. Conclusions

Sowing is a key link in wheat production. The performance of seeding machine directly affects the growth and yield of crops. With the promotion of precision agriculture and the development of precision seeding technology, precision seeding has become the main component of modern agricultural seeding technology system. Adopting precision seeding technology is an important means of large-scale production and realizing cost-saving and efficiency enhancement. The online precision measurement of seeding amount is the key to realize precision seeding and precise control and also the basis of realizing precision seeding in real sense.

In view of the shortcomings of the existing methods, this paper proposed an optimized deep learning model PSO-CNN, which not only achieved better model convergence rate and model parameters but also effectively improved the sowing accuracy and sowing range of wheat showing strong theoretical value and application potential. This work is helpful to realize the fine sowing of wheat and improve the level of agricultural automation. Although the method proposed in this paper has achieved good results, the research in this paper does not consider the effects of planting weather and soil in the process of agricultural sowing. This will be the focus of future research.

In order to improve the accuracy of video image moving target recognition and shorten the recognition time, a video image moving target recognition method based on a generation countermeasure network is proposed. Firstly, the image sensor is used to collect the video image and obtain the video image sequence. The Roberts operator is used for edge detection and Gaussian smoothing of the video image. Secondly, the normalization method is used to extract the key features of moving targets in video images. Finally, training is carried out alternately to generate the countermeasure network model, and the video image moving target recognition sample results are output according to the training results to realize the video image moving target recognition. The experimental results show that the highest recognition accuracy of the proposed method is 98.1%, and the longest recognition time is only 5.7 s, indicating that its recognition effect is good.

1. Introduction

Vision is the most direct way for people to get information. Images are the main way for humans to visually obtain information, and images can vividly and vividly describe the dynamic state of images and can convey information more intuitively and specifically [1–3]. With the advancement of science and technology, the development of computer vision technology has gradually made up for and improved the ability of people's vision that they do not have. Among these data, images and videos are important information carriers for computer vision systems. Recognition of moving objects is the key technology of visual analysis of moving objects, and it is also the most basic problem. It usually extracts moving images from the background and preprocesses them [4–6]. When performing target recognition, it is necessary to effectively detect the target and to classify and preprocess it to facilitate subsequent processing. In each frame of video, each independent moving object or region of interest to the user can be quickly and accurately identified and positioned

to the next node. Therefore, it is of great significance to identify moving objects in video images.

At present, scholars in related fields are studying the recognition of moving objects in video images. Reference [7] proposed a video moving object recognition method based on hierarchical modeling and alternating optimization. Based on the observation that foreground and background are two sides of the same coin, treat them as equivalent unknown variables and pose a joint estimation problem called hierarchical modeling and alternating optimization. For the background, it is decomposed into low and high frequency components in time. For the foreground, a Markov random field is constructed as the axis at low spatial resolution. Based on the hierarchical extension of the two models, under a unified framework called the alternating direction multiplier method, the joint estimation is improved to realize video moving target detection and recognition. Experimental results show that this method can generate more discriminative backgrounds and has better robustness to noise, but there is a problem of low recognition accuracy. Reference [8] proposed

a moving target recognition method in a high dynamic scene of a visual prosthesis. A new unsupervised moving target segmentation model is constructed to automatically extract moving targets in high dynamic scenes. The model utilizes foreground cues with spatiotemporal edge features and background cues with boundary priors to generate proximity maps of moving objects in dynamic scenes according to a manifold ranking function. At the same time, foreground and background cues are ranked, and moving objects are extracted through the integration of the two ranking maps. Experimental results show that this method can evenly highlight moving objects in high dynamic scenes and maintain a good boundary, but there is a problem of long recognition time. Reference [9] proposed a moving target recognition method based on sparse and robust principal component analysis of spatiotemporal structure in complex scenes. The algorithm spatially and temporally regularizes the sparse components in the form of the graph Laplacian. Each Laplacian corresponds to a multifeature map constructed over superpixels in the input matrix. The sparse components are used as eigenvectors for the spatial and temporal graph Laplacian while minimizing the robust PCA objective function. A novel objective function is obtained for separating moving objects in complex backgrounds. The proposed objective function is solved using a linear alternating directions method with multiplier-based batch optimization. In addition, an online optimization algorithm for real-time applications is also proposed. Batch and online solutions are evaluated using six publicly available datasets containing most of the above-given challenges. The experimental results show that the algorithm has higher performance, but there is a problem of poor recognition effect.

In order to solve the problems of low recognition accuracy of video images, long recognition time, and poor recognition improvement in traditional methods, this paper proposes a video image moving target recognition method based on a generative adversarial network. The specific technical route studied in this paper is as follows:

Step 1: collect a real-time image through an image sensor to obtain a video image sequence, preprocess the collected video image sequence, use the Roberts operator to perform edge detection on the video image, and perform Gaussian smoothing on the video image at the same time

Step 2: according to the video image preprocessing result, after the feature vector of the video image moving target is obtained by using the normalization processing method, the key features of the video image moving target are extracted

Step 3: train the generative adversarial network model through interactive training, identify the video image moving target according to the training result and the key features of the moving target, and output the moving target recognition sample, thereby realizing the video image moving target recognition

Step 4: comparing the proposed method with the method of reference [7] and the method of reference [8], the experimental results and conclusions are drawn

2. Design of Video Image Moving Target Recognition Method

2.1. Video Image Preprocessing. The object of video image moving target recognition is video image sequence, which is also called video sequence and dynamic image [10, 11]. A video image sequence is a series of video images with a certain or assumed relative order acquired by an image sensor, and the time interval between two adjacent two pictures is given. The video image sequence can generally be expressed as follows:

$$Q = \{q(e, r, w_0, e, r, w_1, \dots, e, r, w_{N-1})\}. \quad (1)$$

Or,

$$Q = \{q_k(e, r)\}_{k=1}^N. \quad (2)$$

In formulas (1) and (2), $w_i, i = 0, 1, \dots, N - 1$ is the moment when the frame of video image is acquired, e, r is the direction of the sensor in the imaging interval, k is the frame sequence, and N is the total number of frames of the video image sequence.

Due to the restriction of the acquisition environment and the influence of random interference and other factors, the effect of recognizing the moving target of the video image is not good, and it needs to be preprocessed. It consists of two steps: edge detection and smooth noise reduction.

2.1.1. Video Image Edge Detection. There are many operators for edge detection, and the fixed template is convolved to obtain the edge of the image. Select Roberts operator [12] to complete video image edge detection.

The video image gradient and the first-order derivative operator correspond to each other. Assuming that the video image function is expressed as $Q(u, o)$, its gradient is defined as follows:

$$\nabla Q(u, o) = (U_u, U_o) = \begin{pmatrix} \alpha u - \alpha o \\ \alpha u + \alpha o \end{pmatrix}. \quad (3)$$

In formula (3), U_u and U_o represent the gradients at pixels u and o of the video image, respectively, and α is a vector factor. Then, the magnitude of this vector is as follows:

$$\beta = |\nabla Q(u, o)| = \frac{U_u^2}{U_o^2}. \quad (4)$$

For ease of calculation, the magnitude can be expressed in the following different ways:

$$\begin{cases} \beta = \max(U_u, U_o) \\ \beta = |U_u| + |U_o| \end{cases} \quad (5)$$

Using Roberts operator, the process of realizing video image edge detection is described as follows:

$$Y(u, o) = \beta [P(u, o) - P(u + 1, o + 1) + P(u + 1, o)]. \quad (6)$$

In formula (6), $Y(u, o)$ and $P(u, o)$, respectively, represent the gray value of the pixel point (u, o) before and after the edge detection of the video image.

2.1.2. Gaussian Smoothing of Video Image. In the process of edge detection, the noise will cause the edge contour curve of the video image to be not smooth enough, which reduces the description accuracy of the edge contour curve of the video image. To this end, for video images, Gaussian smoothing is also required [13–15]. Assuming that the contour curve of the video image is represented as A , and $A(i)$ is the set of all pixels on the contour curve of the video image, there are

$$A = \{A(i) = (u(i), o(i))\}. \quad (7)$$

In formula (7), $u(i), o(i)$, respectively, represents the pixel points on the contour curve of the video image after Gaussian smoothing.

Using formula (7), all pixels in the outline of the video image can be traversed to achieve smoothing. After edge detection and smoothing, the video image quality is improved.

2.2. Extraction of Key Features of Moving Objects in Video Images. Based on the video image preprocessing results, the key features of moving objects are extracted. In order to improve the accuracy of video image moving target recognition, after normalizing the video image moving target feature vector, the key features of the video image moving target are extracted. The normalization processing method does not require geometric correction of moving objects in video images and can achieve a higher feature recognition rate, reduce the complexity of key feature extraction of objects, and basically eliminate the influence of changes in moving objects in images on feature extraction results., with high application value.

- (1) Normalization of video image moving target feature vector [16, 17]: the depth value of a video image moving target pixel and its neighboring pixels is regarded as the video image moving target feature. Then, the feature vector expression of the video image moving target is as follows:

$$S(u, o) = \frac{[D(u-1, o-1), D(1-u, 1-o)]}{[D(u, o+1), D(u+1, o)]}. \quad (8)$$

In formula (8), $D(u, o)$ is the depth value of the pixel point (u, o) of the video image. Perform the following normalization processing on all video image moving target feature vectors:

$$S'(u, o) = \frac{S(u, o)}{S(u, o)}. \quad (9)$$

In formula (9), $S'(u, o)$ represents the normalized video image moving target feature vector.

After the above-given processing, the key parts of the video image are effectively preserved, thereby reducing the complexity of feature extraction for moving objects in the video image.

- (2) Extraction of key features of moving objects in video images: after the feature vector of moving objects in video images is normalized, redundant features in

moving objects in video images are removed. According to the shape of the moving target area of the video image, the key feature points of the moving target of the video image are determined, and the key lines are drawn from this point as the center. The specific operation process is described by the following formula:

$$\gamma = \prod_{n=5}^F \left[\frac{g_n - g_1}{\sqrt{(g_n - g_1)^2 + (g_n - g_1)}} \right] + \left| \frac{g_{n-1} - g_1}{\sqrt{(g_{n-1} - g_1)^2 + (g_{n-1} - g_1)}} \right|^2. \quad (10)$$

In formula (10), g_n represents the image moving target key point, n is the number of video image moving target key points, and F is the video image moving target key feature point set. After the above process, the key features of the video image moving target are effectively extracted, which lays a foundation for the video image moving target recognition.

2.3. Realization of Video Image Moving Target Recognition. The establishment of a generative adversarial network is based on game theory, which includes two aspects, namely, the generative model and the discriminative model [18–20]. By establishing a generative adversarial network model, using the interactive training generative adversarial network model, optimizing the discriminant network and the generator network, and outputting the video image moving target recognition sample results, the video image moving target recognition is realized. Compared with traditional methods, the generative adversarial network has the following advantages: in principle, the generative adversarial network can approach any probability distribution gradually and can be considered as a nonparametric production modeling method. If the discriminator is well trained, the generator can learn the distribution of training samples perfectly. In the generation countermeasure network training, the reconstruction loss weighting coefficient is set to 0.999, and the countermeasure loss weighting coefficient is set to 0.001.

The objective function of the generative adversarial network model used to realize the recognition of moving objects in video images is derived as follows:

$$\min_L \max_K J(K, L) = Z_{x \sim c_d(x)} \times [\lg(K(x))] + Z_{h \sim c_h(h)} \times [\lg(1 - K(L(h)))] \quad (11)$$

In formula (11), x is the video image, $J(K, L)$ is the generative adversarial network model function, and K, L is the discriminative model and the generative model. $Z_{x \sim c_d(x)}$ refers to the expected value of the actual data after passing through the discriminator, $x \sim c_d(x)$ means that x is subject to the actual data distribution, and $K(x)$ is the discriminator.

$Z_{h \sim c_h(h)}$ refers to the expected value of random data after the generator and discriminator, $h \sim c_h(h)$ refers to the sampling distribution of the randomly generated video image moving objects, and $L(h)$ refers to the generator.

In the training of the discriminator network and the generator network, the alternate training method is adopted, which is optimized, and the corresponding training steps are given:

Step 1: pretrain the generative adversarial network initial discriminator network.

Step 2: input the moving target of the video image to be trained into the discriminator network to obtain the mask δ .

Step 3: extract ε moving target samples from training real video images and their corresponding masks δ_ε . Input ε real video image moving target samples into the discriminator. Input the ε real video image moving target samples and the corresponding mask δ_ε into the generator, generate the realistic video image moving target samples, and input the realistic video image moving target samples into the discriminator.

Step 4: calculate the discriminator loss function according to the discriminant situation:

$$G^D = \frac{1}{\varepsilon} [-\lg(K(x)) - \lg(1 - K(L(h, \delta_\varepsilon)))] \quad (12)$$

Step 5: the discriminator network parameters are updated by the Adam gradient descent algorithm:

$$\theta_d = \text{Adam}(\delta_\varepsilon(G^D), \theta_d) \quad (13)$$

Step 6: according to the discriminant situation, calculate the generator loss function:

$$G^H = \frac{1}{\varepsilon} [\lg(1 - K(L(h, \delta_\varepsilon)))] \quad (14)$$

Step 7: the generator network parameters are updated by the Adam gradient descent algorithm:

$$\theta_h = \text{Adam}(\delta_\varepsilon(G^H), \theta_h) \quad (15)$$

Step 8: repeat step 3 until the upper limit of the number of iterations or the generative adversarial network is close to the Nash equilibrium, and the result of the output video image moving target recognition sample is:

$$\mu = (G^D \times \theta_d) - (G^H \times \theta_h) \quad (16)$$

According to the above-given analysis, the method in this paper first collects the video image through the image sensor and uses the Roberts operator to preprocess the video image to obtain the results of edge detection and Gaussian smoothing. On this basis, the key features of moving objects in video images are obtained by normalized processing, and the recognition of moving objects in video images is realized by using the generative adversarial network to output the sample results of moving objects in video images.

TABLE 1: Parameter settings of the experimental test platform.

Name	Specific parameters
CPU	i7-6770K@4.00 GHz
Hard disk	1 TB SSD
Graphics card	AMD
Memory	8G
Operating system	Windows 10

Through the above-given process, the recognition of moving objects in video images based on the generative adversarial network is realized.

3. Experimental Analysis

3.1. Experimental Design. In order to verify the effectiveness of the video image moving target recognition method based on a generative adversarial network, experimental tests are carried out.

- (1) Experimental hardware environment: the experimental test platform is 64 bit Ubuntu14.04, and the specific parameters of the platform are shown in Table 1.
- (2) Source of experimental data: the images used in this paper are all from the VOC2007 public dataset, which includes 20 different types of video images. Among them, including 5011 pictures and 4952 video images, 50 video image moving objects are selected from this dataset as experimental data to identify the video image moving objects. In order to improve the accuracy of the experimental results, it is necessary to ensure the consistency of the image sample specifications used in the experiment, and to process the samples through MATLAB software.
- (3) Experimental indicators: in the experiment, the video image moving target recognition effect, recognition accuracy, recognition time, target recognition quantity, and recognition rate are analyzed as performance indicators.
- (4) In the experiment, the method of reference [7], the method of reference [8], and the proposed method were used to compare and verify the effectiveness of the proposed method.

3.2. Testing and Analysis of Performance Indicators. Two video images were selected for recognition in the experimental data set to verify the recognition effect of the proposed method on moving objects. By comparing the method of reference [7], the method of reference [8], and the proposed method, the recognition effects of different methods on moving objects in video images are obtained, as shown in Figure 1 and Figure 2.

According to Figure 1, it can be seen that the recognition result of the video image moving target obtained by the method of reference [7] is too dark, and the recognition effect is not good due to too much noise interference. The video image moving target recognition result obtained by

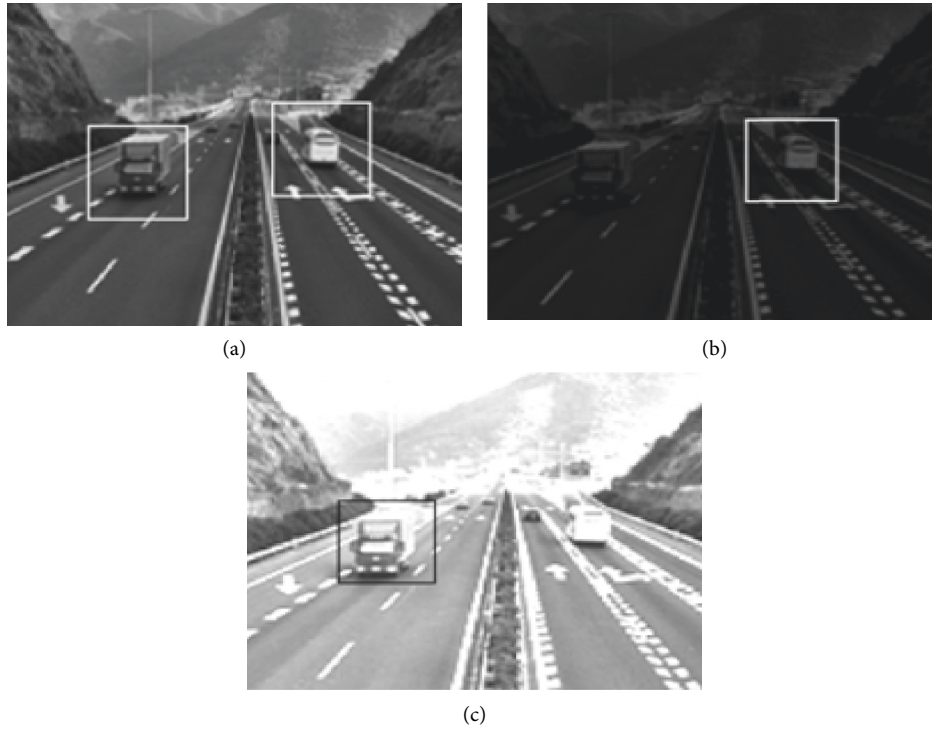

FIGURE 1: Image 1 recognition effect. (a) The proposed method. (b) Reference [7] method. (c) Reference [8] method.

FIGURE 2: Image 2 recognition effect. (a) The proposed method. (b) Reference [7] method. (c) Reference [8] method.

FIGURE 3: Video image moving target recognition accuracy of different methods. (a) Unobstructed. (b) Partial occlusion.

the method of reference [8] is too bright, and the recognition effect is also poor because the edge is not clear enough. In addition, both methods are not good at identifying moving objects. However, the proposed method recognizes moving objects and obtains good results, with moderate brightness, low noise, and clear edges of moving objects. It can be seen from this point that the proposed method is effective and the recognition effect is better.

It can be seen from Figure 2 that when the proposed method is used to identify the moving target in image 2, the head, hands, legs, and footsteps of the athlete in the image can be effectively identified, and the movements are independent of each other and do not appear to identify problems with confusing results. In the recognition method of reference [7], some head movements and footsteps are missing, and the recognition results are not comprehensive enough. The method of reference [8] has the problem of confusion in recognition and recognizes the actions of different moving subjects as one part. It can be seen from the above analysis that the proposed method has a better recognition effect.

