$$\text{Cos_sim}(a, b) = \frac{\vec{a} \cdot \vec{b}}{|\vec{a}| * |\vec{b}|} \quad (10)$$

The formula can also be written as

$$\text{Cos_sim}(a, b) = \frac{\sum_{p \in P} r_{a,p} * r_{b,p}}{\sqrt{\sum_{p \in P} r_{a,p}^2} \sqrt{\sum_{p \in P} r_{b,p}^2}} \quad (11)$$

Select the first K similar users to rate the unreviewed movie collection [22]; the calculation formula is

$$\text{pre}(a, p) = \bar{r}_a + \frac{\sum_{b \in NN} \text{sim}(a, b) * (r_{b,p} - \bar{r}_b)}{\sum_{b \in NN} \text{sim}(a, b)} \quad (12)$$

User u 's rating calculation formula for unrated movie p :

$$\text{pre}(u, p) = \frac{\sum_{i \in NN} \text{sim}(i, p) * r_{u,i}}{\sum_{i \in NN} \text{sim}(i, p)} \quad (13)$$

3.3. NMF Personalized Recommendation Algorithm. The NMF personalized recommendation algorithm combining the scoring matrix and the user's subjective preference is to extract and generate each user's comment [23] and calculate the weight, as shown in Table 6:

\bar{r}_i Is the average rating of user u_i on the movie.

Calculate the interest topics of a user's single movie review:

$$\theta_{ij} = \alpha_p \cdot \theta_{p-i,j} + \alpha_N \cdot \theta_{N-i,j} \quad (14)$$

The formula for calculating the overall interest distribution of users is

$$\theta_i = \frac{\sum_{j \in I} \theta_{ij}}{|I_i|} \quad (15)$$

The following formula measures the similarity between users:

$$D_{KL}(\theta_a \| \theta_b) = \sum_i \theta_a(i) \ln \frac{\theta_a(i)}{\theta_b(i)},$$

$$\vec{M} = \frac{1}{2} (\theta_a + \theta_b), \quad (16)$$

$$D_{JS}(\theta_a \| \theta_b) = \frac{1}{2} \left(D_{KL}(\theta_a \| \vec{M}) + D_{KL}(\theta_b \| \vec{M}) \right),$$

$$\text{sim}(a, b) = 1 - D_{JS}(\theta_a \| \vec{M}).$$

Average the topic distribution of all film reviews:

TABLE 3: Common mixed recommendation models.

Mixed way	Description
Weighted	The calculation results of multiple recommendation techniques are weighted and mixed to generate recommendations
Switching	The calculation results of multiple recommendation techniques are weighted and mixed to generate recommendations
Cascade	The cascading technology constructs the order of preference between different projects in the iterative refinement process
Combined	At the same time, multiple recommendation techniques are used to give multiple recommendation results to provide users with reference
Feature combination	The features generated by a specific recommendation technique are input to another recommendation technique
Increasing features	The output of the former recommended method is used as the input of the latter recommended method
Meta-level mixing	An internal model generated by one recommendation technique is used as an input for another recommendation technique

Predict the distance between the user and the movie according to U, V :

$$\begin{aligned} U_u &= U_u - \alpha \frac{\partial L}{\partial U_u}, \\ V_i &= V_i - \alpha \frac{\partial L}{\partial V_i}, \\ b_u(u) &= b_u(u) - \alpha \frac{\partial L}{\partial b_u(u)}, \\ b_i(i) &= b_i(i) - \alpha \frac{\partial L}{\partial b_i(i)}, \end{aligned} \quad (18)$$

in

$$\begin{aligned} \frac{\partial L}{\partial U_u} &= -\sum_{i=1}^n I_{ui} T_{ui} (Y_{ui} - \bar{d}_{ui}) \times \frac{1}{D_{ui}} (U_u - V_i) + \lambda U_u, \\ \frac{\partial L}{\partial V_i} &= -\sum_{u=1}^m I_{ui} T_{ui} (Y_{ui} - \bar{d}_{ui}) \times \frac{-1}{D_{ui}} (U_u - V_i) + \lambda V_i, \\ \frac{\partial L}{\partial b_u(i)} &= -\sum_{i=1}^n I_{ui} T_{ui} (Y_{ui} - \bar{d}_{ui}) + \lambda b_u(i), \\ \frac{\partial L}{\partial b_i(u)} &= -\sum_{u=1}^m I_{ui} T_{ui} (Y_{ui} - \bar{d}_{ui}) + \lambda b_i(u). \end{aligned} \quad (19)$$

4. Simulation Experiment

4.1. Data Set Characteristics. The experiment selected a real user evaluation album with a time span of 2016.9.1–2017.1.14. The experiment recorded the ID of each user, the content and value of the rating, and the time of the rating. The experiment was carried out on each user who scored. Statistics on the total number of comments has been made. The results show that 48.42% of users have only commented on the movie once, 79.76% of users have commented less than or equal to 5 times, and 89.92% of users have commented less than or equal to 10 times. The results are shown in Tables 7 and 8.

4.2. Evaluation Criteria. The evaluation criteria are shown in Table 9.

4.3. Experimental Results and Analysis. The experiment compares the NMF personalized recommendation algorithm in different dimensions to verify the rationality and performance superiority of the algorithm. An algorithm in the experiment is to only collect user movie reviews without any analysis. This algorithm is called NMF-E for short. The second algorithm ignores the influence of some negative reviews in movie reviews on user interest topics, and only considers positive movie reviews. This algorithm is referred to as NMF-A for short. The experimental comparison results are shown in Figures 3–5:

According to the results of the comparative experiment, we can find that the NMF-E algorithm, which does not do any sentiment analysis on the movie reviews posted by users, is better than ignoring the impact of some negative reviews in movie reviews on user interest topics and only takes into account the positive reviews. The effect of the NMF-A algorithm of the movie review is much better. The accuracy, recall, and $F1$ value of the NMF-E algorithm are the highest among the three algorithms. The accuracy and $F1$ value will decrease as the number of movies recommended by the user increases, and the recall rate will follow the user recommendation. The number of movies decreases as the number of movies increases.

TABLE 6: Weights of topic vectors.

	High score ($r_{ij} > \bar{r}_i$)	Low score ($r_{ij} > \bar{r}_i$)
Forward document weight	$\alpha_p = 1/1 + e^{-(r_{ij} > \bar{r}_i)}$	$\alpha_p = 1/1 + e^{r_{ij} - \bar{r}_i}$
Negative document weight	$\alpha_N = 1/1 + e^{r_{ij} - \bar{r}_i}$	$\alpha_N = 1/1 + e^{-(r_{ij} > \bar{r}_i)}$

TABLE 7: Evaluation record template.

User ID	Time	Movie IDmmcl	Score	Comment
61719620	2016-01-14 13:41:34	10577869	5	Love movie I really like! we met in the dark, of course we love each other, family feelings, family trivial matters, everything is so beautiful... Remember the English accent? The hostess is so beautiful! male starring in sunglasses, handsome! It's worth watching again anyway

TABLE 8: Statistics of user evaluation times.

Number of comments	User number	Percentage (%)
1	237209	48.42
≤ 5	390775	79.76
≤ 10	440539	89.92

4.4. Model Performance Testing. In order to test the effectiveness of the NMF personalized recommendation algorithm, we selected more than 100,000 comments on more than 1,000 movies from more than 900 users, and each user has more than 20 comments on the movie. In order to improve the accuracy of the NMF algorithm and find the most suitable decomposition dimension value, we can conclude from the data in the graph that the value of MAE will first decrease and then increase as the decomposition dimension increases. When the decomposition dimension value is at 6 o'clock, the value of MAE is the lowest. The value of MAE represents the accuracy of the algorithm for personalized recommendation of movies according to the user's preferences, and the recall value is reflected in the recommended movie results, the proportion of users who are really interested in the movie [24]. Among them, the value of MAE is small, indicating that the error of the algorithm is lower, and the value of recall is larger, indicating that the proportion of users who are really interested is more. The relationship between the decomposition dimension and MAE is shown in Figure 6.

After improving the NMF personalized recommendation algorithm, we compare it with the traditional NMF algorithm. Under the condition that the adjacent numbers of the variables are set to 10, 20, 30, 40, and 50, respectively, we compare the MAE values of the two different algorithms. The experimental data is shown in Figure 7:

From the data in the figure, we can conclude that the MAE value of the improved NMF personalized recommendation algorithm is lower than that of the unimproved algorithm. When the number of neighbors is 10, the highest MAE value of the algorithm before the improvement is 0.837. After the algorithm is improved, the MAE value is the highest value is 0.83, and the MAE value has dropped by 0.007, indicating that the error is smaller

after the improved algorithm, and the result of recommending movies is more accurate. In order to further test the effectiveness of the NME algorithm, we compared with 3 other different algorithms and observed their MAE value and recall value. The details are shown in Tables 10 and 11.

From the data in Figure 8, we can conclude that the MAE values of the four algorithms will change with the fluctuation of the number of neighbors. When the number of neighbors is small, the MAE value of the NMF algorithm and the Jaccard algorithm fluctuates greatly. The NMF personalized recommendation algorithm proposed in the article among the four algorithms has the smallest MAE value regardless of the number of neighbors. When the number of neighbors is 10, the MAE value is the largest, and the maximum value is 0.783. The MAE value of the CEHPI algorithm is the largest among the four algorithms. The NCF and Jaccard algorithms are between the two algorithms. The experimental data further shows that the prediction accuracy of the NMF personalized recommendation algorithm proposed in the article is the highest among the four algorithms.

According to the data in Figure 9 and Table 11, we can conclude that the recall value of the four algorithms will increase as the number of neighbors increases. The recall value of the NMF algorithm proposed in the article is the highest among several algorithms, and the highest value can reach 0.200, both high and the highest value of other algorithms. The recall value of the Jaccard algorithm is the lowest among several algorithms, the lowest value is 0.100, and the CEHPI and NCF algorithms are somewhere in between.

4.5. Satisfaction Survey of Recommendation Results. In order to study the user's satisfaction after using the NMF personalized recommendation algorithm, the experiment took the form of questionnaire. The specific data is shown in Figure 10:

According to the data in Figure 10, after using the NMF personalized recommendation algorithm, the user's degree of satisfaction increased from 20% to 50%, an increase of 30%, and the degree of dissatisfaction decreased from 15% to 8%, a decrease of 7%. Relative

TABLE 9: Evaluation criteria table.

	Metrics	Formula
Accuracy	The accuracy measurement standard refers to the ratio of the number of hit movies to the number of recommended movies. The larger the index value, the more accurate the recommendation result.	$Precision = hits_u / recset_u$
Recall rate	The recall rate standard refers to the ratio of the number of hit movies to the theoretical maximum number of hits. The larger the index value, the more accurate the recommendation result.	$Recall = hits_u / testset_u$
F1 measurement	The F1 measurement index can effectively balance the accuracy rate and the recall rate by favoring the smaller value. The larger the index value, the more accurate the recommendation result.	$F1 = 2 \times precision \times recall / (precision + recall)$

satisfaction increased from 52% to 55%, an increase of 3%, satisfaction increased from 35% to 60%, an increase of 25%, and dissatisfaction decreased from 40% to 20%, a decrease of 20%. The experimental results prove that the

NMF personalized recommendation algorithm can provide users with effective decision support, improve user satisfaction, and promote the long-term development of the film industry.

FIGURE 10: User satisfaction survey.

5. Conclusion

Movie reviews are important information that directly reflects the subjective feelings of users. According to user reviews, we can know the theme of the movie and the user's viewing experience. The article combines the scoring matrix and the personalized recommendation algorithm of movie data preferred by the user's supervisor and proposes an NMF personalized recommendation model. When users are faced with dazzling movie data, users no longer have to spend a lot of time searching for movies they are interested in. While the system meets the diverse needs of users, it also promotes the long-term development of the film industry [25]. According to the effective survey results, there are still some users whose satisfaction with the personalized recommendation model needs to be improved. Therefore, the performance of the personalized recommendation model should be continuously improved. This is the invincibility of the Chinese film industry in the face of increasing business competition.

Machine learning only uses single-channel grayscale features to model the target, and the filter solution process is relatively simple. When the target has a large change relative to the initial frame, the tracking effect is poor. When there is the same kind of target interference in the target search area, the tracking results will be poor. The tracking algorithm based on the fully convolutional Siamese network can solve these problems. By learning the similarity measurement function, the similarity between the template and the target search area is evaluated, and the target area is found according to the similarity. It adopts offline pre-training and does not update online for tracking, which has a faster tracking speed. According to this study, (1) considering the accuracy and speed, the target tracking algorithm based on correlation filtering performs well. A sample adaptive update model is introduced to eliminate unreliable samples, which effectively enhances the reliability of training samples. With simultaneous changes in illumination and scale, fast motion and in-plane rotation IPR can still be maintained. (2) Determined by calculating the Hessian matrix, in the Struck function, Bike3 parameter adjustment can achieve fast tracking, and Boat5 ensures that the system stability is maintained in the presence of interference factors. The position of the highest scoring point in the fine similarity score map of the same size as the search image is obtained by bicubic interpolation as the target position. (3) The parallax discontinuity caused by the object boundary cannot be directly processed as a smooth continuous parallax. The MeanShift vector obtained by calculating the target template feature and the feature to be searched can increase the accuracy by 53.1%, reduce the robustness by 31.8%, and reduce the error by 28.6% in the SiamVGG algorithm.

1. Introduction

The tracking algorithm based on the fully convolutional Siamese network (SiameseFC) uses the Siamese network structure to build a tracking framework, which transforms the tracking problem into a similarity measurement problem between sample images and target search regions. The algorithm includes the target sample image, the target search area image, and the CNN network. According to the similarity measurement function, the output features of the upper half and the output features of the lower half are convolved to obtain the similarity, and then the maximum similarity is taken out. Position the maximum similarity and map it back to the original image, and finally use it as the tracking prediction result. By learning the similarity

measurement function, the similarity between the template and the target search area is evaluated, and then the target area is found according to the similarity [1–3]. The method of offline pretraining and no online update is used for tracking. Although it has a faster tracking speed, since the target template is not updated online, when the target changes greatly from the initial frame, the tracking effect is poor. The problem of solving the filter is transferred from the time domain to the frequency domain by using the cyclic structure and the Fourier transform. FCNT obtains the filter by multiplying the counterpoints in the frequency domain. When the target search area has the same interference of the target, the tracking result will be poor. Only single-channel grayscale features are used to model the target [4–7]. Although the filter solution process is relatively simple, the

tracking effect is poor. It is mainly composed of a recurrent neural network. The algorithm has abstraction for feature extraction module selection, such as minimum output square error and traditional pixel features used by the MOSSE filter. In the field of single-target tracking, the Siamese network framework takes a target template patch z (Template patch) and a search area block x (Search patch) as input, where z represents the target object, and x is the larger search area in subsequent video frames. Similar feature maps obtain the classification branch result CIs through CNN and determine the categories of different pixel positions. The KCF algorithm for multichannel HOG features is proposed, and the tracking effect is significantly improved, but the algorithm uses low-dimensional data to represent high-dimensional features when processing multichannel sample features, and the feature information will be lost. The regression branch result Reg is obtained, and the precise position of the tracking target is determined. The tracking algorithm implements the tracking network through classification tasks and regression tasks in the training phase. It is worth noting that the size of z is larger than that of the target template block z extracted by the Siamese network tracking algorithm. The generative model pays more attention to the description of the target, and the discriminative model pays attention to the classification of the target and the background. The generative modeling is time-consuming and fails to consider the background information. The tracking algorithm based on discriminant correlation filtering performs template matching and background discrimination at the same time. After obtaining the tracking model, the feature responses are obtained [8, 9]. In the visual system, geometric features are the main mechanism for humans to recognize or track objects. When the target is deformed, the depth image features can be used as effective information to assist the visual tracking task, which brings new research directions to visual tracking. The traditional discriminative correlation filtering tracking algorithm solves the regression through the samples generated by the closed-form solution loop in the Fourier domain. Deep learning-based discriminative correlation filtering methods use stochastic gradient descent or conjugate gradient methods to avoid boundary effects. A multicue pedestrian detector and an online detector are jointly used to learn individual object models, incorporating visible light and depth data in the same decision framework. Using RGBD features to build a more stable and more discriminative model, it can effectively identify the target area from the background. When visible light changes in illumination and occlusion, the robustness of the model decreases. The essence of image formation is actually a process of projection [10–13]. It can deal with the change of illumination in visual tracking, and the three-dimensional information of the object is lost in the process. How to restore the three-dimensional information has become the main content of binocular stereo vision research. Based on RGBD data for visual tracking task, a special occlusion template set is designed to supplement the existing dictionary to deal with different occlusion situations. Finally, a depth-based occlusion detection strategy is proposed to determine the template update time. The two-dimensional

appearance model and three-dimensional distribution model of the target are simultaneously constructed using visible light and depth images, and the visual tracking task is divided into three parts: detection, learning, and segmentation. The detection and segmentation part uses the above two models to locate the target, and the learning part is used to estimate detections, segmentation errors, and update the target model. The eyes send the collected two-dimensional images to the brain for calculation and processing, and finally form a three-dimensional image of the objective object. The binocular parallax is based on this principle, and the binocular camera is used to obtain two images, one is called the reference image, and the other is called the target map, and the disparity is calculated based on the position difference between the corresponding points in the reference map and the target map. This binocular camera is composed of two monocular cameras with the same parameters on the same horizontal line, and it is used to shoot objects in the real world. Taking multiple photos from different perspectives ensure that the effects of large differences between two photos taken in the same scene due to differences in camera performance and distortion are eliminated. In the test sequence, the result of camera calibration will have a significant impact on the accuracy of subsequent stereo matching, which is an indispensable step in the binocular stereo vision system. In the process of image acquisition, due to the influence of camera distortion, shooting angle, and light and other factors, the collected image may appear partially distorted. On the corrected image pair, after the disparity map of the two images is output in the previous step, the depth information can be determined by combining the internal and external parameters of the camera and the geometric relationship, so as to obtain its real coordinates in the real space, and finally realize the 2D image to 3D scene output update target. The advantage of particle filter is that it has better modeling ability in nonlinear environment, so it performs well in the field of target tracking. The discriminant model directly obtains the decision function from the limited data and directly learns the conditional probability distribution from the perspective of probability. The sparsity of target candidates is achieved using the least squares method. By splicing visible light and thermal infrared features together, both thermal infrared features and visible light features may exist as noise, thermal infrared features in thermal crossover or visible light features in dark conditions, etc. From a machine learning perspective, discriminative tracking is essentially a regression or classification problem [14, 15]. The background information of the image is introduced into the discriminative model. Modeling the object appearance usually uses sparse or low-rank theory to learn the representation coefficients of the features, taking into account the background noise. Some algorithms will use the target and background of recent frames to update the target model at regular intervals during the tracking process. Compared with the generative model, the discriminant has higher robustness to the interference of external factors and its own deformation. Therefore, the input target features should be comprehensively analyzed to greatly improve the robustness of target modeling. The previous algorithms for

constructing the target appearance representation usually directly input the target original features without decomposing them to obtain the target appearance model.

2. Siamese Network Class Tracking Algorithm

2.1. The Principle of Binocular Stereo Vision. Epipolar constraint is one of the most critical constraints in stereo matching. The line segment connecting the optical center of the camera is called the baseline. Abstract function represents the similarity score. But in the case of binocular cameras, a point in the real scene will form two different images on the image plane of the left camera and the image plane of the right camera, respectively. According to the position offset between the two images, plus the camera model and the geometric relationship between them, the depth information of the point can be calculated as shown in Figure 1.

2.2. RGBT-Based Visual Tracking Technology. Depth information can provide valuable features to assist trackers in predicting target locations when dealing with visual tracking tasks. It can not only increase the training speed but also solve the gradient vanishing problem of the sigmoid function. The depth sensor is limited by a limited range, and in practical applications, the RGBD visual tracking algorithm has many limitations. The depth sensor only collects the distance between the scene and the image collector, and it cannot correctly distinguish targets with the same distance, as shown in Figure 2. In recent years, visual tracking based on visible light modality has developed rapidly, and a large number of labeled datasets have been proposed for training models. The visual tracking technology based on RGBT was developed relatively late, and a dataset with ground-truth registration of visible light and thermal infrared was constructed. Dropout is used to alleviate over fitting. The training set is isolated from the test set of target tracking, the test results of the algorithm are more credible, and the ILSVRC dataset is established for the video target detection problem. The background between different frames is linearly correlated, and the moving target appears relatively sparse, so the model of the target appearance is usually based on the theory of sparse representation. Sparse representation to multimodal data fusion is applied, and visible light and thermal infrared reference templates are updated in a jointly optimized way for visual tracking tasks.

4. Simulation Experiment

4.1. Generative Models. In generative models, statistical models are usually generated from a probabilistic perspective, using past information to train a joint probability distribution, and modeling the posterior probability to predict the categories of candidate targets, as shown in Table 1 and Figures 3 and 4. Consider IV = 14, SV = 13, OCC = 15, and DEF = 3 in terms of accuracy and speed. The performance of the target tracking algorithm based on correlation filtering is relatively good. MB = 11, FM = 4, and IPR = 3.93. Most of the current tracking algorithms select the target as the center to cut out a fixed proportion of the area to be searched. The generative model uses the historical frame information to characterize the target and finds the candidate target with the smallest reconstruction error as the new target. OPR = 1.41, OV = 1.94, BC = 1.1, and LR = 1.97. Whether the search locale is set properly has a lot to do with the correct tracking. Depending on the sample size, the central target is cyclically shifted to obtain a set of positive and negative samples. Due to the existence of negative samples, the correlation filter can distinguish the target and the background well. Considering the background information and the diversity of changes in the target's own appearance, the results obtained by applying multiple trackers in the target decision-making layer are used as the final result. The sample adaptive update model is introduced to eliminate unreliable samples and effectively enhance the reliability of training samples. The illumination change IV = 10, the scale change SV = 10, the occlusion OCC = 13, the deformation DEF = 11, and the motion blur MB = 4.

computed through the same feature extraction network, as shown in Table 2 and Figure 5. The feature extractor uses the VGGNet deep network, and then maps the feature maps of different layers to the continuous confidence map in the spatial domain, and finally the center position of the target is determined by calculating the Hessian matrix. In the Struck function, Bike3 = 6.9, Boat5 = 16.6, and Building5 = 99.3. A fine similarity score map of the same size as the search image is obtained by bicubic interpolation Car15 = 42.4, Person21 = 31.2, Truck2 = 42.9, Uav4 = 6.3, Wakeboard2 = 3.1, car1_s = 18.4, and Person3_s = 30.2. The position of the highest scoring point is the target location. By analyzing and calculating the similarity and correlation of adjacent video frames, the estimation of the target position state is realized. The disadvantage of the C-COT algorithm is that the amount of computation and data is very large when training with the VGGNet deep network, which makes it difficult to meet the real-time requirements of target tracking. The assumptions of the method based on optical flow are two points: one is that the brightness of the target is constant when moving, and the other is that the gap between the adjacent video frames is small.

4.3. Parallax Continuity Constraint. Calculate the pixel feature value probability of the target and the frame to be searched to obtain the template and the feature model to be searched. According to the constraint rule that parallax has continuity, the parallax on the surface of this object is considered to be continuous and smooth, as shown in Table 3 and Figure 6. In the HA-SiamVGG calculation template, $A = 0.537$, $R = 0.309$, and $EAO = 0.313$. The parallax discontinuity caused by the object boundary cannot be directly processed as a smooth continuous parallax, due to the different shooting angles and the influence of the front and rear occlusion of the object. That is, the mapping point of a point in the space on the left and right image planes is unique. The target frame of the area to be searched is iterated continuously along the vector direction closest to the target in the first frame, and the convergence result is finally obtained through continuous iteration to locate the target. The pixel regions generated by the projection of the same object under different shooting angles must have consistent or similar properties. Due to the influence of the camera's photosensitive components, the surrounding environment, and noise, when the pixels in the same space are mapped to

the two-dimensional image, the gray value of the pixels will be different. Similarity constraints should be used to make their corresponding matching points have similar properties. Difficult samples in network training are added, data augmentation to solve the spatial location bias of training is used, and the generalization ability of the model is improved.

4.4. Siamese Region Candidate Network Tracking Algorithm.

The confidence of the classified samples is obtained by correlation filtering, and then the target is tracked. The use of signal operations such as fast Fourier transform and dot product greatly improves the real-time performance of target tracking. The depth features are extracted through the same feature extraction network in SiamFC, and the classification branch depth feature map and the regression branch depth feature map are obtained through the RPN network, as shown in Table 4 and Figure 7. Optical flow refers to the use of images to represent the speed of motion, and each pixel is given a speed vector including size and direction. The motion state of the target is judged by the displacement change of the pixels in the adjacent frame images, so as to realize the tracking of the target. The correlation calculation with the template feature is performed to obtain the result feature map of the classification branch and the regression score. It needs to meet the time continuous or the target moves slowly, so the scope of application is small. The MeanShift algorithm is based on the probability density distribution, uses color features to describe the target, and iteratively finds the local optimum along the gradient ascending direction, that is, the position of the target. SiamFC searches based on the scale pyramid method. The calculation of depth features at each scale is time-consuming, and the tracking speed is slow. The introduction of the RPN structure enables SiamRPN to avoid time-consuming multiscale calculations and replace it with bounding box regression, which improves the tracking speed. The algorithm calculates the probability distribution of color features within the target and candidate regions, respectively. The Kalman filter tracking model is used to model the motion as a linear system. The motion state of the target in the current frame depends on the state of the previous frame. The filter is divided into two parts: prediction and observation. Calculate the observed values (speed, acceleration, etc.), and synthesize the observed state and the predicted state to obtain the optimal state estimate. It

is not sensitive to the change of the appearance of the target but has higher requirements on the selection of the motion model and the matching of the noise covariance, and the effect becomes worse when the motion speed is fast.

5. Conclusion

Traditional image acquisition refers to the process of image acquisition of objects in the real scene, while binocular stereo vision uses a binocular camera to achieve this process. Although machine learning has a faster tracking speed, its shortcomings are also obvious. The disadvantages of machine learning are that it takes a lot of time to make machine programs, and the demand for data is huge. Results may be satisfactory, but a fully automated system requires extensive research and analysis. The backups and servers required to maintain and record the acquired data keep piling up, making it increasingly costly. Since the target template is not updated online, when the target changes greatly from the initial frame, the tracking effect is poor. When there is the same kind of target interference in the target search area, the tracking results will be poor. Only single-channel grayscale features are used to model the target, and the filter solution process is relatively simple. The tracking algorithm based on the fully convolutional Siamese network can solve these problems. By learning the similarity measurement function, the similarity between the template and the target search area is evaluated, and the target area is found according to the similarity. It adopts offline pretraining and does not update online for tracking, which has a faster tracking speed. According to this study: 1. Considering the accuracy and speed, IV = 14, SV = 13, OCC = 15, and DEF = 3. The performance of the target tracking algorithm based on correlation filtering is relatively good. MB = 11, FM = 4, and IPR = 3.93. Most of the current tracking algorithms select the target as the center to cut out a fixed proportion of the area to be searched. The generative model uses the historical frame information to characterize the target, and finds the

candidate target with the smallest reconstruction error as the new target. OPR = 1.41, OV = 1.94, BC = 1.1, and LR = 1.97. The sample adaptive update model is introduced to eliminate unreliable samples and effectively enhance the reliability of training samples. The illumination change IV = 10, the scale change SV = 10, the occlusion OCC = 13, the deformation DEF = 11, and the motion blur MB = 4. Fast motion FM = 15, in-plane rotation IPR = 1.96, out-of-plane rotation OPR = 2.2, target out-of-view OV = 1.43, background interference BC = 1.25, and low-resolution LR = 1.74.2 are determined by calculating the Hessian matrix. In the Struck function, Bike3 = 6.9, Boat5 = 16.6, and Building5 = 99.3. A fine similarity score map of the same size as the search image is obtained by bicubic interpolation Car15 = 42.4, Person21 = 31.2, Truck2 = 42.9, Uav4 = 6.3, Wakeboard2 = 3.1, car1_s = 18.4, and Person3_s = 30.2, and the position of the highest scoring point is the target location. 3. In the HA-SiamVGG calculation template, $A = 0.537$, $R = 0.309$, and $EAO = 0.313$. The parallax discontinuity caused by the object boundary cannot be directly processed as a smooth continuous parallax, due to the different shooting angles and the influence of the front and rear occlusion of the object. The target template feature is calculated, and the MeanShift vector obtained by the feature is to be searched. In the SiamVGG algorithm, $A = 0.531$, $R = 0.318$, and $EAO = 0.286$. The visual tracking algorithm is still an active research direction in the field of computer vision. Although detection algorithms have achieved good results, there is still a certain gap in the application in real scenes, and the basic task of target detection is still very challenging. There is great potential and space for improvement.

In this paper, from the perspective of improving the visual communication of brand design, image texture intelligent matching processing is needed, proposing a brand design texture intelligent matching method based on visual communication, constructing a brand design texture intelligent information acquisition model under visual communication, using automatic image imaging technology for texture imaging and feature segmentation of brand design, and extracting typical brand design and ethnic design language of texture histogram, texture segmentation, and automatic matching under visual communication according to histogram distribution, brand design texture information enhancement and optimization detection by regularized feature fusion method, extraction of edge contour feature points of brand design, and texture matching with the extracted edge contour feature points of decorative patterns as input statistics. The adaptive performance of texture matching for a brand design using this method is better, and the texture discrimination ability is stronger, which improves the application research of better reflecting brand design in modern visual communication design and promotes the innovative combination of traditional cultural elements and modern design.

1. Introduction

The concept of visual packaging design is to give the audience visual and psychological cognition from words, graphics, and colors [1]. It establishes the logo, color, and labeling and is used for identification shorthand. For consumers, brand perception is the most beneficial tool to judge and distinguish similar products. The brand is used to reduce the time to choose [2].

A dazzling visual packaging war was staged between TV stations and channels. In the midst of the audiovisual inundation but can not help but disappoint some people. The form does not focus on positioning but only seeks to obtain gorgeous visual effects [3]. In the competition of brand media, not only the formal beauty should be pursued but also the connotation of the theme and the brand effect should be added [4]. The impact of digital packaging on the brand of television media and the important role of brand

image [5]. Through the analysis and systematic elaboration of the packaging process. Misconceptions, drawbacks, and successful columns are taken as the focus of the analysis. To explore the role of media packaging and excellent columns for brand building [6]. Learn from successful packaging and make the production team brand conscious as well through brand awareness implantation [7]. It is important to consider not only positioning, style, and innovation, but also brand awareness in production [8].

Speaking of packaging seems to know what he means, and it has a lot in common with the usual packaging of products. Packaging is also borrowed for the packaging of products. And, the definition of TV packaging is the specification and strengthening of the audiovisual elements of the channel, column, and TV station image as a whole [9]. Packaging design prerequisites are to solve the audience for their channel and the initial recognition of the column and program identification superior poor choice. Such as a channel to broadcast a new TV

series in prime time, before the broadcast to be after the packaging design to edit out the exciting images of the TV series, story conflict, in the postvisual design as a TV series promotional video [10]. Publicity to the audience, this is not the era of good wine is not afraid of the alley, is the need for active marketing and self-promotion of the times [11]. For the status of their own brand, the establishment of personality characteristics is the audience to establish their own channel media must mean of recognition [12].

Packaging is an important part of media brand building. In an era of excessive selectivity, you are successful if you catch the audience's eye, while hasty conversion is your undoing. For viewers to choose you, an initial understanding of you is essential. In addition to the full publicity on the TV screen [13]. This is not enough, in the development of the network today, the popularity of smart phones, tablets, the network, and cell phone platform publicity when it is the way to go. TV media need to actively promote the network if they want to break through [14]. By bringing PPS videos close to other smart-phones and tablets so that they are no longer limited by space, the visual packaging design of the media is the most direct means of publicity for each platform [15].

This is not conducive to the interests of the channel itself, so it is generally more stable, and if there are changes, they are modified and improved in the initial design [16]. We try to keep the original features and optimize only in terms of beautification. For example, the image logo of Phoenix TV is two phoenixes flying together. This logo leaves a deep impression, and whenever you see this logo you will clearly identify this Phoenix TV. Excellent LOGO image will make the audience remember deeply and penetrate into the audience's mind. A fixed memory is formed. When choosing a channel, based on the label viewers will quickly choose what frequency to see [17]. What programs are available on the channel and which ones do they like. Through tags, viewers can establish a connection. The label is in the upper left corner of the screen, which has become an inherent pattern in the media, as a necessary element that is inherent on the TV screen in addition to being fixed on the screen. There is a digital visual design of dynamic video often referred to as logo rendering that scrolls between programs in the channel [18]. When creating the logo image, attention should be paid to simplicity and clarity, outstanding features, reflecting modernity and design, incorporating regional culture, and enhancing viewability and locality [19]. In the channel, the interpretation of LOGO can enhance the sense of coherence between programs, make the rhythm and paragraphs more compact, and fill the gap between programs and advertisements. In media packaging, dynamic LOGO interpretation and image logo design are the cornerstones of tonality and make the features more prominent [20].

2. Image Acquisition and Preprocessing of Brand Texture Patterns

2.1. Image Acquisition of Brand Texture Pattern. In order to realize the intelligent matching of brand design texture based on visual communication, firstly, the 3D image reconstruction method is used for visual information acquisition of brand

texture pattern, and the multimedia digital information reconstruction method is used for intelligent matching of brand design texture, visual feature sampling, and the intelligent matching of brand design texture in the texture distribution area of the image; the image feature reconstruction space technique is used to read the 3D of brand design texture data feature volume, and form the raw file of brand design texture, the brand design texture PBO (OpenGL pixel cache object) is built according to the spatial feature sampling technique, and the image is stored in device memory, the brand design texture information is read, and the brand design texture matching is performed according to the brand design data information in device memory. According to the above-given design idea, it is assumed that the pixel set distribution of brand texture pattern is n , and the amount of label category information features of the output brand texture pattern is $P(1) = [1 - L^{-1}]m - 1$. According to the size and texture complexity of the brand design, the brand texture point pair matching is performed to get the brand texture pattern texture distribution.

$$E_m^{ij} = \sum_{k=0}^{255} e_{mk}^{ij}, \quad (1)$$

where E_m^{ij} is the color information of column j of row i in the m th image of the 3D branded texture pattern data sampling sequence.

$$e_{mk}^{ij} = \begin{cases} -p_k \log(p_k) & p_k \neq 0 \\ 0 & p_k = 0 \end{cases}. \quad (2)$$

Here, e_{mk}^{ij} for the 2×2 brand design edge information.

Combining the pixel frame distribution for texture alignment, the brand texture pattern information is fused using k th order moment feature statistics for the pixel points on each scale $\sigma_l^{(n)} (1, 2, \dots, n)$, and one sampling point is taken in each subinterval to obtain the grayscale histogram of the brand texture pattern.

$$P_k = \frac{n_k}{\sum_{i=0}^{255} n}. \quad (3)$$

For N brand design labels, the information fusion expression for the color, texture, shape, and other features of the brand texture pattern is

$$c(x, y) = [\Delta x \quad \Delta y] \begin{bmatrix} \sum_W I_x^2 & \sum_W I_x I_y \\ \sum_W I_x I_y & \sum_W I_y^2 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}. \quad (4)$$

The intelligent information acquisition model of brand design texture under visual communication is constructed, and the automatic image imaging technology is used for texture imaging and feature segmentation of brand design, and the average energy of the window is examined, and the neighborhood frame intensity at the spatial scale of brand design texture at (x, y, σ) is

$$H = \begin{bmatrix} L_{xx}(x, \sigma) L_{xy}(x, \sigma) \\ L_{xy}(x, \sigma) L_{yy}(x, \sigma) \end{bmatrix}, \quad (5)$$

where $L_{xx}(x, \sigma)$ is the brand design texture convolution, L_{xy} and L_{yy} have similar meanings. According to the fusion result of the edge pixel set of brand design, the multidimensional feature space reconstruction method is implemented for brand texture pattern information collection, and the edge energy value of the regional distribution pixel points $p(i, j)$ of brand design is obtained, which is used as the data input basis for intelligent matching and feature extraction of brand design texture.

2.2. Brand Design Feature Segmentation. The automatic image imaging technology is used for texture imaging and feature segmentation of the brand design, and the texture histogram of the brand design is extracted. According to the known pixel points x of the brand texture pattern, the maximum intensity of the texture distribution of the brand texture pattern is obtained to satisfy $I(x) = 1$, and the regional template matching the value of the brand image is determined as follows:

$$I_{\text{total}} = \frac{L_{\text{total}}}{\rho_{SRm} |S_{SR}|} \quad (6)$$

$$= \frac{\sum_{i=1}^M \sum_{m=1}^{|S_{SR}|} (\lambda_i P_{im} T_{SRm} / \rho_{SRm})}{|S_{SR}|}$$

The adaptive chunking feature matching method is used to determine the priority coefficients of the branded texture pattern output, and the dyadic geometric relationship of the output branded texture pattern is described by the following equation:

$$P = \sum_{i=1}^M \left(\lambda_i \cdot \frac{\sum_{m=1}^{|S_{SR}|} P_{im} T_{SRm}}{\sum_{m=1}^{|S_{SR}|} \lambda_{SRm}} \right). \quad (7)$$

The template alignment of the branded texture pattern is performed using the texture intelligent matching method, and the template alignment function is constructed as follows:

$$\text{STFT}(t, f) = \int_{-\infty}^{\infty} x(\tau) h^*(\tau - t) e^{-j2\pi f \tau} d\tau. \quad (8)$$

Using the pixel difference between the two branded texture patterns K_m and the spatial distribution pixel level s , the branded texture matching window is

$$d_{mn}^{ij}(x, y) = \begin{cases} \frac{\sum_{k=-s}^{+s} |\theta_m^{ij}(x+k, y+k) - \theta_n^{ij}(x+k, y+k)|}{(2s+1)^2}, & m \neq n, \\ 0, & m = n, \end{cases} \quad (13)$$

where m, n are the image projection numbers of the brand texture pattern in 3D; i, j are the feature matching points of

$$\text{SPEC}(t, f) = |\text{STFT}(t, f)|^2. \quad (9)$$

Using the adaptive chunking technique, a brand design texture template matching window of 2^l times the length and width is created, and the brand design texture distribution function is described as follows:

$$U(x) = 1 - \tilde{t}'(x)$$

$$= \omega \tilde{U}(x) \quad (10)$$

$$= \omega \min_{c \in \{r, g, b\}} \left(\min_{y \in \Omega(x)} \left(\frac{I^c(y)}{A} \right) \right).$$

The brand design texture segmentation is performed by means of a two-dimensional function expression, and the schematic diagram of the implementation process is shown in Figure 1.

3. Brand Design Texture Intelligent Matching Optimization

3.1. Texture Histogram Extraction of Brand Design. Based on the above-mentioned construction of the intelligent information collection model of brand design texture under visual communication, the intelligent matching of brand design texture is carried out, and a method of intelligent matching of brand design texture based on visual communication is proposed. With the feature points of edge texture distribution as the center, the fuzzy feature distribution function of the brand texture pattern is calculated in the irregular texture distribution triangle region W_{mE}^{ij} . The initial pixel set of the brand design is described as follows:

$$L(a, b_m) = \sum_{V_m \in P_{res}^n} \in \sum_{P_{rtue}} \frac{|V_m \cap V_n|}{|V|} \log \left(\frac{|V| |V_m \cap V_n|}{|V_m| |V_n|} \right). \quad (11)$$

The scale function of the distribution of feature points of the brand design is obtained and expressed as follows:

$$W_{mE}^{ij} = \frac{E_m^{ij}}{\sum_{m=1}^N E_m^{ij}}. \quad (12)$$

Within the grayscale neighborhood of the brand design, the spatial distribution of texture-matched clusters with center lengths of

the brand texture pattern; θ is the regional rotation angle of the brand texture pattern.

FIGURE 1: Schematic diagram of the implementation process of brand design texture segmentation.

The Taubin smoothing operator is used to reconstruct the brand texture pattern in 3D, and the main directional feature components of the edge contour of the brand texture pattern are noted as follows:

$$D_{mn}^{ij}(x, y) = \begin{cases} 1, & d_{mn}^{ij}(x, y) \geq \text{median}(d_{mn}^{ij}(x, y)), \\ 0, & \text{others,} \end{cases} \quad (14)$$

where $\text{median}()$ is the median operation expression, and the texture matching value W_{mD}^{ij} is obtained according to the sparsity of the boundary pixel points of the brand design.

$$W_{mD}^{ij} = \begin{cases} 1, & n_{mD}^{ij} < \alpha, \\ 0, & \text{others,} \end{cases} \quad (15)$$

where n_{mD}^{ij} is the set of edge pixels of the brand design; α is the ratio of the number of all pixels, set at 5%.

3.2. Visual Communication of Brand Design. Constructing the texture activity contour component of the brand design in the 4×4 subgrid region, setting h as the edge pixel set of the brand design, using the adaptive chunking feature matching method for window template matching, and using w_i as the weighting vector within the $N \times N$ window, the center pixel set and edge pixel set of the brand design is expressed as follows:

$$\begin{aligned} I_{if}(x, y) &= I^* G(x, y, \sigma_i), \\ I_{iv}(x, y) &= I^* \text{stdfilt}(x, y, w_i), \\ S_{gif}(x, y) &= -\log(P_{if}(x, y)), \end{aligned} \quad (16)$$

where $G(x, y, \sigma_i)$ is the multichromatic set of the brand design, and the texture matching hierarchy function of the brand design is calculated at each scale $\sigma_1^{(n)}(1, 2, \dots, n)$ of the brand design.

$$L(a, b_m) = \log\left(\frac{|V||V_m \cap V_n|}{|V_m||V_n|}\right). \quad (17)$$

According to the feature segmentation of the edge contour feature points of the image, the fusion feature distribution of the decorative pattern is obtained as follows:

$$f_R(z) = \begin{pmatrix} f_x(z) \\ f_y(z) \end{pmatrix} = \begin{pmatrix} h_x * f(z) \\ h_y * f(z) \end{pmatrix}, \quad (18)$$

where $f(z)$ is the texture feature component of the brand design and $*$ is the convolution operation.

The amount of edge information features of the brand design is calculated, and the optimized brand design feature extraction output is obtained as follows:

$$E_{int}(vi) = \frac{1}{2}(\partial i |d - |vi - vi - 1||^2 + \beta i |vi - 1 + 2vi + vi + 1|^2), \quad (19)$$

where

$$d = \frac{1}{n} \sum_{i=0}^{n-1} |vi - vi - 1|. \quad (20)$$

Let I_x be the chunked feature matching set of the brand design, where $x = P, N$, The activity profile of the brand design is

$$\begin{aligned} S_c &= [S_0, \dots, S_{Q-1}]_{\text{binary}} = \left[\sum_i^{Q-1} S_i \times 2^i \right]_{\text{Dec}}, \\ S_i &= \sum_j^{W \times W} I_x^j, \end{aligned} \quad (21)$$

where Q is the edge scale of the brand design; W is the amount of weak edge features.

The regularized feature fusion method is used for brand design texture information enhancement and optimal detection, and the output texture intelligent matching map is obtained as follows:

$$w(i, j) = \frac{1}{Z(i)} \exp\left(-\frac{d(i, j)}{h^2}\right), \quad (22)$$

where $Z(i) = \sum_{j \in \Omega} \exp(-d(i, j)/h^2)$ is the symbolic distance function of brand design feature extraction, and let H_x, H_y be the wavelet feature solution of multiresolution brand design, respectively, to obtain the chromatographic distribution matrix of the image as follows:

$$C = O^T O \begin{bmatrix} \sum H_x(t) H_x(t) & \sum H_x(t) H_y(t) \\ \sum H_y(t) H_x(t) & \sum H_y(t) H_y(t) \end{bmatrix}. \quad (23)$$

Using the extracted edge contour feature points of the decorative pattern as input statistics for texture matching, the texture matching output is obtained as follows:

$$O = USV^T, \quad (24)$$

where U is the matrix of pixel training sample set of brand design in $N \times N$ dimensions, and in summary analysis, the intelligent matching of brand design texture based on visual communication is achieved [21, 22].

FIGURE 2: Brand image.

4. Brand Design Effect

There are many different forms of design in digital visual design packaging. Among the many variations, there are also fixed patterns. For modular packaging, the first and foremost is the channel promo. It has many styles, such as brand presenter image propaganda and regional cultural elements propaganda. There are also abstract picture combinations, national elements of traditional painting art, and post-modern three-dimensional post-technology synthesis style show. CCTV's "power of brand" is of great significance to the channel's promotional video. Delicate production, from ancient to the contemporary use of elements: interspersed, ink, ink splash, the use of techniques. It has to be said that it is deeply appealing. The creative form is based on the style of Chinese ink and wash, with the regional landmarks of Greater China. To witness the rise of China and the road to the realization of the Chinese dream. This not only represents the brand of the channel media. It also reflects the disgusted Chinese culture and the rise of the nation. It is a window to the world to declare our dream and the belief to achieve it. It further establishes the cultural communication concept of CCTV and its own brand image. As shown in Figure 2.

Various different channels and different columns in their promotional video production methods also have a lot of different strategies. Such as CCTV's windmill column have mostly children as the audience. Then, it is the pursuit of fantasy, science fiction, and childlike. His style of production, can not be limited to the host of the promo class. More to join the digital technology now three-dimensional animation effects, to produce a fantastic and bizarre fairy tale world to make it more attractive. Fully demonstrate the whimsical mode of thinking of children. In combination with specific channel call signs, etc., such as the CCTV13 news channel, its promos, and headlines

are mostly in the image of reporters and hosts for real-time interview documentary. The picture switches quickly, which makes the content more realistic, comprehensive, and global [23, 24].

In short, each program has its own positioning and presentation. It is the best to seize its own characteristics and find the suitable form of expression as shown in Figure 3.

A place of water and soil nurtures a place of people. This is also true for television media. However, this is also true for digital visual design. The characteristics of the region's packaging can always resonate with the region. For example, in the packaging design of Jinan TV, the application elements always revolve around the characteristics of the spring city. With water and springs, plus the city flower of Jinan. It not only reflects the regional characteristics. Also, for the city to make favorable publicity. For other provinces and cities, according to the different geographical location, cultural background, and ethnic folklore to package themselves to establish a unique style. In the design of highlighting the personality and regional characteristics, folk culture is one of the inevitable choices of the principle of characteristics as shown in Figure 4.

5. Experimental Results and Analysis

In order to verify the overall effectiveness of the self-matching method of significant image feature weights based on visual communication. The hardware environment during the test was an AMDA6-36702.70 GHz CPU, and the computer's memory was 2G The operating system is MatlabR2010b [25].

The time used to match the image feature weights by the three different methods was compared, and the test results of the three different methods are shown in Figure 5.

Analysis of Figure 5 shows that the matching time used in multiple iterations is less than 3 s when the significant

FIGURE 3: Brand image.

FIGURE 4: Cultural image.

image feature weight self-matching method based on visual communication is used to match the image feature weights; analysis of the matching time used in multiple iterations fluctuates around 5 s when the image feature weight self-matching method based on median filtering and the image feature weight self-matching method based on percolation filter are used to match the image feature weights. The matching time used in multiple iterations fluctuates around 5 s when matching. The test results show that the self-matching method of significant image feature weights based on visual communication takes less time to match the image feature weights because the self-matching method of significant image feature weights based on visual

communication uses the linear combination of filter functions to represent the response of the filter, which reduces the number of convolution operations, decreases the amount of operations, and shortens the time used for self-matching the image feature weights, verifying that the self-matching method of significant image feature weights based on visual communication. It is verified that the matching efficiency of the significant image feature weight self-matching method based on visual communication is high.

The image feature weight self-matching method based on the percolation filter are tested, and the matching accuracy of the three different methods is shown in Figure 6.

FIGURE 5: Matching time of three different methods.

FIGURE 6: Matching accuracy of three different methods.

According to the analysis of Figure 6, the matching accuracy is around 90% in multiple iterations. According to the analysis of Figure 6, the matching accuracy of the self-matching method based on the median filter fluctuates around 80% in multiple iterations. According to the analysis of Figure 6, the matching accuracy of the self-matching

method based on an osmotic filter fluctuates around 70% in multiple iterations.

According to the above-given analysis, the matching accuracy of the self-matching method based on visual communication is higher than that of the self-matching method based on median filter and the self-matching

method based on an osmotic filter. Because the self-matching method of significant image feature weight based on visual communication constructs a controllable filter to extract image features, reduces repeated convolution operations, solves the problem of poor subjective visual effect caused by human eye sensitivity, realizes the matching of image feature weight through the ratio method, and improves the matching accuracy of the method.

6. Conclusion

The significance of digital packaging lies in the promotion of the brand. In the process of packaging, publicity, and communication, make the potential output of media concept culture. The audience is unconsciously affected. Digital packaging only beautifies and conveys. Based on the application of the image matching method and visual communication in brand design, this paper is an effective platform to establish a brand and expand the business. At the same time, promote their own value and enhance the brand image of the media.

Track and field is an important part of sports. Track and field athletes are an important reserve force for the development of national sports. An accurate assessment of track and field athletes' performance can help them develop more appropriate training programs and improve their performance. In order to assess the performance of track and field athletes better, this paper proposes an improved logistic regression method. Firstly, this method uses factor analysis to reduce the data dimensions of the factors that affect the performance of track and field athletes, and uses the principal component analysis to select common factors and their corresponding values. Then, according to the common factors, a binary logistic regression model is established to evaluate the performance of track and field athletes. Experiments show that the method can effectively evaluate the performance of track and field athletes and is suitable for athletes of different track and field sports. It has high accuracy, fast evaluation efficiency, and good universality of performance evaluation. For different numbers of athletes, the proposed method has a lower error evaluation index, higher evaluation accuracy, and better evaluation quality. Compared with the other two methods, the proposed method has the shortest evaluation time and is more effective for the performance evaluation of track and field athletes.

1. Introduction

Athletes are an important reserve force for the development of national sports, and the accurate assessment of athletes' performance can develop more applicable training plans for them and improve their performance [1]. In addition to a complete training system, an objective and fair assessment evaluation system is particularly important for training athletic sports talents. An objective evaluation system of track and field sports performance aims to explore the potential of track and field athletes and is conducive to the national selection of more suitable track and field sports talents [2]. Constructing an evaluation model reflects the objective training effects of track and field athletes, finds the strengths and weaknesses of track and field athletes themselves, and then promotes track and field training reform and maximizes the effects and benefits of the sports training reform. At the same time, the feedback information from the model can also promote track and field athletes to clearly

recognize their training situation in the future training process and continuously adjust their training status to achieve the highest training efficiency. This can also serve as a guideline for track and field athletes' career planning.

Factors such as training intensity and track and field athletes' own physical quality can directly affect their performance. Accurately understanding the changing characteristics of track and field athletes' performance can ensure their better performance [3]. This makes it very important to assess track and field athletes' performance. The assessment of track and field athletes' performance is an important part of the athletes' training activities. This work plays a role in diagnosing, regulating, and strengthening the training process of track and field athletes, as well as making value judgments about the effectiveness of their training [4]. The evaluation of the training effectiveness of track and field athletes should be an evaluation of the training effect and training process. The evaluation should not only emphasize the function of screening and selection, but also strengthen

the function of motivation and development [5]. What should we do in the evaluating the training performance of track and field athletes to achieve the purpose of cultivating the training interest of track and field athletes, stimulating the subjective initiative of track and field athletes, and meeting the psychological needs of athletes is directly related to the functional orientation of track and field athletes' training and the realization of training goals. This is a problem that needs to be solved urgently at present.

Athletic athlete performance assessment is not only a test of sports training effects, but also a comprehensive judgment of athletes' sports ability. Whether the assessment is comprehensive, objective and fair, and truly reflects an athlete's actual level in sports [6] is often an concern of the athletes. Therefore, it is particularly important to construct a diversified performance assessment system. The diversification of the assessment system is reflected in the diversification of the assessment content. Athletic performance assessment should not be limited to physical fitness and motor skills, but also include training attitude, physical exercise, training participation, and competition winning together. The assessment should cover various factors such as cognition, emotion, cooperation, learning, and practice of the athletes [7]. The diversification of the assessment system is also reflected in the setting of dual subjects of assessment. They are the summative assessment made by the coach as the main body relying on the assessment results of training programs and the formative assessment made by the athlete as the main body with training activities as the main content [8]. By constructing a diversified track and field athletes' performance assessment system, it further broadens the dimensions and connotations of track and field athletes' performance assessment, which is of practical significance to improve the fairness and comprehensiveness of track and field athletes' performance assessment, enhance track and field athletes' participation and dominance in the process of performance formation, and help track and field athletes understand themselves, discover themselves, and transform themselves more objectively.

The regression model is a predictive model that studies the dependent and independent variables and integrates various possible influencing factors to assess athletes' performance and training effects through multiple regression models [9]. The research methodology in this paper takes the factors affecting the training performance of track and field athletes as the object of study, selects the factors affecting the assessment of track and field athletes' performance as the target variable, and establishes a logistic regression model. In this paper, the historical performance of track and field athletes was selected as the dataset. Among the assessment variables were competition ranking, competition time, age, gender, training duration, BMI, and blood pressure. First, factor analysis is carried out on the evaluation indicators to reduce the dimension of the data, eliminate the correlation between the data, and determine the final indicators. Then, a logistic regression model was established based on the final indicators. Finally, the assessment effects of the models were compared. Compared with the other methods, the method in this paper can achieve high-quality assessment of track

and field athletes' performance, which is very important for their training planning. Accurate assessment of track and field athletes' performance can help them understand themselves and training planning, which is good to improve their performance and make them better and better.

This paper has the following innovative points.

- (1) The factors affecting track and field athletes' performance are multiple. In order to effectively conduct track and field athletes' performance assessment, this paper simplifies the data and influencing factors by the factor analysis method. Discarding secondary factors and selecting primary factors as evaluation variables allows for a more simplified and efficient operation of the algorithm.
- (2) The common factors affecting the performance of track and field athletes were selected using the principal component analysis, and classified and assigned different weight values according to the degree of influence, which can improve the accuracy of the evaluation.

This paper mainly consists of five parts; the first is the introduction, the second is the state of the art, the third is the methodology, the fourth is the experiment and analysis, and the fifth is the conclusion.

2. State of the Art

2.1. Research Status. At present, with the deepening of the concept of "Internet Plus," information technology has been widely used in sports training activities. A large number of scholars have conducted in-depth research on sports performance assessment models and constructed many assessment models. Under the guiding principles of advancement and comprehensiveness, the literature [10] established indicators such as training hours to improve the quality of sports training and to promote further the internalization of athletes' knowledge. The literature [11] established an evaluation model from three aspects of the basic needs theory. The model used hierarchical analysis to analyse the indicator weights and found that the greatest weight was given to the autonomy needs and the least weight to the competence needs. When summarizing the methodological studies on the quantification of performance evaluation in universities, hierarchical analysis was found to be the most representative, but it is very difficult to test whether the judgment matrix is consistent when studying real-world problems and it is difficult to truly reflect the fuzzy nature of human evaluation [12]. Therefore, the literature [13] addresses the shortcomings of expert scoring in the hierarchical analysis method and integrates the principles of fuzzy mathematics to establish a mathematical model to evaluate the training quality more objectively. The literature [14] established an evaluation system from three aspects: training platform, coaches, and athletes. The method is based on AHP to determine the index weights and introduces a fuzzy comprehensive evaluation model for the differences that exist between the consistency of judgment matrix and the consistency of human brain thinking. This

provides a new perspective for athlete training quality assessment. With the continuous improvement of the fuzzy complementary judgment matrix theory, the literature [15] established athlete satisfaction indicators. The theory indicates that the influence of personal factors on the index system is the highest and the influence of gymnasium factors is the lowest, which provides a more scientific and reasonable reference basis for athlete training strategies. The literature [16] investigated the athlete performance prediction method integrating knowledge mapping and collaborative filtering to establish a training knowledge map depicting training information. The algorithm calculates the similarity of training at the knowledge level by the neighbour node-based method and the knowledge graph-based learning method, and integrates the obtained similarity into the collaborative filtering performance prediction framework to obtain athlete performance prediction results. The literature [17] investigates a two-way attention-based mechanism for athlete performance prediction model. The model obtains the attention scores of different attribute features on the first stage and second stage competition performance through two attention calculations, and combines the multi-feature fusion approach to obtain the competition performance prediction results. The historical data-driven prediction method is implemented by historical data. There are many historical data-driven prediction methods such as hidden Markov models, chaotic prediction, and support vector machines [18]. Support vector machines have the advantage of small sample learning and high learning ability in prediction, and hence they are also used to study the historical data-driven athlete performance estimation method. This method uses the KNN algorithm to pre-process the historical performance of athletes to remove the effect of distracting data and classify the data accurately. It uses support vector institutions to build regression prediction models and introduces Lagrangian functions for data transformation to avoid data operations from getting localized [19]. The support vector regression prediction model parameters are optimized using the particle swarm algorithm to reduce the interference of input quantity noise and reduce the complexity of the computation. These evaluation models are built according to different application scenarios and are important for promoting the scientific training of athletes.

2.2. Factor Analysis Method. Factor analysis is a technique to reduce the dimensionality and simplify the data. It explores the underlying structure of the observed data by examining the internal dependencies among many variables and represents the underlying data structure with a few “abstract” variables. These abstract variables are called “factors.” By discarding secondary factors and selecting primary factors as evaluation variables, the model is made more simplified and the efficiency of the algorithm operation is improved. This reflects the main information of the original set of variables. The original variables are observable explicit variables, while the factors are generally unobservable latent variables. The common factors in factor analysis are common influences

that are not directly observable but exist objectively. Each variable can be expressed as a linear function of the common factor and the sum of the special factors [20]. Its mathematical model can be expressed as

$$\begin{pmatrix} i_1 \\ i_2 \\ \vdots \\ i_u \end{pmatrix} = \begin{pmatrix} g_{11} & L & g_{1u} \\ g_{21} & \cdots & g_{2u} \\ \vdots & & \vdots \\ g_{u1} & \cdots & g_{uu} \end{pmatrix} \begin{pmatrix} F_1 \\ F_2 \\ \vdots \\ F_w \end{pmatrix} + \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_w \end{pmatrix}. \quad (1)$$

That is, $I = GF + \varepsilon$, where $I = (i_1, i_2, \dots, i_u)^N$ is an observable u -dimensional random vector. Each component represents an indicator or vector. F in $F = (F_1, F_2, \dots, F_w)^N$ is an w -common factor variable. w is less than or equal to u . It is the factor that appears in the expressions of each original observed variable, which are mutually independent unobservable theoretical variables. Matrix G is called the factor loading matrix. g_{xy} is called the factor loading. It represents the correlation coefficient between the x -th original variable and the y -th public factor variable. The larger g_{xy} indicates the stronger correlation between the public factor F_y and the original variable I . ε is a special factor. It represents the part of the original variables that cannot be explained by the common factor variables, which is equivalent to the residual part in the multiple linear regression analysis.

Factor analysis utilizes the idea of dimensionality reduction, starting from the study of the dependencies within the correlation matrix of the original variables, and groups the original variables according to the magnitude of the correlation, making the correlation between variables within the same group high and the correlation between variables in different groups low [21]. Each group of variables represents a basic structure and is represented by an unobservable composite variable. This underlying structure is called the common factor. Capturing these main factors can help us analyse and interpret complex problems.

3. Methodology

3.1. Regression Models

3.1.1. Regression Model Where the Dependent Variable Is a Qualitative Variable. (1) *Qualitative variables* The dependent variable takes only two outcomes. $j=0$ means that the event did not occur. $j=1$ means that the event occurred. Consider the following expression for a simple linear regression model.

$$\begin{aligned} j_x &= \beta_0 + \beta_1 i_x + \varepsilon_x, \\ E(j_x) &= \beta_0 + \beta_1 i_x. \end{aligned} \quad (2)$$

Since j_x is a Bernoulli random variable of type 0 to 1, the following probability expression is obtained:

$$\begin{aligned} U(j_x = 1) &= \pi_x, \\ U(j_x = 0) &= 1 - \pi_x. \end{aligned} \quad (3)$$

According to the definition of discrete random variable expectation, the following function is obtained:

$$E(j_x) = 1(\pi_x) + 0(1 - \pi_x) = \pi_x. \quad (4)$$

Thus, $E(j_x) = \pi_x = \beta_0 + \beta_1 i_x$.

(2) *Error term* The error term $\varepsilon_x = j_x - (\beta_0 + \beta_1 i_x)$ can only take two values for a dependent variable, i.e., 0 or 1. Its expression is as follows:

$$\begin{aligned} j_x = 1, \varepsilon_x &= 1 - (\beta_0 + \beta_1 i_x) = 1 - \pi_x, \\ j_x = 0, \varepsilon_x &= -(\beta_0 + \beta_1 i_x) = -\pi_x. \end{aligned} \quad (5)$$

The error term is a two-point discrete distribution, and thus it cannot be assumed to be a normal error regression model.

Zero-mean heteroskedasticity means that the error term is zero-mean and its variances are not equal, and the expressions are as follows:

$$D(\varepsilon_x) = D(j_x) = \pi_x(1 - \pi_x) = (\beta_0 + \beta_1 i_x)(1 - \beta_0 - \beta_1 i_x). \quad (6)$$

If a multiple linear regression equation is used to analyse the quantitative relationship between the dependent variable and the independent variable, the relationship function is expressed as follows:

$$j = \beta_0 + \beta_1 i_1 + \beta_2 i_2 + \dots + \beta_w i_w. \quad (7)$$

(3) The left side of the equation j takes 0 or 1, and the right side of the equation can take any real number; the left and right sides do not correspond to each other in terms of the range of values. Therefore, multiple linear regression cannot be used for fitting the dependent variable as a qualitative variable.

3.1.2. Logistic Regression Model. The logistic function has the form [22].

$$f(i) = \frac{e^i}{1 + e^i} = \frac{1}{1 + e^{-i}}. \quad (8)$$

The range of values of its independent variable is $(-\infty, +\infty)$ and the range of values of the function is $(0, 1)$.

The dependent variable j itself takes only two discrete values of 0 or 1. It is not suitable as the dependent variable in the regression model, such that

$$\begin{aligned} \pi_x &= f(i_x) = \frac{1}{1 + \exp(-(\beta_0 + \beta_1 i_x))}, \\ \ln\left(\frac{\pi_x}{1 - \pi_x}\right) &= \beta_0 + \beta_1 i_x, \end{aligned} \quad (9)$$

where π_x is the probability that the random variable j takes 1, and its value varies continuously in the interval $[0, 1]$; thus, π_x can be used as the dependent variable instead of j .

Let j be a variable of type 0 to 1, and t sets of observations be $(i_{x1}, \dots, i_{xu}, j_x)$, where j_1, j_2, \dots, j_t is a random variable that takes the value 0 or 1. The expression for the expected value is as follows:

$$E(j_x) = \pi_x = f(\beta_0 + \beta_1 i_{x1} + \dots + \beta_u i_{xu}). \quad (10)$$

The expression of the function for the logistic regression model [23] is as follows:

$$\pi_x = f(i_x) = \frac{e^{\beta_0 + \beta_1 i_{x1} + \dots + \beta_u i_{xu}}}{1 + e^{\beta_0 + \beta_1 i_{x1} + \dots + \beta_u i_{xu}}}. \quad (11)$$

Thus, j_x is a random variable of type 0 to 1 with mean $\pi_x = f(\beta_0 + \beta_1 i_{x1} + \dots + \beta_u i_{xu})$; and the probability function is

$$\begin{aligned} U(j_x = 1) &= \pi_x, \\ U(j_x = 0) &= 1 - \pi_x. \end{aligned} \quad (12)$$

The random probability of j_x can be defined as:

$$U(j_x) = \pi_x^{j_x} (1 - \pi_x)^{1 - j_x}, \quad j_x = 0, 1; \quad x = 1, \dots, t. \quad (13)$$

The likelihood function of j_1, j_2, \dots, j_t is thus

$$L = \prod_{x=1}^t U(j_x) = \prod_{x=1}^t \pi_x^{j_x} (1 - \pi_x)^{1 - j_x}. \quad (14)$$

The likelihood function is taken logarithmically and the following expression can be obtained:

$$\begin{aligned} \ln L &= \sum_{x=1}^t [j_x \ln \pi_x + (1 - j_x) \ln(1 - \pi_x)] \\ &= \sum_{x=1}^t \left[j_x \ln \frac{\pi_x}{1 - \pi_x} + \ln(1 - \pi_x) \right]. \end{aligned} \quad (15)$$

Bringing equation (2.14) into the equation gives the expression

$$\ln L = \sum_{x=1}^t \left[j_x (\beta_0 + \beta_1 i_{x1} + \dots + \beta_u i_{xu}) - \ln(1 + \exp(\beta_0 + \beta_1 i_{x1} + \dots + \beta_u i_{xu})) \right]. \quad (16)$$

The maximum likelihood estimation yields the estimate $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_u$ of $\beta_0, \beta_1, \dots, \beta_u$.

3.2. Prediction Model

3.2.1. Data Processing. The data taken in this paper are from the historical performance of athletes in a sports school. They mainly contain factors such as competition ranking, competition sports time, age, gender, training hours, and physical fitness at all levels of events. The dataset contains data related to 100 athletes. The dataset consists of training predictor variables and one target variable for track and field sports. The predictor variables include athletic athletes' competition ranking, competition time, age, gender, training time, BMI, and blood pressure, and the variable descriptions are shown in Table 1. The goal of the dataset is to predict athletic athletes' performance based on certain parameter measures contained in the dataset.

The process of data cleaning requires the consideration of the following effects.

- (1) Duplicate or irrelevant data.
- (2) Mislabelled data or multiple occurrences of the same label.

TABLE 1: Variable declaration.

I_1	Competition ranking
I_2	Race time
I_3	Age
I_4	Gender
I_5	The training time
I_6	BMI
I_7	Blood pressure

(3) Missing or empty data points.

(4) Outlier values.

The data are a standard database, and hence there is no duplicate or irrelevant data and no vacant data points have been checked. Since blood pressure, age, and body mass index cannot be 0 in general, and 0 is an abnormal data point, the rows with 0 values in each feature of blood pressure, age, and body mass index were filtered out. There were 724 valid data left after processing.

3.2.2. Factor Analysis

(1) *Applicability Test of Factor Analysis.* The results of the KMO and Bartlett's sphericity tests on the data of track and field athletes using SPSS software are shown in Table 2. It is generally considered that if the KMO measure is greater than 0.5, then factor analysis can be performed. The significance of $p=0$ indicates that there is a certain correlation between the original variables, and the conditions for factor analysis are available.

(2) *Extraction of Common Factors.* Factor analysis was performed on the data, and the extraction of principal components was performed by principal component analysis. Classifying them according to the degree of influence and assigning different weight values improves the assessment accuracy. Under the principle of eigenvalue of 1, three principal factors were retained, i.e., the seven variables were grouped into three categories. This reduces the amount of operations, but categorization causes information loss, and the amount of information retained is 64.49%, and the amount of information lost is large; thus, a common factor is added to make the amount of information lost reside within an acceptable range. The following variance interpretation Table 3 shows that each principal component contains the total variance of each original variable, and the improved retained information is 77.08%.

(3) *Public Factor Naming.* The original factor loading matrix was rotated by extracting the four public factors and performing maximum variance orthogonal rotation to obtain the variance maximum orthogonal rotation matrix, as shown in Table 4.

Based on the rotated component matrix, the four common factors can be named. The first factor Z1 has large loadings on the gender and age indicators. The second factor Z2 has larger loadings on the race ranking and race time indicators. The third factor Z3 has a large loading on BMI and

training duration. The fourth factor Z4 has a larger loading on blood pressure. It can be found that the evaluation indexes corresponding to Z1 are indirect influence data. The evaluation indexes corresponding to Z2 are race performance-related data. The evaluation indexes corresponding to Z3 are other physical data. Z4 represents blood pressure. They are named as indirect factors, competition performance, physical quality, and blood pressure, respectively.

3.2.3. Binary Logistic Regression

(1) *Hosmer-Lemeshaw test.* The original hypothesis H0: the model fits well with the observations. The results are shown in Table 5 $p=0.279 > 0.05$; the original hypothesis is accepted and the regression model can fit the data well.

$$\text{Logit}U = -0.82 + 0.65k_1 + 0.86k_2 + 0.67k_3 + 0.38k_4, \quad (17)$$

(2) As shown in Table 7, the significant p -values are all 0, indicating that BMI, age, gender, and training duration have highly significant effects on the performance of track and field athletes. The effects were ranked from the highest to the lowest: BMI > age > gender > training duration.

(3) As shown in Table 7, the significant p -values are all 0, indicating that BMI, age, gender, and training duration have highly significant effects on the performance of track and field athletes. The effects were ranked from the highest to the lowest: BMI > age > gender > training duration.

(4) The accuracy is shown in Table 6, with an accuracy of 74.9%, which indicates that the model predicts more accurately.

(5) From the regression analysis of multiple factors, a binary logistic regression equation was established. where $U = \beta_0 + \beta_1 i_1 + \beta_2 i_2 + \dots + \beta_w i_w$.

4. Result Analysis and Discussion

Using track and field athletes of a sports school as the experimental subjects, 10 groups of 200m sprinters were randomly selected as the research subjects. The evaluation results are shown in Figure 1. According to Figure 1, the method of this paper can effectively evaluate the performance of 200m sprinters, and the estimated value is very close to the actual value. The experiment proves that the method in this paper can accurately estimate the performance of track and field athletes and has a high accuracy of track and field athletes' performance assessment results.

The athletes of 10 types of track and field sports were randomly selected in this sports school to verify the generality of this paper's method. Using the method of this paper, the athletes' performance of these 10 types of track and field sports was evaluated and compared with the actual values, and the evaluation accuracy of the 10 types of track and field sports is shown in Figure 2. According to Figure 2, it can be seen that for different types of track and field sports, the method in this paper can accurately assess the performance of track and field athletes, and the estimation accuracy is basically maintained at more than 96%. The experiment proves that the method in this paper has good generality and a high estimation accuracy for different types of track and field sports.

Comparing the method of this paper with the methods in the literature [16] and literature [17] clearly indicates that the assessment of athletes' performance of the above-mentioned 10 types of track and field sports was implemented at the same time. The evaluation accuracy and evaluation efficiency of the three methods were tested by comparing, among which literature [16] is a student performance prediction method integrating knowledge mapping and collaborative filtering, and literature [17] is a student performance prediction model based on a two-way attention mechanism. The performance of 100 athletes in each type of track and field sports was selected for testing and the average value was taken to enhance the credibility of the experiment. The accuracy and assessment efficiency of the three methods for

assessing athletes' performance in the 10 types of track and field sports are shown in Figures 3 and 4. According to Figure 3, it can be seen that for athletes of different types of track and field sports, the assessment accuracy of athletes' performance of this paper's method is significantly higher than the remaining two methods, and the average assessment accuracy of this paper's method is 97.7%, the average assessment accuracy of literature [16] is 81.8%, and the average assessment accuracy of literature [17] is 86.5%. The experiment proves that when assessing the performance of athletes in different types of track and field sports, the method in this paper has the highest assessment accuracy, which significantly reduces the estimation error of athletes' performance and increases the credibility of the assessment results at the same time.

According to Figure 4, for athletes of different types of track and field sports, the evaluation time of this paper's method is significantly lower than the remaining two methods, and the evaluation time of this paper's method is always maintained within 20s with less variation, while the estimation time of the remaining two methods is more variable and less stable. This is due to the fact that the algorithm in this paper introduces factor analysis to optimize the parameters affecting the evaluation, which reduces the computational parameters and decreases the computational effort. The experiment proves that the evaluation time of this paper's method is the least and the athlete's performance evaluation is more efficient.

FIGURE 1: Performance evaluation results of the 10 groups of 200m sprinters.

FIGURE 2: Estimation accuracy of the performance of the 10 track and field sports.

Taking 200m sprinters’ performance as an example, the accuracy of the performance assessment of the three methods was tested with different numbers of athletes. The accuracy of the three methods was evaluated by the Mean Absolute Percentage Error (MAPE), an error evaluation index. The results of the error evaluation index tests for the three methods with different numbers of athletes are shown in Figure 5. According to Figure 5, the MAPE values of all three methods increased with the increasing number of athletes. Generally, if the MAPE value is lower than 10, it indicates that the evaluation accuracy of the evaluation methods is higher. With different numbers of athletes, the

MAPE values of this paper are significantly lower than those of the remaining two methods. The MAPE value of this method always stayed within 6, and the MAPE value of the other two methods was lower than 10 only when the number of athletes was less than 200. When the number of athletes was more than 200, the MAPE values of the other two methods were greater than 10.

The experiment proves that the MAPE value of this paper method is the lowest when the number of athletes is different. This indicates that the evaluation value of this paper’s method is closest to the actual value, with a higher evaluation accuracy and high evaluation quality.

5. Conclusion

Based on the model obtained in this paper, the performance of track and field athletes can be effectively evaluated. The main objective of this paper is to evaluate the performance of track and field athletes using a logistic regression model. The method adopts the idea of factor analysis, reduces and simplifies the data, and improves the evaluation effect. The experiments show that the method can accurately estimate the performance of track and field athletes and has a high accuracy of track and field athletes' performance assessment. At the same time, the method has good generality for track and field athletes' performance evaluation, less evaluation time, and higher evaluation efficiency. Overall, the method in this paper can achieve high-quality athlete performance assessment, which is very important for athletes' training planning. The accurate estimation of athletes' performance can help improve their performance and make them better by understanding the training planning they need. Therefore, we study the historical data-driven athlete performance estimation method to improve the accuracy and estimation efficiency of athlete performance estimation, provide more valuable information for athlete training planning, and develop better athletes for the country. However, the good experience of using this method requires a large amount of track and field athletes' historical competition performance data, and the effectiveness of the evaluation for individual track and field athletes' performance is yet to be verified. The experimental data are all track and field athletes' performance, and the generality of the prediction for other non-track and field sports is also yet to be verified. The next step will be to further explore the effectiveness of the model in evaluating the performance of athletes in a wider range of sports, to verify the generality of the model in evaluating athletes' performance, and to expand the scope of the application.

Aiming at the problem that the road traffic flow in intelligent city is unevenly distributed in time and space, difficult to predict, and prone to traffic congestion, combined with pattern recognition and big data mining technology, this paper proposes a research method to analyze and mine the daily travel patterns of urban vehicles. This paper proposes a WND-LSTM model, which mainly includes data preprocessing, data modelling, and model implementation, to analyze the similarity of travel patterns in seasonal changes. Combining the data mining results with the data mining results, the daily travel model of road traffic vehicles in intelligent city is established. The results of the case study showed that the WND-LSTM model outperformed ARIMA (88.48%), LR (65.79%), SVR (70.46%), KNN (68.21%), SAEs (66.95%), GRU (68.43%), and LSTM (70.41%) in MAPE, respectively, with an average accuracy improvement of 71.25% (MAPE of 0.651%).

1. Introduction

At present, with the rapid development of the global economy, the quality of life in a country is booming, especially the rapid changes in clothing, food, housing, and transportation, and the number of household cars is increasing year by year [1]. The urban motor vehicle ownership rate is growing at a rate of no less than 11.5% per year [2]. Despite the rapid development planning of cities and towns in China, the construction of transportation facilities is far from catching up with the rapid growth of vehicles. With the continuous popularization of people's means of transportation, the problems of traffic congestion and traffic pollution are becoming more and more serious [3]. The traditional urban transportation system is facing severe challenges because it seriously restricts the quality of life of citizens.

Consistent with today's urban traffic planning ability, how to optimize the road network capacity and improve the decision-making ability has always been the most difficult problem in traffic management [4]. As one of the core

contents of smart city, its goal is to create a modern, efficient, and stable traffic management system by using the technology of cutting-edge fields (computer information, automation, and artificial intelligence) so as to maximize the road capacity, alleviate or even maximize the road capacity, alleviate or even solve the problem of traffic congestion, and make all citizens live in a stable and orderly environment [5]. As the core element of intelligent transportation system (ITS), the research on transportation network operation mode and people's daily travel behavior can provide real and reliable data information for decision-makers so as to effectively deploy transportation network resources [6].

Today, we are in the age of big data. Data has permeated every industry and every function and has become an important factor in production [7]. As a fundamental part of ITS, the accuracy of traffic flow information collection is particularly important. A wide range of traffic flow information collection technologies such as laser sensing, GPS positioning information microwave detection, geomagnetic coil detection, and camera recording are widely used in this field, and these sensors can be found almost everywhere,

generating huge amounts of real-time traffic data information all the time, with information volumes of up to petabytes [8]. The question of how to fully exploit the “gold” of this data has been met with great enthusiasm by a wide range of knowledgeable people [9]. Big data mining method can use high-speed computer cluster or server cluster to process massive original traffic video data, carry out information mining, extract valuable rule information in a short time, and realize the knowledge transformation of data. Big data technology combines high-speed computing power and powerful storage capacity and will play a key role in reasonably allocating traffic network resources and avoiding various traffic problems [10].

Image recognition and big data mining are widely used artificial intelligence technologies. At present, they are playing a great role in promoting a wide range of industries, including government functions, medical care, industry, commerce, and military. However, the author found that their application in the field of transportation still has great potential. Based on the above background, this paper aims to combine a new perspective with the road network, use the massive traffic data generated by the well-equipped monitoring system in the traffic road network, and use the Hadoop big data processing framework, combined with K -means clustering algorithm and Δ Apriori association algorithm, from the perspective of data feature selection, obtains license plate information through image recognition, mines traffic flow model, and transforms big data into small data. Data are selected from the perspective of data characteristics, big data are converted into small data, and traffic network operation model is established [1]. This allows more targeted data and significantly reduces redundant data, so it has the advantages of cost-effectiveness and efficiency. Based on the traffic flow model and the accurate space-time mode of each vehicle, the designed route guidance algorithm provides real-time and effective route planning services for end users, allows each vehicle to find the route that best meets its requirements at the lowest user cost, reduces the concentrated load on the road, and reduces the causes of traffic congestion to a certain extent. This reduces the causes of traffic congestion, reduces the pressure of traffic management departments, and saves the waste of human and material resources [11].

2. Related Work

Since the turn of the century, computer information technology has developed rapidly, and the era of big data has arrived. Once the concept of big data mining methods was introduced, it has contributed to huge changes in a large number of traditional industries, such as energy, health care, and services, and has promoted the development of many industries. Many experts and scholars are also using the current hot big data analysis methods to solve transportation problems. Reference [12] modelled the public transport system based on discrete choice in terms of the impact of comfort and other aspects on passengers’ choice of travel mode, and [13] modelled the urban public transport system

based on Neighborhood search algorithm. A group intelligence model-based approach is proposed in [14] for open-ended route planning. Deletion algorithm and Ms algorithm are proposed for the shortest path problem, respectively, by [15]. In [16], a model for rail transit path selection is developed based on the Logit model. The model clustering analysis is applied in [17] for efficient detection of the forward speed of the traffic within the detection range. In [18], it is proposed to combine road intersection vehicle data, traffic facility data and traffic accident data with the help of establishing a GIS platform for accident analysis and detection. Reference [19] designed an Android-based GIS online navigation system. In [14], in order to solve the parameter convergence problem, weights’ calculation is added to the particle swarm algorithm, and the right of way is dynamically adjusted according to the roadway load change by combining the discrete selection of fuzzy rules. Reference [15] ensembles neural networks and Bayesian methods for predicting short-time traffic. Reference [16] applies multiprediction models to the field of road section load research. Reference [17] proposed a dynamic stochastic shortest path optimisation method to provide guidance on vehicle path optimisation through stochastic meritocratic planning.

3. WND-LSTM Model

3.1. Model Overview. As shown in Figure 1, our proposed WND-LSTM model mainly consists of three parts: data preprocessing, data modelling, and model implementation. Firstly, in the data preprocessing, the MapReduce parallel processing framework is used to process large-scale taxi GPS track data on the Hadoop distributed computing platform to achieve data extraction, data statistics, and data integration; secondly, the distributed WND-LSTM model is built on Hadoop, and the LSTM model is weighted with time windows and normal distributions. Finally, the WND-LSTM model was executed on MapReduce using Mapper, Combiner, and Reducer functions to improve the efficiency and scalability of the model predictions.

In addition, to address the storage and computational issues that exist when using independent learning models to handle large data of traffic, we introduce a generic MapReduce framework distributed modelling architecture for traffic flow prediction (MF-TFF) in the proposed WND-LSTM model [18].

3.2. Data Preprocessing. As the taxi GPS track data is not only spatiotemporally correlated and nonlinear, but also has the characteristics of huge data volume, variety, high value, low density, and fast speed, it is necessary to do data preprocessing work on the original GPS track data. In this paper, we extracted taxi GPS track point record data from the target road section for data preprocessing respectively. The specific process is shown in Figure 2. The data preprocessing process on MapReduce consists of three main tasks.

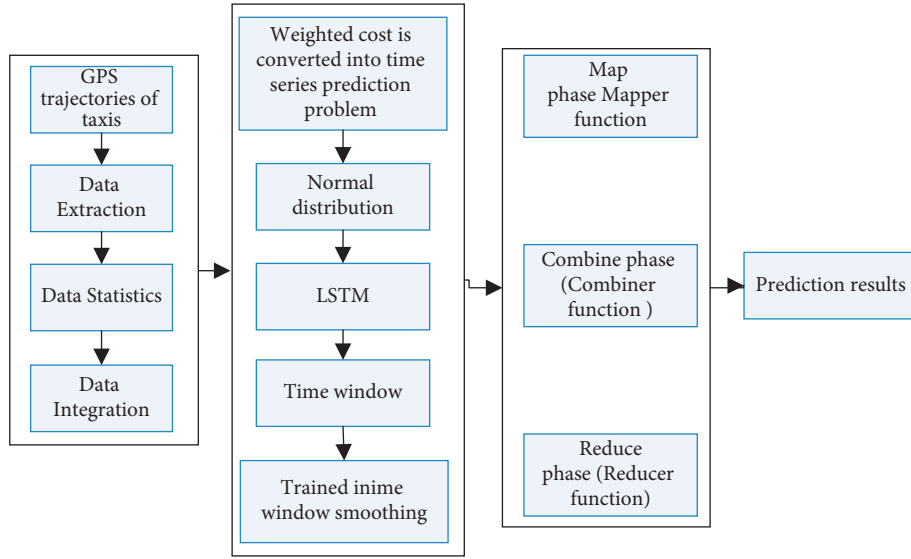

FIGURE 1: WND-LSTM model framework.

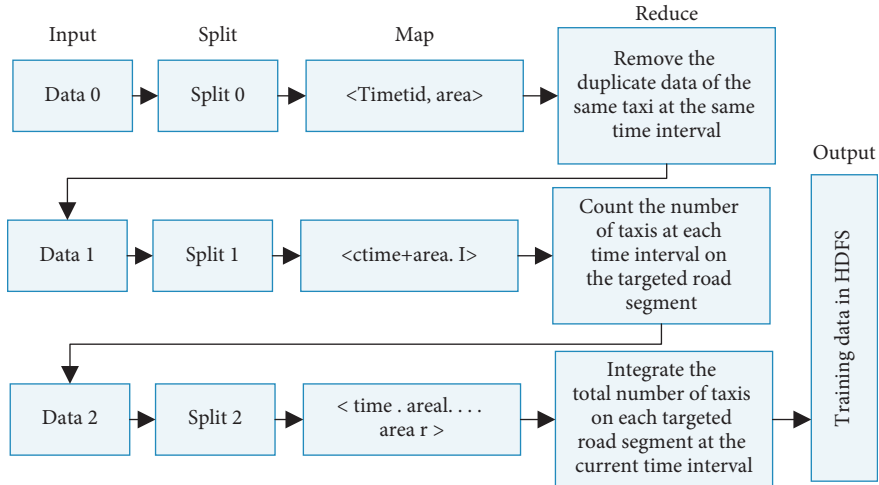

FIGURE 2: MapReduce-based data preprocessing process.

3.2.1. *Task 1: Data Extraction.* Extract the taxi vehicles present in the area of interest on the same day via GPS. Define a key-value pair $\langle \text{key1}, \text{value1} \rangle$ in the first Map task, where key1 represents the time and vehicle ID and value1 represents the number of the area location. Input to the Reduce task, in the Reduce stage, by sorting the time and vehicle number, remove the duplicate data of the same vehicle at the current time, and write to HDFS; see Algorithm 1 for details.

3.2.2. *Task 2: Data Statistics.* Count the number of taxis in each road section every five minutes, read in the information saved in the previous task in the second Map task, and define the key values. In the second Map task, the information saved in the previous task is read in and the key-value pair $\langle \text{key2}, \text{value2} \rangle$ is defined, with key2 representing the time and area number and value2 being entered as count 1. The database may be missing data for the current time point

due to the absence of vehicle information at a certain time point in the previous task. Therefore, a key-value pair $\langle \text{keys}, \text{values} \rangle$ needs to be added to the database at this point in time as a marker to ensure that the number of taxis at this point in time is not missing. As a marker for this moment in time, ensuring that each day has a fixed point in time.

3.2.3. *Task 3: Data Integration.* In the third Map task, the number of taxis counted in the second task is read in, and the key-value pair $\langle \text{key3}, \text{value3} \rangle$ is defined, where the time point is used as key3 and value3 represents the number of taxis counted in each road section.

3.3. *Model Construction.* The LSTM model has a unique structure that not only inherits the general characteristics of RNNs, but also solves the problem of gradient explosion and gradient disappearance when the values are too large or too small. The structure of the LSTM consists of an input layer,

an implicit layer, and an output layer, which also contains a memory cell. The LSTM is structured as an input layer, an implicit layer, an output layer, a memory cell, and three gating units: an input gate, an output gate, and a forgetting gate, which are used to control the flow of information in the input and memory cells, allowing the LSTM to better remember useful information and handle long-term time-dependent relationships.

In an LSTM network, assuming an input $x = (x_1, x_2, \dots, x_t)$ time series, a time series of $h = (h_1, h_2, \dots, h_t)$ in the implicit layer and a time series of $y = (y_1, y_2, \dots, y_t)$ in the output layer, the calculation can be performed by the following equation:

$$\begin{aligned} y &= W_{hy}h_y + b_y, \\ h_t &= H(W_{xh}x_t + W_{hh}h_{t-1} + b_h), \end{aligned} \quad (1)$$

where the implicit layer function of the LSTM can be obtained by the following equation:

$$\begin{aligned} i_t &= \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci}c_{t-1} + b_i), \\ f_t &= \sigma(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf}c_{t-1} + b_f), \\ c_t &= f_t c_{t-1} + i_t g(W_{xc}x_t + W_{hc}h_{t-1} + b_c), \\ o_t &= \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co}c_{t-1} + b_o), \\ h_t &= o_t h(c_t), \end{aligned} \quad (2)$$

where i , o , f , and c represent the input gate, output gate, forgetting gate, and memory cell, respectively, W is the weight matrix, b is the bias vector, and σ is the activation function.

In this work, as a result of simply using the traffic flow sequences upstream and downstream and at each bifurcation intersection to participate in the training, which does not consider the impact of each intersection on the current roadway in the time axis, thus proposing a relatively novel weighting method. A relatively novel weighting method is proposed to improve the prediction accuracy of short-time traffic flow. The LSTM is weighted to find the cost by using the characteristics of normal distribution and time window smoothing, and the cost is transformed into a time series. The problem of predicting traffic flow in a series of single variables over time is used to predict the state of the variables at the current moment.

Therefore, the MapReduce parallel computing framework on Hadoop optimises the traditional LSTM neural network. Firstly, the LSTM neural network is weighted to find the cost using a time window and normal distribution, and the cost is used as a time series prediction problem to form a time-dependent single variable series to predict the state of the variable at the current moment; secondly, on the Hadoop distributed computing platform with large data of taxi trajectories, we can obtain the traffic with time series by the above data preprocessing method. Finally, based on the obtained traffic sequence dataset, we select the target road section and then use WND-LSTM to build a traffic flow prediction model, which consists of the following three steps.