To further verify the accuracy of the video image moving target recognition of the proposed method, the method of reference [7], the method of reference [8], and the proposed method are used to compare, and the accuracy of video image moving target recognition of different methods is shown in Figure 3.

According to Figure 3(a), it can be seen that the difference between the recognition accuracy of video images of the three methods is small. The recognition accuracy of the proposed method is compared with the method in reference [7] and reference [8]. There are certain advantages, but the advantages are not obvious.

According to Figure 3(b), when there are 50 moving objects in the video image, the average video image moving target recognition accuracy of the method of reference [7] is

82.9%, and the average video image moving target recognition accuracy of the method of reference [8] is 66.2%. The average video image moving target recognition accuracy of the proposed method is as high as 98.1%. It can be seen that the proposed method has a high accuracy of video image moving target recognition. This is because the proposed method uses the normalization processing method to extract the moving target features of the video image. This method does not require geometric correction of the moving target in the video image but also achieves a high feature recognition rate and reduces the time required for the extraction of key features of the target. Complexity, which is beneficial to improve the accuracy of target recognition.

On this basis, the proposed method is further verified for the recognition time of moving objects in video images. Comparing the method of reference [7] and the method of reference [8] with the proposed method, the recognition time of moving objects of different methods is obtained, as shown in Table 2.

According to Table 2, with the increase of moving objects in video images, the recognition time of moving objects in video images by different methods increases. When there are 50 moving objects in the video image, the recognition time of the method of reference [7] is 12.5 s, and that in the method of reference [8] is 14.4 s. The time for the proposed method to recognize moving objects in video images is only 5.7 s. It can be seen that the proposed method has a short time for the recognition of moving objects in video images. This is because the proposed method preprocesses the video image before target recognition, which is conducive to more efficient target recognition.

There may be a large number of moving targets in the video image, and whether these targets can be comprehensively recognized is also a key indicator to verify the proposed method. Comparing reference [7] method and reference [8] method with the proposed method, the number

TABLE 2: Video image moving target recognition time by different methods.

Video image moving target (piece)	The proposed method (s)	The method of reference [7] (s)	The method of reference [8] (s)
10	1.2	4.1	6.5
20	2.5	6.8	8.3
30	3.6	8.6	10.8
40	4.8	10.3	12.7
50	5.7	12.5	14.4
60	6.0	13.1	15.4
70	6.5	14.6	16.3
80	6.9	15.2	17.0
90	7.2	16.7	17.6
100	7.4	17.9	18.3

TABLE 3: Comparison results of target recognition number of different methods.

Video image number	The proposed method	The method of reference [7]	The method of reference [8]
1	35	27	34
2	41	38	36
3	29	26	26
4	24	21	19
5	31	25	27
6	34	30	30
7	40	34	35
8	27	22	23
9	26	23	20
10	33	28	28

of moving targets recognized by different methods is obtained, and the results are shown in Table 3.

It can be seen from the data in Table 3 that when the proposed method is used for target recognition on 10 video images, the number of recognized targets is significantly higher than that of reference [7] method and reference [8] method. Taking image 5 as an example, the proposed method identified 31 targets, reference [7] method identified 25 targets, and reference [8] method identified 27 targets; taking image 8 as an example, the proposed method identified 27 targets, 22 targets were identified by reference [7] method, and 23 targets were identified by reference [8] method. By comparison, it can be seen that the number of targets identified by the proposed method is more, indicating that the identification results of this method are more comprehensive. This is because the method uses the normalization processing method to extract the key features of moving objects in video images, which is beneficial to improve the comprehensiveness of object recognition.

Finally, the target recognition rate is used as the experimental index to compare the moving target recognition effects of reference [7] method, reference [8] method, and the proposed method. The results are shown in Figure 4.

According to Figure 4, with the increase of the number of experiments, the recognition rate of reference [7] method, reference [8] method, and the proposed method shows a rapid upward trend, but the recognition rate of the proposed method is always higher than that of reference [7] method and reference [8] method. The highest recognition rate of the

FIGURE 4: Comparison results of recognition rates of different methods.

proposed method is 95%, which is increased by 11% and 13% respectively compared with reference [7] method and reference [8] method. It can be concluded that the recognition effect of the proposed method is better, which further verifies its application value.

4. Conclusion

In order to effectively improve the accuracy of video image moving target recognition, ensure the recognition effect, and shorten the recognition time, a method for video image moving target recognition based on the generative adversarial network is proposed. The main innovations of this method are as follows:

- (1) A video image acquisition method based on an image sensor is adopted to acquire a video image sequence.
- (2) Select the Roberts operator to detect the edge of the video image, use Gaussian smoothing, and then standardize it to obtain the key features of the moving target.
- (3) By establishing a generative adversarial network model, training it, optimizing the discriminant and generator networks respectively, and outputting the sample results of video image moving target recognition to realize video image moving target recognition.
- (4) The experimental results show that the proposed method has a good recognition effect, with moderate brightness, low noise, and clear moving target edges. The recognition accuracy rate reaches 98.1%, and the recognition time is only 5.7 s.

In order to solve the problem that variable working conditions and fault types cannot be diagnosed in gear fault diagnosis of petroleum drilling equipment, four kinds of faults, namely, gear broken tooth, gear crack, gear pitting, and gear wear, are studied in this paper. Based on the SOM neural network algorithm, an intelligent diagnosis model of gear fault is proposed, and the PCA method is used to reduce data dimension and fuse features. The state index of life prediction is determined, and the remaining service life prediction of gear transmission system is predicted based on exponential degradation model. The results show that the accuracy of the SOM model for fault diagnosis is high, and the bearing in gearbox can be replaced or repaired in advance according to the residual life curve, so as to achieve the purpose of predictive maintenance.

1. Introduction

With the manufacturing industry entering the “industry 4.0” era, modern mechanical equipment has absorbed the new technology of modern science and technology development, and the degree of automation of mechanical equipment has become higher. At the same time, the structure of equipment has become more complex. Therefore, higher requirements have been put forward for the safety, reliability, and maintainability of the equipment in the operation process [1, 2]. Fault diagnosis technology plays an important role in ensuring the reliability, safety, and maintainability of equipment operation.

The key transmission equipment of petroleum drilling equipment is the key part to ensure the normal operation and power transmission of the whole equipment system. However, affected by the bad working environment, heavy load, high speed, and other working conditions, some typical parts of petroleum drilling and production equipment, such as gears and rolling bearings, are prone to various types of failures, which will affect the safety and reliability of the whole petroleum drilling system. At least, it will lead to the

decline of product or service quality and even cause huge economic losses and casualties. Monitor the condition of large-scale key gear transmission equipment in the petroleum industry, timely handle the faults in the operation of petroleum equipment, and ensure the safe operation of the equipment. At the same time, predicting the future operation trend and remaining service life of the equipment and carrying out equipment maintenance in advance can save maintenance costs, improve economic benefits of enterprises, avoid accidents, and ensure personnel safety [3, 4].

In the process of fault diagnosis of mechanical equipment, after obtaining equipment information, equipment fault is judged by simple time domain signal in the early stage. With the development of diagnosis technology, this simple diagnosis method cannot meet the development needs, and then more reliable and accurate modern signal processing and feature extraction methods are derived [5]. But as the amount of data storage increases, the amount of data to be processed and the corresponding feature dimension increase, these factors will make the fault database rich, but also weaken the information redundancy, data processing, and computing capacity [6]. In addition, the

application of fault diagnosis in petroleum field is too few, the main research results are also mainly focused on fault diagnosis and analysis under fixed working conditions. Although the structure and principle of the petroleum gear transmission system are the same, the operation conditions of the heavy petroleum gear transmission system are complex, and there are problems of variable speed and variable load, which will increase the difficulty of fault diagnosis [7, 8]. The research on fault prediction and remaining service life prediction of petroleum drilling equipment is relatively less. Moreover, it is also found that the fault diagnosis method based on machine learning and remaining service life prediction of equipment are the development trend of petroleum drilling and production equipment [9, 10].

In order to solve the problem that variable working conditions and fault types cannot be diagnosed in the gear fault diagnosis of petroleum drilling equipment, four kinds of faults, namely, gear broken tooth, gear crack, gear pitting, and gear wear, are studied in this paper. Therefore, in view of the limitations of existing fault diagnosis methods in heavy petroleum gear fault diagnosis, this paper studies the unsupervised machine learning algorithm based on SOM for heavy petroleum gear fault diagnosis under complex working conditions.

2. Fault Classification of Transmission System

As the key transmission equipment of petroleum drilling and production equipment, a heavy petroleum gearbox is the key part to ensure the normal operation of the whole equipment system and transfer power. The components of gear transmission system include gears, bearings, and shafts. According to the statistics in literature [11], the gear and bearing account for 79% of failure parts. Gear failure mainly includes gear broken and crack, gear pitting, gear wear, tooth surface gluing, and tooth profile error caused by manufacturing and installation. As shown in Figure 1, this paper selects four kinds of faults: gear broken, gear crack, gear pitting, and gear wear.

2.1. Gear Broken. Gear broken tooth is a serious fault in gear fault. In the process of gear meshing, when the overload impact and pulse cyclic stress occur, the gear will be broken, which can be divided into two forms: overload and fatigue. The first is the tooth fracture caused by overload, which is mainly due to improper assembly. In the process of operation, the load is concentrated at one end of the gear, or the sudden stop and reversing of the gear cause impact overload, resulting in tooth fracture. The second is fatigue fracture, which is mainly caused by improper design, poor assembly, excessive or unbalanced load, stress concentration caused by surface defects of gear teeth, etc.

2.2. Gear Wear. Gear wear is common in gear failure. The wear is mainly divided into normal wear, medium wear, abrasive wear, interference wear, and corrosion wear. If the degree of wear does not affect the normal operation of the

gear, it is generally called normal wear. Moderate wear is mainly caused by high load on the teeth. In general, the service life of the driving gear will be reduced from large to small. When the sliding of the gear meshing dividing circle is blocked, it will lead to excessive wear of the gear, which shows that the working state becomes bad, the tooth profile changes, and in serious cases, it will cause pitting corrosion and plastic deformation. When there are external particles into the gear meshing surface, it will lead to abrasive wear.

2.3. Gear Crack. Gear crack is an early phenomenon of gear fatigue fracture. When the petroleum film of the gear is damaged, the local stress concentration will be caused at the crack. Under the action of cyclic stress, the crack will slowly expand and eventually cause the crack to fracture. This process can be monitored and predicted where the crack appears as tearing crack on the sliding direction of the tooth surface or the appearance is a ridge shape.

2.4. Gear Pitting. The pitting corrosion of gears can be divided into early pitting and destructive pitting. When the surface of the gear is locally convex and bears a large load, or is affected by the high-frequency variable stress, the early pitting corrosion of the gear will be caused, which generally occurs on the surface of the tooth root near the dividing circle of the gear. When the hardness of the gear surface is low, the viscosity of lubricating petroleum is low, and when the dynamic load caused by local pitting corrosion increases, the destructive pitting corrosion of gear will be caused, which is characterized by the destruction of profile and the large size of pitting corrosion. The pitting formed by destructive pitting often becomes the fatigue source and eventually leads to the fatigue fracture of gear.

3. Fault Diagnosis of Transmission System based on Neural Network

3.1. Self-Organizing Maps (SOM) Neural Network Algorithm. SOM neural network realizes the ordered mapping from high-dimensional distribution to low-dimensional regular grid, which is often used as dimensionality reduction of data features. The output neurons of the SOM network compete with each other to be activated, so only one winning neuron is output at each time. As shown in Figure 2, in the self-organizing map, neurons are placed on the network nodes. Usually, the mesh is one-dimensional or two-dimensional, while the SOM network is different from the BP network in that it only contains input layer and competition layer. Since there is no hidden layer, the SOM network can keep the original topological structure of output layer data, which is a typical feature of the SOM network.

The formation process of SOM can be divided into four stages.

The first stage: initialization, the initial connection weights are randomly initialized and the smaller weights are selected.

The second stage of their numerical competition is called the numerical discrimination of neurons.

FIGURE 1: Fault classification of the transmission system.

FIGURE 2: SOM network structure.

The third stage: cooperation, the winning neuron determines the spatial location of the topological neighborhood of the excited neuron, thus providing the basis for the cooperation of adjacent neurons.

The fourth stage: adaptation, in which the excitatory neurons increase their discriminant function value about the input pattern through the proper adjustment of their synaptic weights, and the response of the winning neurons to the later similar input patterns is enhanced. Based on the formation process of SOM, the algorithm steps of feature mapping are as follows [12]:

- (1) The weight vector W_j is initialized randomly and the smaller weight is selected
- (2) A sample $X = (x_1, x_2, x_3, \dots, x_m)^T$ is randomly selected from the input space to the input layer
- (3) The distance between the weight vector of each neuron and the input vector is calculated, its calculation formular is as follows:

$$d_j = \|X - W_j\| = \sqrt{\sum_{i=1}^m (x_i(t) - w_{ij}(t))^2}, \quad (1)$$

where w_{ij} is the weight between i neuron at the input layer and j neuron at the mapping layer. Through calculation, a neuron with the minimum distance is obtained, which is called the winning neuron and denoted as j^* , that is, a certain unit k is determined, such that $d_k = \min_j(d_j)$ for any j . And the set of adjacent neurons is obtained.

- (4) Modify the weights of output neurons and their adjacent neurons

$$\Delta w_{ij} = w_{ij}(t+1) - w_{ij}(t) = \eta(t)(x_i(t) - w_{ij}(t)), \quad (2)$$

where r is a constant greater than 0 and less than 1, which gradually decreases to 0 as time changes.

$$\eta(t) = \frac{1}{t} \text{ or } \eta(t) = 0.2 \left(1 - \frac{t}{10000}\right). \quad (3)$$

- (5) Calculate the output

$$o_k = f\left(\min_j \|X - W_j\|\right), \quad (4)$$

where $f(*)$ is generally 0~1 function or other nonlinear functions.

3.2. Signal Extraction. Before the fault intelligent diagnosis of heavy petroleum gear, it is necessary to complete the feature extraction of fault vibration signal due to the fact that the internal parts of the heavy petroleum gearbox are coupled with each other under actual working conditions, and the load under variable working conditions is complex and changeable. In order to obtain more useful fault feature information, based on the time domain feature extraction of the original signal, the modulation information affecting the sideband in different faults is extracted, and the high-frequency characteristics are filtered out by Hilbert envelope spectrum method, The modulation frequency information affecting the sideband is extracted from the low frequency signal, and then the feature set is formed with the time domain index characteristics of the original vibration signal, which is used as the data sample of the subsequent intelligent fault diagnosis algorithm.

3.2.1. Extraction Device. The vibration data used is from the QPZZ-II rotating machinery vibration analysis and fault diagnosis test platform [13]. The data has the characteristics of various loads and variable speed. In order to collect vibration signals, nine sensors are installed in the gearbox box, and the installation position diagram is shown in Figure 3.

In order to collect vibration signals, nine sensors are installed in the gearbox box, and the installation position diagram is shown in Figure 3, where X is the radial horizontal direction and Y is the radial vertical direction. The measurement position and type of each channel are shown in Table 1.

In the experiment, the input and output frequencies of the gearbox are 5120 Hz and 880 rpm, respectively. The sampling time of each state is 10 s. The vibration signals collected by sensors 2–9 are selected. Combined with speed and gearbox related result parameters, two-stage meshing

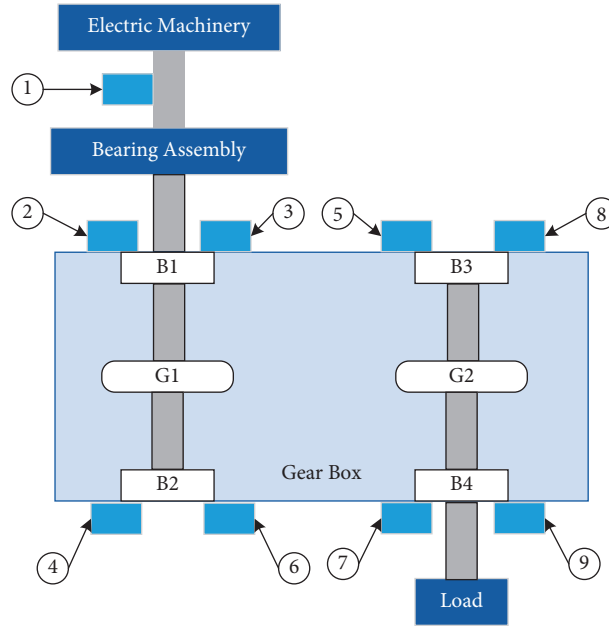

FIGURE 3: Installation position of sensors.

8	CH7	Acceleration	Output shaft motor side bearing X direction
9	CH8	Magnetolectric acceleration	X direction of bearing on load side of output shaft

frequency and fault characteristic frequency of each gear can be obtained, as shown in Table 2.

3.2.2. Sample Extraction. Under the QPZZ-II rotating machinery vibration analysis and fault diagnosis test platform, gear normal, broken teeth, pitting corrosion, and wear data are analyzed. Gear fault features are extracted from time domain, where the state can be divided into normal, broken gear, pitting, and abrasion. Eight features are selected, namely, kurtosis, RMS, ShapeFactor, MarginFactor, peak-to-peak value, waveform factor, margin factor, and energy value under the envelope frequency signal. Four samples are selected for each fault type, and a total of 16 groups of samples are selected to form SOM adaptive network learning samples. The characteristic number of envelope spectrum signal is 8, which makes up $16 \times$. The matrix of 8 is used as the data sample of energy algorithm, as shown in Table 3.

3.3. Fault Diagnosis. The SOM algorithm belongs to an unsupervised algorithm. The difference between the supervised algorithm and unsupervised algorithm is that the supervised algorithm requires input data and corresponding

TABLE 2: Characteristics of gear fault.

	G1	G2

Number of teeth	55	75

label, while the unsupervised algorithm does not need corresponding label of input data, so it has self-learning ability and explores the internal structure of unknown data. Combined with the SOM network algorithm, the flow chart of fault diagnosis is shown in Figure 4.

Different from the supervised algorithm, the SOM network algorithm should design the number of competition layer neurons and network topology before training, and the number of output neurons will also be the final classification results. In this paper, each input is connected to $8 \times$. There are 64 neurons in the hexagonal grid. A two-dimensional output layer composed of 64 neurons is selected, and the index value ranges from 1 to 64. The competitive position of neurons is shown in Figure 5.

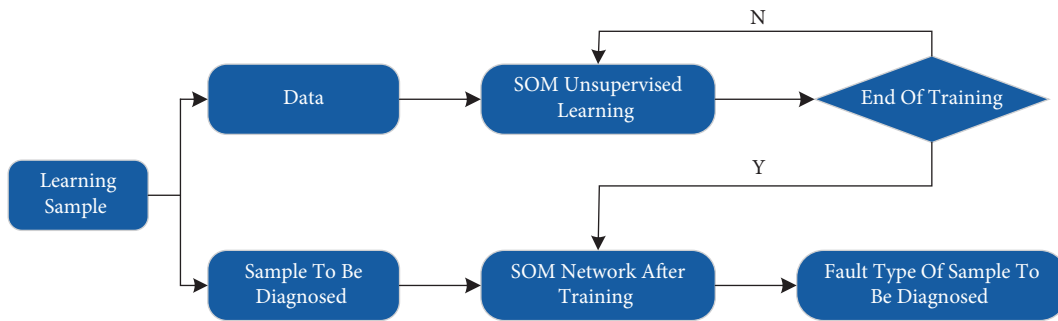

FIGURE 4: Fault diagnosis process of the SOM network.