Step 1. The horizontal intersection section is considered as a network diagram, and V_t^i is defined as the traffic flow value collected from the target section at time t . Using the traffic flow sequence at time t to predict the traffic flow at time $t+1$ V_{t+1}^i , with a sampling interval of 5 minutes, the traffic flow sequence can be expressed as $O_i = \{V_1^i, V_2^i, \dots, V_n^i\}t$, where $i = 1, 2, R$ ($n = 288$), and the predicted traffic flow of any target road is predicted by the current moment of the road section and the related intersection, using the LSTM recurrent neural network. If section i junction is used as the predicted junction, the prediction model inputs and outputs are

$$\begin{aligned} X &= (O_1, O_2, \dots, O_R), \\ Y &= (O_{t+1}^i). \end{aligned} \quad (3)$$

Step 2. A normal distribution is one in which the random variable x follows a normal distribution with a mathematical expectation of μ and a variance of σ^2 , denoted as $N(\mu, \sigma^2)$. The probability density function is the expectation of the normal distribution μ that determines its location (centre line) and its standard deviation σ that determines the magnitude of the distribution. Since it is clearly not reasonable to simply use the traffic flow sequences upstream and downstream and at each bifurcation to participate in the training and does not take into account the influence of each intersection on the current roadway in the time axis, the WND-LSTM uses the idea of a normal distribution to weight the cost of each road segment and then uses the cost as a time series prediction problem to form a single variable sequence over time to predict the state of the variable at the current moment, which allows for artificial control purposes. The mean value of the normal distribution is the target road section, where the empirical value is 0.6 (which can be any reasonable value) and x is the discrete value of the traffic volume on each road section.

$$f(x) = \frac{1}{\sqrt{2\pi}\delta} \exp\left(-\frac{(x-\mu)^2}{2\delta^2}\right). \quad (4)$$

Step 3. Based on the above steps, the traffic flow on the target roadway at time t of the day is selected as V_t^i , and $V_{t-1}^i, V_{t-2}^i, V_{t-3}^i$ of the current historical moment is taken by window smoothing, and a window of size 4 is formed and fed into the training, in the following form:

$$V = \begin{bmatrix} V_1 \\ V_2 \\ \vdots \\ V_{n-3} \end{bmatrix} = \begin{bmatrix} v_1 & v_2 & v_3 & v_4 \\ v_2 & v_3 & v_4 & v_5 \\ \vdots & \vdots & \vdots & \vdots \\ v_{n-3} & v_{n-2} & v_{n-1} & v_n \end{bmatrix}. \quad (5)$$

4. Experimental Results and Analysis

4.1. Experimental Environment. The experimental environment was built on a Hadoop cluster with a MapReduce framework and ArcGIS platform, where the base hardware

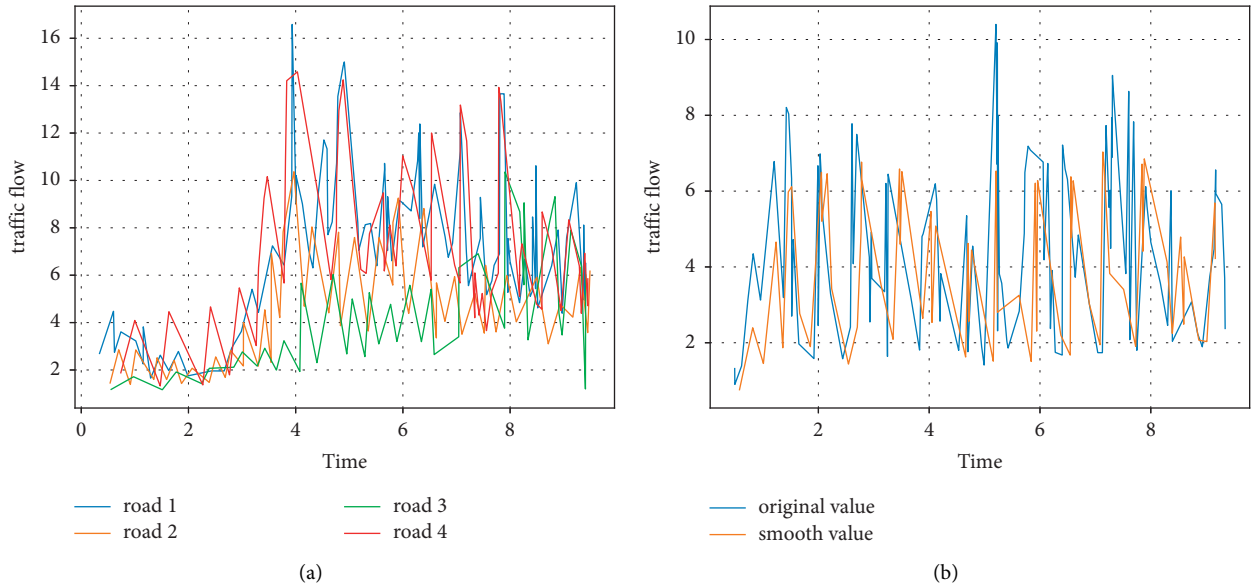

FIGURE 3: Experimental data smoothing. (a) Traffic flow on 4 road sections. (b) Kalman filter smoothing.

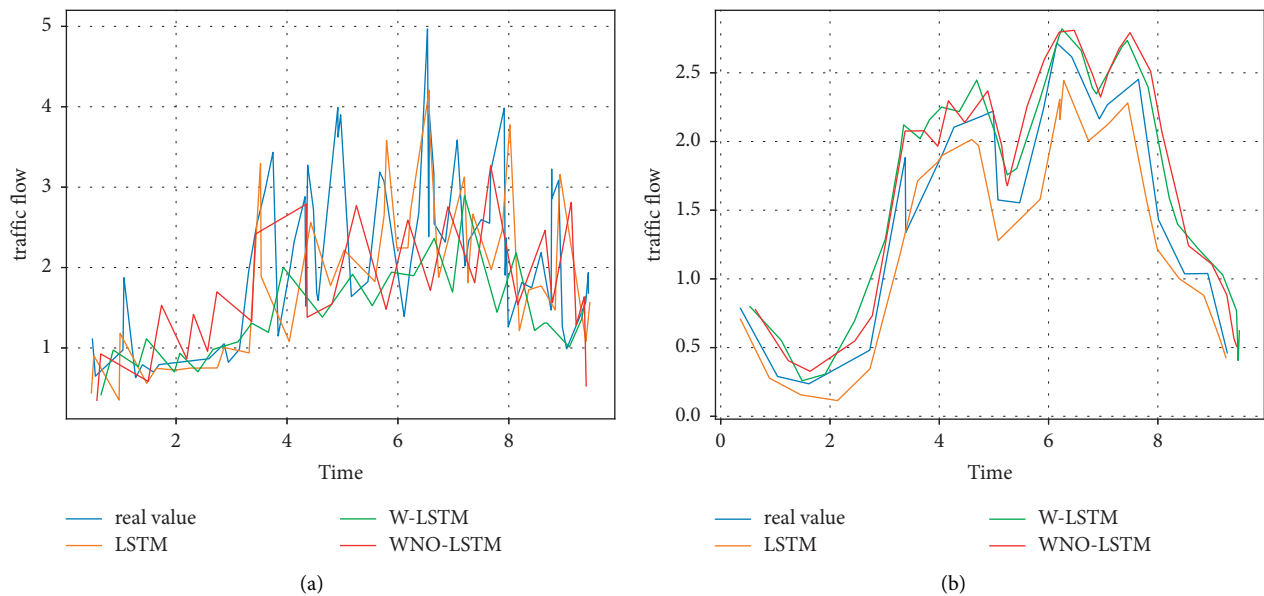

FIGURE 4: LSTM, W-LSTM, ND-LSTM, and WND-LSTM smoothing treatments.

was an HP Z400 workstation with an Intel Xeon 3500 CPU and ECC and DDR3 8.0 GB RAM. We ran all experiments with Hadoop 3.1.1 using Java, Python on Ubuntu 18.64 OS [20, 21].

4.2. Experimental Data. We used real taxi GPS trajectory data (approximately 25 GB) as the experimental data for this case study, which was produced from November 5 to November 18, 2021, in Beijing via 12,000 taxis.

These data consisted of 968 million GPS trajectory points, forming a visible traffic network map of Beijing, China, as shown in Figure 3(a).

In this experiment, we selected datasets from the above datasets for weekdays (November 5 to November 18, 2012) and also divided the datasets into five groups according to 1 day, 3 days, 6 days, 10 days, and 14 days in order to verify scalability, where 168 data were selected as the test set and the rest as the training set at 1 day, and 1 day was selected as the test set and the rest as the training set for all 3 days, 6 days, 10 days, and 14 days [22].

In particular, using the method described in the text, the above dataset was preprocessed based on MapReduce, and the traffic flows of the four road sections are shown in Figure 3(a). In addition, to make the experimental data valid, we used KF filtering to smoothen the set of the counted data

and normalised the data to between $[0, 1]$ by the Min-MaxScaler function, as shown in Figure 3(b).

4.3. Performance Assessment. In general, the more hidden layers a neural network has, the deeper the model is, and the better the representation and learning ability of the model, but it also leads to gradient loss and increases the difficulty of training. In this experiment, the model is trained on a limited dataset. The first part is an input layer of dimension 11, the second part is an LSTM hidden layer of dimension 64, and the third part is an output 1 vector, with batch taken as 1 (grid search) and 100 iterations using a sigmoid optimiser [23].

To evaluate the prediction accuracy of the proposed WND-LSTM model in terms of time windows and normal distribution, we compared it with LSTM, W-LSTM (LSTM with time window smoothing), and ND-LSTM (LSTM with normal distribution).

With the same experimental dataset, we used KF for data smoothing based on similar traffic flow characteristics and,

in particular, for experimental results with the same trend, we chose a dataset of 14 days due to spatial constraints [24], as shown in Figure 4. More importantly, we compared the MAPE values of LSTM, W-LSTM, ND-LSTM, and WND-LSTM, presenting the values of MOEs (MAPE, MAE, RMSE, and ME) for LSTM, W-LSTM, ND-LSTM, and WND-LSTM, respectively, as shown in Table 1 and Figure 5.

Table 1 reports the MOEs for the five datasets of the four LSTM methods, and it can be seen that the MAPE of the WND-LSTM method is lower than that of the other methods. The MAPEs of the WND-LSTM model are significantly lower than those of the other models in most cases, especially for the 14-day dataset, where the MAPEs of the WND-LSTM are lower than those of the LSTM, W-LSTM, and ND-LSTM by 70.41%, 68.92%, and 46.77%, respectively. In particular, the MAPE value for WND-LSTM is 0.651%, indicating a high predictive power [20].

Also for a more visual illustration, Figure 6 presents the traffic flow prediction results produced by WND-LSTM compared to other LSTM models (given the similarity of

trends in each set of experimental results, a 10-day dataset was chosen to present the results). As the dataset increases, the accuracy of the WND-LSTM model increases and the timeliness becomes better, as shown in Figure 7.

To further validate the accuracy of the WND-LSTM model, we compared it with advanced differential autoregressive moving average (ARIMA), logistic regression models (LR), support vector regression (SVR), K -nearest neighbour (KNN), stacked autocoding neural networks (SAEs), gated recurrent neural units (GRUs), and long- and short-term memory neural network (LSTM) prediction models, and the experimental results are shown in Table 2.

5. Conclusions

In this paper, we propose a distributed LSTM weighting model, WND-LSTM, which combines time windows and normal distribution to improve the accuracy of short-time traffic flow prediction (TFP). In addition, we implement the proposed WND-LSTM model on a MapReduce parallel processing framework to address the scalability and efficiency of short-time traffic flow prediction and use KF to filter the raw GPS taxi movement trajectory data to remove anomalies for discrete data smoothing. The results of the case study showed that the WND-LSTM model outperformed ARIMA (88.48%), LR (65.79%), SVR (70.46%), KNN (68.21%), SAEs (66.95%), GRU (68.43%), and LSTM (70.41%) in MAPE, respectively, with an average accuracy improvement of 71.25% (MAPE of 0.651%).

The existing deep learning models have problems such as large weight parameters and slow inference speed of equipment. In practical applications such as fire detection, they often cannot be deployed on equipment with limited resources due to the huge amount of parameters and low efficiency. In response to this problem, this paper proposes a lightweight smoke detection model based on the convolutional attention mechanism module. The model is based on the YOLOv5 lightweight framework. The backbone network draws on the GhostNet design idea, replaces the CSP structure of the FPN and head layers with the GhostBottleNeck module, adds a convolutional attention mechanism module to the backbone network layer, and uses the CIOU loss function to improve the regression accuracy. Using YOLOv5s as the benchmark model, the parameter amount of the proposed lightweight neural network model is 2.75 M, and the floating-point calculation amount is 2.56 G, which is much lower than the parameter amount and calculation amount of the benchmark model. Tested on the public fire dataset, compared with the traditional deep learning algorithm, the model proposed in the paper has better detection performance and the detection speed is significantly better than the benchmark model. Tested under the unquantized simulator, the speed of the proposed model to detect a single picture is 60 ms, which can meet the requirements of real-time engineering applications.

1. Introduction

In 2021, a total of 748000 fires were reported in China, including 1987 deaths, 2225 injuries, and 6.75 billion yuan in direct property losses. In 2020, a forest fire in Yunnan burned for three days and nights. The area of the fire reached 170 hectares, and 5800 people were involved in suppressing the fire. In addition, a bush fire in Australia burned for more than four months, burning an area of 170000 square kilometers and resulting in the loss of many vegetation and animals. The smoke generated by the fire poured into the stratosphere, and the impact cannot be fully restored for a long time [1]. Fire not only seriously threatens the safety of human life but also has a great effect on the ecological environment. Fire prevention is very important to protect people's lives and property and has important scientific research significance [2, 3].

Traditional fire detection technologies include contact-type fire detectors such as temperature detectors [4] and smoke detectors [5, 6], which are commonly used in most

public places. However, the disadvantages of this kind of detector are limited to indoor detection, aging, alarm time delay, etc. Thus, it is difficult to carry out fire monitoring in outdoor spaces. Compared with traditional contact fire detectors, noncontact video fire detection technology has the characteristics of fast response, wide detection range, and low hardware cost and is suitable for fire monitoring in large indoor and outdoor spaces and forests. Video fire detection technology can be divided into flame detection [7] and smoke detection [8] according to the detection object. Generally, in the early stages of a fire, the smoke appears earlier than the flame and is not easy to cover, and the flame will only be generated in the middle of the fire. When the flame is detected, the fire has occurred, which makes it impossible to prevent and control it for the first moments. Therefore, the current video fire detection technology mainly focuses on detecting smoke.

Smoke detection technologies include traditional machine learning-based methods and deep learning-based methods. The smoke detection technology based on

traditional machine learning includes two parts: feature extraction and classifier design. The core research is smoke feature research. Commonly used smoke features mainly include artificially designed features such as the color [9], texture [10], motion [11], background contrast [12], and combinations of various features [13]. Smoke detection technology based on traditional machine learning has difficulty meeting the application requirements of real-time detection in terms of accuracy and false alarm rate. With the successful application of deep learning technology in the field of computer vision, deep convolutional neural networks are widely used in smoke detection. At present, smoke detection algorithms based on deep learning are mainly divided into two categories. One is a two-stage target detection model based on region extraction, such as R-CNN (regions convolutional neural network) [14–16], Fast R-CNN [17], and Faster R-CNN [18], which divide the target detection into the following two steps: feature extraction and feature classification. The other category is a one-stage target detection model that directly performs location regression, such as the SSD (single-shot multibox detector) [19] and YOLO (you only look once) [20] series, which converts target detection into a regression problem.

Most smoke detection algorithms based on deep learning rely on convolutional networks for feature extraction. To solve the problems of efficiency and storage, researchers adopt network pruning [21], network parameter quantization [22], and knowledge distillation [23] and design lightweight networks to improve the speed of inference. For example, MobileNet v1-v3 [24–26] and EfficientDet [27] were proposed by Google, GhostNet [28] was proposed by Huawei, and ShuffleNet [29, 30] and SqueezeNet [31] were proposed by Megvii. These networks are well constructed. It can reduce the number of model parameters and improve the accuracy of the network detection, which plays an important role in real-time smoke detection.

Although smoke detection technology has been widely used, the smoke detection scene is complex and changeable, and the accuracy and robustness of the existing technology in complex smoke scenes still have difficulty meeting the needs of popularization and application. Therefore, this paper designs a lightweight network based on the YOLOv5 framework, draws on the design ideas of GhostNet, and adds the CBAM attention mechanism [32] to achieve model compression and speed up inference without reducing the accuracy of the model. This model greatly reduces the need for hardware environment and uses MNN as the framework for unquantified testing. The specific work is as follows:

- (1) Improve the focus structure to reduce the parameters and calculation amount of the focus layer.
- (2) The backbone network adopts the GhostNet module, and the CSP of the FPN and the head layers is modified to a Ghost bottleneck.
- (3) Add an attention mechanism CBAM to the backbone network layer.

The rest of the paper is arranged as follows: Section 2 introduces the work related to smoke detection; Section 3

focuses on the description of lightweight smoke detection models and implementation details; Section 4 compares the performance of different smoke detection models on smoke detection datasets; finally, a summary and outlook are given.

2. Related Works

Traditional smoke detection technology tries to obtain the characteristics of smoke to distinguish from other interfering substances and performs smoke detection by manually setting the smoke characteristics, but the detection rate and false alarm rate have difficulty meeting the application requirements. With the application of deep learning techniques in the field of computer vision [33–35], researchers have used deep convolutional neural networks for smoke detection [36–39], which can learn deeper feature models. Luo et al. [40] combined convolutional neural networks with traditional foreground extraction methods for smoke detection, extracted suspected smoke regions based on motion and color information, and used a CNN to extract regional features for classification. Pundir and Raman [41] input texture features into deep belief texture learning to train the smoke recognition model. Zhang et al. [42] solved the problem of insufficient sample data by inserting real smoke images in the forest background and adopted Faster R-CNN to detect wildland forest fire smoke. Filoneko et al. [43, 44] adopted classical convolutional neural networks (including AlexNet, Inception-V3, Inception-V4, ResNet, VGG, and Xception) to conduct experimental verification on four large-scale smoke image databases. Sharma et al. [45] used two pretrained deep convolutional neural networks, VGG and ResNet50, to test unbalanced datasets and found that deeper CNNs performed better on more challenging datasets. Yin et al. [46] proposed a 14-layer deep normalization and convolutional neural network (DNCNN) to achieve automatic feature extraction and classification. To further reduce the problem of model overfitting caused by insufficient training samples, more training samples are generated from the original training set by using various data enhancement techniques. Muhammad et al. [47] proposed an energy-saving edge-assisted smoke detection method based on a deep convolutional neural network for foggy monitoring scenes, and the early smoke detection methods outperformed the state-of-the-art methods. Xu et al. [48] proposed a new video smoke detection method based on a deep saliency network, which uses a circular convolutional structure to construct a pixel-level saliency detection network and uses the fused features for saliency reasoning. Li et al. [49] proposed extracting suspicious smoke regions by smoke region proposal, pruning and reconstructing a convolutional neural network to improve real-time detection, and proposing a regularized loss function called score clustering to improve the accuracy of the model. Liu et al. [50] proposed a two-stage smoke detection method. In the first stage, block DNCNN is used to detect the suspicious smoke area from each frame image and put forward the concept of visual change image. In the second stage, the SVM classifier is used to classify the HOG features of the visual change image of the suspected smoke area.

Although smoke detection technology based on deep learning has achieved good results, with the improvement of the performance of the smoke detection algorithm, the number of convolutional layers also increases, resulting in the problems of large weight parameters and slow equipment reasoning speed. In practical applications, it is often unable to be deployed on equipment with limited resources because of the high parameter quantity and low efficiency. To solve the problem of efficiency and storage, researchers have designed lightweight networks to improve the inference speed. For example, the YOLOv3-Tiny [51] network launched for high parameters and inference speed is a simplified version of the YOLOv3 network. Iandola et al. [52] proposed SqueezeNet. The main idea is to replace the 3×3 convolution with a 1×1 convolution and reduce the amount of computation and parameters by reducing the number of channels of the 3×3 convolution. Howard et al. [53] proposed MobileNet, which mainly uses many neural networks designed with depthwise separable convolutions, which can greatly reduce the number of parameters and computations. MobileNetv2 employs a reverse residual block, while MobileNetv3 achieves better performance with fewer floating-point numbers. Based on MobileNetv3, GhostNet [54] adopts an inexpensive linear operation method to obtain richer output feature maps at a lower cost of model parameters to increase the feature extraction capability to solve the redundancy of feature maps. Zhang et al. [55] proposed ShuffleNet, which uses group convolution and channel shuffling operations to effectively reduce the computational complexity of point convolution and achieve superior performance. ShuffleNetV2 further considers practical speed in compact model design. In the field of smoke detection, Silva et al. [56] proposed a novel lightweight CNN model through RGB images, which can be used from aerial images of UAVs and video surveillance systems and combined with edge computing equipment to process images through a convolutional neural network. Pan et al. [57] used weakly supervised fine segmentation and lightweight Faster R-CNN to propose a collaborative area detection and classification framework for fire smoke, which can simultaneously achieve early warning, area detection, and classification of fire smoke. To reduce the complexity of Faster R-CNN, this method introduces knowledge distillation technology to compare the structure of the model. With the advancement of mobile devices and the diversified development of application scenarios, lightweight networks show higher engineering value. This paper balances between the accuracy and speed of the model, reasonably optimizes the YOLOv5 model, and designs a lightweight improved model based on the GhostNet and CBAM attention mechanisms. Without reducing the accuracy of the model, it realizes model compression and improves the reasoning speed, which greatly reduces the dependence on the hardware environment.

3. Methodology

3.1. YOLOv5. YOLO (you only look once) is widely used as a general object detection model. YOLOv1 uses one stage to

complete the classification and positioning of objects, and then YOLOv2 [58] and YOLOv3 [59] further improve the speed and accuracy to accelerate object detection in the industrial world. YOLOv4 [60] can achieve training on an ordinary GPU. Currently, the YOLO series has developed into YOLOv5. Compared with YOLOv4, YOLOv5 is more flexible. To some extent, the YOLOv5 model is the most state of the art of all the known YOLO series. It provides four versions in the following ascending sizes: YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. The model size and accuracy of the four versions increase in turn and are distinguished by the number of bottlenecks. The channel and layer control factors are used to realize the version change, and the appropriately sized model can be selected according to the application scenario. This paper mainly implements model compression and acceleration, making it easier to apply to the embedded devices with limited resources. Therefore, YOLOv5s is used as the benchmark model with the smallest network depth and feature map width. YOLOv5s is mainly composed of the backbone and head. The backbone includes the focus, C3, and SPP modules, and the head includes the neck and detect modules for extracting fusion features.

3.2. Lightweight YOLOv5. Compared with the traditional YOLOv5s, this paper first gives the implementation method of some modules. The main improvements include the Focus_mod module, the GBN module (Ghost bottleneck), and the attention mechanism CBAM. The specific details are presented in the following subsections.

3.2.1. Focus_mod Module. First, we downsample the original image ($640 \times 640 \times 3$) to reduce the calculation of spatial information, then form a $320 \times 320 \times 16$ feature map through convolution, and reduce the loss of image information caused by the downsampling. Next, we perform 16 convolution kernels with 3×3 convolutions to obtain the feature map of complete information, implement MaxPooling again to reduce the layer size, expand the perceptual field, pool to form a feature map of $320 \times 320 \times 16$, and finally combine the residuals and output a $320 \times 320 \times 32$ feature map. Pooling removes redundant information, compresses features, simplifies the network complexity, reduces computation, reduces memory consumption, and makes the smoke feature layer more obvious. Compared with the original focus module, the parameters of the improved Focus_mod module are reduced by 6 times, and the calculation amount is reduced by 7 times, as shown in Figure 1.

3.2.2. GBN (Ghost Bottleneck) Module. GhostNet proposes an innovative Ghost module that generates more feature maps through cheap operations. This new basic unit of the neural network successfully achieves more feature maps with fewer parameters and computations. The implementation of this module is divided into two parts. First, GhostNet uses a normal convolutional calculation to obtain feature maps with fewer channels, then uses a cheap operation to obtain

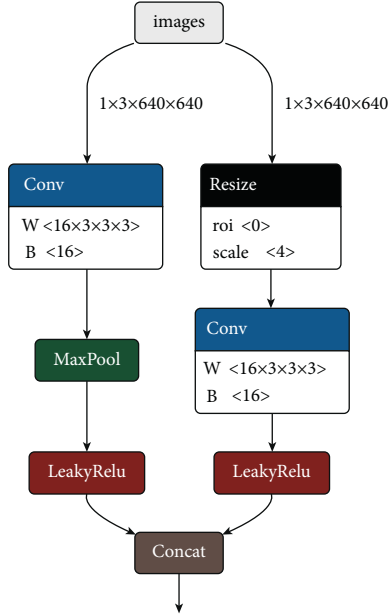

FIGURE 1: Focus_mod module.

more feature maps, and finally concatenates different feature maps together and combines them into a new output, as shown in Figure 2.

In GhostNet, the Ghost bottleneck module is divided into two types according to the stride. The Ghost bottleneck module structure when stride = 1 is modeled on ordinary residuals and is composed of two Ghost modules. The first module acts as an extension layer to increase the number of channels. The second module reduces the number of channels to match the shortcut path and then uses the shortcut to connect the inputs and outputs of these two Ghost modules. The Ghost bottleneck module when stride = 2 has the layout of the standard bottleneck structure and maintains the structural characteristics when stride = 1. By learning from the experience of the linear bottleneck module of MobileNetv2, an intermediate block is added in the middle of the stride = 1 structure. For a lightweight two-dimensional depthwise convolution, the amount of computation is reduced. This method draws on the experience of MobileNetv2. During the design process of the module and when the ReLU activation function is not used after the second Ghost module, the other layers use batch normalization (BN) and the ReLU nonactivation function after each layer. The structure design of the Ghost bottleneck is shown in Figure 3.

3.2.3. Attention Mechanism. The convolutional block attention module (CBAM) is a lightweight convolutional attention module that combines channel and spatial attention mechanism modules [61]. CBAM includes two sub-modules, the channel attention module (CAM) and the spatial attention module (SAM), which perform channel and spatial attention, respectively. This not only saves parameters and computing power but also ensures that it can be integrated into the existing network architecture as a plug-and-play

module. CAM is an adjustment to the structure of the SE module. Based on the SE module, a global maximum pooling operation is added to the CAM. CAM compresses the feature map into a one-dimensional vector in the spatial dimension, uses global average pooling and global maximum pooling to aggregate the feature information of the spatial map, and performs an element-by-element sum operation on the results by sharing the fully connected layer. The structure setting of the double pooling operation can make the extracted high-level features richer and provide more detailed information. SAM performs the concatenating operation on the result of the CAM operation based on the channel and performs single-channel dimensionality reduction through convolution. Similar to CAM, SAM adopts a double pooling operation. CBAM is similar to the SE module. The module structure mostly uses a 1×1 convolution to operate and completes the information extraction of the feature map through the entire channel dimension of the SAM, as shown in Figure 4.

3.3. Lightweight YOLOv5. Figure 5 shows the lightweight YOLOv5 network structure. Based on the YOLOv5s framework, the main improvements involve the two parts of backbone and neck. Combined with the introduction in Section 3.2, the overall structure of the improved lightweight network in this paper can be obtained. The multiscale output of the traditional model is output by the bottleneck module, and the modified multiscale output of the improved model is output by concatenating the two characteristic diagrams.

Table 1 shows the comparison between the parameter quantities of different sub-modules and the calculation quantities of traditional YOLOv5 sub-modules (focus, Conv, and CSP). The number of parameters and calculations of Focus_mod and GBN are significantly reduced. The parameter quantity of the Focus_mod module is 232, and the calculation quantity is 27.85 M. The parameter quantity of the GBN module is 317, and the calculation quantity is 136.4 M.

Table 2 shows the important parameters of the lightweight network model. GBN modules are used in the backbone network and head portion, and the Focus_mod and CBAM attention mechanisms are used in the backbone network portion.

3.4. Loss Function. The loss function of the target detection task consists of classification loss and bounding box regression loss. IoU and its improved algorithm are the most used in the bounding box regression loss. The full name of the IoU algorithm is the intersection over union, which is obtained by calculating the ratio of the intersection and union of the predicted box and ground-truth box, that is, $\text{IoU}(A, B) = (A \cap B) / (A \cup B)$, where A is the prediction box and B is the ground-truth box. IoU can be used as a distance; then, $\text{Loss}_{\text{IoU}} = 1 - \text{IoU}$. The advantage of IoU is that it can reflect the detection effect of the prediction box and ground-truth box. This paper takes CIoU as the loss function of the depth convolutional model, and the specific formula is as follows:

FIGURE 2: Ghost module.

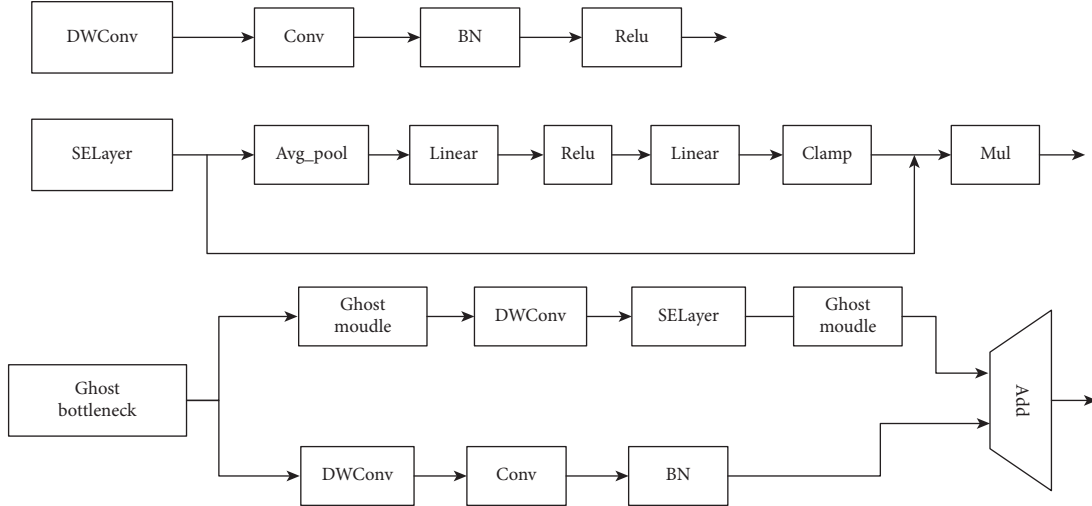

FIGURE 3: Ghost bottleneck module.

FIGURE 4: CBAM module.

$$\begin{aligned} \text{IoU} &= \text{IoU} - \left(\frac{p^2(b, b^{gt})}{c^2} + \alpha v \right), \\ \text{Loss} &= 1 - \text{IoU} + \frac{p^2(b, b^{gt})}{c^2} + \alpha v, \\ v &= \frac{4}{\pi^2} \left(\arctan \frac{w^{gt}}{\pi^{gt}} - \arctan \frac{w}{h} \right)^2, \\ \alpha &= \frac{v}{(1 - \text{IoU}) + v}, \end{aligned} \quad (1)$$

where b and b^{gt} represent the center points of prediction Box B and ground-truth Box B^{gt} , respectively; c represents the square of the diagonal length of the minimum bounding Box C ; p represents the calculation of the Euclidean distance between the two center points; α is the

weight parameter; and v is used to measure the similarity of the aspect ratio.

4. Experimental Results

4.1. Experimental Data and Environment. There is currently no authoritative dataset similar to ImageNet for smoke detection. The dataset used in this paper comes from the dataset published by the Fire Monitoring Technology Laboratory [62] and some network images, including a total of 4829 real smoke images. The sample images are shown in Figure 6. The smoke dataset covers the smoke pictures collected in different scenarios, including indoor monitoring, outdoor monitoring, field monitoring, field monitoring tower, drone shooting, and network pictures. The smoke and background of some images are confusing to some extent. At the same time, we collected many nonsmoke background images as negative samples and

divided the smoke dataset into a training set and a test set at a ratio of 7 : 3.

The experimental environment in this paper is the operating system Windows 10, graphics card NVIDIA GeForce RTX3070, memory 16G, processor Intel(R) i7-11700k, software environment CUDA11.4, and PyTorch 1.8.1.

4.2. Evaluation Standard. In this paper, the precision rate, recall rate, average precision (AP), and mean average precision (mAP@0.5) are used as model accuracy evaluation indicators, where AP represents the area under the PR curve, and mAP@0.5 represents the average AP of all categories when IOU is set to 0.5. The specific formula is as follows:

$$\begin{aligned}
 P &= \frac{TP}{TP + FP}, \\
 R &= \frac{TP}{TP + FN}, \\
 AP &= \int_0^1 PdR, \\
 mAP &= \frac{\sum_{i=1}^N AP_i}{N},
 \end{aligned} \tag{2}$$

where TP is the number of correctly classified bounding boxes that are predicted, the bounding box coordinates are correct, FN is the number of all unpredicted bounding boxes, and FP is the number of predicted bounding boxes that are misclassified or whose bounding box coordinates are not up to standard.

FIGURE 6: Sample images from the dataset.

FIGURE 7: Performance curves of different loss functions.

4.3. *Experimental Results.* In the network model training phase, the iteration batch size was set to 32, the decay coefficient was 0.0005, the initial learning rate was 0.001, and the total number of iterations was 300.

In order to verify the performance of the loss function, the paper uses Alpha-IoU [63] as a comparative experiment and uses CIoU as the benchmark loss function, setting alpha

TABLE 3: The performance of different models.

Model	Parameters	FLOPs (G)	mAP@0.5 (%)
YOLOv5s	7255094	16.86	97.04
YOLOv5s + Ghost	4434246	8.88	97.09
YOLOv5s + Ghost + CBAM	3624520	6.28	97.23
YOLOv5s-Lightweight	2751176	2.56	97.45

(a)

(b)

FIGURE 8: Continued.

FIGURE 8: Performance detection curves of different models. (a) mAP@0.5. (b) Precision. (c) Recall.

values of 1, 2, and 3, respectively. Among them, $\alpha = 1$ corresponds to the method proposed in the paper. Figure 7 shows the loss function curves corresponding to different α values. It can be seen from the figure that the overall performance of the method proposed in the paper is better. When $\alpha = 2$ or 3, the detection curve has obvious fluctuations in the early stage. This means that α is invalid for smoke detection when the value is high.

To verify the overall performance of the proposed method, the paper gives the following comparison algorithms:

- (1) YOLOv5s: YOLOv5s model without optimization.
- (2) YOLOv5s + Ghost: modify the focus structure to Focus_mod, and all the computing modules of the backbone network use the GhostNet module.
- (3) YOLOv5s + Ghost + CBAM: modify the head layer, modify the CSP module to the Ghost bottleneck, and add the CBAM module.
- (4) YOLOv5s-Lightweight: modify the stride = 2 of the first Ghost bottleneck of the backbone network based on the previous network.

In addition, the traditional multiscale output of YOLOv5s is output after the CSP module directly extracts

features, and the lightweight network model is modified to CONCAT to connect dual feature maps for the output. Table 3 shows the parameters and floating-point calculation of the different algorithms. The parameter of the lightweight network model is only 2.75 M, and the floating-point calculation is 2.56 G, which is approximately 38% of the YOLOv5s parameter (7.25 M) and 15% of floating-point computation (16.86 G). Figure 8 shows the precision, recall, and mAP@0.5 curves of the four models. It can be seen from the figure that the accuracy of the lightweight network model is slightly better than that of the other models, the detection speed is the fastest, and the number of parameters is the lowest.

Figure 9 shows the detection results of the lightweight network model in different scenarios (including indoor and outdoor, wild, etc.). It can be seen from the figure that the lightweight network model can accurately identify smoke targets in different scenarios. In addition, we use the deep network inference engine MNN as the framework to conduct unquantified tests on smoke images on a single-core Intel i7. The traditional YOLOv5s network model needs 140 ms, while the lightweight network model only needs 60 ms, which further improves the inference speed, reaching requirements for engineering applications.

FIGURE 9: Detection results with the lightweight network model.

5. Conclusion

To solve the problem of the smoke detection algorithm with large weight parameters and slow device reasoning speed, this paper proposes a lightweight smoke detection model based on GhostNet and CBAM. The model uses Ghost convolution instead of general convolution to improve the detection speed, uses Ghost bottleneck to replace the CSP structure in the original YOLOv5 to reduce model parameters, and increases the CBAM attention mechanism. Finally, CIOU is used as the loss function to improve the detection accuracy. Compared with the benchmark YOLOv5s model, the parameter amount and calculation amount of the improved model are significantly improved, the mAP is slightly better than that of the benchmark model, and the detection speed meets the requirements of engineering applications. The paper strikes a balance between the model accuracy and speed, optimizes the YOLOv5 model reasonably, realizes model compression, speeds up inference without reducing model accuracy, and greatly reduces the dependence on the hardware environment. At present, we have completed the development of the prototype. In the future, we will complete the quantitative processing and deployment of the model on the mobile terminal and further apply it to the field to realize real-time smoke detection.

Accounting information often accounts for more than 70% of an enterprise's financial report information. Accounting information is an important reference for an enterprise to make major decisions, and it is also the fundamental guarantee for an enterprise to remain invincible under the increasingly fierce business competition. With the vigorous development of enterprise informatization, traditional accounting information processing methods can no longer meet the needs of the information age. Therefore, an excellent enterprise must have a complete set of intelligent accounting information systems. How to extract the information we want from the dazzling accounting information data is a hot topic in the current financial industry. On the basis of analyzing the significance of establishing an information system, this paper creates an intelligent recognition model, which solves the shortcomings of traditional methods such as large calculation errors, time-consuming, and labor-intensive. The research results of the article show that (1) the standardized coefficients of the four influencing factors of CSR, ROE, CEO, and SCALE are relatively large, indicating that these four influencing factors have a significant impact on the development of corporate accounting and you can pay attention to these four aspects. (2) To test the performance of the article model, the experiments are compared with other models. The results show that the model proposed in this paper has the highest running success rate on the two test sets, with a success rate of more than 98%, indicating that the model in this paper has certain advantages in accounting information processing. (3) In the page response time experiment, the financial module has the shortest response time, the number of tests is 60 times, the average response time is 0.5 s, and the success rate can reach 100%. It can reach 0.8 s, and the success rate can be kept above 98%, indicating that the system can work normally. In the system operation stability test, the number of test cases designed for the financial module is 70, the number of executed test cases is 70, and the execution rate can reach 100%. This means that the system can work properly and will not fail during operation.

1. Introduction

In today's highly competitive business competition, enterprises must meet the complex and diverse personalized needs of the market. Enterprises must not only formulate internal management systems to ensure the normal operation of enterprises. Traditional computing methods have been gradually eliminated by society. We are in an era of informationization and intelligence. How to combine big data intelligent technology with accounting management work is a problem we need to consider. Accounting information management of an enterprise is related to the

long-term development of an enterprise, so when formulating an enterprise accounting information system, we must consider many aspects. This paper proposes a rational risk assessment model that will help managers assess risk exposure due to potential threats to internal control in computer-based accounting information systems [1]. In this paper, we propose a new algorithm for risk assessment of accounting information systems using AHP [2]. The purpose of this paper is to explain how case-based reasoners can be used to support inexperienced information systems auditors in evaluating controls and making audit recommendations [3]. Based on the author's work and study experience, this

paper analyzes the accounting data processing problems under the background of the times [4]. This paper analyzes the application of intelligent accounting information systems in industrial and commercial enterprises and puts forward relevant suggestions [5]. This paper studies how to identify accounting events expressed in natural language and constructs an expert system [6]. This paper studies how to identify accounting events expressed in natural language and proposes a word transfer method in accounting text analysis by introducing natural language processing technology [7]. According to the method of the Analytic Hierarchy Process, the article assigns the weights to the scheme layer and constructs a complete system of accounting information disclosure indicators in colleges and universities [8]. The article illustrates that e-accounting is a new information technology term based on the changing role of the accountant, where advances in technology have relegated the mechanical aspects of accounting to computer networks [9]. By studying the relationship between the network environment and the accounting information system and the influence of the network environment on the accounting information system, this paper proposes that the internal control measures should have a diversified development trend and proposes specific measures [10]. The article explains the development status of domestic accounting information systems and risk control methods [11]. The article summarizes the development of accounting information and accounting software in China and points out that the new changes in the future will include the birth of social responsibility accounting, the widening of accounting information, and social supervision [12]. This paper describes in detail the necessity of designing an intelligent accounting information system for enterprise accounting management [13]. This study tested the influence of intrinsic and extrinsic motivation on the behavioral intentions of Libyan SMEs to adopt accounting information systems [14]. The purpose of the article is to explain the impact of accounting environmental variables on the relationship between AIS and Iraqi performing SMEs [15].

2. Detailed Design of Accounting Information System

2.1. Introduction to Accounting Information System. The accounting information system is mainly composed of four major modules. The main module is the core part of the accounting information system. The accounting module is the basis of the information system. Interact in real-time. The budget management module realizes budget preparation through the preparation of budget drafts, enters the budget index allocation module based on the enterprise decision-making system, uses intelligent vouchers to transmit indicators to the accounting system, and uses the network to implement departmental transmission between projects. The database records all the accounting information of the enterprise and can be consulted at any time. All accounting databases are combined to form a data management system, which contains all the accounting information data of the enterprise. The functional modules of the

intelligent accounting information system are shown in Figure 1.

2.2. The Significance of Accounting Information System. At present, big data has transitioned from the conceptual stage to the large-scale application stage. The multifunctional and globalized accounting information system based on big data is a brand-new production tool for enterprises. The application of this transformed processing mode can enable enterprises to have more powerful process optimization. Create a more dynamic organizational structure, lead new changes in the field of financial accounting, realize complex business logic management and intelligent decision-making on uncertain markets and organizational methods, and create a full ecological balance system of internal and external, horizontal and vertical dimensions, to help the leap-forward development of smart business and smart enterprises. The management concept and management work of many enterprises have undergone earth-shaking changes, and an intelligent accounting information management system has also been born in the accounting management work. Accounting management is an important part of the operation process of an enterprise. After years of precipitation, the accounting management field has developed a relatively complete and mature development model. The integration of intelligent computing technology into the work of enterprise accounting management not only greatly reduces the complexity and tediousness in the process of enterprise accounting information processing but also solves the problems of low efficiency and large errors caused by manual calculation and also liberates the labor force. In the increasingly competitive business competition, an excellent enterprise must conform to the development of society and the times, make corresponding changes, adjust the development goals of the enterprise, and formulate relevant development strategies.

3. System Establishment of Deep Learning Model

3.1. Model Establishment. To establish an enterprise indicator model, this paper adopts the following model [16]:

$$ZL_{fy} = \sum F + \sum Y + \partial_0 + \partial_1 * P_{fy} + \partial_2 * M_{fy} + \dots \quad (1)$$

Among them, F represents the industry in which the company is located, Y represents the year, and ZL_{fy} represents the change in the strategic value of the company in F industries and Y years; the changes in various accounting indicators of the company and the comprehensive benefits of the changes in the strategy of the entire company are reflected by this value, and ∂_i ($i = 1, 2, \dots, 7$) represents the index coefficient corresponding to the i -th indicator, P_{fy} represents the investment in sales expenses, M_{fy} represents the investment in management expenses, F_{fy} represents the investment in fixed asset renewal costs, D_{fy} represents capital intensity, I_{fy} represents R&D investment, L_{fy} represents corporate financial leverage, and C_{fy} represents cloud computing ability value.

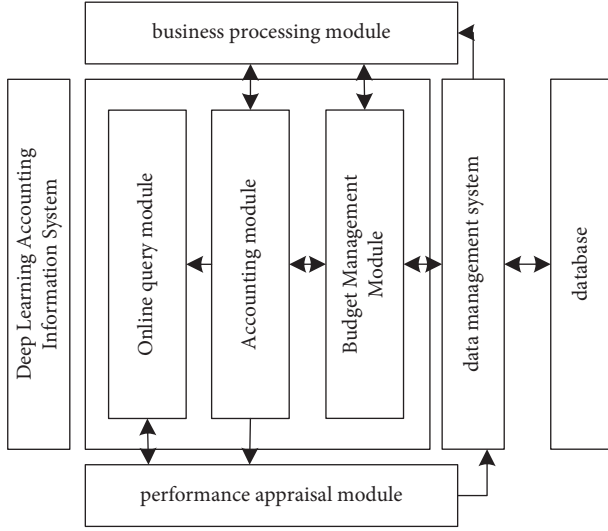

FIGURE 1: System function module.

Sales expense input is as follows [17]:

$$P_{fy} = \frac{SE}{R}. \quad (2)$$

Management fee input is as follows [18]:

$$M_{fy} = \frac{ME}{R}. \quad (3)$$

Fixed assets renewal cost input is as follows:

$$F_{fy} = \frac{NE}{OF}. \quad (4)$$

Capital intensity is as follows [19]:

$$D_{fy} = \frac{NF}{SN}. \quad (5)$$

R&D investment is as follows:

$$I_{fy} = \frac{IF}{R}. \quad (6)$$

Corporate financial leverage is as follows [20]:

$$L_{fy} = \frac{SD + LD + BP}{V}. \quad (7)$$

3.2. Financial Risk Forecast. Financial risk prediction formula is [21]

$$DD = \frac{E(V) - D}{E(V)\sigma_A}. \quad (8)$$

Assuming that the price fluctuations of the real assets of the target company can obey the Wiener process, there are

$$dV_A = \mu V_A dt + \sigma_A V_A dz. \quad (9)$$

The relationship between asset value and equity value can be constructed as follows [22]:

$$V_E = V_A N(d1) - e^{-rt} \times N(d2), \quad (10)$$

$$\sigma_E = \frac{V_A}{V_E} \sigma_A. \quad (11)$$

Expected default rate is as follows:

$$Pt = \text{prob}[V_A^t \leq X_t | V_Z^0 = V_A]. \quad (12)$$

Company asset value is as follows:

$$\ln V t_A = \ln V_A + \left[\mu - \frac{\sigma_A^2}{2} \right] \tau + \sigma_A \sqrt{\tau} \varepsilon. \quad (13)$$

Final default rate is as follows:

$$P_t = N \left[\frac{\ln V_A / X_t + \left(\mu - \frac{\sigma_A^2}{2} \right) \tau}{\sigma_A \sqrt{\tau}} \right]. \quad (14)$$

The evaluation index of enterprise financial risk is as follows [23]:

$$X = (X_1, X_2, \dots, X_p). \quad (15)$$

Linear combination of evaluation metrics is

$$\hat{P} = W_0 + W_1 X_1 + W_2 X_2 + \dots + W_p X_p, \quad (16)$$

in

$$W^* = (W_0, W_1, W_2, \dots, W_p), \quad (17)$$

$$X^* = (X_1, X_2, \dots, X_p). \quad (18)$$

Financial risk prediction model is as follows [24]:

$$P = \frac{\exp(W_0 + W_1 X_1 + \dots + W_p X_p)}{1 + \exp(W_0 + W_1 X_1 + \dots + W_p X_p)}. \quad (19)$$

4. Simulation Experiments

4.1. Model Construction. In order to find out the factors that affect the development of corporate accounting, the experiment selected 11 secondary indicators as impact factors and recorded the data of each impact factor from 2014 to 2018, so as to determine the important indicators that affect the development of corporate accounting. The value of the standardization coefficient is an important reference factor for determining the impact factor and the development degree of enterprise accounting. The larger the coefficient value, the more significant the degree of influence. The specific experimental operation is as shown in Figure 2. The definition of factor variables is described in Table 1.

According to the experimental data in Table 2, in 2014, the standardized values of 11 secondary indicators were all 1. Since 2015, the standardized values of each factor began to change. In 2015, the standardized coefficient of the ownership structure was 3.75, which is 11 items. The highest one of the test indicators indicates that the ownership structure has a greater impact on accounting information. The standardized coefficient of operational management

FIGURE 3: Statistics of factors affecting the level of accounting information disclosure.

independence is 0.1, which is the lowest of the test indicators, indicating that operational management independence has the lowest impact. From 2016 to 2018, the standard coefficients of company size and region are all higher than 1.0, indicating that the two independent variables have a relatively large degree of influence. The description of the impact factors of the secondary indicators is shown in Table 3 and Figure 3.

According to the data in Table 3, in 2014, the standardization coefficient of enterprise nature reached 0.95, indicating that the influence factor of enterprise nature was the largest. From 2015 to 2016, the standardized coefficient decreased, and the coefficient reached 1 in 2018. In 2015, except for the AREA coefficient, which reached 1 after that, the other coefficients are all less than 1, indicating that except for the region where the influence factor of the enterprise is relatively large, other influence factors have no significant influence on the development of the enterprise. In 2016, the standard coefficient of company size exceeded 1. From 2017 to 2018, the standardized coefficients of many indicators exceeded 1, indicating that these influencing factors have an increasingly significant impact on enterprise development.

4.2. Model Comparison Study. In order to test the performance of the accounting recognition model established in the article, the experiment will run the model and the other two models on different test sets and record the experimental results. Model evaluation classification is the last step in building a model; it can effectively help us choose an excellent classifier and improve its performance and plays a very important role. Generally speaking, the training set is used to evaluate the parameters of the model, so that the model can reflect the reality and then predict the future or other unknown information, and the test set is used to evaluate the prediction performance of the model. The experimental results under the two different test sets are as

FIGURE 4: Statistics of model evaluation results.

shown in Figure 4. The model evaluation indicators are shown in Table 4.

According to the data in Table 5, we can conclude that after the training set runs, the correct rate of the model proposed in this article can reach 94.8%, and the accuracy rate can reach 98.23%, which is the highest among the test models. The correct rate is 84.95%, and the accuracy rate is 94.71%, which is the lowest among the test models. The correct rate of the decision tree recognition model is 88.87%, and the sensitivity is 93.36%. The detection results are in the model proposed in the article and the support vector machine recognition model in between.

According to the above model test results in Figure 5 and Table 6, the running accuracy of the model in the training set

TABLE 4: Evaluation index table.

	Formula	Definition
Accuracy	$PPV = TP / (TP + FP)$	Indicates the proportion of the model identified correctly among all results identified by the model as correct samples
Sensitivity	$TPR = TP / (TP + FN)$	Indicates that the model recognizes the correct proportion in the true value of the sample
Specificity	$TNR = TN / (TN + FP)$	Indicates that the model recognizes the correct proportions in which the true value is negative

TABLE 5: Training set model evaluation result table.

Recognition model	Correct rate (%)	Accuracy (%)	Sensitivity (%)	Specificity (%)
Deep learning recognition model	94.80	98.23	96.15	76.32
Support vector machine recognition model	84.95	94.71	87.76	64.71
Decision tree recognition model	88.87	93.75	93.36	60.53

FIGURE 5: Statistics of model evaluation results.

TABLE 6: Evaluation effect of the test set model.

Recognition model	Correct rate (%)	Accuracy (%)	Sensitivity (%)	Specificity (%)
Deep learning recognition model	92.23	97.14	95.56	75.23
Support vector machine recognition model	83.21	93.89	86.22	63.79
Decision tree recognition model	86.14	92.78	92.46	60.48

and the test set is 94.80% and 92.23% respectively, and the running accuracy in the training set and the test set is 81.95% and 92.23% respectively. The accuracy rate is 93.21%. The correct rate of the decision tree recognition model is 88.87% in the training set and 86.14% in the test set. Although the performance of the three detection models is reduced to a certain extent after the test set is run, the detection value of the model in this paper is still the highest among all detection models. The experimental results also show that the detection efficiency of the model proposed in this article is optimal whether it is in the training set or the test set.

4.3. System Test. System testing is to test whether the system can work normally under a certain load [25]. The performance test of the intelligent accounting information system based on the deep learning model studied in this paper is mainly tested from the two indicators of page response time and system operation stability. The method of page response test is to record the system response time under different test times and then observe the response time and operation stability of the system by continuously increasing the number of tests and the ratio of numbers. The components of intelligent accounting information are shown in Table 7

TABLE 7: Components of intelligent accounting information system.

Component	Function
Financial section	Mainly responsible for the company’s daily financial work and financial budget, accounting and financial management, and fundraising, etc., early warning and monitoring of financial risks, and guiding the company’s business activities through financial data analysis
Purchase and sale part	According to the needs of the enterprise, in order to solve the problems of confusing accounts, inaccurate inventory, and untimely information feedback, the purchase, sale, and storage system integrates procurement, sales, inventory management, and receivable and payable management, providing order, procurement, sales, the management of returns, inventory, current invoices, current accounts, salesmen, etc., helps enterprises handle daily invoicing and inventory business, and provides rich real-time query and statistical functions
Management analysis section	Management analysis can make full use of the historical data and other relevant information provided by financial accounting, use certain mathematical methods to process them scientifically, conduct scientific forecasting and analysis for business operations, and help leaders at all levels to make decisions accordingly. Correct decision analysis

TABLE 8: Page response time test results.

Testing frequency	60	70	80	90	100	110	120	130
Financial section	0.5	0.6	0.7	0.8	0.9	1.0	1.1	1.2
Purchase and sale part	0.8	0.9	1.0	1.1	1.2	1.3	1.4	1.5
Management analysis section	1.1	1.2	1.3	1.4	1.5	1.6	1.7	1.8

FIGURE 6: Average response time curve.

TABLE 9: System operation stability test.

Design test cases	70.00	80.00	90.00	100.00	110.00	120.00	130.00	140.00
Financial section	70.00	80.00	90.00	100.00	110.00	120.00	130.00	140.00
Purchase and sale part	68.00	77.00	88.00	99.00	109.00	119.00	129.00	139.00
Management analysis section	67.00	76.00	87.00	98.00	108.00	118.00	128.00	138.00

4.3.1. Page Response Time Test. According to the above experimental results in Table 8 and in Figure 6, the average response time will increase with the increase of the number of tests. The average response time of the financial part is the lowest among all the test modules. When the number of tests is 130, the average response time of the financial part is 1.2

seconds; the average response time of the purchase, sale, and storage part is 1.5 seconds, and the average response time of the management analysis part is 1.8 seconds. The management analysis part contains a huge database, so the response time is the longest, and the response time of the purchase, sale, and storage part is between the financial part

FIGURE 7: Execution test case statistics.

and the management analysis part. Moreover, the execution success rate of the three modules has remained above 98% (Table 9).

4.3.2. System Operation Stability Test. According to the execution rate test of the system in Figure 7, we can know that when the number of design test cases is 140, the number of executed use cases of the financial module is 140, the number of executed use cases of the purchase, sale, and storage module is 139, and the number of executed use cases of the management analysis part is 138. The execution rates of the three modules are kept above 98%, close to 100%, indicating that the system can operate normally.

5. Conclusion

Applying the processing mode transformed by intelligent computing can enable enterprises to have more powerful process optimization, create a more dynamic organizational structure, promote new changes in the field of financial accounting, and realize complex logical management of business and business operations in uncertain markets and organizational methods. Intelligent decision-making, as well as building a comprehensive ecological balance system of internal and external, horizontal, and vertical dimensions, helps smart businesses and smart enterprises to develop forward. The model proposed in this paper solves the problems of long calculation process and high error rate in the human computing process, and the model has a short response time and a high success rate, but the model still has some shortcomings. The model of this paper is to calculate only the accounting information data of a certain enterprise, and the calculation sample capacity is small. In future research work, the calculation capacity should be increased. Accounting management is a very complex task. In the process of accounting work, there will be many accounting calculation methods and related systems that cannot be explained clearly. The relevant departments of the enterprise should pay attention to revising the

relevant policies of accounting management. Effective calculation of accounting information will reduce the occurrence of any illegal operations, thereby promoting the long-term development of enterprises. The construction of the new accounting information system is the result of the development of science and technology of the times. The integration of big data and accounting information processing is a new development trend. Enterprises should seize the opportunity and strive to improve their own development deficiencies. The enterprise accounting information system under big data will develop better and better and can adapt to the pace of scientific and technological development and form an accounting information system with Chinese characteristics in the process of continuous development. Enterprises need to develop and progress. The traditional audit method is inefficient and consumes a lot of manpower and material resources. Before auditing the company's financial statements, auditors can use the identification model in this study to test the possibility of accounting information distortion, clarify the key points and doubts of the audit, form a preliminary evaluation, and then determine the audit scope and audit scope. The review process is a procedure to improve the quality of accounting information audit.

Traditional moral evaluation relies on artificial and subjective evaluation by teachers, and there are subjective errors or prejudices. To achieve further objective evaluation, students' classroom performance can be identified, and the effectiveness of moral education can be evaluated based on student behavior. Since student classroom behavior is random and uncertain, in order to accurately evaluate its indicators, a large amount of student classroom behavior data must be used as the basis for analysis, while certain techniques are used to filter out valuable information from it. In this paper, an improved graph convolutional network algorithm is proposed to study students' behaviors in order to further improve the accuracy of moral education evaluation in universities. The technique of video recognition is used to achieve student behavior recognition, thus helping to improve the quality of moral education evaluation in colleges and universities. First, the multi-information flow data related to nodes and skeletons are fused to improve the computing speed by reducing the number of network parameters. Second, the spatiotemporal attention module based on nonlocal operations is constructed to focus on the most action discriminative nodes and improve the recognition accuracy by reducing redundant information. Then, the spatiotemporal feature extraction module is constructed to obtain the spatiotemporal association information of the nodes of interest. Finally, the action recognition is realized by the Softmax layer. The experimental results show that the algorithm of action recognition in this paper is more accurate and can better help moral evaluation.

1. Introduction

Moral evaluation is a guide and an initiative to carry out moral education in schools. Moral evaluation is defined in the Dictionary of Education as "the process of making value judgments on the performance of moral behavior of individuals using the acquired moral standards" [1]. The broad perspective of school moral evaluation content is to examine the ideological, moral, and political qualities of individuals, and the narrow perspective is to examine the moral qualities of individuals. Both focus on the moral cognition and moral behavior of individuals, especially the moral behavior that is more easily observed [2].

To adhere to "people-oriented" means to maintain human dignity, respect human rights, give full play to human potential, meet human needs, and promote the all-round development of people. By insisting on the college students as

the center, we should not only educate them, guide them, inspire them and spur them on but also respect them, understand them, care for them, and help them to develop good ideological and moral qualities and excellent ideological and political qualities, so as to achieve the purpose of moral education and realize the fundamental goal of establishing moral education for people [3].

In the current reform of quality education, colleges and universities pay more and more attention to the moral education quality cultivation of students, and no longer focus not only on the teaching of students' professional courses but also begin to focus on the overall development of students' comprehensive quality. In order to implement the requirements of quality education cultivation and promote the vigorous development of moral quality education, a matching moral quality evaluation system for college students should be formulated. The traditional evaluation

method of students' moral quality has been rather backward, and it is difficult to ensure the fairness and scientificity by simply relying on human for evaluation, which does not meet the needs of quality education, so it needs technology updating. Innovate student moral quality evaluation mode, introduce information technology support, and use big data technology and computer information technology to create a sound moral quality evaluation system for college students. Scientific design and optimization of system structure in order to improve the efficiency of moral quality education in colleges and universities and guarantee the quality of moral quality education for college students.

Literature [4] constructed the spatiotemporal graph with the natural connections of human joints and proposed the spatiotemporal network model with the graph convolution layer as the basic module. Literature [5] integrated a discrete multiscale aggregation scheme and the spatiotemporal graph convolution operator called G3D to form a powerful feature extraction structure. Literature [6] introduces a context-encoded network for enhancing contextual feature relevance and automatically learning the skeleton topology. Literature [7] incorporates third-order features to effectively capture the relationship between joints and body parts. Literature [8] introduced a novel progressive multiscale convolution for capturing long- and short-term correlations in the spatial and temporal domains. Literature [9] used multiscale temporal convolution and exploited the correlation of the original data to better model the channel topology. Literature [10] describes the skeleton features using Lie groups, then describes the relationship of these features in time order by dynamic temporal regularization, and finally uses multiclass support vector machines for the behavior recognition task. Literature [11] designs a multifeature fusion coding method based on VLAD. Literature [12] designs the spatiotemporal weight coding method based on skeleton features. Literature [13] constructs a motion feature generator based on the existing generative adversarial network framework to perform the learning of judgment optical flow features. Literature [14] investigates temporal pooling and long-term information dependence of behavioral features on the basis of CNNs. In the literature [15], the decomposition model of convolutional networks on spatiotemporal sequences is investigated, i.e., the 3D spatiotemporal convolution is decomposed into 2D spatial convolutional kernel and 1D temporal convolutional layer to accomplish the representation and recognition of human behavior. Literature [16] further investigates the combined strategy of 2D spatial convolution and 1D temporal pooling. Literature [17] extends 2D convolutional operations into 3D convolution and implements a dual-stream I3D. In the literature [18], in order to complete the extraction of human behavior on spatiotemporal features, a dual-stream pooling network is designed to further enhance the feature representation. In the literature [19], a synchronous appearance and relationship module SMART are proposed, and the learning of spatiotemporal features of behavior is accomplished by stacking the model. Literature [20] designs a multi-Fiber network, each Fiber uses lightweight convolution, and the speed of behavior recognition is greatly improved.

In the process of moral education evaluation in colleges and universities, schools can conduct in-depth mining based on big data and provide reference for student management and education service supply by analyzing student classroom behavior data to achieve overall improvement of education level. In order to make full use of the action features in the human skeleton sequence and achieve lightweight action recognition model with improved recognition accuracy, this paper proposes a lightweight adaptive graph convolutional network combining multi-information flow data fusion and spatiotemporal attention mechanism. The human skeleton-based action recognition is very little affected by factors such as illumination and background and has great advantages over the RGB data-based methods. The joint skeleton data of human body are a topological graph, and each joint point in the graph has different number of neighboring joints. Traditional convolutional neural networks cannot directly use the same size convolutional kernel for convolutional computation to process such non-Euclidean data. Therefore, in the field of skeleton-based behavior recognition, a graph convolutional network-based approach is more suitable. The experimental results show that the recognition accuracy of the algorithm in this paper is high, and it can do the work of moral evaluation better.

2. Methodology

2.1. Student Behavior Algorithm

2.1.1. Graph Convolutional Network. In the Euclidean space represented by an image, each pixel in the image is treated as a node, then the nodes are arranged regularly and the number of neighboring nodes is fixed, and the points on the edges can be padding operation. However, in a non-Euclidean space like the graph structure, the nodes are disordered and the number of neighbor nodes is not fixed, and feature extraction cannot be achieved by a traditional convolutional neural network with a fixed size convolutional kernel. A convolutional kernel capable of handling variable-length neighbor nodes is needed [21]. For the graph, features need to be extracted by inputting a feature matrix I of dimension $T \times \nu F$ and an adjacency matrix G of $T \times T$, where T is the number of nodes in the graph and F is the number of input features per node. The nodal feature transformation formula for the adjacent hidden layer is shown below.

$$B^{x+1} = f(B^x, G), \quad (1)$$

where x is the number of layers, the first layer ($B^0 = IB^0$). $f(\cdot)$ is the propagation function, and the propagation function varies for different graphical convolutional network models. Each layer B^x corresponds to the $T \times F^x$ -dimensional feature matrix, and the aggregated features are transformed into the features of the next layer by the propagation function $f(\Delta)$, which makes the features more and more abstract.

2.1.2. Lightweight Graph Convolutional Network Framework. In order to make full use of the action features in human skeleton sequences and to achieve a lightweight action recognition model with improved recognition accuracy, this

FIGURE 1: Network framework.

paper proposes a lightweight adaptive graph convolutional network combining multiple information streams data fusion and spatiotemporal attention mechanism. Taking the input human skeleton sequence as the research object, we first fuse four kinds of data information: joint point information flow, bone length information flow, joint point offset information flow, and bone length change information flow. Then, an embeddable spatiotemporal attention module based on nonlocal operations is constructed to focus on the most action discriminative joints in the human skeleton sequence after the information flow data fusion. Finally, the recognition results of the action fragments are obtained by Softmax, and the main framework of the network is shown in Figure 1.

2.1.3. Multi-Information Flow Data Fusion. At present, the methods based on graph convolution [22] mostly adopt multiple training under a variety of different data sets and carry out decision-making level fusion according to the training results, resulting in a large amount of network parameters. Therefore, the original joint point coordinate data are preprocessed before training to realize the data-level fusion of joint point information flow, bone length information flow, joint point offset information flow, and bone length change information flow, so as to reduce the network parameters and reduce the calculation requirements. The definition of joint points of human skeleton sequence is shown in formula (2).

$$s = \{Q_{x,n} / x = 1, 2, \dots, T; n = 1, 2, \dots, N\}, \quad (2)$$

where N is the total number of frames in the sequence, T is the total number of nodes 18, and x is the nodes at the moment n . Before fusing the multiple information streams, a diverse preprocessing of the skeleton sequence s is required. The node information stream is obtained from the coordinates of 18 nodes obtained by the human pose estimation algorithm OpenPose, which is a significant cost reduction compared to motion capture devices. Other information streams are defined as follows.

Bone Length Information Flow: the node near the center of gravity of the body is defined as the source node, and the coordinates are used to obtain the bone length information flow by making the difference between the two nodes, as shown in the formula (3).

$$H_{x,y,n} = Q_{y,n} - Q_{x,n} = (i_{y,n} - i_{x,n}, j_{y,n} - j_{x,n}). \quad (3)$$

Joint Difference Information Flow: the coordinates of the joint point x of the n th frame are defined as $(Q_{x,n} = (i_{x,n}, j_{x,n}))$, and the coordinates of the joint point x

of the $(n+1)$ -th frame are expressed as $(Q_{x,n+1} = (i_{x,n+1}, j_{x,n+1}))$. The joint difference information Fflow can be obtained by making a difference between the coordinates of the same joint point in adjacent frames, and the formula is shown in formula (4).

$$YD_{x,n,n+1} = Q_{x,n+1} - Q_{x,n} = (i_{x,n+1} - i_{x,n}, j_{x,n+1} - j_{x,n}). \quad (4)$$

Change of Bone Length Information Flow: in two adjacent frames, the same section of the bone due to the action changes caused by the different lengths, defined by the formula (3) the n th frame of the bone length information flow is $H_{x,y,n}$, then the $(n+1)$ th frame of the bone length information flow is $H_{x,y,n+1}$, by the same bone length of adjacent frames for the difference to obtain the bone length change information flow. The formula is shown in formula (5).

$$CH_{x,n,n+1} = H_{x,y,n+1} - H_{x,y,n}. \quad (5)$$

As shown in Figure 2, the multiple data streams are weighted and fused into a single feature vector according to the definitions of articulation point information stream, bone length information stream, articulation point offset information stream, and bone length change information stream. The skeleton sequence dimension is changed from $(4 \times N \times Y \times C_1)Q$ to $1 \times N \times Y \times 4C_1$ as shown below.

$$\text{Fusion} = \{ \omega_1 Q_{x,n} + \omega_2 H_{x,y,n} + \omega_3 YD_{x,n,n+1} + \omega_4 CH_{x,n,n+1}, x = 1, 2, \dots, T; n = 1, 2, \dots, N \}, \quad (6)$$

where the weight $\omega_1 \sim \omega_4$ is determined by the joint point offset degree ($\sigma_1 (\sigma_1 \in [0^\circ \sim 360^\circ])$) and the bone length change degree ($\sigma_2 (\sigma_2 \in [0 \sim 100\%])$). σ_1 is the angle of the line formed by the coordinate point $Q_{x,n}$ in the previous frame and the coordinate point $Q_{x,n+1}$ in the next frame and the coordinate origin, respectively, and σ_2 is defined as formula (7).

$$\sigma_2 = \frac{|Q_{y,n+1} - Q_{x,n+1}| - |Q_{y,n} - Q_{x,n}|}{|Q_{y,n} - Q_{x,n}|}, \quad (7)$$

where the absolute value operation represents the bone length, when $\sigma_1 \geq 30^\circ$ and $\sigma_2 \leq 50\%$, ω_1 and ω_3 weights are 2, ω_2 and ω_4 weights are 1.

When $\sigma_1 \leq 30^\circ$ and $\sigma_2 \geq 50\%$, the weights of ω_1 and ω_3 are 1, and the weights of ω_2 and ω_4 are 2. When σ_1 and σ_2 are less than the threshold, the weights are 1. When both σ_1 and σ_2 are greater than the threshold, the weights are 2. By calculating the offset degree of joint points and the change

FIGURE 2: Data fusion of information flow.

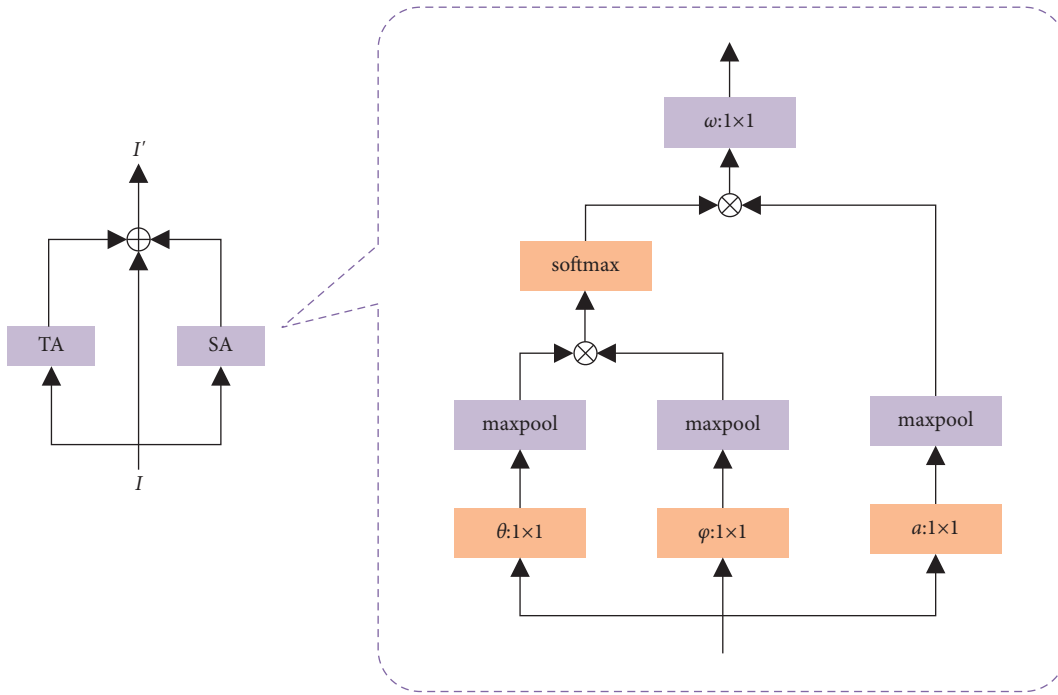

FIGURE 3: Spatio-temporal attention module.

degree of bone length, higher weight is given to the information flow data with large change degree, so as to enhance the representation of action by information flow. Then the fused single feature vector is used to represent the multi information flow data, and the training times are reduced from 4 times to 1 time, which reduces the amount of overall parameters, so as to improve the network operation speed.

2.1.4. Temporal Attention Module Construction. It is also important to ensure the accuracy of action recognition on the basis of the increased speed of network computing. A human skeleton sequence contains all information in the temporal and spatial domains, but only the nodal association information that is discriminative for some of the actions is worthy of attention. The attention mechanism mostly just removes irrelevant terms and focuses on the action region of interest, and the real redundant information comes from other aspects.

The joint point with offset degree $\sigma_1 \geq 30^\circ$ of each joint point is defined as the source joint point, and one source joint point is selected at a time, while the other joint points are the target joint points. The local operation method in the neural network can only calculate the correlation between two individually after traversing the target nodes, so that the source nodes lose the global characterization ability. In order to characterize the correlation of all target nodes to source nodes, as shown in Figure 3. The idea of nonlocal operations is incorporated into the spatiotemporal attention module, and a max pool layer of size 2×2 and step size 2 is added after the feature input to ensure that the number of data and parameters are compressed while preserving the original features as much as possible.

The spatiotemporal attention module (STA) contains a spatial attention module and a temporal attention module. The spatial attention module (SA) captures the intraframe joint correlation, and the temporal attention module (TA) captures the interframe joint correlation, and finally the two

are summed and fused with the input features. The output features of the temporal attention module have the same dimension as the input, and thus can be embedded between the network structures of the graph convolutional network.

The implementation of the module features is divided into 4 steps.

- (1) The dimension of the infeed feature I is $N \times T \times C$, where T, N , and C correspond to the number of frames, joints, and channels, respectively. The input features of the spatial attention module are represented as $k = [k_1^s, k_2^s, \dots, k_T^s] \in R^{N \times T \times C}$.
- (2) Embedding the features into the Gaussian function (θ and φ , convolution kernel dimension 1×1) calculates the correlation of two joints i and j at any position, enumerated by j , and obtains the weighting of the joints i , represented as shown below.

$$j_x^s = \frac{1}{C(k^s)} \sum_{qy} f(k_x^s, k_y^s) a(k_y^s), \quad (8)$$

where k_x^s and k_y^s denote the features of the nodes x and y , respectively. The function a is used to calculate the feature representation of the node y , and ($a(k_y^s) = M_a^s k_y^s$) M_a^s is the weight matrix to be learned. The Gaussian function f is defined as shown below.

$$f(k_x^s, k_y^s) = e^{\theta(k_x^s) \varphi(k_y^s)}. \quad (9)$$

Where ($\theta(k_x^s) = M_\theta^s k_x^s$, $\varphi(k_y^s) = M_\varphi^s k_y^s$), ($C(k^s) = \sum_{qy} f(k_x^s, k_y^s)$) is set as the normalization factor of the correlation representation. In order to reduce the computational cost and maximize the retention of low-order features, a maximum pooling layer of size 2×2 and step size 2 is added after the functions θ , φ , and a .

- (3) The spatial attention information o_x^s ($o_x^s \in R^{N \times T \times C}$) is obtained by making the function weighted.

$$o_x^s = M_o^s j_x^s. \quad (10)$$

- (4) Denote the infant features of the temporal attention module as $k^n = [k_1^n, k_2^n, \dots, k_T^n] \in R^{N \times T \times C}$. The temporal attention information o_x^n ($o_x^n \in R^{N \times T \times C}$) is obtained by repeating (2) and (3), and the temporal attention information o_x ($o_x \in R^{N \times T \times C}$) is obtained by adding and fusing with the spatial attention information and the infant features.

$$o_x = o_x^s + o_x^n + k_x. \quad (11)$$

The discriminative spatiotemporal association information of the nodes is obtained by the attention mechanism based on nonlocal operations, and the interference of irrelevant terms in the action region and the input redundant node information is removed, which reduces unnecessary calculations and thus improves the accuracy.

2.1.5. Spatio-Temporal Feature Extraction Module Construction. In order to extract the features of the skeleton sequence in spatial and temporal dimensions, the dynamic skeleton is first modeled using the spatiotemporal graph convolutional network and a spatial partitioning strategy, and the original expression is shown below.

$$I_{\text{out}} = \sum_x^Z M_x (I_{xt} G_x) \odot W_x, \quad (12)$$

where I_{in} and I_{out} are the graph convolutional input and output features, respectively, Z is the spatial domain convolutional kernel size, M_x is the weight, G_x is the adjacency matrix of node x , \odot represents the dot product, and W_x is the mapping matrix of nodes given connection weights.

Since all mnemonic actions cannot be accurately identified using predefined skeleton structure data, an adaptive adjacency matrix G_x is needed to make the graph convolutional network model adaptive. Therefore, in order to change the topology of the skeleton sequence graph in network learning, the adjacency and mapping matrices that determine the topology in formula (12) are divided into (G_x, B_x) and L_x . The block diagram of the adaptive graph convolution module is shown in Figure 4, and the output features are reconstructed as shown below.

$$I_{\text{out}} = \sum_x^z M_x I_{xt} (G_x + B_x + L_x). \quad (13)$$

In Figure 4, θ and φ are the Gaussian embedding functions in formula (9), and the convolution kernel size is 1×1 . The first part G_x is still the adjacency matrix of the node x . The second part B_x is an additive complement to the original adjacency matrix, which can be updated iteratively through network training. The third part L_x is continuously driven by the data to learn the connection weights, and the node correlation can be calculated by formula (8) and then multiplied with the 1×1 convolution to obtain the similarity matrix L_x .

$$L_x = \text{soft max}(I_{xt}^N M_{\theta x}^N M_{\varphi x} I_{xt}). \quad (14)$$

Through the above calculation, the adaptive graph convolution module is constructed, and then the spatiotemporal information contained in the skeleton sequence is extracted.

The spatiotemporal feature extraction module proposed in this paper is shown in Figure 5. The data are normalized by BN (batch normalization) layer after each convolution operation, and then the model expression capability is improved by ReLU layer. The embeddable spatiotemporal attention module STA has been built in Section 2.1.1, and the features are input to the extraction module to extract the action nodes of interest. Then, the correlation of each joint point of the same frame in the skeleton data is obtained in the spatial dimension by the adaptive GCN, and the relationship of the same joint point of adjacent frames is obtained in the temporal dimension by the temporal convolutional network (TCN). The dropout layer reduces the interaction of hidden layer nodes to avoid overfitting of

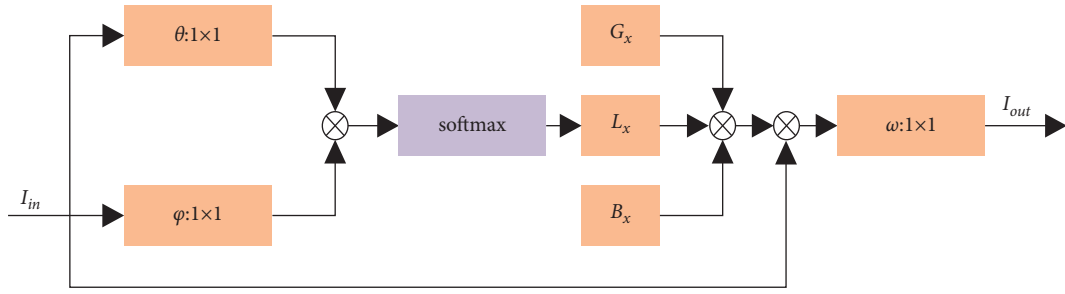

FIGURE 4: Adaptive graph convolutional module.

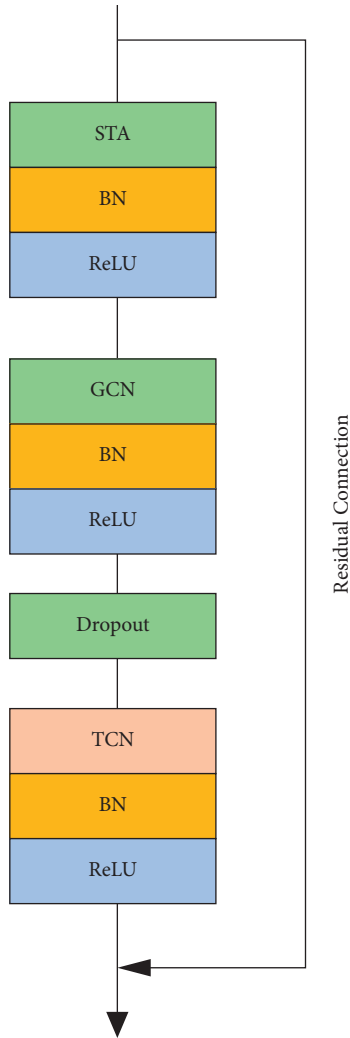

FIGURE 5: Spatiotemporal feature extracting module.

the graphical convolutional network, and the parameter is set to 0.5, while the residual connection is performed to increase the stability of the model.

2.1.6. Overall Network Structure Construction. As shown in Figure 6, the nine spatiotemporal feature extraction modules B1~B9 are stacked. In the direction from feature input I to behavior label output, BN layer is used for normalization after skeleton map input, B1~B3 output feature dimension is

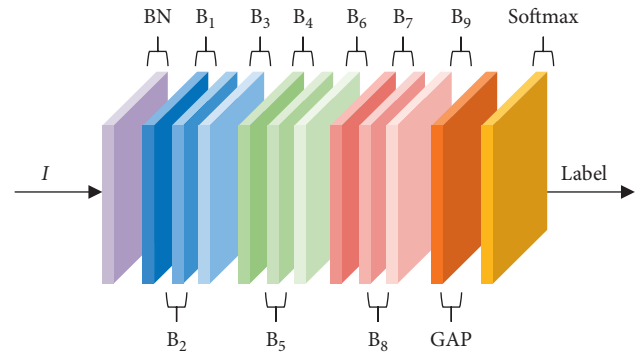

FIGURE 6: Overall network architecture.

Batch $\times 64 \times T \times N$, B4~B6 output feature dimension is Batch $\times 128 \times N/2 \times T$, B7~B9 output feature dimension is Batch $\times 256 \times N/4 \times T$, where the number of channels are 64. The global average pooling (GAP) operation is applied in the spatial and temporal dimensions to unify the feature map sizes of the samples, and finally the data from 0 to 1 are obtained using the Softmax layer for the recognition of human behavior.

2.2. Moral Education Evaluation System in Colleges and Universities

2.2.1. Database Design. In the design of moral education quality evaluation system for college students, the database system is an important material basis for carrying out the work related to comprehensive quality evaluation system for college students, and it plays an important role in the system design and application. Scientific design of database can provide efficient ways and technical support for data storage, avoid data redundancy, and also realize data integrity and unity. The corresponding system can be combined with the basic database structure to build an effective input interface and input format to ensure convenient and effective data input and build a complete basic database for comprehensive student quality evaluation.

2.2.2. System Software and Hardware Design. The hardware design of the moral quality evaluation system for students in colleges and universities should focus on the data collection terminal and data receiving terminal. The specific management software design is the core part of the whole fault

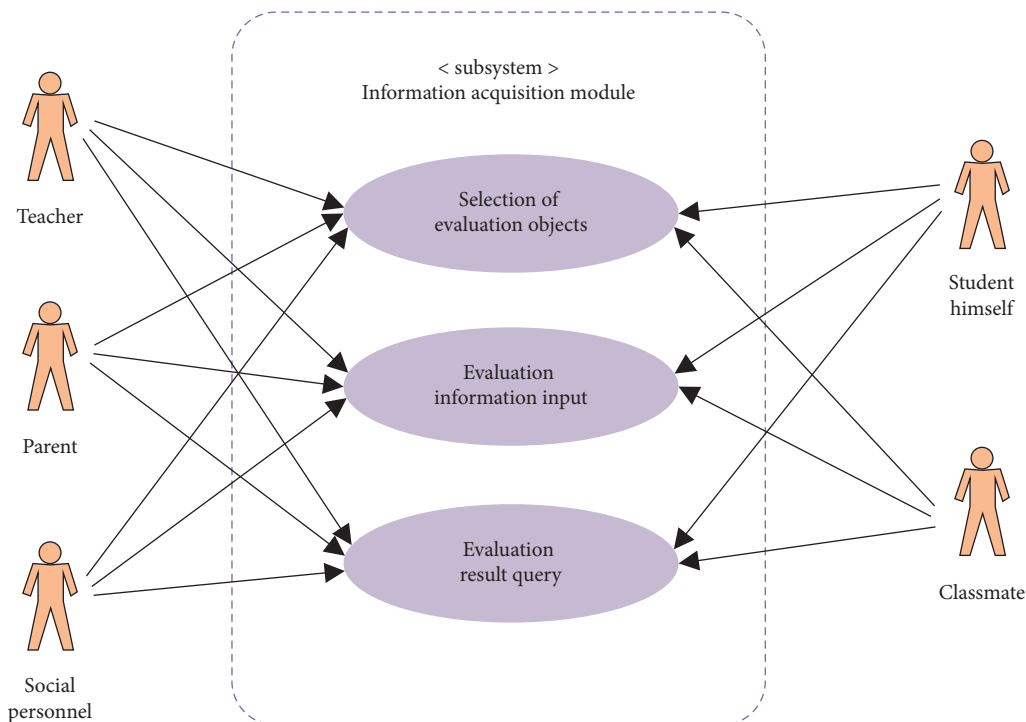

FIGURE 7: UML use case diagram for information acquisition module.

management system, which has a direct impact on the system being able to find the data source quickly and accurately in the data information management. In the software design, the data information management program is designed to achieve effective search of data sources, while the simulation program is used to simulate the parameter signals of large electromechanical integration equipment after docking between the management system and the integration equipment to achieve effective data extraction. In this regard, the management software design takes Windows 2000 as the basic software platform, with the help of VC for interface design, and stores the management mode related to the electronic control system through the database management of access to realize the effective system management program design. The sensor, MCU, AD chip, and other components constitute the data acquisition side. The receiving end is also connected by multiple asynchronous serial ports and also connected with LCD, chip, and other components. And the bus is connected to the wireless transmission module, whose function is equivalent to the terminal receiving device, which can transmit the signal to the control center with the help of antenna, and then transmit the received data information to the host location. In the system hardware design, focus on effective control system architecture and good wiring design. And in the system software design, it contains the data acquisition node, coordinator node, and the main controller design. Through the serial port to receive environmental information from the wireless network, do a good job of parsing and processing, and then save the relevant information and transmit it to the GPRS module to receive relevant control commands or other student quality information data with the help of the

3.2. Analysis of Classroom Behavior Recognition Accuracy. Table 3 lists the classification accuracy rates of 10 types of behaviors commonly seen by teachers and students in the classroom when the model of this paper is used. It can be seen that the classification accuracy rates of most behaviors are over 90%, among which picking up actions and raising hands actions are more easily recognized accurately because of the larger magnitude of the whole body, reaching 98.2% and 98.7% recognition accuracy rates, respectively. For the offending actions (such as playing with the phone), a high recognition rate of 95.3% was also achieved. However, for the recognition of static actions such as writing, although it

did not reach the recognition accuracy of other actions, it still had 82.6% recognition accuracy.

4. Conclusion

The behavior recognition technology based on big data can effectively analyze the classroom behaviors of teachers and students, provide support for moral education evaluation in colleges and universities, and improve the efficiency and comprehensiveness of moral education evaluation in colleges and universities. In this paper, we propose a lightweight graph convolutional network combining multi-information flow data fusion and spatiotemporal attention mechanism to address the core problem in the field of moral education effect evaluation and student behavior analysis in colleges and universities, namely, the recognition speed and recognition rate of two types of algorithms for convolutional neural networks and graph convolutional networks are not high. By combining multi-information stream data fusion with adaptive graph convolution and also improving feature utilization by embedding spatiotemporal attention module, the performance of the model in this paper is optimal and also the recognition accuracy is improved substantially when tested and compared on NTU RGB + D and N-UCLA data sets. The design and improvement of this system can help universities to better carry out comprehensive student assessment and improve their human education. The follow-up work can make more improvements in two aspects: improving the accuracy of individual action recognition and continuing to propose a more lightweight model.

In order to alleviate the problem of over translation and missing translation in NMT, based on the consistency and complementarity of information stored in different covering models, a multicoverage fusion model is proposed, which uses coverage vector and coverage score to guide the attention mechanism at the same time. First, the concept level definitions of words are covered. Then, two kinds of translation history information stored in the cover vector and cover score are used to guide the calculation of the attention score at the same time. Finally, the dual attention decoding method based on the fusion coverage mechanism is adopted. The experimental results show that the multicoverage fusion model can improve the translation quality of NMT.

1. Introduction

Due to the diversity and complexity of natural languages, it is still difficult to translate one language properly into another. At present, neural machine translation (NMT) has shown great potential under the condition of large corpus and computational capacity and has developed into a new machine translation method [1, 2]. This method requires only bilingual parallel corpus, which is convenient for training large-scale translation models. It not only has high research value but also has a strong industrialization ability, which has become a hot spot in current machine translation research [3].

Neural machine translation based on encoder and decoder structure is a general model, which is not fully designed for the machine translation task itself, so there are still some problems to be solved. It requires bilingual dictionaries to be fixed in size. Considering the complexity of training, dictionary size, and sentence length are usually limited to a small range [4, 5]. As a result, NMT is faced with more severe problems of unknown words and long sentences. Only bilingual training data are used, and no

additional prior knowledge is required, such as large-scale monolingual corpus, annotated corpus, and bilingual dictionary. In addition, the structural characteristics of machine translation make it difficult to use external resources. Monolingual corpus, annotated corpus, bilingual dictionary, and other resources can significantly improve translation quality in statistical machine translation [6], but prior knowledge has not been fully applied overtranslation and inadequate translation are the problems of NMT. The overlay mechanism is a common method in statistical machine translation to ensure the integrity of the translation. It is difficult to directly model the covering mechanism in NMT [7]. The attention mechanism is a significant improvement on NMT, but its deficiency is that historical attention information is not taken into account in the generation of target language words, and the constraint mechanism is weak. In addition, in some cases, the generation of target language words does not need to pay too much attention to the source language information. For example, in Chinese-English translation, when the function word “The” is generated, more attention should be paid to the target language information. In addition, there are

problems of OverTranslation and UnderTranslation in NMT [8], and the existing attention mechanism also needs to be improved. Although the above-given methods can alleviate the problems of over translation and missing translation in NMT to a certain extent, due to the structural characteristics of a word for word prediction of the NMT model cannot be completely avoided.

Therefore, in this paper, firstly, the problems of existing coverage models and the possibility of fusion between different coverage models and the possibility of fusion between different methods are analyzed. Then, multiple coverage information fusion methods are used to record translation history information complementary to guide the calculation of attention weight, which can reduce the loss of historical information updating and improve the distribution of attention weight, so as to inhibition the phenomenon of over translation and missing translation.

2. Translation Model Based on Fusion of Multiple Coverage Strategies

2.1. Basic Ideas. The covering idea is proposed in the phrase based statistical machine translation model. In each decoding, all untranslated phrases and their translation results are added to the candidate set. Whenever a phrase translation result is added to the output sequence, the corresponding source language phrase should be marked as “translated,” which ensures that each source language phrase is covered by translation, and is not translated repeatedly.

Covering information is also very important for NMT. Due to the lack of a covering mechanism in the NMT model, it is an effective method to improve the over translation and missing translation problem by adding a covering mechanism to the NMT model.

Specifically, assuming that a sentence sequence of the source language $X = \{x_1, x_2, x_3, x_4, x_5\}$ is given, Its initial coverage set $C = \{0, 0, 0, 0, 0\}$. Among them, “0” indicates that the corresponding source language word has not been translated, while “1” indicates that the source language word has been covered by translation. In addition, assuming that the corresponding target phrase source language phrase $\{x_2, x_3, x_4\}$ is $\{y_m, \dots, y_n\}$, then after $\{y_m, \dots, y_n\}$ is added to the translation output sequence, the overlay set will be updated to $C = \{0, 1, 1, 1, 0\}$. If it is specified that a phrase can only be translated once in the process of translation, then follow this step to translate until the translation is completed, and the overlay set should be $C = \{1, 1, 1, 1, 1\}$. At this point, the phrase and the source language are effectively translated only once.

2.2. Coverage Model

2.2.1. Covering Vector. In the statistical machine translation model, all source language phrases can only be translated once, so its coverage mechanism is a hard alignment. However, the attention mechanism of the NMT model is a kind of soft alignment; that is, the words covered by attention are still allowed to participate in the prediction of the next word. Therefore, it is very difficult to model the

FIGURE 1: Structure of coverage-based attention model.

coverage mechanism directly [9]. In Literature [6], a covering model is proposed, in which a covering vector is set up to explicitly store the historical coverage information of each word in the source language sentence. In order to provide historical information for the translation process, the coverage vector is incorporated into the original attention mechanism model, where more attention is allocated to untranslated words and the weight of translated words is reduced. The structure of the coverage vector guided attention model is shown in Figure 1.

After fusing the covering vector, the calculation method of the attention mechanism is as follows:

$$\begin{aligned} e_{i,j} &= a(t_{j-1}, h_i, CV_{i,j-1}) \\ &= v_a^T \tan h(W_a t_{j-1} + U_a h_i + V_a CV_{i,j-1}). \end{aligned} \quad (1)$$

Among them, $CV_{i,j-1}$ represents the coverage vector corresponding to the source language word x_i before time j , and V_a is the weight matrix.

Since the history information changes after each step of decoding, the coverage vector of each source word needs to be updated. Its method is shown in the following equation:

$$CV_{i,j} = f(CV_{i,j-1}, a_{ij}, h_i, t_{j-1}), \quad (2)$$

where $F(\cdot)$ is a recurrent neural network whose basic neural unit can use only a simple tanh layer or GRU with a more complex structure to capture long-distance dependencies.