FIGURE 5: Location of neurons in the competitive layer.

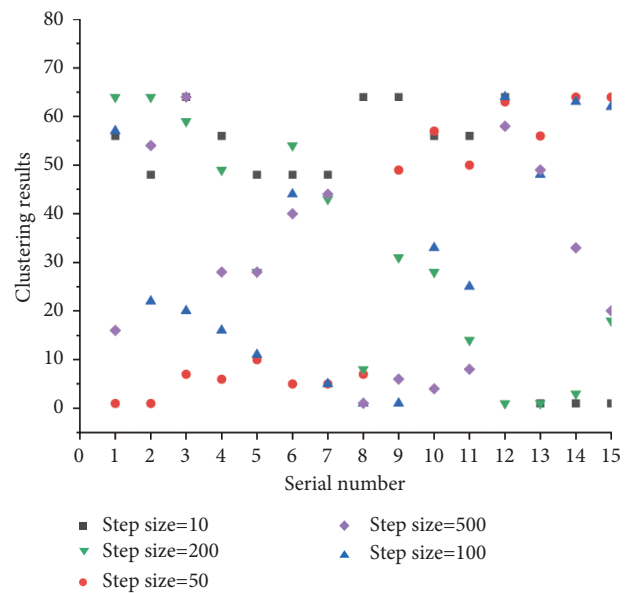

FIGURE 6: Clustering results of the model.

3.4. Result Analysis

3.4.1. Results of Model Training. As shown in Figure 6, when the number of training steps is 10, the number 1 and 5 of fault causes are divided into one category; 2, 6, and 7 are

divided into one category; 3, 9, and 10 are divided into one category; and 13, 14, and 15 are divided into one category. It can be seen that the SOM network can classify the samples in the case of few training steps, but this classification is not

accurate enough. When the number of training steps is increased, the accuracy of classification is also increased, and the SOM network has been able to accurately classify each sample when the number of training steps is increased to 100. However, when the number of training steps continues to increase, it has no effect on the classification results. For example, when the number of steps is 200 and 500, the improvement of training steps has no effect on the accuracy of the results. On the contrary, it will increase the training time.

3.4.2. Results of Sample Diagnosis. Through the comparison of different training times of the SOM model, in order to exclude the influence of too few or too many training steps on the results, the training times of the model are selected as 200, and the test set data numbered 4, 8, 12, and 16 are classified with the SOM network completed by training. The results are shown in Table 4.

Comparing the diagnosis results in Table 4 with the results of 200 training steps in Figure 6, it is found that the SOM network can diagnose the fault types corresponding to the data to be tested, and the accuracy rate reaches 75%.

4. Life Prediction of Equipment

4.1. Prediction Steps. The process steps of residual life prediction of rolling bearing based on the degradation model are as follows:

- Step 1: collect the original vibration signal of rolling bearing with sensor
- Step 2: extract and calculate the eigenvalues by using vibration signal processing and analysis technology and smooth the extracted features
- Step 3: divide the training set and take the early data of the data set as the training data
- Step 4: evaluate the features, use PCA technology to reduce the dimension of the data, and perform data fusion
- Step 5: select the status index
- Step 6: fitting the degradation model of the remaining service life of the training data to obtain the fitting degradation model
- Step 7: use the fitting degradation model to predict the residual life

4.2. State Index Selection. The extraction of the original vibration signal of rolling bearing is the same as before, so the selection of state index is directly described. Among the first six features with large monotonicity, only the peak-to-peak value has better monotonicity. However, if only it is selected as the state index, the information of original data will be lost and error analysis will be caused. Therefore, PCA is used to analyze and fuse multiple features extracted from original data, and the largest principal component is taken as the indicator of state. Through the PCA analysis of vibration signal, the state index is obtained as shown in Figure 7. The

TABLE 4: SOM diagnosis results.

	Normal	Broken gear	Pitting	Abrasion
Serial number to be tested	1	5	9	13
Diagnosis results	59	30	8	1

FIGURE 7: Status indicators.

value of state index increases gradually with time, and it can be seen from the growth trend that the state index has a monotonic increasing trend, which can be used to fit the degradation model.

4.3. Prediction Results. When the state index is selected, the exponential degradation model is used to fit the residual life degradation model of bearing. The model can predict the remaining service life of bearing in real time. The exponential degradation model predicts the remaining service life according to its prior parameters and measured values:

The parameter values are defined as follows:
 $E(\theta) = 1$, $\text{Var}(\theta) = 10^6$, $E(\beta) = 1$, $\text{Var}(\beta) = 10^6$.

The exponential degradation model also provides a function to evaluate the slope. Once the slope of the state index changes significantly, the model will forget the previous observation results and reestimate based on the original prior value. When the slope detection value is adjusted continuously in the model fitting, the final value is 0.025 that the model has the best effect. The degradation model obtained by fitting is shown in Figure 8.

After the model fitting is completed, the life prediction of the data is carried out, and the remaining service life of the bearing is predicted by comparing the threshold value of the input measured value with the final failure threshold value. The residual life curve is shown in Figure 9.

The actual life curve (blue) and predicted life curve (red) show that the slope of input state index changes at 37 min. Before that, the change of slope cannot be detected in this time

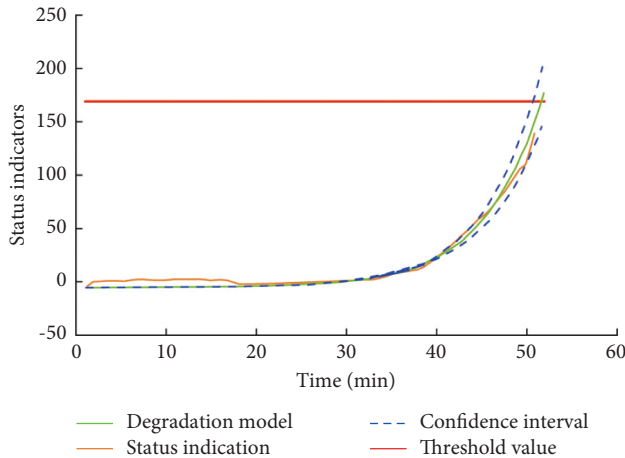

FIGURE 8: Degradation model.

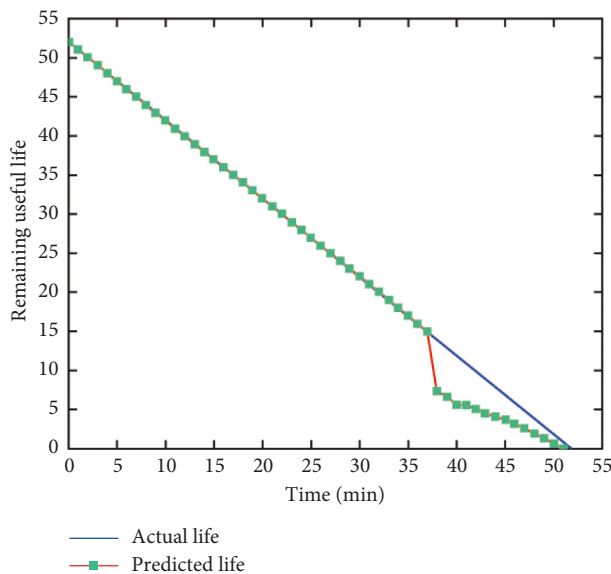

FIGURE 9: Residual life curve of equipment.

area because the change of state index is not obvious. After 37 min, the life curve changes obviously, and the life is 0 at 51 min, reaching the failure threshold one day earlier than the actual life. According to the predicted residual service life curve, the equipment can be maintained in advance and the bearing can be replaced to prevent accidents.

5. Conclusion

In view of the limitations of the existing fault diagnosis methods in gear fault diagnosis of heavy petroleum drilling, this paper proposes a gear fault intelligent diagnosis model based on the SOM neural network algorithm. Under this model, the data not entered into the label are classified. 16 groups of data samples are selected and 8 characteristic indexes are selected. Experimental results show that the accuracy rate of fault classification is 75%. In addition, based on the degradation model, the remaining useful life of drilling equipment is predicted. The results show that the

obvious change of slope can be detected at 37 min, which verifies the effectiveness of the exponential degradation model. The bearing in gearbox can be replaced or repaired in advance according to the residual life curve, so as to achieve the purpose of predictive maintenance.

In order to solve the problem, the psychological identification of athletes in professional competition pressure is difficult. This paper first analyzes the sources of athletes' psychological pressure based on the hierarchical clustering method, and then divides the weights of the sources of psychological pressure, quantitatively scores them and constructs an identification model of athletes' psychological pressure. Then, the clustering process is optimized based on the K-Means algorithm, and its effectiveness is verified. Finally, the psychological stress of 10 players in a football club was analyzed. The results show that the model effectively and reasonably reflects the influence of pressure sources on the athletes' competitive state during the competition, which provides a basis for the decision-making of relief about athletes' stress.

1. Introduction

Competitive sport is a highly stressed profession that high-level athletes often lose in major competitions. With the professionalization of sports and the improvement of athletes' psychological requirements, it is an inevitable trend to relieve the pressure before competition. Therefore, it is very important to identify the stress sources of athletes in sports competitions. Psychological counseling is generally to evaluate the athletes' psychological state by consulting professionals or using some questionnaires [1, 2], where professionals divide the results given by athletes into three grades: high, medium, and low. Different grades give different psychological analysis, and generally, athletes' psychology only needs to be roughly classified according to grades [3]. To alleviate the chronic stress of athletes, team doctors and psychologists need to intervene through investigation and interviews where athletes' thoughts can be understood, and the types of stress can be identified through professional psychological analysis. In the past, the research conclusions often focused on the coping strategies of athletes in a specific event, or on a certain element or link in the coping process, so it is impossible to effectively analyze the overall psychological situation [4, 5]. When the number of athletes increases, psychologists cannot effectively make

personalized judgments according to their personal situation, which is inefficient and the coping strategies and results are not ideal.

The work required for stress relief includes information collection of athletes, identification of stress sources, evaluation of sports psychological state, and formulation of strategies, among which the identification of stress sources generally includes training activity test, team doctor inquiry, real-time evaluation, and self-explanation [6]. For the work of relieving athletes' precompetition stress, source identification is the most basic and the most difficult part to implement, which is determined subjectively by the experience of team doctors, whose uncertainty is high. In the process of identifying the source of athletes' stress, because athletes' own experiences are different and their psychological feedback is different, it is particularly important to deal with the collected psychological index data reasonably. Hierarchical clustering method is a common method in the field of data mining. By grouping data samples, it can quickly summarize the common points of different cluster information and then identify the core information. In addition, it is simple, clear-thinking, and can effectively deal with big data sets, so it has been applied in many fields. However, from the perspective of identifying athletes' stress sources,

FIGURE 1: The process of the clustering algorithm.

the judgment chain of the hierarchical clustering method is still insufficient to deal with relevant data [7, 8].

In order to help psychological experts provide scientific suggestions, this paper carries out automatic simulation from the aspect of data mining, analyzes athletes' psychological pressure by using the clustering algorithm and effectively reflects the influence of pressure sources on the athletes' competitive state in the process of competition, which offers a basis for the formulation of decisions to athletes' stress relief.

2. Identification of the Athletes' Psychological Pressure Based on the Hierarchical Clustering Method

2.1. Clustering Algorithm. Clustering analysis is one of the main methods of data mining, which is used to divide a large number of datasets into several clusters. Typical clustering mainly includes the processes of raw data preparation, feature extraction, proximity measurement, clustering or grouping, and clustering result evaluation [9]. Figure 1 depicts the typical sequence of the first three steps, which includes a feedback route; among them, the output of grouped results will affect the extraction of data features and the calculation of its similarity:

- (1) Primary data preparation. It means preparing data, including processed valid data, number, quantity, type and scale of valid data, standardization, and dimension reduction of data features.
- (2) Feature extraction. Extracting the most effective feature subset from the original feature set to form a new dataset. Therefore, feature extraction is a method of converting the original feature subset into a more significant new feature subset to make the clustering effect more obvious.
- (3) Proximity measurement defines the distance function between pairs of data, which is used to measure the similarity between data;
- (4) Clustering or grouping. For grouping or clustering, you can use a variety of clustering algorithms, such as hard clustering (giving a clear division result) or fuzzy clustering (giving the membership degree of each data in the cluster), and hierarchical clustering algorithm.
- (5) Evaluation of clustering results. Evaluate whether the clustering results are valid by measuring the matching degree of clusters to data or by measuring the matching degree of clusters to benchmarks. The main evaluation methods are the object matching degree and related test evaluation.

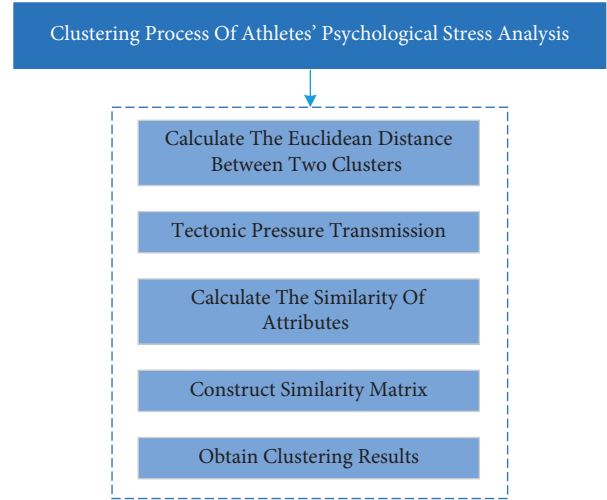

FIGURE 2: Clustering process of athletes' psychological stress analysis.

2.2. Hierarchical Clustering Algorithm. Hierarchical clustering method is a common method to test abnormal data in samples which firstly standardizes multidimensional datasets and then aggregates data categories according to different levels, so that data subsets at different levels have certain similarities, while the gaps between subsets are relatively obvious [10]. According to the difference of hierarchical decomposition methods, it can be further divided into two categories: condensation and classification. Condensation clustering method takes each unit object as an independent cluster and then merges the nearest cluster in turn until the basic conditions set by the system are met or all objects are merged into one cluster. The rule of classification clustering is to treat all units of objects as a cluster and divide each cluster by iteration until the basic conditions set by the system are met or each object is divided into a cluster. Therefore, this method is also called the top-to-bottom clustering method.

2.3. Cluster Analysis Model. In contrast, the operation process of the aggregation clustering method is simpler, which is more suitable for the analysis of the athletes' psychological state. Therefore, this paper adopts this method. The specific clustering process is shown in Figure 2:

- (1) Calculate the Euclidean distance between two clusters as

$$d(i, j) = \sqrt{\sum_{i=1}^m (x_{il} - x_{jl})^2}, \quad (1)$$

where $d(i, j)$ represents the distance between x_i and x_j , which are composed of m attributes; x_{il} and x_{jl} represent the l th attribute value of x_i and x_j , respectively.

(2) Construct pressure transmission.

The clustering method based on Euclidean distance is efficient, but the Euclidean distance is not transitive, that is, through $d(i, j) > t$ and $d(j, k) > t$, $d(i, k) > t$ cannot be directly deduced. In identification of athletes' stress, it is necessary to distinguish the pressure by ordinal utility theory, so that the transmission of pressure must be ensured.

Assuming that n object samples for $\{u_1, u_2, \dots, u_n\}$, and each object is m attributes which are set as $\{a_1, a_2, \dots, a_m\}$, and the i th object has the property of $u_i = \{x_{i1}, x_{i2}, \dots, x_{in}\}$. Then the distance between x_{ik} and x_{jk} of the k th attribute of u_i and u_j is

$$d_k(i, j) = \frac{|x_{ik} - x_{jk}|}{a_{k \max} - a_{k \min}}. \quad (2)$$

Among them, $a_{k \max}$ and $a_{k \min}$, respectively, represent the maximum and minimum values of the k th attribute a_k of each object.

(3) Calculate the similarity of attributes.

The similarity of each attribute of object u_i and u_j is

$$d(i, j) = \frac{\sqrt{\sum_{l=1}^m d_k^2(i, j)}}{m}, \quad (3)$$

where, $d(i, j)$ represents the distance between x_i and x_j , which are composed of m attributes; x_{il} and x_{jl} represent the l th attribute value of x_i and x_j , respectively.

$$s(i, j) = 1 - d(i, j), \quad (4)$$

where, $d(i, j)$ represents the distance between x_i and x_j .

(4) Construct similarity matrix.

The transitive closure $T = T(R)$ of similarity matrix S is obtained by the quadratic method in fuzzy mathematics.

(5) Obtain a clustering result.

The corresponding clustering results can be obtained by establishing the system clustering graph based on T and setting a threshold value for interception.

2.4. Identification of Athletes' Psychological Pressure. The psychological conditions of athletes in different categories of events are selected as basic samples, and the scores of psychological pressures are taken as attributes. The above clustering analysis model is used to analyze the psychological pressures of athletes, so as to identify the clustering results of various pressures. The formula of identification is

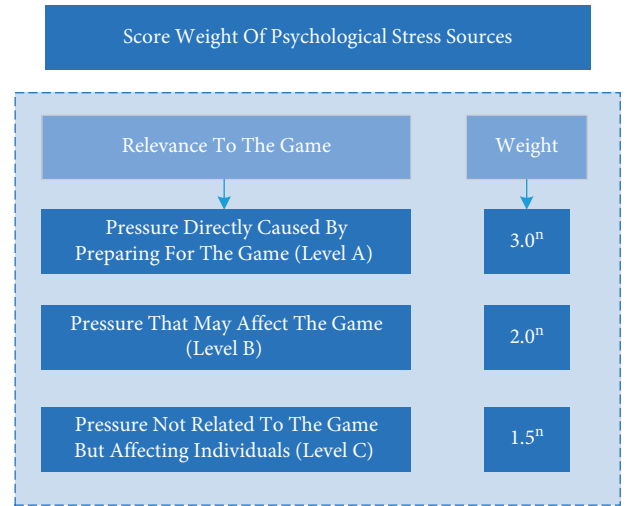

FIGURE 3: Score weight of psychological stress sources.