2.2.2. Coverage Score. It is used to indicate the degree of source language translation. If the translation results have high coverage of the source language words, the corresponding coverage score is also high; on the other hand, if the translation results have low coverage of the source language, the corresponding coverage score is also low. Suppose a sentence pair (X, Y) is given, the number of Chinese words in X and Y is expressed as $|X|$ and $|Y|$ separately. For any source language word x_i , its coverage is defined as all target words y_j . The sum of the attention scores of the words in the source language is shown in the following equation:

$$\text{coverage}_{x_i} = \sum_{j=1}^{|Y|} a_{ij}. \quad (3)$$

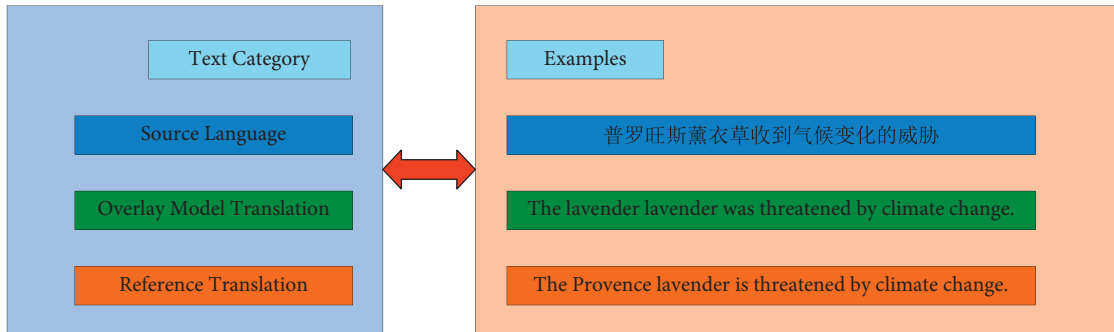

FIGURE 2: An example of NMT model translation based on covering vector.

On this basis, the coverage score of source language sentences is calculated by using the coverage of all source language words. The calculation method is shown in the following equation:

$$cs(X, Y) = \sum_{i=1}^{|X|} \log \varphi(\text{coverage}_{x_i}, \beta). \quad (4)$$

Among them, β is an adjustable parameter, $\varphi(\cdot)$ is truncation function. The coverage score is linearly combined with the original conditional probability function of the model to obtain the final evaluation function. The improved evaluation function is shown in the following equation:

$$\text{score}(X, Y) = a \cdot \log P(Y|X) + b \cdot cs(X, Y). \quad (5)$$

Among them, $\log P(Y|X)$ represents the value of conditional probability predicted by the model, a and b represent an adjustable parameter used to balance the effect of conditional probability and coverage score. The introduction of the coverage score makes the model consider the coverage of source language sentences and reduce the bias of translation results of a short sentence.

2.3. Translation Model Based on Multiple Coverage Strategies

2.3.1. Problem Description. Although the NMT model based on covering vector can alleviate the phenomenon of over translation and missing translation, this problem still exists. As shown in Figure 2, “Lavender” in the original text has been translated twice, while “Provence” has been omitted. When the first lavender is generated, the Coverage vector based NMT model mistakenly allocates more attention to lavender than Provence, which results in repeated translation and missing translation.

From the above-given examples, it can be seen that the NMT model based on covering vector still has further improvement space in attention allocation. As mentioned above, both coverage vector and coverage score can record the coverage information in the translation process in an explicit way. In the decoding stage, the former stores and updates the information abstractly in the form of a vector, calculate and guide the translation of attention through history; the latter is accumulated in the form of constant and used as the coverage of translation results for the selection of

translation results. Compared with the coverage score, the coverage vector cannot directly quantify the coverage of translation results, and there is information loss when using GRU update; while it is difficult to determine the upper and lower limits of the coverage of each source language vocabulary with a fixed value, so it is impossible to compare the coverage between words.

2.3.2. Model Decoding. Coverage vector and coverage score are complementary in the storage of coverage information. In order to combine the advantages of the two methods, this paper proposes a multicoverage fusion model which combines the coverage vector and the coverage score. The coverage score is used to reduce the impact of information loss when the coverage vector is updated, and improve the distribution of attention weight. The concept of word level coverage score is defined first. Then, according to the different fusion methods of coverage vector and coverage score, two kinds of multicoverage fusion models, hierarchical and parallel, are proposed. The overall framework is shown in Figure 3.

The coverage vector and the updated attention vector of each target word in the predicted sentence are obtained through the coverage mechanism layer. The coverage mechanism is shown in Figure 4.

During decoding, the attention weight vector α_t^{src} of text is obtained from the hidden state s_{t-1} at the previous moment, the hidden state sequence H of the source language through the double attention mechanism layer. The key point of the coverage mechanism layer is to maintain a coverage vector C_t in the prediction project. It is the accumulative sum of attention distribution of all previous prediction steps, which records the historical information that the model has paid attention to and avoids focusing on repetitive information, as shown in the following equation:

$$C_t^{\text{src}} = \sum_{\hat{t}=0}^{t-1} \alpha_{\hat{t}}^{\text{src}}. \quad (6)$$

The obtained coverage vector is applied to the attention layer to obtain the updated attention weight, as shown in equations (7) and (8).

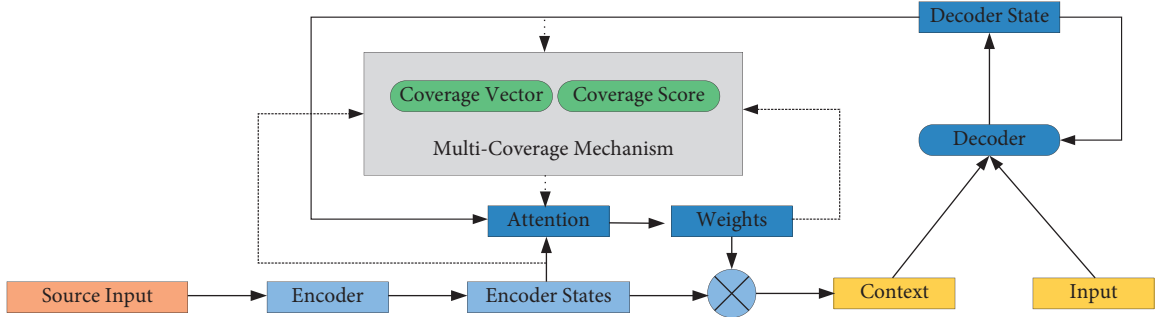

FIGURE 3: NMT model based on multicoverage.

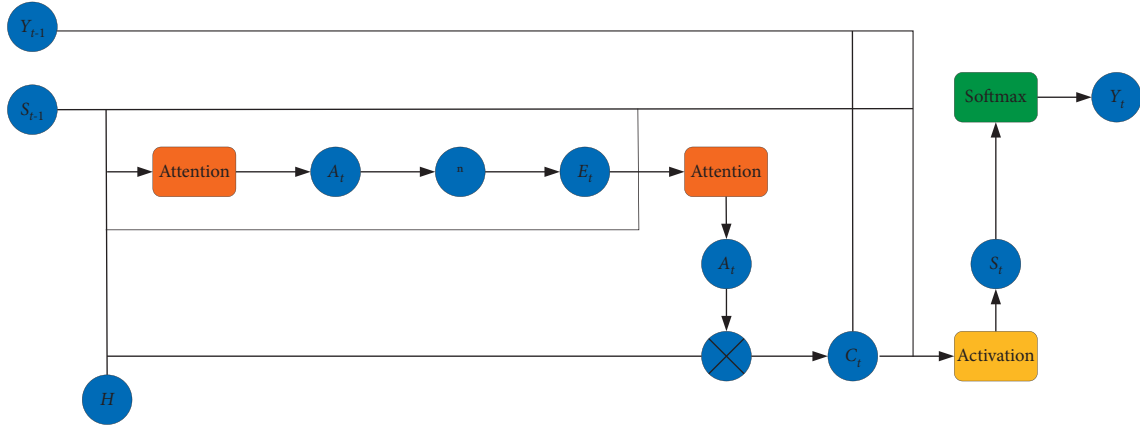

FIGURE 4: Coverage mechanism.

$$e_{t,i}^{\text{src}} = (v_a^{\text{src}})^T \tan h(U_a^{\text{src}} s_t + W_a^{\text{src}} h_i + V_a^{\text{src}} c_{t,i}^{\text{src}}). \quad (7)$$

$$\alpha_{t,i}^{\text{src}} = \frac{\exp(e_{t,i}^{\text{src}})}{\sum_{j=1}^N \exp(e_{t,j}^{\text{src}})}. \quad (8)$$

Among them, $\tan h$ is the nonlinear activation function, $v_a^{\text{src}}, U_a^{\text{src}}, W_a^{\text{src}}$ are the parameters used for learning in the model. The weight $e_{t,i}^{\text{src}}$ can be interpreted as the correlation between the target word generated by the decoder and the source sequence word x_i at t . $\alpha_{t,i}^{\text{src}}$ represents the normalization of the obtained similarity score.

The coverage vector is added as an additional input to affect the prediction of the target language. Then, get the updated context attention vector c_t . The text attention vector c_t at time t is obtained by the weighted sum of the source language implicit state sequence h_i and the weight $\alpha_{t,i}^{\text{src}}$ obtained by the text attention model, as shown in the following equation:

$$c_t = \sum_{i=1}^N \alpha_{t,i}^{\text{src}} h_i. \quad (9)$$

With the updated i_t as the additional input, the candidate implicit state s'_t is used, and the source language attention vector c_t calculates the final implicit state s_t at time t , as shown in equations (10)–(13).

$$z_t = \sigma(W_z^{\text{src}} c_t + U_z s'_t), \quad (10)$$

$$r_t = \sigma(W_r^{\text{src}} c_t + U_r s'_t), \quad (11)$$

$$\underline{s}_t = \tan h(W^{\text{src}} c_t + r_t \odot (U s'_t)), \quad (12)$$

$$s_t = (1 - z_t) \odot \underline{s}_t + z_t \odot s'_t, \quad (13)$$

where z_t is the renewal gate, r_t is the reset gate, \underline{s}_t is the candidate hidden state, s_t is the final hidden state, $W_z^{\text{src}}, U_z, W_r^{\text{src}}, U_r, W^{\text{src}}, U$ is the parameter used for learning in the model.

Finally, output the model, the prediction of the target word y_t at the t moment is related to the implicit state s_t of the target word at the current moment, the target word y_{t-1} generated by the prediction at the previous moment, and the text attention vector c_t , as shown in the following equation:

$$P(y_t | y_{<t}, C, A) = \text{softmax}(f(s_t, y_{t-1}, c_t, i_t)) \propto, \quad (14)$$

$$\exp(L_o \tanh(L_s s_t + L_w E_y[y_{t-1}] + L_o c_t + L_c i_t)),$$

where f and softmax are nonlinear activation functions, and $L_o, L_s, L_w, L_c, L_{ci}$ are parameters used by the model for learning.

3. Experiment and Analysis

3.1. Evaluation Method. BLEU (Bilingual Evaluation Understudy) algorithm evaluates translation performance by calculating the n-element words co-occurring in the translation result and the translation [10]. Firstly, MaxRefCount (n-gram) is calculated as the maximum number of possible occurrences of an n-word in a sentence. Then, it is compared with the number of occurrences of this n-word in the candidate translation, Count(n-gram), and the minimum value between them is taken as the final number of matches of this n-word. As shown in the following equation:

$$\begin{aligned} \text{Count}_{\text{clip}}(n\text{-gram}) \\ = \min\{\text{Count}(n\text{-gram}), \text{MaxRefCount}(n\text{-gram})\}. \end{aligned} \quad (15)$$

And, then the precision P_n of the later co-occurrence n-element words is defined as follows:

$$P_n = \frac{\sum_{c \in \text{candidates}} \sum_{n\text{-gram} \in C} \text{Count}_{\text{clip}}(n\text{-gram})}{\sum_{C \in \text{candidates}} \sum_{n\text{-gram} \in C} \text{Count}(n\text{-gram})}. \quad (16)$$

Since n-gram's matching degree tends to choose shorter sentences, a translation result that only translates part of the original sentence accurately will still have a high matching degree, BLEU introduces Brevity Penalty into the final scoring result to avoid the bias of scoring, as shown in the following equation:

$$\text{BP} = \begin{cases} 1, & \text{if } l_c > l_s, \\ e^{1-l_s}, & \text{if } l_c \leq l_s, \end{cases} \quad (17)$$

where l_c represents the length of the translation result, and l_s represents the length of the reference translation. When there are multiple references, the length closest to the translation result is selected as the length of the reference. It can be found that only when the length of the interpretation result is not exactly the length of the reference text will the punishment factor be presented.

BLEU usually only considers the accuracy of 4-GRAM at most, since the accuracy of n-gram statistics decreases exponentially with the increase of order. In order to balance the effect of statistics of each order, a geometric average is used for weighted summation, and then the length penalty factor is multiplied to obtain the final calculation formula as shown in the following equation:

$$\text{BLEU} = \text{BP} \times \exp\left(\sum_{n=1}^N W_n \log P_n\right), \quad (18)$$

where N is the maximum order of n-element words, W_n is the weight coefficient, $N=4$, $W_n=1/N$.

3.2. Parameter Setting. About 6.5 million sentence pairs were extracted from the bilingual parallel corpus provided by CWMT2018. Using newsdev2017 as a validation set for

parameter tuning and model selection that a total of 2002 sentences are included. Three datasets, newstest2017, cwmt2018, and newstest2018, were selected as test sets to verify the model, each containing 2000, 2481, and 3981 sentences. Before training and testing, the corpus is generalized, the word segmentation of the Chinese and English corpus is carried out by using the open-source tool of NiuTrans, and the subword segmentation is carried out by using byte pair encoding.

The baseline system uses seq2seq, and the settings of the model are displayed in Table 1. The initial learning rate is set to 0.0001. In decoding, the beam search algorithm is adopted, and the length penalty, beam size, and length penalty coefficient are introduced and set to 15 and 1.3, respectively. 350000 steps were trained iteratively on the training set, and the 15 checkpoints with the highest BLEU are saved in the verification set for model testing. The coverage model based on the coverage vector is set up as the control. The coverage vector dimension is set to 10 and the GRU gate function is used to update. In the hierarchical multicoverage model, the balance coefficient is set to 0.5.

3.3. Result Analysis. During training, the 15 models with the highest BLEU were saved on the verification set corpus. In the test, the parameters are averaged first, and the final translation is generated on this basis. The specific experimental results are shown in Figure 5.

According to the experimental results in Figure 5, the average BLEU value of the baseline system on three test sets is 26.78%. On the basis of the baseline system, the coverage model has little improvement, and BLEU is only increased by 0.15%. The results of the two multicoverage fusion models are significantly improved compared with the baseline system and are better than the coverage model. The average BLEU of the HMC model was 27.43%. Compared with the baseline system and coverage model, BLEU increased by 0.65% and 0.5%, respectively; while the average BLEU value of the PMC model is 27.21%, which is 0.43% and 0.28% higher than the baseline system and coverage model, respectively. Compared with the two multicoverage models, the overall promotion effect of the HMC model is more obvious.

The interpretation impact of long sentences is one of the significant records to assess the exhibition of the NMT model. In order to research on the performance of the multicoverage fusion model in different source language sentence length intervals, the source dialects in the test set were assembled by the strategy for Reference [6], and the BLEU of the HMC model was compared with the baseline system and coverage model in the range of translation results on source language length (0, 10], (10, 20], (20, 30], (30, 40], (40, 50] and (50, +∞). The results are shown in Figure 6.

The performance of the HMC model is better than the baseline system and coverage model. Compared with baseline system, BLEU increased by 0.47%, 0.65%, 0.48%, and 0.79%, respectively, and on the basis of coverage model, it increased 0.22%, 0.55%, 0.44%, and 0.63%, respectively. Through the analysis of the corpus, it can be found that this

TABLE 1: Parameters setting.

Parameter	Value

Max_length	50

FIGURE 5: BLEU of translation.

FIGURE 6: BLEU under different source language length.

length interval contains many fragments of long sentences after segmentation. The structure and meaning of these sentences are not complete enough, so the translation performance of the model is affected to a certain extent.

As shown in Figure 7, there are over translation problems in the Baseline system, Coverage model and HMC model, but the number of words in the translation of the coverage model and HMC model is less than that of the baseline system. Among them, the coverage model is 13.5% less than the baseline system, and the HMC model is further reduced by 10.5% on the basis of the coverage model, which shows that the HMC model can further alleviate the over translation problem in NMT on the basis of covering model.

In Figure 2, because the source language word “普罗旺斯 Provence” wrongly establishes a corresponding relationship with “薰衣草Lavender,” which makes the word “薰衣草Lavender” appears in repeated translation. This problem is corrected in the HMC model, as shown in Figure 8. HMC model correctly translates “普罗旺斯薰衣草” into “Provence Lavender.”

FIGURE 7: Evaluation of repeated translation.

FIGURE 8: Solution of over translation problem.

4. Conclusion

Introducing coverage mechanism into the NMT model can alleviate the over translation and missing translation problems. However, the coverage information stored by the covering vector or coverage score is not perfect. Therefore, this paper discusses the information storage, usage, advantages, and disadvantages of different coverage models, and based on the consistency of translation history information and the complementarity between models, a multicoverage fusion model is proposed. Firstly, the concept of word level covering score is defined; Then, the information stored in the coverage score and coverage vector is used to guide the calculation of attention weight. According to the different fusion methods of coverage vector and coverage score, two methods, hierarchical multicoverage model and parallel multicoverage model, are proposed. The experimental results show that compared with the PMC model, the overall promotion effect of the HMC model is more obvious, and the multicoverage fusion method can further reduce the phenomenon of over translation and omission translation.

It is of great theoretical and practical significance to introduce the supply chain concept into micro and small manufacturing enterprises and to build a cost management evaluation model for micro and small manufacturing enterprises based on the supply chain to improve the cost management of micro and small manufacturing enterprises. To this end, based on combing the relevant literature on supply chain and cost management evaluation at home and abroad, this paper analyzes the characteristics of cost management of micro and small manufacturing enterprises because of the problems of cost management of micro and small manufacturing enterprises, adopts the gray fuzzy hierarchical analysis method to assign and evaluate, which takes into account the nonindependence among the elements of each level and the elements of the same level, and also considers the characteristics of grayness and fuzziness of qualitative indicators so that the evaluation results are more credible. The evaluation of cost management of micro and small manufacturing enterprises based on the supply chain was carried out by using gray fuzzy analysis, and the empirical analysis was based on the research data of company B. The evaluation result was “poor,” which verified the applicability of the cost management performance evaluation model of micro and small manufacturing enterprises and indicated the direction for the improvement of cost management of micro and small manufacturing enterprises. And, the proposed intuitionistic fuzzy hierarchical analysis has greater advantages in evaluation accuracy than the traditional fuzzy hierarchical analysis.

1. Introduction

In the context of economic globalization, the competition among enterprises is becoming increasingly fierce. Large and medium-sized manufacturing enterprises can obtain a place for the development and growth of their companies with the advantages of strong capital, advanced technology level, and good reputation [1]. However, SMEs, especially small and micromanufacturing enterprises, are facing a severe test due to factors such as continuous interest rate increase of RMB, rising labor costs, continuous escalation of raw material prices, and difficulties in financing [2].

Facing various difficulties such as difficult survival, high cost, and low profit, the development of small and micro-manufacturing enterprises is seriously restricted. Although

small and micromanufacturing enterprises attach great importance to cost management, the actual effect is not good [3]. The reason is that the cost management evaluation system adopted by micro and small manufacturing enterprises is to emphasize the evaluation of production cost management, but not the evaluation of other cost management links and to emphasize the evaluation of financial indicators, but not the evaluation of nonfinancial indicators [4]. However, the factors affecting the cost of micro and small manufacturing enterprises are extremely complex, especially the lack of a specific and effective cost management evaluation system, so it is urgent to build a set of indicators and methods suitable for the evaluation of cost management of micro and small manufacturing enterprises [5]. This paper analyzes the current situation of cost management performance evaluation of micro and small

manufacturing enterprises by combining the research literature of domestic and foreign scholars, introduces the idea of supply chain management, and focuses on building a cost management evaluation system for micro and small manufacturing enterprises from the perspective of the supply chain, to provide a reference for cost management evaluation of micro and small manufacturing enterprises.

The business characteristics of small and micro manufacturing enterprises are mainly reflected in two aspects: (1) the small scale of production, and (2) risk resistance is weak [6]. As the employees of small and micro manufacturing enterprises are usually only a few dozen, the staff turnover is frequent, the business type is single, it is difficult to realize the production scale, and the market share is weak, which affects the profit source. Any change of external factors will affect the change of internal business environment, and the ability to resist risks is lower than that of large and medium-sized enterprises. Second is the lack of professional quality of managers. Most of the founders of small and micro-manufacturing enterprise's own knowledge structure is not perfect, and they lack a complete corporate development strategy, so it is difficult to lead the enterprise to break the development bottleneck, out of the predicament [7]. Therefore, it is especially important to focus on cost management and effectively improve the level of cost management to enhance the competitiveness of small and micromanufacturing enterprises. However, the evaluation of the financial indicators of cost management of a single link is not a comprehensive and correct evaluation of the level of cost management of micro and small manufacturing enterprises [8].

The globalization of the economy has transformed the competition among enterprises into the competition among supply chains. Large and medium-sized manufacturing enterprises have realized the importance of supply chain management and successfully applied it in their daily activities, which has become a powerful weapon for enterprises to achieve competitiveness, while micro and small manufacturing enterprises have little awareness of supply chain management. Therefore, this paper selects small and micromanufacturing enterprises as the research object, introduces the concept of supply chain management into small and micro manufacturing enterprises, and constructs a cost management evaluation system based on the supply chain for small and micromanufacturing enterprises to provide some reference for theoretical research on cost management evaluation of small and micromanufacturing enterprises.

2. Related Work

The bottom-up evaluation of the performance of bootstrapped enterprises at home and abroad mostly has different perspectives: the authors of [9] conducted a qualitative study on the indicators of social benefits, economic returns, innovation, and entrepreneurship and business activities of SBIC; the authors of [10] argued that Finland's venture capital bootstrapped enterprises focused too much on profitability indicators in the early stage leading to poor performance; the authors of [11] examined the effect of VCs, enterprise support, and indicators of business operations in the evaluation of UK EIS and VCT. The evaluation

of YOZMA introduces the exit success rate, best exit, number of exits, listing and mergers and acquisitions, the effect of government demonstration and guidance, and total asset size; [12] in the evaluation of Australia IIF, the qualification of venture capital enterprise managers and clear guidance direction in the early stage of the venture are considered to be more important in performance evaluation; [13] using the data envelopment analysis (DEA) method to include enterprise size in the performance evaluation assessment, although there is no direct linear relationship between performance score and size, large-scale enterprises tend to perform better. Since the main problem of venture capital bootstrapped enterprises at the local and municipal levels in China is capital sinking and large disparities exist in different regions, enterprise size is not suitable as a direct evaluation index. The authors of [14] argued that bootstrapped enterprises have greater gains in sales and efficiency than supported enterprises within 3 to 4 years, while there is no significant improvement in employment, so the performance evaluation will mainly examine the sales and efficiency of enterprises. The performance evaluation of foreign bootstrapped enterprises focuses on the design of indicators, and the performance evaluation of YOZMA in Israel and EIF in Europe is the most applicable to China because of the parent company model of equity participation [15].

The performance evaluation of bootstrapped enterprises in China is mostly top-down, so the performance evaluation ideas should be clarified based on policies and regulations: the authors of [16] argue that the leverage effect, industrial support, and sustainability factors need to be considered; the authors of [17] argue that the performance evaluation of public financial expenditure, financial science, and technology investment and commercial investment enterprises is of great reference; the authors of [18] argue that strategic bootstrapped enterprises should be evaluated from three perspectives: financial, management, and sustainability; the authors of [19] argue the performance evaluation of strategic Emerging industry bootstrapping enterprises; the authors of [20] consider bootstrapping enterprises as enterprises and applies TOPSIS model for performance evaluation based on the principle of enterprise-balanced scorecard, but the position is not clear.

To sum up, at present, the performance evaluation of guiding enterprises lacks research from a third-party perspective; there are more studies on policy and economic aspects and not enough studies on managerial indicators; there are more studies on hierarchical constructing indicators and not enough studies on practical details; there are more qualitative discussion and not enough empirical studies. Therefore, this paper wants to enrich the detailed indicators of performance evaluation research from the perspective of third-party rating and carry out empirical tests on the constructed evaluation system.

3. Gray Fuzzy Hierarchical Analysis Method

3.1. Hierarchical Analysis Method

3.1.1. Construction of Hierarchical Analysis Structure. As shown in Figure 1, the hierarchy is divided, such as the target layer, criterion layer, and indicator layer.

FIGURE 1: Hierarchical chart.

3.1.2. *Construction of the Judgment Matrix.* The constructed matrix judgment should satisfy the following conditions:

$$\begin{aligned} x_{ij} &= 1, x_{ij} = \frac{1}{x_{ji}}, \\ x_{ij} &> 0 \quad (i, j = 1, 2, 3, \dots, n). \end{aligned} \quad (1)$$

3.1.3. *Hierarchical Single Ranking and Consistency Test.* Calculate the consistency index CI : $CI = (\lambda_{\max} - n) / (n - 1)$, where n is the matrix order. Based on of this, make $CR = CI/RI$ and find the value of CR .

If $CR < 0.1$, the consistency of the matrix can be judged as satisfactory. Otherwise, the matrix should be adjusted for the matrix.

3.1.4. *Hierarchical Total Ranking and Its Consistency Test.* The weight vector of layer 2 to layer 1 is expressed as $\omega_i^{(3)} = (\omega_{i1}, \omega_{i2}, \dots, \omega_{im})^T$, $(i = 1, 2, \dots, n)$, $\omega_i^{(3)}$ for the column vectors to form the matrix: $W^{(3)} = [\omega_1^{(3)}, \omega_2^{(3)}, \dots, \omega_n^{(3)}]$, and then the third layer is $\omega_{ij}^{(3)} = W^{(3)}\omega^{(2)}$ for the first layer combination.

If $CR^{(3)} < 0.1$, the consistency of the judgment matrix passes.

Calculate the weights of each index.

3.2. *Gray Fuzzy Evaluation Method.* Since fuzzy comprehensive evaluation can consider fuzzy factors when judging problems, the fuzzy comprehensive evaluation method has wide applicability. The gray comprehensive evaluation is also applied with incomplete or insufficient information is also applied on some specific occasions. As a combination of gray theory and fuzzy theory, gray fuzzy hierarchical analysis can solve not only fuzzy problems but also gray problems, so it is more widely applicable.

\tilde{A} is a fuzzy subset on the space $X = \{x\}$, while $\mu_A(x)$ is a gray number on $[0, 1]$, then the affiliation of x is with respect to \tilde{A} , then its point grayness is $v_A(x)$, which is denoted as $\tilde{A}_{\otimes} = \{(x), \mu_A(x), v_A(x) | x \in X\}$. It is represented as $\tilde{A}_{\otimes} = (\tilde{A}, A_{\otimes})$ by set pairs, in which $\tilde{A} = \{(x), \mu_A(x) | x \in X\}$ is called the fuzzy part of \tilde{A}_{\otimes} and $A_{\otimes} = \{(x), v_A(x) | x \in X\}$ is called the gray part of \tilde{A}_{\otimes} . If $\mu_A = (0, 1)$, then $\tilde{A}_{\otimes} = A_{\otimes}$. If $v_A(x) = 0$, then $\tilde{A}_{\otimes} = \tilde{A}$.

The space $X = \{x\}$ and $Y = \{y\}$ and the gray fuzzy set $X \times Y$ in the direct product space $\tilde{R}_{\otimes} = \{(x, y), \mu_R(x, y), v_R(x, y) | x \in X, y \in Y\}$ are the gray fuzzy relations on $X \times Y$.

With $\tilde{A}_{\otimes} = [(\mu_{ij}^A, v_{ij}^A)]_{m \times 1}$ and $\tilde{B}_{\otimes} = [(\mu_{ij}^B, v_{ij}^B)]_{1 \times n}$ are two gray fuzzy relations, the synthetic relation of $\tilde{A}_{\otimes} \tilde{B}_{\otimes}$ can be expressed as $\tilde{A}_{\otimes} \circ \tilde{B}_{\otimes} = (\tilde{A} \circ \tilde{B}, A_{\otimes} \circ B_{\otimes}) = [(+F_{j=1}^1(\mu_{ik}^A \bullet F\mu_{ik}^B)), (\bullet G_{j=1}^1(v_{ik}^A \bullet G\mu_{ik}^B))]_{m \times n}$.

4. The Gray Fuzzy Evaluation Method

This paper adopts the hierarchical analysis method and gray fuzzy evaluation method to build a scientific, reasonable, and practical evaluation model. The construction idea of the model is as follows: firstly, starting from the internal supply chain process of micro and small manufacturing enterprises, based on analyzing the characteristics and influencing factors of cost management of micro and small manufacturing enterprises and following the principle of constructing evaluation index system, the evaluation system of cost management of micro and small manufacturing enterprises based on the supply chain is established; secondly, the gray fuzzy hierarchical analysis method is used to carry out the research, to analyze the cost management level of enterprises, and its evaluation idea as shown in Figure 2.

4.1. *Determination of the Weights of Each Index.* The cost management evaluation index system of micro and small manufacturing enterprises based on the supply chain studied in this paper is divided into three layers: target layer, criterion layer, and indicator layer. The criterion layer consists of six aspects: procurement cost management evaluation study, production cost management evaluation study, inventory cost management evaluation study, sales cost management evaluation study, distribution cost management evaluation study, and after-sales cost management evaluation study [21, 22].

① Criterion layer judgment matrix construction and consistency test is shown in Table 1.

The data scored by the experts are input into the MATLAB program, and the maximum characteristic roots of the judgment matrix and the corresponding eigenvectors are found as

$$\lambda_{\max} = 6.2484$$

$$W_0 = [0.4954, 0.7801, 0.0721, 0.3154, 0.1460, 0.1418]^T. \quad (2)$$

The feature vector is normalized to obtain the weight vector of each element as

$$W = [0.2539, 0.3999, 0.0370, 0.1617, 0.0748, 0.0727]^T. \quad (3)$$

A consistency test on this judgment matrix yields

$$CI = \frac{\lambda_{\max} - n}{n - 1} = 0.0497. \quad (4)$$

Checking the table, we can see that when $n = 6$, $RI = 1.24$, and the consistency ratio can be calculated as

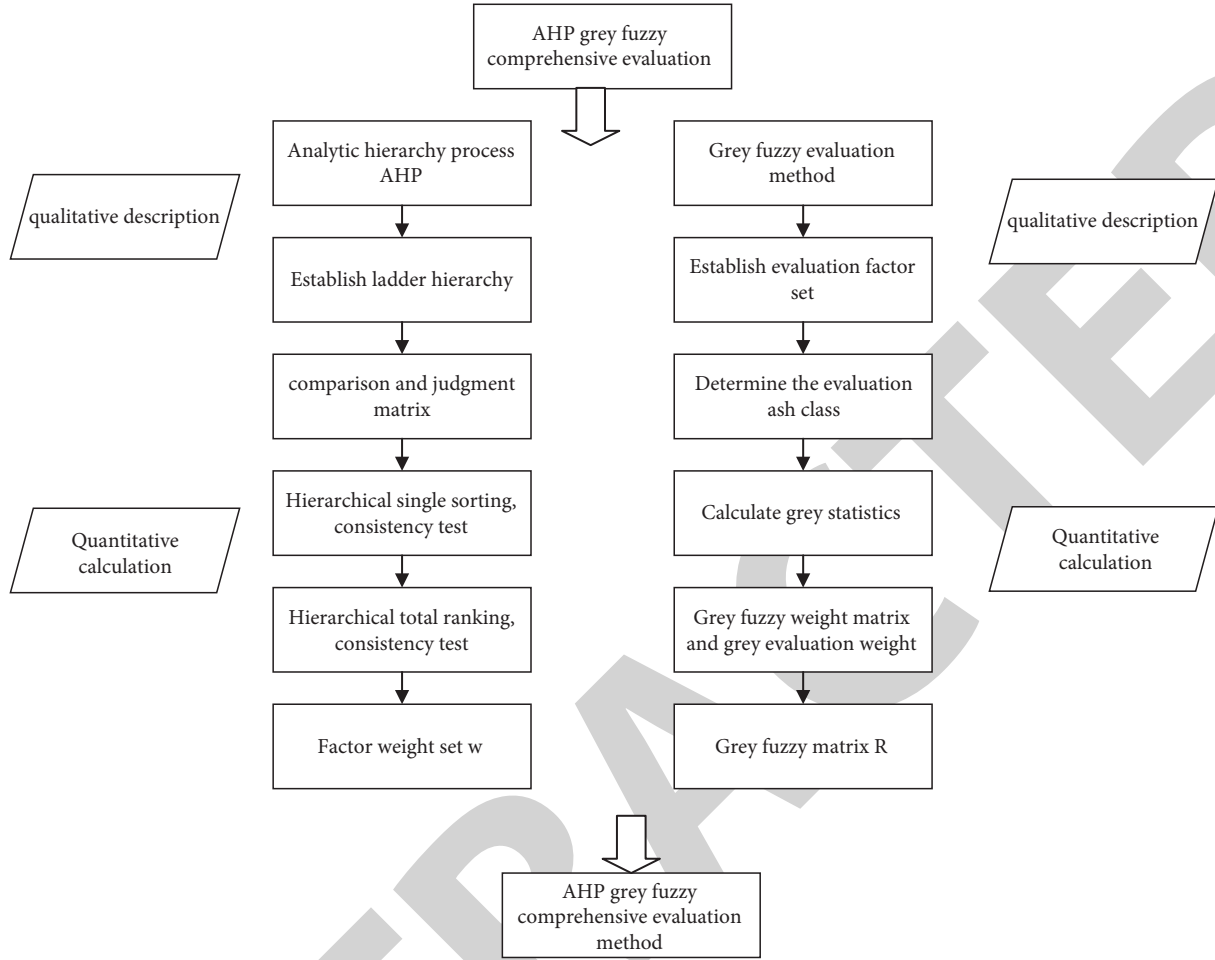

FIGURE 2: Cost management evaluation ideas of small and micromanufacturing enterprises.

TABLE 1: Criterion layer judgment matrix.

Index item	A_1	A_2	A_3	A_4	A_5	A_6
Purchase cost A_1	1	3	5	1/2	2	6
Production cost A_2	1	2	7	4	6	5
Inventory cost link A_3	1/5	1/7	1	1/3	1/2	1
Sales link cost A_4	1/3	1/2	3	2	3	3
Distribution link cost A_5	1/4	1/5	4	1	1/2	1
After sales cost A_6	1/5	1/5	3	1/3	3	2

$$CR = \frac{CI}{RI} = 0.0401. \quad (5)$$

$CR < 0.1$, which passes the consistency test. The judgment matrix construction and consistency test of purchasing link cost (A_1) are shown in Table 2.

The data scored by the experts are input into the MATLAB program, and the maximum characteristic roots of the judgment matrix and the corresponding eigenvectors are found as

$$\lambda_{\max} = 7.4922, \quad (6)$$

$$W_0 = [0.3326, 0.7396, 0.2491, 0.2127, 0.1242, 0.4628, 0.0742]^T.$$

The feature vector is normalized to obtain the weight vector of each element as

$$W = [0.1515, 0.3369, 0.1135, 0.0969, 0.0566, 0.2108, 0.0338]^T. \quad (7)$$

A consistency test on this judgment matrix yields

$$CI = \frac{\lambda_{\max} - n}{n - 1} = 0.0820. \quad (8)$$

Checking the table shows that when $n = 7$ and $RI = 1.32$, the consistency ratio can be calculated as

$$CR = \frac{CI}{RI} = 0.0621. \quad (9)$$

TABLE 2: Cost of procurement (A_1) judgment matrix.

	A_{11}	A_{12}	A_{13}	A_{14}	A_{15}	A_{16}	A_{17}
Purchase batch and purchase batch A_{11}	1	1/2	3	2	3	1/3	4
Supplier stability A_{12}	2	3	2	5	4	4	5
Capital investment ratio of purchasing staff A_{13}	1/3	1/3	2	1/2	3	1/2	6
Online purchase rate A_{14}	1/3	1/4	2	2	3	1/3	3
Standardization of procurement cost management system A_{15}	1/2	1/4	1/2	1/3	1	1/3	3
Intact fulfillment rate of purchase order A_{16}	3	1/3	2	5	4	1	3
Exchange rate and tax rate A_{17}	1/5	1/5	1/6	1/2	1/3	1/4	1

$CR < 0.1$, which passes the consistency test.

4.2. Determination of Evaluation Levels. Based on the views of domestic and foreign scholars, this paper borrows the expert scoring method and scores according to the 10-point system. This paper will be divided into five evaluation levels [23], which are poor, poor, average, good, and good, and the score of each level is $C = \{1, 3, 5, 7, 9\}$, and the whitening weight function of the level “good” is

$$f_j^1(x) = \begin{cases} 0, & x \notin [7, +\infty), \\ \frac{x-7}{9-7}, & x \in [7, 9], \\ 1, & x \in [9, +\infty). \end{cases} \quad (10)$$

The whitening weight function for the grade “better” is

$$f_j^2(x) = \begin{cases} 0, & x \notin [5, 9], \\ \frac{x-5}{7-5}, & x \in [5, 7], \\ \frac{9-x}{9-7}, & x \in [7, 9]. \end{cases} \quad (11)$$

Calculation of gray fuzzy judgment matrix is as follows:

$$B = (b_1, b_2, \dots, b_m) = W \cdot R = (a_1, a_2, \dots, a_n) \begin{bmatrix} r_{11}, r_{12} \dots r_{1n} \\ r_{21}, r_{22} \dots r_{2n} \\ \dots \\ r_{n1}, r_{n2} \dots r_{nm} \end{bmatrix}. \quad (12)$$

Of these, $b_j = \sum_{i=1}^m W_i \cdot r_{ij}$, $j = 1, 2, \dots, m$, normalized to give $\sum_{j=1}^m W_i b_{ij}$.

5. Analysis of the Evaluation Results of Enterprise Cost Management

According to the evaluation results, $3 \leq 3.0695 \leq 5$, which is between “poor” and “average”. It means that the overall cost management level of enterprise B is low.

FIGURE 3: Criteria layer index weights.

5.1. Calculation of Indicator Weights. According to the calculated weight results of the criterion level indicators, we make a graph of the criterion level indicators and get the relative importance of each factor in the criterion level according to the size of the weight value [24, 25]. From Figure 3, it can be seen that the weights of the three indicators, namely, cost management evaluation of production process A_2 , cost management evaluation of procurement process A_1 , and cost management evaluation of sales process A_4 , are 39.99%, 25.40%, and 16.17% respectively, accounting for 80% of the total weights, which are the most important indicators in the criterion level indicators.

5.2. Weighting of Indicators in the Indicator Layer to the Target Layer. Based on the results of the calculated weights of the indicators of the indicator layer, the indicators of the indicator layer are plotted, and the relative importance of the factors of the indicator layer can be obtained according to the magnitude of the weight values. From Figure 4, it can be seen that from the greenness of unit production cost A_{26} , product qualification rate A_{27} , online sales rate A_{44} , distribution method and distribution route A_{51} , purchasing batch, and purchasing lot A_{11} , the weights of these six indicators are greater than 3%, which belong to the more important indicators in the indicator of the guideline layer [26].

(0.55, 0.35)	(0.25, 0.58)	(0.55, 0.55)

TABLE 5: Intuitive preference relationships under indicators.

(0.55, 0.55)	(0.35, 0.55)
(0.55, 0.35)	(0.55, 0.55)

TABLE 6: Intuitive preference relationships under indicators.

(0.55, 0.55)	(0.35, 0.55)	(0.55, 0.35)
(0.55, 0.35)	(0.55, 0.55)	(0.5, 0.4)
(0.4, 0.55)	(0.4, 0.5)	(0.55, 0.55)

5.3. Enterprise Performance Evaluation by Fuzzy Hierarchical Analysis. Based on the situation of enterprises A and B, the intuitionistic fuzzy preference relationships derived from the scoring of five experts are partially shown in the attached table (Tables 3, 4, 5, and 6).

Calculating the distance of R_1 and \bar{R}_1 , we get $d(R_1, \bar{R}_1) = 0.1568 > 0.1$, which does not pass the consistency test. Therefore, further parameters are set for adjustment, so that $\sigma = 0.6$, and we get

$$\bar{R}_1 = \begin{bmatrix} (0.55, 0.55), (0.35, 0.60), (0.2468, 0.5005) \\ (0.60, 0.35), (0.55, 0.55), (0.60, 0.35) \\ (0.5005, 0.2468), (0.35, 0.60), (0.55, 0.55) \end{bmatrix}, \quad (13)$$

$d(R_1, \bar{R}_1) = 0.0997 > 0.1$. Then, matrix \bar{R}_1 passes the consistency test, and \bar{R}_1 is substituted to calculate the weights. Obtain

$$\omega^1 B_1 = (0.1999, 0.6626), \omega^1 B_2 = (0.3400, 0.5125), \quad (14)$$

$$\omega^1 B_3 = (0.2601, 0.5749).$$

Similarly, we can derive the weights of the other indicators where the weights of C_1 are

$$\omega^1 C_1 = A_1 \otimes B_1 \otimes C_1 = (0.3712, 0.5997) \otimes (0.5476, 0.3421) \otimes (0.1999, 0.6626) = (0.0406, 0.9111). \quad (15)$$

Similarly, we can also get the weights of other indicators. Further substitution yields

$$W_1 = \oplus_{j=1}^{24} (\omega_j \otimes \omega_{1j}) = (0.0406, 0.9111) \otimes (0.0265, 0.9396) \otimes (0.0160, 0.8502) \otimes (0.0211, 0.9402) \otimes (0.0317, 0.9200) \otimes (0.0256, 0.9287) \otimes (0.0257, 0.9232) \otimes (0.0182, 0.9462) \otimes (0.0318, 0.9137) \otimes (0.0103, 0.9445) \otimes (0.0173, 0.9305) \otimes (0.0208, 0.9210) \otimes (0.0132, 0.9394) \otimes (0.1316, 0.7243) \otimes (0.0106, 0.9548) \otimes (0.0186, 0.9307) \otimes (0.0129, 0.9439) \otimes (0.0118, 0.9521) \otimes (0.0177, 0.9342) \otimes (0.0240, 0.9174) \otimes (0.0068, 0.9627) \otimes (0.0053, 0.9696) \otimes (0.0096, 0.9632) \otimes (0.0078, 0.9589) = (0.4343, 0.1677). \quad (16)$$

TABLE 7: Comparison of the results of intuitionistic fuzzy hierarchical analysis and fuzzy hierarchical analysis.

	Intuitive fuzzy hierarchical analysis method	Fuzzy hierarchical analysis method
Fund A	0.3893	0.5189
Fund B	0.4447	0.4064

Similarly, for firm B , we can obtain

$$\begin{aligned}
W_2 = \oplus_{j=1}^{24} (\omega_j \otimes \omega_{2j}) &= (0.0220, 0.8871) \otimes (0.0167, 0.9106) \\
&\otimes (0.0100, 0.9403) \otimes (0.0138, 0.9300) \otimes (0.0138, 0.9300) \\
&\otimes (0.0138, 0.9300) \otimes (0.0141, 0.9241) \otimes (0.0154, 0.9207) \\
&\otimes (0.0116, 0.9375) \otimes (0.0184, 0.9061) \otimes (0.0133, 0.9321) \\
&\otimes (0.0227, 0.9018) \otimes (0.0272, 0.8864) \otimes (0.0173, 0.9100) \\
&\otimes (0.1646, 0.8218) \otimes (0.0109, 0.9379) \otimes (0.0154, 0.9241) \\
&\otimes (0.0188, 0.9060) \otimes (0.0086, 0.9513) \otimes (0.0064, 0.9616) \\
&\otimes (0.0111, 0.9409) \otimes (0.0080, 0.9505) = (0.3990, 0.1370).
\end{aligned} \tag{17}$$

Substituting the above results, we get

$$\begin{aligned}
\rho(W_1) &= 0.5 \times (1 + 1 - 0.4343 - 0.1677) \times (1 - 0.4343) = 0.3954, \\
\rho(W_2) &= 0.5 \times (1 + 1 - 0.3990 - 0.1370) \times (1 - 0.3990) = 0.4399, \\
\rho(W_1) &= 0.3954 < \rho(W_2) = 0.4399.
\end{aligned} \tag{18}$$

Comparing the two venture capital bootstrapped enterprises A and B, enterprise A is more focused on policy effect, with standardized management but lack of professionalism, while enterprise B is more focused on economic benefits. Through the performance evaluation method proposed in the paper, we know that enterprise A scores more than enterprise B. This indicates that, for venture capital bootstrapped enterprises, the policy effect is more important, which is in line with the basic idea of venture capital bootstrapped enterprise establishment, that is, weakening economic benefits and favoring policy effect.

5.4. Comparative Analysis with Fuzzy Hierarchical Analysis. Based on the same information set, we evaluated enterprises A and B with fuzzy hierarchical analysis, and the evaluation results with intuitionistic fuzzy hierarchical analysis are shown in Table 7.

From Table 7, we can see that both intuitionistic fuzzy hierarchical analysis and fuzzy hierarchical analysis conclude that enterprise A is better than enterprise B. However, from the perspective of evaluation methods, intuitionistic fuzzy hierarchical analysis is more in line with the actual situation and can more accurately express the perception of decision participants in the case of incomplete information and evaluate each indicator comprehensively in terms of its strength, weakness, and uncertainty. Secondly, in the process of fuzzy hierarchical analysis evaluation, for the judgment matrix that does not pass the consistency test, we can only carry out a new round of test calculation by rescoring from experts, while the intuitionistic fuzzy hierarchical analysis

method sets parameters for judgment matrix adjustment, a process that does not require the participation of decision-makers and is faster and more effective.

6. Conclusion

In this paper, the performance evaluation index system of an enterprise is constructed from the three dimensions of policy benefit, economic benefit, and management benefit by combining the specific conditions of the enterprise; the enterprise performance evaluation method based on intuitionistic fuzzy hierarchical analysis is proposed for the characteristics of the enterprise evaluation index system in obtaining information and the advantages of intuitionistic fuzzy numbers in processing information; finally, the evaluation process is demonstrated using the actual data of an enterprise, and finally, the evaluation process is demonstrated using the actual data of an enterprise, and the proposed intuitionistic fuzzy hierarchical analysis is compared with the traditional fuzzy research, showing that the index system constructed in this paper is applicable to my enterprise performance evaluation and the proposed intuitionistic fuzzy hierarchical analysis has greater advantages in evaluation accuracy than the traditional fuzzy hierarchical analysis.

Data Availability

The experimental data used to support the findings of this study are available from the author upon request.

Digital media can spread data and information. Its wide use not only enriches people's work and life but also brings high efficiency and convenience. However, due to different devices, different data quality, network stability, and other reasons, data quality is usually difficult to guarantee, so it is necessary to evaluate its perceptual integrity. In this paper, the group intelligence sensing technology in the sensor field and AWTC-TT optimization algorithm integrating blockchain technology are proposed to collect users' sensing data and build a model to discuss the complete performance. The experimental results show that (1) for the AWTC-TT algorithm, the processing time of 200 data tasks is less than 60 s; moreover, after optimization, the performance is efficient, which can effectively reduce the running time of data processing, and the performance loss is only 4%. (2) The perceptual quality of data was evaluated, the gain value of the first 0.4 is above 0.3, and the interference of abnormal data on integrity was explored. (3) The test results of the four integrality indexes of the model are good and the quality is stable. (4) The income value of CS2 is 5.8, and the income of distribution with the highest quality is the highest. Finally, the model constructed in this paper is mature, the experimental data and results are good, and the data perception integrity is discussed. The use of various fusion technologies can provide a reference for more subsequent research and application and lay a solid foundation.

1. Introduction

With the rapid changes of the times, many new branches have gradually emerged from the technology with the Internet as the core. With the support of 5G network and computer technology, the idea of connecting and communicating between people and things is no longer a dream [1]. At the same time, a large number of digital media terminal devices enter people's daily life, creating massive data that is difficult to estimate by manpower every day. In this case, a new paradigm of group intelligence perception was born. Through mobile devices and media, people can share perceptual data, which greatly expands the service scope of the Internet of Things. Therefore, the backwardness of some traditional technologies has brought an unbearable burden to the network, and people have to face new problems of data integrity. In addition, the group intelligence awareness

service requires high network nodes and speed. Facing challenges, blockchain technology stands out because of its many advantages and outstanding performance in financial transactions. In this paper, the distributed structure of digital media is the main research object, for its perceptual integrity experiments. In this paper, the AWTC algorithm, which is mainly based on blockchain technology, will be optimized, assisted by a consensus algorithm, incentive mechanism, security and trust guarantee, etc. In order to increase the performance of the experiment, the paper also introduces edge computing, the Internet of Things, and blockchain to integrate technologies, so as to reduce some computing pressure and carry out technological reform and integration innovation.

In order to better provide a relevant theoretical basis and experimental data support for our paper, we collected some literature for reference, as follows: Explore the framework

and typical application of blockchain technology in energy Internet [2]. Collect data through sensors, study MCS system, and explore many aspects from sensor communication to system management and data storage [3]. Analyze some open source projects of blockchain technology, and deeply analyze the basic principles of blockchain [4]. This paper studies the task allocation problem perceived by mobile people for multitasking participants [5]. Critically evaluate the superiority of blockchain technology, analyze the current situation and look forward to the future of this technology [6]. Learn from the successful experience of blockchain in the application of digital crypto currency and explore the theory of trusted data management [7]. The consistent hash algorithm is used to solve the problems of storage space, repeated verification, and data hierarchical management [8]. Considering 6G and the Internet of Things, the data sharing and storage mechanism of blockchain based on the Gossip protocol is proposed [9]. Objectively expound on the hot spots and trends in the field of integrating blockchain and the Internet of Things at the technical and application levels [10]. A multi-layer blockchain network model for edge computing and an adaptive workload proof algorithm are proposed [11]. The basic network structure of blockchain is realized through various encryption means and consensus algorithms, and the security architecture of edge computing and the Internet of Things is designed [12]. The incentive mechanism based on blockchain technology adopts the distributed architecture of blockchain security and applies group intelligence perception [13]. The transaction information is recorded by a three-tier cognitive radio system based on a blockchain of reputation value auction, and the perceived revenue distribution mechanism is constructed [14]. Based on discrete logarithm and computational Diffie-Hellman proposed a node exit mechanism suitable for a signcryption scheme [15]. This paper studies the influence of blockchain technology on ordinary netizens' perception of public opinion information quality and willingness to accept behavior [16].

2. Theoretical Basis

2.1. Distributed Digital Media. "Digital media" [17]: it can be interpreted as an information carrier, mainly in the form of binary numbers, which is closely related to computer information technology. However, from a broad perspective, the recording, processing, dissemination, and acquisition functions of digital media have already penetrated into all aspects of the human world. The coverage of intelligent products promotes the advent of the information explosion era, and digital media is widely used by people for its information acquisition and output technology. Its development is no longer only linked with the Internet and IT technology, but with the development of the whole industry and the whole world. Human society can no longer leave digital media technology. Without this technology, the world will lack the energy and driving force to develop the future.

Combine digital technology and media organically. Digital media is usually carried by terminal devices such as

TV, mobile phone, computer, and tablet, and output in the form of audio, image, and video. In the output process, it will generate massive data, transmit data according to different goals and needs, and share it with people or things. Not only can human-computer interaction be carried out but also the entertainment interest can be enhanced. Cutting-edge technologies in almost all fields can be integrated with digital media technology, and the digital products created fully reflect the value of commerce and spread culture and art.

Compared with the centralized client/server structure, each network node in the distributed structure has multiple paths, and its database is composed of several related databases on the network. Each network node is not closely related, and they all have the ability to process independently. Therefore, when a node goes wrong, it will not cause the whole system to crash. Moreover, the distributed structure is easy to upgrade and maintain, costs less money, and has multiple servers for local operations. When digital media is combined with distributed architecture, it can effectively divide the number of tasks, improve the efficiency of the whole system, balance the load problem, and run multiple applications at the same time.

2.2. Blockchain Technology. BC [18]: it is called "blockchain." BC can be interpreted as an open distributed digital ledger, which is mainly based on a peer-to-peer network (i.e., P2P network). This ledger can record the information of all transactions, and even every node of the whole network keeps a copy of the ledger. Therefore, only one node is needed, and we can obtain and query the whole transaction data. However, we can't change all the data copies on the whole network by modifying the copy on a certain node. Initially, blockchain technology mainly served the network "mining," that is, commercial transactions with Bitcoin as the trading currency. With the success of this technology in the financial field, BC has attracted the attention of experts and scholars at home and abroad because of its encryption mechanism, various computing algorithms, consensus mechanism and other technologies. So far, the research on it has become mature. BC technology is not a new single technology, but a new product of the integration of multiple fields and frontier science and technology. It is a continuous and related data system from the perspective of trust, and it is also a decentralized data recording method. Apart from decentralization, most of BC's network data is open and transparent, but users' true identities can be anonymous. Trust is generated between nodes through the hash algorithm. When data is written, in order to ensure the integrity of data, BC can eliminate all modification interventions without authority. Only when you are authorized to control 51% of the nodes can you change the data content or modify the status in BC.

2.2.1. AWTC-TT Algorithm. AWTC [19]: it is called "account-wise transaction chain" in English. It is also better known as "nano block lattice." Running in the way of winding blockchain, it belongs to a DAG type. It is its existence that enables each account to have a separate

blockchain bookkeeping record, which is the core technology of blockchain. Because BC technology is the main medium of economic transactions, it is necessary to ensure fast, safe, effective, and reliable transactions. Although other methods can achieve the above goals, only AWTC can achieve it quickly and stably. Through this algorithm, we can increase the number of network nodes and transactions in the blockchain. While increasing the number steadily, it can also keep the transaction time stable under the maintenance of the algorithm, without being affected by the increasing number of nodes and transactions, thus avoiding other problems. The AWTC algorithm can improve the computational efficiency and provide faster transaction speed for the network and its users. The Locus Chain protocol based on AWTC can upgrade the processing capacity and solve the problem of data scale expansion after introducing dynamic state fragmentation technology. In addition, even in the most stringent network environment, the Locus Chain protocol can support intelligent contracts of blockchain and avoid malicious attacks on the network. After some excellent transformation to improve the performance, we use the AWTC-TT algorithm in this paper.

2.2.2. Consensus Algorithm. The main function of the consensus algorithm is to make all nodes have distributed structure and reach an effective consensus. Its core principles are safety, fault tolerance, and activity. We analyze and compare several commonly used consensus algorithms, and introduce some of their characteristics, as shown in Table 1.

Among them, the calculation operation of POW is as follows:

$$\text{Hash}(\text{PreHash}, M\text{root}, T\text{stamp}, \text{Nonce}) < \text{Target}. \quad (1)$$

Implementation algorithm of POS:

$$\text{Hash}(\text{block_header}) \leq \text{Target} * \text{coinage}. \quad (2)$$

PBFT is a practical Byzantine fault-tolerant algorithm. In this paper, we propose to use LS-PBFT without removing centralization, so as to combine with edge computing to make the model more efficient.

$$p = v \bmod |R|, \quad (3)$$

$$\langle \langle P, v, n, d \rangle, m \rangle, \quad (4)$$

$$P \in \{\text{PRE_PREPARE}, \text{PREPARE}, \text{COMMIT}\},$$

$$m = m * II\{P = \text{PRE PREPARE}\}. \quad (5)$$

Among them, the view number is represented by v , which can express the status of leader nodes; $|R|$ represents the total number of replica nodes and master nodes in the collection. Formulas (3) and (4) are the messaging normal form of nodes. P refers to the message type; v represents the message view; n represents the message sequence number; d represents the message index; m is the concrete expression of the content of the message itself. In the process of message

delivery, m is passed to other nodes only in the first stage, and m is not passed again in other stages.

2.3. Group Intelligence Perception. ‘‘Crowdsensing’’ [24]: it originated from the use of sensing devices in the Internet of Things. At first, the service purpose of group intelligence perception was only for individuals. However, with the increment of information and the popularity of the Internet, because of the high cost of sensors, people prefer to collect sensing data from mobile phones, computers, and other terminal devices and upload them to servers in the cloud. It can be provided to the party in need. Generally speaking, for different tasks, the perceived time can change, and the perceived data quality is also different. Swarm intelligence sensing technology can process data on a large scale and analyze the quality of sensing data with low cost and quick access.

2.3.1. Incentive Mechanism. In this paper, a user-centered strategy is introduced to obtain perceptual information. Participants provide data and optimization goals that RADP needs to consider the following:

$$\text{RADP: } \max \frac{1}{b_i}. \quad (6)$$

MSensing method [25]: considering the selection of participants, the RADP strategy is improved. Its optimization goal is as follows:

$$\text{MSensing: } \max v(w) \sum_{i \in w} b_i. \quad (7)$$

MAA utility function [26] is as follows:

$$S(x) = \sum_{m=1}^M \omega_m S(x_m), \quad (8)$$

$$\sum_{m=1}^M \omega_m = 1.$$

Then, the optimization objectives of MAA are as follows:

$$\text{MAA: } \max S(x_i), \quad i \in \mu. \quad (9)$$

If the policy is platform-centric, the optimization function is as follows:

$$\text{GBMC: } \max \frac{W'_i}{b_i}, \quad (10)$$

$$\text{ISAM: } \max \frac{d_i}{b_i = \min E(y'_i - y_i)^2 / b_i}, \quad (11)$$

where b_i is the user’s bidding price; w is the chosen winner. And $S(x_m)$ refers to the utility function of attributes; Generation w_m refers to attribute weight; M can represent the number of attributes; W'_i of formula (9) is interpreted as the range that the user can perceive; y'_i and y_i can be interpreted as estimated mean and accurate mean, respectively.

TABLE 1: Compare the performance of the consensus algorithm.

Consensus algorithm name	Characteristics of algorithm	Efficiency	Aggressive resistance	Applicable scenarios
Solo [20]	Single-node consensus model; there is no high availability and scalability	High	Low	Alliance chain or private chain
Kafka [21]	High throughput, low latency, no intentional evil node	High	Low	Alliance chain or private chain
PBFT [22]	Consistency, security, and the number of malicious nodes do not exceed 1/3	High	High	Alliance chain [23]
POW	The hash function is the core; decide who gets out of the block by the calculation difficulty value	Low	High	Public chain
POS	Provide incentive mechanism; it is an improvement of POW	Low	High	Public chain

2.3.2. *Trust Management.* Updatable ways to manage reputation values:

$$\begin{aligned} r_i &= \beta r_i(t) + \alpha r_i^-, \\ \alpha + \beta &= 1, \end{aligned} \quad (12)$$

$$r_i(t) = \frac{(p(t) + \varepsilon)}{(p(t) + n(t) + \varepsilon)}$$

Redefine according to credible value:

$$\text{TSCM: } \max_{i \in w} \sum v_i^r - \frac{b_i}{r_i} \quad (13)$$

3. Research on Perceptual Integrity of Group Intelligence Based on AWTC-TT

3.1. *Evaluate Perceived Quality.* Data quality includes accuracy, completeness, consistency, and other attributes. Exploring the integrity of perceived data is an important aspect to ensure the quality of information data. When the data in the database is input, it may lead to input errors or invalid data due to various reasons. Therefore, integrity is put forward to ensure that the data of data digital media conforms to the rules. Generally speaking, data integrity mainly refers to accuracy and reliability, and this experiment will be based on these two points. In addition, the integrity of data can be divided into three categories: domain, entity, and reference.

Before formally exploring completeness, it is necessary to establish standards to evaluate the quality of perceived data. The higher the quality of the data collected, the higher the return given; low returns should be given to low-quality data that fail to meet the standards. Data classification and sorting algorithms are used for evaluation. It is worth noting that every evaluation standard should be based on energy data. Use the following data set:

$$D = \{D_1, D_2, \dots, D_m\}, \quad (14)$$

$$C = \{C_1, C_2, \dots, C_k\}, \quad (15)$$

$$Z = \{(Z_1^{\min}, Z_1^{\max}), (Z_2^{\min}, Z_2^{\max}), \dots, (Z_k^{\min}, Z_k^{\max})\}. \quad (16)$$

Among them, formula (14) describes the data collected about the task. Formula (15) represents the criteria used for data quality assessment. Formula (16) represents each quantifiable effective range, which is related to the evaluation value of the evaluation standard. Get the evaluation value:

$$s_{i,j} = f_j(D_i). \quad (17)$$

The evaluation value matrix is obtained:

$$S = \begin{bmatrix} s_{1,1} & \dots & s_{1,k} \\ \vdots & \ddots & \vdots \\ s_{m,1} & \dots & s_{m,k} \end{bmatrix}. \quad (18)$$

(1) Classify

Before judging whether the evaluation requirements are met, calculate the deviation degree. Negative correlation:

$$e_{i,j} = \begin{cases} \frac{s_{i,j} - z_j^{\min}}{z_j^{\max} - z_j^{\min}}, & z_j^{\min} < s_{i,j} < z_j^{\max} \\ 1 + \omega, & \text{other.} \end{cases} \quad (19)$$

Positive correlation:

$$e_{i,j} = \begin{cases} \frac{z_j^{\max} - s_{i,j}}{z_j^{\max} - z_j^{\min}}, & z_j^{\min} < s_{i,j} < z_j^{\max} \\ 1 + \omega, & \text{other.} \end{cases} \quad (20)$$

Determine whether the maximum value meets the requirements:

$$e_i^{\max} = \max\{e_i\} = \max\{e_{i,1}, e_{i,2}, \dots, e_{i,k}\}. \quad (21)$$

(2) Quality ranking

Single deviation vector:

$$\begin{aligned} e_i &= (\theta_1 e_{i,1}, \theta_2 e_{i,2}, \dots, \theta_k e_{i,k}), \\ \sum_{j=1}^k \theta_j &= 1. \end{aligned} \quad (22)$$

Bias vector of population:

$$r_i = \left(\sum_{j=1}^k (\theta_j e_{i,j})^2 \right)^{1/2}. \quad (23)$$

Sort the data of HD and LD collections according to the result size. The smaller the value, the higher the quality; the larger the value, the worse the quality. This also shows the integrity of the data.

3.2. Fusion and Optimization Design. In order to meet the requirements of digital media diversification and integrate data resources. In order to find out the excellent model and analyze the data integrity, we tried the fusion design of various methods. First of all, we consider that IoT sensors are closely related to terminal devices such as digital media, coupled with the network support of 5G technology. Secondly, in order to improve the transaction speed of each group intelligence-aware service, we choose to join edge computing. This technology can help reduce the pressure on the cloud center, support mobility and meet the high requirements of digital media devices for network delay, and can better sense the location. Its characteristics are in line with the research direction of this subject. In addition, blockchain can be effectively combined with edge computing, and the published perception tasks can be accounted for by blockchain, while edge nodes can cooperate with other nodes to run together. The data-sharing infrastructure is initially established, and a formal hybrid model will be designed based on this architecture, as shown in Figure 1:

3.3. Model Building. Aiming at the distributed digital media, we publish tasks through the group intelligence sensing network to obtain high-quality sensing data of various terminal devices. Record the transaction information of each perceived service through the blockchain of edge computing. The hybrid model we built is mainly composed of three parts. Blockchain, group intelligence perception, and edge computing are integrated, and the division of labor cooperates with each other. Various terminal devices of digital media upload data; task publishers and perception participants of group intelligence perception query records through blockchain; the blockchain of edge computing serves as a storage network for data transmission, as shown in Figure 2:

4. Experimental Analysis

4.1. Experimental Setup. Before the simulation experiment, we need to prepare the test environment. Limited by space, we show the most important software and hardware of blockchain here, as shown in Table 2 and Blockchain transaction information table is shown in Table 3.

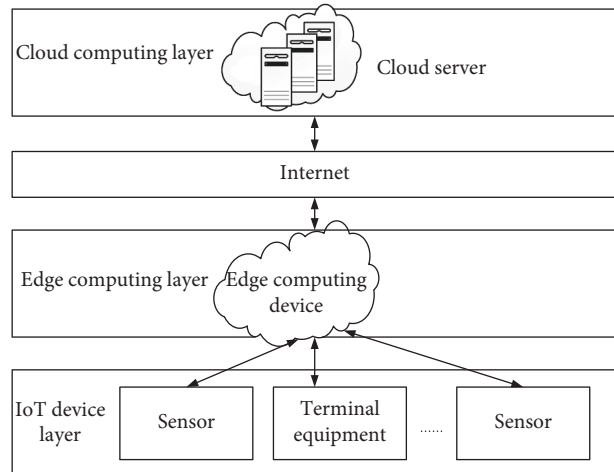

FIGURE 1: Data sharing architecture.

In the fourth round of the AFC Champions League group match, both sides started. Adam3 appeared in China mobile.

Before the simulation experiment begins, it is necessary to preprocess all the collected data. Otherwise, the data are not defined and quantified and cannot be used directly. In the experiment, the task publishers of group intelligence perception released a total of 200 task indicators to perceive the data of digital media terminals.

4.2. Comparison of Model Algorithms. First, in this section, we deploy the model architecture and the corresponding test network and conduct data transactions for 200 tasks. First, we confirm the overall data transaction time of the hybrid model. According to the curve showing an upward trend, we can find that the time spent processing transaction tasks increases with the increase in the number of published tasks. This shows that the average time for the algorithm to run and generate accounting blocks is also increasing. Under the limit of 200 tasks, the average processing time of the model is maintained within 1 minute, and the experimental results are acceptable to users, as shown in Figure 3.

We test the performance of the AWTC-TT algorithm used in the model. Compare the data perception time of the model and the performance loss of the algorithm before and after the application of the optimization algorithm. Nodes package data records into blocks, reach consensus at different edges and connect to the blockchain. The running time of the algorithm is mainly affected by the number of edge nodes. On the whole, the running time of AWTC and AWTC-TT increases with the increase of the number of nodes. However, it can be clearly found that the time of the AWTC-TT algorithm is obviously lower than that of an unoptimized algorithm. The time of the AWTC algorithm in 50 nodes is as high as 1 minute, while the optimization algorithm is only 27.8 s. Until the number of nodes increases to 60, the time spent by the optimization algorithm still does

FIGURE 2: Group intelligence perception hybrid model based on blockchain.

not exceed 50 s, and the highest time can reach 43.9 s. In the comparison of algorithm performance loss, the performance of AWTC-TT is still excellent: in initialization, the performance loss is 20% less than that of AWTC; In the process of

formal calculation, the loss rate of AWTC does not increase with the increase of nodes, and basically maintains at about 4%, while the loss rate of AWTC is as high as 10%, as shown in Figure 4.

FIGURE 3: Model transaction time.

FIGURE 4: Algorithm performance.

4.3. Perception Result Evaluation

4.3.1. Perceived Quality Assessment. The quality of data perception determines the perception integrity to a great extent. Select the data set of sensing device temperature for the experiment, and let the model randomly generate 100 request tasks. Performance gain, time error, position, and data similarity are analyzed. Here, the performance gain formula is as follows:

$$\text{Gain} = \frac{\sum_{i=0}^{[\alpha N]} (M_i^D - M_i^T)}{[\alpha N]}. \quad (24)$$

The smaller the error between task time and perceived data measurement time, the higher the reliability. Time error:

$$s_{\text{Time}} = |t_{\text{task}} - t_{\text{data}}|. \quad (25)$$

The difference between the specified node position and the perceived data position: the closer they are, the higher the confidence. Position error:

$$s_{\text{Location}} = \left((H_{\text{task}} - H_{\text{data}})^2 + (V_{\text{task}} - V_{\text{data}})^2 \right)^{1/2}. \quad (26)$$

The degree of similarity between data determines the reliability of data:

$$s_{\text{Similarity}} = \frac{\sum_{j=1}^m \varphi_{i,j}}{m-1},$$

$$\varphi_{i,j} = \begin{cases} 1 - \frac{|\text{val}(D_i) - \text{val}(D_j)|}{\text{val}_{\max} - \text{val}_{\min}}, & i \neq j \\ 0, & i = j. \end{cases} \quad (27)$$

We measure the gain value of location, time, and similarity. Here, 0 to 1 of the abscissa represents the percentage index of perceived data. According to the trend of the column chart, we can find that the gain value of 40% of previous data is generally greater than 0.3. However, the gain value of the last 50% to 100% of the perceived data is between 0 and 0.3, which is of low quality. This is because the higher the data quality, the closer the value is to the real result, and the higher is its ranking. In addition, from the chart, we can also find that location's data results have the highest performance advantage, so it is the highest column chart among the three indicators. The second is the time index, which can reach a gain value of 0.55 at the highest; among the three, the weakest advantage is the similarity index, and the highest Gain value is 0.43, as shown in Figure 5:

4.3.2. Data of Abnormal Interference. If there is abnormal interference from problematic data in the data, it will also affect the integrity of the perceived data. After quality evaluation, we can successfully judge the high-quality class in the data. We then test the ability of this model method to distinguish abnormal data and test the proportion of non-abnormal data in high-quality data. We set four different digital media application scenarios, A, B, C, and D, collected four perceptual data sets, and set the total evaluation value to 1. According to the increase of abnormal data in the four groups in the figure, the curve fluctuation of Group A and Group B is small, and the proportion of high-quality data is basically maintained at over 90%, which has a good evaluation effect on data integrity. However, the non-abnormal data of Group C and Group D decreased with the increase of abnormal data, and the curve decreased very quickly, always reducing to about 50%. Generally speaking, the method in this paper has a good effect on the perceptual integrity analysis of digital media. However, there are still some scenes with poor analysis results, as shown in Figure 6:

4.3.3. Perception Result Analysis. This experiment is mainly to test the effective integrity of the data in the perception process with the change of iteration times. Let 2000 pieces of data information go through 60 iterations. According to the changes of submitted data, we formulate the changing trend of data integrity. We can find that with the change of iteration times, the average data quality, accuracy, and reliability curve are gradually improved after perceptual processing. Among them, after 60 iterations, the accuracy can be as high as 96%; the reliability and trust of data is about 70%; the average quality of 2000 pieces of data is about 80%. Although the initial fluctuation is large, the data follow-up is

FIGURE 5: Gain effect of data quality.

FIGURE 8: Perceived revenue changes.

FIGURE 6: Data interference.

FIGURE 7: Change trend of perception results.

relatively stable. However, the curve of a malicious attack on data gradually decreases from 45% to about 13%. To sum up, the data integrity analysis results perceived by the model are very good, as shown in Figure 7:

4.3.4. *Perceived Income Distribution.* We set a reliability value of 0 to 10 and compare the revenue values of CS1, CS2, and CS3. The higher the perceptual quality, the higher the benefit of perceptual distribution. We can find that the

maximum return value of CS1 is 2.6; the biggest beneficiary of CS3 is 4.7; the maximum profit value of CS2 is 5.8, and the distribution effect for perceived quality is the best, as shown in Figure 8:

5. Conclusion

In recent years, thanks to the rapid development of the Internet of Things and 5G technology, Internet of Things terminal devices are all over people’s lives. With the application of digital media, all kinds of data increase rapidly, which brings many challenges to human technology. Based on distributed group intelligence perception, aiming at exploring the integrity performance in the process of data sharing, a model framework with a reasonable structure is constructed, and blockchain technology is applied to practical applications. The idea of this paper focuses on the integrity of perceptual data. Through the experimental results, the feasibility of the proposed method and the feasibility of the AWTC-TT algorithm are verified. According to the characteristics of nodes, this paper solves the problem of deploying blockchain at edge nodes. Increase the number of network nodes, improve the quality of data, and also improve the transaction speed of data sharing. It ensures the fault tolerance of the model, effectively analyzes the performance of simulated data, and improves the calculation efficiency. This article has the above results, but the subject of research is not perfect, and there are still some defects and missing places. In the future research and development direction, there are still many jobs that can be optimized and refined. For example, optimize the parameters and set the model framework more reasonably; try to optimize more algorithms in blockchain technology and explore more technologies for integration; there is no unified experimental standard, so data authentication should be improved; a visual front-end interface should be developed to increase visual effects, so as to build a formal system platform according to the model framework; further optimize and improve data processing performance, reduce the loss of algorithm performance, improve computational efficiency, and meet the application in real application scenarios; data

confidentiality should also be carried out for various messages in digital media to ensure security and credibility.

Data Availability

The experimental data used to support the findings of this study are available from the corresponding author upon request.

Physical education is not only an important part of national education but also one of the important means to improve the physical quality of students and citizens. Therefore, the reform of physical education is of great significance to the development of physical education. With the application of data mining technology in the field of physical education, the scale of relevant data increases rapidly. The traditional data analysis methods cannot meet the needs of physical education data analysis. Traditional data analysis methods still have many basic problems to be solved. For example, the professionalism of the structural model and standardization of formal expression are dwarfed by the forefront of the world. There are few real valuable data in the database, and the referentiality is not guaranteed. Therefore, this study puts forward the construction and analysis of discrete system dynamic modeling of physical education teaching mode based on the decision tree algorithm. Through the decision tree algorithm, this study analyzes the data related to physical education and constructs the physical education decision tree system according to the analysis structure. The test results show that the primary influencing factor of physical education teaching is the number of students participating in sports competitions, and the secondary influencing factors are students' liking and teachers' skill level. In addition, teachers' adjustment of physical education teaching contents and methods according to the analysis results of decision tree is conducive to improving students' physical education performance.

1. Introduction

With the rapid development of computer technology, computer technology has been applied to various fields. With the development of various network technologies, the development of computer technology has also brought broad prospects to the modernization of physical education. It also brings unprecedented challenges and opportunities to educators. When the network changes people's way of work, study, thinking, and communication at an amazing speed, the traditional classroom, textbook, and teacher centered teaching mode has also been impacted by the computer network, and the physical education mode should be reformed with the changes of the times. If the traditional teaching mode and scientific teaching method cannot be updated in time, it will cause some outdated teaching

methods cannot be updated in the field of physical education. As an important part of the education system, physical education not only has commonness with other educational disciplines but also has its own characteristics. Sports itself is the integration of humanities and natural sciences. These determine that the physical education discipline is an open, developing, and innovative system.

Physical education is an important part of national quality education. It can not only help students effectively enhance their physique and improve their physical quality but also help students adjust their emotions and improve their psychological state, so as to maintain their physical and mental health [1]. At the same time, the practical course in physical education teaching is an effective and rapid method for students to understand and master corresponding knowledge and skills. With the continuous improvement of

computer technology and the implementation of the domestic education reform system, great changes have taken place in the teaching content and teaching mode of physical education, and the evaluation standard of physical education teaching quality has also changed [2]. Therefore, it has become a research hotspot of physical education reform to understand the influencing factors of physical education teaching quality through physical education teaching evaluation and improve targeted and effective physical education teaching. Modern teaching equipment and management system have produced a large number of relevant data in the application of physical education. If the previous manual means are used to analyze and process these data, it will produce large time cost and labor cost [3]. In addition, it is difficult to quickly analyze the relationship between physical education teaching data in a short time by manual means and determine the factors affecting the quality of physical education teaching according to different courses. Data mining can process and analyze massive data according to the given target task, combined with the technology of machine learning, database, statistics, and other disciplines, and present the effective information that people can understand, extracted from massive data, so as to provide reference statistical analysis data results for people's decisions.

Therefore, this study puts forward the construction and analysis of discrete system dynamic modeling of physical education teaching mode based on the decision tree algorithm, in which the decision tree algorithm is an inductive learning algorithm that can reason in a group of irregular and sequential examples in data mining technology and summarize the expression form of decision tree. Through the construction of the decision tree algorithm to find the potential relationship between various factors of physical education teaching and teaching mode, the corresponding teaching side improvement strategies are obtained. This study is mainly divided into three parts. The first part expounds the development and current situation of data mining. The second part is the construction of the physical education teaching model based on the decision tree algorithm. The third part tests and analyzes the results of the physical education teaching model system based on the decision tree algorithm.

2. Related Work

The popularity of the Internet makes the data in databases in various fields grow at a geometric multiple rate, and the technology of data mining and analysis is also developing [4]. In the era of big data, data mining has been applied in the field of education, which provides data support for the improvement of education and has achieved good results. Some foreign scholars have conducted data mining and corresponding in-depth analysis and research on the education data in the ten years since 1995, concluded the necessity and importance of corresponding research on student data in the field of education, and provided research and analysis results for students, education-related workers, and managers [5]. In addition, foreign scholars apply data

mining technology to the analysis of students' classroom behavior, correct students' wrong behavior in the classroom through the results of data analysis, and formulate targeted teaching measures to help students correct misconduct and improve their grades [6]. In the process of research, some scholars found that there is a certain relationship between students' academic performance and the nature of the school, and the level of socioeconomic status has different effects on the performance of boys and girls [7]. Through the regression analysis algorithm in data mining technology, some scholars have shown that students' parents and their family income are closely related to students' academic performance [8]. Wang used analysis of variance to conclude that students who participate in after-school activity groups usually have better grades. Other scholars have studied the relationship between students' performance and achievement through data mining technology and hope that this research result can provide some guidance for scaffolding teaching [9].

Compared with foreign countries, the application of data mining technology in the field of education in China was about 2001. It was not until the creation of the International Journal of Educational Data Mining in 2009 that China gradually paid attention to the application of data mining technology in the field of education [10]. By 2013, education data mining in its infancy has ushered in an important turning point, and then, China's education data mining began to enter the stage of rapid development. Therefore, compared with foreign countries, the development time of educational data mining in China is relatively short, and there is a certain gap in the breadth and depth of research. In recent years, the research on educational data mining in student modeling, achievement prediction, and learning resource recommendation system is gradually increasing. Based on the research on the current distance education system, some scholars proposed to make up for the deficiency of the distance education system framework through data mining technology, so that network education can give full play to its advantages and continuously improve the quality and level of network teaching [11]. Other scholars have deeply analyzed and elaborated the satisfaction data of college students obtained through data mining technology from the perspective of learning, mined the influencing characteristic factors of college students' learning characteristics and behavior on satisfaction, and verified and analyzed the relationship between them. Their research results provide effective data reference for talent training in colleges and universities [12]. Some scholars analyze the data information generated by students in the process of online English learning through the decision tree algorithm in the data mining algorithm to predict the test results of online English and provide corresponding suggestions and strategies for improving students' English test clearance rate [13]. In addition, some scholars use the ID3 decision tree algorithm to manage and analyze the results of business English practice examination and put forward targeted improvement evaluation and suggestions on the course content according to the data analysis results, thus promoting the reform of teaching quality evaluation

management [14]. But at present, the research on data mining in physical education teaching is still relatively few, and it is still in the preliminary development stage, so more research and practice are needed.

3. Construction of the Physical Education Teaching Model Based on the Decision Tree Algorithm

3.1. Design of the Physical Education Teaching Mode System Based on the Decision Tree Algorithm. Physical education teaching includes not only theoretical knowledge teaching but also practical teaching, which affect and assist each other. Therefore, the application of data mining technology in the field of physical education can count and analyze a large number of relevant curriculum data and realize the analysis and query of students' physical education achievements. According to the results of students' performance analysis of different sports, we can reasonably plan the physical education curriculum, make the physical education teaching mode conform to students' actual physical quality and interests, and finally improve students' enthusiasm to participate in physical education curriculum and carry out personalized physical education on the basis of basic teaching. In physical education class, use light, lively, and interesting music or games to replace the preparation of boring and repeated running. It can create a relaxed and harmonious teaching atmosphere, improve students' learning enthusiasm, and receive good teaching results. Stimulate interest in classroom teaching; teachers should give full play to their language advantages and use enlightening questions, which will effectively arouse students' interest in exploring new causes and arouse students' desire for knowledge. As shown in Figure 1, it is the system framework of physical education teaching mode based on the decision tree algorithm.

In the process of physical education teaching, we need to carry out the fragment teaching of physical education theoretical knowledge points and then master and apply the knowledge points in combination with physical education practice. This requires teachers to explain the knowledge points of each part through horizontal, vertical, systematic, and expansionary ways in physical education teaching. Students choose one or a combination of multiple ways to learn according to their own actual situation and objective environment. In this way, teachers can also carry out personalized teaching according to the learning situation of different students and realize classified teaching. Decision analysis is an important part of the physical education teaching mode system based on the decision tree algorithm. The result of decision analysis is based on students' learning state, physical education teaching content and methods, and knowledge points. It is a long-term dynamic process of data statistics, analysis, and mining. Therefore, the data scale of decision analysis is the decisive factor affecting the accuracy and reliability of decision analysis results, and the decision results will change with the continuous accumulation of data and the change of environmental conditions.

The decisive factors affecting the accuracy and reliability of decision analysis results are the stability of the environment. When the environment is relatively stable, the decision-making made by the organization for similar embryos in the past has a high reference value because the environment faced in the past decision-making is similar to that at present. Market structure: decision-making usually focuses on how to pay close attention to the movements of competitors. The degree of informatization of the organization: organizational decision makers with a high degree of informatization usually have more advanced decision-making means.

Figure 2 shows the application structure of the decision base of physical education teaching mode based on the decision tree algorithm.

3.2. Thinking and Construction of Decision Tree Application. The most important algorithm in the decision tree generation algorithm is ID3 interactive diesel version 3, which was first proposed by Quinlan. Its basic idea is to use mutual information (or information gain) in information theory. As a measure of the classification and discrimination ability of decision attributes, the decision node attributes are selected. In the ID3 algorithm, the concept of entropy in information theory is applied to select the attributes of decision nodes, and the decision tree is established through the attributes with maximum information gain (or maximum entropy compression). The node attributes selected in this way ensure that the decision tree has the minimum number of branches and the minimum redundancy 2.

Decision tree is to recursively search the classification rules in irregular cases from top to bottom through information gain in the form of tree view. In the process of decision tree data classification, it is necessary to analyze and test the obtained dataset and construct the data classification model of physical education teaching mode according to the results. Each decision node of the decision tree is a test point for attribute value comparison. Each branch is a test output of different attribute values, and each leaf node represents the obtained conclusion. The branches formed by the decision tree reflect the data in the training set, that is, in addition to the normal classification, there are abnormal conditions, which is easy to cause excessive data. Therefore, the decision tree needs to be pruned accordingly to remove the abnormal branches, so as to ensure the accuracy of the results. The general idea of the application of decision tree in physical education teaching mode is to construct a decision tree containing the attribute values of each index according to the data of physical education teaching mode and obtain the important influencing factors of physical education teaching by sorting the given index set.

Decision tree strategy: divide and rule from top to bottom.

- (i) The recursive process from root to leaf finds a "partition" attribute at each intermediate node
 - (i) Start: build the root node. All training data are placed in the root node, and - optimal features

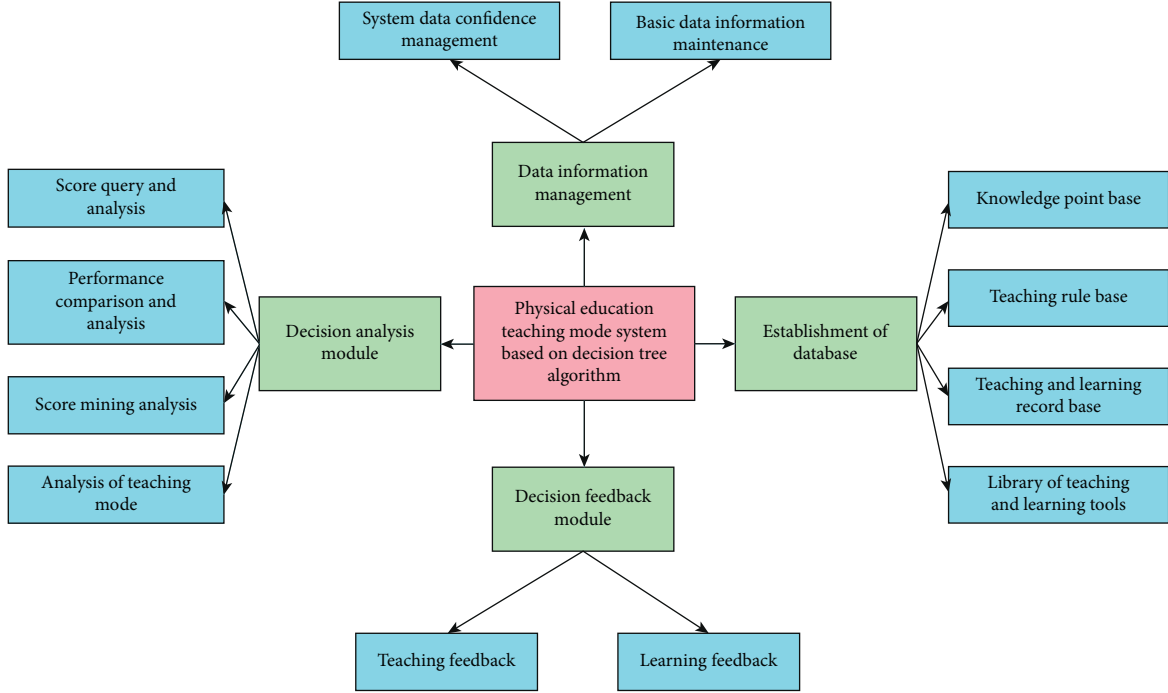

FIGURE 1: System framework of physical education teaching mode based on the decision tree algorithm.

are selected. According to this feature, the training dataset is divided into subsets and entered into subnodes.

- (ii) All subsets are recursively divided according to the attributes of internal nodes
- (iii) If these subsets can be classified basically correctly, build leaf nodes and distribute these subsets to corresponding leaf nodes
- (iv) Each subset is divided into leaf nodes. In this way, a decision tree is generated.

Suppose that the two-dimensional structure data sample set L contains three knowledge point attribute fields and one teaching means attribute field, each knowledge point contains different attribute sets, that is, the knowledge point K_1 is divided into three levels and expressed as $\{A_1, A_2, A_3\}$, the knowledge point K_2 is divided into two levels and expressed as $\{B_1, B_2\}$, the knowledge point K_3 is divided into three levels and expressed as $\{C_1, C_2\}$, and the physical education teaching means include two ways and expressed as $\{T_1, T_2\}$. If the attribute field scale of the sample collection is n and an attribute field of the knowledge point is K_i and $i \in \{1, 2, \dots, n\}$, the corresponding information entropy is shown in the following formula:

$$I(K_i) = - \sum_{i=1}^n p_i \log p_i, \quad (1)$$

where p_i in the formula represents the probability of occurrence of corresponding attribute value, and each field is independent of each other.

Let $|T_i|$ represent the scale of T_i ; then, the information entropy of field L in sample set T is shown in the following formula:

$$I(T) = \left(-\frac{|T_1|}{|T|} \log_2 \frac{|T_1|}{|T|} \right) + \left(-\frac{|T_2|}{|T|} \log_2 \frac{|T_2|}{|T|} \right). \quad (2)$$

Let $|T_i^{A_i}|$ represent the scale of the field corresponding to A_i ; then, the information gain of knowledge point K_1 is shown in the following formula:

$$I(A_i) = \left(\frac{|T_1^{A_i}|}{|T_1^{A_i}| + |T_2^{A_i}|} \log_2 \frac{|T_1^{A_i}|}{|T_1^{A_i}| + |T_2^{A_i}|} \right) + \left(\frac{|T_2^{A_i}|}{|T_1^{A_i}| + |T_2^{A_i}|} \log_2 \frac{|T_2^{A_i}|}{|T_1^{A_i}| + |T_2^{A_i}|} \right). \quad (3)$$

The income of knowledge point K_1 is shown in the following formula:

$$E(K_1) = \frac{|A_1|}{|K_1|} I(A_1) + \frac{|A_2|}{|K_1|} I(A_2) + \frac{|A_3|}{|K_1|} I(A_3). \quad (4)$$

The gain is shown in the following formula:

$$G(K_1) = I(T) - E(K_1). \quad (5)$$

Similarly, if the T_1 scale of the attribute value B_i in the knowledge point K_2 is expressed as $|T_1^{B_i}|$ and the T_2 scale is expressed as $|T_2^{B_i}|$, the information gain is shown in the following formula:

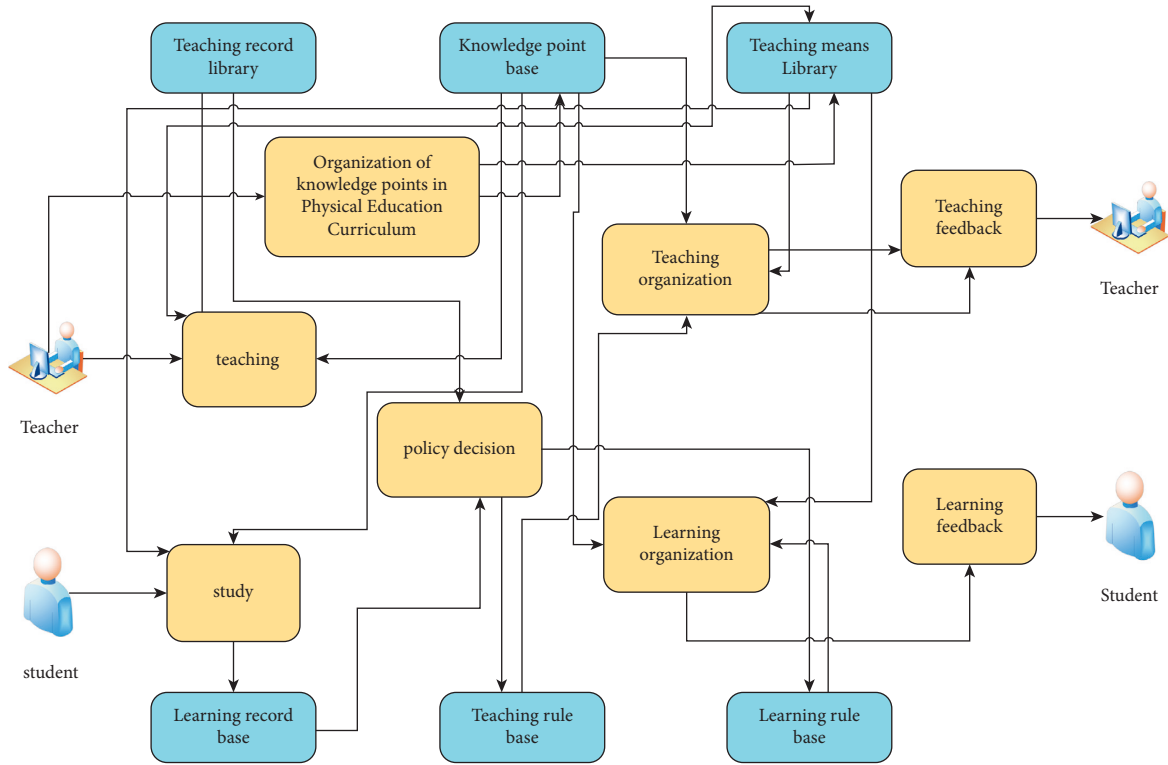

FIGURE 2: Application structure of decision base of physical education teaching mode based on the decision tree algorithm.

$$I(B_i) = \left(-\frac{|T_1^{B_i}|}{|T_1^{B_i}| + |T_2^{B_i}|} \log_2 \frac{|T_1^{B_i}|}{|T_1^{B_i}| + |T_2^{B_i}|} \right) - \left(-\frac{|T_2^{B_i}|}{|T_1^{B_i}| + |T_2^{B_i}|} \log_2 \frac{|T_2^{B_i}|}{|T_1^{B_i}| + |T_2^{B_i}|} \right). \quad (6)$$

The income of knowledge point K_2 is shown in the following formula:

$$E(K_2) = \frac{|B_1|}{|K_1|} I(B_1) + \frac{|B_2|}{|K_2|} I(B_2). \quad (7)$$

The gain is shown in the following formula:

$$G(K_2) = I(T) - E(K_2). \quad (8)$$

Let the T_1 scale of the attribute value C_i in the knowledge point K_3 be expressed as $|T_1^{C_i}|$, and the T_2 scale be expressed as $|T_2^{C_i}|$, and its information gain is shown in the following formula:

$$I(C_i) = \left(-\frac{|T_1^{C_i}|}{|T_1^{C_i}| + |T_2^{C_i}|} \log_2 \frac{|T_1^{C_i}|}{|T_1^{C_i}| + |T_2^{C_i}|} \right) - \left(-\frac{|T_2^{C_i}|}{|T_1^{C_i}| + |T_2^{C_i}|} \log_2 \frac{|T_2^{C_i}|}{|T_1^{C_i}| + |T_2^{C_i}|} \right). \quad (9)$$

The income of knowledge points K_3 is shown in the following formula:

$$E(K_3) = \frac{|C_1|}{|K_3|} I(C_1) + \frac{|C_2|}{|K_3|} I(C_2). \quad (10)$$

The gain is shown in the following formula:

$$G(K_3) = I(T) - E(K_3). \quad (11)$$

Then, calculate and compare the results according to the attribute values contained in the corresponding knowledge points. For example, the results are shown in the following formula:

$$G(K_2) > G(K_1) > G(K_3). \quad (12)$$

It means that among the physical education teaching knowledge points in the sample set, the information gain of knowledge point K_2 is the highest and the information gain of knowledge point K_3 is the lowest. Therefore, the tree root of the physical education teaching decision tree is knowledge point K_2 , which is constructed on this basis. In Figure 3, the frame diagram of physical education teaching decision tree based on knowledge point K_2 is shown.