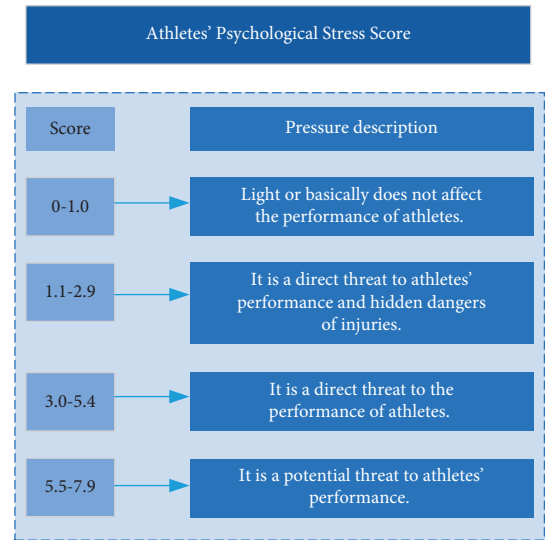

FIGURE 4: Score of athletes' psychological stress.

$$Q = \frac{(\sum_{i=1}^m w_i e_i)}{\sum_{i=1}^m w_i}, \quad (5)$$

where m represents the type of pressure source, w_i represents the score weight from sources of category i , which is directly related to its impact on performance. The stronger the correlation between psychological stress and the performance of the field, the higher the weight, otherwise, the lower the weight. According to "Psychological Instruction Manual for Active Athletes," the weights are distributed and calculated in the form of index. The results are shown in Figure 3:

Among them, n represents the repeated times of the same kind of pressure in different athletes' psychological information.

The description of athletes under different psychological stress scores is shown in Figure 4:

FIGURE 5: Optimization process based on K-Means.

3. Optimized Model of Athletes' Psychological Stress Based on the K-Means Algorithm

3.1. *Optimization Process.* Because the amount of data is small, and there are many features of them, if only a clustering algorithm is used, the discrimination between data will be low. In order to obtain better initial center and time complexity, the above model is improved in a hierarchical way.

Assuming that $X = \{x_1, x_2, \dots, x_n\}$ is the data of n r -dimensional spaces. Firstly, the algorithm uses a contour coefficient to determine the approximate number of clusters. After hierarchical clustering is used to reach this level, the number of clusters and the initial center of iteration are locally adjusted, thus greatly saving the computation for clusters with more levels. In addition, when adjusting the initial center locally, the evaluation standard of intra-class similarity is adopted, the cluster with the lowest similarity is decomposed into two new clusters. In this way, the clusters with insufficient cohesion but mistakenly classified into one class can be adjusted locally, which makes the selection of initial center more reasonable and convenient for operation. The specific implementation steps are shown in Figure 5:

- (1) Data processing is carried out on the original data, and the contour coefficient is calculated. The maximum K is taken as the initial value.
- (2) Two adjacent clusters are combined by using the aggregation hierarchical clustering algorithm to form a new cluster.
- (3) The mean values of two cluster centers at the same level on the new cluster center after merging are calculated.

TABLE 1: Experimental data set.

	Size of dataset	Number of clusters
Iris	150	3
Breast cancer	300	2
Abalone data	4000	30

- (4) Repeat step (2) and step (3) until $(K - R)(0 < = R < K - 2)$ cluster (if $k = 2$, then $R = 0$).
- (5) Calculate the intra-cluster similarity of all the divided clusters, respectively.
- (6) Select the cluster with the smallest similarity in the cluster, that is, the cluster with the largest class radius, decompose the cluster and find out the sample point x_{i1} farthest from the center c_i of the class, and then select the sample point x_{i2} farthest from x_{i1} in the class.
- (7) x_{i1} , x_{i2} and other cluster centers are used as new cluster centers to make K-Means clustering again.
- (8) If the centroid changes, return to step (6), otherwise, the algorithm ends and the result is output.

It can be seen that from step (1) to step (4), the hierarchical clustering algorithm is used to cluster the original data; while from step (5) to step (6), K-Means clustering is started where the number of clusters is reselected according to the number of clusters roughly calculated by the previous hierarchical clustering algorithm, and the initial clustering center of the K-Means algorithm is selected according to hierarchical clustering. Finally, K-Means algorithm is used for secondary clustering from steps (7) to (8).

3.2. Validation of the Model

3.2.1. *The Validation Environment.* In order to verify the effectiveness of the improved algorithm, Iris data, Breast Cancer data, and Abalone data in the UCI database are selected for verification. The size of the dataset and the number of clusters are shown in Table 1.

The experiment is tested on a PC (2.4 GHz Intel CPU, 2G memory, windows7 system). The programming language is R language, which is an open source language and the operating environment for statistical analysis and drawing. But it has stronger statistical analysis and data operation (especially in vector and matrix operation) functions than C language. Therefore, in this paper, the algorithm is implemented with its powerful extended language package and function of matrix calculation [11, 12].

3.2.2. *Validation Results.* The results of clustering are compared from the aspects of operation efficiency and the aggregation degree. The comparison of CPU runtime under different models is shown in Figure 6.

It can be seen from the data that with the increase in datasets, the CPU run time increases significantly. This is because the improved algorithm uses the contour coefficient to predict the value of K in advance, and only performs

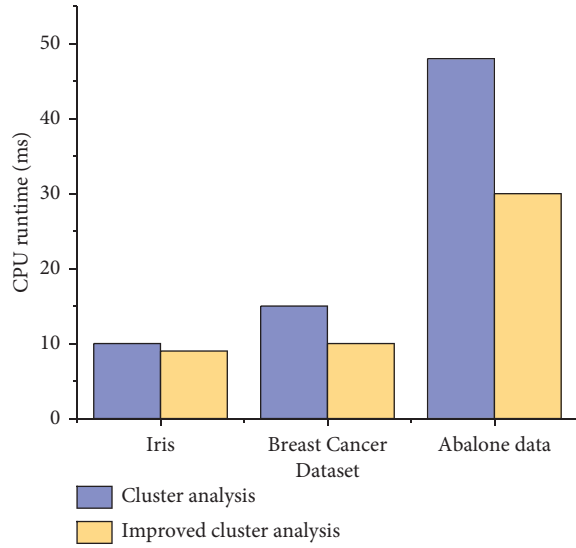

FIGURE 6: Comparison of CPU run time of different algorithms.

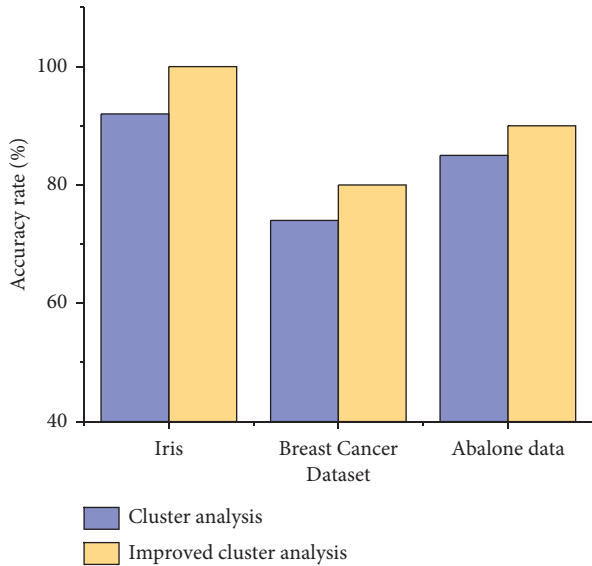

FIGURE 7: Comparison of accuracy under different algorithms.

small-scale optimization near the K value, which effectively reduces the time complexity of the algorithm.

In addition, in order to represent the clustering degree of the cluster, we evaluate the effectiveness of the algorithm through the accuracy rate, and the results are shown in Figure 7.

The accuracy of the improved clustering algorithm is higher than that of the traditional clustering algorithm, which shows that the efficiency and accuracy of the improved algorithm are significantly strengthened for small sample datasets.

4. Case Analysis

4.1. Index Selection. Taking the players in a football club as the research object where 10 players of different ages were

randomly selected for psychological stress analysis. The participants were evaluated with the stress perception scale and the psychological stress tolerance test. The original test data were standardized as the score data of [0, 10] by using the linearization processing, then the identification model of athletes' psychological pressure in Section 4 can obtain the data of psychological stress of athletes in the club, as shown in Table 2.

There are two types of pressure sources [13]: acute pressure and chronic pressure. In specific application, the pressure sources can be further subdivided, and then the corresponding analysis is conducted by using the clustering method, so as to provide reference for the team to relief athletes' pressure.

4.2. Analysis of Athletes' Psychological Pressure. Taking the score data of athletes' psychological pressure under different factors into the algorithm mentioned above, the transfer closure matrix T of each influencing factor can be calculated as follows:

$$T_1 = [1, 0.8, 0.9, 0.9, 0.8, 0.9, 0.9, 0.9, 0.9]^T$$

$$T_2 = [0.9, 1, 0.9, 0.8, 0.8, 0.8, 0.8, 0.8, 0.8]^T$$

$$T_3 = [0.9, 0.9, 1, 0.9, 0.8, 0.9, 0.8, 0.8, 0.8]^T$$

$$T_4 = [0.9, 0.9, 0.9, 1, 0.9, 0.9, 0.9, 0.8, 0.8]^T$$

$$T_5 = [0.9, 0.9, 0.9, 0.9, 1, 0.9, 0.9, 0.8, 0.8]^T$$

$$T_6 = [0.9, 0.9, 0.9, 0.9, 0.9, 1, 0.9, 0.9, 0.8]^T$$

Therefore, the system clustering diagram of this model is shown in Figure 8:

According to the transitive closure T , it is necessary to take 0.90 as the threshold value of the system clustering diagram. Thus, A1 and A2 are combined into a cluster, A4 and A5 are combined into a cluster, and A3 and A6 are formed into a cluster, respectively. Therefore, the psychological pressure of athletes in the club is shown in Table 3.

It can be seen from the above data that 67.87% of athletes' pressure comes from the outside, which is chronic pressure; while 32.13% of them comes from competitions, which is acute pressure. Generally speaking, athletes cannot fully concentrate in the game, and they are easy to be affected by off-site factors. To deal with a large proportion of off-site pressure, the organizers need to assist the team operators to introduce professional psychologists for counseling, so that athletes can focus on the competition.

Through the analysis of the example shows that the athletes clustering algorithm can realize effective pressure source identification, through the study of the automatic classification of athletes psychological pressure information, based on individual rating of athletes get event athletes overall pressure source, for the organizers to provide guidance for alleviating the psychological pressure of the athletes.

Athletes A2, A3, A6, and A9 have less pressure on training and life, which indicates that they have better control of tenacity, lower confidence, and enthusiasm in engagement. In addition, their overall relationship with coaches is better, but it is poor in terms of complementarity

TABLE 2: Psychological pressure scores of athletes under different factors.

Athletes	M1 training	M2 life	Developing M3	M4 family	M5 social networking	M6 score
A1	7.44	4.56	4.48	7.98	3.45	7.89
A2	3.15	7.38	7.26	5.01	6.38	5.06

A9	1	B
A10	0.7	C

that mainly refers to the state of athletes under the guidance. The overall stress level of these athletes is relatively low which shows that they have better psychological quality, higher happiness, and social support.

5. Conclusion

In this paper, an analysis model of athletes' psychological pressure is constructed by the clustering algorithm, and the source of athletes' psychological pressure is identified quantitatively. The validation results show that the optimized psychological pressure analysis model can effectively reduce the time complexity of the algorithm, improve its operation efficiency and accuracy, and can better adapt to the test of psychological stress. In addition, the result of case analysis shows that the overall stress level of athletes A2, A3, A6, and A9 is relatively low, which indicates that they have

better psychological quality, higher happiness, and social support. To sum up, the model realizes the automatic evaluation of athletes' pressure and can be used as an assistant tool for team doctors or psychologists. From a practical point of view, the pressure source identification tool constructed in this paper is practical in large-scale competitions, and the identification of athletes' pressure sources can help each team to pretest athletes' psychological pressure, and then make targeted adjustments, which is conducive to maximizing athletes' potential for competition.

Aiming at the problems of long sharing time, low accuracy, recall, and F1 value in the traditional data sharing method of college dance teaching resource database, a data sharing method of college dance teaching resource database based on PSO algorithm is proposed. Multiple regression KNN method is used to eliminate the data noise of college dance teaching resource database, so as to obtain the missing value and complete the filling of incomplete data of college dance teaching resource database. Taking the preprocessed data as the basic element of transmission object statistics and analysis, establish the data transmission self-service channel of college dance teaching resource database, calculate the similarity of the data according to the unequal length sequence, and use the partial least square method to complete the feature extraction of the resource database data. According to the feature extraction results, particle swarm optimization algorithm is adopted to share the data of college dance teaching resource database. The simulation results show that the accuracy, recall, and F1 value of the data sharing method of college dance teaching resource database based on PSO algorithm are high, and the sharing time is short.

1. Introduction

With the development of information technology in China and the global trend towards interconnection, information resources have received unprecedented attention and are listed as equally important strategic resources as energy resources and material resources. Information resources are of great significance to promote socioeconomic and social development because of their unique characteristics of easy sharing, unlimited dissemination, reuse, and zero pollution [1]. Since entering the twenty-first century, the application of information technology in education and teaching has attracted more and more attention. The degree of educational informatization also occupies an important position in the measurement of national educational modernization. Improving the quality of higher education is not only the need of the development law of higher education itself, but also the need of building an innovative country. Through unremitting efforts, China has made certain achievements in

the construction of educational information infrastructure. Educational informatization has been incorporated into the overall development of national informatization, and the application of informatization in education has been qualitatively improved. Among them, educational informatization in colleges and universities is an extremely important one [2].

How to fully and effectively develop and utilize teaching resources, turn disadvantages into advantages, enhance professional school running characteristics, improve education and teaching quality, and cultivate qualified dance professionals is an important issue in front of us. At present, the development of multimedia technology is changing with each passing day. We rely more and more on multimedia technology in our daily life and work. There are more and more dance videos. Through multimedia, college dance teaching is digitized, and the way of expression is more and more intuitive, both in content and in information [3, 4]. In addition, due to the development and popularization of

network and computer, many video websites, such as iqiyi, Tudou, Tencent, Sohu, and Youku, have many university dance teaching resource databases on these websites, but how to manage these videos has become the key research direction of multimedia information experts [5]. The composition of college dance teaching resource database is very complex, with a large amount of information, which is very different from the general form of text information processing. How to import high-definition dance videos into the video website resource database and let students share the data in the college dance teaching resource database is an urgent problem to be solved [6, 7].

Reference [8] puts forward the storage and sharing method of digital media materials through MVC mode, and [9] puts forward the information-based teaching resource sharing method through multimedia technology. However, the accuracy, recall, and F1 value of the above two methods for teaching resource data sharing are low, resulting in poor sharing effect and short time of teaching resource sharing, resulting in low sharing efficiency. In view of the problems existing in the above methods, this paper proposes a data sharing method of college dance teaching resource database based on PSO algorithm. PSO is the abbreviation of particle swarm optimization algorithm. It is a random optimization technology based on population. Particle swarm optimization simulates the swarm behavior of insects, herds, birds, and fish. These groups look for food in a cooperative way. Each member of the group changes its search mode by learning its own experience and the experience of other members. By collecting the data of college dance teaching resource database and processing the collected data, the data of college dance teaching resource database is shared through PSO algorithm according to the processing results. The experimental results show that this method can share the data of college dance teaching resource database quickly and accurately, and it lays a foundation for improving the quality of dance teaching in colleges and universities.

2. Data Sharing Method of College Dance Teaching Resource Database Based on PSO Algorithm

2.1. Data Preprocessing of Dance Teaching Resource Database in Colleges and Universities. Since the inventory of dance teaching resources in colleges and universities is in incomplete data, this paper uses multiple regression KNN method to fill in the incomplete data of dance teaching resource database in colleges and universities [10–12], and the steps are as follows:

First, initialize the data of college dance teaching resource database, and calculate the classification interval in college dance teaching resource database. The expression is as follows:

$$F = \frac{e \cdot x_i + bg}{s}. \quad (1)$$

In formula (1), e represents the interval value between data and data in the dance teaching resource database

of colleges and universities, b represents the optimal classification function, s represents the objective function of classification, and x_i represents the discriminant function of the i -th data [13].

Second, calculate the Euclidean distance between the target data in the college dance teaching resource database and all data records in the complete value data matrix, and its expression is as follows:

$$d_i = \sqrt{(z_i - o)^t (z_i - o)}. \quad (2)$$

In formula (2), z_i represents the nearest neighbor parameter of the i -th nearest neighbor, and o represents the target data.

Third, the Euclidean distance is calculated through the above process [14]. The data record with the smallest Euclidean distance is selected as the nearest neighbor of the target data and stored in the response position of the data matrix. Fourth, select the data record with the smallest nearest Euclidean distance from each target data from the complete value data matrix and store it in the data group; Fifthly, initialize the nearest neighbor importance of each target data nearest neighbor, and its expression is as follows:

$$R = \frac{F}{d_i(z_i, B)}. \quad (3)$$

In formula (3), R represents the importance of nearest neighbors and B represents the judgment parameter of data importance [15].

Sixth, eliminate the nearest neighbor noise of the target data. The specific judgment criteria are as follows:

$$W = \frac{M}{R/d(x, x_i)}. \quad (4)$$

In formula (4), V represents the noise judgment result of the i nearest neighbor of the target data record, and M represents the noise elimination parameter [16].

Judge the nonnoise nearest neighbor of the target data according to the above calculation, eliminate the nearest neighbor noise, and obtain the missing value. On this basis, map the data from the original feature space to a new feature space through an appropriate nonlinear function, and its expression is

$$w^* = \sum_i^{i=1} W \alpha_i^* y_i x_i. \quad (5)$$

In formula (5), y_i represents the discriminant function and α_i^* represents the set threshold.

Seventh, based on the completion of the above data space mapping, the incomplete data of college dance teaching resource database is estimated and filled according to the missing value [17]. In the process of processing, it should be noted that, in most cases, the component data in the database is different; that is, each

row of data in the database is different data, which is expressed as

$$Q = \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1D} \\ x_{21} & x_{22} & \cdots & x_{2D} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nD} \end{pmatrix}. \quad (6)$$

The above matrix is the observation matrix, n represents the number of rows, that is, the sample size, and D represents the number of columns, that is, the number of parts of the component data [18].

Since the fixed sum of each observation value in the data is different, in order to fill the accuracy, set the adjustment factor, which is expressed as

$$f_{lj} = \frac{V}{w^* Qc * x_{jk}}. \quad (7)$$

In formula (7), x_{jk} represents the equilibrium component of different observed values, c represents the adjustment factor, and V represents the missing value. Through the above process adjustment, the consistency of component data in college dance teaching resource database can be ensured [19]. Finally, the incomplete information of college dance teaching resource database is filled, and its expression is

$$\bar{g} = \sum_k^{i=1} \frac{w_i}{x f_{lj}}. \quad (8)$$

In formula (8), x represents the value of the nearest neighbor response position, and $\sum_k^{i=1} w_i$ represents the missing data judgment parameter.

Continue to iterate the above steps until all the incomplete data in the dance teaching resource database of colleges and universities are filled, so as to complete the filling of the incomplete data in the dance teaching resource database of colleges and universities through the above process [20].

2.2. Establishment of Data Transmission Self-Service Channel.

The preprocessed college dance teaching resource database data can be used as the basic element of transmission object statistics and analysis and can also be used as the collection object and statistical caliber of transmission self-service channel [21]. Users can collect from any number of angles and define the data object of college dance teaching resource database according to the occurrence of the preprocessed college dance teaching resource database data, as shown in Table 1.