According to the node path of the above decision tree, build a rule with the leaf node attribute value T as the rule tail and the nonleaf node attribute value $K_1 \wedge K_2 \wedge K_3$ as the rule head and obtain the probability of T under the rule, that is, confidence λ . For example, the rule that the size of knowledge points is three is shown in the following formula:

$$K_1 \wedge K_2 \wedge K_3 \Rightarrow T, \lambda. \quad (13)$$

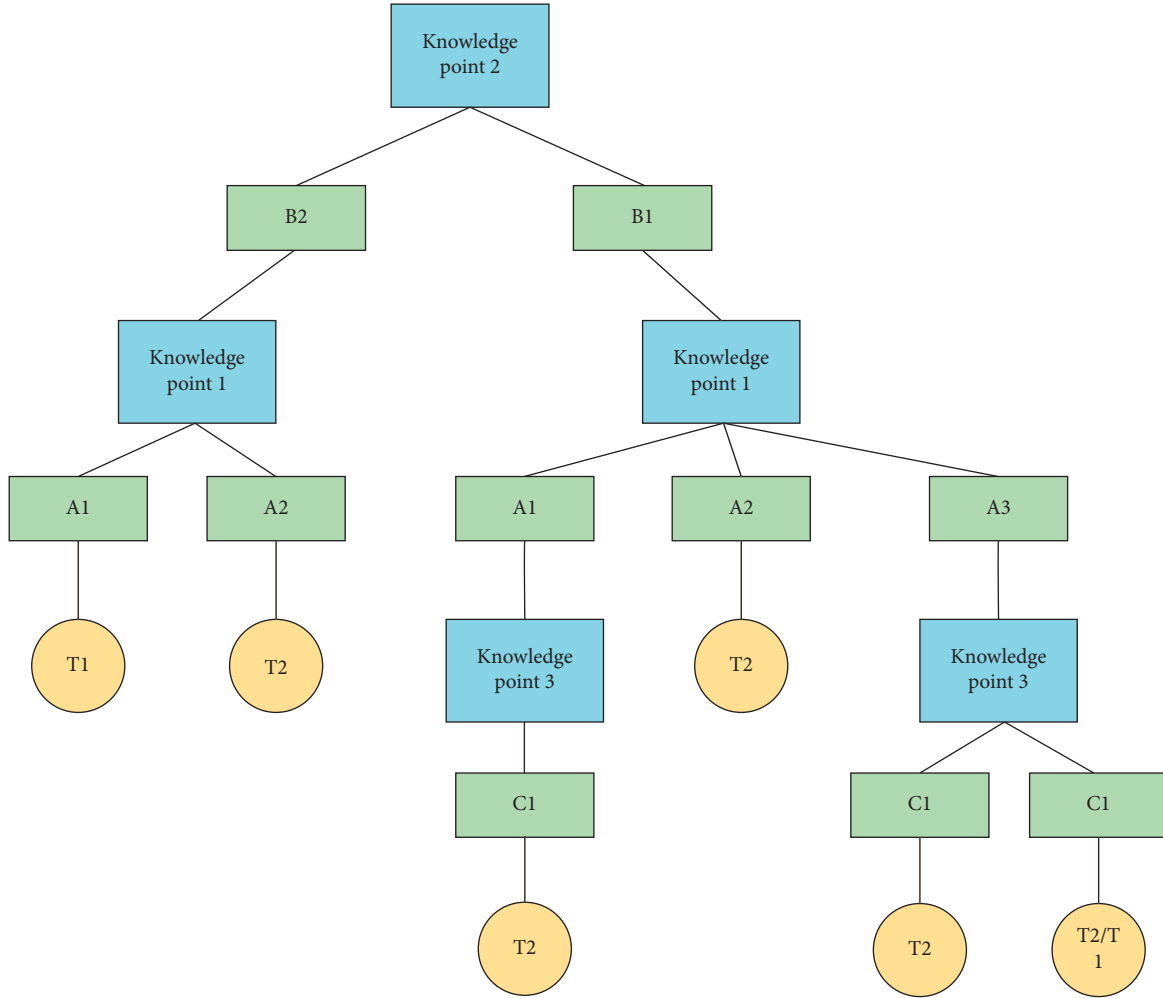

FIGURE 3: Frame diagram of physical education decision tree based on knowledge point K_2 .

The corresponding confidence is shown in the following formula:

$$\lambda = \frac{P_r(k_1 \cup k_2 \cup k_3 \cup T)}{P_r(k_1 \cup k_2 \cup k_3)}, \quad (14)$$

where $P_r(k_1 \cup k_2 \cup k_3 \cup T)$ in the formula represents the probability value of the corresponding four attributes and $P_r(k_1 \cup k_2 \cup k_3)$ represents the probability value of the corresponding three attributes.

The rule that can be obtained according to the physical education decision tree is not the only one, and the physical education teaching method can be selected according to the rule. For example, when the knowledge point 1 is A_1 , the knowledge point 2 is B_1 , and the physical education teaching method is T , the confidence λ expression is shown in the following formula:

$$K_1(A_1) \wedge K_2(B_1) \Rightarrow T(T_1), \lambda. \quad (15)$$

4. System Test of Physical Education Teaching Mode Based on the Decision Tree Algorithm

In this study, 350 students in a certain university are randomly selected as the test objects of the physical education teaching mode system based on the decision tree algorithm. A variety of data collection methods are adopted to collect the basic information of students, and a physical education student database is constructed. Among them, the basic information of students has four basic indicators including students' grade, gender, intelligence level, and physical quality. At the same time, it also makes investigation and data statistics on students' physical education achievements, their love for physical education courses, current physical education teaching contents and methods, their participation in physical education competitions, and the evaluation of the physical education teaching effect. As shown in Figure 4, it is the statistics of eight attribute status of some groups of the training set of analysis variables selected by the test. Among them, the students' intelligence level, physical

FIGURE 4: The tested eight attribute status statistics of some groups of the selected analysis variable training set.

quality, and physical performance are divided into four levels, namely, unqualified, qualified, good, and excellent, which are expressed by the values of 0, 1, 2, and 3, respectively. Students' liking for physical education teaching is divided into like and dislike, that is, the numerical value 1 indicates like and 2 indicates dislike. The number of times students participate in sports competitions is divided into three levels, that is, they have not participated, participated once or twice, and participated more than three times, which are expressed by the values 1, 2, and 3, respectively. Physical education teaching means are also divided into three levels, that is, one teaching means, two to three teaching means, and more than three teaching means. The subtable is expressed in 1, 2, and 3. Teachers' skill levels are divided into national level, level I, and level II, which are expressed by the values 3, 2, and 1, respectively.

When the number of samples is small but the number of features is large, the decision tree is easy to over fit. For one thing, if the number of samples is more than the number of features, it will be easier to establish a robust model. When there are many features, PCA (principal component analysis), ICA (independent component analysis), and feature selection are preferred. Models that do not need data preprocessing are decision tree, random forest, and ICA. Because they do not care about the value of variables, they only care about the distribution of variables and the conditional probability between variables.

Remove the samples in the unqualified training set, set the remaining samples to the random seed mode, and select the sampling mode as random, in which 80% of the effective information is randomly selected as the training sample and the remaining 20% as the test sample. The training sample is

applied to the construction of influencing factors of the physical education decision tree model. The test sample is to test and evaluate the physical education teaching mode system based on the decision tree algorithm. In this study, C5 decision tree software is selected to realize the node, and the attribute of branch node is the information gain rate with the highest and greater than or equal to the average value of all attributes. In Figure 5, the information gain and information gain rate of physical education decision tree are shown.

As shown in Figure 6, it is the decision tree of physical education teaching mode. It can be seen from the figure that the decision-making of physical education teaching mode takes the number of students participating in physical competitions as the root node, which shows that this factor is the most important factor affecting students' physical education performance. The number of students participating in sports competitions shows that students' sports achievements are in a good state and students' achievements are closely related to sports teaching mode. With the increase of the number of students participating in sports competitions, the excellent rate of sports achievements continues to increase, and the recognition of sports teaching mode will also increase. There are two main reasons for this. On the one hand, in the process of preparing for the competition, PE teachers will carry out targeted teaching and practice according to the characteristics of different students and help students improve the proficiency and accuracy of basic sports actions in repeated practice, which lays an important core foundation for students to participate in sports competitions. At the same time, in the process of participating in the competition, students can also have a new understanding of the basic sports skills and movements

FIGURE 5: Information gain and information gain rate of physical education decision tree.

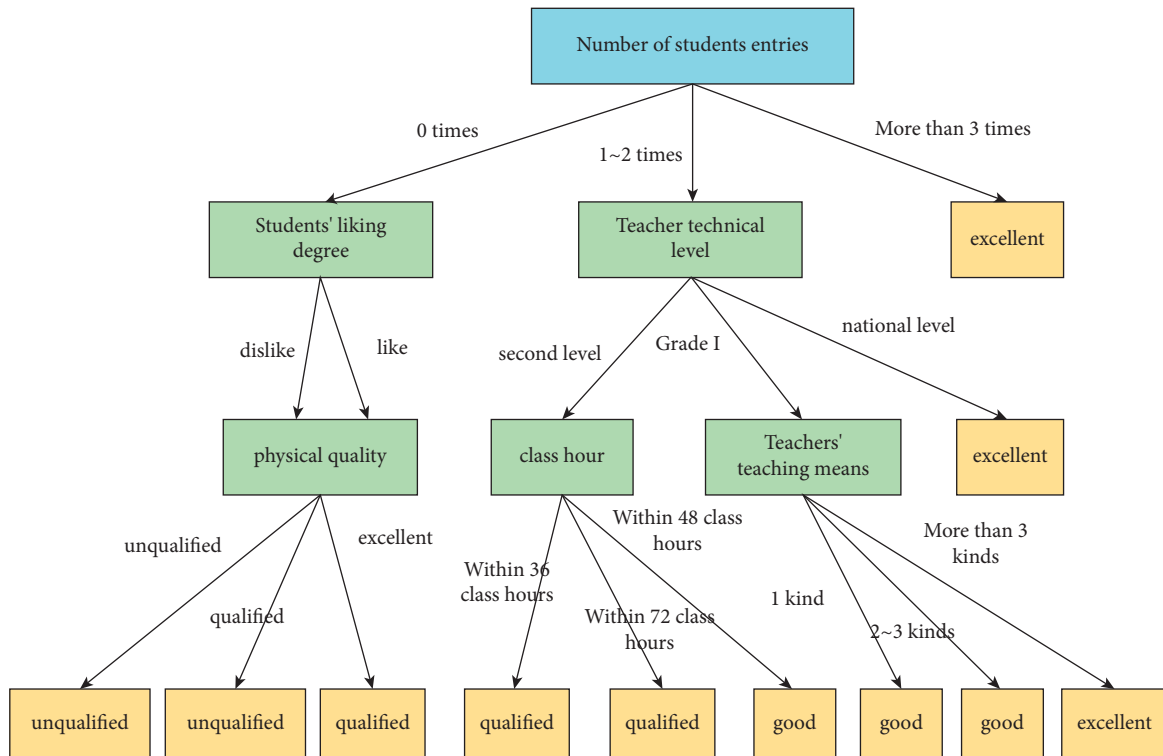

FIGURE 6: Information gain and information gain rate of decision tree.

they have mastered from multiple angles, and the referees and PE teachers can guide students to observe the movements of high-level athletes, which is conducive to improving students' deeper understanding of the participating sports. It can effectively improve the completion ability and

degree of students' sports technical movements. The replay after the competition is also a kind of feedback information for students' learning, which can help students understand their own shortcomings and point out the direction for subsequent exercises. At the same time, teachers can also

FIGURE 7: Comparison of students' achievements after the adjustment of physical education teaching mode.

find the shortcomings of physical education teaching content and teaching mode. Improve physical education teaching according to students' characteristics and current situation. Another reason is that sports competition is a physical education teaching method conducive to cultivating students' on-the-spot performance. Different from the daily physical education teaching environment, sports competition is relatively strange and complex for students, which is easy to affect students' psychological state. This kind of influence may be positive or negative, and the resulting emotions also have positive and negative effects. When participating in sports competitions, students need to actively adjust themselves, overcome the impact of environmental changes, and maintain their stable psychological state, so as to play a good on-the-spot performance ability in the competition.

The influential factor in the decision tree of physical education teaching mode is the students' liking for physical education teaching and the technical level of physical education teachers. Different PE teachers have different teaching styles and teaching methods. Students like the teaching of different PE teachers differently, and their ability to accept the teaching content is also different. Therefore, students' final PE scores are different. Generally, among the students taught by the same PE teacher, the students who like the PE teacher's teaching content and method have higher scores than the students who do not like and have low acceptance ability. Therefore, in the improvement of physical education teaching mode, we should pay attention to cultivating students' interest in physical education and increasing students' enthusiasm in learning physical education teaching content.

There is also a close relationship between teachers' technical level and physical education teaching mode. Physical education teachers with higher technical level can better master the shortcomings of students' basic sports technology and action in the process of teaching, so as to give corresponding guidance and correction.

In addition to the above influencing factors, the diversity of PE teachers' teaching means, the number of PE teaching hours, and students' own physical quality will also affect the effect of PE teaching. The understanding level of different students can be divided into high and low. Teachers who use diversified teaching methods in physical education teaching can help students understand and learn the basic sports knowledge, actions, and skills from different angles, so as to improve students' physical education performance. In addition to learning theoretical knowledge, basic sports movements and skills also need repeated practice. Therefore, a reasonable physical education teaching time can provide students with the necessary opportunities for sports action technology practice, so as to improve students' performance. At the same time, students will also find their own problems in the process of practice and give timely feedback to physical education teachers, and teachers can find the places where their physical education teaching content needs to be strengthened according to students' feedback.

As shown in Figure 7, the results of students are compared after PE teachers adjust PE teaching mode according to the feedback information of decision tree. It can be seen from the data in the figure that after PE teachers adjusted the teaching contents and teaching methods according to the information fed back by the decision tree algorithm, the

good rate of students has been greatly improved and the failure rate has decreased. Although the increase of excellence rate is small, the improvement of good rate lays a foundation for the improvement of excellence rate. This shows that the physical education teaching mode system based on the decision tree algorithm can effectively mine students' performance, behavior, and physical education teaching content and methods, find important influencing factors and the relationship between factors, and provide data support for teachers' adjustment of physical education teaching mode and targeted teaching.

The above discussion is only a beneficial attempt of the application of decision tree data mining technology in the field of physical education teaching in colleges and universities. Data mining refers to the automatic exploratory analysis of a large number of complex datasets by computer. The process of extracting implicit previously unknown and potentially valuable information, rules, and knowledge from massive, high-dimensional, uneven data quality, and random data. It is based on the theory and technology of artificial intelligence, machine learning, pattern recognition, mathematical statistics, database management, parallel computing, and other disciplines. The application of data is upgraded from low-level description and inference to mining knowledge from data, building prediction models and providing decision support. The essential characteristic of data mining technology, which is different from the traditional statistical data analysis, is to obtain the previously unknown, effective, and practical information, rules, and knowledge through data mining methods without explicit assumptions. The introduction of data mining technology into the research field of college physical education teaching will give fresh vitality to the development of college physical education.

5. Conclusion

This study puts forward the construction and analysis of discrete system dynamic modeling of physical education teaching mode based on the decision tree algorithm and analyzes and mines the relevant physical education teaching data through the constructed physical education teaching decision tree system. The test results show that the physical education teaching mode system based on the decision tree algorithm can analyze the given conditions and construct the corresponding decision tree according to the analysis results. The decision tree constructed in this study takes the number of students participating in sports competition as the root node, which shows that sports competition, as a comprehensive physical education teaching model, can play a targeted guiding role for students in a short time and help students correct their mistakes and make up for their deficiencies. Students' love of physical education and physical education teachers' physical education skills are secondary influencing factors. In addition, the diversity of physical education teachers' teaching means the number of physical education classes and students' own quality is closely related to students' physical education achievements. At the same time, according to the analysis results of physical education

teaching decision tree, after the physical education teachers make the corresponding physical education teaching adjustment, the students' performance and before the adjustment have been improved to a certain extent, in which the excellent rate has been significantly improved and the unqualified rate has been significantly reduced. There are still some differences between the conditions of the decision tree test and the actual situation. The scale of basic data is relatively small. Therefore, further application testing is needed to improve the accuracy and reliability of decision tree.

City brain is a complex system, including online center, server network, and system with given algorithm. The core of the city brain is the intelligent system. After putting the urban brain into the intelligent nerve center, on the basis of not changing its original data structure, combining its own characteristics for design and then integrating into application, it can intelligently change the urban management mode. Urban planning leads the development of smart cities on a certain meaning, and smart city planning must have scientific and rational urban planning. The intelligent model is used to make urban planning form a more modern, convenient, and reasonable urban architectural planning. Some influential books on classical architectural theory are the theoretical basis of intelligent urban planning and even the trend and implementation blueprint of how smart cities will develop in the future. In this paper, four algorithms, ant colony algorithm, particle swarm optimization algorithm, genetic algorithm, and improved ant colony algorithm, are proposed to optimize the characteristics of urban architectural planning and landscape design; especially the security research of architecture and landscape characteristics is very important. The improved ant colony algorithm has the shortcoming of insufficient optimization ability in the face of complex path selection. By improving the influencing factors, a new ant colony algorithm is created. The improved ant colony algorithm achieves the best in security features, so it is advocated to use this algorithm for planning and design. The urban form in smart city aims to create a beautiful and comfortable urban environment, improve the competitiveness of cities in the rapid urbanization process, improve the living standards of the public, and shape the image of this beautiful city.

1. Introduction

The intelligent model method contributes to the establishment of the model from different aspects such as architectural planning, landscape design, prediction, and uncertainty analysis of urban and smart city development under the development scenario of this era. We propose a description and analysis of smart city governance based on the qualitative method. Contrary to the idea of a centralized smart city imposed by public actors, we notice that Reynes smart city is the result of governance distributed between different poles [1]. Using the data of 274 prefecture-level cities in China from 2004 to 2017, this paper studies the impact of smart city policies on economic green growth and its internal mechanism, which shows that the establishment of smart cities has obviously promoted the green growth of

China's economy [2]. Binary phase shift keying (BPSK), quadrature phase shift keying (QPSK), 8-PSK, and 16-PSK are used as various modulation levels. Signal-to-noise ratio (SNR) vs bit error rate (BER) and peak signal-to-noise ratio (PSNR) are used as estimation parameters of received image quality for comparing different versions of OFDM with MRC antenna configuration [3]. By drawing system gram to examine the interaction between these elements, it helps to construct the definition of "smart city," then applies the definition to a group of cities, and empirically tests the urban efficiency through data envelopment analysis [4]. By reporting on a brand-new evaluation framework, the global evaluation of the footprint of smart city and community (SCC) projects can also be extended to the cases of smart grid-related projects. The unified smart city evaluation framework is built on three complementary evaluation axes:

the first evaluation axis aims to measure the success of an SCC project according to the predefined project-specific target value [5]. This project proposes a music recommendation system based on user emotion detection, automatic calculation, and classification [6]. This work involves the recent research on pedestrian navigation assistance, aiming at finding an alternative to the widely used map-based wheel-by-wheel navigation system in a smart city environment [7]. This paper briefly describes the comprehensive observation scene of environment and humanities in smart cities [8]. Smart city is still a highly related paradigm, which needs further development in order to give full play to its potential and provide strong and flexible solutions. This paper focuses on the Internet of Things as an enabling technology of smart city [9]. In the security framework, we propose a secure video surveillance model, and implement a secure authentication protocol that can resist man-in-the-middle attack (MITM) and replay attack. For the management of video encryption keys, we introduce the Chinese remainder theorem (CRT) based on group key management to provide efficient and secure key update [10]. This paper compares the impacts of primary industry, secondary industry, tertiary industry, and smart industry on Chengdu GDP [11]. Based on the role and participation of public and private actors in (1) capital, (2) asset ownership, and (3) smart city solution operation, a prototype of smart city business model was developed [12]. Using the regression model ($N=178$), this study shows that the participation difference of public package platform is explained by opinion leaders and political participation, not by community participation and traditional digital inequality [13]. Based on the panel data of 152 prefecture-level cities from 2004 to 2017, this paper uses super-SBM to measure the green land use efficiency [14]. A two-year study of the top ten town halls compared readiness with previous smart city assessment methods: rankings or ISO criteria [15]. Big data analysis in smart cities [16], innovation in information and communication technology (ICT) and the emergence of big data, Internet of Things (IoT), and cloud (BIC) infrastructure have effectively solved the needs of customers and citizens and changed the existing agile city ecosystem [17]. Using the actual data obtained from smart meters installed in Japanese cities, the significance of predicting the temporal and spatial distribution of power demand is demonstrated [18]. Cross-border learning should go beyond the exchange of ideas, suggest facilitators for knowledge transfer, build local policy capacity, encourage cooperative policy transfer, and transition from information-sharing platforms to tool/tool transfer [19]. In this study, the Internet of Things-assisted fog and edge-based smart lamppost are proposed to realize smart infrastructure in smart cities [20]. The reason for formulating an effective urban transformation strategy and transparently selecting independent experts (nonpoliticians) as decision-making and implementation teams is not only the heterogeneity of smart cities in all aspects and the necessary complexity and systematic methods but also the nature of the capabilities and tools required by the concept of smart cities [21]. Reference [22] analyzes in detail

the implementation of the concept of smart city in Poland and Ukraine, which belong to the secondary administrative units of neighboring countries, namely, Lublin and Ravi [23]. Taking smart cities as an example, this paper puts forward the construction of automatic hydroponic greenhouses as a model for sustainable generation of urban food. In the construction of this proposal, it is necessary to study the requirements of vegetable planting under hydroponic conditions so as to establish the technology that should be adopted for its automation and identify the basic chemical and climatological requirements in plant biological production [24]. We discussed the potential impact of pandemic on the application of Internet of Things in medical care, smart home, smart building, smart city, transportation, and industrial Internet of Things [25].

2. Smart City Feature Planning

2.1. Important Characteristics of Urban Brain. High degree of intelligence. The artificial intelligence center of the whole city forms the urban nerve center, an artificial brain system that processes and regulates the information of urban network. If the intelligence of the city is to put a smart hat on the city at any time, then the city brain is to put a host on the city. Locally, wearable smart devices seem to be available, but in essence, they have no ability to operate by themselves and cannot operate jointly with other parts, while the urban brain can coordinate and interact with other parts.

Strong interactivity. Urban brain is a brain-like neuron network related to people, things, and information nodes, and it is also the implementation subject that can solve and deal with various problems and needs of cities. It can bring together data, theory, and algorithm and provide the strongest productivity and production prospect for the information society.

Visualize retina. Visual retina can improve the efficiency ratio from the beginning to the terminal of the urban brain, reduce the algorithm on the line, and make the reflex arc of Internet more accurate and fast. The visual retinal system is based on the two typical application modes of the existing network visual perception system-video acquisition terminal and intelligent terminal. Combining the advantages of the two modes, it can save the storage and bandwidth of urban brain in coding, save the calculation time in online resource consumption, and reduce the delay and improve the accuracy of image feature extraction and analysis.

People-centered. The seventh national census shows that China's population has exceeded 1.4 billion. The construction of population density is the main reference factor of architectural planning, and the core of urban architecture is people. Urban nerve centers can mediate information through the brain. Considering the utilization rate of available resources, the comfort of the surrounding environment to people, air pollution, and other factors, in order to find the optimal solution to meet the necessary needs of human survival and development, a people-centered design concept is comprehensively taken to design a living environment that meets people's own needs.

2.2. Urban Architectural Planning of Urban Brain.

Optimize urban planning and layout. With the improvement of per capita education level, the number of years of education has increased and the sex ratio has also eased. At the same time, it is accompanied by the large increase of floating population, serious aging, and rapid reduction of rural rate. After the opening of the three-child policy, the population is increasing, but the available resources are limited, so the planning of urban resources has become a top priority, and it is extremely urgent to optimize the layout of urban planning. Through the continuous integration of building information model (BIM), urbanization information model (CIM), and geographic information system (GIS), the urban brain makes full use of visual intelligent technology so that the concept of urban brain can penetrate into smart city planning. On this basis, those were combined with typical theoretical books and materials to determine the design scheme, to greatly optimize the effect of urban planning and design, and to provide basic living security for the follow-up of human life and residence. In this way, according to local conditions, the resource allocation is optimized and the utilization rate of available resources is maximized.

Supervise urban risks and prevent and control risks in advance. Smart cities give alarms and reminders before urban risks come. Taking coastal cities as an example, they follow the goal of “watching natural disasters with one screen and managing the whole city with one network,” uphold the concept of horizontal to edge and vertical to the end, and realize the comprehensive system model of urban risk management with full coverage, all-weather, and whole process. On the basis of this system, it is explored for the first time the construction of an alarm mechanism with normal urban operation environment + risk alarm and the integration of peace and emergency. The intelligent urban management platform can play the role of real-time risk monitoring and unified management of postrisk behavior in the urban planning and operation stage, which can not only effectively prevent and deal with some specific measures of risk coming but also make timely response measures in the face of unexpected situations such as tsunami, earthquake, and other natural disasters.

Sustainable development is an inevitable choice. In urban planning and design, the traditional life concept model has delayed people’s pursuit of high-quality life, and the comfort and happiness of people’s life have been greatly reduced, and some commercial and trade industries have also been affected to some extent. Infiltrating the concept of smart city into urban architectural planning and landscape optimization design can improve the practicality of planning in an all-round way and make more usable space. With the help of intelligent and visual technology, the coordination of available resources can be more rational, and the overall coordination of resource utilization can improve the overall quality of life of people in urban planning and promote the sustainable development of other industries in a wide range, led by the real estate industry.

Information sharing. In recent years, with the development of Internet and Internet of Things, information sharing has gradually penetrated into all aspects of life. However, urban architectural planning and landscape design are closely related to the future trend of the city and the quality of human life, so it is necessary to fully collect and obtain information from all aspects and consider the influence of each factor. To a certain extent, the traditional architectural planning will affect people’s quality of life and cannot keep up with the needs of the development of the times. The urban brain permeates the urban planning, collects information at the same time, and establishes a systematic information online sharing platform, which will help coordinate the communication and mutual assistance performance among personnel in various departments, greatly improve work efficiency, and provide experience and reference blueprint for later urban planning. In this way, information sharing is more thorough, the utilization rate is higher, and the information becomes visual, which can effectively promote the accelerated development of society.

3. Programming Algorithm

3.1. *Principle of Ant Colony Algorithm.* If the number of ants on path X is n_x and the number of ants on path Y is n_y , then the total number of ants n is

$$n = n_x + n_y. \quad (1)$$

The probability of choosing path X and Path Y is

$$P_x(n) = \frac{(n_x + k)^h}{(n_x + k)^h + (n_y + k)^h}, \quad (2)$$

$$P_y(n) = 1 - P_x(n),$$

h and k adjust to simulate the real environment of ant colony routing.

Modeling

$$\begin{cases} x = \text{mod}(i, N) - 0.5, \\ y = N + 0.5 - \text{ceil}\left(\frac{i}{N}\right). \end{cases} \quad (3)$$

3.1.1. *Probability Planning.* Ants have two important factors when searching paths, which are the concentration of information and the heuristic function of distance. At one moment, ants move from one grid to another to form a probability, which is expressed as follows:

$$P_{ij}^k(t) = \begin{cases} \frac{\tau_{ij}^a(t)\eta_{ij}^B(t)}{\sum_{s \in \text{allowed}} \tau_{ij}^a(t)\eta_{ij}^B(t)}, & s \in \text{allowed}, \\ 0, & s \in \text{allowed}. \end{cases} \quad (4)$$

The distance heuristic function is expressed in the above formula as follows:

$$\eta_{ij} = \frac{1}{d_{ij}}, \quad (5)$$

$$d_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}.$$

When the heuristic factor α of pheromone concentration is larger, the follow-up ants are more inclined to walk through the nodes they have walked through before, which reduces the diversity of paths and makes the ant colony fall into local optimum. When the heuristic factor α of pheromone concentration is small, the feedback mechanism of ant colony will be weakened, which is not conducive to the convergence of the algorithm. When the visibility heuristic factor β is large, the randomness of ant selection will decrease; otherwise, it will increase. Therefore, it is necessary to adjust these two parameters in the simulation experiment

3.1.2. Update of Information Elements. The update formula of information elements is as follows:

$$\tau_{ij}(t+1) = (1 - \rho)\tau_{ij}(t) + \Delta\tau_{ij}, \quad (6)$$

$$\tau_{ij}(t) = \sum_{k=1}^m \Delta\tau_{ij}^k(t).$$

3.2. Model Updates

(1) In the Ant-Cycle model, the formula $\Delta\tau_{ij}(t)$ is as follows:

$$\Delta\tau_{ij}(t) = \begin{cases} \frac{Q}{L_k}, \\ 0, \text{ otherwise.} \end{cases} \quad (7)$$

(2) In the Ant-Quantity model, the formula $\Delta\tau_{ij}(t)$ is as follows:

$$\Delta\tau_{ij}(t) = \begin{cases} \frac{Q}{d_{ij}} \\ 0, \text{ otherwise} \end{cases} \quad (8)$$

(3) In the Ant-Density model, the formula $\Delta\tau_{ij}(t)$ is as follows:

$$\Delta\tau_{ij}(t) = \begin{cases} Q, \\ 0, \text{ otherwise.} \end{cases} \quad (9)$$

3.2.1. Classical Improvement of Algorithm. The difference between the elite ant algorithm and basic ant colony algorithm lies in the different pheromone updating methods, and its pheromone updating formula is as follows:

$$\tau_{ij}(t+1) = \rho\tau_{ij}(t) + \Delta\tau_{ij}(t) + e\Delta\tau_{ij}^{bs}(t) \quad e = (0, 1). \quad (10)$$

The pheromone increment formula of ant sorting algorithm is as follows:

$$\tau_{ij}(t+1) = \rho\tau_{ij}(t) + \Delta\tau_{ij}(t) + e\Delta\tau_{ij}^{bs}(t),$$

$$\tau_{ij}(t+1) = \sum_{k=1}^w \Delta\tau_{ij}, \quad (11)$$

$$\Delta\tau_{ij}(t) = \begin{cases} \frac{(v-k)Q}{L_k}, \\ 0, \text{ otherwise.} \end{cases}$$

The max-min ant algorithm is a classical improved ant colony algorithm, which effectively improves the slow convergence speed and is easy to fall into the local optimum of basic ant colony algorithm. The update formula of information elements is as follows:

$$\tau_{ij}(t+1) = \rho\tau_{ij}(t) + \Delta\tau_{ij}(t) + \Delta\tau_{ij}^{bs}(t). \quad (12)$$

When the basic algorithm is used to plan the path, the ant colony has not left pheromones on the path at the initial stage, and the pheromones on the path are scarce at this time, so the feasible path cannot be searched quickly. The new heuristic function is as follows:

$$\eta_{ij} = \frac{1}{(d_{ij} + d_{jE})^2}. \quad (13)$$

Considering the influence of volatilization factor on algorithm performance, the improved information element updating strategy in this chapter is as follows:

$$\rho(t+1) = \frac{T}{T+t} \times \frac{1}{e^{1-\rho(t)}}, \quad (14)$$

where T is the total number of iterations and t is the current number of iterations.

The volatilization factor in the basic ant colony algorithm has a very important influence on the performance of the algorithm. If the value is set irrationally, the ant may lose the ability of global search, and the convergence speed will also be affected. ρ is always constant in the basic algorithm. If ρ is too small, when ants find a better path instead of the optimal path, pheromone volatilization is slow due to the influence of ρ , which leads to more pheromone accumulation on this path and attracts ants, so it is difficult for ants to find other better paths, which makes the search results fall into local optimal solution. On the contrary, if the ρ setting is too large, the pheromone will volatilize at a faster speed, and the residual amount on the path cannot attract ants to search, so it is difficult for ants to choose the next moving grid depending on the pheromone concentration, which reduces the search ability and leads to slow convergence speed.

3.3. Ant Colony Algorithm

3.3.1. *Modeling.* Specific process of initializing population is as follows:

- (1) Set the parameters needed by the algorithm.
- (2) Judge whether the grid is continuous, and its judgment method is as follows:

$$\Delta = \max\{abs(x_{i+1} - x_i), abs(y_{i+1} - y_i)\}. \quad (15)$$

When $\Delta = 1$, the two grids are continuous; otherwise, the grid is inserted using the average method, which is calculated by

$$\begin{cases} x'_i = \text{int}\left[\frac{1}{2}(x_i + x_{i+1})\right], \\ y'_i = \text{int}\left[\frac{1}{2}(y_i + y_{i+1})\right], \\ P'_i = x'_i + y'_i. \end{cases} \quad (16)$$

3.3.2. *Algorithm Improvement.* Influencing factors are considered in the fitness function, and the new fitness function is as follows:

$$\text{fit} = a \times \text{fit}_1 + b \times \text{fit}_2, \quad (17)$$

where a and b are their weights, and fit_1 is the length factor. fit_1 is the length factor:

$$\text{fit}_1 = \frac{1}{\text{length}}, \quad (18)$$

fit_2 is the smoothness factor:

$$\text{fit}_2 = \sum_{i=1}^{\text{end}} \frac{1}{\theta}, \theta = \sum_{i=1}^{\text{end}-1} \left| \arccos \left| \frac{x_i - x_{i+1}}{y_i - y_{i+1}} \right| - \arccos \left| \frac{x_i - x_{i+1}}{y_i - y_{i+1}} \right| \right|. \quad (19)$$

The max-min ant algorithm is a classical improved ant colony algorithm, which effectively improves the slow convergence speed and is easy to fall into the local optimum of basic ant colony algorithm. The algorithm mainly consists of three parts. First, like the idea of sorting ant algorithm, the shortest path in the current iterative path is strengthened by pheromone, which improves the convergence speed of the algorithm; second, in order to reduce the influence of pheromone concentration on the search results of the algorithm, the range of pheromone quantity on each path is set; and finally, in order to avoid negative feedback leading to pheromone accumulation, set a maximum value for pheromone.

4. Experiment

4.1. *Simulation Experiment.* Set the total number of ant experiments to 50, the maximum iteration times to 100, and

TABLE 1: Results of four simulation experiments.

Parameters	First	Second	Third	Fourth
Optimal path length	31.23	31.28	31.25	31.26
Average number of iterations	31.19	32.03	32.19	30.75
Average operation time	11.06	10.98	11.31	11.24

carry out four simulation experiments with different iteration times. The simulation results are as shown in Table 1.

When the path becomes complex, the path searched by the basic ant colony algorithm becomes more complicated and tortuous, and it still does not converge when the iteration times reach the maximum, and its optimization ability is extremely unsatisfactory. Its shortcomings are very obvious in a large-scale environment. After improving the ant colony algorithm, we compare the convergence ability of the two, as shown in Figure 1:

The comparison of simulation results shows that the improved algorithm has superiority in optimization effect; that is, it reflects the effectiveness of the algorithm in terms of operation time and shortest path. The improved AG algorithm has obvious advantages in convergence speed and optimal path. It can be well applied in architectural planning and landscape design, and the relative path between buildings can be optimally designed. Smart city landscape design has to bring the best experience to tourists and can bring better time advantage to users visually and temporally.

4.2. *Model Comparison.* The urban landscape pattern is the representative of regional characteristics. 500 residents are selected for statistical investigation, and the characteristics of residents' urban architectural planning are counted by the ant colony improvement algorithm. The data are shown in Figure 2.

According to the statistical investigation of residents' desire for urban architectural landscape and the factors of

5. Conclusion

Urban planning leads the intelligent development of cities on a certain meaning, and smart urban planning must have scientific and logical urban planning. For the development of smart cities, smart city planning must have scientific and logical urban planning. The architectural planning and landscape design of smart cities make the urban planning more modern, convenient, and rational. In this paper, intelligent model is used for planning and design, and the research results are as follows:

- (1) In the simulation experiment, the improved ant colony algorithm before and after the optimal path, average moving times, average calculation time, three parameters comparison, and the improved algorithm is indeed more excellent.
- (2) According to the convergence curve of the algorithm, it can be seen that under the complex path, the convergence ability of the ant colony algorithm without improvement is poor, but it increases greatly after improvement.
- (3) Three algorithms are used to study and compare the characteristics of four kinds of architectural landscapes: tree-lined, lawn, entertainment square, and public places.
- (4) In the comparison experiment, the improved ant colony algorithm is slightly superior to the particle swarm optimization algorithm by comparing the optimal values of the performance comparison table of the three kinds of algorithms mentioned in this paper.

Recent studies on unsupervised object detection based on spatial attention have achieved promising results. Models, such as AIR and SPAIR, output “what” and “where” latent variables that represent the attributes and locations of objects in a scene, respectively. Most of the previous studies concentrate on the “where” localization performance. However, we claim that acquiring “what” object attributes is also essential for representation learning. This study presents a framework, GMAIR, for unsupervised object detection. It incorporates spatial attention and a Gaussian mixture in a unified deep generative model. GMAIR can locate objects in a scene and simultaneously cluster them without supervision. Furthermore, we analyze the “what” latent variables and clustering process. Finally, we evaluate our model on MultiMNIST and Fruit2D datasets. We show that GMAIR achieves competitive results on localization and clustering compared with state-of-the-art methods.

1. Introduction

The perception of human vision is naturally hierarchical. We can recognize objects in a scene at a glance and classify them according to their appearances, functions, and other attributes. It is expected that an intelligent agent can also decompose scenes to meaningful object abstraction, which is known as an object detection task in machine learning. In the last decade, there have been significant developments in supervised object detection tasks. However, its unsupervised counterpart continues to be challenging.

Recently, there has been some progress in unsupervised object detection. Attend, infer, repeat (AIR, [1]), which is a variational autoencoder (VAE [2])-based method, achieved encouraging results. Spatially invariant AIR (SPAIR [3]) replaced the recurrent network in AIR with a convolutional network that attained better scalability and lower computational cost. SPACE [4], which combines spatial attention and scene-mixture approaches, performed better in background prediction.

Despite the recent progress in unsupervised object detection, the results of previous studies remain unsatisfactory. One of the reasons for this could be that previous studies on unsupervised object detection were mainly concentrated on object localization. They lacked analysis and evaluation of the “what” latent variables, which represent the attributes of objects. These variables are essential for many tasks such as clustering, image generation, and style transfer. Another important concern is that they do not directly reason about the category of objects in the scene, which is beneficial to know in many cases, unlike most of the studies on corresponding supervised tasks.

This study presents a framework for unsupervised object detection that can directly reason about the category and localization of objects in the scenes and provide an intuitive way to analyze the “what” latent variables by simply incorporating a Gaussian mixture prior assumption. In Section 2, we introduce the architecture of our framework, GMAIR. We introduce related works in Section 3. We analyze the “what” latent variables in Section 4.1 and Section

4.4. We describe our model for image generation in Section 4.2. Finally, we present quantitative evaluation results of both clustering and localization in Section 4.3.

Our main contributions are as follows:

- (i) We combine spatial attention and a Gaussian mixture in a unified deep generative model, enabling our model to cluster discovered objects.
- (ii) We analyze the “what” latent variables, which are essential because they represent the attributes of the objects.
- (iii) Our method achieves competitive results on both clustering and localization compared with state-of-the-art methods.

2. Gaussian Mixture Attend, Infer, Repeat

In this section, we introduce our framework, GMAIR, for unsupervised object detection. GMAIR is a spatial attention model with a Gaussian mixture prior assumption for the “what” latent variables, and this enables the model to cluster discovered objects. An overview of GMAIR is presented in Figure 1.

2.1. Structured Object-Semantic Latent Representation. To attain object abstraction latent variables, the image is divided into $H \times W$ regions. Latent variables $\mathbf{z} = (\mathbf{z}_1, \mathbf{z}_2, \dots, \mathbf{z}_{HW})$ are a concatenation of HW latent variables, where \mathbf{z}_i is the latent variable for the i th region representing the semantic feature of the object centered in the i th region. Furthermore, for each region we divide \mathbf{z}_i into five separate latent variables, $\mathbf{z}_i = (\mathbf{z}_i^{\text{pres}}, \mathbf{z}_i^{\text{what}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}})$, where $\mathbf{z}_i^{\text{pres}} \in \{0, 1\}$, $\mathbf{z}_i^{\text{what}} \in \mathbb{R}^A$, $\mathbf{z}_i^{\text{cat}} \in \{0, 1\}^C$, $\mathbf{z}_i^{\text{where}} \in \mathbb{R}^4$, $\mathbf{z}_i^{\text{depth}} \in \mathbb{R}$, A is the dimension of “what” latent variables, and C is the number of clusters. $\mathbf{z}_i^{\text{pres}}$ is a binary variable indicating the existence of the object. $\mathbf{z}_i^{\text{what}}$ is a vector representing the object’s attribute. $\mathbf{z}_i^{\text{where}}$ specifies the relative position between the object and the i th region of an image. $\mathbf{z}_i^{\text{depth}}$ is a real number specifying the relative depth of the object, and $\mathbf{z}_i^{\text{cat}}$ is an one-hot vector for category.

GMAIR imposes a prior on those latent variables as follows:

$$p(\mathbf{z}) = \prod_{i=1}^{HW} p(\mathbf{z}_i^{\text{pres}}) \cdot p(\mathbf{z}_i^{\text{cat}})^{\mathbf{z}_i^{\text{pres}}} \cdot p(\mathbf{z}_i^{\text{what}} | \mathbf{z}_i^{\text{cat}})^{\mathbf{z}_i^{\text{pres}}} \cdot p(\mathbf{z}_i^{\text{where}})^{\mathbf{z}_i^{\text{pres}}} \cdot p(\mathbf{z}_i^{\text{depth}})^{\mathbf{z}_i^{\text{pres}}}. \quad (1)$$

2.1.1. Gaussian Mixture Prior Assumption. Latent variables \mathbf{z}^{cat} are one-hot vectors that act as classification indicators. They obey the categorical distribution, $\text{Cat}(\pi)$, where $\pi \in [0, 1]^C$. For simplicity, we assume that $\pi_k = (1/C)$ for all $1 \leq k \leq C$.

We assume that $\mathbf{z}_i^{\text{what}}$ conditional on $\mathbf{z}_i^{\text{cat}}$ obeys a Gaussian distribution. In that case, $\mathbf{z}_i^{\text{what}}$ obeys a Gaussian mixture model, that is,

$$p(\mathbf{z}_i^{\text{what}}) = \sum_{k=1}^C p(\mathbf{z}_{i,k}^{\text{cat}} = 1) p(\mathbf{z}_i^{\text{what}} | \mathbf{z}_{i,k}^{\text{cat}} = 1) \\ = \sum_{k=1}^C p(\mathbf{z}_{i,k}^{\text{cat}} = 1) f(\mathbf{x}; \mu_k, \sigma_k^2), \quad (2)$$

where $f(x; \mu, \sigma^2) = (1/\sigma\sqrt{2\pi})\exp(-(x - \mu)^2/2\sigma^2)$ is the probability density function of Gaussian distribution, and μ_k, σ_k ($k = 1..C$) are the mean and standard derivation of the k th Gaussian distribution. We let μ_k and σ_k be learnable parameters that are jointly trained with other parameters. During the implementation, $\mu_k = \mu(\mathbf{z}_i^{\text{cat}})$ and $\sigma_k = \sigma(\mathbf{z}_i^{\text{cat}})$ if $\mathbf{z}_{i,k}^{\text{cat}} = 1$, where μ and σ can be modeled as linear layers. They are called “what priors” module in Figure 1.

For other latent variables, \mathbf{z}^{pres} is modeled using a Bernoulli distribution, $\beta(p)$, where p is the present probability. $\mathbf{z}^{\text{where}}$ and $\mathbf{z}^{\text{depth}}$ are modeled using normal distributions, $\mathcal{N}(\mu_{\text{prior}}^{\text{where}}, \sigma_{\text{prior}}^{\text{where}^2})$ and $\mathcal{N}(\mu_{\text{prior}}^{\text{depth}}, \sigma_{\text{prior}}^{\text{depth}^2})$, respectively. All priors of latent variables are listed in Table 1.

2.2. Inference and Generation Model

2.2.1. Inference Model $q_\phi(\mathbf{z}|\mathbf{x})$. In the inference model, latent variables conditional on data \mathbf{x} are modeled as follows:

$$q(\mathbf{z}|\mathbf{x}) = \prod_{i=1}^{HW} q(\mathbf{z}_i^{\text{pres}}|\mathbf{x}) \cdot q(\mathbf{z}_i^{\text{where}}|\mathbf{x})^{\mathbf{z}_i^{\text{pres}}} \cdot q(\mathbf{z}_i^{\text{depth}}|\mathbf{x})^{\mathbf{z}_i^{\text{pres}}} \\ \cdot q(\mathbf{z}_i^{\text{cat}}|\mathbf{x}, \mathbf{z}_i^{\text{where}})^{\mathbf{z}_i^{\text{pres}}} \cdot q(\mathbf{z}_i^{\text{what}}|\mathbf{x}, \mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{cat}})^{\mathbf{z}_i^{\text{pres}}}. \quad (3)$$

During implementation, feature maps with dimension $H \times W \times D$ are extracted from a backbone network using data \mathbf{x} as input, where D is the number of channels of feature maps. Further, the posteriors of \mathbf{z}^{pres} , $\mathbf{z}^{\text{where}}$, and $\mathbf{z}^{\text{depth}}$ are reasoned by pres-head, where-head, and depth-head, respectively. Input images are cropped into $H \times W$ glimpses by a spatial transformer network, and each of these is transferred to the cat-encoder module to generate posteriors of \mathbf{z}^{cat} . Subsequently, we use the concatenation of the i th glimpse and $\mathbf{z}_i^{\text{cat}}$ ($1 \leq i \leq HW$) as the input of the what-encoder to generate posteriors of \mathbf{z}^{what} .

2.2.2. Generation Model $p_\theta(\mathbf{x}|\mathbf{z})$. In the generation model, each $\mathbf{z}_i^{\text{what}}$ ($1 \leq i \leq HW$) is changed back into a glimpse using a glimpse decoder. Then, a renderer combines HW glimpses to generate $\hat{\mathbf{x}}$. We use the same render algorithm as in previous studies [1, 3].

2.3. The Loss Functions

2.3.1. Evidence Lower Bound. In general, we learn parameters of VAE jointly by maximizing the evidence lower bound (ELBO), which can be formulated as follows:

$$\text{ELBO} = \mathbb{E}_{q(\mathbf{z}|\mathbf{x})} \left[\log \left(\frac{p(\mathbf{x}, \mathbf{z})}{q(\mathbf{z}|\mathbf{x})} \right) \right] \\ = \mathbb{E}_{q(\mathbf{z}|\mathbf{x})} [\log(p(\mathbf{x}|\mathbf{z}))] - \mathbb{E}_{q(\mathbf{z}|\mathbf{x})} \left[\log \left(\frac{q(\mathbf{z}|\mathbf{x})}{p(\mathbf{z})} \right) \right], \quad (4)$$

where the first term is called the reconstruction term denoted by $-L_{\text{recon}}$, and the second term, the regularization

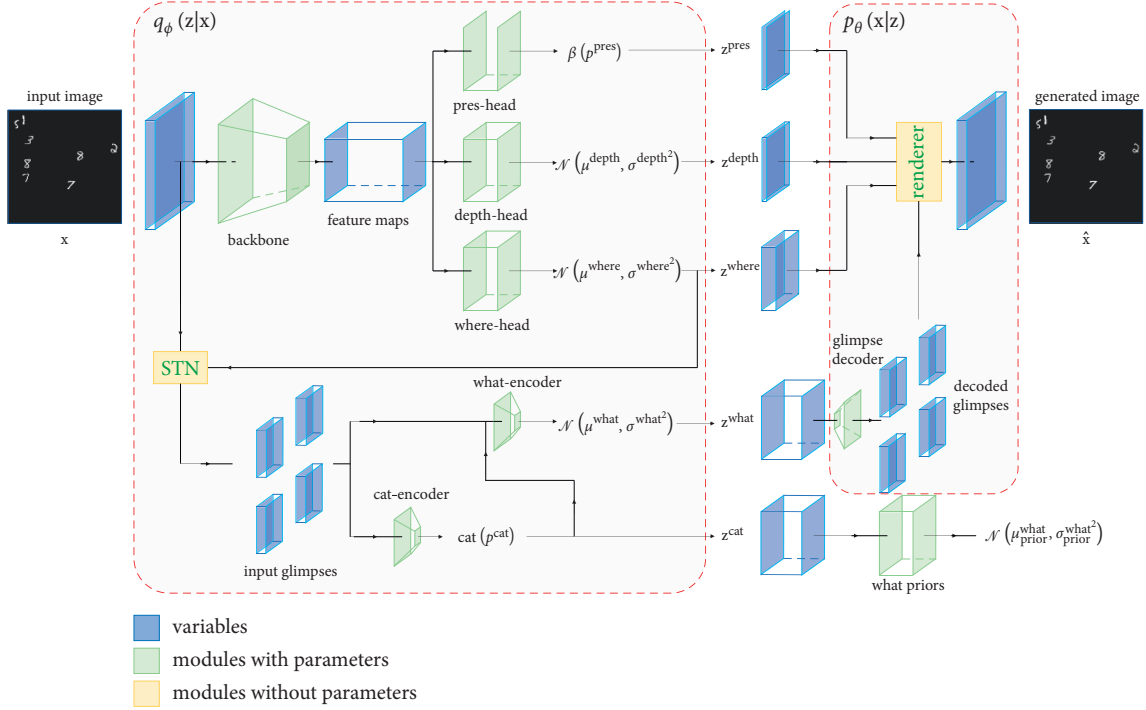

FIGURE 1: Architecture of GMAIR. This is a VAE-based model that consists of a probabilistic encoder, $q_\phi(\mathbf{z}|\mathbf{x})$, and a probabilistic decoder, $p_\theta(\mathbf{x}|\mathbf{z})$. In encoder $q_\phi(\mathbf{z}|\mathbf{x})$, feature maps with dimension $H \times W \times D$ are extracted from data \mathbf{x} going through a backbone network representing feature of $H \times W$ divided regions. They are then fetched into three separated modules: pres-head, depth-head, and where-head, which produce the posterior of \mathbf{z}^{pres} , $\mathbf{z}^{\text{depth}}$, and $\mathbf{z}^{\text{where}}$, respectively. A cat-encoder module generates the posterior of \mathbf{z}^{cat} with $H \times W$ input glimpses transformed by a spatial transformer network (STN) as input, and the posterior of \mathbf{z}^{what} is generated by a what-encoder module with $H \times W$ input glimpses and \mathbf{z}^{cat} as input. In decoder $p_\theta(\mathbf{x}|\mathbf{z})$, each $H \times W$ latent \mathbf{z}^{what} is fetched into a glimpse decoder to generate decoded glimpses rendered by the renderer to recover to the final generated image. Finally, the priors of \mathbf{z}^{pres} , $\mathbf{z}^{\text{depth}}$, $\mathbf{z}^{\text{where}}$, and \mathbf{z}^{cat} are fixed, whereas the prior of \mathbf{z}^{what} is generated by a “what priors” module using \mathbf{z}^{cat} as input.

TABLE 1: Priors of latent variables.

Latent variables	Priors
\mathbf{z}^{pres}	$\beta(p)$
\mathbf{z}^{what}	$\mathcal{N}(\mu(\mathbf{z}^{\text{cat}}), \sigma(\mathbf{z}^{\text{cat}})^2)$
\mathbf{z}^{cat}	Cat(π)
$\mathbf{z}^{\text{where}}$	$\mathcal{N}(\mu_{\text{prior}}^{\text{where}}, \sigma_{\text{prior}}^{\text{where}^2})$
$\mathbf{z}^{\text{depth}}$	$\mathcal{N}(\mu_{\text{prior}}^{\text{depth}}, \sigma_{\text{prior}}^{\text{depth}^2})$

term. The regularization term can be further decomposed into five terms by substituting (1) and (3) into (4), and each of the five terms corresponds to the Kullback–Leibler divergence (or its expectation) between a type of latent variables and its prior:

$$\mathbb{E}_{q(\mathbf{z}|\mathbf{x})} \left[\log \left(\frac{q(\mathbf{z}|\mathbf{x})}{p(\mathbf{z})} \right) \right] = L_{\text{pres}} + L_{\text{where}} + L_{\text{depth}} + L_{\text{cat}} + L_{\text{what}} \quad (5)$$

The terms in (5) are as follows:

$$L_{\text{pres}} = \sum_{i=1}^{HW} KL^{\text{pres}}, \quad (6)$$

$$L_{\text{where}} = \sum_{i=1}^{HW} q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x}) KL^{\text{where}}, \quad (7)$$

$$L_{\text{depth}} = \sum_{i=1}^{HW} q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x}) KL^{\text{depth}}, \quad (8)$$

$$L_{\text{cat}} = \sum_{i=1}^{HW} q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x}) \mathbb{E}_{q(\mathbf{z}_i^{\text{where}}|\mathbf{x})} [KL^{\text{cat}}], \quad (9)$$

$$L_{\text{what}} = \sum_{i=1}^{HW} q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x}) \mathbb{E}_{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{cat}}|\mathbf{x})} [KL^{\text{what}}], \quad (10)$$

where $KL^x = KL(q(\mathbf{z}_i^x|\cdot) \| p(\mathbf{z}_i^x|\cdot))$. A complete derivation is given in Appendix A.

2.3.2. Overlap Loss. During actual implementation, we find that penalizing on overlaps of objects sometimes helps. Therefore, we introduce an auxiliary loss called overlap loss. First, we calculate HW images with size $3 \times H^{\text{img}} \times W^{\text{img}}$, where H^{img} and W^{img} are, respectively, the height and width of the input image, transformed by HW decoded glimpses by a spatial transformer network. The overlap loss is then calculated as the average of the sum subtract by the maximum for each $H^{\text{img}} \times W^{\text{img}}$ pixels.

This loss, inspired by the boundary loss in SPACE [4], is utilized to penalize if the model tries to split a large object into multiple smaller ones. However, we achieve this using a

different calculation method that incurs a lower computational cost.

2.3.3. *Total Loss.* The total loss is as follows:

$$L = \sum_{x \in S} \alpha_x L_x, \quad (11)$$

where $S = \{\text{recon, overlap, pres, where, depth, cat, what}\}$, and α_x is the coefficients of the corresponding loss terms.

3. Related Works

Several studies on unsupervised object detection have been conducted, including spatial attention methods such as AIR [1], SPAIR [3], and SPACE [4], and scene-mixture methods such as MONet [5], IODINE [6], GENESIS [7], and GENESIS-v2 [8]. Most of them including our work are based on the VAE [2] model.

3.1. *AIR.* The AIR framework uses a VAE-based hierarchical probabilistic model marking a milestone in unsupervised scene understanding. In AIR, latent variables are structured into groups of latent variables $\mathbf{z}_{1:N}$, for N discovered objects, each of which consists of “what,” “where,” and “presence” variables. A recurrent neural network is used in the inference model to produce $\mathbf{z}_{1:N}$, and there is a decoder network for decoding the “what” variables of each object in the generation model. A spatial transformer network [9] is used for rendering.

3.2. *SPAIR.* Because AIR attends one object at a time, it does not scale well to scenes that contain many objects. SPAIR attempted to address this issue by replacing the recurrent network with a convolutional network that follows a spatially invariant assumption. Like YOLO ([10]), in SPAIR, the locations of objects are specified relative to local grid cells. SPAIR achieved a better performance and scalability than AIR.

3.3. *MONet.* MONet [5] is a scene-mixture model for unsupervised scene decomposition. Like AIR, MONet also uses a recurrent neural network to infer objects. However, it learns the attention masks to obtain the segmentation results of objects instead of the bounding boxes.

3.4. *IODINE.* IODINE [6] is also a scene-mixture model for unsupervised scene decomposition. Unlike MONet, which infers a mask for one object at a time, in IODINE, all segmentation results are inferred simultaneously. A recurrent neural network is used to refine the segmentation results further.

3.5. *GENESIS.* GENESIS [7] replaced the recurrent neural networks in previous works with the convolutional neural networks. This improvement makes GENESIS more scalable to inputs with a larger number of scene components.

3.6. *GENESIS-v2.* GENESIS-v2 [8] also performs unsupervised object segmentation. It is similar to GENESIS but uses a parameter-free clustering algorithm to avoid iterative refinements.

The scene-mixture models such as MONet, IODINE, GENESIS, and GENESIS-v2 perform segmentation instead of explicitly finding the $\mathbf{z}^{\text{where}}$ location of the objects. The bounding boxes of the discovered objects need to be calculated by the object masks.

3.7. *SPACE.* SPACE [4] employs a combination of both methods. It consists of a spatial attention model for the foreground and a scene-mixture model for the background. By detecting the foreground and background separately, SPACE achieved a better detection result when the background is complicated.

In the area of deep unsupervised clustering, recent methods include AAE [11], GMVAE [12], and IIC [13]. AAE combines the ideas of generative adversarial networks and variational inference. GMVAE uses a Gaussian mixture model as a prior distribution. In IIC, objects are clustered by maximizing mutual information of pairs of images. All of them show promising results on unsupervised clustering.

GM AIR incorporates a Gaussian mixture model for clustering, similar to the GMVAE framework (the authors also refer to a blog post (<http://ruishu.io/2016/12/25/gmvae/>) published by Rui Shu). It is worth noting that our attempt may simply be a choice among many given options. Unless previous research, our main contribution is to show the feasibility of performing clustering and localization simultaneously. Moreover, our method provides a simple and intuitive way to analyze the mechanics of the detection process.

4. Models and Experiments

The experiments were divided into three parts: (a) the analysis of “what” representation and clustering along with the iterations, (b) image generation, and (c) quantitative evaluation of the models.

We evaluate the models on two datasets:

- (i) MultiMNIST: A dataset generated by placing 1–10 small images randomly chosen from MNIST (a standard handwritten digits dataset [14]) to random positions on 128×128 empty images.
- (ii) Fruit2D: A dataset collected from a real-world game. In the scenes, there are 9 types of fruits of various sizes. There is a large difference between both the number and the size of small objects and large objects. The ratio of the size of the largest type of objects to that of the smallest type of objects is ~ 6 , and there are ~ 31 times objects in the smallest size than in the largest size. These settings make it difficult to perform localization and clustering.

In the experiments, we compared GM AIR with two models, SPAIR and SPACE, both of which achieve state of the art in unsupervised object detection in localization

performance. Separated Gaussian mixture models are applied to the “what” latent variables generated by the compared models to obtain the clustering results. We set the number of clusters $C = 10$ and Monte Carlo samples $M = 1$ except as otherwise defined for all experiments. All experiments were conducted on a Ubuntu 16.04.6 server with an Intel(R) Xeon(R) Silver 4110 CPU with 8 cores and 2 TITAN RTX GPUs. We present the details of the models in Appendix B.

It is worth mentioning that the model sometimes successfully locates an object and encloses it with a large box. In that case, IoU between the ground truth and the predicted one will be small and, therefore, will not count to be a correct bounding box when calculating AP. We fix this issue by removing the empty area in generated glimpses to obtain the real size of predicted boxes.

4.1. “What” Representation and Cluster Analysis. We conducted the experiments using the MultiMNIST dataset. We ran GMAIR for 440k iterations and observed the change in the values of the average precision (AP) of bounding boxes, accuracy (ACC), and normalized mutual information (NMI) of clustering until 100k iterations. We also visualized the “what” latent variables in the latent space during the process, as shown in Figure 2. Although all values continued to increase even after 100k iterations, the visualization results were similar to those at the 100k iteration. For integrity, we reserved the results from 100k to 440k iterations in Appendix D. Details of calculating the AP, ACC, and NMI are discussed in Appendix C.

The results showed that at an early stage ($\sim 10k$ iterations) of training, models can already locate objects well with $AP > r_{bin}0.9$ (Figure 2(a)). At the same time, \mathbf{z}^{what} , representations of objects, was still evolving, and the results of clustering (in Figure 2(b)) were not desirable ((ACC, NMI) was (0.24, 0.15)); the digits were a blur in Figure 2(f). After 50k and 100k iterations of training, the clustering effect of \mathbf{z}^{what} was increasingly apparent, and the digits were clearer (Figures 2(g) and 2(h)). The clustering results ((ACC, NMI) was (0.55, 0.43) at 50k and (0.65, 0.55) at 100k iterations) were improved (Figures 2(c) and 2(d)).

The explanation relates to the fact that while the model learns general features of objects and can locate the objects, object classification presents a new challenge for the model. As a result, the model is forced to cluster the feature vector of discovered objects into a small number of categories, which requires the model to learn the similarities between objects and thus requires a large number of training iterations.

It should be noted that even if the clustering effect of \mathbf{z}^{what} is sufficiently enough, the model may fail to locate the centers of clusters (e.g., the large cluster in light red in Figure 2(d)), leading to poor clustering results. In the worst case, the model may learn to converge all μ_k, σ_k ($1 \leq k \leq C$) to the same values, μ^*, σ^* , and the Gaussian mixture model may degenerate to a single Gaussian distribution, $\mathcal{N}(\mu^*, \sigma^{*2})$, resulting in a miserable clustering result. In general, we found that this phenomenon usually occurs at the early stage of training and can be avoided by adjusting

the learning rate of relative modules and the coefficients of the loss functions.

4.2. Image Generation. It is expected that μ_k ($1 \leq k \leq C$) represents the average feature of the k th type of objects, and \mathbf{z}_i^{what} latent variable can be decomposed into the following:

$$\mathbf{z}_i^{what} = \mathbf{z}_i^{avg} + \mathbf{z}_i^{local}. \quad (12)$$

$\mathbf{z}_i^{avg} = \mu_k$ ($1 \leq k \leq C$) if the i th object is in the k th category, and \mathbf{z}_i^{local} represents the local feature of the object. By altering \mathbf{z}_i^{avg} or \mathbf{z}_i^{local} , we should obtain new objects that belong to other categories or the same category with different styles, respectively. In the experiment, we altered \mathbf{z}_i^{avg} and \mathbf{z}_i^{local} and observed the generated images for each object, as shown in Figure 3. In Figure 3(a), objects in each cluster correspond to a type of digit, which is exactly what we expected (except for digit 8 in column 3). In Figure 3(b), categories with a large number of objects are grouped into multiple clusters, while categories with a small number are grouped into one cluster. This is due to the significant difference in number between various types. However, objects in a cluster come from a category in general.

The structure of GMAIR ensures its ability to control object categories, object styles, and the positions of each object of the generated images by altering \mathbf{z}_i^{avg} , \mathbf{z}_i^{local} , and \mathbf{z}^{where} . Examples are shown in Figure 4.

This could provide a new approach for tasks such as style transfer, image generation, and data augmentation. Note that previous methods such as AIR, SPAIR, and its variants can also obtain similar results, but we achieve them in finer granularity.

4.3. Quantitative Evaluations. We quantitatively evaluate the models in terms of the AP of bounding boxes and ACC and NMI of the clusters, and the results are listed in Table 2. In the first part, we show the results of GMVAE for unsupervised clustering on MNIST dataset for comparison. In the second part and the third part, we compare GMAIR to the state-of-the-art models for unsupervised object detection on MultiMNIST and Fruit2D dataset, respectively. The clustering results of SPAIR and SPACE are obtained by the Gaussian mixture models (GMMs). The results show that GMAIR achieves competitive results on both clustering and localization.

4.4. Ablation Study on the Importance of a Gaussian Mixture. The most significant difference between GMAIR and other models is that GMAIR uses a Gaussian mixture model for the “what” latent variables. To investigate whether the Gaussian mixture structure does affect the “what” representation, we also visualized “what” latent variables in latent space generated by SPAIR and SPACE, which have a similar structure of GMAIR and use a Gaussian model instead of a Gaussian mixture model for “what” latent variables. The results are shown in Figure 5. They show that without a Gaussian mixture model, “what” latent variables of different categories tend to follow a single distribution. This is

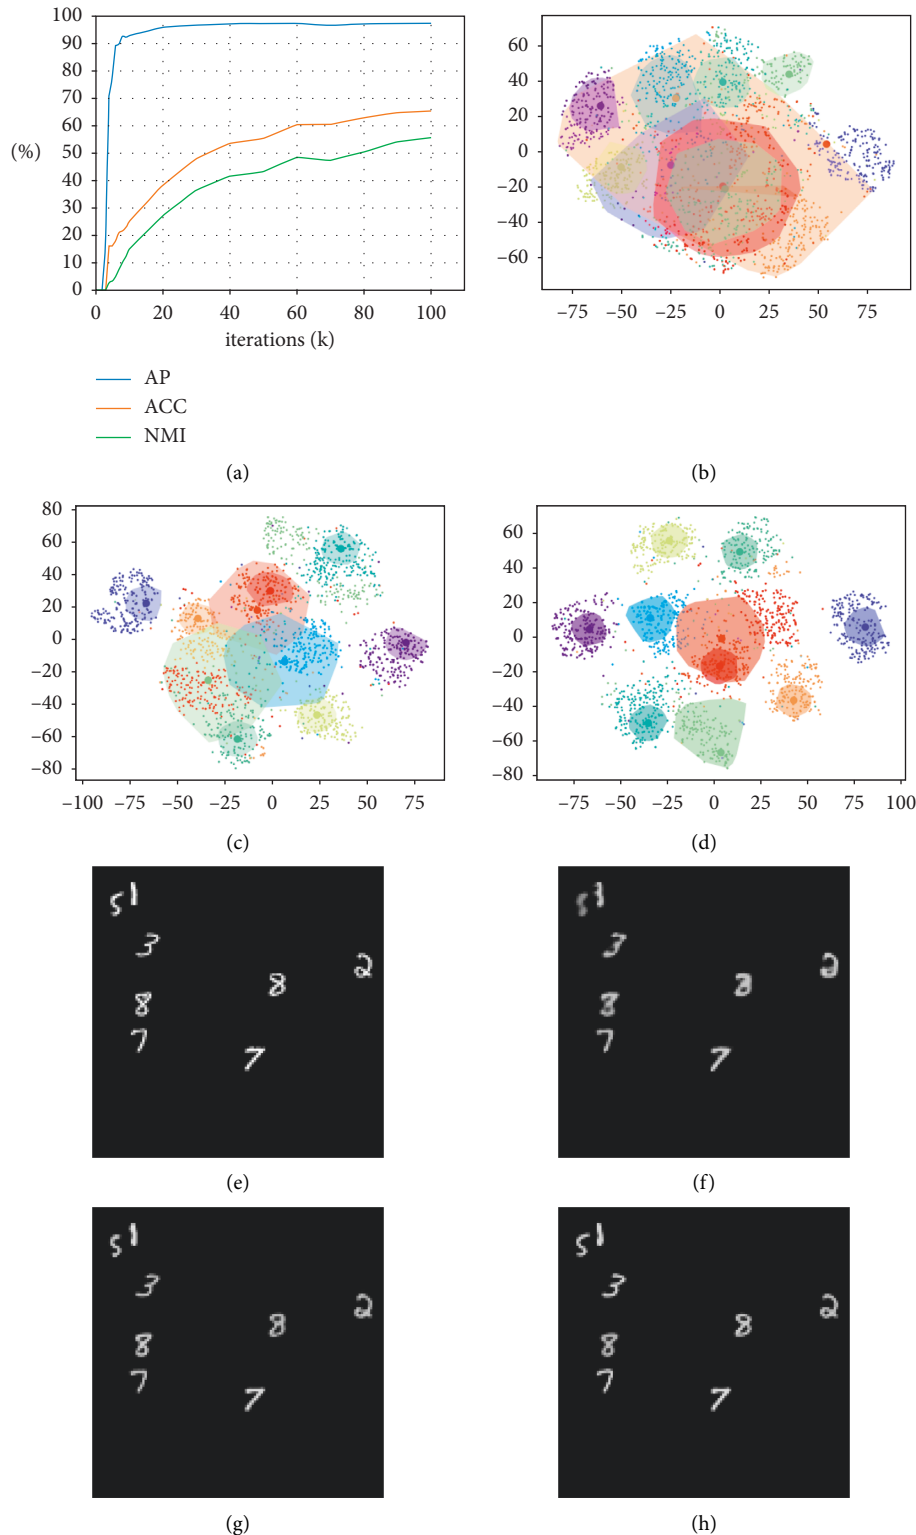

FIGURE 2: "What" representation and cluster analysis. (a) Average precision (AP), accuracy (ACC), and normalized mutual information (NMI) during training. (b-d) Visualized "what" latent space by t-SNE ([15]) at 10k, 50k, and 100k iterations, respectively. Each small dot represents a sample of \mathbf{z}^{what} , and different colors represent the ground truth categories of the corresponding objects. The large dots are μ_k ($1 \leq k \leq C$) described in Section E 2.1, and each of these can be seen as the center of a cluster. The closures represent results of clustering, which are closures of the closest $n\mathbf{z}^{\text{what}}$ points to μ_k that are assigned to the k th cluster (where $1 \leq k \leq C$ and we choose $n = 200$). The color of μ_k ($1 \leq k \leq C$) and closures are decided by a matching algorithm such that a maximum number of \mathbf{z}^{what} are correctly classified to the ground truth label. (e) Sample of original image. (f-h) Samples of generated image at 10k, 50k, and 100k iterations, respectively. (a) AP (IoU = 0.5), ACC, and NMI during training. reasonable since we try to minimize the KL divergence of \mathbf{z}^{what} and a Gaussian model in these models. Therefore, the Gaussian mixture model structure helps to gather “what” latent variables of a category and keep those of different categories away from each other.

5. Limitations and Societal Impact

The biggest limitation of GMAIR is that it can currently only be applied to simple compositing scenarios, such as games. However, the automatic mining of object localization and category from simple scenes is still a step towards artificial general intelligence. Although the current detection performance of GMAIR for complex scenes is poor, it cannot be ruled out that it may be applied to some scenes for unethical automatic detection or that it may learn biased or discriminatory features that may cause negative social impact. All these aspects are to be further investigated.

6. Conclusion

We introduce GMAIR, which combines spatial attention and a Gaussian mixture such that it can locate and cluster unseen objects simultaneously. We analyze the “what” latent variables and clustering process, showing that the model has the ability to detect and cluster similar objects automatically. For the downstream task, we show an

example of image generation that may be applied to data augmentation or synthetic data generation. We also evaluate GMAIR quantitatively compared with SPAIR and SPACE, showing that GMAIR archives the state-of-the-art detection performance.

As the number of data increases and the cost of annotation rises, unsupervised object detection will play an increasingly important role in the future. Future research should be devoted to improving the detection performance for complex scenes. One possible option is to make use of advanced results in supervised learning. Another important topic is to balance multiple loss functions better.

Appendix

A. Derivation of the KL Terms

In this section, we derive the KL terms in Eqn. (6). By assumption of $q(\mathbf{z}|\mathbf{x})$ and $p(\mathbf{z})$ (Eqn. (3) and Eqn. (1)), we have the following:

$$\mathbb{E}_{q(\mathbf{z}|\mathbf{x})} \left[\log \left(\frac{q(\mathbf{z}|\mathbf{x})}{p(\mathbf{z})} \right) \right] = \sum_{i=1}^{HW} \mathbb{E}_{q(\mathbf{z}_i|\mathbf{x})} \log \left(\frac{q(\mathbf{z}_i|\mathbf{x})}{p(\mathbf{z}_i)} \right). \quad (\text{A.1})$$

The term $\mathbb{E}_{q(\mathbf{z}_i|\mathbf{x})} \log(q(\mathbf{z}_i|\mathbf{x})/p(\mathbf{z}_i))$ can further be expanded as follows:

$$\begin{aligned} \mathbb{E}_{q(\mathbf{z}_i|\mathbf{x})} \log \left(\frac{q(\mathbf{z}_i|\mathbf{x})}{p(\mathbf{z}_i)} \right) &= q(\mathbf{z}_i^{\text{pres}} = 0|\mathbf{x}) \log \left(\frac{q(\mathbf{z}_i^{\text{pres}} = 0|\mathbf{x})}{p(\mathbf{z}_i^{\text{pres}} = 0)} \right) + q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x}) \\ &\cdot \left(\log \left(\frac{q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x})}{p(\mathbf{z}_i^{\text{pres}} = 1)} \right) + \mathbb{E}_{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}}|\mathbf{x})} \left[\log \left(\frac{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}}|\mathbf{x})}{p(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}})} \right) \right] \right) \\ &= KL(q(\mathbf{z}_i^{\text{pres}}|\mathbf{x})\|p(\mathbf{z}_i^{\text{pres}})) \\ &+ q(\mathbf{z}_i^{\text{pres}} = 1|\mathbf{x}) \mathbb{E}_{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}}|\mathbf{x})} \left[\log \left(\frac{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}}|\mathbf{x})}{p(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}})} \right) \right]. \end{aligned} \quad (\text{A.2})$$

Eqn. (A.2) is continued to expand:

$$\begin{aligned} &\mathbb{E}_{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}}|\mathbf{x})} \left[\log \left(\frac{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}}|\mathbf{x})}{p(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{depth}}, \mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{what}})} \right) \right] \\ &= \mathbb{E}_{q(\mathbf{z}_i^{\text{where}}|\mathbf{x})} \log \left(\frac{q(\mathbf{z}_i^{\text{where}}|\mathbf{x})}{p(\mathbf{z}_i^{\text{where}})} \right) + \mathbb{E}_{q(\mathbf{z}_i^{\text{depth}}|\mathbf{x})} \log \left(\frac{q(\mathbf{z}_i^{\text{depth}}|\mathbf{x})}{p(\mathbf{z}_i^{\text{depth}})} \right) \\ &+ \mathbb{E}_{q(\mathbf{z}_i^{\text{cat}}, \mathbf{z}_i^{\text{where}}|\mathbf{x})} \log \left(\frac{q(\mathbf{z}_i^{\text{cat}}|\mathbf{x}, \mathbf{z}_i^{\text{where}})}{p(\mathbf{z}_i^{\text{cat}})} \right) \\ &+ \mathbb{E}_{q(\mathbf{z}_i^{\text{what}}, \mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{cat}}|\mathbf{x})} \log \left(\frac{q(\mathbf{z}_i^{\text{what}}|\mathbf{x}, \mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{cat}})}{p(\mathbf{z}_i^{\text{what}}|\mathbf{z}_i^{\text{cat}})} \right). \end{aligned} \quad (\text{A.3})$$

By the definition of the Kullback–Leibler divergence, the four terms in the RHS of Eqn. (A.3) are indeed:

$$\begin{aligned} &KL(q(\mathbf{z}_i^{\text{where}}|\mathbf{x})\|p(\mathbf{z}_i^{\text{where}})), \\ &KL(q(\mathbf{z}_i^{\text{depth}}|\mathbf{x})\|p(\mathbf{z}_i^{\text{depth}})), \\ &\mathbb{E}_{q(\mathbf{z}_i^{\text{where}}|\mathbf{x})} [KL(q(\mathbf{z}_i^{\text{cat}}|\mathbf{x}, \mathbf{z}_i^{\text{where}})\|p(\mathbf{z}_i^{\text{cat}}))], \text{ and} \\ &\mathbb{E}_{q(\mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{cat}}|\mathbf{x})} [KL(q(\mathbf{z}_i^{\text{what}}|\mathbf{x}, \mathbf{z}_i^{\text{where}}, \mathbf{z}_i^{\text{cat}})\|p(\mathbf{z}_i^{\text{what}}|\mathbf{z}_i^{\text{cat}}))], \end{aligned} \quad (\text{A.4})$$

respectively. Therefore, we complete the proof of Eqn. (5).

During the implementation, we model discrete variables \mathbf{z}^{pres} and \mathbf{z}^{cat} using the Gumbel-Softmax approximation ([17]). Therefore, all variables are differentiable using the reparameterization trick.

B. Implementation Details

Our code is available at <https://github.com/EmoFuncs/GMAIR-pytorch>.

B.1 Models. Here, we describe the architecture of each module of GMAIR, as shown in Figure 1. The backbone is a ResNet18 ([18]) with two deconvolution layers replacing the fully connected layer, as shown in Table 3. Pres-head, depth-head, and where-head are convolutional networks that are only different from the number of output channels, as shown in Table 4. What-encoder and cat-encoder are multiple layer networks, as shown in Table 5. Finally, the glimpse decoder is a deconvolutional network, as shown in Table 6.

For other models, we make use of code from https://github.com/yonkshi/SPAIR_pytorch for SPAIR and <https://github.com/zhixuan-lin/SPACE> for SPACE. We utilize most of the default configuration for both models and only change A (the dimension of $\mathbf{z}_i^{\text{what}}$) to 256 for comparison, the size of the base bounding box to 72×72 for large objects.

B.2 Training and Hyperparameters. The base set of hyperparameters for GMAIR is given in Table 7. The value p (the prior on \mathbf{z}^{pres}) drops gradually from 1 to the final value $6e - 6$, and the value α_{overlap} drops from 2 to 0 in the early stage of training for stability. The learning rate is in the range of $[5e - 5, 1e - 4]$.

B.3 Testing. During testing phase, to obtain deterministic results, we use the value with the largest probability (density) for latent variables \mathbf{z} , instead of sampling them from the distributions. To be specific, we use π , μ^{depth} , p , μ^{what} , and μ^{where} for \mathbf{z}^{cat} , $\mathbf{z}^{\text{depth}}$, \mathbf{z}^{pres} , \mathbf{z}^{what} , and $\mathbf{z}^{\text{where}}$, respectively.

C. Calculation of AP, ACC, and NMI

The value of AP is calculated at threshold IoU = 0.5 using the calculation method from the VOC ([19]). Before calculating the ACC and NMI of clusters, we filter the incorrect bounding boxes. A predicted box PB is correct if there is a ground truth box GB such that $\text{IoU}(PB, GB) > 0.5$, and the class of a correct predicted box PB is assigned to the class of the ground truth box GB such that $\text{IoU}(PB, GB)$ is maximized. After filtering, all correct predicted boxes are used for the calculation of ACC and NMI. Note that we still have many ways to assign each predicted category to a real category when calculating the value of ACC. In all of the ways, we select the one such that ACC is maximized, following [12]. Formulas are shown in Eqn. (C.1) and Eqn. (C.2) for the calculation of ACC and NMI:

$$\text{ACC} = \frac{\sum_{k=1}^C \max_{1 \leq j \leq C'} \left| \{i | G_i = j, P_i = k\} \right|}{|P|}, \quad (\text{C.1})$$

$$\text{NMI} = \frac{2I(G, P)}{H(G) + H(P)}, \quad (\text{C.2})$$

where G and P are, respectively, the ground truth categories and predicted categories for all correct boxes, C and C' are

the number of clusters and real classes, and $H(\cdot)$ and $I(\cdot, \cdot)$ are the entropy and mutual information function, respectively.

D. Additional Experimental Results

The graphs of “what” representation after 100k iterations are shown in Figure 6.

Data Availability

The data included in this study are available without any restriction.

Disclosure

This article was published on arXiv in preprint form [16].

This paper proposes a secure clustering strategy based on improved particle swarm optimization (PSO) in the environment of the Internet of Things (IoT). First, in the process of cluster head election, by considering the residual energy and load balance of nodes, a new fitness function is established to evaluate and select better candidate cluster head nodes. Second, the optimized adaptive learning factor is used to adjust the location update speed of candidate cluster head nodes, expand the local search, and accelerate the convergence speed of global search. Finally, in the stage of forwarding node election and data transmission, in order to reduce the energy consumption of forwarding nodes, each cluster head node elects a forwarding node among the ordinary nodes in its cluster, so that the elected forwarding nodes have the optimal energy and location relationship. Experiments show that the proposed method effectively prolongs the network lifetime compared with the comparison methods. The average node degree of the proposed method is less than 2.5.

1. Introduction

With the development of information society, the information industry is more and more vigorous, and the scope of information application is more and more extensive [1]. Especially in the process of the big data era, the acquisition of information has attracted more and more attention, and become one of the important hotspots of scientific research and value-added industry [2–4]. Effective information acquisition is the basis of information transmission, processing, mining, and application. Sensors connect the physical world and the digital world by capturing and revealing the physical phenomena of the world and transforming them [5]. Wireless sensor network (WSN) is a self-organized network composed of a large number of sensor nodes with information collection, processing, and transmission functions. Each sensor node can realize the data collection, processing, and transmission of the sensing area, and the whole network can cooperate to complete the information collection in the target area [6–8]. Through the deployment and use of the network, the ability of human society

to obtain information can be enhanced. It has changed the situation that people only rely on their own feelings and simple tools to perceive information since ancient times and greatly improved the accuracy and sensitivity of human access to data and information [9, 10].

WSN is often used to monitor events of interest in the surrounding environment. A typical WSN monitoring system consists of sensor nodes, base stations, and monitoring centers [11–13]. The remote user or monitoring center can send data acquisition, processing, and transmission commands to the sensor nodes in the network through the base station, and finally, receive the interested data through the base station [14–16].

In the environment of IoT, aiming at the problems of large node energy consumption and short network life cycle caused by the unbalanced location distribution of cluster head nodes screened by clustering routing protocol of wireless sensor networks and unreasonable data transmission path of forwarding nodes, a secure clustering strategy based on improved PSO algorithm in the IoT environment is proposed. The innovations of the proposed method lie in the following:

- (1) In the process of cluster head election, considering the residual energy and load balance of nodes, a new fitness function is established to evaluate and select better candidate cluster head nodes, which effectively shortens the communication distance.
- (2) The optimized adaptive learning factor is used to adjust the position update speed of candidate cluster head nodes, and the concave function nonlinear decreasing strategy is used to improve the inertia weight, which speeds up the convergence speed of global search.
- (3) For each cluster head node, a forwarding node is selected from the ordinary nodes in its cluster, so that the selected forwarding node has the optimal energy and location relationship, and the node communication overhead is reduced.

The remaining chapters of this paper are arranged as follows. Section 2 introduces the related research in this field; Section 3 introduces the system model; Section 4 introduces the proposed clustering routing algorithm based on improved PSO algorithm; Section 5 is the experiment, and Section 6 summarizes this study.

2. Related Works

Compared with plane routing, cluster routing saves the energy consumption of the network to the greatest extent, facilitates data fusion, and is easier to expand [17–19]. As a simple and effective random search algorithm, intelligent algorithm has good application prospects in finding the optimal solution of function and neural network recognition [20]. In the late 19th century, James Kennedy of the United States proposed PSO for the first time. It is famous for its simplicity and effectiveness. Therefore, scholars at home and abroad choose PSO algorithm in cluster head selection. Reference [21] defined a new cost function to minimize the communication distance between cluster members and cluster heads and used the PSO to select cluster heads with higher energy to optimize network clustering. Reference [22] proposed a new clustering mode EECS for wireless sensor networks, which specified the size of clusters in the network. Clusters far from the base station have a larger radius, and clusters close to the base station have a smaller radius, so as to balance the energy consumption of cluster heads. Reference [23] proposed a new hierarchical clustering protocol PSO-HC, which balanced the network energy consumption by reducing the number of cluster heads and transmitted the information collected by cluster heads to the base station by multihop. Based on the clustering of the LEACH protocol, reference [24] used the ant colony algorithm to optimize the distance location between each node and the base station and obtained the best path. Through this path, the cluster head transmitted the information to the next cluster head in sequence until the information was transmitted to the base station.

Reference [25] proposed an improved PSO algorithm to optimize the running time of the network. The algorithm comprehensively considered the factors of energy and distance to realize the selection of target nodes and proposed the introduction of relay nodes to share the transmission

work of cluster head nodes. Reference [26] combined harmony search (HS) algorithm and PSO to select cluster head nodes. The algorithm not only had the efficient search efficiency of harmony search algorithm but also had the dynamic ability of the PSO algorithm, which could better improve the performance of the network. According to the uneven clustering algorithm, reference [27] used ant colony optimization algorithm to calculate the optimal distance between the node and the base station and transmitted the data of each cluster head node to the base station through the selected optimal path. The disadvantage of this algorithm is that the path from each cluster head to the base station needs to be calculated, so it will lead to excessive energy consumption. Reference [28] proposed a clustering strategy based on FBECs (fuzzy based enhanced cluster head selection). In the clustering stage, fuzzy logic algorithm was used to calculate the qualification index of each node according to the residual energy of the node and the distance between the node density and the base station. The node generated the cluster head by comparing the randomly generated random number with the qualification index. Reference [29] proposed a clustering method based on energy center search using PSO (EC-PSO), which used geometric method to select CHs and searched energy centers in CHs selection.

3. System Model

3.1. Network Model. In order to better optimize the algorithm, this model makes the following assumptions.

- (1) The nodes are randomly deployed in the target area. After deployment, the nodes will no longer move, and each node has a unique ID.
- (2) All nodes have the same initial energy, computing power, and communication ability and can automatically adjust the transmission power.
- (3) Each node can communicate with the base station independently, and the location of the base station is known.
- (4) The node can calculate its relative position according to the angle of arrival and signal strength.

3.2. Energy Model. The same energy model as LEACH is used for communication between nodes. According to the distance $d_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}$ between node i and node j , the channel model is selected. The energy consumed by a node to send k bit data to the node with a distance of d is

$$E_{TX}(k, d) \begin{cases} k(E_{elec} + \alpha_{fs}d^2), d < d_0, \\ k(E_{elec} + \alpha_{mp}d^2), d > d_0, \end{cases} \quad (1)$$

$$d_0 = \sqrt{\frac{\alpha_{fs}}{\alpha_{mp}}}$$

The energy consumed by the node to receive and fuse k bit data is

$$\begin{aligned} E_{RX}(k) &= kE_{elec}, \\ E_{DA}(k) &= kE_{da}, \end{aligned} \quad (2)$$

where E_{elec} is the energy consumed to receive or send 1 bit data and E_{da} is the energy consumed by the node to fuse 1 bit data. The transmission model selected by the node for communication is determined by d_0 . α_{fs} and α_{mp} are the energy required for power amplification of free space channel model and multipath fading model. When the distance between nodes $d < d_0$, choose the free space channel model; otherwise, choose the multipath fading model.

4. Clustering Routing Algorithm Based on Improved PSO Algorithm

4.1. Cluster Head Election

4.1.1. Cluster Head Initialization. Because the calculation of the PSO algorithm is relatively complex, in order to avoid increasing the energy consumption of nodes in election calculation, the clustering and routing calculation based on the PSO algorithm will be completed by the base station with unlimited energy. In the initialization process, all nodes send their residual energy, location, and number information to the base station, and the base station receives and saves the information of each node. After the base station completes the clustering calculation based on the PSO algorithm, the base station broadcasts the calculation results. Each surviving node obtains the specific location information of the elected node and routing node according to the received broadcast information. PSO algorithm selects particles randomly, which is easy to fall into local optimization, resulting in uneven distribution of nodes in the cluster. To solve this problem, the energy of nodes participating in cluster head node election is limited.

Suppose there is N surviving nodes in the WSN, the energy of node i is $E(i)$, and the base station calculates the average residual energy of all nodes in the WSN as $E_a = 1/N \sum_{i=1}^N E(i)$.

In order to ensure that the selected cluster head nodes have sufficient energy to process the data in the cluster, the base station forms a set EA of all nodes with energy greater than or equal to E_a , then randomly selects K nodes from the EA, and stores them in the candidate cluster head node set to form a particle. After initially determining a group of candidate cluster head nodes, other noncluster head nodes join the cluster head nodes closest to them, respectively, to complete the establishment of initial clustering. Then, continue to select K nodes in EA in a random way, conduct a total of M times of screening, and finally generate the M groups of initial cluster head node set; that is, M particles, and form the M groups of clusters.

4.1.2. Fitness Function. The cluster head node is responsible for most activities and needs to consume more energy, which may lead to premature failure due to excessive energy

consumption and reduce the performance of the whole network. Therefore, when selecting the cluster head node, it should consider the following two aspects: select the cluster head node with large residual energy and balance the load of the cluster head node at the same time.

First, consider selecting the cluster head node set with large residual total energy. Suppose that K is the number of cluster head nodes selected by the current particle. CH represents the cluster head set and CH_k represents the cluster head node of k cluster. The ratio f_1 of the current residual energy of all nodes to the residual energy of the cluster head node set is

$$f_1 = \frac{\sum_{i=1}^N E(i)}{\sum_{i=1}^N E(CH_k)}, \quad (3)$$

where $E(i)$ represents the residual energy of the sensor node i in the particle.

After the current particle selects the cluster head node, the set CS_k is used to represent the member node set of the cluster k . C_k is used to count the number of member nodes in the cluster k . If the node j joins the cluster k , it can be expressed as $j \in CS_k$, and the C_k plus 1.

After clustering the current particles, it should further consider the load of the current cluster. The load of the cluster mainly includes the load in the cluster and the load between clusters. For the load balancing in the cluster, it is considered from two aspects: the number of member nodes in the cluster and the distance from the member nodes in the cluster to the cluster head.

Let f_2 represent the average of the deviation between s and the maximum distance between each cluster head node and its nodes in the cluster.

$$f_2 = \sum_{k=1}^K \frac{1}{K} \left| \max \left(\sum_{j=1}^N d(j, CH_k) - s \right) \right|. \quad (4)$$

Let f_3 represent the difference between the number of member nodes in each cluster and the average number of members in the cluster. The smaller the difference, the closer the number of members between clusters, and the more effective it is to balance the energy consumption between cluster heads, so as to prolong the life cycle of the network:

$$f_3 = \sum_{k=1}^K \frac{1}{K} \left| \frac{N}{C_k} - K \right|, \quad (5)$$

where $d(x, y)$ refers to the distance between node x and node y . r is the radius of clusters when the whole network area can be covered. Ideally, the area of each cluster is evenly distributed in the network area, and there is no coverage area between each cluster. The area of each cluster should be $A/(\text{pro} \times N)$, where A is the area of the whole network area, pro is the preset proportion of cluster heads and $\text{pro} \times N$ is the number of cluster heads, so the ideal r value is $\sqrt{A/(\text{pro} \times N)}$.

f_4 represents the average distance between cluster heads. The smaller the average distance between cluster heads, the smaller the load between clusters, which can reduce the communication energy consumption of the network.

$$f_4 = \frac{2(\sum_{k=1}^{K-1} \sum_{j=k+1}^K d(CH_k, CH_j))}{((K-1)/K)}. \quad (6)$$

In the fitness function, the node residual energy and load balance are comprehensively considered, and the multi-objective optimization problem is transformed into a single objective optimization problem by means of weighted sum:

$$F = \alpha f_1 + \beta f_2 + \chi f_3 + \delta f_4, \quad (7)$$

where α , β , χ , and δ are weighting factors.

4.1.3. Update Method of Speed and Position. According to the initial fitness calculation and the initially generated local optimal location and global optimal location, start a round of iterative calculation. First, update the location of the candidate cluster head node set, and then calculate the fitness of the candidate cluster head node after location update. In order to complete the location update of the candidate cluster head node set and obtain the optimization results, let the velocity components of the candidate cluster head nodes in the x and y directions be v_x and v_y , respectively, and the position components be x_x and x_y , respectively.

The calculation of the two velocity components is initially generated randomly, but in each subsequent iteration, it is determined according to the change relationship between the velocity component of the previous round of the candidate cluster head node set and the local optimal position (p_{xi}, p_{yi}) and the global optimal position (p_{xg}, p_{yg}) . The specific calculation is as follows:

$$\begin{cases} v_x(t) = wv_x(t-1) + c_1 l_1 (p_{xi}(t-1) - x_{xi}(t-1)), \\ \quad + c_2 l_2 (p_{xg}(t-1) - x_{xi}(t-1)), \\ v_y(t) = wv_y(t-1) + c_1 l_1 (p_{yi}(t-1) - x_{yi}(t-1)), \\ \quad + c_2 l_2 (p_{yg}(t-1) - x_{yi}(t-1)), \end{cases} \quad (8)$$

where w is the inertia weight, which indicates the influence of the speed of the previous $t-1$ iteration of the candidate cluster head node set on the speed of the candidate cluster head node set in this t iteration. c_1 is a cognitive learning factor and c_2 is a social learning factor, which, respectively, represent the acceleration weight of the candidate cluster head node set close to the local optimal position and the global optimal position. $l_1, l_2 \in (0, 1)$ are the random numbers.

Based on the two velocity components, the calculation method of the position components $x_{xi}(t)$ and $x_{yi}(t)$ of the candidate cluster head node in the direction x and y is as follows:

$$\begin{cases} x_{xi}(t) = x_{xi}(t-1) + v_{xi}(t), \\ x_{yi}(t) = x_{yi}(t-1) + v_{yi}(t). \end{cases} \quad (9)$$

4.1.4. Improved Inertia Weight. Among the parameters that can be adjusted by the PSO algorithm, researchers often improve the important parameter of inertia weight. A larger

inertia weight value is conducive to improve the global search ability of the PSO algorithm, and a smaller weight value will enhance the motion ability of particles.

Under the same convergence accuracy, the concave function decreasing strategy greatly improves the convergence speed of PSO compared with other improved strategies, and can more effectively control the balance between global search and local search.

The rule for improving inertia weight by using concave function nonlinear decreasing strategy is as follows:

$$w = (w_{\max} - w_{\min}) \left[\left(\frac{C_{\text{Cur}}}{C_{\text{Loop}}} \right)^2 + 2 \frac{C_{\text{Cur}}}{C_{\text{Loop}}} \right] + w_{\max}, \quad (10)$$

where $w \in [0.5, 0.9]$ and C_{Cur} represent the number of rounds of the current iteration and C_{Loop} represents the total number of iterations.

4.1.5. Location Mapping Strategy. After each round of iteration, the location of the candidate cluster head node set will be updated, and the updated node location may not find a matching surviving node in the WSN. At this time, location mapping is needed. The basic idea is to adopt the proximity principle to map the updated location to the location of the nearest surviving node. Take x_{xi} and x_{yi} as the updated node coordinates and CM_{nx} and CM_{ny} as the coordinates of the surviving node CM_n in the network. The location mapping process is as follows:

$$\begin{aligned} CM_n &= \left\{ (CM_{nx}, CM_{ny}) \mid \min \sqrt{(CM_{nx} - x_{xi})^2 + (CM_{ny} - x_{yi})^2} \right\}. \end{aligned} \quad (11)$$

The location mapping strategy solves the mismatch between the updated location and the actual surviving node location caused by the discrete distribution of network nodes. When the updated position coordinates of multiple nodes are the same, it is necessary to set a flag while updating the node. When updating and mapping the positions of other nodes, first check whether the flag has been identified as the cluster head node. If so, select the next closest node position in turn for mapping.

After completing the location mapping, take the candidate cluster head node set after the location update as the optimization result, and calculate the fitness value of each candidate cluster head node set. According to the calculation results, the local optimal location of each group of candidate cluster head node set and the global optimal location of M groups of cluster head node sets in this round are updated. If the iteration is not finished, continue to update and map the location of candidate cluster head nodes. Otherwise, the candidate cluster head node set of the global optimal position is calculated as the optimal cluster head node set, and the cluster head election is completed.

After completing the cluster head election, the base station further calculates the distance from the noncluster head node to each cluster head node and adds the noncluster

head node to the nearest cluster head node to complete clustering. Ordinary nodes only send data. After receiving the data from ordinary nodes, the cluster head node performs data fusion and then sends it to the corresponding forwarding node. The forwarding node needs to be further selected from ordinary nodes. It receives the data from the cluster head, selects the optimal path to the base station, and sends the data to the base station.

4.2. Election and Data Transmission of Forwarding Nodes

4.2.1. Election of Forwarding Nodes. After the cluster head node election is completed, the corresponding forwarding node will be selected for the cluster head node. If there are too few forwarding nodes in the network, multiple cluster head nodes send data to the base station through a small number of forwarding nodes, which will increase the energy consumption of forwarding nodes. To solve this problem, the existing WSN routing protocol adopts the way that one cluster head node corresponds to one forwarding node to increase the number of forwarding nodes, but it selects all nodes randomly without considering whether the residual energy and location of the selected nodes are balanced.

In the forwarding node election, the improved PSO algorithm of the above cluster head node election is adopted to elect a forwarding node for each cluster head node among the ordinary nodes in its cluster, so that the elected forwarding node has the optimal energy and location relationship, and avoid speeding up its energy consumption due

to too few forwarding nodes in WSN. In the calculation and evaluation of forwarding nodes, because forwarding nodes can only be elected in one cluster, the calculation methods of energy factor and location balance factor are different from those of cluster head node election. Similarly, N represents the number of surviving nodes in the WSN. After selecting K cluster head nodes, the WSN is divided into K clusters. During initialization, according to the cluster head node screening method, candidate forwarding nodes with high residual energy are screened out in each cluster to form a set of candidate forwarding nodes. Each candidate set contains K nodes. After initialization, the number of ordinary nodes is $N - 2K$. Let $E_{RN}^r(i)$ represent the residual energy of candidate forwarding node RN_i in round r , and $E_{CN}^r(i)$ represent the residual energy of ordinary node CN_j in round r . The calculation formula of energy factor fit_1 is

$$fit_1 = \frac{(N - 2K) \sum_{j=1}^{N-2K} E_{RN}^r(i)}{K \sum_{j=1}^{N-2K} E_{CN}^r(i)}. \quad (12)$$

Let $d(CN_k, CH_j)$ represent the distance between the ordinary node CN_k and the corresponding cluster head node CH_j , $d(RN_i, BS)$ represent the distance between the forwarding node RN_i and the base station BS , $d(RN_i, CH_j)$ represent the distance between the forwarding node RN_i and the corresponding cluster head node CH_j , and $d(RN_i, RN_m)$ represent the distance between the forwarding nodes RN_i and RN_m . The calculation method of the location equalization factor fit_2 of the forwarding node is as follows:

$$fit_2 = \frac{K^2 \sum_{j=1}^{N-2K} d(CN_k, CH_j)}{(N - 2K) \left(\sum_{i=1}^K d(RN_i, BS) + \sum_{i=1}^K d(RN_i, CH_j) + \sum_{i=1}^{K-1} \sum_{m=i+1}^K d(RN_i, RN_m) \right)}, \quad (13)$$

where the ordinary node CN_k is located in the cluster where the cluster head node CN_k is located and the candidate forwarding node RN_i corresponds to the cluster head node CH_j . The closer the candidate forwarding node set is to the base station, the smaller the distance between the cluster head node and the forwarding node in each cluster; the smaller the distance between the forwarding nodes in the candidate forwarding node set, the more balanced the location distribution of the candidate forwarding node set, and the greater the fit_2 value.

Based on the ability factor and location balance factor of candidate forwarding node election, the fitness function F_2 for the evaluation of candidate forwarding node set constructed by weighting method is as follows:

$$F_2 = bfit_2 + (1 - b)fit_2, \quad (14)$$

where $b \in (0, 1]$ is the weight. The higher the residual energy of the candidate forwarding node set and the more balanced the location, the greater the fitness value of the candidate forwarding node set, indicating that the candidate forwarding node set is better. In the iterative election process of candidate forwarding node set, the

speed update and location mapping method similar to cluster head node election is used to select the optimal forwarding node set.

4.2.2. Data Transmission. WSN forward routing mainly selects relay nodes for cluster heads far away from the base station, and relay nodes reduce the load of cluster heads by forwarding data packets from cluster heads. Assuming that the data packet needs to be sent to the base station through n hop; that is, through $n - 1$ relay nodes, the optimal relay node should have the following characteristics:

- (1) The distance between relay nodes should be as balanced as possible.
- (2) The relay node should have high energy to meet the data transmission requirements.
- (3) The total distance should be as close as possible to the direct communication distance between the cluster head and the base station.
- (4) The selection of relay nodes should avoid selecting other cluster heads.

- (5) The load of relay nodes should be as small as possible to avoid over development.

According to the above requirements, the corresponding fitness function is designed, which can be expressed as

$$F_3 = \varepsilon \left(\frac{E_{\min}}{E_{\text{init}}} + \frac{1}{\text{load}_{\max}} \right) + \phi \left(\frac{d_{\min}}{d_{\max}} + \frac{d_{\text{init}}}{d_{\text{total}}} \right), \quad (15)$$

where E_{\min} is the node with the smallest energy among the relay nodes; the load of the node is determined by the number of data packets received by the node. load_{\max} is the node with the largest load in the relay nodes; d_{\min} and d_{\max} are the minimum and maximum distance between adjacent nodes in the forward routing path, respectively; d_{init} and d_{total} are the sum of the distance between the cluster head and the base station and the sum of distance of the whole forward routing path; $\varepsilon = 0.5 + 0.5E_{\text{loss}}/E_{\text{total}}$; $\phi = 1 - \varepsilon$. The total energy consumption of the nodes in the cluster is changed into the energy consumed by the cluster head that needs to plan the route, and the total energy in the cluster is changed into the initial energy of the cluster head. With the operation of the network, the parameter weight ratio is dynamically adjusted.

5. Experiments and Analysis

5.1. Experimental Setup. Simulating the generation of WSN in MATLAB and setting the base station outside the network, in this environment, the secure clustering strategy based on improved PSO algorithm is tested. The experimental computer is configured with 2.3 GHz, Intel Core I7, 8 GB RAM, and 64bit Windows10. The experimental environment and parameter settings related to WSN initialization, cluster head node, forwarding node election, and data processing are shown in Table 1.

5.2. Performance Index Comparison of Topology Generated by Different Schemes. In order to prove the performance of the proposed method under the same experimental conditions, the proposed method is compared with the methods in references [28, 29], and the comparison results are shown in Figure 1. In order to compare the algorithms effectively without losing generality, it is assumed that n sensor nodes are randomly deployed in the target monitoring area of 200×200 .

As can be seen from Figure 1(a), the average link length of the three methods continues to decrease with the growth of n . The proposed method can maintain the global connectivity of the network with a short average link length and has strong advantages in reducing the overall energy consumption of the network.

Figure 1(b) shows the comparison results of the average node degree of the three control schemes. It can be seen from the figure that the average node degree of the other two methods tends to rise with the increase of the network scale, while the topology obtained by the proposed method has a low average node degree, which is basically maintained below 2.5, and the average node degree is relatively stable

TABLE 1: Experimental parameters setting.

Parameter name	Value
Number of nodes	150
Base station location	(50,100)
Network scale	200 m \times 200 m
E_{fs} (pJ.(bit·m ²) ⁻¹)	10
E_{mp} (pJ.(bit·m ⁴) ⁻¹)	0.002
E_{elec} (nJ.bit ⁻¹)	60
$d0$ (m)	70
Maximum number of rounds	2500
The number of iterations of the algorithm	200
Optimal number of clusters	10
Number of particle	20
Data packet length/bit	5000
Control packet length/bit	100
Node initial energy $E0$ (J)	0.7

and will not change greatly with the change of the network scale. It shows that this method has good stability and low interference.

As can be seen from Figure 1(c), when the network size is 70, the average number of joint points of the methods in references [28, 29] is 3.0 and 2.3, respectively, and the number of joint points of the proposed method is 0. The number of joint points of the methods in references [28, 29] decreases with the continuous growth of the network size, but the method in this paper has better stability and can ensure that there are basically no joint points under different network sizes. This is because the proposed method comprehensively considers the residual energy and load balance of nodes, establishes a new fitness function, and can select better candidate cluster head nodes. Therefore, compared with the other two methods, the proposed method can better ensure the connectivity of topology when clusters are connected.

5.3. Location Balance Test of Cluster Head Nodes. The location balance factor reflects the distribution balance of cluster head node set and forwarding node set in WSN. The more balanced the node distribution is, the smaller the total communication distance in WSN communication is, and the lower the node energy consumption will be. Based on the above experimental environment, the total distance from all ordinary nodes to cluster heads and the total distance from all cluster head nodes to base stations in multiple iterations of the methods proposed in this paper, references [28, 29] are tested, respectively. The experimental results are shown in Figures 2 and 3, respectively.

As can be seen from Figures 2 and 3, with the increase of the number of iterations, the total distance from all ordinary nodes to cluster heads and the total distance from all cluster heads to base stations in the three methods become smaller and smaller. In the method of reference [28], the energy and location of nodes are not considered in cluster head election. Initially, the two distances in Figures 2 and 3 are the largest, but the two distances drop rapidly after 2600 rounds. This is because their communication distance is large, energy consumption is large and unbalanced, and node death is fast.

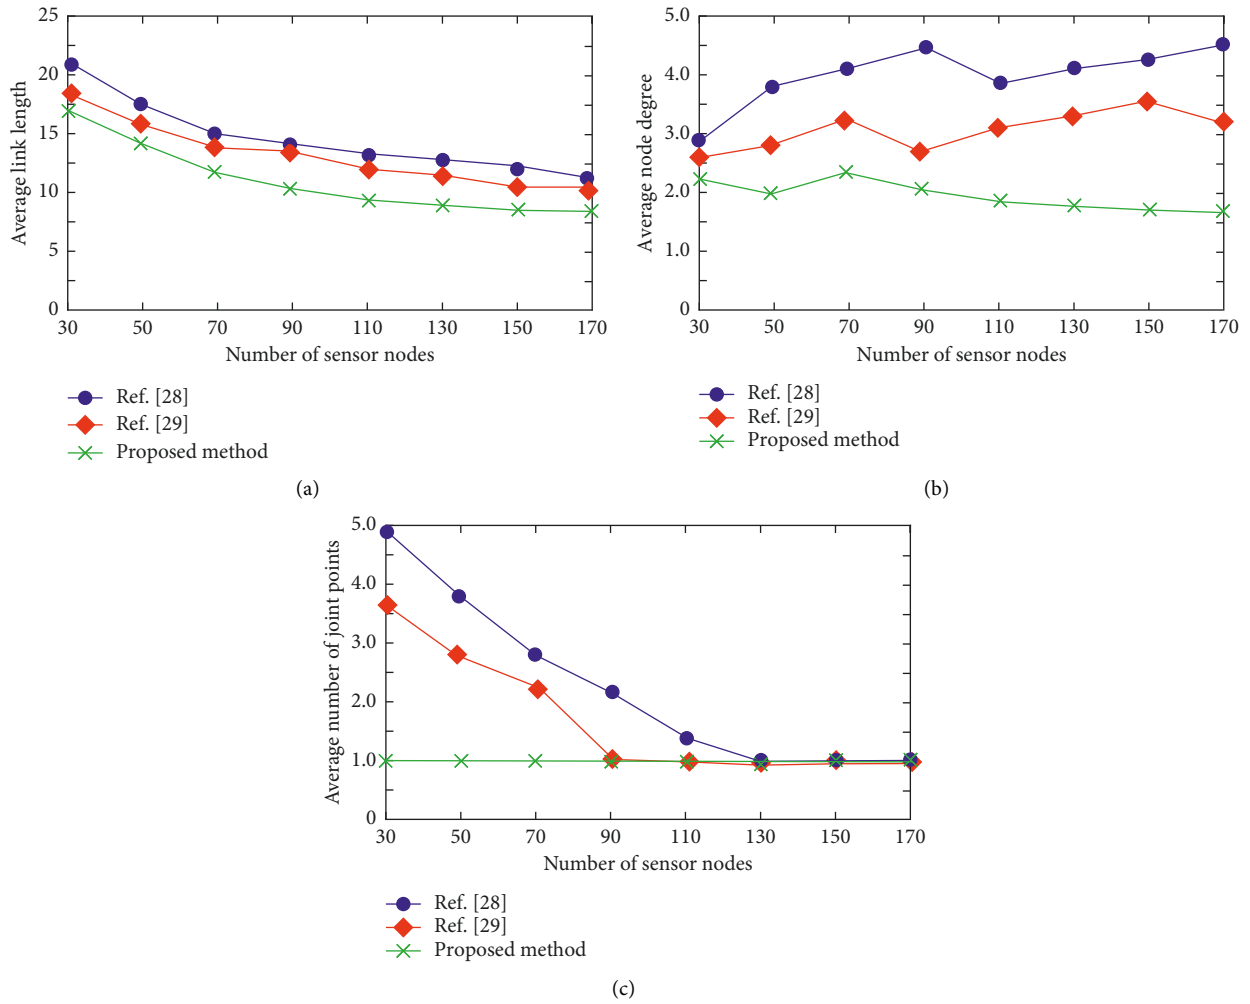

FIGURE 1: Comparison of performance indices of topologies generated by different schemes: (a) comparison of average link length; (b) comparison of average node degree; (c) comparison of average number of joints.

FIGURE 2: Sum of distances from ordinary nodes to cluster heads in different methods.

FIGURE 3: Sum of distances between cluster heads and base station in different methods.

With the large reduction of surviving nodes, their communication distance decreases, and the life cycle of WSN is greatly shortened. This is because, the proposed method elects a forwarding node for each cluster head node among the ordinary nodes in its cluster so that the selected forwarding node has the optimal energy and location relationship, which effectively reduces and balances the node energy consumption. The number of dead nodes decreases linearly and slowly, the change is relatively stable and prolongs the life cycle of WSN.

The method in reference [29] considers the location information. At the beginning, the two distances are relatively reduced, the energy consumption is reduced, and the life cycle of WSN is prolonged. The optimization of the inertia weight in the method of reference [29] makes the elected cluster head nodes close to the global optimization. The two distances measured at the beginning are lower than those in the method of reference [28], the node energy consumption is reduced, and the life cycle of WSN is longer than that in the method of reference [28]. The methods in references [28, 29] have fewer surviving nodes due to the proliferation of dead nodes in the later stage of iteration. The measured two distances are smaller than the proposed method, but the life cycle is smaller.

6. Conclusion

A secure clustering strategy based on improved PSO algorithm in the environment of IoT is proposed. Considering the residual energy and load balance of nodes, a new fitness function is established, the better candidate cluster head nodes are evaluated and selected. The location update speed of candidate cluster head nodes is adjusted through the optimized adaptive learning factor, so as to elect a forwarding node for each cluster head node among the ordinary nodes in its cluster for reducing the energy consumption of forwarding nodes. Experiments show that under the same conditions, the average node degree of the proposed method is less than 2.5, which is better than the comparison methods. Compared with the comparison methods, the proposed method can significantly improve the network life cycle of clustering method and optimize node energy consumption.

In WSN clustering routing protocol, the selected cluster head nodes usually accounts for only a small part of the total nodes, so it has sparse characteristics. In future research work, sparse theory can be introduced to solve the problem of cluster head node selection in WSN clustering routing. In addition, in practical applications, the location of sensor nodes is not fixed, so energy optimization can be studied for large-scale dynamic networks.

Trace inspection is a key technology for collecting crime scenes in the criminal investigation department. A lot of information can be obtained by restoring and analyzing the remaining traces on the scene. However, with the development of digital technology, digital trace inspection has become more and more popular. So, the main research of this article is the design and realization of the trace inspection system based on hyperspectral imaging technology. This article proposes nondestructive testing technology in hyperspectral imaging technology. Combining basic principles of spectroscopy and the image of residual traces such as car tires, shoe soles, and blood stains, it can identify the key traces. Then, based on the image denoising and least squares support vector machine method, this study improves the accuracy and restoration of the image. Therefore, this study designs a test for the trace inspection system for testing hyperspectral imaging technology. The test items include the performance of the trace inspection system, the noise reduction of the trace inspection system, and the ability of the trace inspection system to inspect blood stains. The final collected data are improved to get the trace inspection system based on hyperspectral imaging technology proposed in this study. Compared with the traditional trace inspection system, the experimental results show that the trace inspection system based on hyperspectral imaging technology can improve the accuracy by 5%–28%, compared with the traditional trace inspection system. The image restoration degree of the hyperspectral imaging technology trace inspection system can be improved by 1%–19%, compared with the traditional trace inspection system.

1. Introduction

The universality of traces at the crime scene, material objectivity, close correlation with criminal behavior, and obvious intuition play an important role in criminal activities. Through the analysis and investigation of traces, we can judge the implementation process and specific circumstances of the crime and provide the direction and clues of the investigation. It provides a reliable basis for compound investigations and important physical evidence to prove facts. The last trace may be file storage to provide clues and evidence for investigating the current incident. Traditional trace inspection technology cannot

adapt to the current complex and intelligent crime situation due to its low accuracy and inspection efficiency. Therefore, it is necessary to reform the past trace inspection technology.

With the maturity of hyperspectral imaging technology, it has been applied to many fields such as aerospace tongue coating imaging and pork detection. Its powerful functions are gradually brought into play and have attracted the attention of various countries. The research of tracking detection system based on hyperspectral imaging technology has a wide range of research space and application prospects. So, this study designs a trace inspection system based on hyperspectral imaging technology.

Saliency detection is a hot topic in recent years, and the results of saliency detection are difficult to use in general applications. Wang et al. believed that the main reason is the unclear definition of salient objects. In order to solve this problem, he claimed that the saliency should be defined in the context and took the saliency band selection in the hyperspectral image (HSI) as an example [1]. He studied the application of hyperspectral images in saliency detection, and this article mainly studies the application of hyperspectral images in trace inspection. Deep learning that represents data through hierarchical networks has been proven effective in computer vision. In order to study the role of depth features in hyperspectral image (HSI) classification, Ma et al. focused on how to extract and use depth features in the HSI classification framework [2]. Ma et al. studied the results of hyperspectral images in deep learning. If trace detection can be analyzed, it will be more in line with the purpose of this article. In order to study the application of hyperspectral images in SAJSRC, Fu et al. proposed a new shape-adaptive joint sparse representation classification (SAJSRC) method for hyperspectral image (HSI) classification. The method he proposed adaptively explores spatial information and incorporates it into a joint sparse representation classifier [3]. He is studying the application of hyperspectral images in adaptive joint sparse representation classification, and this article mainly focuses on trace inspection. The objective function of the classical non-negative matrix factorization (NMF) is nonconvex, which affects the obtaining of the optimal solution. Yan et al. proposed an NMF algorithm, which is based on the constraints of minimizing endmember spectral correlation and maximizing endmember spectral difference [4]. The method he proposed is based on the endmember spectrum, and this article studies hyperspectral images. Although there is little correlation, it still has a certain reference value. Shao et al. introduced an effective method for estimating the structure of probability classes. The SSL graph based on sparse representation adopts a method based on edge weighting, adding probability structure information to the sparse representation model. The graph construction method he proposed is superior to several traditional methods [5]. In September 1991, while hiking in the mountains of southern Austria, very close to northern Italy, Erika, and Helmut Simon stumbled upon the upper part of a human corpse protruding from a glacier. Larcher judged by the method of trace inspection that this was a hiker who disappeared in the area a few years ago [6]. He used the method of trace inspection to determine the identity of the corpse, which has a certain reference value for this article, but it is not great. In the oxygen minimum zone (OMZ), the oxygen concentration is at the limit of analytical detection. However, it does not undergo sulfate reduction, which is called hypoxia. Nitrate is usually used as the terminal electron acceptor for heterotrophic respiration. This respiration is highest near the top of the OMZ, where Cutter et al. observed the maximum of nitrite and other redox-active substances [7]. Its research is to detect the lowest area of oxygen, and this article mainly studies trace inspection. Hyperspectral images provide a wealth of spectral information for remotely distinguishing

subtle differences in ground cover plants. The ever-increasing spectral dimensions and information redundancy make the analysis and interpretation of hyperspectral images a challenge. Zhao et al. proposed a new nonlinear feature extraction method for hyperspectral images [8]. The nonlinear feature extraction method of hyperspectral image proposed by Zhao et al. mainly studies feature extraction, while this article mainly studies trace inspection. Most of the documents cited in this article are about hyperspectral images, and trace inspection is rare, so this article needs to study the related knowledge of trace inspection in depth.

The innovation of this study is to combine the nondestructive testing technology with the hyperspectral imaging technology to analyze residual traces such as car tires, shoe soles, and blood stains. Through the method of image denoising and least square support vector machine, this study further refines and restores the trace image. Compared with the traditional trace inspection system based on hyperspectral imaging technology, the trace inspection system has the characteristics of high accuracy and high image recovery ability. This study also designed experiments to verify the performance of the trace inspection system, the noise reduction of the trace inspection system, and the ability of the trace inspection system to inspect blood stains.

2. Combined with the Application Method of Hyperspectral Imaging Technology in Trace Inspection

2.1. Hyperspectral Image Acquisition Method. Hyperspectral imaging technology [9] uses an imaging spectrometer with a spectral range from ultraviolet to near infrared (200–2500 nm). Tens or hundreds of spectral bands are continuously imaged within the spectral coverage of the target object. While acquiring the spatial feature image of the object, it also acquires the spectral information of the measured object [10]. It includes comprehensive technologies including precision optical technology, detector technology, mechanics, computer technology, signal detection technology, and information analysis technology knowledge. Its application area is shown in Figure 1.

Hyperspectral imaging technology can not only obtain the spatial information of the object but also obtain the spectral information of the object. Hyperspectral imaging technology can obtain continuous spectral bands of objects [11], and the number of bands reaches hundreds. Each pixel of the collected hyperspectral image has a complete reflectance spectrum curve. Compared with multispectral imaging technology, hyperspectral imaging technology can obtain more information in a narrower frequency band, and the spectral resolution can be accurate to a few nanometers.

2.1.1. Nondestructive Testing Technology. Nondestructive testing technology [12] is a comprehensive application discipline developed with modern physics, material science, electronic science, and computer science. According to different measurement principles and information processing methods, there are more than 70 types of

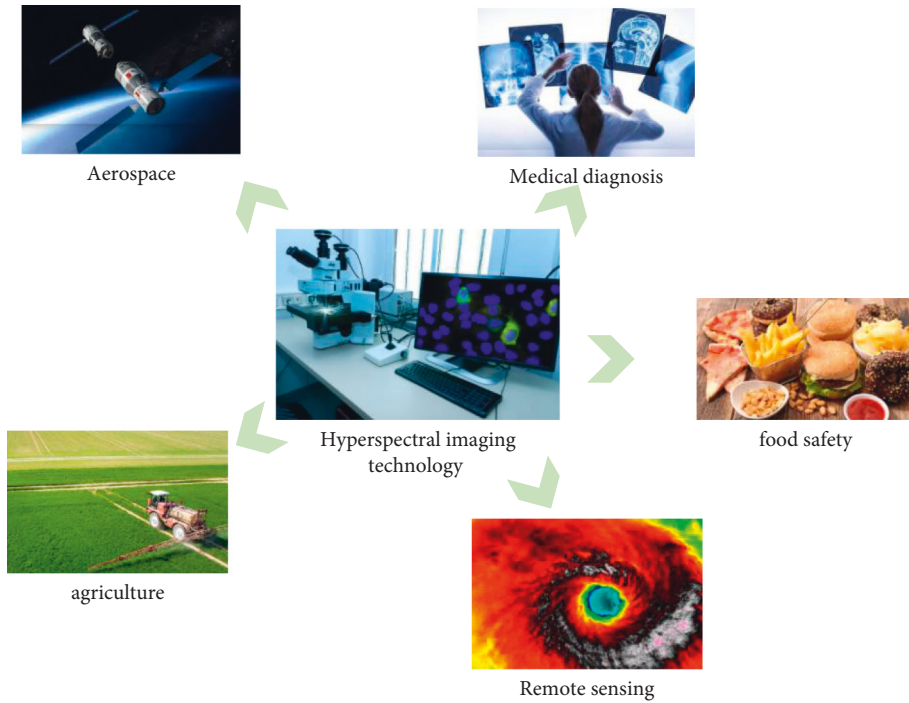

FIGURE 1: Application of hyperspectral imaging technology.

nondestructive testing, covering all branches of modern physics. The basic measurement principle is shown in Figure 2. According to the different responses of the test object to external stimulation, the output information of the test object is collected, the correlation relationship with the input information is established, and then the physical and chemical properties of the test object can be diagnosed.

2.1.2. Basic Principles of Spectroscopy. The matter is always in motion, and the atoms and molecules that makeup matter are also in motion. The rotation of electrons in molecules around atoms is called electronic movement. The vibration of atoms in a molecule is called molecular vibration. The rotation of the molecule itself is called molecular rotation [13]. Different exercise methods have different energies, divided by energy level, that is, electronic energy level, vibration energy level, and rotational energy level. When a substance is stimulated by a specific external energy, the state of molecular motion will change, and the energy level will also change accordingly. This form of change is achieved through the absorption or divergence of energy photons, as shown in Figure 3. Particles absorb energy photons and then transit from the ground state to the excited state, and from the excited state back to the ground state, and they emit energy photons. This form of energy is electromagnetic radiation, commonly known as light. Arranging electromagnetic radiation according to a certain energy level or frequency order is the electromagnetic radiation spectrum or spectrum [14]. As shown in Figure 4, according to the difference between absorption and divergence energy, it is divided into absorption spectrum and divergence spectrum.

Near-infrared spectroscopy [11] (780–2526 nm) is the earliest nonvisible spectrum discovered by mankind, and it

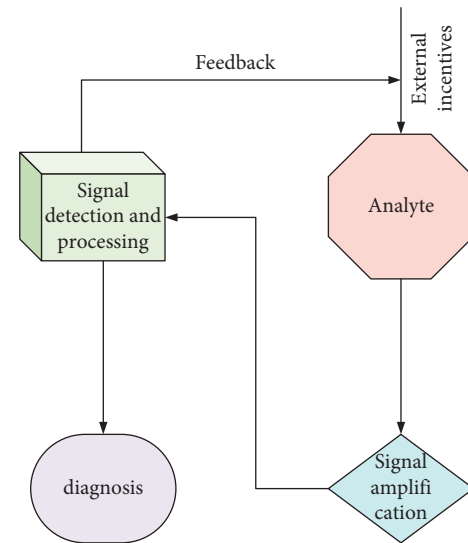

FIGURE 2: Basic measurement principle of nondestructive testing technology.

FIGURE 3: Schematic diagram of particle absorption or dissipation of energy.

FIGURE 4: Spectral images of different ranges and the molecular motion modes generated by energy.

is also one of the earliest researched spectra. The generation of near-infrared light is mainly caused by the internal vibration of polyatomic molecules. It contains a wealth of chemical bond information, such as hydrogen bond, bond strength, chemical species, and dielectric properties.

2.2. Trace Inspection. Trace inspection [15] is the analysis, identification, and judgment of various characteristics of the formation and change characteristics of criminal traces and the object of trace creation [16]. Therefore, in the process of trace inspection, the collection of traces is very important. The main method is shown in Figure 5.

In the process of trace inspection, any on-site traces need to be used as evidence and should be extracted from the site and preserved in their original form for use by inspectors. The main methods of extracting traces are as follows: transfer method, such as transferring trace materials to a specific carrier by a specific method; molding methods, such as using silicone rubber or plaster liquid to make trace models for three-dimensional traces; photocopying methods, such as the use of electrostatic adsorption to extract traces of dust; the original extraction method, such as direct collection and extraction of small-volume trace objects and trace-bearing objects. The photographic method is a method that can be used for all kinds of trace extraction in the process of trace collection. It can not only achieve lossless acquisition [17] but also perform multiple acquisition processes. Moreover, the photographic method is also a work step that must be carried out before trace extraction, and it is a necessary means to ensure the originality of traces.

The collection of traces includes the collection of pictures and text. It is a highly professional work. Only comprehensive and correct collection can reflect the actual work situation of on-site investigation and trace inspection, and the basic role of traces can be brought into play.

Image [18] has been used in forensics since it was invented in 1839. After entering the digital age, the frequency of use of images has become higher, an alternative to

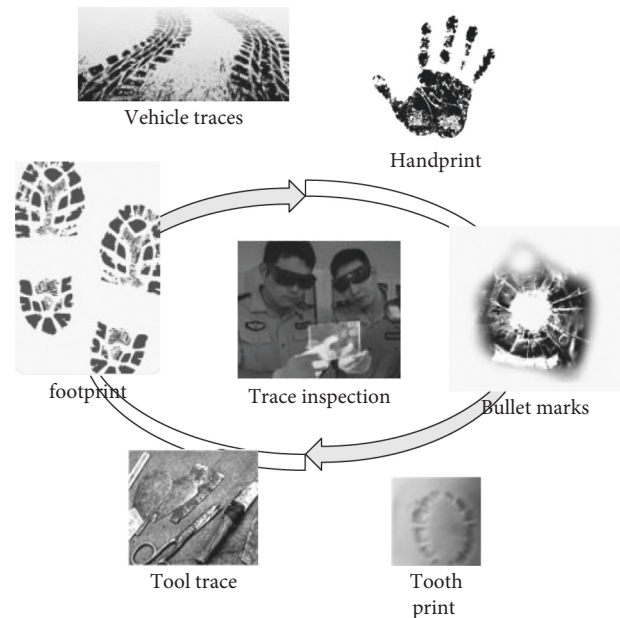

FIGURE 5: Main methods of trace inspection.

analog images—digital images have the advantages of environmental protection, low collection error rate, and convenient use, and it plays an increasingly important role in the process of trace inspection.

In the digitization of trace inspection, the collection of digital images is one of the important methods of trace collection. It mainly refers to the process of receiving light waves reflected or emitted by objects in the scene, recording and storing them, or obtaining image data through other scientific and technological equipment.

There are many ways to collect images. At present, there are four most commonly used collection methods in this article: using a digital camera to take photos directly, using a scanner to scan analog images, capturing video frames, and creating using drawing software. In the trace inspection, the

collection of traces must be a true and objective reflection, so the image collection of traces mainly uses the first three methods.

2.2.1. Tire Tracks on the Road. As the main component of the vehicle, tires play a role in supporting the weight of the vehicle, changing the direction of travel, transmitting braking and driving force, and alleviating road impact. Carbon black, which is a compounding agent for tire rubber materials, adheres to the road surface and leaves marks. In the case of high friction between the mud and the road, the heat release rate is lower than that of the mud of the tire, and the melting point of the tire and the road is relatively low, so the mud rubber becomes soft, black, peeling, and black when attached to the road. The tire traces on the road, such traces can be extracted from the debris of mud rubber [19], and the principle is shown in Figure 6.

In the process of collecting tire traces at the accident site, the tire traces of vehicles related to the accident can be judged according to the new degree of tire traces. The tire marks of a puncture on the road are flat sandwich marks with dust marks and rubber particle marks. Dust traces are usually only displayed on newly repaired roads. In most cases, those are potential traces. In contrast, the rubber particles of cement are easier to observe on the road track (usually displayed when the mud and the road slide against each other). The new tire truck leaves a lot of rubber particles on the road, and the color becomes darker. If the tire of the vehicle involved in the accident slips, then there will be obvious scars on the road surface. Old tire trucks generally have no particles of tire marks. Generally speaking, the new tire tracks are the tire tracks of the vehicles involved in the accident.

2.2.2. On-Site Shoe Sole Trace Pattern Image Extraction Method. There are various methods for extracting pattern images of shoe sole traces on-site [20], but the determination of the extraction method is mainly based on various conditions such as the trace-bearing object of sole traces and the complexity of the site.

The photographic extraction method is the most frequently used method of fixing and extracting on-site traces without damage. Physical evidence photography is mainly used to take photos of shoe sole traces at the scene. This is also an effective way to faithfully record the original state, location, and surrounding relationships of the sole trace pattern image. However, the use of photography to extract images of shoe sole traces will also encounter some problems. If the scale bar and the sole trace surface are not in the same plane, and the height difference is still relatively large, then this will cause the measurement error to become larger due to the perspective deformation of the near and far. The requirements for photographing conditions are relatively strict, so when using photographing methods to extract the image of shoe sole trace patterns, it must be strictly in accordance with the specifications.

The photocopy extraction method is mainly aimed at flat footprints, especially flat dust footprints. The photocopy

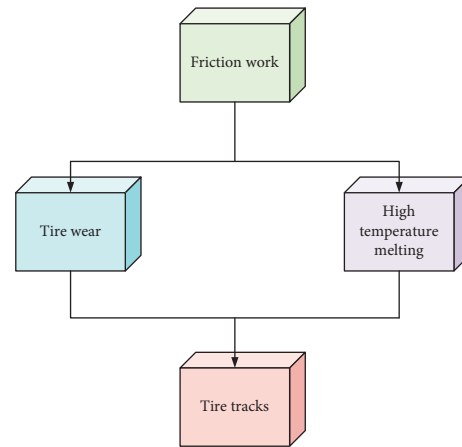

FIGURE 6: The formation mechanism of tire marks.

extraction method transfers the sole traces from the trace-bearing object to other objects with larger color contrast, which is convenient for observation and photo fixation. Copy extraction methods include the electrostatic copy method and paste copy method. Among them, the electrostatic photocopying method is mainly to add or subtract layers of dust sole traces left on the surface of relatively flat and dry objects such as cement floors, terrazzo floors, wooden surfaces, floors, towels, and textiles. The paste copying method is to use relatively a wide palm print tape or sole trace special tape to attach clear dust flat sole traces or sole traces after powder brushing and stained fixed sole traces, etc.

The mold extraction method is mainly aimed at the three-dimensional sole traces. After taking photos of the three-dimensional sole traces, a model of the sole traces must be made. Molding methods include the plaster molding method and cassia gum molding method. Molding methods are also different for different mark-bearing objects. For example, mold making on snow cannot use water at room temperature to prepare plaster liquid. It is necessary to use water temperature close to snow to mold, or use snow trace wax, snow sole trace fixative, etc. to fix the snow sole traces before molding. The cost of cassia glue molding is higher, but in major cases, the cassia glue molding method can be used for local small sole traces. The model made of cassia glue is elastic, not easy to break or break, and the shape is delicate, which can better reflect the characteristics of the traces of the sole.

For the visualization of potential footprints at the crime scene, powder and chemical visualization methods are often used. The chemical display method also includes the red blood salt color method of dust sole traces, the value indicator method of dust sole traces, the "502" glue display method, and the tetramethylaniline solution method of blood footprints.

No matter which extraction method is used, the extraction must be performed in accordance with the specifications; otherwise, the extracted sole trace pattern image will lack information and affect the subsequent processing work.

2.2.3. Footprint Detection Research Technology

(1) *Height Identification.* Most surveys and statistics show that there are many types, many patterns, and high overlapping characteristics of footprints left on crime scenes. To a certain extent, it affects the reflection of traditional footprint features, such as the interaction between legs and bearing objects during walking. At the same time, the extraction method of on-site footprints is also one of the important factors affecting the inspection results [21]. First of all, in order to improve the accuracy of the inspection, before analyzing and inspecting the footprints, it is necessary to determine the symptom extraction method to be used based on various footprints and various on-site environments.

(2) *Age Analysis.* In the past, in some films and TV works, it was often seen that the police judged the age of the characters left by the footprints left at the crime scene. Judging their age through footprints is very helpful in investigating criminal cases.

Age is the length of time from birth to death, usually expressed in “years.” Age is not only a natural sign based on biology but also an important time sign in physiological processes. The characteristics of human footwork are also closely related to age. The characteristics of footwork reflect a person’s physiological state and can correctly reflect person’s various physiological states.

2.3. *Image Denoising.* At present, many methods have been proposed to filter out the noise in the image. The smoothing of images is generally divided into two categories: global processing and local processing. Global processing is to correct the entire image or most of the image. This method is relatively computationally expensive. Local processing is the use of local operators on the image. Calculating the neighborhood of a specific pixel greatly reduces the amount of calculation.

The following sections describe several commonly used image denoising methods:

2.3.1. *Neighborhood Average Method.* The neighborhood average method [22], called the average filtering method, is a simple spatial region processing method. The basic idea is to replace the gray value of each pixel with the average value of the gray values of several pixels. $f(a, b)$ is a noisy specific $K \times K$ image. After the neighborhood averaging process, the image $h(a, b)$ is obtained. $h(a, b)$ is determined by the following formula:

$$h(a, b) = \frac{1}{j} \sum_{(i, j) \in D} f(i, j). \quad (1)$$

2.3.2. *Median Filtering Method.* The median filter method [23] is the most widely used statistical filter in image processing, and it is also the most famous sequential statistical filter. The neighborhood averaging method blurs the edges

of the image while removing noise. In contrast, the middle finger filtering is better than neighborhood averaging.

Median filtering is done on the one-dimensional sequence $f_1, f_2, f_3, \dots, f_k$. The length of the window is taken as j , and the number of j from the sequence $f_{x-v}, \dots, f_{x-1}, f_x, f_{x+1}, \dots, f_{x+v}$ is extracted as the center point of the window, where

$$v = \frac{(j-1)}{2}. \quad (2)$$

The number of j is arranged by size at a time, and the middle value is taken as the output value:

$$b_x = \text{med}\{f_{x-v}, \dots, f_{x-1}, f_x, f_{x+1}, \dots, f_{x+v}\} \quad x \in k. \quad (3)$$

The two-dimensional median filter is represented by the following formula:

$$b_x = \text{med}\{f_{xy}\}. \quad (4)$$

2.3.3. *Low-Pass Filtering Method.* Both the neighborhood averaging method and the median filtering method process the image in the spatial domain. The low-pass filtering method [24] is a method of processing images in the frequency domain.

The mathematical expression of the filter is as follows:

$$H(a, b) = G(a, b)F(a, b). \quad (5)$$

Among them, $F(a, b)$ is the Fourier transform of the original image, $H(a, b)$ is the Fourier transform of the image smoothed by the filter, and $G(a, b)$ is the transfer function of the filter.

The edges, jumps, and grain noise of the image are the high-frequency components of the image. The background area represents the low-frequency components, so the simplest low-frequency filter is to obtain the high-frequency components in the Fourier transform of the image. The corresponding filter is called a two-dimensional ideal low-pass filter (ILPF), and its transfer function is as follows:

$$G(a, b) = \begin{cases} 1, & S(a, b) \leq S_0, \\ 0, & S(a, b) > S_0. \end{cases} \quad (6)$$

Among them, S_0 is the designated non-negative value, and $S(a, b)$ is the distance between point (a, b) and the origin of the frequency rectangle. In addition to ideal low-pass filters, low-pass filters also include Butterworth low-pass filters (BLPFs) and Gaussian low-pass filters (GLPFs). This article uses the Gaussian slow path filter. The transfer function of the Gaussian slow path filter is as follows:

$$G(a, b) = q^{-S^2(a, b)/2S_0^2}. \quad (7)$$

Among them, $S(a, b)$ is the distance from the origin of the Fourier transform.

There are many methods for image sharpening, such as high-pass filtering, gradient sharpening, and Laplacian sharpening. The high-pass filter includes ideal high-pass filter (IHPF), Butterworth high-pass filter (BHPF), and

Gaussian high-pass filter (GHPF). This article only introduces gradient sharpness and Laplacian sharpening.

(1) *Gradient Sharpening*. Gradient processing is often used in industrial inspections, auxiliary manual defects, or more general automatic inspection preprocessing. For image f , the gradient at point (a, b) is as follows:

$$H[f(a, b)] = \left[\left(\frac{\gamma f}{\gamma a} \right)^2 + \left(\frac{\gamma f}{\gamma a} \right)^2 \right]^{1/2}. \quad (8)$$

For discrete images, the above formula can be approximated by the difference method to obtain the following equation:

$$H[f(a, b)] = \{ [f(a, b) - f(a-1, b)]^2 + [f(a, b) - f(a, b-1)]^2 \}^{1/2}. \quad (9)$$

In order to facilitate programming and improve calculations, it can be further simplified as follows:

$$H[f(a, b)] = |f(a, b) - f(a-1, b)| + |f(a, b) - f(a, b-1)|. \quad (10)$$

(2) *Laplacian Sharpening*. Like the gradient, Laplace operation is also a linear combination of partial differential operations, which is a linear operation accompanied by rotation invariance as follows:

$$\nabla^2 f = \frac{\gamma^2 f}{\gamma^2 a} + \frac{\gamma^2 f}{\gamma^2 a}. \quad (11)$$

For discrete digital images, the Laplacian operator can be expressed as follows:

$$\begin{aligned} \nabla^2 f &= \frac{\gamma^2 f}{\gamma^2 a} + \frac{\gamma^2 f}{\gamma^2 a} = f(a+1, b) + f(a-1, b) \\ &+ f(a, b+1) + f(a, b-1) - 4f(a, b). \end{aligned} \quad (12)$$

The following formula is used to deal with the image blur caused by the diffusion effect:

$$h(a, b) = f(a, b) - k\theta \nabla^2 f(a, b). \quad (13)$$

Among them, $k\theta$ represents the coefficient related to the diffusion effect. The value of $k\theta$ must be moderate; otherwise, it will affect the sharpening effect of the image. If $k\theta = 1$ is taken, then the formula is transformed as follows:

$$\begin{aligned} h(a, b) &= 5f(a, b) - f(a+1, b) - f(a-1, b) \\ &- f(a, b+1) - f(a, b-1). \end{aligned} \quad (14)$$

2.4. Least Squares Support Vector Machine. There is a modeling set $\{a_n, b_n\}_{n=1}^K$ composed of K data, where the input data are $a_n \in R^K$ and the output data are $b_n \in R$. Using a nonlinear function $\gamma(\cdot)$, the input data are mapped to a high-dimensional feature space and a relationship model is established:

$$b(a) = w^S \gamma(a) + y. \quad (15)$$

In the formula, $w \in R^K$ is the weight vector and b is the bias value. When using least squares support vector machine to solve, the function fitting problem can be described as the following optimization problem:

$$\min M(w, q) = \frac{1}{2} w^S w + \frac{1}{2} \mu \sum_{n=1}^K q_n^2. \quad (16)$$

The constraints are as follows:

$$b_n = w^S \gamma(a) + y + q_n, n = 1, \dots, K. \quad (17)$$

In the formula, $R^k \rightarrow R^{k_n}$ is the kernel space mapping function, μ is the penalty coefficient, and q_n is the error variable. According to the formula, the model is transformed into the dual space to solve it, and the following Lagrange function is obtained:

$$L(w, y, q, x) = M(w, q) - \sum_{n=1}^K x_n \{ w^S \gamma(a_n) + y + q_n - b_n \}. \quad (18)$$

In the formula, the Lagrange multiplier $x_n \in R$ is called the support value. The partial derivative of each variable is obtained to get the following conditional equation:

$$\begin{aligned} \frac{\phi L}{\phi w} = 0 &\rightarrow w = \sum_{n=1}^K x_n \gamma(a_n), \\ \frac{\phi L}{\phi y} = 0 &\rightarrow \sum_{n=1}^K x_n = 0, \end{aligned} \quad (19)$$

$$\frac{\phi L}{\phi q_n} = 0 \rightarrow x_n = \mu q_n, n = 1, \dots, K,$$

$$\frac{\phi L}{\phi x_n} = 0 \rightarrow w^S \gamma(a_n) + y + q_n - b_n = 0, n = 1, \dots, K.$$

After eliminating the variables w and q , the system of linear equations can be obtained:

$$\begin{bmatrix} 0 & \vec{1}^S \\ \vec{1} & \rho + \mu^{-1} I \end{bmatrix} \begin{bmatrix} y \\ x \end{bmatrix} = \begin{bmatrix} 0 \\ b \end{bmatrix}. \quad (20)$$

$$\text{In the formula, } \begin{cases} b = [b_1, \dots, b_K], \\ \vec{1} = [1, \dots, 1], \\ x = [x_1, \dots, x_K], \\ \rho = \{\rho_{nl} | n, l = 1, \dots, K\}, \end{cases} \text{ and}$$

$$\rho_{nm} = \gamma(a_n)^S \gamma(a_l) = N(x_k, x_l), n, l = 1, \dots, K.$$

$N(x_k, x_l)$ is the kernel function that must satisfy Massa's theorem. The commonly used kernel functions include linear kernel functions, polynomial kernel functions, radial basis kernel functions, and multilayer acceptor kernel functions. The kernel function used in this article is a nonlinear radial basis kernel function:

$$N(x_k, x_l) = \exp \frac{-(a-b)^2}{2e^2}. \quad (21)$$

Thus, the fitting model of the least squares support vector machine can be obtained as follows:

$$b(a) = \sum_{n=1}^K x_n N(a, a_n) + y. \quad (22)$$

3. Test Experiment of Trace Inspection System Based on Hyperspectral Imaging Technology

3.1. Retrieval Performance Experiment of Trace Inspection System. In order to verify the retrieval performance of the imaging spectrum image trace inspection system proposed in this study, the average retrieval accuracy before and after feature randomization encryption is compared in the experiment. It also compares the average precision and retrieval time of the encryption method in this study and the order-preserving encryption method in image retrieval. It is a comparison of the retrieval performance of the imaging spectral image security retrieval system before and after the introduction of relevant feedback.

In order to prove the effectiveness of the feature randomization encryption method, this experiment compares the recall curve and average accuracy of image retrieval before and after encryption. Figure 7 shows the recall-precision ratio curve before and after feature encryption. It can be seen from the figure that the precision and recall rates after feature encryption have not changed much compared with that before feature encryption.

In order to visually see the impact of feature encryption on the retrieval accuracy, Table 1 lists the results of the average retrieval accuracy before and after encryption.

It can be seen from the table that the average precision before encryption using feature randomization is 86.10% and after encryption is 85.25%, and the overall performance of the image retrieval average precision before and after encryption is equivalent. That is, the method in this study has little effect on the accuracy of the retrieval system. The method in this study can effectively protect the image feature information while ensuring the accurate retrieval of imaging spectral images.

In order to further prove the effectiveness of the feature randomization encryption method in this study, this experiment compares the exact recall rate and the average precision rate with order-preserving encryption. Figure 8 shows the recall-precision curve of the two encryption methods. It can be seen from the figure that the retrieval performance of the feature randomization encryption method in this study is better than that of the existing order-preserving encryption methods in the laboratory.

In order to compare the retrieval performance of the two methods intuitively, the average precision of image retrieval of the two methods is given in Table 2.

It can be seen from the table that the average precision of the randomized encryption method in this study is 85.25%, and the average precision of the order-preserving encryption method is 83.26%, which is about 2% higher. It proves the

effectiveness of this method. The table also lists the comparison of encryption time and retrieval time of two different feature encryption methods. The feature encryption time of the method in this study is 5.0×10^{-3} s, the time to retrieve an image after encryption is 1.0 s, the order-preserving encryption method requires 1.10 s for feature encryption, and the time to retrieve an image after encryption is 3.0 s. Whether in terms of feature encryption or retrieval speed, the performance of this method is optimal. The main reason is that the form of the hash code of the depth spectrum-spatial feature in this article speeds up the calculation speed.

3.2. Hyperspectral Image Denoising Experiment. If there is a large amount of hyperspectral image data, then it will affect the subsequent processing. Therefore, the ENVI software is used to cut a part of the calibration image without data and delete redundant data information. Since hyperspectral technology was originally used in the field of remote sensing, it was originally used to process hyperspectral remote sensing images.

The amount of data in hyperspectral images is very large, the number of bands is large, and the data and information between bands are repetitive and redundant. The original CCD detection that records the reflection spectrum of each band is very sensitive, and the existence of dark current has an impact on the experimental data. The steps to reduce hyperspectral image noise are as follows: open the ENVI software, select the hyperspectral image after the black and white frame calibration, click [MNF Rotation] under the [Conversion] function key, select [Forward MNF], and perform the positive change with minimum noise.

The spatial subset adjusts the size of the sensing area of the hyperspectral image, so that the tracking range to be processed is included in the sensing area, and redundant background information is suppressed to a minimum. In the second step, the inverse transformation of the MNF rotation algorithm is performed. The noise-free file processed in the previous step is selected, the image size is set to be the same as the size of the sensing area in the previous step, and the noise-reduced file and the noise-removed hyperspectral image are saved, as shown in Figure 9.

It can be seen from the figure that after the noise reduction of the hyperspectral image, the burrs of the reflection spectrum curve of the traces are reduced and become smoother.

3.3. Hyperspectral Image Fusion of Different Bloodstain Samples. Because the pictures obtained in this experiment are hyperspectral images of all bands, not all of them are suitable for image fusion processing. This article needs to find images that are valuable for the experiment to be fused. As far as blood handwriting pictures are concerned, there are two factors that affect the fusion effect: one is the clarity of the blood handwriting itself and the other is the clarity of the background image of the blood handwriting carrier. Generally speaking, blood writing and carrier background under different wavebands will not reach the clearest degree at the same time, because the degree of absorption and response to

I	6.21	10.26	55.27	47.68

the same wavelength of light is different between the blood and the carrier. Therefore, this article needs to select two types of pictures for fusion: one is the picture with the clearest blood writing and the clearness of the carrier background. The second is the clearest background image of the carrier, and the clearness of blood handwriting is uncertain. Combining the two pictures together can get a clear picture of the blood handwriting image and the carrier background image. The experimental results are listed in Table 3.

Through the evaluation indicators in the table, it can be found that after the fusion, the average value of the blood handwriting image increases, and the visual effect of naked-eye observation is improved. The standard deviation of blood handwriting images increases, and the amount of information tends to maximize. The average gradient of the blood handwriting image increases, and its sharpness increases. The information entropy increases, and the amount of information increases. It shows that the image obtained by wavelet fusion is clearer and more informative than the blood handwriting image of a single band, which can greatly improve the ability of hyperspectral bloodstain detection.

Regarding the hyperspectral image fusion of blood fingerprint samples, 6 images that meet the requirements were selected for fusion in the experiment. The selected images and the fusion results are listed in Table 4.

Through the evaluation indicators in the table, it can be found that after the fusion, the average value of the blood fingerprint image increases, and the visual effect of naked-eye observation is improved. The standard deviation of blood fingerprint images increases, and the amount of information tends to maximize. The average gradient of the blood fingerprint image increases, and its sharpness increases. The information entropy increases, and the amount of information increases. It shows that the image obtained by wavelet fusion is clearer than a single-band blood fingerprint image and has a larger amount of information, which can greatly improve the ability of hyperspectral bloodstain detection.

For the hyperspectral image fusion of conventional bloodstain samples, three images that meet the requirements are selected for fusion processing in the experiment. The selected images are listed in Table 5.

Through the evaluation indicators in the table, it can be found that after fusion, the average value of conventional

bloodstain images increases, and the visual effect of naked-eye observation is improved. The standard deviation of conventional bloodstain images increases, and the amount of information tends to maximize. The average gradient of the conventional bloodstain image increases, and its sharpness increases. The information entropy increases, and the amount of information increases. It shows that the image obtained by wavelet fusion is clearer and more informative than the conventional bloodstain image of a single band, which can greatly improve the ability of hyperspectral bloodstain detection.

4. The Image Trace Inspection Capability of the Trace Inspection System on Account of Hyperspectral Imaging Technology

Based on the hyperspectral imaging technology and the knowledge of trace inspection, this study designs a trace inspection system based on hyperspectral imaging technology. The system can improve the degree of trace recovery and also improve the accuracy of the image. The system can inspect residual traces such as car tires, shoe soles, and blood stains. In this regard, this study designs a set of controlled experiments. They were compared with a trace inspection system based on hyperspectral imaging technology and a traditional trace inspection system. There are 10 sets of pictures in each group, and the detection accuracy and recovery degree are compared respectively. The experimental results are shown in Figure 10.

It can be seen from the figure that the accuracy of the trace inspection system based on hyperspectral imaging technology can reach 80%–95%, while the traditional one is only 67%–75%. Therefore, the trace inspection system of hyperspectral imaging technology designed in this study can improve the accuracy by 5%–28%. The recovery degree of the trace inspection system of hyperspectral imaging technology can reach 80%–92%, while the traditional one is only 73%–79%. It shows that the trace inspection system of hyperspectral imaging technology can be improved by 1%–19%, compared with the traditional one. By analyzing the experimental results, the trace inspection system based on hyperspectral imaging technology has the characteristics of high accuracy and high image recovery ability compared with the traditional trace inspection system. This is very important for criminal investigation trace inspection.

5. Conclusion

This study mainly studies the application of hyperspectral imaging technology in trace inspection. In order to explore how it can be used in trace inspection, this article combines the nondestructive testing technology of hyperspectral imaging technology. By recognizing images of residual traces such as car tires, shoe soles, and blood stains, and then combining image denoising and least squares support vector machine methods, this article denoises and restores the images. This study also designs the retrieval performance experiment of the trace inspection system to verify the performance problems of the hyperspectral imaging

technology. It designed a hyperspectral image noise reduction experiment to verify its degree of noise reduction. It also designed a hyperspectral image fusion experiment of blood stain samples to verify the fusion recovery capability of hyperspectral imaging technology.

Based on real sales data, this article constructed LGBM and LSTM sales prediction models to compare and verify the performance of the proposed models. In this article, we forecast the product sales of stores in the future $T + 3$ days and use MAPE as the evaluation index. The experiment shows that the product sales prediction model based on the convolutional LSTM (ConvLSTM) network has better prediction accuracy. From a store point of view, ConvLSTM prediction model MAPE was 0.42 lower than the long short-term memory (LSTM) network and 0.68 lower than LGBM. From the perspective of commodity categories, different commodity categories are suitable for different forecasting methods. Some categories are suitable for regression forecasting, while others are suitable for time-series forecasting. Among the categories suitable for time-series forecasting, the ConvLSTM model performs the best.

1. Research Background

In recent years, the Internet has developed rapidly with the passage of time, and enterprises have accumulated massive valuable data, which contains a huge value and is waiting for people to dig. In addition, due to the rise of big data and artificial intelligence, our life has undergone great changes, and many emerging fields of science and technology have emerged. Traditional enterprises also want to take the ride of big data and artificial intelligence to bring scientific analysis and guidance to companies and enterprises.

New retail, supported by artificial intelligence, big data, mobile Internet, and other cutting-edge technologies, emerges in the trend of China's residents' consumption upgrading. With new concepts such as scenarioization, fragmentation, and experientialization, new retail formats are reconstructed, leading to the transformation and upgrading of China's retail market. The traditional retail has come to the stage of contraction, the development of traditional e-commerce has reached a bottleneck today, and the sales industry is in a very challenging period. In the near future, the traditional offline or pure online form may no longer exist, and the full integration of online and offline new retail will be the general trend.

While the new retail industry has been changed, there are also many new challenges. Competitors from a variety of online and offline channels and an increasingly rich variety of goods, especially in the face of changing user needs, force enterprises to constantly make adjustments in the process of pursuing market profits [1]. The development direction of new retail is still to meet the changes of users' needs. As a result, predicting users' needs accurately is very important and presents more challenges in the context of the new retail industry.

2. Related Works of Demand Forecasting

Research on demand forecasting has always been a hot topic for experts at home and abroad. Accurate forecast results are extremely important in different industries, especially for the emerging new retail, which will directly affect the sales of enterprises. Combined with the research of domestic and foreign experts on demand forecasting, the forecasting method is divided into qualitative forecasting and quantitative forecasting.

Qualitative sales forecasting methods mainly include the subjective probability method, expert judgment opinion

method, Delphi method, mutual influence method, scenario prediction method, etc [2–4]. Quantitative sales forecasting methods mainly include the time-series method (e.g., autoregressive series analysis [5], ARIMA model [6]), machine learning method [7] (e.g., artificial neural network [8, 9], extreme learning machine [10], support vector machine (SVR) [11], and ensemble algorithms), and deep learning method.

Because the qualitative prediction method is mainly to predict the future demand through experts combined with their rich business experience, this method is more applicable when there are few influencing factors and the sales information cannot be fully quantified. However, due to its shortcomings such as subjective factors and poor reproducibility, in the face of an increasingly complex business environment, this method is not accurate in demand forecasting. Therefore, this article mainly expounds the research status of demand forecasting at home and abroad from the quantitative forecasting methods, namely the time-series method, machine learning method, and deep learning method.

2.1. Time-Series Prediction. Autoregressive series analysis is one of the most popular methods in time-series application, which only uses single-dimension sales data for forecasting. Back in 1927, some mathematicians proposed the earliest autoregressive model for analyzing sequence data, referred to as the AR model [12]. On the basis of the AR model, scientists combined the autoregressive process AR with the moving average process MA to produce the autoregressive moving average model, referred to as ARMA [13, 14]. AR and ARMA models have good model effects when facing stationary time-series scenes, but they are not suitable for nonstationary sequence scenes which are common. Therefore, people consider introducing difference transformation to stabilize them and generate the differential autoregressive moving average model with difference transformation, ARIMA for short [15].

For example, researchers used the beverage sales data of an enterprise, which only included sales data without other additional features; established stationary series models such as MA and ARMA for analysis and prediction, respectively, and nonstationary ARIMA models for comparative analysis; and obtained very ideal prediction results. In 2018, Facebook opened the time-series prediction algorithm Prophet, which represents the time series as the sum of trend term, period term, holiday term, and error term, which can well fit and predict the time series in the business field.

2.2. Machine Learning Prediction. With the development of machine learning, it is found that the time-series problem can be transformed into a machine learning regression problem, that is the future target data can be regression as “label.” This method can not only use the sales dimension, but also add time, holidays, weather, and other characteristics of different dimensions. Common machine learning algorithms include support vector regression (SVR) algorithm, decision tree regression algorithm, Leo Breiman and

Adele Cutler-proposed bagging ensemble learning on the basis of decision tree, and the random forest algorithm generated by the fusion of multiple decision trees. Boosting ensemble learning is introduced, which iterates multiple base learning devices, and the generated GBDT algorithm, a series of extended tree model algorithm, and an artificial neural network can solve the regression problem [16].

Avanija et al. used XGBoost to predict the house price in 2021 [17], which improved the accuracy of sales forecast and realized effective control of inventory. Experimental results show that XGBoost can fully consider the influence of external factors and historical data on sales volume and effectively predict sales volume. SVR model is used to predict the sales volume [18]. Through comparative experimental analysis with the ARIMA model and linear regression model, it was proved that the SVR model has higher prediction accuracy. Because the SVR algorithm can transform complex nonlinear regression problem into linear regression problem of high-dimensional feature space, it can be widely used in various time-series prediction problems, such as weather prediction, traffic flow prediction, etc.

2.3. Deep Learning Prediction. In recent years, with the growing enterprises accumulating the amount of data, the sales environment is becoming more and more complex and the traditional prediction method of machine learning also exposed the shortcomings, such as training time being too long, it is not easy to convergence. Therefore, people have thought more deeply about the prediction model and started to use deep learning methods to build the prediction model [19]. In terms of prediction, Shih et al. proposed a model to forecast short-term goods demand in an e-commerce context [20]. They found that short-term demand for goods could not be predicted by the periodicity of historical data, so they built a database based on buyers’ reviews to predict short-term demand for goods from this unique perspective. Based on the combination of traditional statistical model and deep learning model, the demand for e-commerce products is predicted, and good prediction results are obtained [21].

3. Sales Forecasting Modeling

The sales volume forecast of commodities can be predicted by the regression method, or the sales data can be fitted by time series. Whether regression prediction or time-series prediction, there is a specific assumption that the features are independent of each other, and the samples are independent of each other. Features are independent of each other and can be solved by constructing associative features. However, the samples are independent of each other, and there are some defects in the scenario where multiple commodities need to be predicted, that is the interaction between different commodities is not considered. There is a certain relationship between commodities, which are mutually exclusive and complementary. Some commodities are of the same type. If you select commodity A, you will not select commodity B with the same attributes. Similarly, some

commodities have complementary relationships and can be sold together, after you select commodity A, you need to match commodity C.

This chapter introduces the sales prediction model based on related commodities. Word2Vec model is used to group the predicted commodities first, and then the ConvLSTM network is used to predict the sales of the commodities after grouping in the future $T + 3$ days, as shown in Figure 1. First, Word2Vec is used for low-dimensional spatial mapping of feature words, which can make words with similar context have similar spatial mapping and extract the semantic characteristics of words. Starting from the receipt data of goods, the vector representation of goods is obtained, so as to extract the association of different goods. Then, ConvLSTM can learn the long-term dependence of data and extract the spatial characteristics of data to predict the sales volume of associated goods.

3.1. Commodity Association Clustering Based on Word2Vec. At present, there are many association analysis algorithms, such as Apriori and FP-growth. The basic idea is to select the commodity combination with high frequency by counting various commodity combinations. However, these algorithms have some disadvantages, they need to traverse all the collections in the data set globally, which consumes a lot of time. At the same time, in the face of a large amount of data, the commodity associations that can be mined are limited.

Word2Vec is a shallow neural network model, which is often used for natural language tasks. It can map feature words into low-dimensional word vectors and map semantically similar feature words into similar projection spaces. First, we need to build a Word2Vec model for commodity ticket data, train the vector representation of commodities, and then conduct association clustering according to the vector representation of commodities.

3.1.1. Commodity Word Vector Model. The vector representation of Word2Vec training commodity needs to be preprocessed for commodity receipt data according to the input requirements of the model, and then appropriate training methods are selected for unsupervised learning. Finally, the vector mapping space of the commodity is obtained. In the model, the vector space of the commodity is the network parameters from the input layer to the hidden layer.

(1) Data Preprocessing. To train the word vector of goods by using the receipt data of goods, the receipt data need to be processed according to the algorithm requirements of the Word2Vec model. The discovery of receipt data shows that (1) there are some dirty data in receipt data, such as shopping bags, price difference compensation, and returns; (2) the same user makes multiple receipts when shopping at one time; (3) the user buys fewer goods; and (4) there are multiple same goods in the same receipt. Figure 2 shows the processing process of receipt data.

First, it is necessary to remove the dirty data in the data and delete nonpredictive goods in the receipt. These dirty

FIGURE 1: The structure of the model.

data are similar to stop words in natural language, which will interfere with model training and destroy the mapping space of vectors. Then, data integration is carried out on the receipt data. There may be multiple receipts for one user and multiple same goods in one receipt. We need to summarize the goods purchased by the same user in the same day and then eliminate the duplicate goods in the receipt data.

Word2Vec model is a three-layer neural network, which predicts its context according to known characteristics or predicts the feature word according to the context of the feature word. The input of the model is the unique heat coding of the known feature word. When used for vector representation of goods, it is necessary to carry out unique thermal coding for the goods contained in the invoice data first and establish a mapping dictionary to transform the goods into the form of unique thermal coding before the commodity input model is known.

(2) Commodity Word Vector Training. Word2Vec has two models. CBOW model is used this time. The input layer is other commodities in the same receipt data of the commodity to be predicted, and the output layer is the one-hot vector of the predicted commodity.

When training the Word2Vec model, you need to set the size of the context window, and the dimension of the word vector. In general, the input is $2n$ commodities up and down the commodity w_t , because the location relationship of commodities is not considered in the receipt data, the user checks out randomly during shopping, and any commodity in the ticket data should be associated with other commodities in the same ticket. Therefore, n should include all commodities as much as possible. Assuming that the total number of commodities in the ticket is m at most, $n = m - 1$ should be set.

As for the dimension of the word vector, the decisive factor is the number of neurons in the hidden layer N , and the input data are spatially mapped through matrix $W_{V \times N}$, where vector $\{h_1, h_2, \dots, h_i, \dots, h_n\}$ is the commodity of commodity w_t and $W_{V \times N}$ is the transfer matrix of the transformation of the word vector.

3.1.2. Commodity Association Clustering. According to the commodity vector trained by Word2Vec, the commodities are correlated and clustered. Similar commodities have similar distances. The clustering algorithm can be used to group commodities and predict the relevance of commodities. The commonly used clustering algorithms include K-means clustering, mean-shift clustering, DBSCAN clustering, expectation-maximization (EM) clustering using

FIGURE 2: Model network structure.

Gaussian mixture Model (GMM) clustering, hierarchical clustering, etc. Each clustering has its advantages and disadvantages, and it is necessary to select the appropriate clustering method according to the manifestation of data samples.

In combination with the vector representation of commodities, this article will select the appropriate clustering method based on K-means clustering and DBSCAN clustering. K-means clustering is a clustering algorithm based on partition. Its main idea is to make the spacing of data samples within clusters as small as possible and the spacing of samples between clusters as large as possible, and it is a local optimal algorithm, and the results of multiple clustering will be different. The time complexity of the K-means algorithm is low, and the algorithm has excellent performance and high efficiency when facing the scene of large data sets. However, the algorithm is sensitive to outliers, and the selection of the total number of cluster classes and the initial cluster center has a great influence on the clustering effect. K-means is suitable for processing data sets with spherical data distribution.

Among the clustering algorithms, DBSCAN clustering is based on density, the general idea is to find a high density of samples first. Then the high density around samples will gradually come together, eventually forming a cluster around each sample point. However, unlike K-means clustering, DBSCAN does not specify the number of clusters to be formed. Under the same settings, the results of multiple DBSCAN clustering are consistent. The advantage of DBSCAN is that it is insensitive to noise and can cluster clusters of different sizes and arbitrary shapes. However, it is sensitive to the radius of the circle and the threshold value of samples in the circle. When the density of data clusters is different, it is difficult to select an appropriate radius, thus affecting the clustering effect. DBSCAN works with clusters of any shape, but requires roughly the same density between clusters.

Through data visualization, it can be found that the total number of commodities to be clustered is not large, which is 500, the distribution of commodity vectors is irregular, there is a small amount of noise, and the density between clusters is roughly the same. Therefore, the DBSCAN algorithm is selected to represent the association clustering of commodity

vectors. Taking the vector representation of 500 commodities trained by Word2Vec as input, using the DBSCAN algorithm, the distance threshold EPS is set as 0.1 and the sample number threshold min_Samples as 10, and the Euclidean distance is used as the distance measurement parameter to cluster the commodities.

4. Forecast Model of Commodity Sales Based on ConvLSTM

In the previous chapter, we constructed a commodity relevance clustering model based on Word2Vec, whose practical significance is to mine the association relationships between different products, the input of ConvLSTM prediction model is constructed, and the prior knowledge of product association is integrated. This section will mainly introduce the commodity sales forecast model based on ConvLSTM, including model input and output, network structure design, activation function selection, model training, etc.

4.1. Input and Output Structure Design of Network. The product sales forecast based on ConvLSTM is actually a supervised learning, which uses the sales data of stores to predict the product sales on the n th day in the future. Input data should not only contain sales data, discount information, and time characteristics of stores, but also conform to the requirements of the ConvLSTM neural network for input data.

In the figure, we splice the data of N days before time T into a two-dimensional tensor, and then sort these two-dimensional tensors according to time, thus forming an example of neural network input. It is worth noting that each two-dimensional tensor is combined according to the sales situation of each commodity and the results of commodity association clustering. Among them, the two-dimensional tensor acts as the time-sharing sales volume of a single commodity in each time period every day, and the column first puts the similar commodities in each cluster together according to the clustering results of commodities, and then according to the distance between clusters, the clusters close to each other are combined to arrange all the commodities to be predicted.

S_T can be considered as the sales data of the day T , then each example is composed of samples $\{S_{T-H}, \dots, S_{T-I}, \dots, S_{T-1}, S_T\}$ and label, where H is the number of ConvLSTM network neurons, that is the sales data of consecutive H days in history input at one time, N is the time span to be predicted, and the output of ConvLSTM network is the sales data S_{T+N} of the $T+N$ day. The input of the whole model requires S_T fusion with other external data of the day T , which will be explained in detail in the model network design in the next section.

4.2. Model Network Design. LSTM network model is very suitable for dealing with problems with time-series characteristics. The network transmits information according to the forward propagation of time step, and the cell state will be updated gradually, and the information is transmitted and forgotten through three gated systems. LSTM sales prediction model can add a feature extraction layer before data input LSTM to improve the prediction effect. For example, the prediction model based on the WaveNet-LSTM network adds a layer of the WaveNet network before the LSTM layer and uses causal convolution to obtain local and global information of the whole time series.

The convolutional neural network has a strong representation learning ability and can recognize features of different locations in space by using convolution operation and pooling operation of data samples. The convolutional neural network takes advantage of the feature that convolution operation can capture local information of data and uses multiple filters (convolution kernel) to extract information at the same time, thus realizing local perception to obtain global information. In this chapter, the advantages of convolution operation for spatial feature extraction will be utilized, and the vector operation of LSTM will be replaced by convolution operation, and combined with external influencing factors of sales volume, a sales prediction model for associated goods will be constructed. The model network diagram is shown in Figure 2.

The model is divided into two parts. In the first part, the store's sales characteristics, discount information, time characteristics, and other features are fused to form the input of the ConvLSTM network. For the input data of the model, first, the attribute features such as daily discount information and time features are fully connected, then the extracted feature reshape is the same size as the sales feature, and finally the concat operation is used to form the input of the ConvLSTM network for the sales features and the reshaped features. The second part consists of a ConvLSTM network prediction module, which consists of a ConvLSTM network layer and a fully connected layer. After the extracted features are inputted into the network, the prediction information is outputted, and the final prediction result is obtained through the full connection layer.

ConvLSTM network can be used to extract time-series characteristics and spatial characteristics of sales volume of various commodities for the following reasons:

First, traditional sales forecasting methods assume that different commodities are independent of each other and

can only forecast independent commodities. The prediction method based on time series can use single-dimension sales data to forecast, but only one kind of commodity can be predicted. To forecast multiple commodities, multiple models need to be constructed. Regression-based prediction method can predict multiple commodities simultaneously by constructing feature engineering, but it cannot obtain time-series characteristics. The idea of the ConvLSTM network is to extract and transfer information of time series from two-dimensional matrix data, so that time-series prediction of multiple commodities can be made simultaneously.

Second, in real life, commodities often interact with each other. When shopping, people will consider the repetition and collocation of commodities. For commodities with repetitive functions, they will choose only one of them, while for commodities with complementary functions, they will buy them with each other. Based on this, the ConvLSTM network can not only capture the time-series characteristics of various commodities, but also extract spatial information of data and capture the interaction between commodities through convolution operation. However, the introduction of convolution operation may bring a series of problems, such as the selection of convolution kernel and poor fitting effect.

The model needs to capture the interaction between goods through the convolution operation, but convolution can only capture part of the local information; it is difficult to obtain global information, that is when there are too many goods, the convolution operation often cannot capture the association between goods with a long distance. If the convolution is extended, more commodity association information can be obtained at the same time, but too many parameters will affect the fitting effect. We integrate the association information of commodities in advance to obtain the prior knowledge of the association relations of commodities and put the commodities with certain association relations together, and then spliced them into the two-dimensional matrix form required by the network, so that even if the size of the convolution kernel cannot contain all commodities and cannot capture the association relation of commodities with relatively distant positions, the influence will not be great. In the process of data preparation, the relationship between goods located far away from each other is poor.

4.3. Selection of Activation Function. The activation function can introduce nonlinearity into the network model and enhance the expression ability of the model. In the gated mechanism of ConvLSTM, information is also forgotten and transmitted through activation functions, commonly used activation functions are as follows:

- (1) *The Sigmoid Function.* The sigmoid function expression is as follows:

$$y = \frac{1}{1 + e^{-x}}. \quad (1)$$

Sigmoid is a commonly used nonlinear activation function. The value range of expression is $[0, 1]$, and

the range of derivative is $[0, 0.25]$. The function is easy to fall into the saturation zone on both sides, and the gradient disappears, and the output is not zero mean, which makes the model convergence slow.

- (2) *Tanh Function*. Tanh function is expressed as follows:

$$y = \frac{e^x - e^{-x}}{e^x + e^{-x}}. \quad (2)$$

The range of the Tanh function is $[-1, 1]$, and the range of its derivative is $[0, 1]$, which solves the problem that the sigmoid output is not zero mean value, but the problem of gradient disappearance still exists.

- (3) *The ReLU Function*. ReLU function is expressed as follows:

$$y = \max(0, x). \quad (3)$$

When the input value of the function is greater than 0, the output of the ReLU function is equal to the input value. When the input value of the function is less than 0, the output is 0. Function can solve the problem of gradient disappearance in the process of model back propagation, but it can only be used in the hidden layer.

According to the network structure of ConvLSTM, the default activation function of input gate and output gate is the Tanh function, and its output range is $[-1, 1]$. However, according to the actual data, it can be found that most of the sales data of commodities are too large, which will change the distribution of data, cause the gradient to disappear, and the dimensions between different commodities are the same. If the data are forcibly normalized, some data will be extremely small, which will affect the effect of the model. In addition, when the sales data of commodities is relatively large, it is not necessary to consider the negative semi-axis when selecting the activation function. Therefore, the ReLU function is chosen.

4.4. Model Training. The training process of a neural network mainly includes two stages: the first stage is the forward propagation stage, and the second stage is the back propagation stage. Specifically, once the data set is ready and the model is built, model training can be carried out. First, it is necessary to set initial values for network parameters and then input model training data. Data samples enter the model network one by one and generate model predicted values through the forward propagation of network. The back propagation process uses an optimizer to update network parameters according to the error between the predicted value and the target value of the model until the termination condition of the model is met.

The effect of model training is affected by many factors, including initialization of parameters, selection of optimizer, selection of learning rate, etc.

4.4.1. Initialization of Parameters. The training effect of the neural network model mainly depends on the updating of parameters by the optimizer. The optimizer back propagates the parameters through the gradient descent method, and the initialization of parameters greatly affects the convergence result of the model. If the initial value of the parameter is set too large, the gradient value of the parameter during back propagation will be too large, the gradient explosion will occur, and the amplitude of network update will be too large, which will make the model difficult to converge. If the initial value of the parameter is set too small, the gradient will be too small and the gradient will disappear, which will slow down the convergence speed of the parameter and make the model converge to the local optimal solution.

The initial value of network parameters should not be too large or too small and should keep the parameter positive or negative half as much as possible, and the expectation is 0. Network parameters can be initialized to small random numbers, such as random sampling with a Gaussian distribution with a standard deviation of 1 and mean of 0, or initialization with Xavier, but requires the activation function to be symmetric with respect to 0.

4.4.2. Selection of Optimizer. In a neural network, parameter optimization mainly relies on the back propagation of the optimizer. The optimizer takes advantage of network errors, calculates gradients, and updates parameters so that the model approaches or achieves the optimal solution, that is, minimizes the objective function. The most basic optimizer is gradient descent, but in the optimization process, each epoch needs to consider all samples, which wastes time and occupies memory. In order to solve the inefficiency of the gradient descent method and accelerate the convergence speed, SGD (stochastic gradient descent) is introduced. Each iteration only uses one sample of all data to update the parameter gradient. Although SGD accelerates the model training speed, it will lead to convergence oscillation and lower accuracy, so it is not a globally optimal optimization algorithm. In order to accelerate the convergence of the model and improve the fitting accuracy, researchers also put forward a momentum optimization algorithm and adaptive learning rate optimization algorithm.

In this application, there is a large amount of actual data. A store has more than 300 examples a year, a total of more than 1000 stores, and the sales data will continue to increase and accumulate, and the data are sparse, so the Adam algorithm is selected. The Adam algorithm can adaptively change the learning rate of each parameter. It is very suitable for processing sparse data. It is not only conducive to the first-order distance estimation mean, but also makes full use of the gradient second-order distance estimation variance.

4.4.3. Selection of Learning Rate. Learning rate is an important super parameter in network training; it plays a decisive factor in whether the objective function can converge to the local optimal value and how long it takes to converge to the optimal value. If the learning rate is small, the convergence speed of the model will become very slow. A

small learning rate can ensure that the model will not miss any local optimal solution, but it will consume more time to make the model converge, especially when the model converges to the plateau area. When the learning rate is large, the model training speed becomes faster, but it may not converge, it is easy to cross the optimal value, and the gradient fluctuates back and forth around the optimal value.

Choosing an appropriate learning rate can ensure that the model can converge to the local optimal solution in a short time. This article will choose the method of learning rate attenuation to continuously adjust the learning rate in the training process. In the training process, a smaller learning rate training model is selected first and the learning rate after each round of iteration is gradually increased. By drawing a two-dimensional chart of learning rate and loss, we can find the optimal learning rate before the loss is no longer reduced.

5. Data Processing

5.1. Data Introduction. The data set of this experiment selects real commodity sales data of Q company, including sales statistics and receipt data of stores, covering four categories of commodities: meat, vegetables, cooked food, and aquatic products. This experiment selects the sales data of 5 stores, covering the period from January 1, 2017 to December 31, 2018, with a total of 11,393,481 pieces of data, including about 500 kinds of goods that appeared in the last 4 months.

5.2. Dividing Data Sets. In the experiment, the sliding window method is used to divide the data set, and the time step is 1 and the sequence length is 30. As shown in Figure 3, the feature in each example is the historical sales data of the store within 30 days, and lable is $T + 3$ to predict the sales volume of goods on the day.

6. Ablation Experiments

6.1. Comparison Method. The previous chapter mainly introduces the sales forecasting model based on the ConvLSTM network. This section will introduce the experimental comparison model, LightGBM prediction model, and LSTM prediction model. The two models will transform the sales forecasting model into a regression problem and a time-series problem, respectively:

- (1) LightGBM prediction model: GBDT is used as the base learner to make regression prediction of sales volume through feature engineering.
- (2) LSTM prediction model: it consists of one dense layer and one LSTM layer and then outputs the prediction results of the model through the full connection layer.

6.2. Parameter Setting. In experiment 1, the LightGBM prediction model, the features used are as follows: historical seven-day sales feature, time-sharing sales feature, pedestrian flow feature, weather feature, monthly feature, weekly

FIGURE 3: Data set partitioning by sliding window method.

TABLE 1: Parameter configuration of LightGBM sales prediction model.

Parameter	Setting
boosting_type	GBDT

colexample_bytree	0.8
feature_fraction	0.9
lambda_ll	0.1
lambda_l2	0.0

feature, weekend feature, price change feature, promotion feature, temperature feature, weekly feature, and quarterly feature. The LightGBM prediction model adopts the grid search method for parameter tuning, and parameter settings are shown in Table 1.

In experiment 2, LSTM prediction model, the input data were first extracted through a Dense Layer to reduce the network parameters of the LSTM layer. Here, the dimension of the full connection layer was set as $1 * 10$, and the specific parameters of the model were set as follows:

- (1) *Optimizer.* Adam optimizer is selected to adaptively adjust the learning rate.
- (2) *Learning Rate.* Set this parameter to 0.001 in the experiment.
- (3) *Activation Function.* The three gating devices for information transmission in LSTM are equipped with activation functions, and the activation function is the ReLU function.
- (4) *Dropout Random Inactivation Rate.* To prevent overfitting, set dropout to 0.1.
- (5) *Error Function.* The error function is set as MSE in the experiment.
- (6) *Batch Size.* Batch size (batch_size) is set to 256 in the experiment.
- (7) *Iteration Times.* The training iteration times epoch is set to 1000 in the experiment.

Experiment 3 was based on the sales prediction model of the ConvLSTM network. In order to compare with

TABLE 2: Comparison of forecast results of different stores.

Shop_Number	MAPE_LGBM	MAPE_LSTM	MAPE_ConvLSTM	MAPE_SVR	MAPE_ARIMA

101016	40.31	39.83	38.50	37.1	38.21
101031	35.70	36.34	36.80	35.33	36.41
101044	40.83	41.95	40.00	39.89	38.98
101166	41.06	39.07	39.95	38.34	38.9
Mean value	40.98	38.728	38.03	37.34	37.55

TABLE 3: Comparison of prediction results for different categories.

Category_Number	MAPE_LGBM	MAPE_LSTM	MAPE_ConvLSTM	MAPE_SVR	MAPE_ARIMA
10001	36.65	39.72	42.86	35.45	36.67
10002	40.41	39.56	37.69	38.55	36.43
10003	38.50	41.88	41.32	39.41	37.54
10004	39.60	37.47	35.89	39.31	36.52
10005	40.46	41.04	39.52	38.99	38.12
10006	38.28	32.15	32.50	36.81	33.23
Mean value	38.92	38.64	38.02	38.08	36.41

experiment 2, the training mode of the ConvLSTM prediction model was the same as experiment 2. Adam optimizer was selected, and the learning rate was 0.001, etc. The difference is that ConvLSTM network will conduct convolution operation in the process of state transfer, and convolution-related parameters need to be set:

- (1) *Number of Convolution Kernels.* Here, the convolution kernels extract spatial features of two-dimensional data and set filters to 16.
- (2) *The Size of the Convolution Kernel.* In the experiment, the kernel_size of the convolution kernel is set to $10 * 10$.
- (3) *Convolution Step.* Set strides to (1,1).
- (4) *Zero-Complement Strategy.* In order to retain the convolution result at the boundary, the padding is set to the same in the experiment.

In this experiment, all models will be compared on the basis of the same original data set, and the model will predict the product sales within 3 days ($T + 3$) of the input data, and MAPE will be selected as the evaluation index of the model.

7. Analysis of Experimental Results

In this section, the prediction results of the three models will be compared and analyzed from two perspectives: the prediction results of the three models in different stores and the prediction results of the three models for different categories of goods. The prediction results used for comparison are all the best prediction results after the adjustment of the three models.

7.1. Comparison of Forecast Results of Different Stores. The comparison of the prediction errors of the three models in different stores is shown in Table 2, which shows the optimal performance of the three models in the evaluation index MAPE after the adjustment. On the whole, it can be

seen that the prediction effect of the LSTM model is better than that of LGBM model. The average MAPE of the LGBM model's five stores is 38.98, which is 0.26 percentage points higher than that of the LSTM model. It can be seen that LSTM has advantages in dealing with time series, and the same applies when forecasting sales.

Most importantly, the ConvLSTM model performed best among the three prediction models, with an average MAPE of 38.3, 0.68 percentage points lower than that of the LGBM model and 0.42 percentage points lower than that of the LSTM model, indicating a significant performance improvement.

7.2. Comparison of Forecast Results of Different Categories of Commodities. As can be seen from the clustering results in the previous section, the whole commodity is divided into ten categories, six of which are selected in the experiment to show the prediction performance of the model in different categories, as shown in Table 3, and the comparison of prediction errors of the three models in different categories of commodity.

As shown in Table 3, the error performance of the three models is compared for different categories of goods. It can be found that models have different performance for different categories. For example, the LGBM model has better prediction effect for categories numbered 10001 and 10003, while the LSTM model and ConvLSTM model have better prediction effect for categories numbered 10002, 10004, 10005, and 10006. And the difference between the models is obvious. Categories 10001 and 10003 were suitable for regression prediction, and categories 10002, 10004, 10005, and 10006 were suitable for time-series prediction, and ConvLSTM outperformed LSTM in terms of the categories suitable for time-series prediction.

The above experiments show that the ConvLSTM model has better predictive performance than the LSTM model and LGBM model on the whole, but for individual commodities,

some commodities are more suitable for regression prediction, and the LGBM model performs better. ConvLSTM network can learn the association information between goods through convolution operation and extract the dependence information of time series by LSTM, which realizes the capture of spatial information and time information and greatly improves the prediction ability of the model.