According to Table 1, according to the definition of dance teaching resource objects in colleges and universities, the transmission object categories are divided. Each transport unit can use these transport object definitions, but only the data belonging to the respective transport unit can be seen. For the cross-domain data center, the expression form

of the dance teaching resource catalog is not important, and the openness and detailed content are the standards to measure the quality of data [22]. The relative value of dance teaching resources lies in its openness. While ensuring the security of dance teaching resources, the public should be aware of the dance teaching resource database data. The sharing of dance teaching resource database data is built on the openness of data. If there is no flow, the value of data will be generated at a very slow speed. Therefore, on the basis of data security, the catalogue of dance teaching resources in colleges and universities should be open to stakeholders and value creators [23]. Therefore, the data transmission interface is described according to the data transmission object definition of college dance teaching resource database, as shown in Table 2.

According to the format in Table 2, set up the self-service channel interface for the data transmission of the university dance teaching resource database. By mobilizing the university dance teaching resource object to define the category, after the module receives the data of the teaching resource database, call the back-end interface, and update the records in the data transmission of the teaching resource database. Finally, the index module is called to complete the establishment of the data transmission self-service channel of the dance teaching resource database in colleges and universities [24].

2.3. Feature Extraction Method of Resource Database Data.

The data similarity problem in the university dance teaching resource database is transformed into the measurement problem of data. The unequal length sequence query matrix in the university dance teaching resource database is set as C , the reference matrix is marked with K , and the measurement value is marked with α . The corresponding relationship between the matrices is as follows:

$$|C_i| < |K_i|. \quad (9)$$

In the formula, K_i and K_i both represent unequal length sequences of college dance teaching resource database data. According to the unequal length sequence relationship obtained above, the data of college dance teaching resource database is traversed and slid along the window units with a long sequence by using the sliding window theory. Set K_i as the corresponding sequence of C_i , and the subsequence acquisition results between them are as follows:

$$\begin{cases} Z(Q)_j = Q_i(j, j + |C_i| - 1), \\ j = 1, 2, \dots, |Q_i| - |C_i| + 1. \end{cases} \quad (10)$$

In the formula, $Z(Q)_j$ represents the acquired subsequence window, $K_i(j, j + |C_i| - 1)$ represents the j subsequence in the window, $|C_i|$ represents the window length, and i and j are nonzero constants [25].

Based on the above calculation results, calculate the sequence sliding similarity of the window corresponding to the dance teaching resource database data in colleges and universities. The process is as follows:

TABLE 1: Definition of data transmission object of dance teaching resource database in colleges and universities.

Object category	Object description	Object type	Object mode
10	Dance teaching resources in colleges and universities	User	List
A	A	User	Descriptive text
BESTACT	Activity	User	List
CESTCATE	Category	User	List
BESTPLAM	Platform	System	List
Exp	Dance species	System	List
PROJECET	Theme	User	Descriptive text
SQL	Number of resources	System	List
BESTSEAS	Project	User	List

TABLE 2: Data transmission interface information of dance teaching resource database in colleges and universities.

Format	Interface type	Null value allowed	Describe the results
AAM	String	No	File name
AAS	List	No	Information package
ABF	String	Yes	Binary font
ABK	List	No	Backup files

$$S_{ei}(C_i, Z(C_i)_j) = 1 - \frac{(D_{ij}(C_i, Z(C_i)_j))}{D_{\max}}. \quad (11)$$

In the formula, $S_{ei}(C_i, Z(C_i)_j)$ represents the sliding similarity vector of the data sequence of the university dance teaching resource database, $(D_{ij}(C_i, Z(C_i)_j))$ represents the distance between the reference sequence C_i and the sliding sequence, and D_{\max} represents the maximum distance.

Based on the similarity of the data of college dance teaching resource database obtained above, the partial least square method is used to complete the feature extraction of college dance teaching resource database [26].

It is set that there are m pairs of data samples in the college dance teaching resource database B , marked in the form of (P, Q) , and $(P, Q) = \{(p, q)\}_{i=1}^m \in R$. The mapping direction of the college dance teaching resource database is expressed in β and χ . The mapping projection is as follows:

$$\begin{cases} p^* = P\beta, \\ q^* = Q\chi. \end{cases} \quad (12)$$

In the formula, p^* and q^* , respectively, represent the mapped projection area of dance teaching resource database in colleges and universities. Based on the above calculation results, the maximization function criterion of college dance teaching resource database is established. The process is as follows:

$$J_{\text{pls}}(\beta, \chi) = \frac{(\beta^T H_{p,q} \chi)^2}{[\beta^T \beta][\chi^T \chi]}. \quad (13)$$

In the formula, $J_{\text{pls}}(\beta, \chi)$ represents the criterion function of the established college dance teaching resource database, $H_{p,q}$ represents the covariance matrix, and T represents the function coefficient. According to the above criterion function, formulate the corresponding data

orthogonal constraints, mark the $\beta_k^T \beta_i = \chi_k^T \chi_i = 0$ form, and use the Lagrange multiplier to convert the feature extraction problem of the data of the university dance teaching resource database into the equation form. The process is as follows:

$$\begin{cases} H_{p,q} H_{q,p} \beta = \delta^2 \beta, \\ H_{q,p} H_{p,q} \chi = \delta^2 \chi. \end{cases} \quad (14)$$

In the formula, $\delta^2 \beta$ and $\delta^2 \chi$ represent the characteristic equation of transformation. Set the mapping vector of the university dance teaching resource library as r , the number of relative mapping vectors does not exceed group d ($\leq r$), set the nonzero eigenvalue of the university dance teaching resource library as δ_j^2 , use onipils algorithm to complete the optimal mapping area of the first pair of mapping data vectors in the University Dance Teaching Resource Library, and obtain the irrelevant constraints of the data mapping vector. The process is as follows:

$$\begin{cases} \beta_{k+1}^T H_p \beta_i = \chi_{k+1}^T H_q \chi_i = 0, \\ i = 1, 2, \dots, k. \end{cases} \quad (15)$$

In the formula, H_p represents the data variance value in the β direction, H_q represents the covariance difference in the χ direction, T represents the function coefficient, and k and i represent the vector parameters, respectively.

Integrate the mapping parameters of the university dance teaching resource database data into D_p and D_q forms, and complete the solution and calculation of the characteristic equation of the university dance teaching resource database data according to the above calculation results. The results are as follows:

$$\begin{cases} FH_{p,q} H_{q,p} \beta_{k+1} = \delta \beta_{k+1} \times F \times I, \\ LH_{q,p} H_{p,q} \chi_{k+1} = \delta \chi_{k+1} \times L \times I. \end{cases} \quad (16)$$

In formula (16), $\delta \beta_{k+1}$ and $\delta \chi_{k+1}$ represent the calculation results of the data characteristics of the dance teaching resource database in colleges and universities, F and L represent the equation parameters, and I represents the constant coefficients. Finally, according to the calculation results of the data characteristic equation of the university dance teaching resource database, the data characteristic vector value of the university dance teaching resource database is extracted to provide important information for the

data sharing of the university dance teaching resource database.

2.4. Data Sharing of Dance Teaching Resource Database in Colleges and Universities

2.4.1. PSO Algorithm. Particle swarm optimization (PSO) algorithm is proposed by Kennedy and Eberhart. Its algorithm idea is to study and simulate the foraging behavior of birds. The bird in the bird group is compared to the particle in the particle group, which represents the candidate solution of the problem. The flight space of birds corresponds to the search space of particle group, and the process of birds looking for food corresponds to the process of looking for the optimal solution. All particles are randomly assigned to the search space as the initial state of the algorithm. The total number of particles is recorded as N and the dimension of the search space is recorded as D . Each particle includes a D -dimensional velocity vector $V_i = (v_{i1}, v_{i2}, \dots, v_{iD})$ and a D -dimensional position vector $X_i = (x_{i1}, x_{i2}, \dots, x_{iD})$. By learning from its own individual extreme value $pbest_i = (p_{i1}, p_{i2}, \dots, p_{iD})$ and the global extreme value $gbest_i = (g_1, g_2, \dots, g_D)$ of the population, the particle velocity and position are updated until the optimal solution is found. The speed and position of particles are updated as follows:

$$\begin{aligned} V_i^{t+1} &= wV_i^t + C_1 * \text{Rand}_1() \times (pbest_i - X_i^t) \\ &\quad + C_2 * \text{Rand}_2() \times (gbest_i - X_i^t), \quad (17) \\ X_i^{t+1} &= X_i^t + V_i^{t+1}. \end{aligned}$$

In the formula, V_i^t, V_i^{t+1} represents the velocity of the i -th particle in the t -th and $t+1$ -th iterations, respectively; w represents the inertia weight, which is the coefficient to maintain the original speed; X_i^t, X_i^{t+1} represents the position of the i -th particle in the t -th and $t+1$ -th iterations, respectively; C_1 is the weight of the particle to learn its own individual extreme value, indicating the particle's understanding of itself, which is usually assigned as 2; C_2 is the weight of the particle to learn the global extreme value of the population, which indicates the particle's understanding of the whole population. It is usually assigned as 2; $\text{Rand}_1(), \text{Rand}_2()$ is the random number in the interval (0, 1); $pbest_i$ is the individual extreme value of the i -th particle, which is the historical optimal value found by the particle, also known as individual optimal; $gbest_i$ is the global extremum of particle swarm, which is the group optimal value found by the whole particle swarm, also known as global optimal.

2.4.2. Data Sharing Based on PSO Algorithm. The particle swarm optimization algorithm is adopted for fuzzy iteration and adaptive learning in the process of data sharing of college dance teaching resource database, and the particle swarm mutation optimization control model for data sharing of college dance teaching resource database is established. The tightness index of data sharing of college

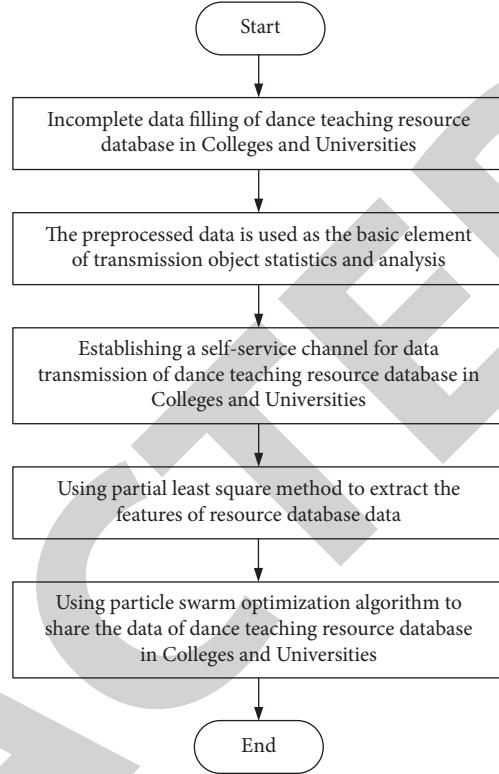

FIGURE 1: Specific flow chart of data sharing method of college dance teaching resource database based on PSO algorithm.

dance teaching resource database is (RT_1, RT_2) . The k associated node is selected for particle swarm evolution of data sharing of college dance teaching resource database, Statistical probability distribution of data sharing particle swarm variation in college dance teaching resource database:

$$p_D = k \frac{4}{3} \pi R X_i^{t+1}. \quad (18)$$

In the formula, R is the particle swarm variation dimension of university dance teaching resource database data sharing. The quantitative feature decomposition of university dance teaching resource database data sharing is carried out by using individual extreme value iteration technology, and the following results are obtained:

$$R_k = F_{Z_{\min}} p_D. \quad (19)$$

Using the adaptive optimization technology, the redundant individual search for the data sharing of the university dance teaching resource database is carried out, and the variation individual extreme value $F_{Z_{\min}}$ of the university dance teaching resource database data is obtained. According to the individual differences in the process of particle swarm evolution, the shortest link iteration technology is adopted to obtain the feature mining output of the university dance teaching resource database data:

$$S(x) = \frac{F_{Z_{\min}}}{R_k}. \quad (20)$$

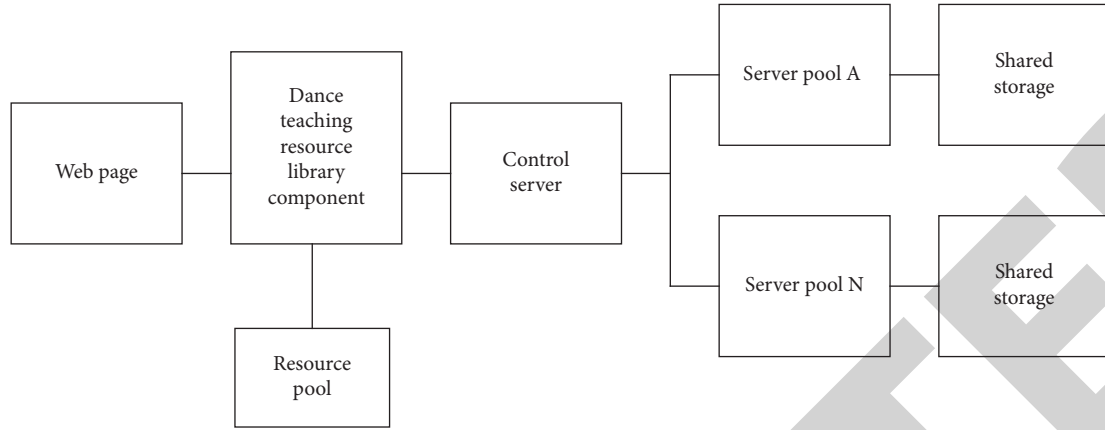

FIGURE 2: Physical architecture of teaching resource database.

TABLE 3: Experimental parameter setting.

Name	Parameter
The server	Intel Xeon processor e5430266ghz, ddr3-1336mhz SSD500G
Client	Intelcpu3. 06 GHz, memory above 2G, hard disk
Server operating system	Windows2008R2
Client operating system	Win7
Database	Oracle
Database server	192.168. 44.254
Test tools	Mercury loadrunner6
Accuracy	95-100%
Recall	95-100%
F1 value	0.95-1

To sum up, PSO algorithm is used to design the data sharing of dance teaching resource database in colleges and universities.

Let s_k and a_k be the characteristic quantity of association rule information of college dance teaching resource database data, and the visual characteristic quantity of each particle in the search space is $\phi(w)$. Randomly select z uniform college dance teaching resource database data visual analysis nodes to locate the optimal location of college dance teaching resource database data sharing, and obtain the optimal location distribution:

$$p_z = \phi(w)a_k(1 - s_k). \quad (21)$$

The improved inertia weight analysis method is adopted to carry out the sharing scheduling of college dance teaching resource database data. The particle is near the optimal particle. The optimal characteristic of the adaptation function of college dance teaching resource database data is extracted, and c_1, c_2 is set as the initial value to obtain the optimized data sharing output result:

$$\alpha = \frac{c_1 + c_2}{p_z}. \quad (22)$$

According to the individual differences of particle swarm optimization, the classification and reorganization in the process of data sharing of college dance teaching resource database are carried out. The data visual sharing design of

college dance teaching resource database is carried out by using particle swarm optimization algorithm and association mining method.

To sum up, the specific flow of the data sharing method of college dance teaching resource database based on PSO algorithm proposed in this paper is shown in Figure 1.

According to Figure 1, it is necessary to complete the incomplete data filtering of the university dance teaching resource database, and then the preprocessed data is used as the basic element for the statistics and analysis of the transmission object, so as to build a self-service channel for the data transmission of the university dance teaching resource database. Finally, the partial least square method is used to extract the characteristics of the resource database data, and complete the data sharing of the university dance teaching resource database based on the particle swarm optimization algorithm, so as to realize the process.

3. Simulation Experiment Analysis

In order to verify the effectiveness of the data sharing method of college dance teaching resource database based on PSO algorithm in practical application, a college dance teaching resource is selected as the experimental object for a simulation experiment analysis. The physical structure of college dance teaching resource library is shown in Figure 2.

Under the above environment, set the experimental parameters, as shown in Table 3.

FIGURE 3: Accuracy comparison results.

FIGURE 5: F1 value comparison results.

FIGURE 4: Comparison results of recall rate.

FIGURE 6: Comparison results of data sharing time of dance teaching resource database in colleges and universities.

This paper selects the accuracy rate, recall rate, and F1 value as the experimental indicators and uses the data sharing method of college dance teaching resource database based on PSO algorithm and [8] and [9] to carry out the experimental test. The test results are shown in Figures 3–5.

According to Figure 3, the accuracy of the data sharing method of college dance teaching resource database based on PSO algorithm proposed in this paper can reach 100%, and the recall rate and F1 value are high, while the accuracy, recall rate, and F1 value of [8] and [9] are not ideal. The reason is that the algorithm in this paper establishes a data transmission self-service channel and takes the pretreated college dance teaching resource database data as the basic element for the statistics and analysis of transmission objects. Users can collect from any number of angles according to the occurrence of the pretreated college dance teaching resource database data. Set up the self-service channel

interface for the data transmission of the university dance teaching resource database. By mobilizing the university dance teaching resource object to define the category, after the module receives the teaching resource database data, call the back-end interface, operate the records in the data transmission of the teaching resource database, and finally call the index module, which is conducive to improving the performance to a certain extent.

In order to further verify the effectiveness of this method, the data sharing method of college dance teaching resource database based on PSO algorithm, [8] and [9] proposed in this paper are used to compare and analyze the data sharing time of college dance teaching resource database. The comparison results are shown in Figure 6.

According to Figure 6, the data sharing time of university dance teaching resource database based on PSO algorithm proposed in this paper is within 4S, which is shorter than

that of university dance teaching resource database in [8] and [9]. The reason is that this algorithm proposes data sharing based on PSO algorithm, adopts particle swarm optimization algorithm to carry out fuzzy iteration and adaptive learning in the process of data sharing of university dance teaching resource database, and establishes a particle swarm mutation optimization control model for data sharing of university dance teaching resource database, which is conducive to reducing the sharing time.

To sum up, the research algorithm has good performance. Taking the resource sharing platform as the integration of college dance teaching resource library, the new development of teachers' and learners' autonomous learning ability, research ability, and cooperation ability has been strengthened, and teaching resources have attracted more and more attention.

4. Conclusion

This paper designs the data sharing method of dance teaching resource database in colleges and universities through PSO algorithm. It is best to verify the effectiveness and practicability of this method through experimental comparison. Taking the resource sharing platform as the integration of dance teaching resource library in colleges and universities and strengthening the new development of autonomous learning ability, research ability, and cooperation ability of teachers and learners, teaching resources have attracted more and more attention and have good performance.

The data sharing method of university dance teaching resource database based on PSO algorithm designed in this study has preliminarily realized the basic functions designed in advance, but due to the limitation of technology level and time, the method still has many shortcomings. Through reflection and summary of the whole development and trial operation process, the following two shortcomings are highlighted, which are also the direction for improvement in the future:

- (1) Although corresponding support is provided for various activities using the teaching resource sharing method, sufficient personalized support is not provided for the individual differences of users. Therefore, how to provide adequate personalized support is a key direction of follow-up research.
- (2) There is no strong support for different types of dance teaching resources in universities. This is another focus of the subsequent development of this method. In the future study and work, I will continue to study and discuss the above problems, so as to further develop and improve the teaching resource sharing method theory and teaching resource sharing platform in colleges and universities.