8. Conclusion

This article combines the real sales data set of Q company to make an example application of commodity sales forecasting model based on ConvLSTM. Before modeling, the data set was fully explored, and the whole modeling process of data preprocessing, feature engineering, and experimental result analysis was described in detail, in which the experimental result analysis made a detailed analysis of commodity clustering results, experimental comparison results, and model prediction effect. We found that by using ConvLSTM network, the model can not only extract the characteristics of time series, but also capture the characteristics of data space and predict the future sales of associated goods, and the ConvLSTM network model performs well in most of the time, but sales forecasting is a very complicated task, which is affected by many factors and still faces great challenges.

The mental health problems of college students have attracted the attention of all sectors of society. In order to keep college students in a good mental state and effectively analyze their mental health, an intelligent evaluation system of college students' mental health based on big data is designed. Based on big data technology, this article constructs an intelligent evaluation system for college students' mental health, which is divided into six layers, namely, application layer, decision layer, interface layer, analysis layer, data layer, and basic layer. Then, the mental health data of college students were collected based on C/S architecture. On the basis of extracting and integrating data characteristics, six evaluation indexes of personality, will, emotion, depression, fear, and psychosis were screened, and then, the intelligent evaluation was completed according to the weight of indexes. On the basis of the preliminary verification of the performance of the system in this article, according to the comparative experimental results, the mental health data acquisition time of the system is less, the accuracy of data feature extraction and the recall rate of evaluation results are higher.

1. Introduction

Mental health refers to the various aspects of psychology and activity process in a good or normal state. The ideal state of mental health is to maintain intact character, normal intelligence, correct cognition, appropriate emotion, reasonable will, positive attitude, appropriate behavior, and good adaptation [1, 2]. Mental health is influenced by both heredity and environment, especially the upbringing style of the family of origin in childhood. Mental health is prominent in social, production, and life to maintain good communication or cooperation with others, and can well deal with various situations in life. Individuals can adapt to the developing environment and have perfect personality characteristics. Their cognition, emotional response, and volitional behavior are in a positive state and can maintain normal regulation ability. In life practice, people can correctly understand themselves, consciously control themselves, and correctly treat external influences, so as to

maintain psychological balance and coordination, and have the basic characteristics of mental health [3, 4].

Affected by the pressure of life, work, and study, psychological problems often baffle all kinds of people. Taking college students as an example, in the face of high intensity of academic pressure and inevitable employment pressure, psychological level often produces drastic changes, and mental health is greatly affected. With the increasingly fierce competition in modern society, the competition of physical strength and intelligence is far from satisfying the development of society, and the competition of psychological quality is the core competitiveness of this era. If the psychological quality is poor, it will seriously affect the study and life and even more seriously affect the future development and employment [5]. The mental health of college students is related to their own growth and the future development of the country, and more and more tragedies caused by mental health problems occur in the society, which not only affect their own life and future, but also cause serious harm to their

families and others. Therefore, the mental health problems of college students have attracted the attention of all sectors of society. Early detection of whether college students have mental health problems is conducive to timely treatment or auxiliary prevention programs to help students develop healthily, and it is also of great social significance to promote the stable operation of schools [6].

Reference [7] designed a woA-improved random forest-based mental health assessment system for college students. The system divides college students' mental health into nine dimensions: psychosis, paranoia, terror, hostility, depression, anxiety, interpersonal sensitivity, compulsion, and somatization. Then, according to scl-90 total score, Chinese Conventional Model Evaluation Guide, and College Students' Mental Health Evaluation Standard, the mental health data are processed and evaluated discretely. Reference [8] designed an RFC college student mental health evaluation system based on the whale optimization algorithm. The system first collected RFC college students' mental health data, and then according to the current five common mental health problems of college students and the relevant evaluation criteria and data processing, the whale optimization algorithm was used to complete the mental health evaluation, which provided the decision basis for college students whether to carry out psychological counseling and treatment. Reference [9] designed a college student mental health assessment system based on VPMCD. Firstly, from the social environment, campus environment, family environment, and personal environment, the main factors that affect the mental health of contemporary college students are analyzed in detail, and then, the evaluation index system of mental health is established by using analytic hierarchy process, and the numerical calculation method of each level index is given. On this basis, a mental health assessment model based on VPMCD was established.

However, in practical application, it is found that the above traditional intelligent evaluation system of college students' mental health has some problems such as timeliness and accuracy. Therefore, this study designed an intelligent evaluation system for college students' mental health based on big data. The design ideas are as follows:

- (1) Build the overall system structure from the application layer, decision layer, interface layer, analysis layer, data layer, and base layer.
- (2) Build a data collection model of college students' mental health based on the C/S architecture.
- (3) Extracting and integrating the data characteristics of college students' mental health.
- (4) Select 6 evaluation indexes of personality, will, emotion, depression, fear, and psychosis.
- (5) Assign value to index weight, and then, complete intelligent evaluation according to index weight.

2. Design of Intelligent Evaluation System for College Students' Mental Health

Based on big data technology, this study constructs an intelligent evaluation system for college students' mental

health. Big data refers to the huge amount of data involved, which cannot be retrieved, managed, processed, and sorted into more active information to help enterprises make business decisions in a reasonable time through mainstream software tools. "Big data" requires a new processing mode to have stronger decision-making power, insight and discovery power, and process optimization ability to adapt to a massive, high growth rate and diversified information assets. The strategic significance of big data technology lies not in mastering huge data information but in the professional processing of these meaningful data. In other words, if big data is compared to an industry, the key to the profitability of this industry lies in improving the "processing capacity" of data and realizing the "value-added" of data through "processing." Technically, big data cannot be processed by a single computer and must adopt distributed architecture. Its feature is that distributed data mining for massive data must rely on the distributed processing, distributed database, cloud storage, and virtualization technology of cloud computing. The system is divided into six layers, namely, application layer, decision layer, interface layer, analysis layer, data layer, and basic layer. The overall structure of the system is shown in Figure 1.

2.1. Hierarchical System Design. According to the overall structure of the college students' mental health intelligent evaluation system constructed above, the hierarchical design is carried out.

2.1.1. Based Layer. The basic layer of the system is the database software, dynamic environment, network environment, and hardware equipment necessary for the construction of the system and is also responsible for data collection, which is transferred to the data layer for storage.

2.1.2. Data Layer. The system data layer mainly includes mental health assessment database, expert team database, and student information database, which provides data support for the analysis layer.

The data layer also includes two parts: student information management module and online consulting module. Among them, the student information management module includes student registration and login and other related operations. Online psychological counseling services can be provided for students only after they log in successfully. After entering the function interface, students can view and modify personal information and other related operations. When the student information is modified, the system will immediately notify online teachers and students to contact. The online counseling module is mainly responsible for providing psychological counseling services for students. The system of psychological counseling for students is free of charge, and the main purpose of psychological counseling is to help students better understand themselves, at the same time to solve the students' mental health problems. In special cases, psychology teachers can also turn off the SMS notification function.

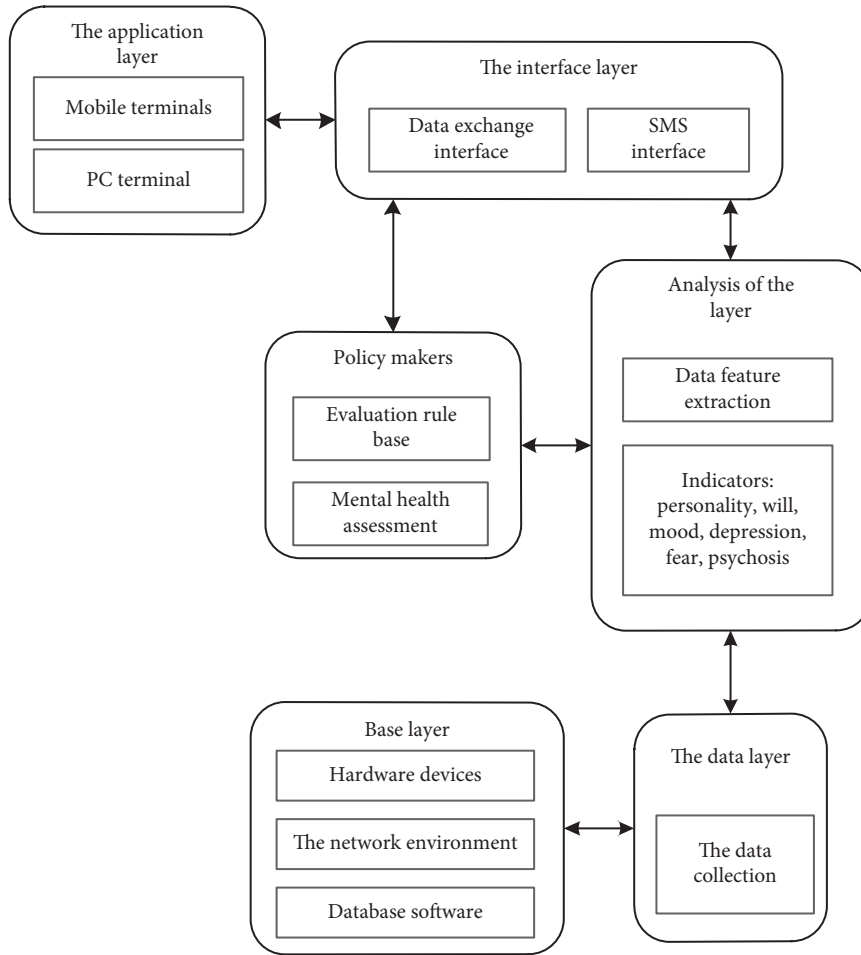

FIGURE 1: Overall structure diagram of intelligent evaluation system for college students' mental health.

2.1.3. *Analysis Layer.* The main work of the system analysis layer consists of two parts. One part is the classification of evaluation reference cases summarized based on existing evaluation results and the classification of mental health evaluation materials [10–12]. The other part of the work is to use big data technology as the basis to extract students' personality, emotions, preferences, and other characteristics.

The analysis layer includes two parts: psychological test module and psychological test topic management module. Among them, the psychological test module is the core module of the system, but also the functional module that students mainly use, which mainly contains the emotion test and social test submodules. According to the data results generated by the module, the mental health problems of college students are divided into three levels: serious, general, and potential psychological problems or no psychological problems, which correspond to the three levels of screening of the mental health intelligent evaluation system. The psychological test topic management module mainly manages the psychological test topic of the student mental health intelligent evaluation system. Among them, it mainly includes the operation of adding and deleting evaluation topics. Among them, the classification of topic types is completed by teachers, and the operation of adding and deleting psychological test topics is completed by administrators.

TABLE 1: Evaluate the field setting of the scale.

The serial number	The field name	The field type
1	Test topics	The integer
2	Content of the test	Character
3	Test time	The date type
4	The user information	The integer

2.1.4. *Policy Makers.* After the analysis, the results were transmitted to the decision-making layer of the system, which evaluated the mental health of college students based on the evaluation rule base and iterative optimization rules.

At the decision-making level, scale test and social software data analysis are combined to conduct research, and the scale test results include test topic, test content, test time, user information, and other contents. Field settings of the evaluation scale are shown in Table 1.

2.1.5. *Interface Layer.* The system interface layer has SMS interface and data exchange interface, which can be connected to the system for data exchange.

2.1.6. *Application Layer.* The application layer of the system feeds back the mental health evaluation results to the

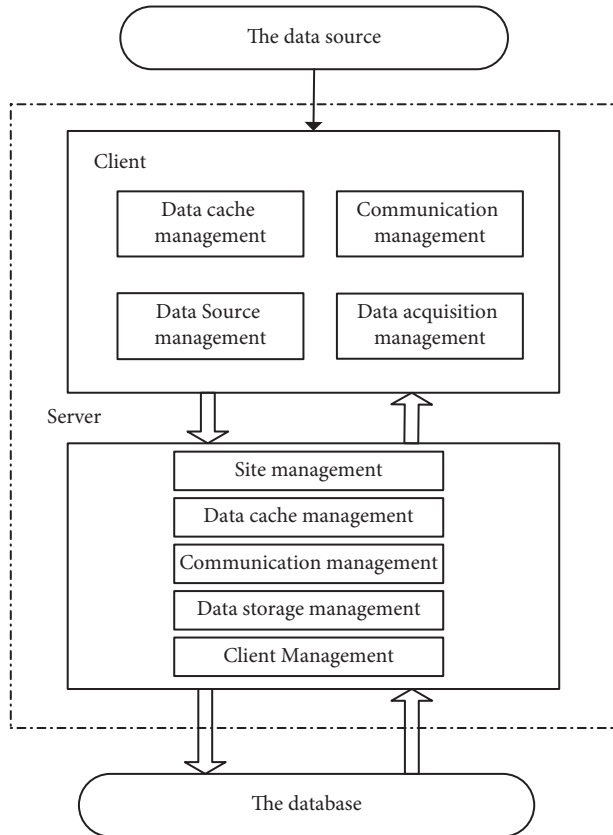

FIGURE 2: Structure diagram of data collection model for college students' mental health.

application layer through the interface layer and provides the evaluation results to college students through the mobile terminal or PC terminal.

2.2. Intelligent Evaluation Process Design

2.2.1. Mental Health Data Collection of College Students.

This study constructs a data collection model for college students' mental health based on the C/S architecture, and its overall structure is shown in Figure 2.

The server side uses the basic attributes of the measurement points to realize the mapping between the data source measurement points and the target measurement points and provides the client with the required information related to the mental health data of college students. In order to facilitate management and search, the attributes of measurement points are generally stored in real-time database, and the client can only save the copy without manual revision [13–15]. If the monitoring point configuration changes, the server will immediately push the modification information to the client and get the updated local copy.

Client management includes configuration management and real-time situation management. Configuration management can achieve rapid client basic information fusion, and real-time situation management can test the current client binding information, obtain the specific value of data link traffic, evaluate the client operating mode and form, and

FIGURE 3: Schematic diagram of mental health packet pattern of college students.

monitor the network communication, and complete independent management. In the process of mental health data collection of college students, the server side uses the identification string to sort out the logical relationship between the measurement points and the client side [16–18].

The specific collection process is as follows:

Step 1: Configure preprocessing. Configuration preprocessing is the basis of mental health data collection of college students. Firstly, double calibration of data is carried out to remove the point data that is not available in the mental health data source, so as to prevent the inaccurate data collection caused by the difference between the server side and the data source of the measurement point category [19, 20]. In the preprocessing stage, select some attribute values to complete the mapping table reconstruction, which can enhance the search rate, reduce the packet length, and improve the transmission quality.

Step 2: Data transformation. After reading the current mental health data from the source database, three data transformations are performed according to the point configuration. Numerical quadratic transformation can deal with unit and reference value of metadata. The one-to-many transform can solve the problem of a single source measuring point responding to several target measuring points and maintain the completeness of data collection by using the transform process.

Step 3: Data transfer. The important function of the acquisition model is data transmission [21, 22]. In order to enhance the timeliness of data transmission, data transmission is processed from the following two perspectives in the system interface layer:

- The network link shall use the long connection mode. Due to the long distance between the data source and the target server, long connection is used for data transmission in order to obtain a faster transmission rate. If the amount of transmitted data is not large, periodically transmit heartbeat packets to keep the link stable and reduce network transmission disconnection due to timeout policies of routers and firewalls.
- Use of variable-length packets. According to the data packet header message, realize the data overall verification, subcontracting and analysis. The variable-length packet pattern is shown in Figure 3.
- The introduction of data caching in the transmission sector. Based on the collection characteristics

FIGURE 4: Data cache architecture diagram of college students' mental health.

of college students' mental health data, the data cache is substituted in the transmission plate. If the network fails in a short period of time, the data will be cached to the memory, and the system does not contain any running cost [23, 24]. If the collection model fails for a long time, the data will be saved in a local file to maintain the authenticity of the later collection results.

Figure 4 shows the data cache architecture of college students' mental health. In order to maintain the safety of college students' mental health data, thread-safe queues were used to reduce the correlation between functional plates of the model and achieve the goal of high-quality data collection when multifunctional plates of the model interact.

2.2.2. Feature Extraction and Fusion of College Students' Mental Health Data. The characteristics of college students' mental health mainly include behavioral characteristics, attribute characteristics, content characteristics, and social relationship characteristics, among which behavioral characteristics refer to the user's behavior on social network, including likes, comments, and online browsing traces. Attribute characteristics refer to the user's individual information, including name, age, gender, occupation, and hobbies. [25, 26]. Content features include users' chat content and posts on social software. Social relationship features refer to the interaction between users in the whole social network, which is manifested in the number of mutual attention and fans.

Firstly, the validity of the collected data information is inferred. If it is valid, the collected data information is converted into the data form directly processed by the system, which requires the introduction of the concept of time window to extract the mental health features of college students. The scale data and users' social network data are converted in batches, and different samples are divided. One sample corresponds to one window. The data in this time window are used to complete feature extraction, and the feature extraction results are classified and labeled. The time window selected here is 24 hours in order to obtain more comprehensive mental health data information of college students.

In order to further excavate the mental health state of college students and obtain more accurate psychological

characteristics of users, the multifeature fusion analysis is carried out on the mental health data of college students. The mental health data obtained from multiple channels are analyzed as a whole to provide a basis for intelligent evaluation.

Neural network is an effective nonlinear data fusion method, which can transform input space into hidden space and analyze data more conveniently in hidden space. Therefore, neural network has strong data processing ability, and meets the requirements of large-scale data processing and is suitable for multifeature fusion analysis.

Assuming that the transformation function used by the hidden layer in the neural network is Gaussian function, the radial basis function output by the first element is

$$F(i) = \exp\left(-\frac{\sum_{i=1}^n x_i - y_i}{2\partial^2}\right)^2, \quad (1)$$

where x_i represents the input quantity of mental health features of unit i , y_i represents the feature transformation quantity of unit i in the hidden layer, and ∂ represents the control parameter of unit i .

By inputting and extracting the characteristic data of college students' mental health and calculating the radial basis function according to the above formula, the multifeature fusion processing of college students' mental health data features can be realized.

2.2.3. Determine Evaluation Indicators. Scl-9 mental health measurement form is the standard for the evaluation of indicators in this study. The selected evaluation indicators are personality $I1$, willpower $I2$, emotion $I3$, depression $I4$, fear $I5$, and psychosis $I6$, and the target layer is mental health evaluation. The psychological test data of college students in a certain university in recent three years were collected, and 90 samples were randomly selected as mathematical model samples according to the scl-90 scale integral method. The statistical results are shown in Table 2.

2.2.4. Intelligent Evaluation of College Students' Mental Health. In this article, the mental health evaluation module in the decision-making layer of the system uses analytic hierarchy process to evaluate the mental health of college students. First, assign a value to the index weight and then complete the intelligent evaluation according to the index weight. The specific process is as follows:

Step 1: construct the judgment matrix model. Use 1–9 scaling and reciprocal measurement, and compare the importance of one indicator to another indicator pairwise, according to the comparison results to construct judgment matrix J .

Step 2: Use formula (2) to obtain the eigenroot solution of matrix J , and obtain the weight value of importance between the corresponding index of the same level and another index after normalization. Then, perform consistency test on the judgment matrix, and the process is as follows:

TABLE 2: Scl-90 scale score.

Evaluation indicators	The serial number					The mean	The variance
	1	2	3	...	90		
I1	1.44	1.77	1.45	...	1.21	1.55	0.59
I2	1.41	1.70	1.86	...	3.35	1.87	0.70
I3	1.67	1.10	1.40	...	2.90	1.90	0.71
I4	1.65	1.12	1.42	...	2.19	1.86	0.72
I5	1.11	1.85	1.27	...	2.25	1.55	0.55
I6	1.44	1.90	1.63	...	2.45	1.74	0.66

$$\sigma J = \mu_{\max} \sigma^{-1}, \quad (2)$$

σ and μ_{\max} represent eigenvectors and maximum eigenvalues, respectively.

In the implementation of consistency test, the critical index value C_I of each matrix should be calculated first, and the random consistency index R_I should be searched at the same time, and the random consistency C_R can be obtained through calculation:

$$C_R = \frac{C_I}{R_I}, \quad (3)$$

where C_I and R_I represent the consistency index and consistency ratio, respectively. When the value of C_R is less than or equal to 0.1, it is proved that the hierarchical single-sort structure has a relatively suitable consistency. When C_R value is greater than 0.1, the index value of the matrix needs to be obtained again:

$$\left\{ \begin{array}{l} \mu_{\max} = \sum_{j=1}^m \frac{(\sigma J)_j}{(\sigma J_j)} CI = \frac{R_{\max} - m}{m - 1}, \end{array} \right. \quad (4)$$

where m represents the dimension of the matrix.

Step 3: use expert evaluation method to calculate index weight. Experts score the indicators based on rules relating to mental health status. The results can avoid the subjective opinions in the expert reference opinions and have rationality and objectivity.

Assuming that there are k experts, k_I represents the scoring value of experts for each indicator, then the weight calculation formula of mental health evaluation indicators is as follows:

$$\omega_I = \sum_1^k \frac{k_I}{k}. \quad (5)$$

Step 4: construct independent factor evaluation matrix. Let the fuzzy subset of factor U_I be u_I , and obtain the membership degree of each evaluation index of mental health status through expert judgment method. When there are κ experts whose judgment grade of factor U_I is L_j , the evaluation matrix expression formula is as follows:

$$V = \frac{\kappa \times u_I \times L_I}{k}. \quad (6)$$

Step 5: Use the linear weighted sum of objectives to construct intelligent evaluation, and the process is as follows:

$$M = \sum_{I=1}^6 \frac{V \times P_I \times \omega_I}{k}. \quad (7)$$

where P_I represents the scoring value of item I . Input the extracted mental health feature data of college students, and calculate the target linear weighted sum according to the above formula, so as to realize multifeature fusion, further mine the mental health status of college students, obtain more accurate user psychological features, and conduct multifeature fusion analysis on the mental health data of college students. Analyze the mental health data obtained from multiple channels as a whole to provide basis for intelligent evaluation. The calculation process of target linear weighting sum is an effective nonlinear data fusion method, which can transform the input space into hidden layer space, and it is more convenient to analyze data in hidden layer space. Therefore, it has strong data processing ability, meets the needs of large-scale data processing, and is suitable for multifeature fusion analysis, so as to complete the design of College Students' mental health intelligent evaluation system.

3. Experiment and Result Analysis

In order to verify the practical application effect of the above designed intelligent evaluation system for college students' mental health based on big data, the source of mental health data of college students is the knowledge base of machine learning data set, which collects open datasets contributed by data scientists participating in machine learning projects; the following test process is designed.

3.1. Experimental Design. The simulation environment test system was built under MATLAB software. Experimental environmental parameters are shown in Table 3.

The experiment invited 50 students from the third grade of a university as the research object, including 25 boys and 25 girls. During the period of school, the experimental subjects generally have excellent academic performance and good comprehensive development.

First of all, preliminary validation is carried out to verify the quality of the system application indicators and the

TABLE 3: Experimental environmental parameters.

I_4	0.0174	0.8325
I_5	0.2600	0.7605
I_6	0.1433	0.88326

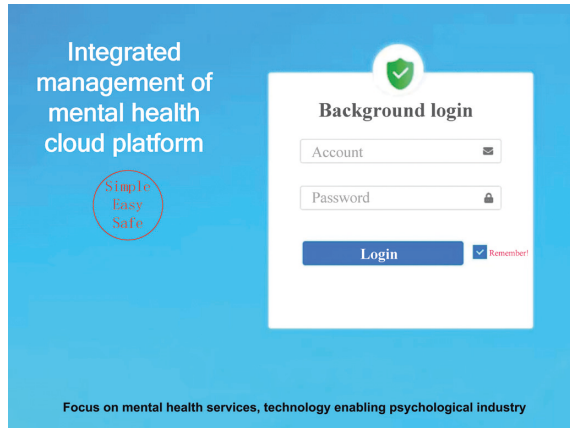

FIGURE 5: System login interface.

FIGURE 6: System stability test results.

stability of the system. Then, the woA-improved random forest college student mental health evaluation system in reference [7] and RFC college student mental health evaluation system based on the whale optimization algorithm in reference [8] are compared. Comparative verification was carried out from the three perspectives of data acquisition time of college students' mental health, data feature extraction accuracy, and recall rate of the evaluation results.

Finally, the system is applied to test the mental health of 50 students and comprehensively analyze the mental health of college students from the perspectives of social factors, family factors, and personal factors.

3.2. Test Analysis

3.2.1. Preliminary Verification. First, verify the quality of the system application index and the stability of the system. The system login interface is shown in Figure 5.

On the basis of assigning index weights, formula (4) is used to calculate the scores of each index, and the results are shown in Table 4.

As can be seen from Table 4, the calculation results of index scores are between 0 and 1. The score is divided into different grades: 0.9-1 is excellent, 0.8-0.9 is good, 0.7-0.8 is good, 0.6-0.7 is passing, and 0.6 is poor. It can be seen that all the indicators in the index layer have reached the good level, indicating that all the indicators are of the same importance to college students' mental health evaluation.

Then, the number of system running threads was used as an indicator to measure the stability of the system, and the system stability was tested. The results are shown in Figure 6.

FIGURE 7: Comparison of mental health data collection time of different systems.

Analysis diagram 6 shows that with the increase in the system running time, the system thread count showed a trend of rise at first and then remained stable, and 15 hours before the system running, the system number of threads increases slowly, but the increase is not obvious, and when the system running time exceeds 15 hours, the number of system running threads always stays within the range (20, 60). It can be seen that the number of threads is stable and the running state of the system is always stable.

FIGURE 8: Statistical graph of data feature extraction accuracy of different systems.

3.2.2. *Comparison Verification.* Firstly, the mental health data acquisition time of different systems was tested, and the results are shown in Figure 7.

According to the results shown in Figure 7, with the increase in the number of experiments, the mental health data acquisition time of different systems also changes. The acquisition time of system of reference [8] rises first and then decreases, and the global maximum value is 8.1 min. The acquisition time of system of reference [7] fluctuates frequently, and the global maximum value is 7.9 min. In contrast, the collection time of system of this article is less, which is always less than 6 minutes, indicating that the timeliness of system of this article is higher.

Then, the accuracy of data feature extraction is taken as the index to verify the reliability of different systems, and the results are shown in Figure 8.

By analyzing the results shown in Figure 8, it can be seen that when the number of experiments is 50, the data feature extraction accuracy of reference [7] system and reference [8] system reaches their maximum. When the number of experiments is 40, the accuracy of data feature extraction of this system reaches the global maximum, which can reach 0.95. It can be seen that the data feature extraction accuracy of this system is higher, which shows that the reliability of this system is higher.

Finally, the recall rate of evaluation results of different systems was tested, as shown in Figure 9.

By analyzing the results in Figure 9, it can be seen that with the increase in the number of experiments, the recall rate of evaluation results of different systems shows a downward trend. After more than 30 experiments, the recall rate of the evaluation results of the system in this article is gradually stable, while the two comparison systems do not show a stable trend of data, and the recall rate of the evaluation results of the system in this article is always higher than that of the two comparison systems, indicating that the method in this article is more effective.

FIGURE 9: Comparison diagram of recall rate of evaluation results of different systems.

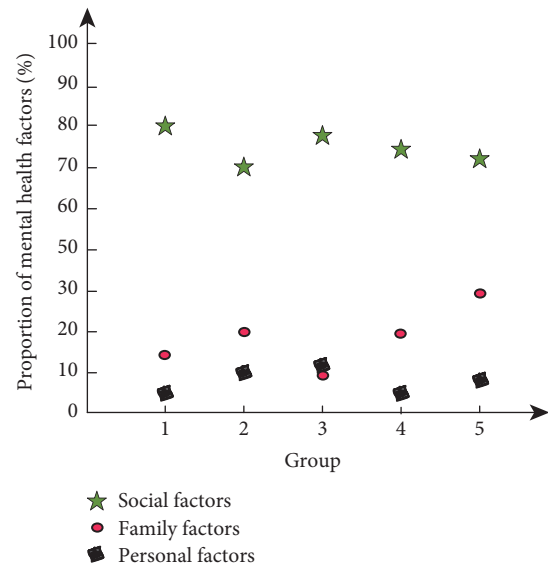

FIGURE 10: Mental health assessment and analysis.

3.2.3. *The Practical Application.* Fifty students were divided into groups on average, and the mental health status of 50 students was tested by using the system of this article. The proportion of factors leading to mental health status of students in each group was tested from the perspectives of social factors, family factors, and personal factors, and the mental health status of college students was comprehensively analyzed, as shown in Figure 10.

As can be seen from Figure 10, among the test results of the mental health status of the 5 groups of students, the

primary factors affecting their mental health status are social factors, followed by family factors and personal factors. Among the students in the third group, the family factors are lower than the personal factors, which is due to the difference of test subjects. In the five groups of assessment, social factors accounted for more than 70%, and family factors accounted for the highest proportion of about 32%; it can be seen that the social environment and small family environment are the main factors affecting students' mental health status, and compared with social and family factors, personal factors accounted for a relatively small.

To sum up, the designed intelligent evaluation system of college students' mental health based on big data has good performance, all indicators in the index layer reach a good level, and all indicators have the same importance to the evaluation of college students' mental health. In this article, the number of threads is stable when the system is running, and the running state of the system always remains stable. The acquisition time is less, which is always kept below 6 min, and the timeliness is higher. The data feature extraction of this system has higher accuracy and reliability. Social environment and family environment are the main factors affecting students' mental health. Compared with social factors and family factors, personal factors account for a relatively small proportion.

4. Conclusion

In order to provide effective data support for college students' mental health project, this study designed an intelligent evaluation system for college students' mental health based on big data.

Based on big data technology, the system of this article builds an intelligent evaluation system for college students' mental health on the basis of designing six layers: application layer, decision layer, interface layer, analysis layer, data layer, and basic layer. Then, based on the C/S framework, the mental health data of college students are collected and the data characteristics are extracted. Secondly, six evaluation indexes—personality, will, emotion, depression, fear, and psychosis—were screened, respectively, and then, the intelligence evaluation was completed according to the index weight.

In the experiment, the quality of the application index of the system is good and the stability of the system is high. After comparison and verification, it is found that the mental health data acquisition time of the system is less, the accuracy of data feature extraction and the recall rate of evaluation results are higher. Finally, a comprehensive analysis of the mental health of college students is made with the practical application of the system of this article.

In view of the less current user data of the cultural industry, its classification and presentation form are complex. This paper constructs the MKD of the cultural industry integration through the RDF graph model and realizes the distributed vector representation of cultural project semantic information by using the fine-tuning translation distance model TransH. The semantic information of cultural industry fusion is mapped to a continuous vector space, and the distributed vector representation of cultural projects is realized. The results show that it is helpful to accurately express the correlation between different regions and cultural types and to explore the data association and implicit relationship of innovation and integration development in the cultural industry.

1. Introduction

Artificial intelligence should support the development and growth of cultural operators, enhance innovation function, accumulate innovation value, promote cultural products and related services to take on a new look, and fully display its cultural connotation, so as to realize the good dissemination of the mainstream value. The massive accumulation of cultural big data and the development of algorithms are the technical basis of the advanced AI cultural industry. It is the increasing amount of data provided by the big data industry that makes deep learning algorithms possible and brings the application and development of computer vision, voice technology, natural language processing, and planning decision systems in the field of the cultural industry.

The integration development of the cultural industry includes the realization of cultural knowledge inheritance and the dissemination of cultural knowledge on this basis. Therefore, how to use digital technology to promote the inheritance and dissemination of the cultural industry has become the key. However, there are still some problems in the digital development of China's cultural industry. First of all, cultural knowledge inheritance aims to realize the

continuity of knowledge, and the emphasis is on the standardization and integrity of knowledge organization. However, the existing organization of cultural knowledge still stays in the single-line organization mode based on a certain feature, and the internal relevance and complexity of the cultural industry have not been effectively described [1, 2]. Therefore, organizing the cultural industry to realize its standardized description and revealing the relevance and complexity of industries have become the primary problems to be solved in the integration and development of the cultural industry; second, the change of technology has changed the communication environment. The birth of media technology has reshaped the existing communication environment, and the traditional mode of communication has gradually declined; the innovation of the cultural industry has to comply with the development of technology and the needs of users, make good use of the relationship between the cultural industry and users, find effective ways of communication, and build a bridge between users [3].

In recent years, mapping knowledge domains (MKDs) have been favored by researchers in various fields for its advantages of extensive data collection, comprehensive knowledge coverage, quantitative analysis macro, and data

graphic visualization. With regard to the development of the cultural industry, the relevant research has a long history, a large number of studies, and a wide range of achievements, which has a strong practical value and theoretical significance to objectively and comprehensively show the historical context of the development of the cultural industry, focus on research hotspots, explore the future development trend, and optimize the protection path.

2. Related Works

2.1. MKD. MKD is a technology that presents the relationship between knowledge in a graphical way, which is widely used in the field of culture, mainly focusing on ontology and semantic relations. The national network cultural heritage advocacy organization of the United States specializes in the digital construction of intangible cultures, such as semantic information architecture, semantic relations, keyword index presentation, and digital reconstruction of cultural content [4]. The European digital museum has earlier adopted the semantic web technology to unify the information resources of different institutions and metadata standards through the semantic association between scattered and heterogeneous digital cultural resources, which has become an important European cultural resource platform [5]. Lamborao et al. [6] proposed to use RDF technology of MKD to code and classify Italian cultural resources, and finally use SPARQL language to query and retrieve the association between various cultural industries.

According to the classification and presentation of different cultural industries, researchers focus on the digitization of cultural industries and semantic relations. Sun [7] used knowledge representation, knowledge engineering, and other technologies to construct a knowledge framework model of folk dance, providing a reference for the digital protection of folk dance. By combing the application status of MKD, it is found that resource integration based on linked data is applied in the fields of network information resources, digital libraries, etc., showing a trend from theoretical research to applied research, and a large number of practical projects appear [8]. At present, the construction and application of cultural industry digitization is rich, mainly in ontology, semantic relationship, data association, resource aggregation, and so on. Besides, it is a hot topic in the research of MKD to establish related data by using semantic relation and making it a part of ontology construction. Few researches based on MKD focus on digital human semantic web and data association construction, while there is a lack of deep understanding and application of knowledge and services in the field of culture. The construction of MKD is an important part of the presentation of digital resources in the cultural industry, which involves not only semantic knowledge analysis, expression framework design, and knowledge representation methods but also complex links such as character relationship presentation and knowledge reasoning.

2.2. Recommendation Algorithm Based on MKD. In recent years, as a knowledge network containing a large number of

entities and the relationships between entities, the MKD can discover rich relationships between objects or users, and enhance the semantic information of data. It has important research significance for some recommendation algorithms that need semantic information of items and users. Literature [9, 10] shows a kind of embedding method, which can map the entities in the MKD and the relationship between them to the low dimensional vector space, and take the learned entities or relationship vectors with semantic information as the knowledge representation of the original objects. Literature [11] regards MKD as a heterogeneous information network to assist in the construction of a recommendation system by constructing a metagraph. The feature of a meta graph is that only one start node and one end node are required, and the middle structure is not constrained. Therefore, more complex semantic information can be integrated into the recommendation problem to fully mine the item information. Path-based approaches can use MKD in a more intuitive way, but they rely heavily on manually designed meta paths or meta graphs, whereas domain knowledge is usually required to define the type and the number of meta paths, which is difficult to tune in practice [12]. According to the literature [13], most of the previous recommendation studies only considered a single relationship type, but in fact, in many cases, the recommendation problem exists in the scenario of heterogeneous information networks.

At present, most of the recommendation algorithms based on the MKD are based on the existing recommendation algorithms. While the integration of the cultural industry is in the development stage, the available user data is less. Therefore, in this paper, the semantic information of cultural industry fusion is mapped to a continuous vector space to realize the distributed vector representation of cultural projects. In addition, the accuracy of the representation vector of the cultural projects is verified by link prediction.

3. Construction of Cultural Industry Integration MKD

This paper starts from the content, type, and presentation of cultural industry information, and follows the logic from knowledge construction, knowledge storage, knowledge management to knowledge application, and constructs a cultural knowledge base characterized by regional distribution, so as to solve the problems of low coupling, weak relevance, low response, and high delay of cultural industry digital resources. The construction framework is shown in Figure 1. In terms of semantic search, RDF is used as the description framework to describe resource entities and attributes, reveal their semantic relations, and form data association of the cultural industry, which is convenient for network retrieval and digital dissemination.

3.1. Knowledge Construction. As shown in Figure 2, there are mainly unstructured, structured, and semi-structured data of cultural industry integration.

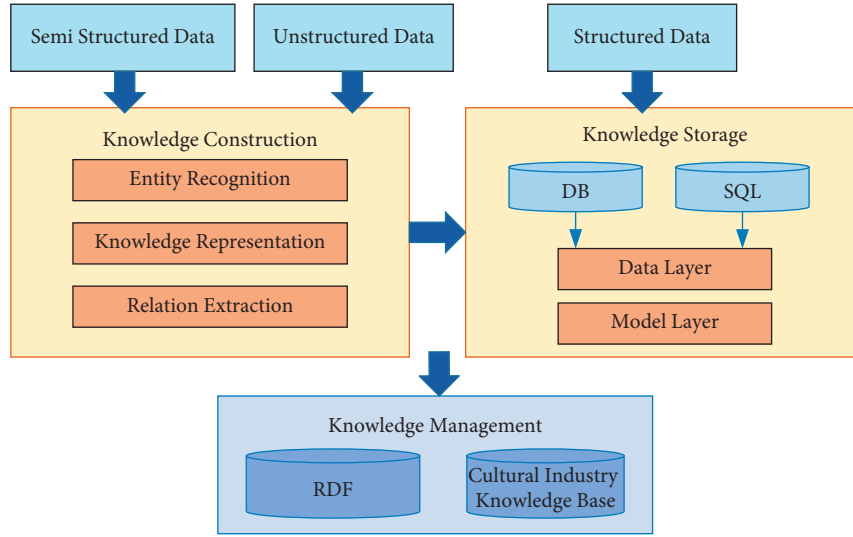

FIGURE 1: Construction of the MKD framework.

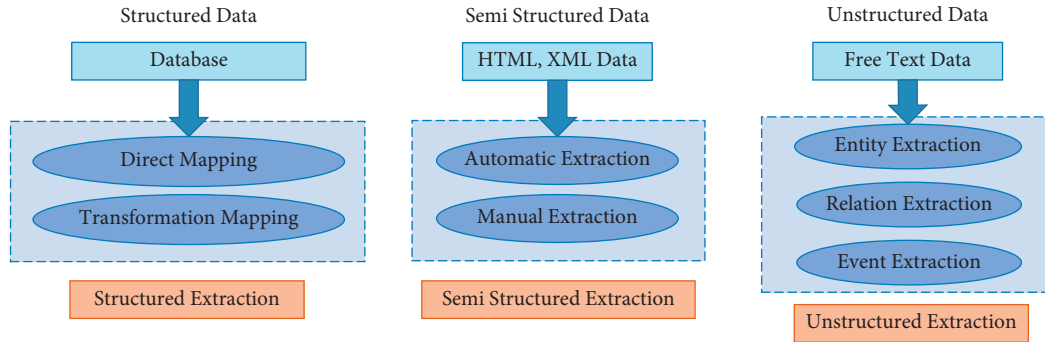

FIGURE 2: Integration data of the cultural industry.

Structured data itself already exists in the database, and its knowledge organization computer can identify and extract it easily. It only needs to directly map or transform the knowledge in relational data to RDF data. The semi-structured data from web pages and tags do not conform to the rules. Unstructured extraction is to extract knowledge from free text, including the following three modules: entity, relationship, and event. The extraction process is mainly based on the existing annotation rules and knowledge base, which is the most difficult among the three data sources; noise and error may exist in data collection, text processing, entity extraction, and relationship extraction, which seriously affect the accuracy of knowledge acquisition. The purpose of entity extraction is to extract entity information from the analysis text of the cultural industry, such as project name, inheritor, region, time, and cultural category. When dealing with unstructured data, API interface technology is used to allow users to extract text information entities and relationships according to rules, so as to ensure the accuracy of the construction of the cultural industry MKD.

In the knowledge base, the relationship name is single, while the corresponding relation language expression in the network resources is diverse. The accuracy of relation extraction will be reduced if the relation is matched directly,

and the introduction of relation keywords can solve this problem well, where the optimization of classifier corpus is different from manual annotation, which often leads to omissions or errors, and it can only be used for simple MKD relationship extraction. Classifier corpus optimization is used to set the tagged corpus as a positive example, and set the unlabeled corpus as a negative example. According to this algorithm, the final text classification is completed. In the classifier model, conditional probability is the key to relation extraction, as shown in the following formula:

$$P(x | y) = \frac{1}{Z(x)} \exp \left[\sum_{i=1}^k \lambda_i f_i(x, y) \right], \quad (1)$$

where x is the context, y is the keyword label, $Z(x)$ is the normalization factor, λ_i is the weight of the equation, and $f_i(x, y)$ is the characteristic equation. In relational extraction, it is 1 when x and y meet the conditions, and 0 otherwise.

Event extraction mainly refers to extracting the event information that users are concerned about from natural text and presenting it in a structured form, which includes meta-event extraction and topic-event extraction. Topic events refer to certain core events and related activities. For

example, for a certain cultural industry project, we can get its cultural industry name, inheritor, region, heritage category, and other information from the cultural industry text library. Event extraction can collect relevant information from unstructured text data to achieve a complete description of entities. Meta event refers to the occurrence or state change of action, involving time, place, and participants.

3.2. Knowledge Storage. In the graph database storage, the cultural industry data is huge, so it is necessary to build a graph database framework which can access the data efficiently to improve the efficiency of MKD storage. There is a big difference between graph database storage and traditional database storage; traditional database storage needs to consider the dynamic read-write operation of data, while the storage of MKD is based on triples, and the information of triples exists in the form of subject, predicate, and object, and its data organization is fragmented and flexible. It is necessary to consider the cost of data storage, such as fast access to data and data storage graph. When the data scale is large, distributed storage can be used to improve the scalability of the storage system. In distributed storage, each RDF data node is distributed and relatively independent. Therefore, there are two ways to store the MKD of the cultural industry: attribute storage and graph data storage. In the distributed environment, based on the data structure of MKD, attribute storage is used to manage the relationship between data and reduce the number of self-joins, which has high efficiency. In the graph data storage, RDF data is stored in a three-column structure table that corresponds to the subject, predicate, and object data of the triple. When a user makes a query request, the system will make multiple self-joins in the triple table to get the user search results. Efficient MKD storage architecture includes a data layer and a model layer, as shown in Figure 3.

In the MKD, different entity types are stored in a block mode, and the undefined objects are treated by the feature clustering method and are classified into similar semantic types. The stored procedure of the graph database follows the principle of unified semantic relationship and centralized storage, that is, the same storage structure is used to process different types of data, and different database query languages are compatible in semantic search.

In the triple, the nodes and edges are labeled to show the semantic association of MKD. The definition of the RDF graph model is as follows: assuming U , B , and L are the uniform resource identifier, empty node, and literal of the finite set, respectively, while each RDF triple $(S, P, O) \in (U \cap B) \times U \times (U \cup B \cup L)$ is a declarative sentence, where S is the subject, P is the predicate, and O is the object, then (S, P, O) represents the attribute of resource S , and P takes the value of O .

In the RDF graph model, the ellipse represents an entity, the rectangle represents an attribute value, and the edge represents a triple predicate. Taking the inheritance of music culture and industrial integration in ethnic areas as an example, the triple (Changyang folk song, cultural category,

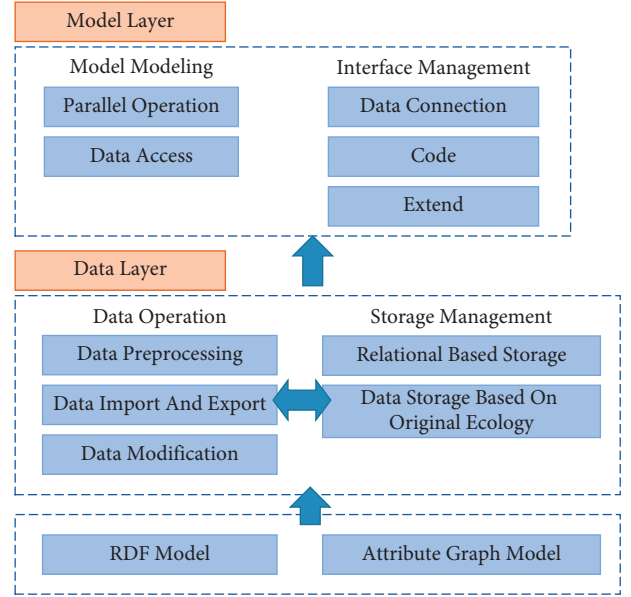

FIGURE 3: Data storage model.

and traditional music) indicates that the heritage category of the Changyang folk song is traditional music. The Changyang folk song belongs to Changyang Tujia Autonomous County. However, information on the specific declaration area cannot be obtained. In fact, the edge attributes represented by the RDF graph model are not clear, so it is necessary to introduce extra points to represent the whole triple, and the original edge attributes are represented as new triples.

As shown in Figure 4, Dec_area is introduced in this paper for Changyang folk song, declaration area, and Changyang Tujia Autonomous County, using three elements of the triple RDF: subject and RDF; predicate and RDF; object. In this way, a new triplet is formed, whose set form is as follows: $G = ((Dec_area, RDF: subject, Changyang folk song), (Dec_area, RDF: predicate, declaration area), (Dec_area, RDF: object, Changyang Tujia Autonomous County))$

The RDF graph model is a special directed tag graph. In this paper, we use these tag graphs to connect all resources to form a large-scale MKD of the cultural industry. In the label graph, the predicate of a triple can also be the subject or object of another triple, which is mapped in the data label graph.

4. Recommendation Algorithm Based on MKD

The basic idea of the recommendation algorithm based on the MKD of cultural industry projects is that on the basis of the MKD of cultural industry projects constructed in the previous chapter, through the use of TransH (translation on hyperplanes), the distributed vector representation containing semantic information of cultural industry projects is learned, and the historical behavior data of users are used to calculate and compare with the cultural industry projects; finally, a top-N recommendation list is generated according

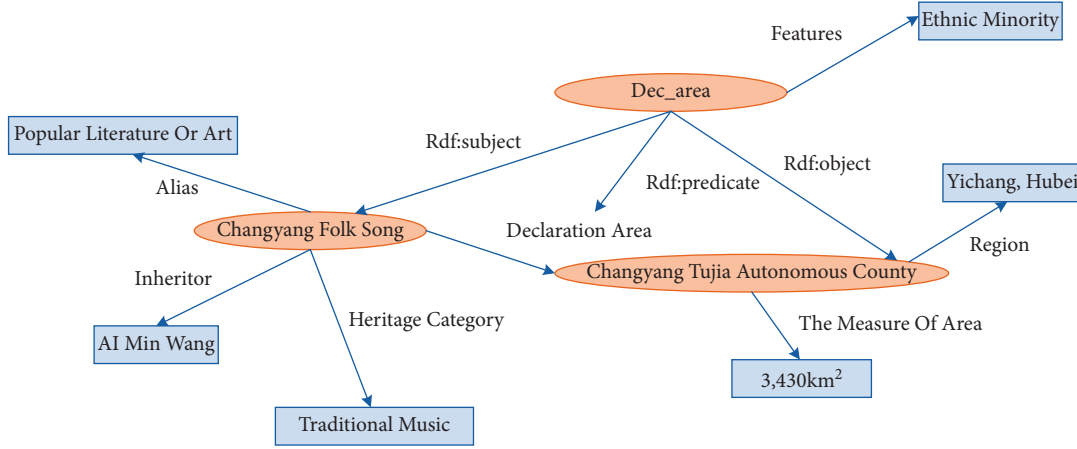

FIGURE 4: RDF edge attribute of Changyang folk song.

FIGURE 5: Recommendation algorithm flow.

to the calculated similarity. The specific algorithm flow is shown in Figure 5.

4.1. Scoring Function. The main purpose of knowledge representation learning in MKD is to embed the semantic information of the research object into the low-dimensional vector space, and express it as a dense low-dimensional real value vector, so as to pave the way for the subsequent semantic similarity calculation and recommendation operation. The TransH algorithm is adopted after fine-tuning to train, and the project of cultural industry integration is expressed by vectorization.

The head entity h and tail entity t are projected onto the hyperplane determined by the normal vector Wr to obtain vectors h_{\perp} and t_{\perp} . On this hyperplane, there exists a relation to represent the vector dr . After training, equation (2) can be satisfied:

$$h_{\perp} + d_r = t_{\perp}. \quad (2)$$

In TransH, a scoring function is defined to measure the accuracy of the mapping entity vector and relation vector in triple.

$$f_r(h, t) = h_{\perp} + d_r - t_{\perp}^2. \quad (3)$$

Through constraints $\|Wr\| = 1$, there are

$$h_{\perp} = h - w_r^T h w_r, t_{\perp} = t - w_r^T t w_r. \quad (4)$$

The modified scoring function can be obtained as follows:

$$f_r(h, t) = (h - w_r^T h w_r) + d_r - (t - w_r^T t w_r)^2. \quad (5)$$

4.2. Objective Function. For the above scoring function of a single triplet, we define the margin-based ranking loss (formula (6)) as the objective function of model training

$$\mathcal{L} = \sum_{(h,r,t) \in \Delta} \sum_{(h',r',t') \in \Delta'} [f_r(h, t) + \gamma - f_r(h', t')]_+. \quad (6)$$

In the objective function, $[x]_+ \triangleq \max(0, x)$ is a hinge loss function, which can avoid the negative loss value and lead to failure of convergence, Δ is the collection of positive example triples in the MKD of cultural industry projects, Δ' is a set of negative example triples formed by randomly replacing the head entity or tail entity of a positive example triple, and γ is the distance between the positive and negative triples.

When minimizing the loss value, the following constraints (formula (7)–(9)) should be considered:

$$\forall e \in E, \|e\|_2 \leq 1, // \text{scale}, \quad (7)$$

$$\forall r \in R, \left| \frac{w_r^T d_r}{d_{r2}} \right| \leq \epsilon, // \text{orthogonal}, \quad (8)$$

$$\forall r \in R, w_{r2} = 1, // \text{unit normal vector}, \quad (9)$$

where formula (7) ensures that the vectors of all entities are normalized; formula (8) is used to ensure that the normal vector Wr and the relation vector dr are orthogonal and

perpendicular, and dr is on the hyperplane; formula (9) guarantees that the modulus of the normal vector is 1.

The loss function is converted into the following unconstrained loss function by using soft constraint:

$$\mathcal{L} = \sum_{(h,r,t) \in \Delta} \sum_{(h',r',t') \in \Delta'} \sum_{(h,r,t)} [f_r(h,t) + \gamma - f_r(h',t')]_+ + C \left\{ \sum_{e \in E} [\|e\|_2^2 - 1]_+ + \left[\sum_{r \in R} \frac{(w_r^T d_r)^2}{d_r^2} - \epsilon^2 \right]_+ \right\}, \quad (10)$$

where C is a super parameter of weighted soft constraint importance.

5. Experiment and Analysis

5.1. Model Training. Based on the abovementioned objective function, this paper uses the adaptive moment estimation (Adam) optimization algorithm to train the cultural industry triples, update the model parameters, and keep a single learning rate different from the traditional random gradient descent. The Adam algorithm introduces a momentum factor, where independent adaptive learning rates are calculated for different parameters by calculating the first and second moment estimates of the gradient, which accelerates the convergence of the loss function [14]. When the loss function converges or reaches the maximum number of iterations, the training ends and the distributed representation vectors of entities and relationships in the MKD are obtained. The steps of the algorithm are as follows:

Step 1. Initialize and normalize the entity and relation vectors

Step 2. Select batch training data of m in training set S

Step 3. the current loss function gradient $\alpha L/\alpha\theta$ was and multiply it by the learning rate ϵ to obtain the current gradient descent distance to update model parameters, $\theta = \theta - \epsilon \cdot \alpha L/\alpha\theta$

Step 4. Repeat Step 3 until the maximum number of iterations is reached, stop traversing the sample, and output model parameter values, entity, and relationship vectors.

5.1.1. Experimental Data. From the MKD of the cultural industry project, the data set of the relationship between various industries is derived, and the abovementioned model is used for training. There are three tables in the dataset: entity table, relation table, and triple table. Among them, the entity table contains MKD class of the cultural industry, some data attributes, and a generated unique ID. There are 700 entities, including 493 cultural project entities, 106 regional entities, 61 project type entities, and 5 ethnic attribute entities. The relationship between the ID and the unique relationship includes the type of relationship generated by the set. In addition, 4781 groups of triples are in the

triple table, which are divided into a training set, verification set, and test set according to the ratio of 8:1:1.

5.1.2. Evaluation Index. In this paper, the method of link prediction is used to evaluate the effect of model training. A triplet is broken into incomplete triples, and each entity is used to fill in the vacancy, then, a new triplet is reconstructed. The score of the triplet is calculated by using the scoring function. The correct triplet is sorted according to the score that is based on the ranking results, and two evaluation criteria are used to evaluate the effectiveness of model training: MeanRank (average ranking of correct triples) and Hits10 (the probability that the correct triples are in the top 10 bits).

5.1.3. Results and Discussion. In order to make the TransH model perform better, we set different values for the parameters in the model. The initial learning rate of the Adam algorithm is set to 0.001, the batch size of single batch data is selected in {8, 12, 16}, γ is {0.25, 0.5, 1}, and the iteration times of each experiment are 50. Many experiments show that when the batch size is equal to 12, γ of 1 is a better choice. The experimental results of the model in different entity embedding dimensions are shown in Figure 6.

As shown in Figure 6, the evaluation index of MeanRank under different dimensions generally shows a trend of high on both sides and low in the middle. With the increase of dimensions, when the dimension is in 20 dimensions, the best accurate value is obtained, and the average rank of correct triples reaches 22.43.

As shown in Figure 7, the Hit10 under different dimensions tends to be low on the left and high on the right. When the embedded dimension is set to 10, the value of Hit10 is the lowest. With the increase of the dimension, when the dimension is 30, the most accurate index value is obtained. At this time, the Hit10 reaches 67.78%, indicating that the average probability of correct triples ranking in the top 10 is 67.78%.

To sum up, when embedded in the vector space with dimensions between 20 and 30, the evaluation indexes of MeanRank and Hit10 perform best, which realizes the accurate embedding of the entity vector and the relation vector of MKD of cultural industry projects. In this paper, the 30 embedded dimension is selected to train the representation vector containing semantic information of cultural industry projects, which provides the following recommendation algorithm based on the MKD of the cultural industry.

5.2. Effectiveness of the Recommendation Algorithm. Formula (11) is used to calculate the similarity P_{ui} between the cultural industry i and industry j :

$$P_{ui} = \sum_{j \in C(u) \cap S(i,k)} \omega_{ij}^l r_{uj}, \quad (11)$$

where $C(u)$ is the set of items that the user u has fed back, and the feedback here refers to the user's implicit feedback behavior. $S(i, k)$ is the set of k items most similar to item i ,

FIGURE 6: MeanRank in different dimensions.

FIGURE 7: Hits10 in different dimensions.

FIGURE 8: Effectiveness of the recommendation algorithm.

that is, the set of items composed by the first k items after they are arranged according to the size of item similarity, and k is called the number of neighbors. r_{uj} is user u 's interest in project j . If user u has clicked project i , r_{uj} can be set to 1; otherwise, it is 0. ω_{ij} is the similarity between items i and j .

The specific calculation process is as follows: Extract all items clicked by user u and find out the similarity degree of the first k items similar to each item clicked by user u . Add all the similarity degrees of item I to obtain the similarity degree of item I . In this way, the items are sorted in the order of similarity, and the first N items are recommended to users, that is, top- N recommendations.

The effect of top- N recommendation is usually measured by precision, recall, and $F1$. The results are shown in Figure 8.

It can be seen from Figure 8 that the accuracy rate of the proposed recommendation algorithm based on the MKD of the cultural industry is between 7% and 11%, the recall rate is between 11% and 18%, and the $F1$ value is between 8% and 14%. By comprehensive comparison, when k value is 20, a higher accuracy rate, recall rate, and $F1$ value can be obtained, and the top- N recommendation effect is the best. To sum up, the feasibility of the top- N algorithm is verified; when the number of neighbors is 20, the recommendation effect is the best.

6. Conclusion

In the era of big data, the development of the MKD provides a new direction for innovation and development of the cultural industry. This paper analyzes the data storage architecture, main models, and management methods. From the perspective of cultural communication pragmatics, this paper applies the MKD of the cultural industry to the recommendation algorithm, and designs a top- N recommendation algorithm; a link prediction experiment is designed to evaluate the training effect of the model. The results show that when it is embedded into the vector space with a dimension between 20 and 30, the evaluation indexes of MeanRank and Hit10 are the best, which realizes the accurate embedding of the entity vector and relation vector of the MKD of the cultural project; in addition, when K is 20, top- N recommendation has the best recommendation effect.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

At the same time that my country has shifted from high-speed development to high-quality development, my country has also put forward new requirements for education development. Due to the limited study time during college, each student's study habits and learning process are also different, and the degree of connection between tennis lessons is high, so there will be polarization when learning tennis. With the development of science and technology, more and more technological innovations are integrated into the classroom, and traditional teaching methods can no longer keep up with the pace of the times. Tennis teaching is a subject of equal proportion between theory and practice. The traditional teaching method simplifies the theory, which makes students to have some bad phenomena when they practice. Aiming at this series of problems, this paper uses algorithms such as softmax function and threshold function to construct an application model of virtual image technology based on the artificial neural network in tennis teaching. The research results of the article show that: (1) the average accuracy rate of the method in this paper is 97.22%, and the highest accuracy rate is 99.17%. The average accuracy rate also tends to increase with the increase of sample size; the recall rate is the highest, and the highest recall rate is 99.36%. The average recall rate is 96.77%; the highest correct rate is close to 100% and is significantly higher than the other three methods; the average correct rate reaches 98.8%; the response time is the shortest; the average response time is 33 ms; and the response time increases with the increase of the sample size. (2) After using this model, tennis skills have been improved, with an average of 12 in situ flips, an average of 7 in situ rackets, an average of 5 in situ forehand draws, and an average of 3 in situ backhand draws. (3) The average forehand and backhand scores of the class after the experiment were 90 and 86; the average forehand and backhand stability were 8 and 7; and the average forehand and backhand accuracy were 31 and 29, respectively. The average depth of forehand and backhand is 36 and 32. (4) Most of the students are satisfied with this model, and they all choose to strongly agree and relatively agree, and the percentage of very agree that helps stimulate learning has reached 60.52%, and no students choose to disagree very much.

1. Introduction

At present, although the traditional teaching methods of tennis in colleges and universities are helpful for students to understand and master the basic tennis movements, the traditional methods are relatively simple and cannot provide deeper guidance to students. Therefore, this paper uses the softmax function and threshold function to construct the application model of virtual image technology based on an artificial neural network in tennis teaching. Improve students' learning ability of tennis through virtual imaging technology. This paper has received a lot of support on the

basis of previous results. Artificial neural networks solve many problems that are difficult for modern computers to solve in the field of model recognition [1]. It exhibits good intelligence properties [2]. Artificial neural networks are proposed in the technology of modern neuroscience research results [3]. Neuron processing units can represent different objects [4]. Artificial neural networks enable parallel distributed systems [5]. It adopts a completely different mechanism from traditional artificial intelligence and information processing technology [6]. And it has the characteristics of self-adaptation, self-organization, and real-time learning [7]. Virtual is a description of distance and

impossibility [8]. The most favorable narrative method of digital images is its virtuality [9]. Virtual imaging technology uses information as material and transforms information into perceived reality [10]. Virtual can merge the vast and the subtle into one [11]. Virtual image technology combines art design and computer technology [12]. Virtual imaging technology is a general term for existing virtual reality, augmented reality, and projection technologies [13]. The artificial neural network model mainly considers the topology of network connections [14]. An artificial neural network is a nonlinear, adaptive information processing system composed of a large number of interconnected processing units [15].

2. Basic Knowledge

2.1. Artificial Neural Network

2.1.1. Neural Network Model. Artificial Neural Network (ANN for short) [16] is an information processing system established by humans based on the understanding of the operating rules of the brain neural network. The system can imitate the structure of the brain neural network to achieve certain functions. A neural network is an adaptive nonlinear dynamic system composed of multiple linear and nonlinear neurons connected to each other according to a certain method, in which neurons are the storage and processing units of information, and the learning process of the neural network is based on the input between neurons. The pattern connection weights are continuously adjusted to form a memory for the input pattern. A simple neuron model is shown in Figure 1.

In Figure 1, the input of the neuron is represented by $X = (x_1, x_2, x_3, \dots, x_n)$; the corresponding weight value of each input is represented by $W = (w_1, w_2, w_3, \dots, w_n)$; the bias value of the neuron is represented by b ; the activation function of the neuron is represented by $f(\cdot)$; and the input of the neuron is represented by y .

$$\cdot = \sum_{i=1}^n w_i x_i + b, \quad (1)$$

$$y = f(\cdot). \quad (2)$$

2.1.2. Neuron Activation Function. The activation function is the main processing method of artificial neural network information. The activation functions proposed according to different research problems can be divided into three categories:

(1) Linear activation function: the main function of the linear activation function is to linearly process the input information of the neuron, that is, the output information and the input information satisfy a linear relationship. The most common linear activation function is the pure-line activation function [17]. The function expression is

$$f(x) = kx. \quad (3)$$

FIGURE 1: Artificial neural network model.

(2) Nonlinear activation function: the main function of the nonlinear activation function is to nonlinearly process the input information of the neuron. The two activation functions of Sigmoid and Tanh are mainly used. The function expressions are as follows:

Sigmoid function:

$$f(x) = \frac{1}{1 + e^{-x}}. \quad (4)$$

Tanh function:

$$f(x) = \frac{1 - e^{-x}}{1 + e^{-x}}. \quad (5)$$

(3) Threshold function: the threshold function adopts a step function, and the output of the neuron is a binary variable [18]. Its function expression is

$$f(x) = \begin{cases} 1, & x \geq 0 \\ 0, & x < 0 \end{cases}. \quad (6)$$

(4) Softmax function: the softmax function is defined as follows:

$$S_i = \frac{e^{y_i}}{\sum_j e^{y_j}}. \quad (7)$$

The softmax function shows the concept of mutual exclusion, that is, the closer the judgment result is to a certain class, the closer the corresponding value of this class is to 1, and the closer to 0 for other classes.

(5) Gaussian error linear unit: the Gaussian error linear unit (GELU) adjusts the output value through a gating mechanism, defined as follows:

$$GELU(x) = xP(X \leq x), \quad (8)$$

where $P(X \leq x)$ is the cumulative distribution function of the Gaussian distribution.

The Gaussian error linear unit is approximated by the Tanh function:

$$GELU(x) \approx 0.5x \left(1 + \tanh \left(\sqrt{\frac{2}{\pi}} (x + 0.044715x^3) \right) \right). \quad (9)$$

Approximate using the logistic function:

$$GELU(x) \approx xL(1.702x). \quad (10)$$

2.1.3. Loss Function. The loss function is usually used to describe the difference between the prediction result of the model on the sample value and the actual value, which represents the accuracy of the model to a certain extent. The loss function includes the mean square error function and the cross-entropy function.

(1) Mean square error function: the mean square error function uses the mean square error in statistics to characterize the deviation of the predicted value from the actual value and is defined as follows:

$$\text{Loss} = \frac{\sum (y - y')^2}{n}, \quad (11)$$

where y is the label value, y' is the predicted value, and n is the number of samples.

(2) Cross-entropy function: the cross-entropy function represents the deviation between two probability steps. Assuming that both p and q represent the law of probability, the cross entropy of p represented by q is

$$H(p, q) = - \sum_x p(x) \log_2 q(x). \quad (12)$$

2.2. Artificial Neural Network Algorithm. The learning process of the artificial neural network is composed of forward propagation and back propagation [19]. The algorithm process is as follows.

Initialize weights and thresholds [20]: after the network BP (n, q, m) is determined, the network algorithm includes the weight from the i unit of the input layer to the j unit of the hidden layer, the weight of W_{ij}^1 ($i = 1, \dots, n; j = 1, \dots, k$) from the j unit of the hidden layer to the k unit of the output layer, and the weight of W_{ij}^0 ($j = 1, \dots, q; k = 1, \dots, m$). The activation threshold of the j unit of the hidden layer is θ_j^H ($j = 1, \dots, q$), and the activation threshold of the j unit of the output layer is θ_k^0 ($k = 1, \dots, m$). The above weights and initial thresholds are randomly generated before the network is trained.

Training sample information [21]: assuming that P is a common training sample, input the r ($r = 1, \dots, p$) training sample information to the first hidden layer of forward propagation and obtain the output information of the hidden layer through the action of the activation function $f(x)$.

$$H_{jr} = f\left(\sum_{i=1}^n w_{ij}^1 x_{ir} \theta_j^1\right), \quad (j = 1, \dots, q; r = 1, \dots, p). \quad (13)$$

The hidden layer output information is transmitted to the output layer, which may be the final output result [22].

$$Y_{kr} = f\left(\sum_{j=1}^q w_{jk}^0 H_{jr} \theta_k^0\right), \quad (k = 1, \dots, m; r = 1, \dots, p). \quad (14)$$

In the process of forward propagation of learning information in the network, the error of another process is backpropagated [23]. If there is an error between the network output and the desired output value, then backpropagate the error, using all adjusted network weights and thresholds.

$$\Delta w(t+1) = \eta \frac{\partial E}{\partial w} \alpha \Delta w(t), \quad (15)$$

where $\Delta w(t)$ is the modified value of the t training weight and threshold [24] and η and α are the scale factor and momentum factor, respectively.

$$E = \frac{1}{2} \sum_{k=1}^m \sum_{r=1}^p (Y_r - t_r)^2. \quad (16)$$

The above two procedures are repeated until the error between the network outputs reaches a certain requirement and desired output.

2.3. The Basic Principle of Artificial Neural Network. The input net_j^m for the j neuron in layer m is

$$\text{net}_j^m = \sum_{i=1}^n w_{ij}^{m-1} o_i^{m-1} + b_j^m. \quad (17)$$

Then, the output o_j^m of the j neuron in the m layer is

$$\begin{aligned} o_j^m &= f_j^m(\text{net}_j^m) \\ &= f_j^m\left(\sum_{i=1}^n w_{ij}^{m-1} o_i^{m-1} + b_j^m\right). \end{aligned} \quad (18)$$

$$\begin{aligned} o^n &= f^n\left(w^{n-1} f^{n-1}\left(\frac{\dots (w^{i+1} f^{i+1}(w^i o^i + b^{i+1})) \dots}{n-2}\right)\right) \\ &\quad + b^{n-1} + b^n, \end{aligned} \quad (19)$$

where w_{ij}^{m-1} is the weight between the i neuron in the $m-1$ layer and the j neuron in the m layer, b_j^m is the bias value of the j neuron in the m layer, and o_i^{m-1} is the second layer. Three neurons were applied to output; f_j^m is the activation function of the j neuron in the m layer.

Thus, the expression of the final output information of the neural network about the input information can be obtained. The expression is represented by a vector as follows:

$$o^n = f^n(w^{n-1} f^{n-1}(w^{n-2} o^{n-2} + b^{n-1}) + b^n). \quad (20)$$

2.4. Learning Rules of Artificial Neural Networks. The error function generated for sample a and the h output neuron is defined as follows:

$$e_h = d_h - o_h. \quad (21)$$

In order to make the partial derivative continuous, a quadratic error function is generally used, and the total error function for sample a is

$$E = \frac{1}{2} \sum_h^L (d_h - o_h)^2. \quad (22)$$

When training, when p training sample is input at a time, the total error function is

$$E_p = \frac{1}{2} \sum_{p=1}^P \sum_{h=1}^L (d_h^p - o_h^p)^2. \quad (23)$$

When using the fastest gradient descent algorithm [25]. The formula is

$$w_{ij}^m(k+1) = w_{ij}^m(k) - lr \frac{\partial \hat{E}_p}{\partial w_{ij}^m}, \quad (24)$$

$$b_j^m(k+1) = b_j^m(k) - lr \frac{\partial \hat{E}_p}{\partial b_j^m}, \quad (25)$$

where $w_{ij}^m(k+1)$ and $w_{ij}^m(k)$ are the weight values between the i neuron in the $m-1$ layer and the j neuron in the m layer in the $k+1$ and k iterations, respectively; $b_j^m(k+1)$ and $b_j^m(k)$ are the $k+1$ and the bias value of the j neuron in the m layer at the k iteration, respectively; lr is the learning rate; and \hat{E}_p is the approximate error at the k iteration.

3. Application of Virtual Image Technology in College Tennis Teaching

3.1. Overview of Virtual Imaging Technology

3.1.1. Concept of Virtual Image Technology. The virtual image is a visual technology and art based on digital technology. Virtual imaging technology is a combination of photography technology, projection technology, display technology, and other technologies, which can help people better understand the known real space and the unknown virtual space. It simulates and reorganizes text, images, and other information through digital technology to form abstract or real spatial scenes with interactivity, virtuality, and immersion.

3.1.2. Classification of Virtual Imaging Technology. Virtual imaging technology can be divided into virtual reality technology, augmented reality technology, holographic projection technology, fog screen stereo imaging technology, wall projection technology, and interactive projection technology as shown in Table 1.

3.1.3. Technical Characteristics of Virtual Images. Virtual imaging technology has the characteristics of integration, fidelity, immersion, imagination, artistry, and interaction as shown in Table 2.

3.2. Basic Principles of Tennis Teaching. Tennis teaching has the principle of health, which means that the physical safety of students should be guaranteed first in the tennis teaching process; in the process of tennis teaching, the teaching content should be gradual and the principle of low level to high level, starting from the actual principle, from simple to complex and gradually improve. According to the students' physical load and practice venues to arrange teaching, students consciously and actively participate in learning activities; students should firmly grasp the knowledge of all aspects of tennis.

3.3. Model Construction. In this paper, a model of college tennis teaching based on virtual image technology based on an artificial neural network is constructed, as shown in Figure 2. The tennis teaching model in colleges and universities is divided into three steps: the first step is audition learning, the second step is practical mastery, and the third step is interactive analysis.

In the first step in tennis teaching, students first need to wear virtual imaging technology equipment to gain a preliminary understanding of tennis teaching through the equipment and then take off the equipment, and the teacher will demonstrate and explain the standard movements; after the teacher's explanation, the students need to wear the equipment again and watch a continuous tennis movement to speed up their understanding of the action.

In the second step, the students take off the instrument again and practice freely. The teacher guides the students' movements during this process; after the teacher finds the students' problems, the students wear the instruments again to compare their movements to find their own problems; Remove the instrument again, repeat the previous practice, and correct the problems found in the process; and the teacher also corrects the problems of the students in the process.

Finally, in the third step, students form groups to practice and supervise each other and wear the instrument again to consolidate the practice.

4. Experimental Analysis

4.1. Model Testing. In this paper, an application model of artificial neural network-based virtual image technology in college tennis teaching is constructed, and algorithms such as softmax function and threshold function are used in the model. First, the model will be tested, and the advantages of the model will be checked by comparing it with BP neural network, deep neural network, and traditional methods, and whether it meets the requirements.

In the model testing stage, in order to test the accuracy, recall, correctness, and response time of the model under different sample sizes, the standard degree of students' actions in the learning process was selected as the research object. The experimental sample sizes were divided into 6 groups, namely 10, 30, 50, 70, 90, and 110.

TABLE 1: Classification of virtual imaging technology.

Classification	Content
Virtual reality (VR)	Virtual reality technology is a general term for a technical system used to establish a virtual environment for the experimenter to observe and interact with. Use 3dmax, Unity3d, and other software to model and create virtual scenes, capture and simulate human movement through hardware facilities such as Kinect and Arduino, and interact with virtual scenes; generate instructions through C language and Java programming; and form feedback.
Augmented reality (AR)	Augmented reality technology will recognize and analyze images observed with the camera; classify and identify matching images, images, and other digital information in a database; and display it on the screen overlaid with the actual scene.
Holographic projection technology	Holographic imaging technology projects the image onto the actual environment or transparent medium without the audience wearing the device, creating the illusion that the image is suspended in the air. Then, interact with the image through the interactive device.
Fog curtain stereo imaging technology	Fog screen stereo imaging technology uses a spray device instead of a traditional projection screen to generate an artificial water mist wall and generates a flickering fog screen projection image through an electric device to form a holographic image.
Wall projection technology	Wall projection technology is mainly used for the outer panels of urban buildings. The urban exterior wall projection is mainly composed of a laser projector, a screen segmentation control matrix technology, and an exterior wall laser projection system composed of an intelligent central control system.
Interactive projection technology	Interactive projection technology is a projection system composed of projection equipment, infrared sensors, motion capture equipment, and computers. The captured data is analyzed using infrared cameras and sensors to track and identify data such as body movements and the voice of the experimenter. Combined with real-time image interaction tracking, it produces real-time interaction effects between participants and projects.

TABLE 2: Technical characteristics of virtual images.

Feature	Content
Integration	Virtual image technology is the product of technology development and traditional images. Virtual image technology is a new image technology supported by projection technology, display technology, sensing technology, and other technologies.
Fidelity	Virtual imaging technology is to reproduce reality through the current simulation or focus on the current image; contrary to the real optical illusion, the user's visual authenticity and the authenticity of the image are unified. There are many real experiences in real vision, intelligence, vision, and relationships.
Immersion	In fact, outside of the ideal visual image, people are really confused about pain. The combined behavior of public experience and sensory psychological factors creates an illusion of interest in the user's real environment. Through sensory technology and real-time, users can connect to virtual environments to create physical and mental experiences.
Imaginative	Virtual images not only can reproduce the real environment but also can imagine an illustrative environment, satisfying the curiosity as well as the visual and psychological needs of the experimenter. The creative process of virtual image technology is special, so it can be integrated into the imagination of the creative stage, increase the scale of the work, and increase the scope of human knowledge and imagination.
Artistry	The production of virtual image content is people's thinking and behavior, and art is also designed and used based on people's main aesthetic preferences, emotions, thinking, and behavior.
Interactivity	Through the recognition of the experienced expressions and sounds, the information of body movement is captured and temporarily returned in real time, and the interaction of images is formed.

The criteria for the model to meet the requirements are as follows: the average accuracy rate of the test samples is more than 97%, the average recall rate is greater than 96%, the average accuracy rate is greater than 98%, and the average response time is less than 34%; then the model meets the requirements.

According to the results in Figure 3 and Table 3, the average accuracy rate of the method in this paper is 97.22%, and the highest accuracy rate is 99.17%. The average accuracy rate also tends to increase with the increase of the sample size, indicating that the method in this paper meets the requirements. And, by comparing the method in this paper with the other three methods, it can be seen that the

method in this paper has obvious advantages and the highest accuracy.

As can be seen from Table 4, the recall rate of the method in this paper is the highest; the highest recall rate is 99.36%; and the average recall rate is 96.77%, which meets the inspection standard. According to Figure 4, it can be clearly seen that the overall recall rate is on the rise, and it is concentrated between 94% and 96%.

The results in Figure 5 and Table 5 show that the highest accuracy rate of the method in this paper is close to 100%, which is significantly higher than that of the other three methods, and the average accuracy rate reaches 98.8%, indicating that the method in this paper meets the

FIGURE 2: Tennis teaching model.

requirements. On the whole, the correct rate of the four methods is above 94%; the average correct rate of the BP neural network is 97.3%; the average correct rate of the deep neural network is 96.6%; and the average correct rate of the traditional method is 96.9%.

The experimental results in Figure 6 and Table 6 show that the method in this paper requires the shortest response

time, with an average response time of 33 ms, and the response time increases with the increase of the sample size. The traditional method had the highest response time, which was twice as high as the other methods with a sample size of 30.

It can be seen from the experimental results that the method in this paper has reached the standard in terms of

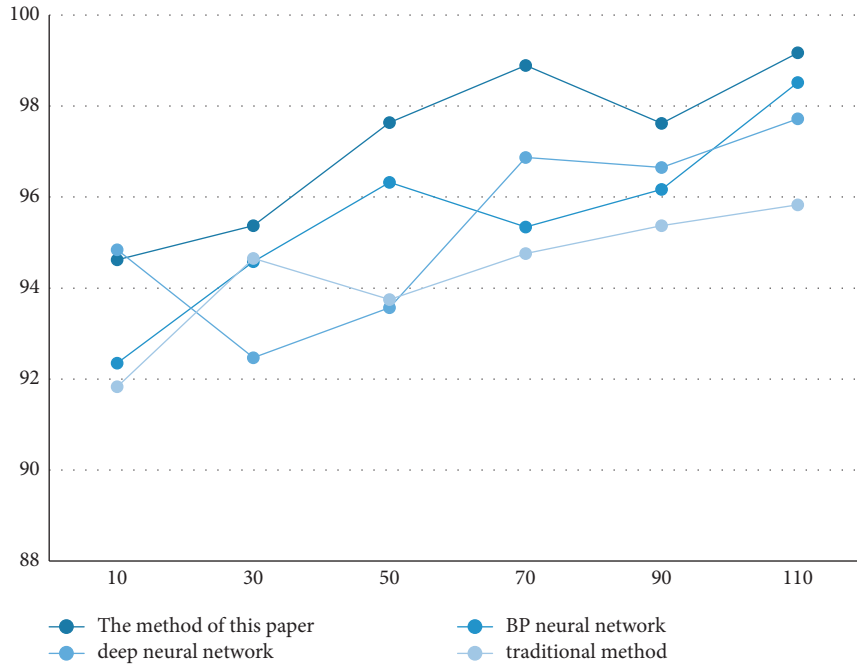

FIGURE 3: Accuracy.

TABLE 3: Accuracy (%).

Model	10	30	50	70	90	110
The method of this paper (%)	94.62	95.37	97.64	98.89	97.62	99.17
BP neural network (%)	92.35	94.58	96.32	95.34	96.17	98.52
Deep neural network (%)	94.84	92.47	93.57	96.87	96.65	97.72
Traditional method (%)	91.83	94.65	93.75	94.76	95.37	95.83

average precision, average recall, average correct rate, and average response time and meets the requirements. Compared with the other three methods, the method has obvious advantages and is feasible.

4.2. Experimental Simulation. After the model meets the test criteria, it will be used in formal teaching. In order to test the students' learning effect under the model, the students' learning results will be compared with those before the experiment.

4.2.1. Comparison of Student Tennis Skills. Students in one class were randomly selected to conduct the experiment, and their average number of in situ hits, average in situ rackets, average in situ forehand draws, and average in situ backhand draws were recorded before and after the experiment. The experimental results are shown in Figure 7.

From the results in Figure 7, it can be seen that the tennis skills of the students before the experiment were relatively weak. After using the model, the tennis skills were improved. The average number of in situ flips was 12 times; the average number of in situ racquets was 7; and the average in situ strokes were 7 times. There is an average of five forehand draws and three backhand draws.

4.2.2. Comparison of Forehand and Backhand Performance. Forehand and backhand assessment, stability, accuracy, and depth of stroke are also important components of tennis assessment in tennis teaching.

Forehand and backhand skill evaluation is to score students' actions during the hitting process; forehand and backhand stability is based on students hitting the ball 10 times with forehand and backhand, respectively, and the number of hits is the final score. Forehand and backhand

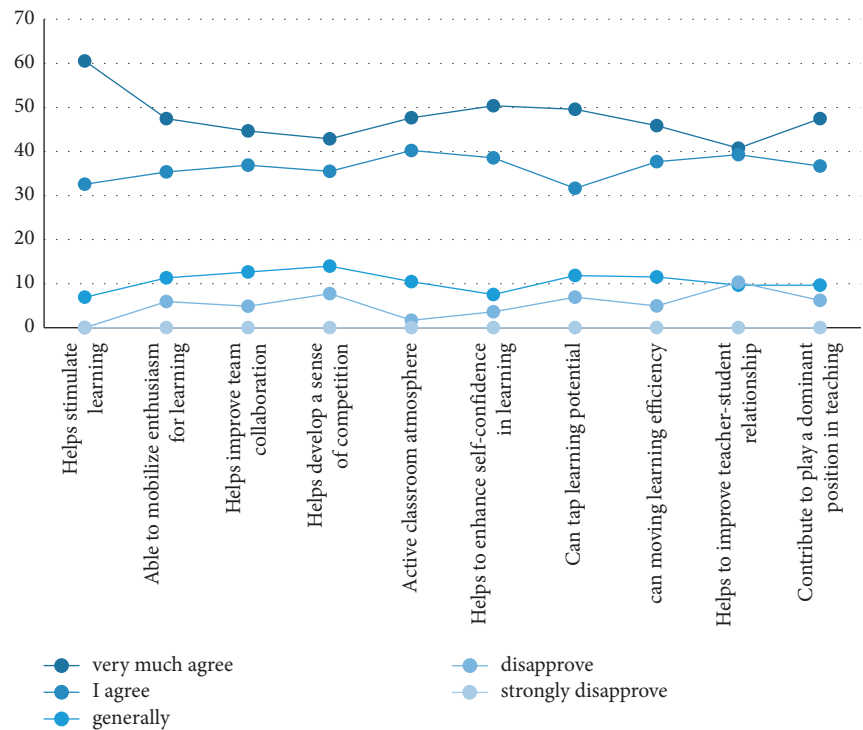

FIGURE 9: Model evaluation.

accuracy: it means that each student hits the ball 10 times alternately within the specified different score areas and hits the ball to get the corresponding score; the depth of forehand and backhand hitting is the depth area corresponding to each student's different scores. Figure 8 shows the average scores of the students in this class before and after using the model in this paper:

The results in Figure 8 show that the average forehand and backhand scores of the class before the experiment were 81 and 80, the average forehand and backhand stability were 7 and 5, and the average forehand and backhand accuracy were 28 and 24, respectively. Forehand and backhand depths are 30 and 25. The average forehand and backhand scores of the class after the experiment were 90 and 86 points,

respectively; the average forehand and backhand stability were 8 and 7 times, respectively; and the average forehand and backhand accuracy were 31 points and 29 points, with an average forehand and backhand depth of 36 and 32 points, respectively. And the scores of the students in this class have improved after using the model, indicating that the model has obvious advantages in improving students' performance.

4.3. Model Evaluation. After the experiment, the classmates' evaluation of the tennis teaching model using virtual image technology was statistically analyzed by means of questionnaires. It is evaluated in 7 aspects: to cultivate a sense of competition, activate the classroom atmosphere, enhance self-confidence in learning, tap learning potential, improve learning efficiency, enhance teacher-student emotion, and play a dominant role in teaching. The evaluation results are shown in Figure 9.

It can be seen from Figure 9 that most of the students are satisfied with this model, and they all choose to strongly agree or agree, indicating that the students have a high degree of recognition of the tennis teaching model using virtual image technology. And the percentage of very agreeable to help stimulate learning reached 60.52%, and no classmates chose to be very disapproved.

5. Conclusion

College physical education is an important part of the teaching process in colleges and universities, and tennis teaching is a subject that combines theory and practice, so the teaching mode of tennis is different from that of other subjects. With the development of the times, the traditional tennis teaching method has a certain lag in the teaching process. Therefore, this paper uses various algorithms such as softmax function and threshold function to construct a virtual image technology based on an artificial neural network in tennis teaching. Improve students' tennis skills through a combination of tennis teaching and virtual technology.

The findings of the article show that

- (1) The average accuracy rate of the method in this paper is 97.22%, and the highest accuracy rate is 99.17%. The average accuracy rate also tends to increase with the increase of the sample size, indicating that the method in this paper meets the requirements.
- (2) The recall rate of the method in this paper is the highest; the highest recall rate is 99.36%; and the average recall rate is 96.77%, which meets the inspection standard.
- (3) The highest accuracy rate of the method in this paper is close to 100%, which is significantly higher than that of the other three methods, and the average accuracy rate reaches 98.8%, indicating that the method in this paper meets the requirements.
- (4) The response time required by the method in this paper is the shortest, with an average response time

of 33 ms, and the response time increases with the increase of the sample size.

- (5) The tennis skills of the students before the experiment were relatively weak. After using the model, the tennis skills were improved. The average number of in situ flips was 12; the average number of in situ rackets was 7; and the average in situ forehand was drawn. The ball is 5 times, and the average backhand kick is 3 times.
- (6) The scores of the students in this class have improved after using the model, indicating that the model has obvious advantages in improving students' performance.
- (7) Most of the students are satisfied with this model, and they all choose to strongly agree or agree, indicating that the students have a high degree of recognition of the tennis teaching model using virtual imaging technology.

According to the experimental results, in the following teaching process, students' interest in learning and autonomous learning ability should be strengthened; teachers' own teaching ability professional level should be improved; an open and free learning division should be created to increase students' interest in the class. Although the artificial neural network-based virtual image technology constructed in this paper has obvious advantages in the application model experimental results of tennis teaching, there are still many shortcomings and certain limitations. The model constructed in this paper is limited to tennis teaching. It is hoped that in the following research, researchers can conduct in-depth research on the scope of application so that the model is not limited to tennis teaching and increases the scope of application of the model.

Precision medicine for cancer affords a new way for the most accurate and effective treatment to each individual cancer. Given the high time-evolving intertumor and intratumor heterogeneity features of personal medicine, there are still several obstacles hindering its diagnosis and treatment in clinical practice regardless of extensive exploration on it over the past years. This paper is to investigate radiogenomics methods in the literature for precision medicine for cancer focusing on the heterogeneity analysis of tumors. Based on integrative analysis of multimodal (parametric) imaging and molecular data in bulk tumors, a comprehensive analysis and discussion involving the characterization of tumor heterogeneity in imaging and molecular expression are conducted. These investigations are intended to (i) fully excavate the multidimensional spatial, temporal, and semantic related information regarding high-dimensional breast magnetic resonance imaging data, with integration of the highly specific structured data of genomics and combination of the diagnosis and cognitive process of doctors, and (ii) establish a radiogenomics data representation model based on multidimensional consistency analysis with multilevel spatial-temporal correlations.

1. Introduction

Tumor heterogeneity, one of the main characteristics of malignant tumors, poses great challenges to its accurate diagnosis and treatment, which is also manifested by multiple genotypes and multiple gene expression patterns in the same tumor cells [1]. The same tumor presents distinctly different therapeutic effects and prognosis in different individuals, and even tumor cells in the same individual present varied characteristics though with the same genome [2]. As shown in Figure 1, tumor heterogeneity is manifested in both space and time. In terms of space, the combined effects of molecular variation and tumor microenvironment lead to differences in tumor regions [3], which can be classified as follows: (i) intertumor heterogeneity, that is, differences between tumors in different patients; (ii) intratumor heterogeneity, that is, completely different or even opposite patterns of the expression patterns of cells in different tumor regions, which may result in the changes in

structure and differential responses to therapeutic drugs [4]. In terms of time, tumor is a dynamic system, and tumor cells evolve over time with multiple variations and temporal heterogeneity, which requires the reproducible detection in time. However, current genomics technology is static and can only reflect the information of a point (snapshot) on the time axis. Current molecular profiling analysis on locally extracted tumor tissues at a single time point reflects only a small part of the information of the entire tumor in both the spatial and temporal dimensions and fails to fully analyze the characteristics of the tumor. Quantitative description of tumor heterogeneity may lead to one-sided or even erroneous diagnosis, affecting the treatment options, and leading to drug resistance and disease recurrence in patients.

Genome analysis technology attempts to solve the problem of tissue sampling and analysis under tumor heterogeneity, such as the multiregion sampling strategy for spatial heterogeneity, and the micro-cutting of different tumor tissues for the isolation of small tissue fragments.

FIGURE 1: Intertumoral, intratumoral, and time related (temporal) heterogeneity of tumors (from Burrell et al., Nature, 2014 [5]).

DNA of these fragments has been analyzed [6]. However, this method requires precise localization of the tumor area during sampling to ensure the sampling genes obtained coming from tumor cells, which greatly limits the success rate of such a method. Longitudinal sampling attempts to solve the problem of temporal heterogeneity. Pathological sections are obtained at different stages of tumor treatment to track the variation of tumor-related genes and accurately analyze tumor heterogeneity [7–9]. However, the longitudinal sampling method requires multiple acquisition of patient tissue samples, and the invasive nature of this method terribly limits its feasibility in clinical practice. In short, the heterogeneity of tumors brings considerable challenges to precise diagnosis and treatment. Merely relying on linear, invasive, and single-time-point genomics technology cannot well meet the needs of precise clinical diagnosis and treatment, making it necessary to explore a three-dimensional, noninvasive, and reproducible method.

Broadly speaking, tumors are made of evolved and heterogeneous populations of cells that are resistant to matched targeting therapy. Thus, it is not enough reliable to evaluate effects of tumor treatment and diagnosis only from the perspective of tumor abnormality [10, 11]. Tumor genome analysis has been the gold-standard technique for molecular mapping [12, 13]. Nevertheless, the study on genomic heterogeneity has revealed that individual tumor may be clonally independent without shared driver gene alterations [14]. There is a proof-of-concept study demonstrating that morphological heterogeneity reflects structural and functional divergence. Moreover, there is a close link between morphological phenotypes and stromal and cancer-cell-related features that allow prediction of the morphological pattern [15]. Furthermore, a better understanding of the molecular background is conducive to preventing adverse drug reactions for defined patient groups [16, 17].

However, drug therapy matched to the molecular target does not necessarily produce positive results [18, 19]. This is affected by multiple factors such as tumor microenvironment and tumor heterogeneity. In summary, the foregoing findings demonstrate that the genetically, morphologically, phenotypically, and topologically distinct primary cancers can not only be present in an individual patient but also are of great significance to personalized medicine approaches, as they can limit therapeutic efficacy, and they are resistant to therapy.

This paper was aimed at reviewing the methods in literature regarding the precise diagnosis and prognosis prediction of neoadjuvant chemotherapy for tumors, using breast MRIs, for example. Taking tumor heterogeneity as the core issue, the deep learning-based radiogenomics analysis of breast tumor heterogeneity was studied, and the relationship between the imaging characteristics of heterogeneous tumors and molecular expression features was correspondingly explored as well. At the same time, geometric algebra was applied to design a framework for analyzing dynamic contrast enhanced MRI radiogenomics, and fully mining the rich spatial images, spatial signals, and semantic features in breast multidimensional magnetic resonance imaging. According to the heterogeneity of different tumors, an individualized model of neoadjuvant chemotherapy efficacy prediction was established by combining MRI information, molecular typing information, and clinical information of patients suffering from breast cancer, which provided scientific guidance for accurate diagnosis, treatment, and prognosis of patients, improved the survival rate of tumor patients, enhanced the life quality of patients after surgery, and achieved effective and rational utilization of medical resources.