Labor education is a complex concept whose value is not only the sum of labor + education. It plays an extremely important role in the growth education of students. Its fundamental purpose is to cultivate students' good technical literacy, improve their practical skills, and form innovative thinking. The monitoring data show that the path of labor education in schools is good, but there are also problems such as unbalanced development of labor practice, insufficient leading role of schools, insufficient basic role of families, and serious lack of social support. Responsibility index, learning motivation, motor health, and self-awareness are significantly and positively correlated with labor practice index. Based on the gray relationship theory, this paper selected relevant data of Chinese students, calculated the comprehensive gray relationship degree between each factor and students' labor education level, and analyzed the variables; the new connotation of education, the construction of labor education evaluation index system, and the construction of labor education support system were studied.

1. Introduction

Labor education means organizing students to learn certain technical knowledge of labor and to participate in certain labor activities so that they can acquire the viewpoint of labor, develop labor habits, understand the basic principles of modern production technology, and master the corresponding basic skills so that they can use them in the future [1], engage in educational activities, and lay the foundation for various occupations [2, 3]. The current labor education in colleges and universities can be analyzed from the perspective of colleges and students [3–5]. The following problems exist: lack of labor education courses in colleges and universities and lack of conducting labor education courses as basic courses in universities; but, few schools actually include labor education in their course syllabus [6]. Even if the school reluctantly opens the door to this course and the teacher does not say so, it is painful for both teachers and students to offer this course [7]. Students are not aware of labor education; most students grow up in the context of examinations and still have a utilitarian purpose of education after the university. Students have been immersed in the

frenzy of textual research, neglecting the development of their own interests and creative consciousness and lacking the awareness of actively improving their practical skills [8].

From basic education to higher education, we have emphasized the all-round development of students. However, in terms of concrete implementation, we have been following a talent development route that emphasizes achievement at the expense of ability [9]. Labor education is a bridge between students' learning and employment. Students can acquire relevant practical skills through labor education to prepare for their future employment [10–12]. Schools are an important platform for implementing labor education. First, schools should invite vocational and labor education talents to popularize labor education for all teachers so that college teachers can understand labor education objectively and change old concepts [13]. Secondly, schools should cooperate with enterprises and select outstanding talents from enterprises to provide relevant practical courses for students in schools, which can not only enrich students' campus life but also exercise their practical skills and give them a comprehensive understanding of labor education. Finally, schools should develop corresponding

labor education bases according to local characteristics, which can not only establish the school brand but also provide students with sufficient training opportunities [14–16].

Labor education is closely related to each of us, and it permeates all aspects of our lives [17].

In this paper, we monitored two aspects: the development of students' labor education in school and at home and students' labor concepts, labor dynamics, and labor habits, including four dimensions of self-service, homework, in-school labor, and out-of-school labor [18]. It can be seen that the gap between urban and rural areas and disciplines is not very large in terms of support for labor education in schools. Urban teachers are slightly higher than rural teachers in counties and villages, and math and science teachers are slightly higher than Chinese teachers. Parents generally believe that labor education can promote the healthy development of their children. When asked if students'

participation in labor is a good exercise, 65.2% of parents strongly agreed and 24.4% agreed. Parents are very satisfied with the current state of education in their schools, and 84% of parents say they are relatively satisfied or very satisfied. Also, comparing urban and rural data, there was no significant difference between urban and rural parents [19].

2. Gray Relational Analysis

2.1. Calculation of Gray Absolute Relevance Degree. First, determine the reference sequence X_0 and the comparison sequence X_i according to the specific problem of the study:

$$\begin{aligned} X_0 &= (x_0(1), x_0(2), \dots, x_0(n)), \\ X_i &= (x_i(1), x_i(2), \dots, x_i(n)), \quad (i = 1, 2, \dots, m). \end{aligned} \quad (1)$$

Next, find the zeroed image of the starting point of the reference sequence and the comparison sequence:

$$\begin{aligned} X_0^0 &= (x_0^0(1), x_0^0(2), \dots, x_0^0(n)) = (x_0(1) - x_0(1), x_0(2) - x_0(1), \dots, x_0(n) - x_0(1)), \\ X_i^0 &= (x_i^0(1), x_i^0(2), \dots, x_i^0(n)) = (x_i(1) - x_i(1), x_i(2) - x_i(1), \dots, x_i(n) - x_i(1)). \end{aligned} \quad (2)$$

Finally, find the gray absolute correlation degree ε_{0i} of the reference sequence X_0 and the comparison sequence X_i :

$$\varepsilon_{0i} = \frac{1 + |S_0| + |S_i|}{1 + |S_0| + |S_i| + |S_i - S_0|}. \quad (3)$$

Here,

$$\begin{aligned} |S_0| &= \int_1^n X_0^0 dt \\ &= \left| \sum_{k=2}^{n-1} x_0^0(k) + \frac{1}{2} x_0^0(n) \right|, \\ |S_i| &= \int_1^n X_i^0 dt \\ &= \left| \sum_{k=2}^{n-1} x_i^0(k) + \frac{1}{2} x_i^0(n) \right|, \end{aligned} \quad (4)$$

$$|S_i - S_0| = \left| \sum_{k=2}^{n-1} (x_i^0(k) - x_0^0(k)) + \frac{1}{2} (x_i^0(n) - x_0^0(n)) \right|.$$

2.2. Calculation of Gray Relative Correlation Degree. First, find the initial value of X_0 and X_i as X_0' and X_i' :

$$\begin{aligned} X_0' &= \frac{X_0}{x_0(1)} = \left(\frac{x_0(1)}{x_0(1)}, \frac{x_0(2)}{x_0(1)}, \dots, \frac{x_0(n)}{x_0(1)} \right), \\ X_i' &= \frac{X_i}{x_i(1)} = \left(\frac{x_i(1)}{x_i(1)}, \frac{x_i(2)}{x_i(1)}, \dots, \frac{x_i(n)}{x_i(1)} \right). \end{aligned} \quad (5)$$

Next, find the zeroing image of the starting point of X_0' and X_i' .

Finally, find the relative correlation degree r_{0i} between X_0' and X_i' .

$$r_{0i} = \frac{1 + |S_0'| + |S_i'|}{1 + |S_0'| + |S_i'| + |S_i' - S_0'|}. \quad (6)$$

2.3. Finding the Gray Comprehensive Correlation Degree. $\rho_{0i} = \theta \varepsilon_{0i} + (1 - \theta) r_{0i}$, where $\theta \in [0, 1]$. (6) is generally acceptable when $\theta = 0.5$. If we pay more attention to the relationship between absolute quantities, it can be larger. If you pay more attention to the rate of change, θ can be smaller.

3. Data Collection

Student labor practice mainly includes on- and off-campus labor organized by the school, as well as student self-service and housework. As shown in Figure 1, the survey found that junior high school students have relatively good on-campus labor practices and weaker off-campus practices, self-service is relatively good, and housework is relatively weak. In terms of self-service and housework, students in private migrant schools are significantly stronger than students in other schools, but there is no significant difference in labor practices inside and outside the school. In different regions and gender dimensions, the labor practices of students are basically similar.

Table 1 further analyzes the students' participation in labor practice activities organized by the school and presents the types and frequencies of students' participation in labor practice both inside and outside the school.

FIGURE 1: Structural characteristics of labor practice of junior middle school students in Zhejiang province.

TABLE 1: The situation of students participating in labor practice.

		No	Annually	Once a semester	Once a month	Once a week
School labor practice	Frequency	2.4%	1.2%	8.1%	26.7%	61.9%
	Type (multiple choices)	Practice-based learning	Various service posts of the school	Professional postexperience activities	other	
		42.4%	51.6%	18.9%	39.1%	
Off-campus labor practice	Frequency	Never	1~2 times	3~6 times	6~10 times	More than 10 times
	Type (multiple choices)	Community convenience and public welfare services	Cultural publicity activities	Environmental voluntary activities	Caring and serving others	Other
		25%	55.4%	16.4%	2.1%	1.5%
		22.6%	23.4%	32.9%	31%	52.9%

The data show that the frequency of students' on-campus labor practice is relatively high, and the proportion of students participating in on-campus labor practice once a week is 61.8%. Although the types of students' off-campus labor practice are relatively rich, the frequency is generally low. 24.9% of the students have never participated in off-campus labor practice, and less than 20% of the students have participated three or more times. Junior high school should be the initial stage of career experience, and 18.6% of students have participated in career experience activities. In addition, 38.8% and 52.8% of students have participated in "other" on-campus and off-campus labor practices other than the options, respectively, which shows that the types of labor practices are quite diverse.

Junior high school students have strong self-service ability, and 62.1% of the students take the initiative to organize their daily life and school supplies at least three times a week. Junior high school students participate better in housework. Table 2 presents the frequency of students doing housework in different regions and genders. 40% of students said they do housework at least three times a week, and 39.4% said they do housework once or twice a week. Among

the students who do housework every day, towns and villages account for the highest proportion (19.2%). In terms of gender, boys who do housework at least three times a week account for 41.9%, 3.9% points higher than girls. Most of the students who do not do housework are urban students or boys. It can be seen that the participation in housework of rural students in townships and villages is better than that of students in the county and urban areas.

The data in Table 3 show that 5.6% of the students do the "cooking" housework every day on weekends, 26.8% of the students do the "cooking" housework once or twice a month, and 39.4% of the students basically do not do the "cooking" housework.

The monitoring data show that the labor education path of junior high schools in Zhejiang province is sound. Figure 2 presents school labor education implementation from teacher questionnaires.

As can be seen from Figure 2, among the compulsory courses for labor, technology, and comprehensive practice activities in schools, 1-2 times a week accounted for 30.9% and 1-2 times every two weeks accounted for 17.6%. Schools carry out sanitation, green planting, class activities with the theme

TABLE 2: Frequency of housework for students in different regions and genders in the province.

		Do it every day (%)	Four times on Wednesday (%)	Twice a week (%)	Once or twice a month (%)	Basically not (%)
Whole province		15.6	24.4	39.5	12.4	8.4
Regional nature	City	12.96	22.3	40.4	15.1	9.8
	County town	12.5	22.6	41.5	14.3	8.9
	Rural township	19.3	26.4	37.6	9.8	7.4
Gender	Male	17.3	24.7	36.7	12.2	9.5
	Female	14.1	23.9	42.3	12.6	7.4

TABLE 3: Frequency of students doing “cooking” housework on weekends.

	Never or hardly (%)	Once or twice a month (%)	Once or twice a week (%)	3 or 4 times a week (%)	Every day or almost every day (%)
Whole province	39.5	26.9	22.6	5.7	5.7

FIGURE 2: Distribution of school labor practice activities.

of labor education, clubs, interest groups, and other on-campus labor more frequently. In terms of the frequency of teachers organizing students to carry out on-campus labor, 1-2 times a week accounted for 30.2%, at least once a month accounted for 40.2%. The school also offers labor practice expansion elective courses such as housekeeping, cooking, handicraft, and gardening to enrich the course content. The frequency of offering these courses is 1-2 times a week, accounting for 21.9%, and 1-2 times every two weeks, accounting for 14.5%. The school promotes and evaluates the effectiveness of home labor education in the form of homework assignments. The frequency of homework assignments for students is 16.5% once or twice a week and 15.1% is once or twice every two weeks. The frequency of off-campus labor practices such as public welfare activities, voluntary services, research trips with labor education as the theme, and social practice organized by schools is relatively low, accounting for 57.4% once or twice per semester and

9.1% once or twice a week. This shows that although the school can carry out labor practice education normally, its frequency is relatively low and the content is single. It is urgent to build a scientific labor education curriculum system and explore diversified labor education practice paths.

The data in Table 4 show that among teachers who arrange homework once or twice a week, the proportions of urban, county, and township and rural teachers are 18.9%, 16.9%, and 14.5%, respectively. It can be seen that urban teachers' homework assignments are better than county teachers, and county teachers are better than township and rural teachers.

4. Results and Analysis

According to the calculation result of the gray correlation degree, the correlation degree of each factor is compared in pairs and the judgment matrix is constructed. Scales 1, 3, 5, 7, and 9 are used to indicate that factor X_i is equally important, slightly important, clearly important, strongly important, and extremely important compared to factor X_j , while scales 2, 4, 6, and 8 indicate the difference between the above judgments. After the judgment matrix is constructed, use the following formula to calculate its influence:

$$\lambda_{\max} = \frac{1}{n} \frac{(BW)_i}{W_i}. \quad (7)$$

Here, λ_{\max} represents the largest eigenvalue of the judgment matrix B ; W represents the normalized eigenvector corresponding to λ_{\max} ; W_i represents the influence of the ranking of the constituent factors; and n represents the dimension of the judgment matrix B . In order to check the consistency of the judgment matrix B , the consistency index CI needs to be calculated and the corresponding calculation formula is as follows:

$$CI = \frac{\lambda_{\max} - n}{n - 1}. \quad (8)$$

TABLE 4: Frequency of homework assignments.

	Never or hardly (%)	Once or twice a month (%)	Once or twice a week (%)	3 or 4 times a week (%)	Every day or almost every day (%)
City	13.12	32.2	21.3	14.8	18.7
County town	16.2	30.2	21.6	15.6	17.1
Rural township	17.9	31.2	21.2	15.3	14.7

We compare CI with the average random consistency index RI to test whether the judgment matrix B is consistent. For matrices of orders 1 to 16, the values of RI are listed in Table 5.

The first-order and second-order judgment matrices are completely consistent. Starting from order 3, the random consistency ratio of the judgment matrix needs to be calculated: $CR = (CI/RI)$. When $CR < 0.1$, it is considered that the judgment matrix has satisfactory consistency; otherwise, the judgment matrix is readjusted.

As shown in Table 6, the correlation analysis was made between the labor practice index and monitoring indexes, such as sense of responsibility, learning motivation, sports health, self-cognition, family education, teacher-student relationship, parent-child relationship, hobbies, parent participation, and peer relationship. It shows that there is a significant positive correlation between each monitoring index and the labor practice index and the labor practice index has the highest correlation with the sense of responsibility index.

Responsibility refers to the process by which students take responsibility for themselves, others, collectives, and society by performing certain normative behaviors, including fulfilling obligations, duties, and other requirements. On the one hand, students with a strong sense of responsibility often participate in more labor practices; on the other hand, labor practice activities are just a good carrier to enhance students' sense of responsibility and develop courage and perseverance [20–22].

It can be seen from Figure 3 that with the improvement of the level of responsibility index, the score of labor practice index is getting higher and higher and the two sub-dimensions also have similar conclusions. The labor practice index scores for each level of "citizen responsibility" are higher than those of "self-responsibility." It can be seen that the awareness of civic responsibility has a relatively large impact on labor practice.

It can be seen from Figure 4 that with the improvement of family education level, the score of labor practice index is getting higher and higher and the three subdimensions also have similar conclusions. The labor practice index scores corresponding to each level of "democracy and respect" are higher than those of "affirmation and encouragement" and "independence training." It can be seen that the family education method of "democracy and respect" has a relatively large impact on labor practice.

As can be seen from Figure 5, from the perspective of the relationship between participation in various types of

regular on-campus labor practice activities organized by the school and students' sense of responsibility, the scores of students' sense of responsibility index who participated in on-campus activities were much higher than those who did not participate in on-campus activities and participating in vocational postexperience activities was more helpful in the formation of a sense of responsibility.

As can be seen from Figure 6, from the perspective of the relationship between participation in various types of regular off-campus labor practice activities organized by the school and students' sense of responsibility, students who participated in off-campus activities scored much higher than those who did not participate in off-campus activities and participated in community-friendly public welfare services or cultural activities. Publicity activities are more conducive to the formation of a sense of responsibility.

Labor education has the comprehensive educating value of cultivating morality, enhancing intelligence, strengthening body, and nurturing beauty, and it is of great significance to fully tap its hidden value of promoting the healthy growth of students. In fact, labor education must not only be presented at the material level but also must be sublimated at the spiritual level and attention should be paid to cultivating students' labor literacy. For example, in the process of doing housework, students learn to manage their own time, coordinate the relationship between housework and study, and do things in a short time and efficiently. Students undertake housework as much as they can, cultivate their sense of independence and the ability to overcome difficulties, appreciate the hardships of labor, cherish the fruits of labor more, feel the joy of labor, and form a positive attitude towards labor.

5. Countermeasures and Suggestions

Based on the monitoring results and the analysis of the current situation of labor education in Zhejiang province, the following three suggestions are put forward for the comprehensive promotion of labor education for junior high school students.

5.1. Endowing Labor Education with New Connotation.

Monitoring data show that labor education has a positive effect on the formation of students' "responsibility"; some studies have also shown that "responsibility" and "learning motivation" have a significant positive effect on students' academic performance. It can be seen that it is necessary to give the original labor education a new connotation.

TABLE 5: Average stochastic consistency indicators RI.

Orders	1	2	3	4	5	7	8	9	10	11	12	13	14	15	16
RI	0	0	0.53	0.88	1.13	1.25	1.37	1.42	1.46	1.51	1.54	1.57	1.59	1.60	1.62

TABLE 6: Relationship between monitoring index and labor practice index.

Index	Correlation coefficient
Responsibility index	0.352
Learning motivation index	0.278
Exercise health index	0.257
Self-cognition index	0.255
Family education index	0.219
Self-cognition index	0.256
Family education index	0.219
Teacher-student relationship index	0.215
Parent participation index	0.207
Peer relationship index	0.173

FIGURE 3: Responsibility index.

It can be seen that in terms of standpoint, it is necessary to fully realize the combination of the “substance” rather than “form” of education and productive labor. In terms of content, it embodies a developmental view of education, emphasizing leisure education and consumer education. In terms of function, it emphasizes labor. The existential value of the individual is to endow the individual with a sense of value and meaning of self-existence in labor education, enrich their relationship attributes, and enhance their aesthetic personality; in practice, it should cultivate students' correct labor concepts and attitudes and build an integrated and open labor education practice system. This kind of labor education focuses on the cultivation of labor literacy and cannot be simply understood as the establishment of labor classes. Morality, intelligence, physique, beauty, and labor mentioned in the educational policy are all concepts of literacy, and they do not correspond to specific disciplines; that is, it cannot be said that “morality” corresponds to the

FIGURE 4: Labor practice index scores under different family education levels.

discipline of moral education and “physical” cannot be regarded as a physical education class. In the same way, students' labor literacy is not only cultivated in labor classes but also in the daily care of home and school, the sanitation rotation of the class, the layout of the environment, the physical measurement and field investigation of subject teaching, the practical activities of various comprehensive practice courses and the cultivation function of labor literacy [23, 24].

Junior high school students are in adolescence, and their growing physical maturity prompts them to seek independence psychologically, gradually reduce their dependence on their parents, and hope to get rid of their parents' “control.”

However, they also face many challenges and problems in their studies and life and still need the support, companionship and guidance of their parents. Therefore, parents need to change their educational roles, adjust their parenting methods, give their children trust and understanding, provide timely help and guidance, infiltrate the cultivation of sense of responsibility in labor education, and stimulate children's learning motivation.

5.2. *Constructing the Labor Education Evaluation Index System.* Schools should incorporate labor education into their teaching plans, set up labor courses, cultivate labor literacy, continuously improve labor education programs and security systems, and implement refined labor education evaluations. According to the “opinions,” a labor education evaluation index system with regional characteristics is formulated. For example, curriculum settings generally

FIGURE 5: Relationship between different types of on-campus labor practices and sense of responsibility.

FIGURE 6: The relationship between different types of off-campus labor practices and sense of responsibility.

include labor compulsory courses, labor development courses, labor weeks, and subject penetration. Teaching implementation includes teaching content, teaching form, teaching resources, and teaching evaluation. The guarantee mechanism includes system guarantee, teacher guarantee, funding investment, and safety. Labor literacy includes labor concepts, labor knowledge and skills, labor habits, and labor practice capabilities. Curriculum settings can also draw lessons from mature foreign experience. For example, Japan's labor courses include home economics, lunch education, and field education; Germany's labor courses include technology, economics, home economics, and vocational skills; Finland's labor courses include handicraft, home economics, programming courses, and comprehensive courses.

At the same time, the results of students' usual labor are included in the personal comprehensive quality evaluation and the education supervision department incorporates the results of school labor education into the school's developmental assessment to promote the effective achievement of labor education goals.

5.3. Construction of the Labor Education Support System. Labor education must permeate the moral, intellectual, physical, and aesthetic education in schools and cannot be done without the operation and social support of the home and school. Therefore, it is necessary to strengthen the cooperation between school, family, and society to carry out labor education and ensure the effective implementation of labor education. Teachers should make full use of the special activity classroom as the main post to educate students about labor so that they can form correct labor values; they should praise students in the class who love labor and have strong labor skills and encourage other students to follow them. Schools should carry out relevant activities to stimulate students' interest in labor, such as organizing tree planting festivals and small production competitions, which not only help transform passive labor into conscious labor but also improve students' ability to use their hands and brains.

Data Availability

The experimental data used to support the findings of this study are available from the author upon request.

Conflicts of Interest

The author declares that there are no conflicts of interest regarding this work.

In the process of promoting school aesthetic education, some schools have some problems, such as insufficient construction of campus aesthetic education environment, lack of aesthetic thinking in various disciplines, and so on. In view of these problems, combined with the concept of the flipped classroom and the characteristics of artificial intelligence task-driven teaching, taking PHP, HTML + CSS + JS, and other development technologies as the main development technologies, and relying on the flipped classroom teaching mode of network learning space, this paper constructs an artificial intelligence core course website as a teaching platform for graduate teaching and undergraduate extended learning. The platform seeks the optimal solution of multiple combination optimization based on a genetic algorithm effectively improves the teaching quality of artificial intelligence courses and students' learning efficiency.

1. Introduction

Aesthetic education enhances aesthetic qualities, cultivates sentiment, warms the soul, stimulates innovation and creativity, and is an indispensable element in the overall development of students [1].

Aesthetic education informatization refers to the process of teachers incorporating modern information technology in the top-level system design, campus culture enhancement, teacher training, teaching platform construction, resource development, and implementation of teaching activities to accelerate the modernization of aesthetic education [2–4].

This document clarifies the why, what, and how of school aesthetic education in the new era, strengthening the nurturing function of school aesthetic education, which is an important model for guiding the whole society to value aesthetic education and creating a social atmosphere that jointly promotes the development of school aesthetic education [5]. Teachers should attach importance to aesthetic education and make it permeate and permeate all aspects of

education and teaching. Information technology is a booster for improving the quality of education, and promoting aesthetic education with information technology is the direction and trend of education development and a necessary stage of education modernization [6]. At present, information technology in aesthetic education has become a new area of research in the field of aesthetic education, and its research is on the rise [7].

Aesthetic education is an important part of school education, and the construction of the campus environment is very important for cultivating students' aesthetic thinking. The campus environment can be a visual representation of a school's understanding and interpretation of aesthetic education [8]. However, some primary and secondary schools have a single style of campus environment construction and do not pay attention to the importance of the campus environment to the cultivation of students' aesthetic thinking, lacking an environmental design that reflects the unique local humanities, beautification style, and the core concept of campus culture [9].

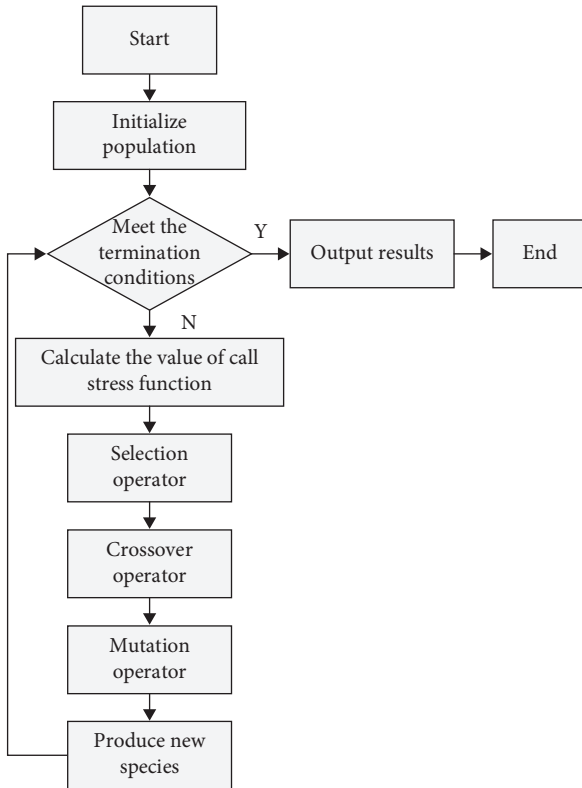

FIGURE 1: Flow chart of a traditional genetic algorithm.

The most pressing need in aesthetic education is the issue of teacher development. Nationally, there is still a considerable shortage of teachers for aesthetic education in terms of quantity, and even more so in terms of quality. [10] Interviews with some teachers and students revealed that there is a serious shortage of teachers with an arts background in some schools, so schools are lowering the bar when recruiting, which in turn leads to overall low quality of art teachers. In terms of curriculum arrangement, art and music courses are often taken up or switched at will by the main teachers, which leads to a lack of assurance in terms of class time and teaching quality in the Aesthetic Education curriculum [11].

Our schools have not invested enough in the infrastructure and teaching resources for Aesthetic Education's information-based teaching activities, and there is a general problem of low popularity and small scale. Although teaching resources in the information age have been greatly enhanced in terms of quantity, quality, and content, some teachers fail to select appropriate resources to make them fit with classroom teaching content when making use of the abundant teaching resources. At the same time, the construction of regional educational resource banks is in its infancy, and the use of information resources for the teaching of Aesthetic Education in Chinese primary schools is still far from the goal of abundant and effective use of resources [12].

Artificial Intelligence is a core course in the discipline of computer application technology. Through the study and practical application of this course, students can be trained to master the basic theories, cutting-edge technologies, and the ability to do things on their own and to be innovative

[13]. Students are required to have a basic understanding of the classical algorithms and reasoning mechanisms of artificial intelligence theory and to develop intelligent systems based on the main research content after completing the basic theory and experimental teaching courses [14]. This requires a wide range of knowledge, deep basic theories, and strong practical skills in the teaching of AI courses [15–17].

In this paper, relying on the flipped classroom teaching mode of the online learning space, combined with the actual teaching cases based on the task-driven teaching mode, a website of artificial intelligence core courses is constructed as a teaching platform for postgraduate teaching and undergraduate extended learning, which effectively improves the artificial intelligence courses. Teaching quality and student learning efficiency.

2. Artificial Intelligence Web-Based Teaching Platform Positioning and Related Technologies

2.1. Online Teaching Platform Positioning. The construction of an online teaching platform for core courses in artificial intelligence mainly includes a flipped teaching concept, course content based on a task-driven teaching model, and an interactive and shared online platform. These two are complementary and mutually reinforcing. Secondly, mature network technology is needed to build the platform framework, so that the best course content can be displayed on the network platform, thus realizing the purpose of sharing and applying course resources [18]. In this paper, the teaching cases of AI core course teams in the past ten years are collected and collated, and an online teaching platform based on the flipped classroom teaching model is constructed.

2.2. Web-Based Teaching Platform Related Technologies. PHP is a server-side scripting language; MySQL is the most widely used Web database today. PHP and MySQL are a natural pair, and the combination of the two can be used to achieve many powerful features in web development. CSS makes it easy to control the appearance of a website's interface, making it easy to create web pages. CSS is also a great solution to the problem of page layout, making web pages smaller and faster to download [20].

3. Introduction to Traditional Genetic Algorithms and Hierarchical Decision Model

Genetic algorithms, or GA for short, are computational models that combine biological evolution and genetics. They can mathematically model the natural evolutionary process of organisms, corresponding the process of problem solving to the selection, crossover, and mutation of chromosomal genes during biological evolution and are thus used to find the optimal solution for multi-combination optimization.

The specific flow chart of the traditional genetic algorithm is shown in Figure 1.

The algorithmic components of a traditional genetic algorithm (GA) include chromosome encoding (containing

the initialized population), fitness functions, and genetic operators (selection, crossover, variation). The traditional genetic algorithm firstly encodes and randomly generates an initial population, then conducts individual evaluation, and selection, determines whether to output, followed by random crossover and mutation operations and finally turns to individual evaluation to start a new cycle.

In order to establish a systematic risk assessment system for sports injuries, it is necessary to decompose the decision object based on the idea of the decomposition method and build a hierarchical model accordingly. According to the above-mentioned points, the hierarchical analysis model is constructed as shown in Figure 2.

The basic level of the model: decision target refers to the final derived result; criterion layer is the criteria for the model judgment to make a decision; program layer refers to each specific program limited by the decision target and criterion layer. In the model, the highest risk factor is used as the target: severity and incidence as the criterion; four types of risk: sports instruction, partner cooperation, personal factors, and sports combination as the alternative. Next, a comparison matrix is constructed and solved, and finally the highest risk category is determined in a logical way, and those risk exposures with higher incidence and more severe consequences are identified and focused on [21–25].

The relative importance of the above-given four factors was compared between the two under the constraints of the criterion level. The importance ratings of coaches and athletes on the seven major exposures of the four risk categories were first arithmetically averaged in terms of categories and then weighted in terms of the ratio of the number of coaches and athletes participating in the study to obtain the final values of the matrix factors, and the judgment matrix was constructed.

The fourth-order matrix A formed is as follows (A_{ij} is the ratio of importance between risks ij , $A_{ji} = 1/A_{ij}$):

$$A = \begin{bmatrix} 1.00 & 4.00 & 7.00 & 9.00 \\ 0.25 & 1.00 & 4.00 & 6.00 \\ 0.14 & 0.25 & 1.00 & 3.00 \\ 0.11 & 0.16 & 0.33 & 1.00 \end{bmatrix}. \quad (1)$$

To achieve the sports training injury risk assessment model, the big data fusion scheduling method is used for big data information sampling of sports training injury risk assessment, combined with the statistical information mining method for sports training injury risk assessment, dividing the level of sports training injury risk assessment $X^{(0)}$, into N levels, as $X^{(1)}, X^{(2)}, \dots, X^{(N)}$, i.e. $X^{(0)} = \cup_{i=1}^N X^{(i)}$, with fuzzy feature distributed mining method for statistical analysis and optimal assessment of sports training injury risk, establishing a big data analysis model for sports training injury risk assessment, adaptive learning for sports training injury risk assessment, and obtaining a statistical function for sports training injury risk assessment as.

The above-given equation is a big data fusion model of sports training injury risk assessment for quantitative analysis of sports training injury risk assessment [26, 27], and the correlation distribution relationship of the constraint covariate set R^N, X^N of sports training injury risk assessment is established as follows.

Combining the autocorrelation feature matching method for sports training injury risk assessment big data sampling, according to the sampling results for sports training injury risk optimization evaluation and decision making. The feature matching function of sports training injury risk is established, $\{x(t_0 + i\Delta t)\}$, $i = 0, 1, \dots, N - 1$. The optimization-seeking trajectory of machine learning is as follows.

The fuzzy parametric identification of sports training injury risk assessment is carried out by using output stability gain assessment and the fuzzy decision method is constructed as follows.

TABLE 3: Sports training risk factors category statistics.

No.	Risk factor category	Frequency	Cumulative percentage (%)
A-a	Student movement behavior risk	162	20.12
C-b	Sports equipment risk	148	39.69
C-a	Activity venue risk	139	55.36
A-b	Student self-management risk	125	71.03
B-a	School safety management risk	100	82.55
D-b	Man-made environment risk	75	92.36
B-b	School medical supervision risk	35	96.77
D-a	Natural environment risk	28	100

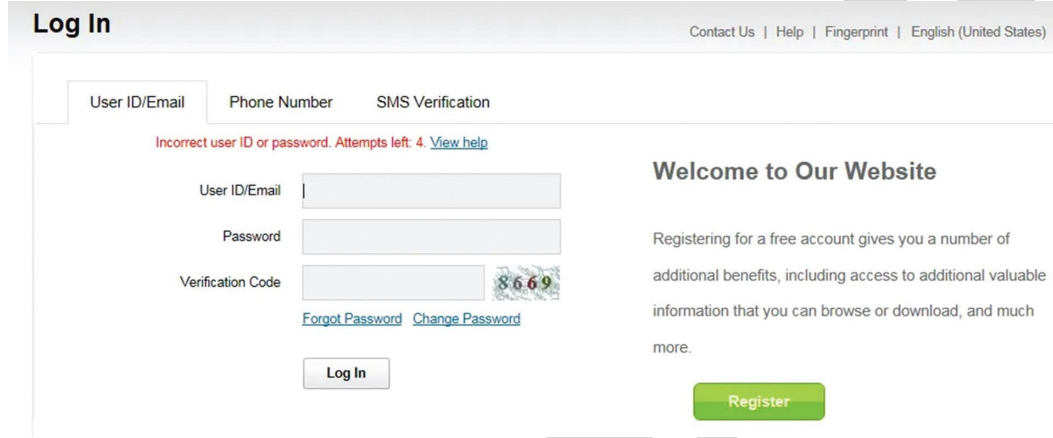

FIGURE 3: System login interface.

FIGURE 4: Website home page.

In the following equation, λ represents the fuzzy distribution factor of the big data for sports training injury risk assessment, combined with the statistical feature analysis method for sports training risk assessment. The sports training injury risk assessment is obtained as follows:

$$\sum_{s_c \in S^2} p\{C_k^i / A_k^i B_k^b\} p\{A_{k+1}^j / A_k^i B_k^b C_k^i\} \quad (2)$$

The linear fit equation for the risk assessment of physical training injuries is

$$P_{id}^{new} = \begin{cases} p_{id} + m() (X_{max} - p_{id}) & \text{if } m() > 0 \\ p_{id} + m() (p_{id} - X_{min}) & \text{if } m() \leq 0 \end{cases} \quad (3)$$

The similarity analysis method is used for adaptive assessment of sports training injury risk, and the fuzzy control in the process of sports training injury risk assessment is as follows:

$$SL_i = \begin{cases} L_i & \text{if } i = 1 \\ N_{ew} & \text{otherwise} \end{cases} \quad (4)$$

The association rule distribution function for sports training injury risk assessment is M_h , and the joint association rule mining method is used to obtain a finite dataset of association dimensional distribution for sports training injury risk assessment.

$$X = \{x_1, x_2, \dots, x_n\} \subset R^2 \quad (5)$$

Among them, the sports training injury risk assessment contains n samples, and the expert system analysis model of sports training injury risk assessment is established, and the control sample function is obtained as $x_i, i = 1, 2, \dots, n$, and the feature quantity of sports training injury risk assessment is obtained by combining the hierarchical gray-scale correlation analysis method p_q , and the quantitative relationship of sports training injury risk assessment is as follows.

To sum up, the analysis, to achieve the optimization of sports training injury risk and improve sports training injury risk control.

4. Overall Design of the Artificial Intelligence Web-Based Teaching Platform

4.1. Overall Design of the Web-Based Teaching Platform. The Artificial Intelligence Network Teaching Platform, with its efficient, remote, and resource-sharing features, allows advanced and rich course resources to be shared on the Internet, enabling teachers and students to download and

FIGURE 5: Interaction process of micro class.

FIGURE 6: Grass damage diagnosis and treatment system.

share electronic resources such as teaching contents and cases, microlessons and courseware, and scientific research results and papers. Students can rely on the flipped classroom teaching model in the online learning space to customize and personalize their learning or rely on the teaching platform for interactive and shared communication and as a supplementary teaching tool to traditional teaching.

4.2. Design of the Database. To design an effective database, a systems engineering perspective is required. As the website is an AI web-based teaching platform, it has a wide range of course resources and therefore a large number of corresponding data sheets, including article system Data Sheet; Downloading system Data Sheet; Electronic lesson plans Data Sheet; FLASH System Data Sheet; Classified information Sheet; Electronic lesson plans Data Sheet. The electronic lesson plans Data Sheet; the FLASH System Data Sheet; the Classified information Sheet; the Photo System Data Sheet, etc. The electronic lesson plans and FLASH System Data Sheet are shown in Tables 1 and 2.

4.2.1. Electronic Lesson Plan Data Sheet. The Electronic lesson plans Data Sheet is an information management tool for electronic lesson plans, which includes: title, special attributes, title image, and release time information. The corresponding fields are shown in Table 1.

4.2.2. FLASH System Data Sheet. The FLASH System Data Sheet is the information management for FLASH files, including Title, Special Attributes, Author, FLASH Address, FLASH Width, and FLASH Height. The corresponding fields are shown in Table 2.

5. Functional Implementation of a Web-Based Platform for Artificial Intelligence Courses

5.1. Experiments. Pareto analysis was applied to assess the overall risk factors of sports training, and the results of the overall risk assessment of sports training were obtained, as shown in Table 3.

The artificial intelligence course network teaching platform is divided into the following six functional modules:

Course introduction: provide users with course introduction and courseware materials.

Teaching team: briefly introduce the teaching team of the course website, so that users can have a certain understanding of the teachers of the website.

Teaching achievements: the teaching achievements module is a platform for teachers' achievements display and sharing. Users can browse teachers' teaching achievements on the website, such as teachers' papers, certificates, and projects.