The remainder of the paper is structured as follows: Section 2 discusses challenges in the analysis of tumor

heterogeneity using radiogenomic approaches; the main framework for radiogenomics analysis in literature is presented in Section 3, where the mathematical models applied for tumor diagnosis and the evaluation of tumor treatment and prognosis performance via multiomics are presented; Section 4 addresses outlook and future work, where a multilevel deep learning model named BiGRU-RNN is proposed for predicting the efficacy of neoadjuvant chemotherapy using radiogenomics. It is represented by introducing geometric algebra and enables the multidimensional unified analysis of dynamic contrast enhanced MRI radiogenomics; finally, Section 5 summarizes the most significant parts in each section in a simplified manner.

2. Challenges in the Analysis of Tumor Heterogeneity Using Radiogenomic Approaches

In biomedical analysis, tumor heterogeneity characteristics and multiple physiological tumor characteristics are not combined, and multimodal (parametric) imaging technology is not widely used [20]. Various “spectrum” analyses of images from different perspectives describing these physiological characteristics have led to the one-sidedness and singularity of the research. In addition, current radiogenomics analysis on tumor heterogeneity assumes that the voxel of each tumor image presents a single specific tissue characteristic. However, tumors are highly heterogeneous. Current resolution of clinical diagnostic images is rather finite, and the observed signal at a certain position (voxel) of the tumor may be a mixture and superposition of components of different characteristics [21, 22]. From the perspective of signal processing, tumor image heterogeneity is manifested as a multivariate (component) mixed signal processing problem. In this regard, a lot of preliminary researchers work on the DCE-MRI subcomponent decomposition [23, 24], the corresponding molecular information decomposition [25, 26], and an unsupervised convex analysis analyzing the components of different tissue characteristics of heterogeneous tumors [6]. These researches afford a further understanding of the physiology and molecular characteristics of tumors.

At present, this method is only applied for two-dimensional analysis of DCE-MRIs [27–29], and there is no further development of heterogeneous analysis of tumors based on three-dimensional multi-modal MRIs [30–32]. The radiogenomics issues such as the correlation between different subcomponents after decomposition and the application of tumor diagnosis and treatment also need further exploration. Additionally, current heterogeneity analysis and subregion/subcomponent decomposition research mainly focus on the tumor itself, ignoring the fact that tumor does not exist in isolation, which constantly exchanges information with the surrounding substance and microenvironment during the growing process, and is also affected by the surrounding substance. Tumor cells can reshape the microenvironment, and the changed microenvironment can

further affect the behavior and status of tumor cells, leading to tumor progression and metastasis. Therefore, the formation of tumor heterogeneity is the result of the joint action of the tumor body and its surrounding substance. Currently, heterogeneity analysis is mostly limited to the structure and function of the tumor itself, and there is few literatures reporting the heterogeneity of tumor stroma [33, 34].

In recent years, there have been several researches concerning the radiomics research of tumor stroma. For example, King et al. found that the increase in the dynamic enhancement rate of fibroglandular mammary glands was associated with higher mammary cancer morbidity [35], who divided the body into several band-shaped regions according to the distance from the tumor and investigated the relationship between these regions and the disease-free survival of breast cancer [36]. However, the analysis of tumor heterogeneity in these studies was still preliminary, qualitative, or semiquantitative analysis. No systematic work has been performed to quantitatively analyze the relationship between the tumor and the surrounding substance or analyze the heterogeneity of the substance. In addition, the analysis of tumor heterogeneity in radiogenomics research at this stage generally focuses on image feature analysis. The collected gene molecular information is assumed to be homogeneous by default, but in fact, the tissue collected in molecular expression analysis may be a mixture of tissues with different “content” and different characteristics [37]. Besides, current radiogenomics research does not analyze the heterogeneity of the tumor itself, resulting in the inaccuracy of the associated study, and even the appearance of “false relationships.” Previous research was conducted in terms of signal subcomponent decomposition analysis, biological verification research on gene expression values of different tissue characteristics (human brain, liver, and lung), and unsupervised identification of mixed tissue characteristics [31, 32]. The gene expression signal of heterogeneous tumors has not been further analyzed. Therefore, the research of radiogenomics based on the decomposition of gene information is urgently required.

3. Methodology of Radiogenomics in Literature

As a noninvasive modality, the multidimensional radiogenomics analysis based on Magnetic Resonance Imaging (MRI) has become a special field of study on the tumor grading. The field of radiogenomics has been advanced substantially by novel MR imaging sequences that reflect underlying oncogenic processes. MRI-based radiogenomics combines a mass of quantitative data extracted from multidimensional MR images with individual genomic phenotypes and builds a prediction model through deep learning, which aims to make a diagnosis for patients, offer guidance for therapeutic strategies, and make an evaluation on clinical outcomes [38]. Additionally, some issues existing in radiogenomic analysis are specified, and corresponding solutions from prior works are provided [39]. Illustratively, the abundance of immune and stromal cells in the Tumor Microenvironment (TME) indicates the levels of

inflammation, angiogenesis, and desmoplasia. It has been proven that radiomics, an approach of extracting quantitative features from radiological imaging to characterize diseases, can predict molecular classification, cancer recurrence risk, etc. However, the ability of radiomics to predict the abundance of various cells in the TME remains unknown. Arefan et al. [40] carried out studies by applying a radiogenomics approach and building machine learning models to capture one-to-one relationships between radiomic features from Dynamic-Contrast Enhanced Magnetic Resonance Imaging (DCE-MRI) and cell abundance of gene expression data and then predict the infiltration of multiple cells in breast cancer lesions. It is concluded that radiogenomics contributes to computer-aided diagnosis, treatment, and prognostic prediction for patients with tumors in a routine clinical setting.

3.1. Tumor Diagnosis Research Based on Radiogenomics. Radiogenomics, as an important application, reveals and reflects the molecular pathological characteristics of tumor tissues, such as dynamic enhancement characteristics for tumor and mammary-gland tissue [33, 34] and breast asymmetry characteristics [34] in distinguishing benign and malignant tumors using noninvasive and dynamic imaging technology.

Tumor molecular classification is an important index in clinical diagnosis. In several studies, quantitative image features, such as the dynamic enhancement ratio of the lesion to the background area, gray-scale histogram features, and 66texture, are used to predict these molecular indicators [37, 41]. It has been reported that there are 90 extracted image features, including the morphology, dynamic enhancement, and bilateral asymmetry of breast cancer tumors and their background regions, all of which are used to distinguish four molecular subtypes of breast cancer [42]. In recent years, radiomics features, including tumor volume, shape, edge morphology, and dynamic characteristics, have also been used to predict the expression of gene chips for clinical diagnosis, such as MammaPrint, Oncotype DX, and PAM50 gene arrays [43–45]. Additionally, some researchers have studied the MR image characteristics of breast cancer in the TCIA database and the molecular information such as miRNA, gene somatic mutation, protein expression, and copy number variation of these patients in the corresponding TCGA database. It has been found that there are several genetic signaling pathways, gene mutation sites, and image feature modules significantly related to gene expression modules [46]. The above-mentioned study in image group characteristics and gene expression correlation is to explore the imaging biomarkers of tumor molecular characteristics, thus providing services for clinical diagnosis [47].

3.2. Tumor Treatment and Prognosis Research Based on Imaging Group Feature Analysis. Currently, a large amount of research regarding radiogenomics focuses on exploring the relationship between imaging group and molecular features.

Some work bypasses the association between imaging and molecular information and directly uses imaging features to predict treatment results.

It has been investigated that the imaging phenotype of the tumor can be used to provide information on the outcome of tumor treatment, such as chemotherapy efficacy and prognosis. Fan et al. extracted 156 image features of breast tumors and background regions using DCE-MRIs and selected several distinguishing heterogeneous features reflecting gray-scale unevenness, such as kurtosis and skewness, to predict the effectiveness of NAC for breast cancer [48]. Huang et al. extracted the gray-scale texture features of colorectal cancer images to predict lymph node metastasis (disease-free survival) before surgery [49]. Some researchers used cluster analysis to divide the imaged tumor into different regions according to the dynamic enhancement mode, analyzed the differences in the texture characteristics of these regions before and after chemotherapy, and predicted the efficacy of chemotherapy using the detected features [26], proving that the imaging characteristics of different tumor areas could be used to predict the efficacy of NAC. Additionally, key tumor genes were detected and identified by analyzing the differences in the network structure of the tumor genome before and after treatment, combined with the analysis of the tumor volume growth pattern of MRIs in terms of its longitudinal time, to predict the treatment response of tumors [50].

With the use of perfusion magnetic resonance (MR) imaging, Wu et al. characterized intratumoral spatial heterogeneity and studied the tumor homogeneity to predicate the recurrence-free survival (RFS) of the patients with breast cancer [51]. Figure 2 proposed a two-stage intratumor partition framework, including stage I: individual level cluster; and stage II: population level cluster. Primarily, at a personal level, every tumor is exceedingly segmented via superpixels using four kinetic features, that is, percentage and signal enhancement ratios, as well as the wash-in and wash-out slopes, according to DCE-MRIs [52–54]; secondly, at the population level, a consensus cluster can be used to aggregate and uniformly mark all superpixels from the entire population. Additionally, it is possible to establish the congruent relationship between tumor subregions across patients among the given population. Breast cancer is constituted by several subregions with different spatial features, and the intratumoral spatial heterogeneity is characterized and quantified via the defined multi-regional spatial interaction (MSI) matrix. As a distinct independent prognostic factor, imaging heterogeneity is beyond those traditional predictive risk factors; similar radiogenomics is also used for predicting NAC efficacy [50, 55–57], prognosis [26, 48], survival period [58], distant metastasis [59], etc. However, most tumor treatments based on radiogenomics regimen only focus on describing and analyzing the overall gray-scale unevenness (texture, etc.) of imaged tumors [43], and the influence for diagnosis and treatment is rarely analyzed and measured in terms of the subregions (components) of heterogeneous tumors [44].

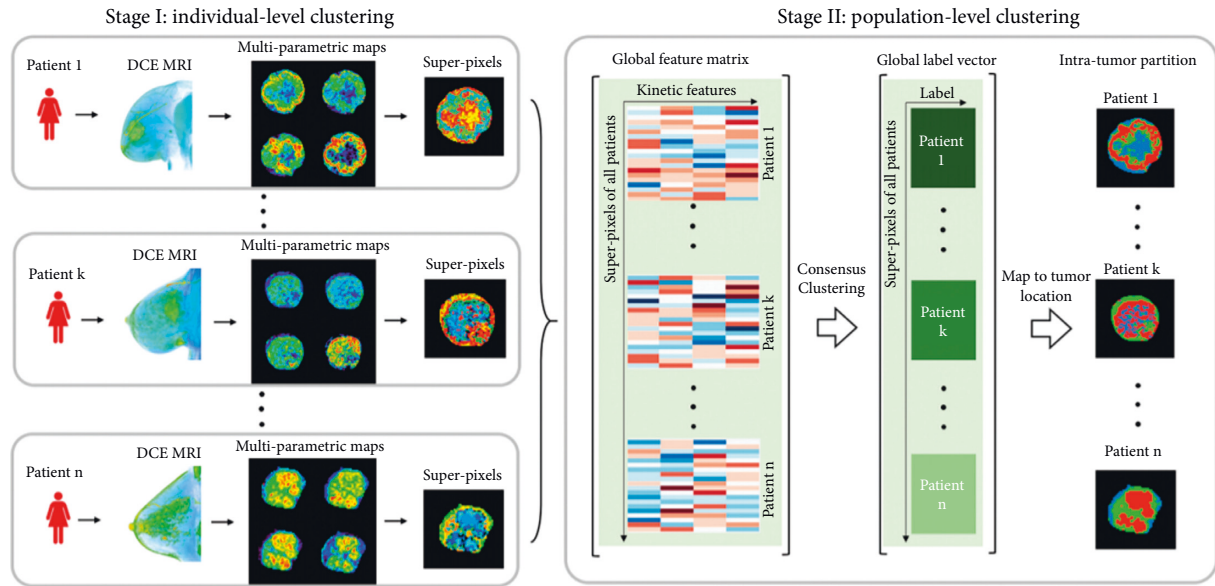

FIGURE 2: Introduction of the Two-Stage Intratumoral Partition Framework, that is, stage I: individual level cluster; and stage II: population level cluster, showing the use of matrix originating from intratumor partition diagrams. Quantitative imaging characteristic were obtained from MSI matrix for the sake of the measurement towards the spatial heterogeneity in tumors [51].

3.3. Tumor Treatment and Prognosis Research Based on Multiomics Approaches. Apart from the mentioned analysis of imaging group features, some researchers have also attempted to establish a multiomics approach for tumor diagnosis and treatment by combining image features and molecular features. For example, it was found that imaging methods exhibited different prediction results for patients with different molecular subtypes of breast cancer. Specifically, HER2-positive breast cancer was found to have a higher accuracy rate for its NAC treatment, while human epidermal growth factor receptor 2 (HER2) and triple-negative breast cancer (TNBC) had a lower accuracy rate [60], since patients with HER2-NBC and TNBC types presented high heterogeneity. During the establishment of tumor diagnosis and treatment models, intrinsic molecular characteristics shall be combined (HER2, etc.) to increase prediction accuracy. Sutton et al. found in the study of predicting breast cancer molecular subtypes based on image features that the accuracy of the model was significantly improved after adding clinical data and pathological data, including age of patients, tumor volume, tumor pathological grade, and accumulation of lymph node [61].

It was revealed that imaged tumor features and patient symptoms could be complementary, and the combination of the two could improve the accuracy of the prediction model. Although researchers have made considerable efforts on tumor diagnosis and treatment based on the analysis of clinical and molecular pathology information and image characteristics, there are few results in the research of precision diagnosis and treatment models combining the two features, and the methods and technologies in this area shall be studied and resolved. Besides, repeatability and reproducibility are the two relatively major problems [62] regarding radiogenomics analysis. The former refers to the consistency of multiple measurements under the same

environment and experimental conditions, while the latter denotes that of grouped image features in different locations, imaging parameters, and experimental subjects. Solutions to these two problems, especially the latter, are the key to the radiogenomics diagnosis and treatment model, which requires the combination of theory and practice. Although some scholars have made exploratory attempts in this regard, such as the use of validation sets to analyze the consistency of radiogenomics [63], there are still few basic methods of radiogenomics, especially tumor heterogeneity analysis, radiogenomics study, and evaluation of the application of scientific methods and models in clinical tumor diagnosis and treatment.

Tumor heterogeneity poses challenges to the precise diagnosis and treatment of breast tumors. Its systematic analysis provides extensive information for the characterization of breast tumors, and effective application of this information is of great significance to improve the accuracy of breast cancer diagnosis and treatment. Fan et al. [48] explored the heterogeneity of tumors by analyzing the subclones with a mass of gene modifications and functional effects, which offered a deeper understanding of the method to identify the bioactivity of certain subclones with a radiogenomic analysis, and predicted the prognosis non-invasively and clinically.

Besides, a modelling framework was proposed by Fan et al. [48], as shown in Figure 3, where multiscale intratumor heterogeneity was modelled, and the radiogenomic analysis was carried out regarding 1310 patients suffering from breast cancer on 5 datasets of 3 data groups. This modelling framework consisted of three phases. Firstly (Phase 1), a nonsupervision deconvolution analysis on gene expression profiles was adopted to achieve genomic subclones, including prognostic genomic signatures; secondly (Phase 2), radiogenomic genomic characterization was established by

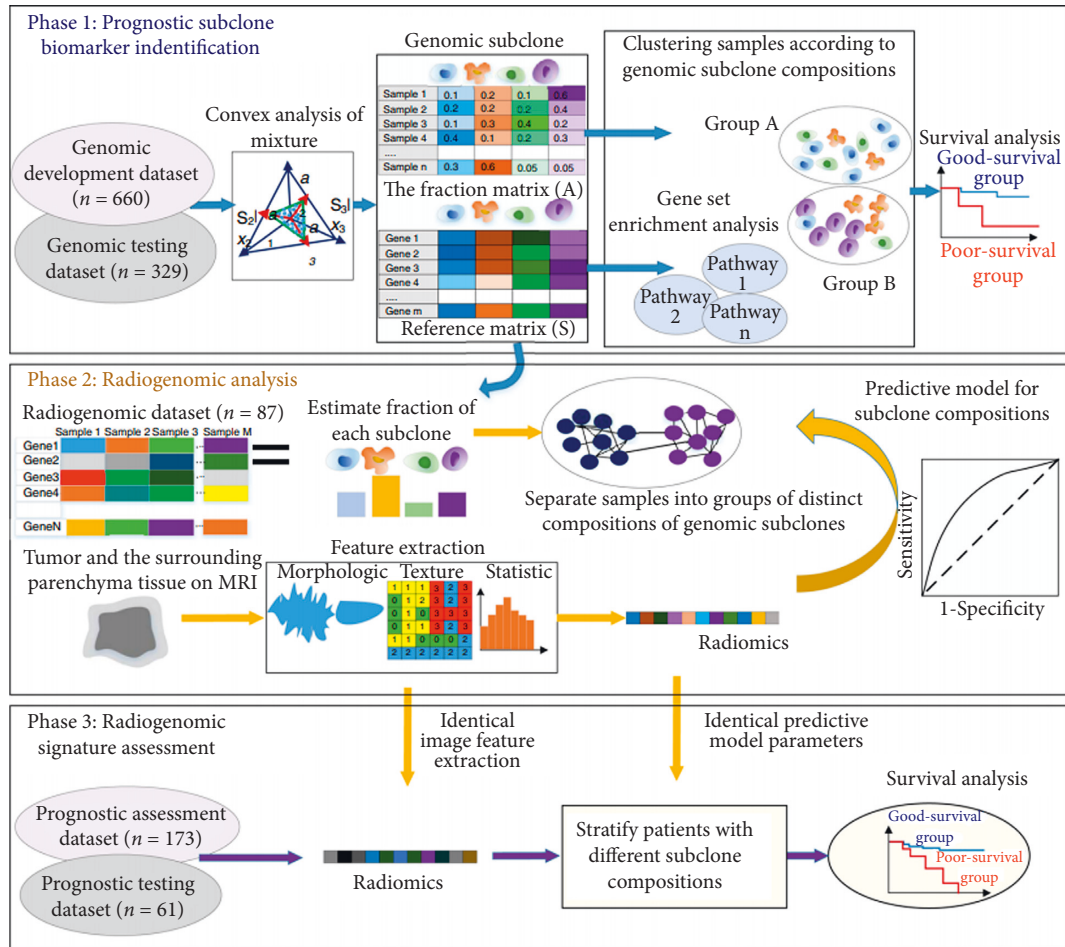

FIGURE 3: Framework of the Three-phase Study. Firstly (Phase 1), the nonsupervision deconvolution analysis on gene expression profiles is conducted to recognize prognostic subclone biomarkers. The gene set enrichment analysis is conducted to infer the biological functions of subclones; secondly (Phase 2), radiomic features onto compositions of prognostic subclones are mapped to establish radiogenomic signatures; thirdly (Phase 3), radiogenomic signatures are evaluated on another two independent datasets containing imaging and survival outcomes data [48].

means of mapping radiomic features onto compositions of prognostic subclones in an independent dataset containing the suited imaging and gene expression data from each tumor; thirdly (Phase 3), the predicated value of the recognized radiogenomic signatures was further investigated using another two independent datasets containing imaging and survival data. The findings provided a noninvasive and reproducible method to be used to identify tumor genomic subclones and their underlying biological clinical functions.

Table 1 is designed to intuitively classify and introduce the mentioned radiogenomics techniques and approaches in literature for diagnosis, treatment, and prognosis research.

4. Outlook and Future Work

Based on the radiogenomics techniques, this section aims to develop novel multidimensional mining algorithms, focusing on the key core issue of tumor heterogeneity. The proposed algorithms will lead to the identification of tumor patterns in complex geometric spaces. Through the analysis of multimodal images and molecular information reflecting

different functional characteristics of tumors, we aim (1) to deeply mine the spatial, temporal, and semantic features of breast multidimensional images across scales; (2) to reveal the relationship between the overall and regional imaging phenotypes of tumors and recognize their joint functional characteristics with gene expression together with molecular typing; (3) to provide new intelligent solutions for breast tumor clinical diagnosis and neoadjuvant chemotherapy efficacy prediction, which can effectively assist doctors to make correct treatment decisions and improve patients' health.

4.1. Temporal-Spatial Consistent Correlation Model Based on MRI Radiogenomics. According to different description methods for tumor heterogeneity, the analysis on tumor radiogenomic correlation is to be carried out at three levels, that is, analysis of the whole tumor region, tumor subregions, and tumor subcomponents; regarding a single time point; and longitudinal time axis. Different levels of tumor heterogeneity can be mapped using geometry algebraic

decomposition in relation to the multidimensional image space, image subspaces in different directions corresponding to the same dimensional image vector, and the cross-dimensional image signal vector features in different directions.

It is a crucial basis for accurate analysis of radiogenomics to realize the rapid and automatic parameter extraction of unstructured breast radiomics data and the effective fusion of unstructured feature vectors with diagnostic value found in structured data.

Based on the theory of geometric algebra, tumor images with different structures are transformed from complex geometric objects to straightforward geometries like dots, lines, and polygons that can be directly expressed in Euclidean space, so as to realize the hierarchical decomposition of the complex geometric data of breast tumors. Appropriate image segmentation and deep clustering methods should be adopted to analyze multiple geometric vectors in different dimensions. The final aim is to achieve deep learning and feature extraction of tumor heterogeneity based on multidimensional uniformity analysis in a multivector space and achieve the transition from unstructured imaging to structured genomics data.

As discussed in [64], it is easy to extend a scalar product to Clifford or geometric product to explain errors caused by patient movement, extract nonlinear features from images, or clarify observed scaling changes across the dimensions of a tumor, as illustrated in Figure 4.

4.2. Deep Association Learning between MRI Radiomics and Genomics. There are three parts proposed below for further realization of the deep association learning between MRI radiomics and genomics, as illustrated in Figure 5.

4.2.1. Global Heterogeneity Analysis via the Correlation between Image and Molecular Features. Weak supervision can facilitate the acquisition of the datasets marked manually. Weak supervision learning enables the application of inexpensive weak labels, and such labels can be exploited to build a powerful prediction model. The overall heterogeneity

FIGURE 4: Geometric neuron based on McCulloch-Pitts neuron for MRI Imaging Datasets based on General Framework mentioned in References [64, 69] where sp presents a scalar product; $\{\sigma_i\}$, $i = 1, 2, \dots, n$ orthonormal basis vectors; and gp, geometric product.

of tumors can be measured, analyzed, and classified using weakly supervised learning [66–69] of imaged tumors. Weakly supervised spatial clustering can be used to sort the decomposed subregions according to the value of the cluster center position.

Taking DCE-MRI as an example, the clustering results of the initial enhancement speed and the later decline speed of the enhancement curve can be sorted out to obtain several (i) “omics” features, and this process for all tumor images (j) can be sorted out to obtain an $i \times j$ matrix, so that feature calculation and classification research can be performed on the same time signal dimension.

Meanwhile, in view of the characteristics of biomedical functions reflected in tumor images, it is proposed to study the correlation based on multimodal (parametric) image features and molecular analysis features. In order to comprehensively analyze the heterogeneity of different functional characteristics of tumors, image registration [70–73] is performed for calculating different functional images of tumors, including DCE-MRI and DWI, to obtain multiple “dimensions,” which means that each pixel point corresponds to dynamic characteristics, diffusion characteristics,

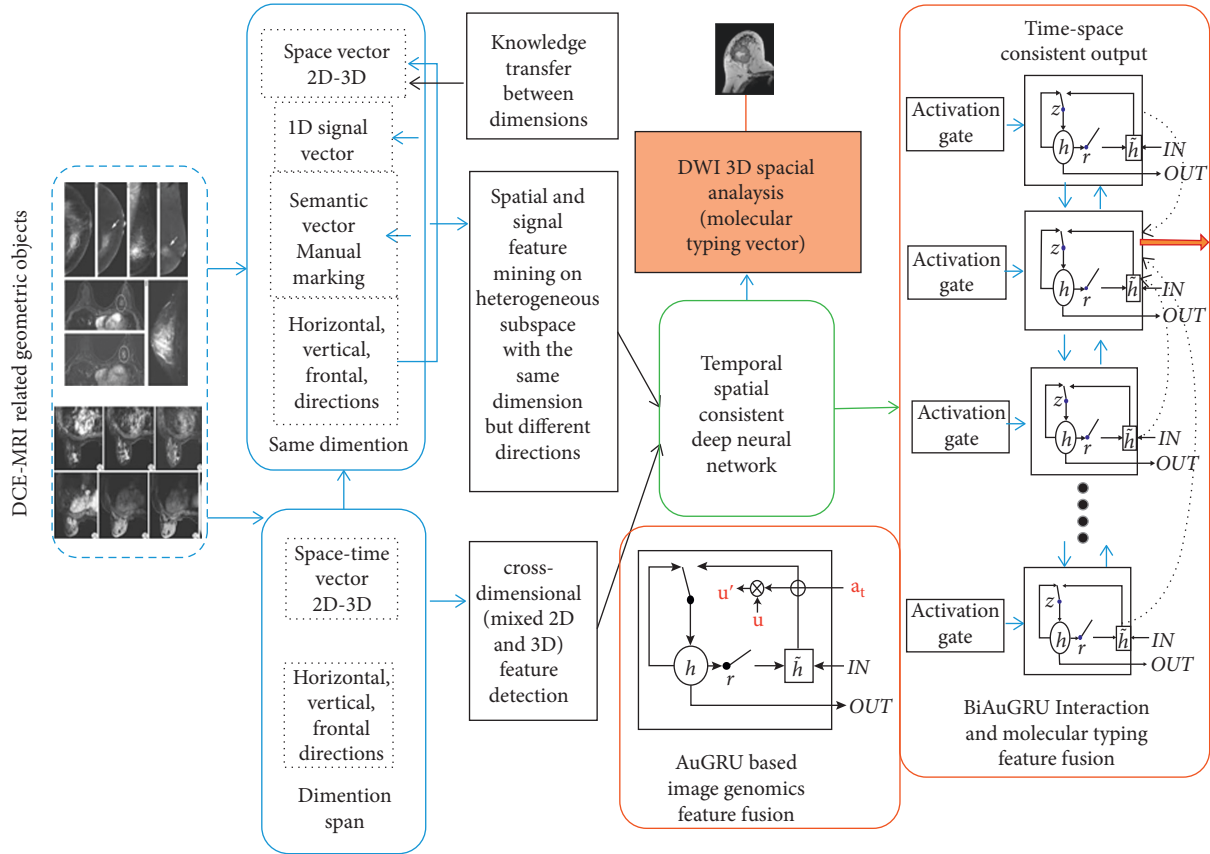

FIGURE 5: Framework regarding the association of MRI group and genome based on the analysis of spatial-temporal consistency.

etc. Such characteristic can be further used to calculate high-dimensional characteristics of imaged tumor heterogeneity and their correlation with molecular fractal characteristics.

4.2.2. Correlation between Heterogeneous Image and Molecular Features via Subdomain Decomposition. To fully analyze the correlation between heterogeneous image features and molecular features, the mixed images and gene molecular expression signals are suggested to be decomposed separately. This practice is to realize high- and multidimensional vector analysis in an integral space, also the multidimensional subspace region analysis, and spatial-temporal consistency analysis of heterogeneous subcomponents. The goal is to establish correlation models at different levels and achieve more accurate relationship to highlight key entities for the image or signal processes and the relationship between multiple entities (spatial-temporal) in multidimensional vector space or subspace.

Simultaneously, the gene expression data can be analyzed using subpathways, submodules, and enrichment methods, thereby dividing them into several representative pathways, marked modules, and gene clusters. The expression signal is expected to break down according to different tissue and cell characteristics using the signal decomposition method, which will in turn constitute a “convex hull,” each containing some “marked” genes [74].

In order to study the correlation between characteristic components in terms of different tissues, the correlation

between the subregions (components) of the tumor heterogeneity should be analyzed and sorted by the spatial-temporal consistency-based algorithm after the decomposition of the image group and gene expression data, as shown in Figure 5. Taking the dynamic enhanced image as an example, it is supposed that there are three subcomponents with different tissue features sorted into three levels according to the enhancement curve of each subcomponent after decomposition, that is, fast blood flow, medium blood flow, and slow flow velocity.

Each sample is decomposed into these three types of subcomponents, and then the radiogenomic association of each subcomponent (fast, medium, and slow) is analyzed separately for all samples. Unlike traditional analysis methods, the attention-based deep learning network aims to study and analyze the correspondence between high-dimensional image vectors and gene expression subcomponents and try to obtain more accurate map of relationships based on the relationship between “pure” subcomponents with the directions of themselves.

4.2.3. Bidirectional Threshold Recurrent Neural Network (BiGRU-RNN) Model. The effective embedding of radiomics and genomics information plays a key role in establishing spatial-temporal consistent model of radiogenomics. The genomics information of breast multi-dimensional dynamic imaging is intricate, including image sequence information, and time series information, both unstructured

FIGURE 6: BiGRU-RNN network model based on attention. Symbols $\{w_1, \dots, w_n\}$ are input parameters in relation to MRI radiomics, and the output vectors $\{u_w\}$ and $\{u_{at}\}$ regard the hidden layer vector $\{h_1, \dots, h_n\}$ and the radiomics feature vector V_{at} through the multilayer perceptual network. Similarity matrix δ contains the similarities between the genomics vector u_g and output attention weight vector ψ : namely, the ultimate output of radiogenomics eigenvector is achieved in accordance with the concealed layer vector $\{h_1, \dots, h_n\}$ and AuGRU weight vector δ . Radiogenomic feature fusion is conducted as an AuGRU cell.

data of magnetic resonance imaging and structured vector of genomics. The design of gated loop unit with memory mechanism is important not only for timing information, but also for the memory and integration of image and genomics information.

Therefore, the two-way activation embedding method of the gated cyclic unit is designed based on the lightweight BiGRU, and the activation gate is introduced to process the genomics data of breast cancer patients with individual differences. The AuGRU model enables effective fusion of the genome sequence-related output and tumor heterogeneity analysis via radiogenomics, along with molecular typing for classification.

Additionally, it is of importance to design a bidirectional threshold recurrent neural network (BiGRU-RNN) model based on memory and attention mechanism, which highlights tissue-level radiomics feature input and molecular typing feature vector and encodes the contextual interaction mechanism of the genomics feature vector of tumor. Such a model plays a key role in carrying out the effective correlation of the spatiotemporal features of dynamic images and constructing a joint representation model of image data and genomics data. The schematic diagram summarizing the proposed attention-based BiGRU-RNN network model is shown in Figure 6.

5. Discussion

Radiogenomics characteristics reveal multiscale intratumoral heterogeneity concerning biological functions and survival in breast cancer. These studies performed diagnosis and treatment analysis by measuring the characteristics of overall tumor heterogeneity. For example, the research group of Huang et al. used 132 texture features of CT images to forecast the Disease-Free Survival (DFS) of non-small cell lung cancer (NSCLC) [49], and Goh et al. used fractal dimension features to diagnose and analyze colorectal cancer

[75]. However, the heterogeneity features extracted by these methods are basically a measure of the degree of overall tumor heterogeneity (inhomogeneity) based on the gray-scale of tumor images, which fails to reflect the basic facts that heterogeneous tumors are composed of tissues with different characteristics. Biomedical analysis of tumors shows that different spatial regions may exhibit changed physiological characteristics [76], leading to specific regions corresponding to different cancer treatment responses, molecular subtypes [77], etc. In order to analyze the heterogeneity of subfunction regions, Diehn et al. selected two regions with high dynamic enhancement rate and low enhancement rate in DCE-MRIs in gliomas. The hypoxia gene expression values of these two tissue regions also showed corresponding high expression values and low expression values; that is, the tumor heterogeneous expression regions are significantly related to imaging characteristics [78]. The first international study explored the correlation between tumor imaging regional features and molecular features. However, the study only detected the heterogeneity between different tumor regions through imaging methods but failed to achieve precise positioning and quantitatively describe the distribution and characteristics of the heterogeneous regions.

In order to accurately locate and describe the imaging heterogeneity of tumor subregions, researchers around the world have made some preliminary attempts to describe the heterogeneity of different tissue characteristics using different imaging modalities [63, 77, 79]. Tumor heterogeneity analysis must first define “content” from the perspective of the image and assign different “attribute” at each voxel to tissue characteristics in the image. For instance, DCE-MRIs measure the status of tumor blood flow and blood vessels; diffusion-weighted images reflect the diffusion and permeability of tumor water molecules; perfusion images measure tumor vascular proliferation, etc. [80] In this way, different tumor tissue characteristics and pathological

characteristics can be reflected through a variety of imaging techniques from different perspectives. Taking DCE-MRI as an example, it is reported that DCE-MRIs can be divided into several different representative feature regions according to a certain threshold, and texture features are calculated in these regions to measure the heterogeneity degree of these regions [77, 81, 82]. An increasing number of sophisticated methods cluster similar dynamic enhancement patterns [13, 83, 84] and describe the heterogeneity of vascular characteristics in tumor spaces through DCE-MRIs. But technically, the current stage of tumor heterogeneity analysis is still in its infancy.

As mentioned previously, malignant tumor has become one of the most common diseases harmful to human health, whose precise diagnosis and treatment are studied internationally, but remains unsettled. This paper focused on the precise diagnosis and prognosis prediction of neoadjuvant chemotherapy for cancer disease. Centering the tumor heterogeneity, this paper investigated radiogenomic methods for tumor heterogeneity analysis based on machine learning and explored the relationship between the imaging characteristics and molecular expression characteristics of heterogeneous tumors. A multidimensional MRI radiogenomics data analysis framework was designed based on geometric algebraic representation model to comprehensively explore the rich spatial images, spatial signals, and semantic features in multidimensional multimode MRIs. Besides, a spatial-temporal representation model was designed by focusing on both local and the global feature spaces in different hierarchy, and diversified self-attention mechanisms were implemented. Regarding the heterogeneity of different tumors, this paper proposed an individualized radiogenomic model combining the information about tumor imaging, molecular classification, and tumor clinical treatment for predicting the curative effect of neoadjuvant chemotherapy. It provides scientific guidance for accurate diagnosis, treatment, and prognosis of breast tumor patients, for the purpose of improving the cure rate of the patients with tumor, enhancing the well-being of patients after surgery, and using medical resources effectively and reasonably.

6. Conclusions

Tumor heterogeneity is a determinant playing a key role in therapeutic effect and is scarcely known from the perspective of molecular [85]. This paper aims to review the leading research on MRI radiogenomics methods based on the research frontiers in the fields of artificial intelligence and machine learning and focuses on the key core issue of tumor heterogeneity. By analyzing multimodal MR images and molecular information, it is expected to afford methods that can reflect the different functional heterogeneities of tumors. This paper provides a new framework related to temporal-spatial consistent correlation model based on MRI radiogenomics and offers novel intelligent solutions for tumor clinical diagnosis and curative effect prediction in aspects of neoadjuvant chemotherapy, aiming to effectively assist doctors in making correct treatment decisions and improve

patients' survival rate and well-being. Two contributions are represented in this paper: (1) an in-depth exploration is conducted for the cross-scale spatial, temporal, and semantic features of multidimensional MR images to be analyzed to reveal the spatial and temporal heterogeneity of tumors with geometric algebra onto radiogenomic methods and achieve correlation analysis from the local functional area to the global semantic space; (2) a novel bidirectional Gated Recurrent Unit (GRU) recurrent neural network (BiGRU-RNN) model is proposed to establish a multidimensional consistent deep learning of tumor heterogeneity with integrating MR imaging parameters and gene expression and predict the curative effect of tumor neoadjuvant chemotherapy.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Under the current big data background, the training mode of radio and television director technology is obsolete, and the technical means do not meet the needs of modern development. In this article, a self-adaptive multivariate data statistical model of radio and television directors based on the least squares support vector machine is proposed, which combines the students' views with the diversified teaching methods and teaching contents needed by university teachers in the process of vocational education and television education. This article applies the technology integration degree measurement, market integration degree measurement, business integration degree measurement, and integration degree comprehensive analysis to analyze the data of major video websites and major radio and television media. It is found that the market share of major radio and television media is increasing, and the number of broadcasts of major video online stores is also excellent.

1. Introduction

According to China's demand for talents in radio and television industry and the status of education professionals, the director of experimental teaching of radio and television specialty should actively introduce the advanced teaching concept of postmodernism; evaluate and innovate from the aspects of experimental teaching mode, process, method, and behavior; build an experimental teaching system with the characteristics of postmodern teaching theory; and cultivate the innovative spirit and practical ability of radio and television art complex [1]. With the continuous development of new media technology, the market demand for employment is gradually increasing, but the market competition is becoming increasingly fierce. The development of radio and television specialty in China needs more radio and television professionals, and the requirements for talents' skills and quality are also improved. With the rapid development of new media, the demand for applied talents of radio and television director specialty is gradually increasing [2]. A new discrete particle swarm optimization method is

proposed to induce rules from discrete data. The proposed algorithm initializes the population by considering the discrete nature of the data. It assigns different fixed probabilities to the current, local, and global optimal positions. Based on these probabilities, each member of the population iteratively updates its position [3]. The explicit model-based approach to phylogenetic analysis of discrete morphological data opens up several new research approaches, including combined data likelihood analysis (morphological + sequential data), likelihood ratio test, and Bayesian analysis [4]. Linear hybrid models have become the main parameterization tool for analyzing continuous longitudinal data. This article shows how to implement different methods in the SAS software package [5]. Data interpolation is created under two models: multivariate normal model with rounding and discrete model with conditional designation. JM method introduces deviation in reference curve, while FCS does not. This article concludes that FCS is a useful and easy-to-apply flexible alternative to JM [6] when convenient and realistic joint distribution cannot be specified. Cha-meleon algorithm technology focuses on finding clusters in

datasets and detailed information of its main functions, dynamic modeling information of chameleon and comparison between interconnectivity and similarity (limitations of traditional clustering algorithms) [7]. This article evaluates the changing role of dynamic modeling in understanding and discrete dynamic modeling of diversified adaptive data for broadcast and television directors. It discusses new modeling tools for problem scoping and consensus building among a wide range of stakeholders and describes four case studies where dynamic modeling has been used to collect and organize data, synthesize knowledge, and build consensus on the management of complex systems [8]. Two methods to solve the problem of dynamic allocation and route guidance are studied: first, the optimal control method to realize the optimization of a dynamic system or user; second, to establish the feedback concept of dynamic user optimal conditions [9]. Landscape and physical environment shape migration schedules and affect people's ability to interpret patterns observed during stop-overs. Modeling these factors may lead to new insights into migration adaptation in heterogeneous environments [10]. Scale dependence and spatiotemporal dynamics are the two issues that underpin the considerable attention that modelers and statisticians now devote to the quantitative study of ecological edges and boundaries. We introduced the links between methods for demarcating boundaries, monitoring boundary changes, and modeling edge-related dynamics. In this process, we clarify the statistical and mathematical methods of ecological edge and boundary research and discuss the important remaining problems in the field of quantitative edge research [11]. In order to adapt to the gradual diversified development, a diversified training mode for graduate students has been formed. At the same time, in order to meet the needs of people's learning and creation in modern society, graduate education presents an international, diversified, modern, and personalized development trend [12]. Their most influential discrete imaging (DT) uses nanoscale technology to generate a large amount of data. Data footprint production (DFR) is a process that uses almost all of given ETF data at a shorter storage speed. His very advanced lossless compressor or classical probability model is very suitable for final application requirements, such as "arbitrary depth" (ABD) solutions and "dynamic data scale, exploring data-related information" [13]. The moving window detection process of discrete data is studied. The probability of detection waiting time and the limit of expected value are derived. The boundary is evaluated for independent and identically distributed zero-Bernoulli test, binomial and Poisson random variables, and two-state stationary Markov chain. The results are applicable to radar detection theory, time-sharing system, and quality control [14]. For goals and training programs, by constructing a scientific curriculum system, establishing characteristic curriculum relations, expanding diversified teaching forms, strengthening innovative practical teaching concepts, and developing digital laboratories and other measures, we can train talents, explore Sino-foreign cooperative training methods suitable for the development of China's digital media design industry, and improve the quality and level of

digital media design talents training [15]. The development of big data technology has brought new opportunities and challenges to the development of various industries. The radio and television director industry has been widely favored by the broad masses of the people, and its development is directly related to everyone's daily life. People's daily life can no longer be separated from big data technology, whether it is the TV we watch every day or a mobile phone. They all use the technical support of big data, better demonstrate the skills developed in the data age, and show stronger conditions for the progress and formation of the data age. Therefore, in the current development of education, we must master the technical support of big data, expand the content and form of TV director better, help the content of TV education show more power, and lay a solid foundation for improving the quality of TV director content. In order to better cope with the impact and challenges of the big data era and the relevant requirements for talents in the era of big data, colleges and universities need to implement diversified training modes, cultivate high-skilled and high-quality talents, and provide college students with due guarantee in the ability to use big data technology and the ability to use and build big data technology. It can show the creativity of talents in TV choreography and the significance of TV choreography more deeply, and optimize, improve, and systematically train the existing talent training system, so as to provide talent support for the development of radio and TV choreography industry. Based on this, this article introduces the diversified literacy requirements of radio and television directors in the era of big data and summarizes the diversified training strategies of radio and television directors in the era of big data, so as to better promote the development and technical requirements of TV directors in the era of big data and promote the further formation of talents.

2. The Strategy of Cultivating Diversified Applied Talents of Radio and Television Directors

2.1. Cultivating Students' Ability to Analyze and Control Big Data. In the era of big data, the most important thing is information. The available material found in several lines of information is ability. According to big data, it is skill to analyze the development trend of events. Using big data to guide public opinion to develop in the expected direction depends on skills.

If you want to create excellent radio and television programs, you can select useful information on the big data platform and then recombine the useful information. At present, the idea of many reality shows is to find out what the audience likes to watch through big data analysis and then summarize and extract useful information for innovative creation, which is the source of the embryonic form of reality shows.

It is necessary to cultivate students' ability of information prediction and early warning. In the era of big data, a large amount of information is released all the time. As a radio

and television-related worker, he must have the form of predicting the future development through this information. When some events are constantly fermenting, he should be aware of the seriousness of the situation in time, so as to make preventive plans in advance.

Finally, it is the ability to use big data to guide the trend of public opinion. Choreographers need to put forward their views in a timely manner, which should be novel and attract the attention of a broad audience, so as to make public opinion tilt towards the favorable side.

2.2. Curriculum Setting of Diversified Choreography Specialty.

The purpose of the curriculum is to increase the content of education. In addition to the original editorial guidance courses, students must broaden their horizons, edit art and news programs, and add data and information courses. Teachers should not only let students stay in the studio and broadcast live, but also go out, use big data to keep abreast of the latest developments, capture creative inspiration, and apply the latest technology and film and television processing technology to their programs. In order to help students learn how to analyze, acquire, edit, and transmit information to capture creative themes, data information courses can be added to break through the bottleneck of choreography and creation and become diversified talents.

2.3. Focusing on Cultivating Students' All-Media Thinking Mode.

With the popularization of the Internet and the development of information technology, the types and functions of broadcasting are constantly updated, and the program content is gradually diversified. The TV also adds images and text based on video data. In this context, the director talent training strategy should be further refined, focusing on cultivating students' all-media thinking, so that students can choose the most suitable media mode according to the content of radio and television programs and the characteristics of media audiences. At present, different forms of media are developing together. If radio and television students do not have all the media and energy to study professional knowledge, while ignoring literature, society, and nature, they are likely to limit your major and your own development.

2.4. Perfecting the Practical Teaching Function of Choreography Specialty.

First of all, we can join practical activities in the teaching process of choreography. Practice is the basic work of radio and television director, and it is the materials close to life that are more likely to resonate with the audience, so as to ensure attention and click-through rate. Second, schools can work with major media to provide students with more practical opportunities. After graduation, media work is no stranger to students, which effectively shortens the adjustment time. Schools and media organizations will benefit from this process. Students can help the media analyze and organize information. Schools can take the advantage of big data analysis and visual advantages to

gain more practical communication opportunities between schools. The media are more closely linked. In the past teaching activities, students majoring in choreography cannot finish news writing or program creation because they do not have practical materials. With the advent of the era of big data, students have realized their dream of seeing what is going on in the world without leaving home. Students can grasp the current audience's interest trend by analyzing research reports and news information and then summarizing these contents. After analysis and screening, they can provide themselves with complete director materials.

2.5. Cultivating Students' Ability to Interpret Radio and Television Programs.

Schools can improve students' ability to interact with big data. When cultivating choreographers' storytelling ability, they can use big data to analyze social current affairs, explore the information value behind big data, and use topics that can attract social attention to create big data and create inspiration for their own creative inspiration. At present, topics with high attention in society often come from people's daily life. Topic content with life as the theme and high statistical attention is likely to become radio and television content with less investment and high popularity. The cultivation of this ability is especially suitable for the current choreography major, and stories supported by big data analysis will be more convincing.

3. Improvement in Online Adaptive Least Squares Support Vector Machine Algorithm

3.1. Online Adaptive Least Squares Support-Oriented Computer Algorithm. Let the sample set be $T = \{(x_1, y_1), \dots, (x_l, y_l)\}$, where $x_i \in R^n$, $y_i \in R$, $i = 1, 2, \dots, l$ constructs the decision function $f(x) = w^T \Phi(x) + b$ and use the sample data to solve the objective function of minimizing structural risk, which is expressed as

$$\min_{w,b} \frac{1}{2} \|w\|^2 + c \sum_{i=1}^l \zeta_i^2, \quad (1)$$

$$y_i = w \cdot \Phi(x) + b + \xi_i, \quad i = 1, 2, \dots, l, \quad (2)$$

where $\Phi(x_i)$ is x_i nonlinear mapping, w and b are function parameters, c is a parameter, and ξ_i is a prediction error.

The above problem can be transformed into formula (3) by using the related Lagrange function:

$$L(w, b, \xi, a) = \frac{1}{2} \|w\|^2 + c \sum_{i=1}^l \xi_i^2 - \sum_{i=1}^l a_i (w \cdot \Phi(x) + b + \xi_i - y_i), \quad (3)$$

where $a = [a_1, a_2, \dots, a_l]$ is the Lagrange multiplier; $\xi = [\xi_1, \xi_2, \dots, \xi_l]$ is the training set prediction error vector. According to the optimization conditions, formula (4) can be obtained as

$$\frac{\partial L}{\partial w} = 0, \frac{\partial L}{\partial b} = 0, \frac{\partial L}{\partial \xi_i} = 0, \frac{\partial L}{\partial a_i} = 0. \quad (4)$$

Formula (5) can be solved as

$$\begin{cases} w = \sum_{i=1}^l a_i \Phi(x_i), \\ \sum_{i=1}^l a_i = 0, \\ 2c\xi_i = a_i. \end{cases} \quad (5)$$

Formula (6) can be obtained by substituting formula (5) into formula (2).

$$y_i = \sum_{j=1}^l (a_j \cdot \langle \Phi(x_i), \Phi(x_j) \rangle) + b + \frac{1}{2c} a_i. \quad (6)$$

If $K(x_i, x_j) = \langle \Phi(x_i), \Phi(x_j) \rangle$ is defined as a kernel function, formula (6) is transformed into a set of linear equations, which is expressed as

$$\begin{bmatrix} 0 & 1 & 1 & \cdots & 1 \\ 1 & K(x_1, x_1) + \frac{1}{2c} & K(x_1, x_2) & \cdots & K(x_1, x_l) \\ 1 & K(x_2, x_1) & K(x_2, x_2) + \frac{1}{2c} & \cdots & K(x_2, x_l) \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & K(x_l, x_1) & K(x_l, x_2) & \cdots & K(x_l, x_l) + \frac{1}{2c} \end{bmatrix} \cdot \begin{bmatrix} b \\ a_1 \\ a_2 \\ \vdots \\ a_l \end{bmatrix} = \begin{bmatrix} 0 \\ y_1 \\ y_2 \\ \vdots \\ y_l \end{bmatrix}. \quad (7)$$

To cause

$$H = \begin{bmatrix} K(x_1, x_1) + \frac{1}{2c} & K(x_1, x_2) & \cdots & K(x_1, x_l) \\ K(x_2, x_1) & K(x_2, x_2) + \frac{1}{2c} & \cdots & K(x_2, x_l) \\ \vdots & \vdots & \ddots & \vdots \\ K(x_l, x_1) & K(x_l, x_2) & \cdots & K(x_l, x_l) + \frac{1}{2c} \end{bmatrix},$$

$$y = [y_1, y_2, \dots, y_l]^T,$$

where $e = [1, \dots, 1]_{1 \times l}^T$; $a = [a_1, a_2, \dots, a_l]^T$.

Formula (8) can be derived as

$$\begin{cases} a = H^{-1}y - H^{-1}e \cdot \frac{e^T H^{-1}y}{e^T H^{-1}e}, \\ b = \frac{e^T H^{-1}y}{e^T H^{-1}e}. \end{cases} \quad (8)$$

To solve the decision function, formula (8) is substituted into formula (9), which is expressed as

$$f(x) = \sum_{j=1}^l a_j K(x, x_j) + b. \quad (10)$$

When the prediction of the model has a large deviation, it is updated online.

First, the sample point i closest to the current new sample $\{x_{new}, y_{new}\}$ is found in the original sample space, as in formula (10).

$$i = \arg \left(\min_{k=1, \dots, l} \|x_{new} - x_k\| \right). \quad (11)$$

Second, the row and column corresponding to the i sample in Matrix H are exchanged with the last row and column to obtain H_1 , as shown in formula (11).

$$H_1 = I_{Ri \leftrightarrow Rl} H I_{Li \leftrightarrow Ll}, \quad (12)$$

$$\text{where } H_1 = \begin{bmatrix} K(x_1, x_1) + 1/2c & \cdots & K(x_1, x_i) & \cdots & K(x_1, x_l) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ K(x_i, x_1) & \cdots & K(x_i, x_i) + 1/2c & \cdots & K(x_i, x_l) \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ K(x_l, x_1) & \cdots & K(x_l, x_i) & \cdots & K(x_l, x_l) + 1/2c \end{bmatrix};$$

$I_{Ri \leftrightarrow Rl}$ and $I_{Li \leftrightarrow Ll}$ represent row i and l interchange and column i and l interchange of identity matrix, respectively.

$$I_{Ri \leftrightarrow Rl} = I_{Li \leftrightarrow Ll} = I_{Ri \leftrightarrow Rl}^{-1} = I_{Li \leftrightarrow Ll}^{-1}.$$

To cause

$$H_1 = \begin{bmatrix} G & g_1 \\ g_1^T & k_1 \end{bmatrix},$$

$$k_i = K(x_i, x_i) + \frac{1}{2c},$$

$$g_i = [K(x_1, x_i), \dots, K(x_{i-1}, x_i), K(x_l, x_i), K(x_{i+1}, x_i), \dots, K(x_{l-1}, x_i)]^T.$$

Because $A^{-1} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}^{-1} = \begin{bmatrix} A_{11}^{-1} + A_{11}^{-1}A_{12}B^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}B^{-1} \\ -B^{-1}A_{21}A_{11}^{-1} & B^{-1} \end{bmatrix}$,
of which $B^{-1} = A_{22} - A_{21}A_{11}^{-1}A_{12}$, so

$$H_1^{-1} = \begin{bmatrix} G & g_i \\ g_i^T & k_i \end{bmatrix}^{-1} = \begin{bmatrix} G^{-1} + G^{-1}g_i r_i^{-1} g_i^T G^{-1} & -G^{-1}g_i r_i^{-1} \\ -r_i^{-1} g_i^T G^{-1} & r_i^{-1} \end{bmatrix}$$

$$= \begin{bmatrix} G^{-1} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} G^{-1}g_i r_i^{-1} g_i^T G^{-1} & -G^{-1}g_i r_i^{-1} \\ -r_i^{-1} g_i^T G^{-1} & r_i^{-1} \end{bmatrix},$$

(14)

where $r_i = k_i g_i^T G^{-1} g_i$.

At the same time, we might as well make:

$$H_1^{-1} = \begin{bmatrix} G^{-1} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} \tilde{h}_{11} & \tilde{h}_{12} \\ \tilde{h}_{21} & \tilde{h}_{22} \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix},$$

where $\tilde{h}_{11} = G^{-1}g_i r_i^T G^{-1}$; $\tilde{h}_{12} = -G^{-1}g_i r_i^T$; $\tilde{h}_{21} = -r_i^{-1} g_i^T G^{-1}$; $\tilde{h}_{22} = r_i^{-1}$; $G^{-1} = h_{11} - \tilde{h}_{11} = h_{11} - h_{12} h_{22}^{-1} h_{21}$.

Therefore, G^{-1} can avoid direct inversion of matrix.

The parameters related to the new sample are calculated to replace the original wrong data.

$$g_{\text{new}} = [K(x_1, x_{\text{new}}), \dots, K(x_{l-1}, x_{\text{new}}), K(x_l, x_{\text{new}}), K(x_{i+1}, x_{\text{new}}), \dots, K(x_{l-1}, x_{\text{new}})]^T,$$

$$k_{\text{new}} = K(x_{\text{new}}, x_{\text{new}}) + \frac{1}{2c},$$

$$r_{\text{new}} = k_{\text{new}} - g_{\text{new}}^T G^{-1} g_{\text{new}},$$

$$\text{So: } H_2^{-1} = \begin{bmatrix} G^{-1} + G^{-1}g_{\text{new}} r_{\text{new}}^{-1} G^{-1} & -G^{-1}g_{\text{new}} r_{\text{new}}^{-1} \\ -r_{\text{new}}^{-1} g_{\text{new}}^T G^{-1} & r_{\text{new}}^{-1} \end{bmatrix}.$$

Finally, the updated decision function coefficient can be obtained from the following equation:

$$\begin{cases} \hat{a} = H_2^{-1} \hat{y} - H_2^{-1} e \cdot \frac{e^T H_2^{-1} \hat{y}}{e^T H_2^{-1} e}, \\ \hat{b} = \frac{e^T H_2^{-1} \hat{y}}{e^T H_2^{-1} e}, \end{cases} \quad (17)$$

where $\hat{y} = [y_1, \dots, y_{i-1}, y_l, y_{i+1}, y_{\text{new}}]^T$.

4. Fusion Degree Measurement

4.1. Measurement of Technology Integration Degree

- (1) This article collates the investment scale of the central nervous system and broadband fees from 2012 to 2016 of four major video websites and four major radio and television media (Table 1)

In order to better reflect the classification of advertising revenue, the classification data of major video websites and major radio and television media are sorted out (Table 2)

- (2) Sample unit HI value calculation (Table 3)

- (3) Evaluation of fusion degree

From Table 4, the HI values of CND and broadband fee investment scale of major video websites and major radio and television media from 2012 to 2016 are substituted into different integration degree interval values. It can be seen that the technology integration degree of major video websites and major radio and television media is generally low, among which, in 2012, 2013, 2015, and 2016, it was in a low-to-medium integration state, and in 2014, it was relatively good and in a moderate integration state.

According to the HI value of CND and broadband fee investment scale of major video websites and major radio and television media in each year, the change chart of CND and broadband fee investment HI value from 2012 to 2016 is drawn, as shown in Figure 1.

4.2. Measurement of Market Integration Degree

4.2.1. Collation of Sample Unit Data. According to the statistics of State Administration of Press, Publication, Radio, Film and Television in 2016, this article collates the

TABLE 1: Investment scale of CND and broadband fees of major video websites and major radio and television media.

Unit	CND and broadband fee investment scale (10,000 yuan)

substituted into different integration degree interval values, respectively, and it can be seen that the market integration degree of major video websites and major radio and television media is in a low integration state (Table 8).

According to the HI value of advertising revenue of major video websites and major radio and television media in each year, the change chart of advertising revenue HI value from 2012 to 2016 is drawn, as shown in Figure 2.

4.3. *Measurement of Service Convergence Degree.* Collation of sample unit data. From 2012 to 2016, the PC page playback, PC client playback, mobile page playback, and mobile client playback are given in Tables 9–12, respectively.

According to Tables 9–12, we calculate the average number of times that Heyi group, Tencent video, Sohu video, and Iqiyi play on PC page side, PC client side, mobile page side, and mobile client side, and then draw a histogram as shown in Figure 3.

In order to better observe and judge the abovementioned major video websites and major radio and television media from 2012 to 2016, the overall classification of playing platforms such as PC page side, PC client side, mobile page side, and mobile client side, the overall development trend and development stage of major video websites and major radio and television media in terms of business integration degree are calculated. Figure 3 shows the video development of four different platforms in different years. Mobile clients have developed rapidly, and in 2016, mobile clients are

Major radio and television media	38.58	62.09	97.27	103.16	753.50

almost the sum of other platforms. On the whole, the development of PC as a media is slow, and the basic processing stops. According to the relevant data calculated in Tables 9–12 above, this article analyzes and summarizes the classified data of major video websites and major radio and television media (Tables 13–16).

According to Tables 13–16, we calculate the average number of times played by major video websites and major radio and television media on PC page side, PC client side, mobile page side, and mobile client side, and then draw a histogram as shown in Figure 4.

Sample unit HI value calculation: according to the calculation model of Herfindahl index method, the HI values of PC page playback, PC client playback, mobile page playback, and mobile client playback of major video websites

and major radio and television media from 2012 to 2016 are calculated, as given in Tables 17–20.

According to Tables 17–20, we calculate the average HI values of the playing times of major video websites and major radio and television media on PC page side, PC client side, mobile page side, and mobile client side, and then draw a histogram as shown in Figure 5.

Evaluation of fusion degree: according to Tables 17–20, the playback frequency of major video websites and major radio and television media on PC page side, PC client side, mobile page side, and mobile client side was in a low convergence range from 2012 to 2016, and only in 2016, the playback frequency on PC page side showed moderate convergence, among which major video websites were superior to major radio and television media as a whole.

Major radio and television media	-	3.34	20.66	134.16	516.09

FIGURE 4: Comparison of average playback times from 2012 to 2016.

The smaller the HI value, the higher the degree of industrial integration, and the greater the HI value, the lower the degree of integration. Through comparative analysis in Table 21, the overall integration of radio and television media and new media is low. Among them, the performance of technology integration, market integration, and business integration of radio and television media lags far behind the new media industry. The new media based on the Internet undoubtedly has great communication power, influence, and mobilization power and has been in a comprehensive leading state in technology, market, and business, occupying the strategic highland of various media. Compared with the

telecommunications industry, the radio and television media as a whole are dwarfed.

Generally speaking, the media integration of radio and television industry is divided into three levels. First, the initial integration, that is, the programs are uploaded to the network platform and transformed into terminals suitable for mobile phones, desktops, and tablet computers by means of disassembly, packaging, and reorganization, so as to adapt to network communication. The second is moderate integration, that is, in news collection and editing, news materials are collected through handheld terminals, desktops, and radio and television channels, and news events are

broadcasted by editors on new media platforms and then made into audio and video programs for broadcasting on radio and television stations. This way can realize the linkage

transmission mechanism of the same news content in different carriers such as radio and television, WeChat Weibo, network, car and outdoor TV, newspapers, and periodicals. Third, deep integration, through cooperation with professional video websites and portal websites, expands the transmission path of radio and television through advantageous network platforms, so as to increase the penetration rate and influence of radio and television programs. At present, although the vast majority of radio and television stations above the prefecture level have set up video and audio websites, and some have set up Weibo accounts, WeChat official account, and developed boutique program applications and clients, they are still in the initial and moderate integration stage as a whole. As the market continues to mature and become more perfect, social capital will become more important and the competition between industries will intensify further, especially with the diversification of TV audience program signal receiving methods. With the increase in traditional media and the emerging audio and media integration services, users' consumption habits change gradually, and cable TV users turn to IPTV, OTT, video websites, and other new media. The market share of cable TV is declining day by day, and the

Major radio and television media	46.43	76.34	141.67	263.83	1,442.52

competitive pressure of radio and television industry will be increasing.

4.3.1. Degree of Technology Integration. On the one hand, we can see that the degree of technology integration is better than the degree of market integration and business integration as a whole, and the overall performance is getting better from 2012 to 2016, which reflects the efforts made by radio and television media in technology integration to a certain extent. For example, CCTV is committed to China's video cloud service platform; integrates CCTV news, mobile TV platform, and CCTV audio-visual and other new media platforms; promotes the preinstallation of CCTV audio-visual and news clients and China Mobile cooperative models; establishes collaborative linkage between different receiving terminal platforms; and distributes content to desktop computers, tablet computers, mobile phones, televisions, outdoor large screens, and other terminals. China National Radio connects the car network and the mobile Internet market by building a China broadcasting cloud platform. From the analysis of the proportion of major video websites and major radio and television media (CND and broadband fee investment in advertising revenue in Table 22), it can be seen that major radio and television media still attach great importance to the investment in technology, and the related investment in 2014 and 2016 even exceeded the total advertising revenue of that year. From 2012 to 2016, CCTV, China National Radio, China Radio International, and Hunan Radio and Television have invested a total of 2.899 billion yuan in CND and broadband. The four major video websites have invested a total of 14.4 billion yuan in

CND and broadband, with a difference of 4.97 times. Among them, the investment of any of the four major video websites in CND and broadband far exceeds the total investment of the four major radio and television media. The capital strength of new media and the high investment in technology integration can be seen. Generally speaking, some radio and television organizations have not paid enough attention to the subversive impact brought by media convergence, and still muddle along in the hotbed of vested interests of radio and television; and some simply transplant traditional radio and television programs to websites and new media platforms, but do not interpret the programs as the suitable broadcasting form and customer acceptance habit paradigm for the Internet, especially the mobile Internet.

4.3.2. Degree of Market Integration. Advertising revenue is a barometer of the media market. In the new media market, four major video websites have occupied a dominant position, among which the advertising revenue in 2016 was 15.5 billion yuan, accounting for 41% of the national related advertising revenue of 37.5 billion yuan. On the other hand, the related advertising revenue of the four major radio and television media in 2016 was 1.25 billion yuan, accounting for only 3.33% of the national related advertising revenue. It is precisely because of the versatility of assets brought about by technological progress and media convergence that once news and other audio and video programs are produced, due to the noncompetitive sharing and weak increase in reproduction costs, the production cost is saved, and due to the pressure of external competition, the price competition is

obvious. Compared with the business packages of telecommunication departments that provide three-in-one services of TV, telephone, and Internet, the price competitive disadvantage of radio and television media is self-evident and directly affects the share of advertising revenue. Generally speaking, affected by administrative monopoly factors, the market behavior of radio and television industry is extensive, and the efficiency of market resource allocation needs to be further improved. It is necessary to make rational use of radio and television resources, further reduce market access, and effectively form a good competitive situation. With the in-depth integration with new media, the editing process and organizational structure of radio and television media will undergo profound changes; form a production process of collecting multimedia generation and multi-channel and multiplatform information release; realize collaborative communication and integrated production; improve the productivity of various departments; promote the improvement in the economic benefits of the whole media; realize the multiple appreciation of media assets and resources; realize the full utilization and reallocation of common elements and common assets; change the weak cost increase between radio and television media into the weak cost increase within the new media; and realize the improvement in market performance. Of course, radio and television media have also made a lot of efforts in market integration and actively explore new ways of marketing on the basis of continuing to adhere to the principle of “content is king.”

4.3.3. Degree of Business Integration. The performance of the three integration indicators is the worst, and there is a slow upward trend in the later period, indicating that the business integration of the two industries is gradually deepening, but the pace is relatively slow. Of course, the contribution of major video websites in this respect is major. As given in Table 23, the total playing frequency of major video websites on PC page side, PC client side, mobile page side, and mobile client side has increased rapidly, reaching 1,673.101 billion times in 2016, which is 11.6s times of the 144.252 billion times of major radio and television media. Although the total broadcast frequency of major radio and television media is also increasing greatly, it is generally inadequate, especially the broadcast frequency of PC clients, which is basically blank in China National Radio, China Radio International, and Hunan TV Station. Media convergence will give birth to a large number of new products and services, which not only enrich the audience’s choices, but also become the tools and fields for radio and television media to compete with new media. Audience’s choice of radio and television programs is voted by remote control. When the program is broadcast, netizens can express their views to the contestants, and the TV screen can also present the opinions of Weibo netizens in real time, so as to realize the three-screen interaction among TV screen, mobile phone screen, and computer screen, which meets the audience’s opinion expression and interaction needs and successfully attracts young network users to the TV screen. Hunan

Satellite TV pays attention to the integration with its own new media to produce programs and realizes the deep integration of traditional media and new media content production by means of joint research and planning, separate organization and implementation, unified arrangement and production, and external integration and presentation.

The data in above tables are missing, mainly because there is no corresponding data source. Some media have not been applied on the Internet before, and many data cannot be verified or have no relevant data application.

5. Conclusion

Big data endows the radio and television director industry with new characteristics. In order to meet the needs of the times and find the space for students to survive and develop in surgical guidance, colleges and universities need to transform their skills, adopt diversified open teaching methods, optimize the existing professional personnel training mode, rationally organize radio and television teacher courses, and form a double-qualified team. Strong teachers cultivate data, better cultivate more radio and television directors to meet the development needs of the big data era, contribute to the sustainable and long-term development of cultural enterprises, and study and formulate a brand-new talent training strategy. The next step is to analyze the application characteristics of different media in communication effect and commercial value. From different business recommendations, the media application in precision business model has a new application prospect, which is suitable for the method proposed in this article and needs further verification.

With the full popularity of China's railwayization process, it has brought about the problem of the management ability of railway traffic safety. Railway traffic safety emergency management capabilities are low. When an accident occurs, clearer data cannot be obtained in the first time to have a general understanding of the accident. Therefore, the problem of organizing rescue has always plagued relevant railway workers. This study aims to study the improvement of railway traffic emergency management based on image recognition technology in the context of big data. To this end, this study proposes image recognition technology based on deep learning, and through the relay of the railway traffic emergency management system, so that the railway traffic problems can be dealt within time as soon as they occur, and designed an experiment to explore the ability of image recognition. The results of the experiment show that the efficiency of the improved railway traffic emergency management system has increased by 27%, and the recognition capability has increased by 64%. It can very well help current railway workers to carry out emergency management for railway traffic safety.

1. Introduction

Transportation is an important driving force for economic development, and railway transportation is the main driving force for transportation. Railway transportation plays a basic role in stimulating social and economic development and protection. In today's China, with the rapid development of the railway transportation industry, railway emergencies frequently occur, which bring more and more serious harm to society. After in-depth digging, it was discovered that there are obvious loopholes and defects in the domestic railway disaster prevention system and organizational structure, application mechanism, and resource guarantee, which will inevitably bring bad effects. Therefore, perfecting the domestic railway traffic emergency management system from a systematic level has a very important fundamental role in the overall rapid development of the domestic social economy.

With the rapid development of domestic railway traffic, railway traffic accidents are frequently seen in social life, and this has exposed many loopholes in the construction of

railway emergency response systems and accident resolution implementation actions. Therefore, the cause of casualties and losses of personnel and property is not only due to the occurrence of the accident itself. The imperfect emergency response plan, the unfavorable command, the inability to rescue in time, and the lack of relevant medical rescue knowledge are the important reasons for the vicious development of sudden accidents and even the related secondary accidents. Therefore, building a complete accident emergency management system is an important factor in preventing, controlling, and handling accidents. A region or department needs a relatively perfect emergency management system.

With the comprehensive popularization of railway construction in China, the total length of railway lines in China has become the world's number one, and what follows is the emergency safety management of railway traffic. Through the research and application of image recognition technology, the emergency management of railway traffic safety has been greatly improved, and this has made more

and more people begin to invest in related research. Luan X proposed distributed optimization, calculated the real-time traffic management efficiency of large railways, and carried out separate planning for each area [1]. Thielen SV proposed a conflict prevention strategy to quickly and efficiently solve the huge and complex railway network security problems [2]. Yongfu pointed out that we urgently need to innovate and improve the past railway traffic safety management model [3]. In his research, Duan Z conducted a careful investigation of the collision on the Metro Line 10 in Shanghai, China, on September 27, 2011, based on data recorded by anonymous mobile phones. He conducted research on the evacuation process of the accident and analyzed the impact of the accident on urban commuting. After analyzing 7 billion cell phone records for 11 days, the author found that the evacuation followed a two-stage pattern [4]. Liu Z believes that the improvement of the urban traffic emergency management system can start with the optimization of the internet of things and network mining technology to improve its response level [5]. Mauro Z developed a sensor to monitor chicken farms but observed some limitations related to the time required to detect hens. In this research, he proposed a major improvement to the sensor. They are achieved through image pattern recognition technology, which is applied to thermal imaging images obtained from the housing system [6]. Zhang R proposed a segmentation algorithm for large-scale flower species identification. His method is based on identifying potential object areas during detection [7]. Wei L believes that in order to quickly determine the effective bentonite content, the selection of the process is very important. He proposed that based on image recognition technology, he developed a fast automatic analyzer for the effective content of bentonite in waste clay sand [8]. Tai F believes that with the continuous development of science and technology, people can apply more and more technologies to the cultivation of children's abilities. In the process of cultivating children's abilities, the most important thing is the research on executive function, which is also the research topic of this study. In the past, in the research on children's executive ability, training methods such as music, mindfulness, and exercise were used to promote the development of executive function in preschool children. While various approaches have yielded some results, researchers have been exploring more comprehensive approaches to effective training. He aims to study how to use image recognition technology to analyze the intervention analysis of break dance to promote executive function in preschool children. To this end, he proposed image recognition technology based on deep learning neural network, and researched, analyzed, and improved related technologies obtained from deep learning. This makes it more suitable for the research topic of this study and to design related experiments and analyses to explore its relevant performance. His experimental results showed that the improved image recognition technique improved the accuracy by 31.2%. The performance of its algorithm has also improved by 21%, which can be very effective in monitoring the performance of preschool children in break dance [9]. The above documents are quite good for the research on image recognition

technology and railway traffic emergency management, and the instructions for the use of related technologies are quite detailed. However, the depth of research on image recognition technology is still not enough. Basically, it stays at a shallow level. If want to conduct in-depth research on it, it needs to have a certain understanding of image recognition algorithms.

The innovation of this study is based on the theory of system establishment and the technical support of image recognition technology based on deep learning, improving the emergency management system of railway traffic, and improving the image recognition ability and feature extraction efficiency, thereby greatly improving the efficiency of emergency response in the event of a railway accident.

2. Railway Traffic Management Methods

2.1. Railway Traffic Emergency Management System

2.1.1. System Function Goal. The railway hub train monitoring system monitors the railway tracks, platforms, passages, and other scenes in real time, analyses and processes the monitored sequence images, and recognizes the state of the vehicles in the images. In this way, it is judged that there is an accident or danger at the scene and responds to different levels of alarms according to the identification results. According to the degree of danger, it is divided into three levels, namely, the highest level in red, the more dangerous level in orange, and the safe level in blue. The railway staff take corresponding emergency measures according to the corresponding alarm level to achieve the purpose of reducing the accident rate, thereby greatly improving the safety of railway transportation [10].

According to the characteristics of railway transportation and railway trains that need to be guaranteed strong and continuous, the train image monitoring system of railway hubs must have the following characteristics:

- (1) Real time: the system requires the ability to collect real-time train images and perform image recognition in real time, so that the real-time situation can be reflected to the staff in order to take emergency measures in time [11]. Therefore, there is no doubt that the system requires extremely high real-time performance.
- (2) Accuracy: only accurate image recognition can ensure that the alarm will not be responded to by mistake, not only to ensure the safety of the train but also to ensure that the alarm is correspondingly accurate [12]. Therefore, the judgment of the on-site identification of the railway hub must be accurate and there must be no errors.
- (3) Stability: due to the differences in the pros and cons of different monitoring environments, no matter what the environment, the system needs to stably and reliably work for a long time; otherwise, it will bring trouble to the railway passenger transport service [13].

FIGURE 1: Train image monitoring system structure.

2.2. System Design. The train monitoring system is mainly composed of four interconnected parts: display screen, digital hard disk video recorder, high-performance computer, camera, and alarm equipment [14].

2.2.1. Display. Completing one-to-one or one-to-many video surveillance tasks, it can monitor different locations such as railway tracks and platforms in the office to monitor the jurisdiction [15].

2.2.2. Digital Hard Disk Video Recorder. The basic function of a digital hard disk video recorder is to convert analog audio and video signals into MPEG digital signals, store them on the hard disk (HDD), and provide functions corresponding to recording, playing, and managing programs, and voice and alarm interfaces.

2.2.3. Camera. It is mainly responsible for collecting real-time images of trains [16].

2.2.4. Alarm Equipment. The alarm equipment mainly sends out an alarm when the train encounters an accident or is in danger [17]. The structure of the train image monitoring system is shown in Figure 1:

The train monitoring system captures the train image through the CCD camera and then transmits the moving image sequence to the computer for real-time processing. The system designed in this study includes image capture, preprocessing, background extraction, target detection, postprocessing, train number statistics,

etc. [18]. The image recognition process is shown in Figure 2.

Each part has a certain relationship with the previous part, which can be said to have a feedback effect. For example, it can be segmented through preprocessing, and the system is not separated. In order to perform that function, each part effectively plays a role so that it can obtain necessary information from the outside world [19]. This external information refers to the opinions, ideas, and personal laws on handling and solving problems. According to that features of the actual image, an appropriate preprocessing method is adopted. The image is segmented in the recognition part, the feature are extracted, the sizes are classified, and finally the structural information required for analysis is provided. The relationship between image processing and recognition and image understanding is shown in Figure 3.

In this system, the result of the whole system is the description and interpretation of the image [20]. Image feature extraction and image classification belong to image recognition, while structure syntax analysis involves the process from image segmentation to image structure analysis. When a new object (image) is fed into the system, it can be explained to show what it is.

The train image target detection is located in the lower part of the train image recognition system. Whether the target area of the train image can be extracted from the train image correctly and quickly, this will be the key to the subsequent train target recognition processing [21]. Among them, in the train image recognition of railway hubs studied in this study, the interference of light intensity changes is particularly important [22].

FIGURE 2: Image recognition process.

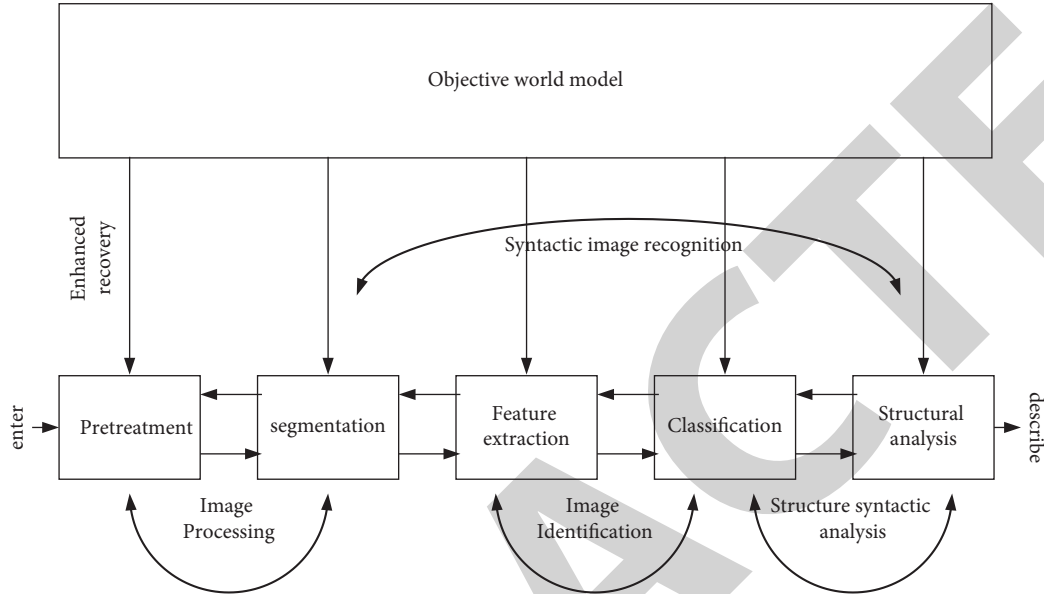

FIGURE 3: The relationship between image processing and recognition and image understanding.

FIGURE 4: Three kinds of train image detection methods.

Generally speaking, there are two classification methods for moving target detection algorithms. One is divided into indoor scene monitoring and outdoor scene monitoring according to the monitored scene; the other classification method is divided into target detection of static background and moving background according to the image sequence formed by the moving target. When the camera and the scene are relatively static in the video

surveillance system, the size and position of the background image will not change at different frame rates [23]. The scene studied in this study belongs to the indoor scene of a railway hub, and the camera and scene are relatively static [24].

In railway train image recognition, real-time segmentation of moving targets from train video image sequences is a basic and important link [25]. At present, there are mainly

three types of train image detection methods, as shown in Figure 4.

2.3. Image Recognition Technology Based on Deep Learning. Deep learning is a subfield of machine learning, which attempts to abstract deep learning of data through a series of multilayer nonlinear transformations. By stimulating the nervous system of the human brain, a hierarchical model structure similar to the human brain is established, and the input data are extracted step by step to form a more abstract high-level representation.

2.3.1. Neuron Model. Simply put, a neuron node is a nonlinear activation function that receives multiple input values and records them as follows:

$$w = (w_1, w_2, \dots, w_n). \quad (1)$$

Then, the input signal W is weighted and summed to obtain Z . Finally, Z passes through a nonlinear activation function to output the activation value a , as shown in formulas (2) and (3).

$$z = \sum_{i=1}^n x_i * w_i + b, \quad (2)$$

$$a = f(z). \quad (3)$$

Among them, X_i represents the weight parameter, and b is the bias term.

2.3.2. Feedforward Neural Network. Given a group of neurons, we can form a hidden layer or input and output layer, and further connect these layers to form a network. Neural networks can have many topological structures, and the simplest and most commonly used is the feedforward neural network. The data propagation formula of the feedforward neural network is as follows:

$$\begin{aligned} z^{(l)} &= W^{(l)} \cdot a^{(l-1)} + b^{(l)}, \\ a^{(l)} &= f_i(z^{(l)}). \end{aligned} \quad (4)$$

We combine the above two formulas to get the following:

$$z^{(l)} = W^{(l)} \cdot f_l(z^{(l-1)}) + b^{(l)}. \quad (5)$$

According to the above formula, the feedforward neural network transfers the input information layer by layer to the next layer, and finally, the output of the network is as follows:

$$\begin{aligned} w &= a^{(0)} \longrightarrow z^{(1)} \longrightarrow a^{(1)} \longrightarrow z^{(2)} \longrightarrow \dots \longrightarrow a^{(l-1)} \\ &\longrightarrow z^{(l)} \longrightarrow a^{(l)} = y. \end{aligned} \quad (6)$$

2.3.3. Backpropagation Algorithm. In order for the neural network to work normally, we need to train the parameters in the neural network. The most common method is the

backpropagation algorithm. In general, as long as there is a large enough dataset and training samples, we can train a well-performing Xianjing network. The objective function is as follows:

$$I(W, b) = \sum_{i=1}^N L(y^{(i)}, f(x^i | W, b)) + \frac{1}{2} \lambda \|W\|_F^2, \quad (7)$$

$$I(W, b) = \sum_{i=1}^N J(X, b; w^{(i)}, y^{(i)}) + \frac{1}{2} \lambda \|W\|_F^2.$$

In order to minimize the weight and bias vector, we modify its parameters, as shown in the following formula:

$$\begin{aligned} w^{(l)} &= w^{(l)} - \alpha \frac{\partial J(Wb)}{\partial W^{(l)}}, \\ w^{(l)} &= w^{(l)} - \alpha \sum_{i=1}^N \left(\frac{\partial J(w, b; x^{(i)}, y^{(i)})}{\partial W^{(l)}} \right) - \lambda W^{(l)}, \\ b^{(l)} &= b^{(l)} - \alpha \frac{\partial J(W, b)}{\partial b}, \\ b^{(l)} &= b^{(l)} - \alpha \sum_{i=1}^N \left(\frac{\partial J(w, b; x^{(i)}, y^{(i)})}{\partial b} \right), \end{aligned} \quad (8)$$

where α is the learning rate of the parameter.

In order to update $W^{(l)}$, we transform the above formula as follows:

$$\frac{\partial J(w, b; x, y)}{\partial W_{ij}^{(l)}} = \text{tr} \left(\left(\frac{\partial J(w, b; x, y)}{\partial z^{(l)}} \right) \right)^T \frac{\partial z^{(l)}}{\partial W_{ij}^{(l)}}. \quad (9)$$

For the l th layer, we define an error term as follows:

$$\delta^{(l)} = \frac{\partial J(w, b; x, y)}{\partial z^{(l)}} \in R^{n'}. \quad (10)$$

Let us analyze the second item on the right first, because

$$z^{(l)} = W^l \cdot a^{(l-1)} + b^l. \quad (11)$$

So we can get the following:

$$\frac{\partial z^{(l)}}{\partial W_{ij}^{(l)}} = \frac{\partial (w^l \cdot a^{(l-1)} + b^l)}{\partial W_{ij}^{(l)}}, \quad (12)$$

$$\frac{\partial J(w, b; x, y)}{\partial W_{ij}^{(l)}} = \delta^{(l)} a_j^{(l-1)}.$$

We further sort out the following:

$$\frac{\partial J(w, b; x, y)}{\partial W^{(l)}} = \delta^{(l)} (a^{(l-1)})^T. \quad (13)$$

The same can be obtained as follows:

$$\frac{\partial J(w, b; x, y)}{\partial b^{(l)}} = \delta^{(l)}. \quad (14)$$

Next, we further solve the error term of the L th layer as follows:

$$\begin{aligned}\delta^{(l)} &= \frac{\partial J(w, b; x, y)}{\partial z^{(l)}}, \\ \delta^{(l)} &= \frac{\partial a^{(l)}}{\partial z^{(l)}} \frac{\partial z^{(l+1)}}{\partial a^{(l)}} \frac{\partial J(W, b; x, y)}{\partial z^{(l+1)}}, \\ \delta^{(l)} &= \text{diag}(f'_l(z^{(l)})) \cdot (W^{(l+1)})^T \cdot \delta^{(l+1)}, \\ \delta^{(l)} &= f'_l(z^{(l)}) \Theta (W^{(l+1)})^T \delta^{(l+1)}.\end{aligned}\quad (15)$$

After calculating the error term of each layer, we can update the parameters according to the gradient of the parameters of each layer, and the training process of the feed-forward neural network is basically completed within three steps. The steps are as follows: (1) calculating the state and activation value of each layer according to the forward propagation formula; (2) calculating the error term of each layer according to the backpropagation formula; and (3) calculating the partial derivative of each layer and update parameter.

2.4. Railway Traffic Safety Emergency Management. Railway accident analysis and application, with the goal of preventing accidents and faults in advance, integrate the unstructured accident fault text data of various business departments, for example, safety supervision report, accident fault tracking report, accident library, and fault library, and gradually realize the functions of full-text search, feature extraction, intelligent classification, correlation analysis, cause recommendation, key accident fault analysis, and key area analysis of unstructured accident fault text.

2.4.1. Overall Structure. The railway big data service platform mainly includes data collection, storage, management, exchange, sharing, analysis, and visualization systems. Railway accident fault text big data analysis is based on a unified railway big data service platform, applying text big data analysis technology to realize massive unstructured railway accident text data analysis. Railway accident fault text big data analysis application standard system is mainly to clarify the scope of railway accident fault text data, data interface, access method, and the use standard of accident fault terminology. It covers the standard specifications of the whole process of railway accident fault text data collection, storage, analysis, and visualization application. The railway accident fault text big data application guarantee system mainly includes railway safety guarantee, railway talent guarantee, railway evaluation, and assessment guarantee. Railway accident fault text big data analysis application logic architecture is mainly composed of a data source layer, data integration layer, data storage layer, data service layer, data analysis layer, data application layer, visualization layer, data standard system, and data guarantee system. Here, we focus on the data storage layer, data application layer, and

visualization layer. Among them, the logic architecture of railway traffic safety management big data analysis application is shown in Figure 5.

- (1) Data source layer. It is mainly unstructured text data related to accidents and failures, and structured data related to equipment structure, basic information of accidents and failures, and safety-related business system monitoring.
- (2) Data integration layer. It is mainly for the data at the data source layer, according to the characteristics of the data type and real-time requirements, and the data are extracted and converted through different collection methods such as ETL tools, JDBC/ODBC, FTP/SFTP, and real-time data collection for storage.
- (3) Data storage layer. It is mainly for the data collected by the data integration layer to store the original accident and fault text data in the distributed file system. At the same time, an index is established on the distributed database Elasticsearch, and the content of the unstructured text is stored on Elasticsearch.
- (4) Data service layer. It is mainly to realize the processing of railway unstructured accident fault text data and related structured data, and to provide processed data for the analysis of accident fault text.
- (5) Data analysis layer. It is the structured data for the structured accident fault text data and the related equipment structure, and the basic information of the accident fault and the monitoring of the safety-related business system after the feature is extracted. The unstructured analysis platform is unstructured data analysis based on Hadoop, Spark, Mahout, Python, TensorFlow, etc. [26].
- (6) Data application layer. Through the mining results of the big data analysis application of the accident fault text, the full-text retrieval of the accident fault document is realized.
- (7) Data visualization. Through GIS, pie charts, data dashboards, chord charts, character clouds, line charts, etc., the result data of the accident fault analysis are dynamically displayed so that the railway-related staff can view and apply them [27].

2.4.2. Functional Architecture. Railway accident fault text big data analysis application functions mainly include the following: accident fault feature extraction, accident full-text retrieval, accident failure area, key accident failure analysis, accident failure reason recommendation, accident failure correlation analysis, system management, and other functions. On the basis of a unified railway big data service platform, each function realizes the digital management of railway unstructured accident fault text and the analysis, diagnosis, rectification, management and control, and prevention of the accident fault through the mutual cooperation between the modules, dig out the evolution law of accidents and failures, analyze the main factors of accidents

FIGURE 5: Logical architecture of railway traffic safety management big data analysis application.

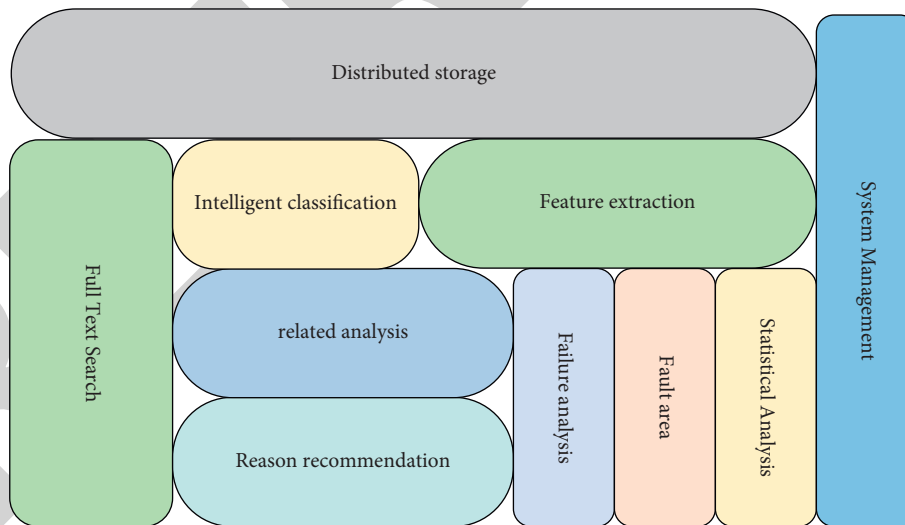

FIGURE 6: The functional architecture of railway traffic emergency management application.

and failures, and prevent the occurrence of similar accidents and failures in the future. The functional architecture diagram of the railway accident fault text big data analysis application is shown in Figure 6.

The distributed storage of railway accident fault text big data is the basis of railway accident fault text big data analysis application. On this basis, a section of accident fault text description can be converted into a certain type of accident

fault, and then based on the accident fault entity and cause entity data extracted from the railway accident fault feature, the relevant analysis and cause intelligent recommendation of the railway accident fault can be realized. The analysis of key accidents and the failure areas of frequent accidents are mainly based on the dynamic display of structured data after the extraction of the characteristics of railway accidents and the use of character clouds. System management is mainly to

3. Train Number Image Recognition Experiment

3.1. Train Number Character Recognition Test. In the experiment of character recognition, the three types of characters, namely, Chinese characters, English letters, and numbers, are trained with 320 images of each type, and the training model is obtained by using the OC-SVM classifier and the MC-SVM classifier joint classifier. During the test, 1200, 1200, and 2400 images of Chinese characters, English letters, and numbers were taken, respectively, for testing. The results are shown in Table 1.

From the data results shown in Table 1, it is not difficult to see that the recognition rate for the three different characters is still relatively high. According to the recognition results, we can calculate the recognition rate, as shown in Table 2.

From the data results shown in Table 2, it can meet the requirements of the application.

3.2. Comparison of Test Results of Recognition Algorithms in Multiple Environments. The correct rate and error rate are compared with the number character recognition algorithm based on template matching, train number feature, and image recognition. The number of train number image samples participating in the test is 1000, and the results are shown in Table 3.

From the data results shown in Table 3, it can be seen that the correct rate of the algorithm proposed in this study is the highest among several algorithms, which proves that the algorithm has practical application value.

4. Recognition Efficiency and Accuracy

4.1. Experimental Analysis Based on the Integrated Fault Classification Model

4.1.1. BiGRU and BiLSTM Overall Weight Distribution. The training set and the verification set synthesized by ADASYN are extracted and expressed by TF-IDF and input into the BiGRU and BiLSTM network for training. The loss

function value of the first-level training process is shown in Figure 7.

In order to view the change in the loss function value in the second-level training process, we compare it with the change in the loss function value in the first-level training process and explore the law of its change. This study designs an experiment to train it, and the results are shown in Figure 8:

From the comparison in Figure 8, it can be seen that the loss function of the second-level classification is smaller than that of the first-level classification.

After $K=5$ times of training, 30% of real samples are used to evaluate the BiGRU and BiLSTM training models. The evaluation results are shown in Table 4:

4.2. Classification of Integrated Models. It can be concluded from the above experiments that the weight of each category of image recognition and BiGRU should be higher than the overall weight of BiLSTM. Different overall weights are given to BiGRU and BiLSTM, the two image recognitions are combined by combining weights, and the output of the two networks will be recalculated to obtain a common classification prediction result. The classification index of the model is shown in Figure 9:

The representative algorithm of integrated image recognition model bagging is the random forest, and the representative algorithm of boosting is gradient boosting tree. It can be seen from Table 5 that the image recognition integrated model designed in this study has a significantly

	Secondary fault classification	0.8549	0.8614	0.8536

higher evaluation index than the mature integrated recognition algorithms RF and GBDT.

4.3. Feature Extraction Analysis in Different Environments.

This section is based on a self-built train number image library. For number recognition, a feature extraction method with rotation invariance and scale invariance is selected, that is, improved SIFT feature extraction. Because the train recognition is affected by the natural environment, rain and snow when capturing the image, the interference items of the image must be removed. At the same time, the image capture is performed on the

wireless client, which requires the image to have a certain degree of adaptability to its own rotation and scaling, and the improved SIFT feature satisfies these performance requirements well.

In order to meet a wider range of actual matching marks, this study divides the images to be matched into two types of simple images and complex images for experimental testing. The test result is shown in Figure 10.

Through the understanding of Figure 10, we can see that in terms of the accuracy of feature extraction, basically all extraction methods can reach more than 85%, but the relative advantage of SIFT is more obvious.

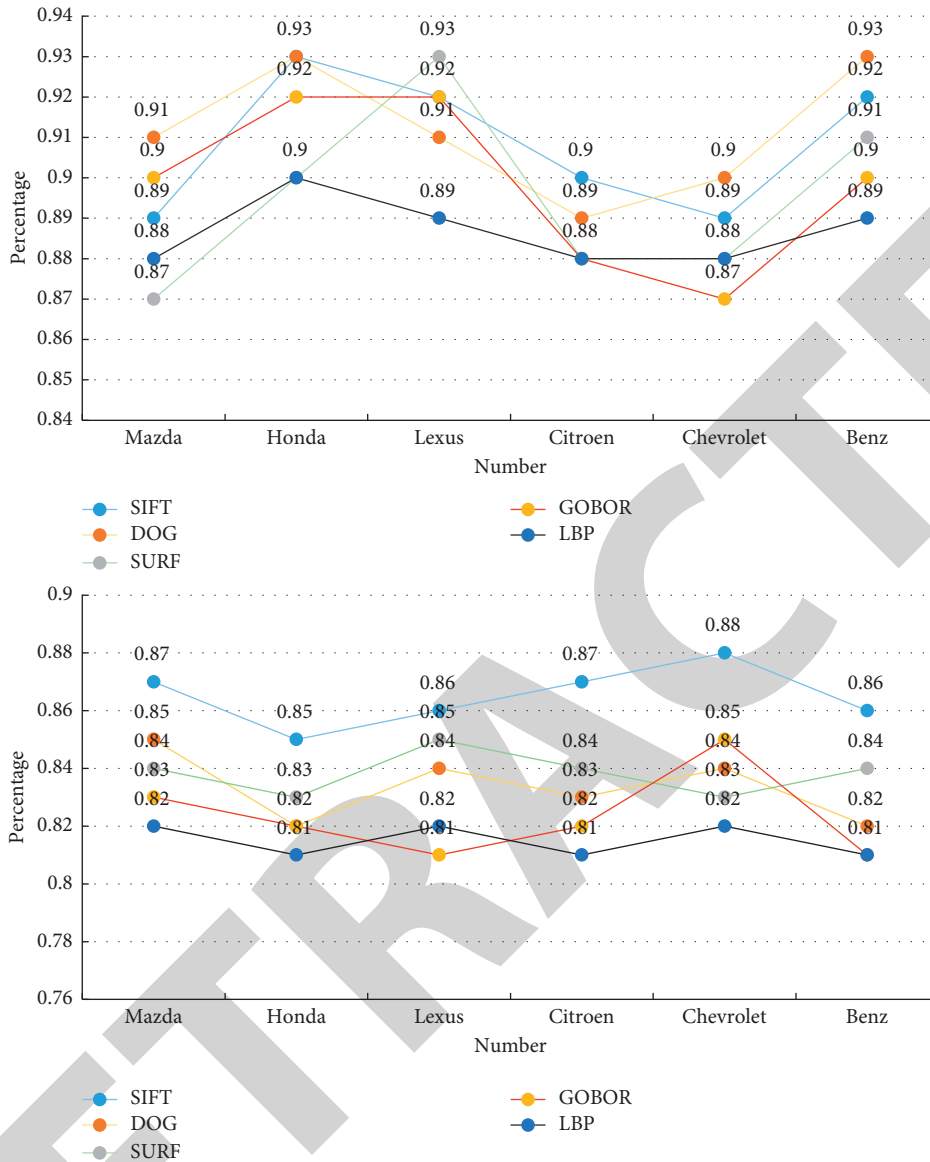

FIGURE 10: Feature vector extraction in different environments.

5. Conclusions

This study is mainly about the research of railway traffic emergency management, through the use of image recognition technology under the background of big data to improve the accident risk monitoring in the actual train operation process. For image recognition technology, this study uses image recognition technology based on deep learning to identify traffic emergency handling problems during train operation. When an accident occurs, the train number can be effectively identified, and the identification ability in the identification process is analyzed and explored experimentally. The results show that the improved image recognition technology based on deep learning has increased the recognition ability of trains by 64%, and the efficiency of emergency handling of railway traffic safety has increased by 27%, which effectively solves the monitoring and

management capabilities for railway traffic safety, and improves the efficiency of emergency accident handling.

The application of sports game video analysis in athlete training and competition analysis feedback has attracted extensive attention, but the traditional sports human body posture estimation method has a large error between the athlete's human body posture estimation results and the actual results in the complex environment and the athlete's body parts are blocked. Therefore, this study proposes a convolutional neural network for athlete pose estimation in sports game video. Based on the improved model, multiscale model, and large perception model, a superimposed hourglass network is constructed, and the gradient disappearance problem of the convolutional neural network is solved using intermediate supervision. The experimental results show that the athlete pose estimation model based on the convolutional neural network can improve the accuracy of athlete pose estimation and reduce the negative impact of occlusion environment on athlete pose estimation to a certain extent. In addition, compared with other athletes' standing posture estimation methods, the model has competitive advantages and high accuracy under widely used standard conditions.

1. Introduction

With the continuous development of computer vision technology, sports video analysis technology has been widely used in the event analysis of sports competitions. It can provide athletes and coaches with corresponding data as a reference through video analysis and make a relatively systematic evaluation of individual athletes' and groups' performance in sports competitions [1]. In recent years, the number of sports videos has increased geometrically, and at the same time, there is a large amount of interference information in the huge amount of sports videos [2]. The information that athletes and coaches need and pay attention to occupies relatively little in the game video, so how to quickly find the needed information in the massive video information has become a research hotspot in sports video technology.

Sports competition training analysis is mainly divided into technical analysis and tactical analysis, in which technical analysis is the analysis of athletes' personal technical ability, movement standardization, and physical quality in

the competition, and tactical analysis is the guidance of the competition and the application of tactical methods, etc. [3, 4]. Through the analysis of sports competition videos, it can effectively help athletes understand their competitive level and competitive strength of competitors and learn the competitive technology of excellent athletes [5]. With the continuous application of human posture estimation and human motion recognition technology based on the deep neural network, sports training analysis technology based on human posture estimation has also developed rapidly. The athlete's human posture recognition and estimation technology can recognize and estimate the athlete's posture in the high-resolution recorded competition video, decompose the athlete's posture in multiple dimensions, obtain the real action data of the athlete in the competition, and then combine the analysis algorithm with scientific analysis to obtain the final evaluation result of the athlete's performance [6, 7]. In addition, the same movement of athletes in the same sport can be compared horizontally to find out the gap and problems between athletes' movements and standard movements, which will help athletes improve and reduce the

possibility of repeated training [8]. At the same time, it allows athletes to more intuitively understand the training content and give rapid feedback to reduce sports injuries caused by irregular sports [9]. However, the traditional athlete posture recognition and estimation methods cannot fully extract image features. Although the time required is relatively small, when the athlete's posture changes greatly in training, the error between the estimation results and the actual results will become larger [10]. Therefore, estimating the posture recognition of skilled athletes in complex environment has become a challenge for sports video analysis technology.

Combined with the convolution neural network, this study studies the method of athlete posture estimation in sports training. This study creatively constructs a layered hourglass network based on improved module, multiscale module, and large perception field module. The intermediate supervision method is used to avoid the gradient vanishing problem of the convolutional neural network. Compared with the traditional athlete posture estimation method in image feature information extraction, this method has more practical application value. It solves the problem that there is a large error between the estimated results and the actual results when the environment in the sports video is complex or the athletes' body parts are blocked.

To solve the above problems, this study proposes a convolutional neural network research on athletes' human posture estimation technology in sports game training, which is mainly divided into three parts. The first part introduces the development of human posture estimation technology. The second part is the construction of the athlete posture estimation model based on the convolutional neural network and introduces the adopted model. In the third part, the performance experiment and simulation experiment of the athletes' human posture estimation model based on the convolutional neural network are carried out, and the experimental results are analyzed.

2. Related Work

Since the 1980s and 1990s, people have proposed and studied the corresponding human posture estimation methods. However, in the early research stage, computer equipment and deep learning technology are still in the exploration and development stage. Therefore, most of the traditional human posture estimation methods are based on the graphical structure model [11]. Some scholars have improved the graph structure based on statistical combination to obtain the tree structure, which can reduce the computational complexity, but it is difficult to correctly estimate the human posture in the case of complex environment scene or partial occlusion of the human body [12, 13]. To solve these problems, it is suggested to add corresponding constraints to the occluded part of the human body to achieve improvement and combine the confidence propagation algorithm to estimate the corresponding human posture. Therefore, even in the case of human occlusion, human joint points can be predicted relatively accurately [14]. With the in-depth study of human posture

and the development of learning technology, many algorithms have achieved good results in the field of human posture estimation.

The current human pose estimation is mainly divided into overall human pose estimation algorithms and human pose component estimation algorithms [15]. The algorithms for overall human pose estimation usually use a nonlinear mapping between images and nodal positions to achieve human pose estimation [16, 17]. A deep neural network-based human pose estimation algorithm has been proposed to obtain pose estimation values with high accuracy using DNN regression quantities, which has the advantage over other algorithms in that it performs pose inference through a holistic approach [18]. It has also been proposed to incorporate domain prior knowledge in the DCNN framework and combine the variability mixture component for end-to-end human pose estimation [19]. Normalized distances in overall human pose estimation methods like this can have a large impact on the localization of nodes. For the human component estimation algorithm, the human model is built based on the appearance and position of the component or joint, and then, the corresponding optimization is performed to obtain the corresponding energy function [20]. Traditional joint point models are manually performed with image feature design, which makes the real appearance of their representations have a large error, while deep learning can solve this problem. It has been proposed to combine human joints, parts affinity force fields combined with greedy algorithms for learning body parts and individual connections in images through non-parametric representations, and such an approach can achieve real-time performance while maintaining low error regardless of the number of individuals in the image [21, 22]. However, body pose estimation by body parts is prone to loss of body information, while the bottom-up approach increases the chances of joint point misdetection. Therefore, in the field of sports game training and analysis, there are many problems in human posture estimation technology, which need to be further developed and solved.

3. Construction of the Athlete Posture Estimation Model Based on the Convolutional Neural Network

The convolutional neural network has two characteristics: local sensing and parameter sharing. Local sensing, namely, the convolution neural network, proposes that each neuron does not need to perceive all pixels in the image. Only the local pixels of the image are sensed, and then, the local information is combined at a higher level to obtain all the representation information of the image. The nerve units of different layers are connected locally; that is, the nerve units of each layer are only connected with some nerve units of the previous layer. Each nerve unit only responds to the areas within the receptive field and does not care about the areas outside the receptive field. Such local connection mode ensures that the learned spatial local mode of convolution check input has the strongest response. Due to the complex background of the application scene, the flexibility of

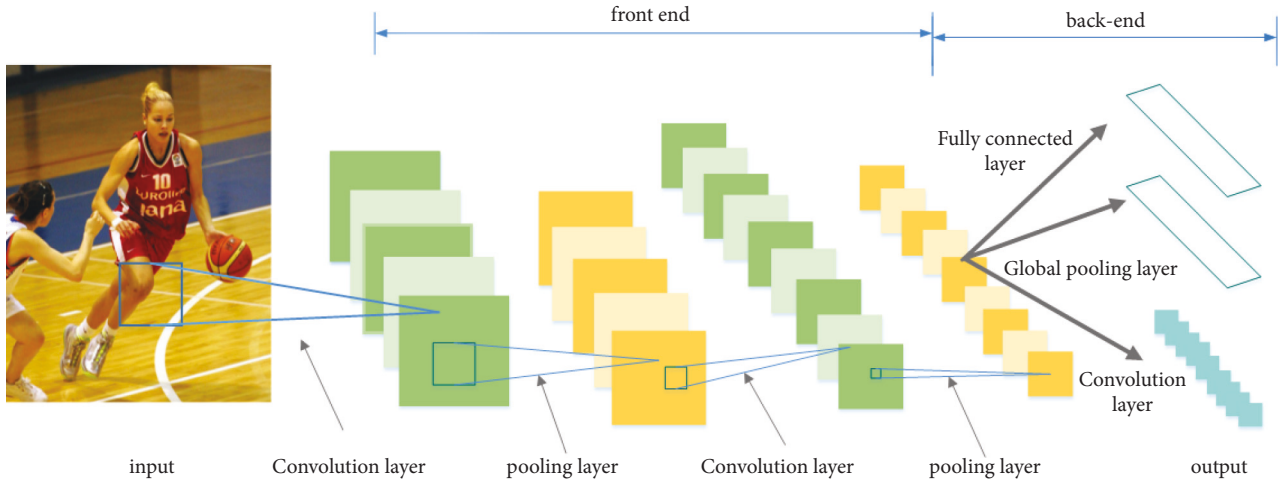

FIGURE 1: Simplified architecture of the convolutional neural network.

athletes' limbs, and the serious occlusion of various parts of the human body, the traditional human posture estimation methods show limited representation performance in practical application and produce unsatisfactory posture estimation results. The athletes' attitude estimation method based on the convolutional neural network has good non-linear transformation ability, and the improvement of the convolutional neural network and other auxiliary methods can further improve the athletes' attitude estimation accuracy in game training.

3.1. Multiresidual Modular Convolutional Neural Network Athlete Pose Evaluation Model. Among the deep learning models of human pose estimation algorithms, convolutional neural networks have the unique advantage of being feed-forward neural networks with deep structure and after continuous development currently contain mainly convolutional layers, pooling layers, fully connected layers, activation functions, normalization layers, inputs, outputs, etc. The pool layer is sandwiched in the middle of the continuous convolution layer to compress the amount of data and parameters and reduce overfitting. If the input is an image, the main function of the pooling layer is to compress the image [23]. A simplified architecture of the convolutional neural network is shown in Figure 1.

In convolutional neural networks, the convolutional layer is a feature extraction layer by having convolutional kernels for abstract feature extraction, to reduce the number of parameters; it mainly takes local sensing and weight sharing methods [24]. The pooling layer, on the other hand, reduces the number of neurons by counting and down-sampling the features [25]. The following equation is the convolution operation.

$$F(i, j) = X(3 \times 3)_{i \times j} \otimes f(3 \times 3), \quad (1)$$

where the $F(\cdot)$ denotes the features after convolution, (i, j) denotes the pixel points of the image, $X(\cdot)$ denotes the matrix of the pixel points and the neighboring pixel points at the corresponding position, and $f(\cdot)$ denotes the filter. If the

size of the input image is denoted as $H \times W$ and the size of the convolution kernel is N , the size of the feature map obtained after the operation with the convolution step is shown in S as follows:

$$H_{\text{feat}} = \frac{H - N}{S} + 1, \quad (2)$$

$$W_{\text{feat}} = \frac{W - N}{S} + 1. \quad (3)$$

If the complementary zero operation is added, the input image size is M , as shown in equation:

$$W_{\text{feat}} = \frac{M + 2K - N}{S} + 1. \quad (4)$$

Although the performance of the convolutional neural network in athlete posture estimation is better than that of traditional methods, there are still some problems, such as gradient problem and small sensing domain of the feed-forward network. Therefore, this study selects a convolutional neural network with stacked hourglass structure and improves it combined with multiple modules [26]. The superimposed hourglass grid is constructed using grid and intermediate supervision method, which not only solves the problem of gradient disappearance, but also has high network performance and athlete attitude estimation accuracy. However, the performance of a single module cannot meet the requirements of athletes' posture estimation technology. Therefore, this study selects large sensory field module, improved module, and multiscale module for network construction.

The accurate performance of the neural network is improved to estimate athletes' posture, so that the neural network can carry out very in-depth training. However, its own unit mapping will also make the response change increase with the increase in depth. Therefore, the laminated hourglass network will have a great response impact when training deeper networks, which increases the difficulty of parameter optimization and estimation error. Based on the traditional laminated hourglass grid, the improved

FIGURE 2: Improved hourglass grid stacking diagram.

laminated hourglass grid replaces the unit mapping with normalization layer, ReLU, and convolution and introduces spatial attenuation layer 3×3 before the convolution, as shown in Figure 2.

When estimating athletes' posture in game training, the correlation and connection between the whole body parts and joints are affected by the effective receptive field of neurons to the surrounding area. The size of the mapping range of the pixel points corresponding to each layer of the output feature mapping in the convolution neural network on the original image is the receptive field, which corresponds to the receptive field of the first layer, as shown in the following equation:

$$F_i = F_{i-1} + (k - 1) * \text{stride}(i), \quad (5)$$

where is the F_{i-1} perceptual field size of the previous layer, k denotes the current convolution kernel size, and $\text{stride}(i)$ denotes the step product of the previous $(i - 1)$ layers; i.e., $\text{stride}(i) = \text{stride}(1) * \text{stride}(2) * \dots * \text{stride}(i - 1)$.

The effective receptive field of the improved module is still very small, so a large receptive module is constructed based on the improved module. The schematic diagram of large magnetic field residual module is shown in Figure 3.

When helping the deep residual learning to achieve a breakthrough in the task of image recognition and classification, the module is shown in the following equation:

$$p_{i+1} = h(p_i) + F(p_i, W_i^F). \quad (6)$$

The corresponding input of the first i residual module is denoted as p_i , and the output is denoted as p_{i+1} , F denotes the convolution that forms the stack, and $h(p_i) = p_i$ denotes the unit mapping. The large sensory field residual module is shown in the following equation:

$$p_{i+1} = h(p_i) + F(p_i, W_i^F) + Q(p_i, W_i^Q). \quad (7)$$

The offset problem is one of the common problems faced by equipment manufacturers who use stepping or servo motors in the process of equipment setting, commissioning, and use. The deviation is caused by improper mechanical fittings, mutual interference of equipment in

the workshop, or improper grounding wire treatment in the equipment setting. The problem of large positioning error of joint points is caused by the change in athletes' body shape in the competition video. This requires the integration of multiscale modules on the basis of large receiving field modules. This requires the integration of multiscale modules on the basis of large receiving field modules, as shown in Figure 4.

As can be seen from the figure, the multiscale module in (1), (2), and (3) is the same as the large sensory field module, while branch (4) $Q(p_i, W_i^Q)$ is a new addition with the structure of $\text{pool}2 * 2 + \text{conv}3 * 3 + \text{pool}2 * 2 + \text{conv}3 * 3 + \text{upsample}2 * 2 + \text{upsample}2 * 2$, from which we can see that there are two downsamples in this branch, which means that the feature map size is 25% of the input feature map, and after upsampling to the input feature mapping size, it is fused with the other three branches in series. In the other branches, the feature map size of branch (3) is 50% of the input feature map, and the feature map sizes of branches (1) and (2) remain unchanged. The expressions are shown in the following equation:

$$p_{i+1} = h(p_i) + F(p_i, W_i^F) + Q(p_i, W_i^Q) + G(p_i, W_i^G). \quad (8)$$

Figure 5 shows the overall framework of the convolutional neural network. As shown in the figure, it can be divided into two parts, the first half and the second half. The first half of the framework is composed of convolution, large field of view module, and pool, which is used to learn athletes' pose estimation in the feature map. After convolution kernel operation, the size of the feature map remains in the second half. The second half of the frame is composed of hourglass subgrid structure, with intermediate supervision at the end of each hourglass, and the feature map is processed multiple times between high resolution and first resolution to form a stacked hourglass grid.

3.2. Off-Node Prediction and Athlete Pose Estimation Dataset. The predicted positions of the joint nodes are mainly regressed by the score map, i.e., the score map

FIGURE 3: Schematic diagram of large receptive field residual module.

corresponding to each hourglass subnetwork and human joint point in the multi-residual convolutional neural network. Let the actual labeled position of the joint point be denoted as $V = \{V_k\}_{k=1}^K$ and position of the first k joint point is denoted as $V_k = (x_k, y_k)$, and then, the fractional map of the actual position is calculated as shown as follows:

$$S_k(t) \sim N(v_k, \Sigma), \quad (9)$$

where the predicted positions of the nodes are denoted as $t \in \mathbb{R}^2$, and Σ denotes the unit matrix. If the number of nodes is K one, the number of predicted score maps obtained for each hourglass subnetwork is K , i.e., $\hat{S} = \{\hat{S}_k\}_{k=1}^K$. The hourglass end loss function is shown in the following equation:

$$L = \sum_{m=1}^M \sum_{k=1}^K \left\| S_k - \hat{S}_k \right\|_2^2, \quad (10)$$

where M denotes the number of samples. The position at the highest score on the score graph of the last hourglass subnetwork after the prediction process is marked as the prediction node position, which is denoted as \hat{v}_k , as shown in the following equation:

$$\hat{v}_k = \arg \max_t \hat{S}_k(t), \quad k = 1, 2, \dots, K. \quad (11)$$

The MPII dataset, LSP dataset, and MS COCO dataset are commonly used for experimental training of athlete's pose estimation in competition video, and the LSP dataset and its extensions are included in this study. In the LSP

dataset, there are many pictures of athletes with rich posture and recognized high difficulty in posture estimation, and the number of joints for human posture estimation is 14 joints, which is challenging for the experiment. The estimated number of joints in human posture is sixteen joints, and the evaluation criterion is the percentage of correct joints, i.e., PCK; after normalizing the data annotation, if the joints are still within the distance of the threshold value, then the joints are correct, as shown in the following equations:

$$D_p = \frac{\sqrt{(x^p - x^g)^2 + (y^p - y^g)^2}}{\text{HoH}}, \quad (12)$$

$$\text{PCKh}@s = \frac{\sum_p \delta(D_p < s)}{\sum_p 1}, \quad (13)$$

where s is the threshold value and $s \in \{0.1, 0.2, 0.3, 0.4, 0.5\}$, p is the number of nodes, and $(x^p - x^g)$ and $(y^p - y^g)$ are the predicted and actual values, respectively. The prediction is wrong when $D_p > s$ and correct when the opposite is true, $\text{PCKh}@s$.

The number of estimated joints of human posture in the MS COCO dataset is 17, which is evaluated in terms of the average accuracy, i.e., mAP, as shown in the following equations:

$$\text{mAP} = \text{mean}\{AP@ (0.5: 0.005: 0.95)\}, \quad (14)$$

$$AP@s = \frac{\sum_p \delta(\text{OKS}_p > s)}{\sum_p 1}. \quad (15)$$

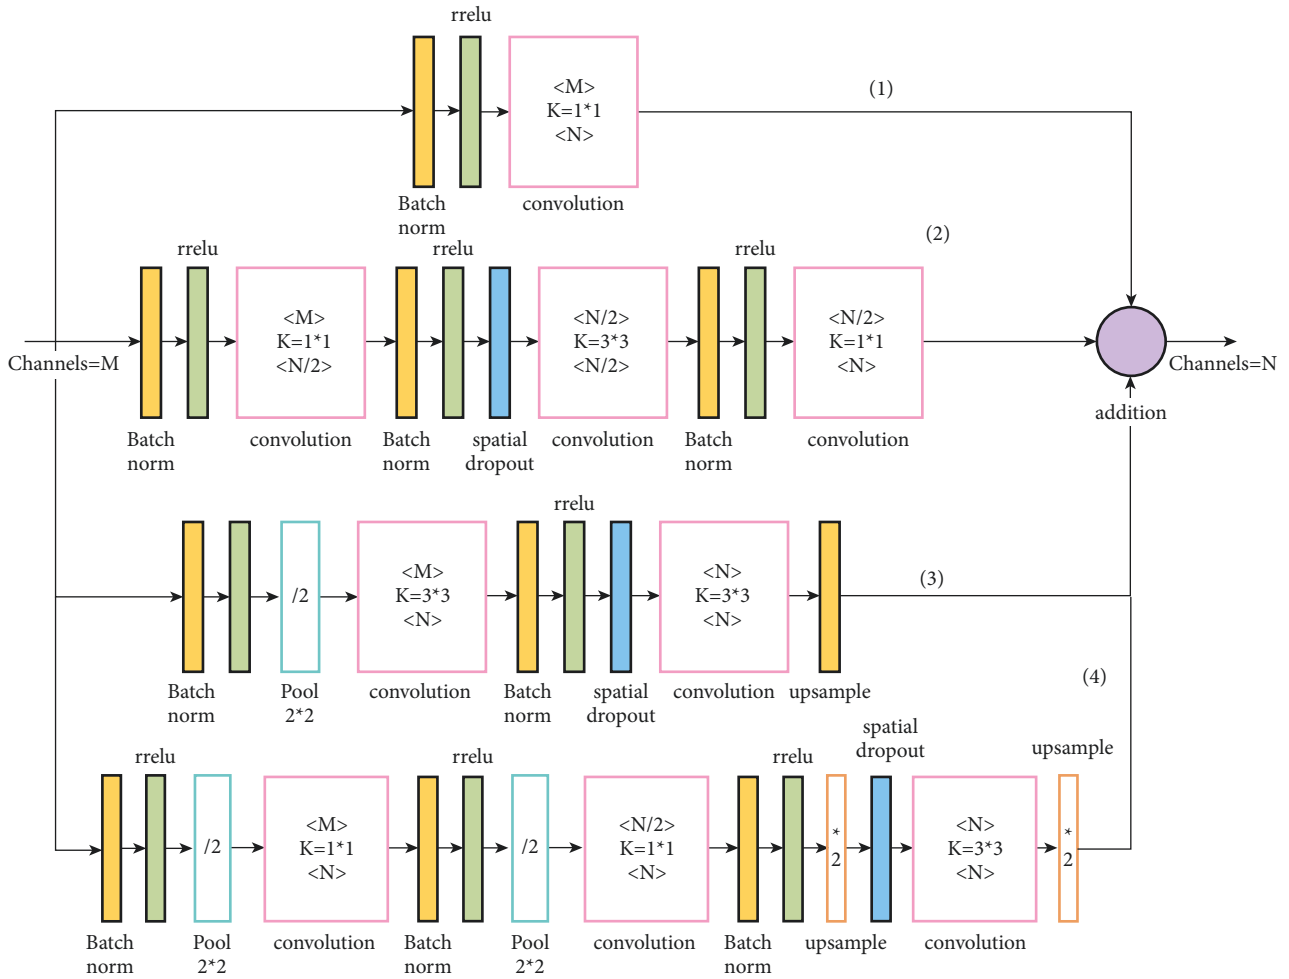

FIGURE 4: Schematic diagram of multiscale residual module.

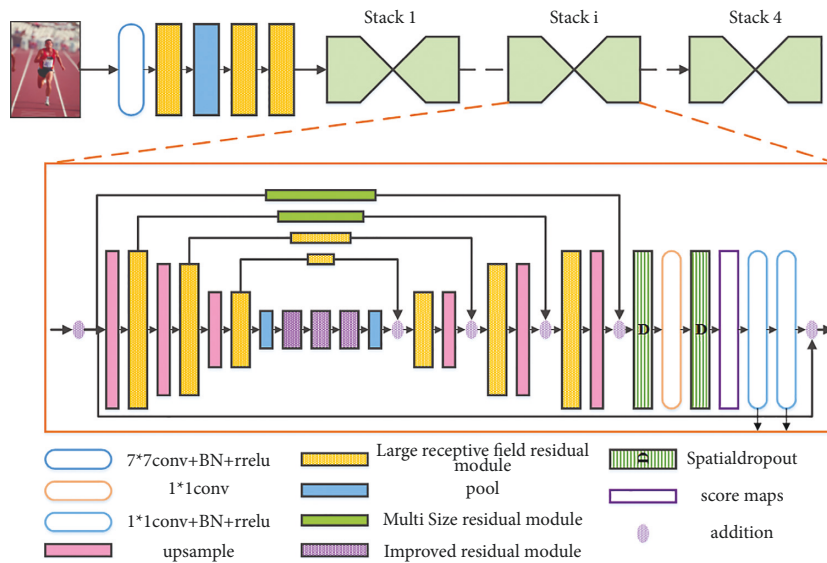

FIGURE 5: Overall framework of the convolutional neural network.

FIGURE 6: Examples of joint points in three datasets.

The threshold value of OKS $s \in [0, 1]$, which is the evaluation criterion for the similarity between the actual and predicted values of the nodes. An example of three dataset nodes is shown in Figure 6.

4. Experimental Results of Athlete Pose Estimation in Sports Game Video Combined with the Convolutional Neural Network

4.1. Experimental Results of Performance of the Athlete Posture Estimation Model Based on the Convolutional Neural Network. The convolutional neural network human posture estimation model is mainly composed of the sand leak subnetwork. Therefore, this study makes an experimental study on the impact of the establishment of sand leak subnetwork on the performance of athletes' human posture estimation. Under the same other experimental conditions, experiments are carried out on different numbers of sand leak subnetworks on the dataset. As shown in Figures 7 and 8, the experimental results of the training model composed of different number of sand leakage subnetworks under the evaluation standard conditions are shown. Figures 9 and 10 show the overall PCK and PCP curves, respectively. The horizontal coordinate represents the threshold of measurement, and the vertical coordinate represents the accuracy of each joint or different part of the athlete in the video.

From the results in the figure, we can know that the performance of the athlete pose estimation model based on the multi-residual module convolutional neural network effectively improves with the increase in the number of

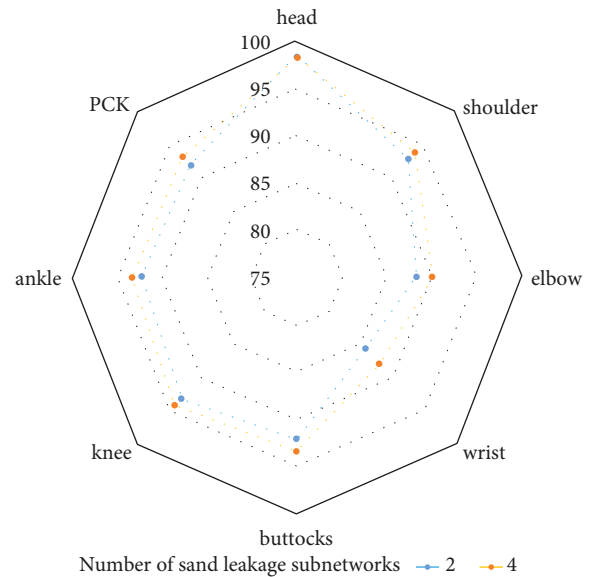

FIGURE 7: PCK results on the LSP dataset.

hourglass subnetworks. This is mainly because the individual hourglass subnetworks can only learn a limited number of image features and their effective perceptual field is relatively small, but the stacked hourglass networks are much more capable of learning feature information and can acquire more feature information. After related experiments, the number of hourglass subnetworks finally selected in this study is 4, which has the best performance in the experiment and has a certain degree of positive impact on the accuracy of the athlete's pose estimation.

FIGURE 8: PCP results on the LSP dataset.

FIGURE 10: Overall PCP curve.

FIGURE 9: Overall PCK curve.

4.2. Experimental Results of the Athlete Posture Evaluation Model Based on the Convolutional Neural Network. To help the athletes' posture estimation model based on the convolutional neural network learn better, this study combines the LSP dataset and MPII dataset for model training. Through the performance test, the experimental comparison results of PCK and PCP are obtained, while the results of other competition video athlete posture estimation methods are from the corresponding references. As shown in Figure 11, the PCK standard comparison results of the athlete posture estimation model based on the multimodule convolutional neural network on the LSP dataset are shown. Figure 12 shows the comparison results of PCP standard of athlete posture estimation model based on the convolutional neural network on the LSP dataset.

It can be seen from the results in the figure that the athlete posture estimation model based on the convolutional

neural network is competitive with other athlete posture estimation methods. Its experimental results on LSP data show that the prediction accuracy of posture estimation is high. In the standard of athletes' posture estimation results, the index to measure and evaluate the estimation accuracy of athletes' body parts is PCP. In sports training, the upper and lower arms of athletes are most affected in the fuzzy environment. However, the data results in the figure show that the accuracy of the upper arm and lower arm of the athlete posture evaluation model based on the multiresidual module convolution neural network is 88.7% and 82.3%, respectively, both of which are relatively accurate. It can be seen that the athlete posture estimation model based on the convolutional neural network can reduce the negative impact of occlusion on athlete posture estimation to a certain extent.

As given in Table 1, after training on the MPII dataset, the results of the athlete posture evaluation model based on the convolutional neural network are compared with other widely used human posture estimation methods.

It can be seen from the table that the simple superimposed hourglass model and the improved superimposed hourglass model used for athlete posture evaluation are slightly higher than the convolution neural network based on multimodule. However, in the network design of laminated hourglass, either the simple laminated hourglass model or the improved laminated hourglass model selects 8 hourglass subnetworks, while the athlete posture evaluation model based on the multimode convolution neural network only uses 4 hourglass subnetworks. This shows that the athlete posture evaluation model based on the convolutional neural network has a certain degree of improvement in the accuracy of human posture estimation. This is mainly because the athlete posture evaluation model based on the multimode convolution neural network fully considers the influence of human body part size and model large perception field when reasoning athletes' human joints. Thus, in the model training, we can fully learn the image feature

FIGURE 11: PCK standard comparison results of different athlete posture evaluation models on the LSP dataset.

Model of this study	97.7	96.0	90.6	86.0	89.7	86.3	82.6	89.7

information of different sizes, and the extended perception field provides a good basis for learning the correlation of human joints. Therefore, the accuracy of athlete pose estimation in sports game video can be improved.

With the continuous diffusion of sports training data, it becomes more and more difficult for coaches and athletes to find relevant data in a large number of videos. Sports training analysis technology has been widely used in sports and sports competitions. It can not only improve the viewing experience of the audience but also systematically evaluate the performance of individual and team athletes in high-resolution video. We can also analyze athletes' postures in visual training from multiple dimensions to obtain the real movement data of athletes in the competition. These data can help coaches and athletes understand the gap between their own movements and standard movements and can also understand the economic level of other athletes through parallel comparison, to reduce the possibility of repeated training.

5. Conclusion

Combined with the convolution neural network, this study studies the method of athlete posture estimation in sports training. In this study, a layered hourglass network based on improved module, multiscale module, and large perceptual field module is constructed. The intermediate supervision method is used to avoid the gradient vanishing problem of the convolutional neural network. The experimental results show that the athlete posture evaluation model based on the multimode convolution neural network can effectively realize the learning of multiscale image feature information in the training process. To a certain extent, it reduces the negative impact of occlusion environment on athletes' posture estimation and improves the accuracy of athletes' joint position prediction. Compared with other athletes' pose estimation methods, the athletes' pose estimation model based on the dataset convolution neural network has certain advantages and competitiveness and shows high accuracy under the widely used standard conditions. However, this method only estimates the pose of a single athlete in the sports game video and cannot solve the pose estimation problem of multiple athletes. It has shortcomings in practical application and needs further research.

Enterprise strategic management is not only an important part of enterprise work, but also an important factor to deepen the reform of management system and promote the centralized and unified management of enterprises. Enterprise strategic management is to study the major problems of survival and development of enterprises in the competitive environment from the overall and long-term point of view. It is the most important function of senior leaders of modern enterprises. Starting from the characteristics of the recognition object, this paper analyzes the individual differences of biometrics through intelligent face image recognition technology to identify biometrics, which can be used to identify different individuals. This paper studies the main problems of personnel identity authentication in the current enterprise strategic management system. Based on identity management and supported by face image recognition technology, deep learning, and cloud computing technology, the personnel management model of the management system is constructed, which solves the problems of personnel real identity authentication and personnel safety behavior control. Experiments show that the model can simplify the workflow, improve the operation efficiency, and reduce the management cost. From the perspective of enterprise system development, building a scientific enterprise strategic management system is of great significance to improve the scientific level of enterprise system management.

1. Introduction

Enterprise strategic management is not only an important guarantee for the orderly operation of the government, but also an important content of the government's own construction. The centralized management of enterprise office area is an important part of enterprise affairs and an important factor to deepen the reform of enterprise management system and promote the centralized and unified management of affairs [1]. Integrity function is the most basic function of the system. In general, the system not only has more quantitative provisions than the simple superposition of partial forces, but also has some new properties that do not have qualitative Provisions [2]. Investigating the integrity of things and understanding and handling problems from the perspective of integrity will improve the work efficiency of the organization [3]. Enterprise strategic management is an important part of system management, especially in enterprise reform and development. It plays an

important role in ensuring, coordinating, advising, and encouraging them [4]. The enterprise system urgently needs a technology that can effectively and quickly identify and control enterprise managers. Biometric technology can meet this requirement. Biometric recognition technologies such as fingerprint, iris, and face image recognition have been more and more widely used in the market because of their efficient, stable, fast, and unique characteristics [5]. Face image recognition technology is a biometric recognition technology based on face feature information. Relevant personnel can use mobile phones, tablets, and other devices to collect face image information or video stream and compare it with the template face image information in the database [6].

Enterprise strategic management innovation is the overall innovation of the system and the attribute of metabolism and self-renewal of the enterprise system itself [7]. The goal, core, and value orientation of enterprise management innovation is to realize the overall leap and

overall efficiency of the management system and promote the coordinated development and overall progress of the social system [8]. Because the existing identity information samples in the enterprise strategic management system are extremely limited, there is usually only one employee face sample. This brings challenges to the deep neural network model that needs to rely on a large number of samples for training, resulting in that the recognition results are vulnerable to various external factors, and false recognition occurs from time to time [9]. This poses a potential threat to the safe production of the strategic management system. The conditions for realizing enterprise management innovation are to improve the overall quality of managers, build a scientific and reasonable management system structure, straighten out the boundary between management system and environment, and create a good institutional environment [10]. Promoting the scientific, information, and intensive construction of centralized office areas is of great significance for organ affairs management and building a service-oriented and efficient government [11]. This paper studies the main problems of personnel identity authentication in the current enterprise strategic system and constructs an enterprise system personnel management model based on identity management, face image recognition technology, deep learning, and cloud computing support, so as to solve the problems of personnel real identity authentication and personnel security behavior control.

Face image recognition technology is a research hotspot in the field of recognition in recent years. In terms of the characteristics of the recognition object, it realizes biometric recognition by analyzing the individual differences of the characteristics of the organism itself. Therefore, it can be used to identify different individuals [12]. Face image recognition products have been widely used in people's production and life. For example, the construction of examinee authentication system using face image recognition technology can effectively improve the accuracy and speed of examinee authentication in educational examination [13]. At this stage, the enterprise strategic management system has insufficient binding force on people and lacks the management of personnel identity security, unclear personnel identity information, and nonstandard employment, resulting in management problems in the management process, but it can not accurately locate the person in charge [14].

Based on the theoretical research of face image recognition and combined with work practice, this paper discusses the application of face image recognition technology in centralized office area. There are many changes in the details of face images, and the related motion changes also have different forms. It is the nonlinear characteristics of human face that increase the difficulty of face detection and recognition technology. The personnel management model of enterprise system based on cloud computing intelligent image recognition can simplify the workflow, improve the operation efficiency, and reduce the management cost. From the perspective of the development of enterprise strategic system, the construction of scientific personnel management

system is of great significance to improve the scientific level of enterprise work in the future.

This paper studies the main problems of personnel identity authentication in the current enterprise strategic management system. The contribution of research and innovation includes the construction of the personnel management model of the management system, which solves the problems of personnel real identity authentication and personnel safety behavior control. Simplify workflow, improve operation efficiency, and reduce management cost. From the perspective of enterprise system development, building a scientific enterprise strategic management system is of great significance to improve the scientific level of enterprise system management. Based on innovation, through face image recognition technology, face image recognition technology is organically combined with anti-violation inspection and safety performance evaluation to achieve comprehensive improvement.

2. Related Work

Face recognition is a kind of biometric recognition technology, which integrates multifeilds and multidisciplines. The research direction covers a large number of basic theories, classical algorithms, and mathematical models. It is the in-depth study of these theories that makes the face recognition technology develop continuously [15]. Especially, with the remarkable improvement of computer computing ability, the algorithms and models of face image recognition can break through the bottleneck of hardware, thus entering a period of rapid development. Tong [16] puts forward a face feature point detection method based on region point projection, converts the extracted features into feature vectors, and performs similarity matching with the feature vectors processed in the database, thus completing face image recognition. In order to overcome the potential influence of external environmental factors and self-factors on face image recognition, Chen [17] proposed a geometric feature extraction method based on active appearance model, thus realizing the accurate location and extraction of face feature points. Liu et al. [18] propose to use the edge detection method in image preprocessing combined with projection function to locate the key parts of the face and construct the corresponding feature vectors. Yang [19] introduces the idea of feature vector weighting according to the correlation degree of the importance of different feature vectors to the final recognition result, so that good recognition results can be achieved in different types of data sets.

Because the face image can be regarded as a high-dimensional matrix, the subspace-based method aims to perform a series of complex algebraic transformations on the matrix, so that it can be projected from the high-dimensional space to the low-dimensional space, and keep the contents with different degrees of correlation with the face image according to the actual needs, thus reducing the computational complexity and improving the recognition accuracy. Forlano et al. [20] adopt a method combining bidirectional two-dimensional principal component analysis and neural

network. The former is used to extract features and transform them into feature vectors, while the latter uses the extracted features for training, thus completing face image recognition. In order to fully extract the information contained in the sample, Eriyanti and Noekent [21] put forward a weighted combination of principal component analysis algorithm and linear discriminant analysis algorithm for feature extraction and adopt genetic algorithm to optimize the obtained feature space. Using multitask cascade deep learning network, it can identify the individual's age, gender, and other characteristics and attributes, which has powerful functions. The above recognition algorithms with high recognition rate are based on larger learning and training libraries and more advanced computing processors and supported by a cloud platform with larger capacity. It is a big expense to install these devices or use cloud services in a single mine.

3. Principle of Face Image Recognition Technology

3.1. Face Detection. The strategic management system includes the formulation of strategy, implementation strategy, and evaluation strategy, which form a cycle of three stages. The purpose of promoting the sound development of enterprises' strategic management is to tap and create new development opportunities, obtain sustainable competitive advantage, and realize the long-term development goal of enterprises. The premise of strategic management is that enterprises must adapt to the external economic environment. The foundation of strategic management is based on the internal resource capability of the enterprise. The key to strategic management is to formulate a correct development strategy. The core issue of strategic management is to adapt the enterprise's own resources and capabilities to the external business environment.

Face image recognition technology is to judge the existence of face on the input face image or video stream and identify the face according to the face features compared with the face in the known database. At present, the commonly used face databases in the field of face recognition mainly include FERET face database and so on. Created by FERET project, it contains 14051 gray face images illuminated by multipose light. It is one of the most widely used face databases in the field of face recognition. This paper uses this database [22]. The problems of face image recognition mainly include face detection, recognition, and type judgment. Face detection is a prerequisite for all work. It is necessary to extract faces from various data sources to provide effective data support for subsequent research work [23]. Face detection is generally divided into two categories: (1) based on still images: judge the existence of the face part in the image and circle it; (2) based on video image: the video recorded by the camera can be used for image detection, which can mark the area containing the face. This method has high requirements for the algorithm. It can also be divided into detection methods based on color image (screening by skin color) and detection methods based on

gray image (matching by face feature, appearance, and face template).

3.2. Face Image Recognition Technology and Method

3.2.1. Face Image Recognition Method Based on Geometric Features. Geometric feature method regards the unique contour information, size, and position of a certain part or obvious organ of human face as the feature vector for identifying the features of individual information, and human face can be regarded as a whole, composed of ears, mouth, nose, and chin [24]. Face parts can be identified and determined according to the geometric relationship and position relationship between these parts. Firstly, a face feature extraction model is established to accurately extract and locate the geometric features of the face in the image. Secondly, the extracted geometric features are used to construct face feature vectors. Finally, the constructed feature vector is quickly compared with the feature vector in the database. If the similarity with a feature vector in the database is higher than the threshold, the comparison is successful. Under different facial expressions, facial ornaments, and different illumination, these geometric features may be deformed, so the robustness of the algorithm needs to be enhanced. If only geometric features are used for recognition, its effect is extremely unstable, so it is difficult to popularize its practicability.

3.2.2. Face Image Recognition Method Based on Feature Template. After transforming the high-dimensional image space, a new set of orthogonal bases is obtained, and the important orthogonal bases are retained, from which the low-dimensional linear space can be constructed [25]. If the projections of face in these low-dimensional linear spaces are separable, these projections can be used as feature vectors for recognition, which is the basic idea of feature template method. Firstly, the face in the original database is encoded. Secondly, the coded face images are stored. Finally, the detected images are coded in the same way. When matching is identified, the coded images are compared with the coded images in the library, and the results are obtained. The number of features in a template refers to the number of features in a subwindow. The so-called feature refers to every form formed by the feature template sliding in a subwindow with any size in turn. The form types of all features of the window can be determined by sliding various features in sequence in the window to be checked. After determining the form of features, the number of rectangular features is only related to the size of subwindows.

3.2.3. Face Image Recognition Method Based on Neural Network. The input of neural network can be face image with reduced resolution, autocorrelation function of local area, second moment of local texture, etc. [26]. This kind of method also needs more samples for training. Neural cognitive machine is a special case of neural network, and its weight sharing network structure is its greatest advantage.

This structure is very similar to the biological neural network, so that the network model can be simplified. When the input of the network is a multibit image, this advantage can be more obvious. The method of face detection based on neural network mainly studies the problems of noise and shaking caused by the natural acquisition of face images, and it is sometimes difficult to detect between a face and a nonhuman face by methods based on geometric features or templates. The detection method based on neural network needs to train and learn a large number of face samples and nonhuman face samples and determine the rule information of the two types of samples, which can distinguish between face and nonhuman face. The learning performance depends on the representative ability of the sample library to face and the accuracy of the model.

3.3. Processing Process of Face Image Recognition System. Regional feature analysis algorithm is widely used in face image recognition technology. It integrates computer image processing technology and the principle of Biostatistics, uses computer image processing technology to extract human image feature points from video, and uses the principle of biostatistics to analyze and establish mathematical model, namely, face feature template [27]. The built face feature template is used to analyze the face image of the tested person, and a similar value is given according to the analysis results. Through this value, whether it is the same person can be determined. Face feature extraction is mainly realized by algorithm, including the following steps: (1) face detection and location: detect whether there is a face in the picture. (2) Image preprocessing: process the extracted face to enhance face features. (3) Face feature extraction: extract the key features of face information. (4) Face image recognition: match the input face with the face in the database, find the face image with the smallest distance, and verify the matching degree. The face image recognition and matching process is shown in Figure 1.

The personnel behavior identification process in the enterprise strategic management system is shown in Figure 2.

Generally, the input of the system is a face image or a series of face images with undetermined identities, and several face images with known identities or corresponding codes in the face database, while the output is a series of similarity scores, indicating the identities of faces to be recognized.

4. Face Feature Recognition Based on Convolutional Neural Network

The basic structure of the convolutional neural network is shown in Figure 3. Although it is a lightweight model, it already has the basic framework of depth model, which is mainly composed of convolution layer, pooling layer, full connection layer, and Softmax layer [28].

4.1. Convolution Layer. In the convolution layer, after convolution operation, the image matrix is added with an

FIGURE 1: Face image recognition matching process.

offset, and a new feature plane can be obtained by activating the activation function. The specific calculation is as follows:

$$u_j^i = \sum_{i \in M_j} x_i^{l-1} * w_{ij}^l + b_j^l, \quad (1)$$

$$x_j^{l-1} = f(u_j^l),$$

x_j^{l-1} represents the pixel value of a point in the feature image of the previous layer; w_{ij}^l represents the $N \times N$ matrix formed by the internal parameters of the convolution kernel; $*$ represents the convolution operation when extracting features; M_j represents the feature of the previous layer involved in the operation A subset of the image; b_j^l represents the bias term, which is used to increase the nonlinearity of the model; l represents the current calculation is in the first layer.

4.2. Pool Layer. The pooling layer is used to select the features extracted by convolution. In the convolution neural network, the dimension of feature space is reduced, but the depth will not be reduced. The convolution kernel of “1 times 1” plays the role of reducing the depth. When the maximum pooling layer is used, the maximum number of input areas is used, and when the average pooling is used, the average value of input areas is used. Pooling layer is usually connected behind convolution layer and used together with convolution layer [29]. The purpose of pooling is to cluster the same features at different positions in the image, thus greatly reducing the calculation parameters in the network and effectively avoiding overfitting. At the same time, the features obtained by pooling are robust to changes such as translation, scaling, and rotation.

4.3. Full Connection Layer. Generally, the full connection layer appears after the convolution layer and the pooling layer and is used to realize the complete connection between the neurons in this layer and the neurons in the previous layer. Its main function is to transform the two-dimensional feature map output by the convolution-pooling layer into a one-dimensional vector and finally enter the Softmax layer.

4.4. Softmax Layer. The appearance of Softmax layer extends the traditional two-classification problem to multi-classification. This layer can map the input value of the fully connected layer into a probability value, and the sum of all probability values is always 1. Suppose that the input feature is recorded as $x^{(i)}$, and the sample label is recorded as $y^{(i)}$, thus forming the training set $s = \{(x^{(1)}, y^{(1)}), \dots, (x^{(m)}, y^{(m)})\}$.

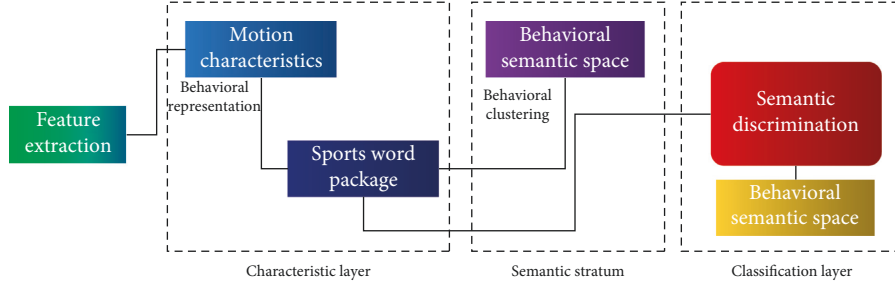

FIGURE 2: Enterprise personnel behavior identification process.

FIGURE 3: Basic structure of convolutional neural network.

When given input x , use the model to estimate each category j and get its probability value $p(y = j|x)$, where the hypothesis function is

$$h_{\theta}(x^{(i)}) = \begin{bmatrix} p(y^{(i)} = 1|x^{(i)}; \theta) \\ p(y^{(i)} = 2|x^{(i)}; \theta) \\ \dots \\ p(y^{(i)} = k|x^{(i)}; \theta) \end{bmatrix} = \frac{1}{\sum_{j=1}^k e^{\theta_j^T x^{(i)}}} \begin{bmatrix} e^{\theta_1^T x^{(i)}} \\ e^{\theta_2^T x^{(i)}} \\ \dots \\ e^{\theta_k^T x^{(i)}} \end{bmatrix}. \quad (2)$$

Among them, $\theta_1, \theta_2, \dots, \theta_k$ is a trainable parameter in the model, and $\sum_{j=1}^k e^{\theta_j^T x^{(i)}}$ is a normalized term. It aims to make the sum of all probabilities equal to 1, thereby obtaining the cost function:

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m \sum_{j=1}^k 1\{y^{(i)} = j\} \log \frac{e^{\theta_j^T x^{(i)}}}{\sum_{l=1}^k e^{\theta_l^T x^{(i)}}} \right], \quad (3)$$

$1\{\bullet\}$ is the judgment function. When the value in the brackets is true, the function outputs the result 1, and if the value in the brackets is false, the output is 0. Equation (3) is a generalization of logistic regression, so the cost function can be changed to

$$\begin{aligned} J(\theta) &= -\frac{1}{m} \left[\sum_{i=1}^m (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)})) + y^{(i)} \log h_{\theta}(x^{(i)}) \right] \\ &= -\frac{1}{m} \left[\sum_{i=1}^m \sum_{j=0}^1 1\{y^{(i)} = j\} \log p(y^{(i)} = j|x^{(i)}, \theta) \right]. \end{aligned} \quad (4)$$

For the partial derivative of the SoftMax cost function $J(\theta)$, the gradient formula is obtained:

FIGURE 4: Trend chart of the accuracy of the deep convolutional neural network verification set.

$$\nabla_{\theta_j} J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m x^{(i)} (1\{y^{(i)} = j\} - p(y^{(i)} = j|x^{(i)}, \theta)) \right], \quad (5)$$

$\nabla_{\theta_j} J(\theta)$ is a vector, and its l th element $\partial J(\theta)/\theta_{jl}$ is the partial derivative of $J(\theta)$ with respect to the l th component of θ_j . After obtaining the above formula for solving the partial derivative, use the relevant optimization algorithm to minimize the cost function $J(\theta)$. Then, the parameters need to be updated at each iteration:

$$\theta_j = \theta_j - \alpha \nabla_{\theta_j} J(\theta) \quad (j = 1, 2, \dots, k). \quad (6)$$

Finally, the SoftMax multiclassification model is obtained.

The face image recognition method based on convolutional neural network mainly relies on feature extraction from a large number of face samples. Compared with the traditional artificially designed feature extraction operator, the advantage of convolutional neural network is that it can complete the whole recognition process through its own learning mechanism without excessive human intervention. That is, using its own deep structure, the input face images are convoluted and pooled layer by layer, and after continuous nonlinear mapping transformation, the best feature extractors and classifiers can be obtained from a large number of samples.

5. Result Analysis and Discussion

During the training phase of the model, it will be tested on the verification set regularly. After continuous analysis and comparison, we finally chose 65 training times as the best training times under the condition that the batch size is 30. Figure 4 shows the trend of accuracy on the verification set along with the training process. Therefore, we can know that increasing the training times in a certain range can improve the performance of the model. On the contrary, too many training times will lead to overfitting, and the performance of the model will decrease. It can be seen that the accuracy of the verification set of the network is increasing with the convergence of the model, which verifies the correctness of the convergence of the network and the effectiveness of the network in feature extraction.

In feature extraction, it is necessary to select the most representative or prominent feature according to the application scenario, so as to ensure that the staff to be detected can successfully distinguish from other objects and achieve the best classification and recognition effect. In the detection part of neural network, several initial modules and several convolution layers are adopted, which has good nonlinear fitting characteristics. At the same time, in the part of enhanced recognition, the object features related to behavior are combined to enhance the recognition ability. The influence of feature differences between a block and its surrounding image blocks decreases with the increase of distance. The relationship between visual sensitivity and eccentricity is shown in Figure 5.

The initial model is adjusted horizontally and vertically; that is, the training times, convolution layers, convolution kernel size, optimizer type, and learning rate are changed. Finally, the structure of the neural network model is 8 layers, including 3 convolution layers, 3 pooling layers, 1 fully connected layer, and 1 output layer. Figure 6 is the accuracy curve of the model, and Figure 7 is the loss function curve. With the increase of training times, the accuracy of the network is increasing, and the loss function value is decreasing gradually, and the network basically converges after training 73 times.

During training, the loss function reflected by verification is gradually increasing rather than decreasing, which indicates that network training has entered the trap of local optimization. Figure 8 shows the relationship between iteration times and normal training and overfitting training.

The establishment of enterprise strategic management organization and its relationship depend on the long-term plan. In the process of strategic planning, the mission and vision always guide the direction and requirements of strategic formulation. The core values guide the way of thinking and implementation strategy of strategy. External environment includes macro environment and industrial environment. Corporate culture: the impact of corporate culture on corporate strategy mainly includes the following points: decision-making style, preventing strategic change, overcoming obstacles to strategic change, leading values, and cultural conflict.

FIGURE 5: The relationship between visual acuity and eccentricity.

FIGURE 6: Accuracy rate curve.

FIGURE 7: Loss function curve.

FIGURE 8: The relationship between the number of iterations and normal training and overfitting training.

Enterprise strategic management is an organic whole system composed of multiple institutions, and its structure is the contact between institutions. The establishment of its institutions and the relationship between them must be subject to the overall objectives and efficiency of enterprise management. The general model searches the image to obtain the best matching window with the tracking manager. In the training process, the classification results are obtained through the data processing process of convolution neural network and compared with the corresponding label data to calculate the corresponding relative error. After a certain number of training, the weights on the convolution window in the convolution neural network are continuously modified to reduce the relative error and finally converge.

By manually marking the reference frame as the reference true value of each frame of the actual scene video, the distance accuracy curve and success rate curve of tracking the actual scene video can be drawn, as shown in Table 1 and Figure 9. From the experimental results, it can be seen that video analysis based on convolutional neural network has better tracking effect for practical application scenes.

In the tracking process, the algorithm will give a rectangular tracking box to represent the area identified as the target, and we already know the real area box of the target in advance. By evaluating the overlap between two frames, we can effectively judge the effect of the algorithm. Figure 10 shows the tracking results of different pixels of the video by the deep convolution neural network.

In the calculation of loss function, in addition to the classification information and location information of the original target, the shape information of the target is also considered. Because the marking method of mask is more detailed than that of rectangular box, pixel level recognition can be realized. Experiments show that the model can simplify workflow, improve operation efficiency, and reduce management cost. The goal, core, and value orientation of enterprise strategic innovation are an organic

whole with internal relations. The primary goal of strategic innovation is to realize the overall leap of the enterprise itself, including the perfection and integration of its constituent elements, structure, and function. As an enterprise system, its basic elements are enterprise system and enterprise personnel. The overall efficiency of the strategic system depends on the work efficiency of various

departments and personnel. From the perspective of the development of enterprise strategic system, building a scientific enterprise strategic management system is of great significance to improve the scientific level of enterprise management. Only by establishing a scientific and reasonable overall structure of the system and coordinating the relationship between the whole and the part and between the part and the part can we ensure the consistency of the whole and the part in the operation direction and speed, reduce mutual interference, restrict and offset them, and improve the overall function of the system.

6. Conclusions

Intelligent video surveillance system is the inevitable product of the development of video surveillance technology. At present, face image recognition technology is mainly used in the fields of enterprise and residential security management, e-passport and ID card, public security, judicial and criminal investigation, information security, and so on. The overall innovation of enterprise strategic system is a process of theoretical innovation, practical innovation, and their interaction and organic combination. This process needs not only theoretical innovation to guide the direction, but also practical innovation to open up the road. From the perspective of institutional development, building a scientific enterprise management system is of great significance to improve the scientific level of management in the enterprise system. Any social organization is composed of people. Therefore, the overall progress of the enterprise system depends on the general improvement of personnel quality and creativity. In the final sense, both the goal of innovation and the efficiency of innovation should be subject to the overall interests of the whole society and the needs of long-term sustainable development.

Based on the idea of parallel computing, the improved multiface real-time detection algorithm in this paper transforms the multiface detection problem into a single face detection problem through image segmentation technology, so as to realize the real-time detection of multifaces in video images. The enterprise strategic system management model based on cloud computing intelligent image recognition can simplify the workflow, improve the operation efficiency, and reduce the management cost. Based on innovation, the management system can organically combine face image recognition technology with anti-violation inspection and safety performance evaluation through face image recognition technology to achieve all-round improvement. However, there are still some problems that need to be modified. There are still some problems in the face image recognition algorithm in intelligent video surveillance system, such as the optimization of big data video image and the stability of the algorithm, which need to be further studied.

Gymnastics is an increasingly popular sport and an important event in the Olympic Games. However, the number of unavoidable injuries in sports is also increasing, and the treatment after the injury is very important. We reduce the harm caused by the injury through the identification and research of pictures. Image preprocessing and other methods can in-depth learn about gymnastics sports injuries. We identify the injured pictures of athletes to know the injury situation. Through the analysis of the force of the athletes during exercise, they can be better integrated into picture recognition for sports injuries. More appropriate prevention and treatment measures are suggested.

1. Introduction

The purpose of this article is to recall NCAA monitoring data on women's gymnastics injuries and to identify areas of potential injury prevention measures. Between 1988 and 1989, 1,550 people participated in the women's varsity gymnastics team. In 2003, the number of varsity teams decreased, affecting many participants. The results showed that the average annual injury rate during the sample period decreased, but not in practice. In 16 years, the injury rate in the competition was higher than the actual rate, and the lower half of the body was injured more frequently. The reason for the injury was explained, and suggestions were made for those with bare feet. Athletes use prophylactic tape to reduce the risk of injury, and preventative measures will add more planning to training to enhance the correct mechanism and make the device more absorbent [1]. Sports trainers collected injury information from many participants and looked at a wide variety of injuries. Compared to other sports, injuries to the back and lumbar regions were more frequent, and bare feet injuries were also common because the thigh and the leg were overused; it can be seen from the above that

women's gymnastics has great room for improvement in many aspects [2]. This article examines the number and types of injuries in non-professional gymnasts. At the same time, it can also know what are most dangerous, and investigate whether various factors such as the proportion of participants' coaches affect the injury rate. Survey data show that professional gymnasts have higher injury rates and non-athletes have lower rates. To sum up, the level of competition has a great relationship with the injury rate [3]. College-level injury testing data are limited. The researchers still have not caught non-time-loss injuries. The purpose was to describe the epidemiology of injuries in women's gymnastics by pooling injury and exposure data from 11 sports. Athletic data, injury rates, injury rates for body parts, diagnoses, and equipment for collegiate athletes participating in women's gymnastics were derived from 28 seasons of data [4]. Long-term exercise for youth training and competitions can lead to back pain that must not be relaxed. Measures should be taken to treat it when one is young, and treat it in the early stage to achieve a higher therapeutic effect. For pain that lasts for a long time, one should pay attention to the need for careful inspection, and bone scans and other techniques should be performed

if necessary. Diagnose the cause [5]. Gymnastics has a lower frequency of injuries in sports. At the same time, based on objective information such as gender and age, the pattern of injury can be predicted. Girls are more likely to be injured. Most of them have wrist pain and low back pain, while some spinal abnormalities were also found. Imaging can also guide the recovery of injured athletes, and parents should know that recreational gymnastics has fewer injuries while more injuries have been found in high-level athletes [6]. According to sports clinic observations, patellar joint pain syndrome is higher, sprains are the biggest problem in emergency surgical treatment, overuse is related to the training intensity, and motor skills can also lead to serious leg injuries [7]. Michelle is the club's project manager. With a large number of gymnasts, Michelle is an integral part of the national team plan, who has been training athletes and has produced many gold medal winners. Michelle has an excellent educational background and wrote the Gymnastics School of Excellence program. Michelle will talk about the prevalence of injuries to better care about the growth of youth sports [8]. Infrared images have many advantages, which can make up for the deficiencies of infrared image face clarity. This technology is an important research direction in the field of face recognition. On the basis of analyzing the characteristics of infrared images, it also analyzes humans. The characteristics of a facial recognition software and a new infrared image recognition method are proposed. Experiments show that this method is feasible [9]. Image recognition methods require a large number of samples to achieve good performance. In some cases, a large number of samples cannot be obtained, which will lead to poor performance. However, commonly used neural network classifiers minimize empirical risk. This paper establishes a method to combine wavelet giant and svm by finding the optimal solution. In the simulation, various tank images are extracted and identified separately. The results show that the algorithms that combine the two are better in small sample cases [10]. The correlation matching algorithm is of great significance, but also faces a key problem. The problem is with sudden changes in the image. This paper examines different application areas and investigates new methods to solve the problem. One is to rotate and rebuild new model diagrams under laboratory conditions. Another approach is to exploit fixed features along with image variance and symbolize them as cells of the correlation matching map [11]. Medical images are the research subject, and the characteristics of images cannot be effectively expressed at present. Therefore, in order to improve the recognition rate, a new algorithm is proposed, which combines two kinds of data. The result is that the fused features can be better expressed for medical images, reducing the workload, and decision-level data fusion can achieve higher recognition rates [12]. In image edge distortion correction, the edge fitting is poor, and hence the correction error is large. In this paper, an image edge true correction algorithm based on the equalization algorithm is proposed, the parameters are adaptively switched by the method, and the image is optimized according to the image

denoising result. According to the extraction results, the optimization function is obtained. This paper considers the noise barrel distortion and pincushion distortion images as the research objects [13]. In order to meet the requirements, a new hot-stamping image recognition algorithm is proposed. The minimum point is the best result through subsequent operations such as digital image conversion and spatial extraction of channels. The results show that identifying the hot-stamping area and improving the matching speed have guiding significance for the quality detection of this technology [14]. At present, image recognition has research value in the field of computer recognition. With the development of national strength, the application of these innovative technologies to pig detection is of great help to the breeding of animal husbandry and the convenience of human beings. This paper makes a great introduction to the individual identification technology of pigs and the current research direction of this innovative technology [15].

2. Image Recognition Research

2.1. Image Recognition of Static Objects. We mainly use the following four methods for image recognition: data feature analysis, image preprocessing, feature extraction, and pattern recognition.

2.1.1. Data Feature Analysis. To achieve static object recognition, the data in a specific object image must first be analyzed to determine what data to retrieve in the object image. According to these characteristics, we analyze the characteristics of the image data, choose the appropriate method during the analysis, and find ways to remove the background and highlight the target. From this, we can see that when performing this step, we need to have a comprehensive understanding of the picture, and different methods need to be used for different picture objects.

2.1.2. Image Preprocessing. Because the image will be damaged and polluted by noise, it will more easily become unsuitable for people's needs or lose the essence of the image during transmission and storage. Therefore, we should preprocess the image to reduce its influence on the image. For simpler image recognition systems, image preprocessing usually includes image enhancement and restoration, but for slightly more complex images, we also perform image segmentation on the image.

This step is mainly to weaken the features that people do not need very much to avoid affecting judgment, and at the same time strengthen the features that people need to pay attention to. Spatial domain methods include processing images directly in the spatial domain, which can be divided into two aspects: point operations and neighborhood operations (local operations). The frequency range method only calculates the image transformation value of the specified image transformation area, calculates the image spectrum of the transformed area, and then inverts the final calculated image in the spatial area. The frequency range

method is generally divided into high magnification filter, low magnification filter, bandpass filter, and notch filter.

Image restoration is to change the image into its original essence, using prior knowledge to change the process of degrading the image. Image restoration technology needs to establish a degradation model and reverse the degradation process to obtain the optimal image before degradation.

Image segmentation first divides the image into several meaningful regions, then determines whether there are objects of interest in these regions, and narrates the content on the image. At present, we divide image recognition and segmentation into two methods. The first is a region-based image segmentation algorithm and the second is a boundary-based segmentation algorithm. Image segmentation also has its own disadvantages, and image segmentation algorithms have certain limitations in their application. For example, the key to the threshold method is the selection and determination of the threshold. Different thresholds have completely different effects. Setting the threshold too low will produce noise, and setting the threshold too high will eliminate noise. With no noise signal, it is difficult to define the starting points and similarity criteria in region growing methods, and the quality of the adjustments greatly affects the efficiency of segmentation. Edge detection difficulty is a way to balance detection accuracy and noise immunity. The watershed method is too sensitive to noise and thin lines and is prone to over-segmentation. In general, some image segmentation algorithms must target specific types of images or specific applications. Thus far, no general and effective image segmentation algorithm suitable for all image segmentation has been found, and there is no generally accepted objective standard to evaluate segmentation performance.

- (1) Information acquisition: It is to convert information such as light or sound into electrical information through sensors. Information can be two-dimensional images such as text, images, etc.; can be one-dimensional waveforms such as sound waves, electrocardiograms, and electroencephalograms; or physical quantities and logical values.
- (2) Preprocessing: It can include A/D, binarization, image smoothing, transformation, enhancement, restoration, filtering, etc., and mainly refers to image processing.
- (3) Feature extraction and selection: In pattern recognition, it is necessary to extract and select features. For example, a 64×64 image can obtain 4096 data, and the original data in the measurement space can be obtained through transformation. Features that reflect the nature of the classification process are feature extraction and selection.
- (4) Classifier design: The main function of classifier design is to determine decision rules through training, such that the error rate is the lowest when classifying according to such decision rules.
- (5) Classification decision: Classify the recognized objects in the feature space.

2.2. Research Status Based on Image Recognition Technology. Image recognition technology uses computer technology to realize the recognition function of human vision, i.e., to detect and recognize objects from images and other information. Most of the applications of recognition technology in modern augmented reality systems are computer vision-oriented image recognition, including sign-based augmented reality and unsigned augmented reality. The basic principle of augmented reality based on symbol recognition is to solve the current pose of the camera by performing image recognition on the symbol points of fixed geometric figures using ARToolKit, ARTagl, etc. However, augmented reality systems based on sign recognition are narrower in scope, as signs must be within the camera's range. Meaningless augmented reality based on natural characteristics is the application of image recognition technology in augmented reality systems. The feature is that there is no need to arrange panels in advance, and the application scenarios are wide. In 1999, Neunn et al in the University of Southern California began to combine in-image target recognition and tracking algorithms to propose an augmented reality system for scene annotation based on industrial 3-D images.

3. Muscle Model

3.1. Muscle Model. One of the most important tasks in sports biodynamic farming is selecting the correct muscle model. The most basic muscle model consists of springs and cushioning materials. The muscle model class proposed by Hill in 1938 reflects a single viscoelastic property of muscle. The ground model consists of linear and viscoelastic elements, and the model has been widely used since then for biomechanical analysis. The hedgehog muscle model consists of three elements: an active contraction element, a parallel elastic element, and a series of elastic elements. Among them, the active contraction element is described by three relational expressions: longitudinal tension ratio, velocity tension ratio, and muscle activation level. Muscle activation levels range from 0 (disabled) to 1 (fully activated). When a muscle becomes fully tonic, both muscle strength and muscle fiber length are within a certain range, indicating a "parabolic" relationship. Maximum contractile force occurs at $-N$. Here death is the optimal length of muscle fibers.

The active force-length curve of a muscle is described by the following parabolic function:

$$\int_L^{\text{act}} = 1 - \left[\frac{(L^M/L_0^M) - 1}{0.5} \right]^2. \quad (1)$$

In this formula, \int_L^{act} is the length tension relationship when main power is supplied; L^M is the muscle length; and L_0^M is the relatively optimal muscle fiber length. The passive dynamic length curve of the muscle is described below.

The relationship between passive force and length:

$$\int_L^{\text{pa}} = \left(\frac{L^M}{L_0^M} \right)^3 \exp \left(8 \frac{L^M}{L_0^M} - 12.9 \right). \quad (2)$$

The relationship between force and velocity can be represented by a hyperbola when the muscle is coaxially isometrically contracted:

$$\int_v = \frac{v_0^M - v^M}{v_0^M + cv^M}. \quad (3)$$

v_0^M and v^M represent the speed of retraction and contraction, and in off-axis isometric contraction; the relationship between force and speed is defined as:

$$\int_v = \frac{2v_0^M - b' + v^M(a'/F_0^M)}{v_0^M - b'}. \quad (4)$$

We assume that the contraction speed of the muscle will be little affected by the viscous effect of the muscle, while the tension speed curve and the tension length N line of the active force of the muscle both need to be scaled by the activation level $a(t)$ before they can be used, and there is feathering angle:

$$a = \arctg\left(\frac{L_0^M \sin \partial_0}{L^{MT} - L_S^T}\right). \quad (5)$$

$L^{MT} = L^T + L^M \cos \partial_0^{MT}$ is the total length of the muscle-tendon component; L_S^T is the relaxed length of the tendon; ∂_0 is the feathering angle at optimal fiber length; thus, the total muscle force F^{muscle} can be expressed as:

$$F^{\text{muscle}} = F_0^M (f_L^{\text{act}} f_v a(t) + f_L^{pa}) \cos(\partial). \quad (6)$$

The expression of muscle activation level $a(t)$ is:

$$a(t) = \frac{(u^2 - ua)}{t_{\text{rise}}} + \frac{(u - a)}{t_{\text{fall}}}. \quad (7)$$

F_0^M represents peak muscle force at optimal muscle length, u indicates muscle excitability, and t_{rise} and t_{fall} represent the ascending and descending processes of muscle activation, respectively.

3.2. Huxley Muscle Model. Although the Hill model is widely used, it cannot directly reflect the biochemical process of muscle energy production. The principle of chemistry was cited in 1957, when Huxley developed the Huxley muscle model, also known as the sliding silk model.

Huxley and later Zahalak used the distributed torque approximation method when using the slip-line model. The distributed torque approximation transforms the Huxley model into a series of ordinary differential equations, allowing the method to be solved numerically.

The Huxley-Huxley muscle model accounts for the speed of myofilament connection and separation, the overlapping function of calcium activation (the relationship between the sarcomere strength and the sarcomere length), and the relationship between calcium concentration and the activation level in fibers when describing muscle contraction. In optimization theory, the frequency of muscle stimulation is a variable that affects the magnitude of the total muscle force. The frequency range for muscle

stimulation is $<1100>124$ Hz. The Huxley muscle model is based on the sliding filament theory and describes the biochemical effects of muscle during the contraction process. The distribution function $n(\theta)$ represents the distributed number of cross-bridge connections, i.e., the logarithm of actin and myosin bonds as a function of cross-bridge length. Since bridging and breaking are assumed to be time-dependent functions $n(\theta, t)$, the muscle force velocity curve becomes an implicit function. The connection rate f and the disconnection rate g of the cross-bridge depend on the normalized cross-bridge length θ .

$$f(\theta) = \begin{cases} 0 - \infty < \theta < 0 \\ 43.3\theta 0 < \theta < 1 \\ 01 < \theta < \infty \end{cases}, \quad (8)$$

$$g(\theta) = \begin{cases} 209 - \infty < \theta < 0 \\ 10\theta 0 < \theta < 1 \\ 10\theta 1 < \theta < \infty \end{cases}.$$

The muscle force-length relationship is included in the overlap factor $\partial(l)$ middle:

$$\partial(l) = \begin{cases} 1 - 6.25(l - 1)^2 l < = 1 \\ 1 - 1.25(l - 1) l > 1 \end{cases}, \quad (9)$$

$l = l_s / l_{s,\text{opt}}$, where $l_{s,\text{opt}}$ corresponds to the sarcomere length when the sarcomere can provide maximum muscle force.

The distribution function $n(\theta, t)$ can be expressed as:

$$\frac{\partial n(\xi, t)}{\partial t} - v(t) \frac{\partial n(\xi, t)}{\partial \xi} = r(t) f(\xi) [\alpha(l) - n(\xi, t)] - g(\xi) n(\xi, t). \quad (10)$$

3.3. Image Recognition Digitization. To process images on a computer, we convert the processed analog images into digital image information. Image digitization refers to the sampling and quantization of images, i.e., converting continuous image signals into discrete digital signals for computer processing.

Sampling is the process of discretizing (coordinates) the real space scene to form a digital representation (i.e., the image is represented by the gray value of some points in space, and these points are called sampling points).

A black and white image can be viewed as a two-dimensional continuous function $f(x, y)$, and its value is expressed as the (x, y) brightness of the location image. A compute digital image is represented by a matrix or two-dimensional matrix $[f]_{m \times n}$. Matrix operation is performed on the digital image to obtain the desired image from a two-dimensional continuous function $f(x, y)$ to digital image matrix $[f]_{m \times n}$. It involves taking the function values of different data as samples, and using the discrete values that can be obtained to represent the two steps to complete the picture.

Sometimes, the original information of the image obtained after scanning cannot be preserved, i.e., the spatial

density of the sample is not suitable or the brightness of the sample is not enough in scale, and the image must be reconstructed from the restoration.

Sampling is the first step in image digitization. In digital images, samples should be taken from two spatial directions. The matrix is obtained by taking M along the x -direction of the image and N points along the y -direction. After a sample has been extracted from an image, the value of the resulting sample must be determined before entering it into a computer. Specifically, span a range of sample values and then use a single value to represent all the values of that layer. According to the integer storage convention in the computer, the value range of the sample value can be divided into $k = 2^i$ level, generally $i = 8, 7, 6$, and the gray pixel value can be divided into 64, 128, 256 levels, generally called 64, 128, 256 grayscale. The higher the number of layers, the closer the actual image retrieved by the quantized value of the sample is to the original image.

Image reconstruction is the inverse process of image sampling done from image $f_s(x, y)$ to consecutive images $f(x, y)$. The commonly used quantization scheme is uniform, namely the length of the sub-cycle. When the sampling theorem is satisfied, we have:

$$F(u, v) = \Delta x \Delta y F_s(u, v) H(u, v), \quad (11)$$

which is:

$$f(x, y) = \Delta x \Delta y h(x, y) * f_s(x, y),$$

$$H(u, v) = \begin{cases} 1 & u \in [-w_u, w_u], \quad v \in [-w_v, w_v] \\ 0, & \text{other.} \end{cases} \quad (12)$$

Thus,

$$h(x, y) = 4w_u w_v \sin c(2\pi w_u x) \sin c(2\pi w_v y). \quad (13)$$

However,

$$f(x, y) = k \sin c(2\pi w_u x) \sin c(2\pi w_v y) * f_s(x, y). \quad (14)$$

Again,

$$f_s(x, y) = \sum_{m=-\infty}^{+\infty} \sum_{n=-\infty}^{+\infty} f(m\Delta x, n\Delta y) \delta(x - m\Delta x, y - n\Delta y). \quad (15)$$

The above derivation shows that the reconstructed image is the result of the weighted summation of many two-dimensional sinc functions located on $x = m\Delta x, y = n\Delta y$.

One-dimensional case:

$$f(x) = k \sum_{m=0}^{M-1} \sin c[2\pi w_u(x - m\Delta x)] f(m\Delta x). \quad (16)$$

The essence of sampling is how many points are used to describe an image, and the quality of the sampling results is measured by the image resolution mentioned above. Quantization refers to the range of values to be used to represent each point after the image is sampled. The result of quantization is the total number of colors that the image can hold, which reflects the quality of the sampling. The amount

of image data obtained after digitization is very huge, and coding technology must be used to compress the amount of information. In a certain sense, coding and compression technology are key to realize image transmission and storage. There are many mature coding algorithms applied to image compression. The most commonly used are image prediction coding, transform coding, fractal coding, and wavelet transform image compression coding.

Quantization is the process of converting the corresponding continuous change interval of brightness on the sampling point into a single specific number. After quantization, the image is represented as an integer matrix. Each pixel has two properties: position and grayscale. Positions are represented by rows and columns. Grayscale is an integer representing the lightness and darkness at that pixel location.

3.4. Image Preprocessing. In the process of image acquisition, due to the influence of signal transmission, camera, brightness, etc., the acquired image will have great noise suppression. In the case of restoring most of the original image, suppress the image noise as much as possible.

Bilateral filtering is a nonlinear filtering method that expresses compromise processing by combining the spatial proximity of images and the similarity of pixel values.

Usually we use: mean filter, median filter, maximum and minimum filter, bilateral filter, and guided filter.

Since the spatial information and grayscale similarity are considered, the purpose of edge preservation and denoising can be achieved. It's native, non-iterative, and simple. The biggest advantage of bilateral filters is that they preserve edges. Since the algorithm in this paper needs to analyze the motion characteristics of gymnastics contours and preserve boundary information, bilateral filters are selected as the image preprocessing method. Bilateral filter is a nonlinear filtering method, which is a compromise processing combining the spatial proximity of the image and the similarity of the pixel value.

The expression for a noisy image is:

$$g(x, y) = f(x, y) + n(x, y), \quad (17)$$

where f refers to the image after noise reduction and n is the noise. The pixel values of the image restored by the bilateral filter are obtained by the method of local weighted average:

$$\hat{f}(x, y) = \frac{\sum_{(i,j) \in S_{x,y}} w(i, j) g(i, j)}{\sum_{(i,j) \in S_{x,y}} w(i, j)}. \quad (18)$$

$S_{x,y}$ is a neighborhood representing the size of the center point A, and $g(i, j)$ represents each pixel in the neighborhood.

$$w_s(i, j) = e^{-|(i-x)^2 + (j-y)^2| / 2\delta_s^2},$$

$$w_r(i, j) = e^{-|g(i, j) - g(x, y)|^2 / 2\delta_r^2}, \quad (19)$$

$$w(i, j) = w_s(i, j) w_r(i, j),$$

w_s represents the spatial proximity factor and w_r represents the luminance approximation factor. The bilateral filter is affected by three parameters: the filter half-width N , and parameters δ_r and δ_s . The larger the N , the stronger the smoothing effect, δ_s and δ_r ; then, control the attenuation degree of the spatial proximity factor and the luminance approximation factor, respectively.

w_s represents the spatial proximity factor and w_r represents the luminance approximation factor. They determine the smoothing effect of image preprocessing. Control the attenuation of the spatial proximity factor as well as the luminance proximity factor.

When we identify objects, the most critical factor is the gradient (a lot of feature extraction, SIFT, HOG, etc. are essentially the statistical information of the gradient); the gradient is the edge and is the most essential part; to calculate the gradient, naturally grayscale images are used. The color itself is very easy to be affected by factors such as light, and there are many changes in the color of similar objects. So the color itself is difficult to provide key information. 2010PAMI has some work of colorSIFT, which is also the gradient of different channels.

4. Analysis of the Experimental Research

4.1. Comparison of the Research Methods. There are various methods for image model recognition. According to the features extracted from image pattern recognition, image recognition methods can be divided into the following categories: feature-based shape recognition technology, color feature-based recognition technology, and texture feature-based recognition technology. Among them, the graph-based learning method finds and describes the shape of the object in the image and completes the classification of different images. The common variables that are used to represent shape include parameters, area, circularity, eccentricity, etc. Color detection technology is mainly based on color images, and the color histogram is relatively simple and insensitive to image size, rotation, and type recognition. To detect texture features, various methods that analyze the statistics of very regularly structured lines in the image or the distribution of color intensity in the image are used as shown in Figures 1–3.

Sports injury pictures need more detailed methods to identify; we usually use texture features to identify sports injuries.

After investigating five sets of data, we can clearly see that the three commonly used image recognition methods have their own advantages and disadvantages. In terms of promotion, the public is accustomed to distinguishing from color first; thus, the color features are the most popular, and texture features are the most rigorous and accurate. The rate is the highest, and the shape features are in between.

According to the difference of pattern features and decision patterns, the types of image recognition patterns can be roughly divided into two categories: statistical methods (decision theory) and syntactic (structural) thinking methods. In addition, with the continuous research of pattern recognition technology in recent years, the fuzzy

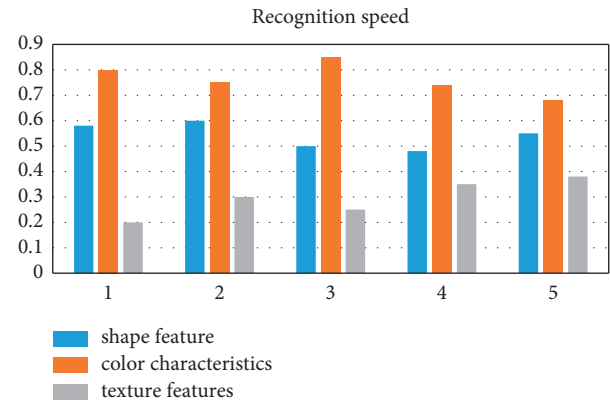

FIGURE 1: Comparison of the recognition speed.

FIGURE 2: Comparison of the recognition accuracy.

FIGURE 3: Comparison of the recognition promotion degrees.

pattern recognition method and the neural network pattern recognition method have also been widely used.

Various retrieval methods based on shape features can effectively use the target of interest in the image for retrieval, but they also have some common problems, including: ① The current retrieval methods based on shape still lack a relatively complete mathematical model; ② If the target is deformed, the retrieval results are often unreliable; ③ Many shape features only describe the local properties of the target, and a comprehensive description of the target often requires high computing time and storage capacity; ④ Many shape

features reflect that the target shape information is not completely consistent with human intuition, or the similarity in the feature space is different from the similarity perceived by the human visual system. In addition, the 3D object represented from the 2D image is actually just the projection of the object on a certain plane in space. The shape reflected from the 2D image is often not the real shape of the 3D object, due to the change of viewpoint, and various distortions may occur.

It can be clearly seen that the three commonly used image recognition methods have their own advantages and disadvantages. In terms of promotion, the public is accustomed to distinguishing from color first, so color features are the most popular, texture features are the most rigorous, the recognition accuracy is the highest, and shape features are the highest in between.

4.2. Research Objects and Methods

4.2.1. Research Objects. The famous rhythmic gymnasts participating in the “China Art Sports Cup” National Rhythmic Gymnastics Championship are shown in Table 1.

4.2.2. Research Methods. We use sports injury registration in medical research institutes and perform pathological picture recognition on gymnasts. Sports injury identification is related to physical health. We adopt a more rigorous texture identification and mainly investigate the injury situation in the past year.

The above Figure 4 is an example of the injuries caused by gymnastics. We can judge the severity of the injury by performing texture recognition on the pictures and come up with a better treatment plan. After more than 100 case studies, the research results were obtained.

4.3. Research Results

4.3.1. Overall Incidence of Sports Injuries. During the survey, we identified the pathological pictures of the sports injuries of 126 athletes to determine the injuries. The survey results showed that only a small number of athletes were not injured, and the injury rate was as high as 80%. See Table 2 below.

4.3.2. Injury Nature of Sports Injuries. We investigated the injury nature of sports injuries, and the results showed that a total of 172 cases (person) had mild or severe injuries in sports. Our survey results are shown in the following Table 3. (See Table below).

4.3.3. Injury Degree of Sports Injuries. We investigated the injury degree of sports injuries and found that the degrees of sports injuries were different. Mild injuries accounted for 84.30% of the surveyed proportions, moderate injuries accounted for 14.53%, and severe injuries accounted for 1.16%. See Table 4.

4.3.4. Injured Tissue of Sports Injuries. We surveyed 172 injured athletes and found that there were 0 skin injuries, accounting for 0% of the total injuries; 84 injured athletes had muscle injury, accounting for 48.84% of the respondents, 35 injured athletes had joint injury, accounting for 20.35% of the respondents, 52 people had skeletal injury, accounting for 30.23% of the respondents, and 1 person had nerve injury, accounting for 0.58% of the respondents. See Table 5.

4.3.5. Injury Site of Sports Injury. Rhythmic gymnasts were injured in the following order: spine (68), bare feet (45), lower limbs (30), knee joint (20), shoulder (3), wrist (2), elbow (20), head (1), and chest and abdomen (1). See Table 6.

4.3.6. Injury Causes of Sports Injuries. According to consultation documents, expert opinions, and conversations with athletes, techniques, drawbacks, equipment, designated venues, poor physical conditions, insufficient training activities, chronic excessive exercise, inappropriate training methods, etc. are the main causes of injury. A questionnaire based on the same causes was circulated to the athletes. There are 10 types of damage from fatigue, and one or more causes of damage can be selected for each type of damage. The causes of injury were classified as: prolonged excessive exercise (78 cases), improper training methods (38 cases), technique (23 cases), fatigue (14 cases), inertia (10 cases), insufficient preparation (10 cases), and many other specific reasons. See Table 7.

4.3.7. Treatment and Prognosis of Sports Injuries. In this survey, many athletes use traditional Chinese techniques such as acupuncture, massage, cupping, scraping, etc. for treatment, and some also use stretching, fixed reduction, and strength training physiotherapy for rehabilitation. The specific survey results are shown in Table 8. Athletes feel that the treatment effect is not obvious.

4.4. Analysis of the Research Results

4.4.1. Overall Incidence of Sports Injuries. As shown in Figure 5, this study investigated 126 rhythmic gymnasts participating in the “China Rhythmic Sports Cup” National Gymnastics Championships. Among them, 102 athletes had injuries of varying degrees. The high incidence of total injuries is a huge risk for the development of rhythmic gymnastics in our country. It can be seen that in the development process of gymnastics, more attention should be paid to sports injuries and the active measures and the effectiveness of preventive measures to prevent or reduce the occurrence of athletes’ injuries as much as possible.

4.4.2. Injury Nature of Sports Injuries. The ratio of acute to chronic injuries in a survey of 172 injuries is shown. We found that chronic injuries in gymnastics are much higher than in other sports. Chronic injuries are becoming more common as training intensity increases the physical wear

and tear on the body. As with most competitive sports, chronic injuries in rhythmic gymnastics are more common than in other sports. The incidence of chronic injuries has

gradually increased due to the increased technical difficulty and increased exercise duration, load, and intensity in addition to non-systematic rehabilitation after acute injury,

training with injury, and chronic injury. This suggests that solutions for chronic injury and post-injury training and rehabilitation are still insufficient as shown in Figure 6.

4.4.3. *Injured Tissue of Sports Injuries.* As shown in Figure 7, among the 172 injuries in this investigation, the proportion of injured tissue in each athlete in sports injuries is shown in the figure. Obviously, we can conclude that muscle and spinal cord injuries and keen injuries are due to gymnastics and cause polyrhythmic damage. Skeletal muscle injuries were particularly common, suggesting that problems with

post-exercise muscle strength and rhythm recovery should be of great concern to gymnasts.

4.4.4. *Injury Site of Sports Injury.* Gymnastics sports injuries mainly include three injured parts: the spine, ankles, and lower limbs, as shown in Figure 8, which corresponds to the characteristics of rhythmic gymnastics. Gymnast rhythm is a fighting art that requires various combinations of movements, such as balance, dance, rotation, and similar movements; the spine is the center of the trunk activity, and the muscles are the driving force for spinal movement. Spinal cord injuries include cervical, thoracic, lumbar, the five segments of the coccyx, the muscle and fascia of the vertebral lobe, and the upper vertebral body. The rhythm of gymnasts requires athletes to have good spinal flexibility, strong muscle strength, and three-dimensional dynamics to