Teaching resources: including teaching resources such as course content based on flipped teaching concepts (WeChat, PPT, WeChat platform, etc.), course cases, and syllabus based on task-driven teaching mode. Users

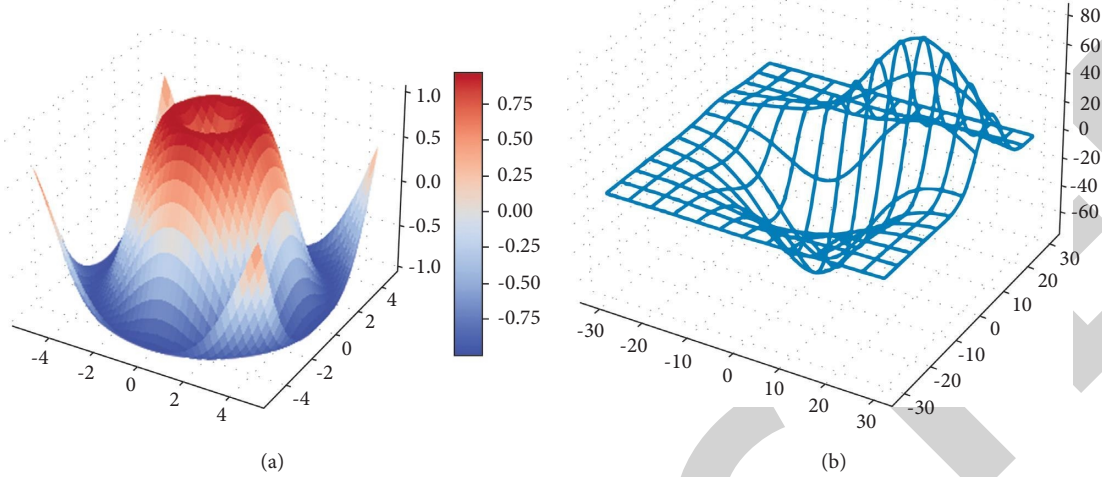

FIGURE 7: Utilisation of learning resources.

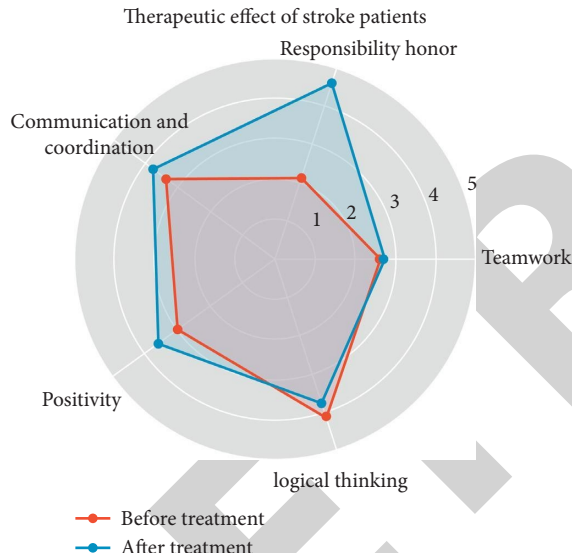

FIGURE 8: Radar chart of school resources and student status.

can freely choose the required materials for browsing and learning.

Learning garden: the learning garden is a display platform for scientific papers and excellent homework and a platform for interactive communication between teachers and students, providing users with reference materials for learning and reference.

Data download: it mainly completes the function of uploading and downloading electronic resources. The courseware includes relevant videos, a question bank, and courseware.

5.2. Platform Implementation. According to the function of the platform, it realizes six modules: course introduction, teaching team, teaching results, teaching resources, learning garden, and data download. Different modules correspond

to different pages, with simple structure and clear content. The function menu of the website is expanded in the form of a single row list, which makes the whole page appear orderly, concise, and clear. Users can easily browse the content of the website according to their needs and introduce the implementation process of the platform with the login interface and teaching resource module of the website.

5.2.1. Login Operation. This module is the system login interface. Its function is to detect whether the login user is legal and prevent illegal users from invading the system by verifying their user name and password. The system shall automatically judge the correctness of the user name and password entered. If the login is normal, the system shall record the current user name so that other operations can be assigned with appropriate permissions. The system login interface and website home page are shown in Figures 3 and 4.

5.2.2. Teaching Resource Module. The teacher resource module is the main functional module of the course platform. The module includes: teaching cases, teaching content, teaching video, teaching calendar, microclass, and PPT. Administrators release teachers' teaching videos and other teaching content to provide users with browsing and learning resources. After users select the required course resources and download them, they can view the course resources such as the course content and teaching cases [21, 22].

(1) Course Content Module. In the course content module, the teaching platform integrates the microcourse and diagnosis and treatment system of flipped classroom concept [23]. The flipped classroom is a new teaching model, which is composed of three basic elements: technical elements (mainly microvideo), process elements (before class-in class-after class), and environmental elements (intelligent diagnosis learning system). Flipped classroom focuses on the

FIGURE 9: School teaching platform conversion matrix.

whole process of teaching activities, focuses on the teaching interactive behavior of teachers and students supported by a multimedia environment, and focuses on the active awakening of students' innovative spirit [24]. Based on this new concept of "flipped classroom," this paper designs the teaching design process and mode based on the public platform, as well as how to carry out the learning and interactive process of the micromobile course based on the WeChat public platform and develops the microcourse of principles of artificial intelligence based on the WeChat public platform and the corn pest diagnosis and treatment system in smart agriculture, as shown in Figures 5 and 6.

Figure 5 shows the characteristics of the flipped classroom. Teachers and students use multimedia technology to interact and communicate in time in the classroom. This teaching method plays a very good role in cultivating students' autonomous learning ability, autonomous problem discovery, and problem-solving ability. Figure 6 is the interface of the grass damage diagnosis and treatment system. The system is the application of artificial intelligence in grass damage diagnosis and treatment. Students can learn independently after class and diagnose grass damage by themselves [25–27].

6. Effectiveness of Aesthetic Informatics

Campus culture has a subtle effect on teachers and students, influencing both their values and the learning atmosphere on

campus. An information-based campus environment can enhance the breadth and depth of campus culture communication, break the constraints of time and space, enhance the attractiveness of campus culture, stimulate students' curiosity and creativity, and improve the efficiency of campus culture construction. Firstly, schools should actively use information technology to promote communication between students and the outside world and to stimulate their imagination and creativity in beauty. As shown in Figure 7 for its 3D distribution of resource use, schools use the network to share campus aesthetic culture resources, which can create a campus culture building platform for teachers, students, and parents to participate in, bringing individual campus culture in line with popular culture. Schools should use new media technology to create an information-based aesthetic environment for students, such as providing them with brightly colored pictures, pleasant music, lively animations, and virtual simulation images so that they can perceive the charm of campus aesthetic culture in many ways.

Schools should train teachers in all subjects at the generalist level of aesthetic education, set out beauty design requirements for teaching design and courseware, regulate teachers' teaching language and processes in terms of beauty, and integrate aesthetic education organically into the teaching of all subjects. As shown in the radar diagram of the functions of different resources in schools in Figure 8, the practice of specialized courses in aesthetic education should be increased so that students can perceive first-hand what is

around them. Schools can also try to integrate humanistic customs and local characteristics of landscape resources from around the world; for example, by offering a weekly practical lesson on aesthetic education and allowing teachers to take students outside for viewing and learning. Such a teaching approach that combines aesthetic education with local natural and humanistic landscapes can broaden the scope of aesthetic education, allowing students to appreciate the beauty of their hometowns and lives while enriching their own aesthetic world and enhancing their own aesthetic sensibilities.

Exploring information technology to facilitate cooperation between home, school, and society Aesthetic education in the new era requires schools to co-ordinate and integrate social resources to implement the goal of enhancing students' aesthetic abilities in a home-school approach. With the increasing improvement of the school's information technology hardware construction and the increasing awareness of information technology, the learning effect of different campus websites, as shown in Figure 9, which can release school information or communicate with parents and society. Schools should pay full attention to and make use of the social resources around them, using information technology as a medium to design feasible aesthetic education collaborative projects to benefit students.

7. Conclusions

In the process of promoting aesthetic education, as the main body, the school has many shortcomings. Schools should strive to find strong and feasible initiatives in terms of system construction, teaching methods, teachers, digital resources, and improvement of conditions to find a breakthrough and anchor point for information-based aesthetic education and enhance students' aesthetic literacy. This paper combines the teaching objectives of the AI course and the characteristics and steps of the task-driven teaching method to develop an online teaching platform for the core AI course, which breaks the time and space limitations of the traditional teaching mode and enables teachers and students to learn and communicate anytime and anywhere, rather than being confined to the classroom. This provides a new mode of learning for the core AI course and has a positive effect on students' learning [19].

The film industry has also caught the fast train of Internet development. Various movie resources have come into view. Users need to spend a lot of time searching for movies they are interested in. This method wastes time and is very bad. The article proposes an NMF personalized movie recommendation algorithm, which can recommend movies to users based on their historical behavior and preference. The research results of the article show the following: (1) the experiment counts movie reviews of different users in the same time span. The results show that 48.42% of users have only commented on a movie once, 79.76% of users have posted less than or equal to 5 comments, and 89.92% of user reviews have posted less than or equal to 10 times. (2) In the comparative experiments of the NMF algorithm in different dimensions, the effect of the NMF-E algorithm is much better than that of the NMF-A algorithm. The accuracy, recall, and $F1$ value of the NME-E algorithm are all 3 types. The experimental results show that the NME-E algorithm is the best among all algorithms. (3) In the experiment to test the effectiveness of the NMF personalized recommendation algorithm, comparing the experimental results, the MAE value of the improved NMF personalized recommendation algorithm is lower than that of the unimproved algorithm. When the number of neighbors is 10, the highest value of the improved MAE of the previous algorithm is 0.837. After the improved algorithm, the MAE value is the highest (0.83), and the MAE value has dropped by 0.007, indicating that the error is smaller after the improved algorithm, and the result of recommending movies is more accurate. The recall value of the four algorithms will increase as the number of neighbors increases. Among them, the recall value of the NMF algorithm proposed in the article is the highest among several algorithms. The highest value can reach 0.200, which is higher than the highest value of other algorithms. It shows that the recommendation effect of NMF algorithm is the best. (4) According to the results of the questionnaire, after using the NMF personalized recommendation algorithm, users' satisfaction increased from 20% to 50%, an increase of 30%, and their dissatisfaction decreased from 15% to 8%, a decrease of 7%. Relative satisfaction increased from 52% to 55%, an increase of 3%, satisfaction increased from 35% to 60%, an increase of 25%, and dissatisfaction decreased from 40% to 20%, a decrease of 20%, indicating that the algorithm can meet the requirements of most people.

1. Introduction

With the rapid development of the information age, we will be faced with very complex digital and networked data. How users choose effective information from the tedious information, personalized recommendation algorithms can help users filter out the information they want and solve the needs of the vast majority of people. The film industry in China has also been developing rapidly in recent years. There are many movies released every year. The personalized recommendation of movie data can effectively solve the different needs

of users. There are many types of movies released every year in our country. When faced with so many movies, users will inevitably be at a loss and do not know how to choose. Literature [1] proposed a new cross-space affinity learning algorithm on different spaces with heterogeneous structures. The algorithm records and saves the record of the movie watched by the user, as well as the record of the comment. According to the user's comment, the user's movie hobby can be calculated. The article also compares the performance of the algorithm with the benchmark movie recommendation set, and the results show that the algorithm proposed

in the article has advantages. Literature [2] focuses on how to design a reliable and highly accurate movie recommendation algorithm. Literature [3] proposed an improved deep reinforcement learning algorithm to recommend movies. Literature [4] proposed an efficient privacy protection collaborative filtering algorithm based on differential privacy protection and time factors. Literature [5] discussed the problems of traditional collaborative filtering algorithms and proposed improvements. Literature [6] introduced virtual prediction items in a relatively sparse rating database. Literature [7] is combining collaborative filtering and association rules to accurately improve user recommendations. Literature [8] proposed a hybrid collaborative filtering algorithm based on user preferences and item characteristics. Literature [9] is inspired by the user-item rating matrix of the network and introduces an improved algorithm that combines the similarity of items with the dynamic resource allocation process. Aiming at the problem of insufficient demand mining for movie recommendation systems, literature [10] proposed a personalized movie recommendation system based on the collaborative filtering algorithm. Literature [11] proposed a spark-based matrix factorization recommendation algorithm, which uses spark memory computing and parallel data processing. Literature [12] focuses on the application of the latent factor model in the movie recommendation system and improves the latent factor model to overcome its shortcomings that it cannot give recommendation explanation. Literature [13] proposed a distributed collaborative filtering recommendation algorithm. Literature [14] researched using the concept of data warehouse to create a movie recommendation system. Literature [15] introduced the theory of semantic computing to label the semantic tags in movie clips and candidate advertisements.

2. Research on Personalized Movie Recommendation Technology

2.1. Research Background and Significance. This paper considers the introduction of other important movie information under the framework of collaborative filtering algorithm and combined with scoring data for hybrid recommendation [16]. It is worth noting that there is a kind of rich and valuable information on movie websites-movie reviews, but this kind of information is often ignored. Movie sites do hope that users can give more and more detailed reviews because considering that when users decide whether to watch a movie, the movie reviews given by other users will provide them with reference opinions, and a large number of movie reviews can improve users' perceptions. The level of interaction between users, thereby, potentially increases user stickiness. Generally, users always express the points or aspects that they care about most in their reviews of a certain movie, and these aspects often reflect the user's potential preference for the movie. A general rating can only indicate whether a user likes the movie or not, but it cannot give a specific reason why the user likes or hates the movie [17]. The user's specific evaluation of the movie is shown in Table 1.

2.2. Current Status of Movie Recommendation Research. Since review information is user-generated content, which contains the opinions and emotions of the reviewer, it is worth digging deeper to describe the "unique attributes" of users by using the review text. However, in the field of movie recommendation, film reviews should be digging. Relatively speaking, there are still very few studies. From the perspective of the recommendation field as a whole, some researchers have realized the rich information contained in text reviews and the value contained therein, but most of the researches use topic models to directly extract the topic distribution of text reviews without considering to the emotional factor in the comments. The user's film reviews actually reflect the user's likes and dislikes of a movie from certain angles. The previous research mixed texts with different emotional tendencies for analysis and could not fully extract the user's favorite and dissatisfied aspects of the movie. The use of sentiment analysis is to refine and divide the reviews and extract the user's satisfaction and dissatisfaction with the movie, which is the significance of mining reviews [18].

2.3. Personalized Recommendation Process. It can be regarded as first data collection of movie information evaluated by users, combined with user's movie reviews for sentiment analysis, and then imported into the NMF personalized recommendation model. The model will predict the movies that the user may like based on the user's historical behavior information and the supervisor's preference. Sort the movies according to the degree of preference. The first one is the one that the user may be most interested in, and then the list is recommended to the user. The basic flow chart is shown in Figure 1.

3. Research on the Recommendation Algorithm of Scoring Matrix and User Supervisor Preference

3.1. User Subjective Preference Recommendation Algorithm. The recommended algorithm steps are shown in Figure 2.

Construct a user movie rating table, as shown in Table 2.

I_u is a collection of movies rated by user u , and I_v is a collection of movies rated by user v [19]; user similarity is

$$\text{sim}(u, v) = \frac{|I_u \cap I_v|}{|I_u \cup I_v|} \quad (1)$$

Recommended results:

$$\bar{r}_{ui} = \sum_{j \in S(j,k) \cap N(u)} \text{sim}(i, j) r_{uj}. \quad (2)$$

$N(u)$ is a collection of movies rated by the user u , and $S(j, k)$ is a collection of movies j similar to K movie collections [20].

The formula for calculating the degree of preference between user u and other movies v is

TABLE 1: User evaluation form.

User ID	Time	Comment	score
68547261 (A)	2018-02-23 17:47:06	Watching "Interstellar," the initial surprise comes from music. The first climax of the film is the appearance of the song called comfield chase. Perhaps the reason why this song became the core of the film is this kind of senseless spirit of exploration. Director Nolan said after listening to this piece: My movie is ready for shooting. Hans Zimmer's soundtrack makes this film the uncrowned king in many people's hearts.	4
58691048 (B)	2019-02-12 23:55:04	Why can this science fiction movie stand out and be included in the history of film and television? Interstellar is a real hard science fiction movie. The movie incorporates the concept of five-dimensional space. This is a film that fully uses the concept of time and space. Its script is more based on data theories and formulas to support the development of the entire plot. Compared with other movies with no scientific basis, it is judged high.	5
78651562 (C)	2018-10-25 9:53:09	"Interstellar," Nolan is another magical film, and it should be the greatest science fiction film. Leaving aside the science fiction elements in the movie, after all, I do not understand [covering face]. From a human point of view, Nolan always likes to put the complexity of human nature in front of people, facing the instinct to survive, calling him the Earth. The hopeful professor Mann has become another Harvey Dante, with a feeling of DK series.	5
78961310 (D)	2014-11-16 00:49:28	Anne Hathaway said, I love him, but that does not mean I'm wrong. Love is something that humans cannot understand. It may be given to us by more advanced creatures. Although we think it is sensibility, it may be the highest level of wisdom. Anne Hathaway's short hair is very beautiful, like a smart and stubborn little boy, with human wisdom and love, who would not love her?	4

FIGURE 1: Flowchart of personalized recommendation.

$$S(u, v) = \sum_{V \in N(u)} \cos(R(:, v)^T, R(:, v)). \quad (3)$$

Common mixed recommendation models are shown in Table 3:

Build user characteristics such as in Table 4.

Calculate user G 's preference for your teenage movie:

$$r = \frac{1}{n} \sum_{i=1}^n (x_i - ave). \quad (4)$$

Movies users may like

FIGURE 2: Overview of user recommendation algorithm.

TABLE 2: User rating matrix.

User	Movie A	Movie B	Movie C	Movie D	Movie E
A	3	4	0	3.5	0
B	4	0	4.5	0	3.5
C	0	3.5	0	0	3
D	0	4	0	3.5	3

$$\cos(U, I) = \frac{\sum U_a \times I_a}{\sqrt{\sum U_a^2} \times \sqrt{\sum I_a^2}} \quad (5)$$

Error value of movie prediction:

$$\text{MAE} = \frac{\sum_{u,i \in T} |r_{ui} - \bar{r}_{ui}|}{N} \quad (6)$$

Movie recommendation accuracy rate:

$$\text{RMSE} = \frac{\sqrt{\sum_{u,i \in T} (r_{ui} - \bar{r}_{ui})^2}}{N} \quad (7)$$

Movie ranking prediction:

$$\text{Precision} = \frac{\sum_{u \in U} |R(u) \cap T(u)|}{\sum_{u \in U} |R(u)|} \quad (8)$$

3.2. Score Matrix Recommendation Algorithm. In the recommendation system, $U^m = \{u_1, u_2, \dots, u_m\}$ represents the user level, $I^n = \{i_1, i_2, \dots, i_n\}$ represents the movie set, and $R^{m \times n}$ represents the $m \times n$ -dimensional rating matrix [21] as shown in Table 5.

The similarity between users is expressed as

$$\text{PCC_sim}(a, b) = \frac{\sum_{p \in P} (r_{a,p} - \bar{r}_{a,p})(r_{b,p} - \bar{r}_{b,p})}{\sqrt{\sum_{p \in P} (r_{a,p} - \bar{r}_{a,p})^2} \sqrt{\sum_{p \in P} (r_{b,p} - \bar{r}_{b,p})^2}} \quad (9)$$

Among them, P represents the collection of movies that users a and b have rated together, and $\bar{r}_{a,p}$ and $\bar{r}_{b,p}$ represent the average ratings of users and based on the common movie collection P , respectively.

Cosine similarity:
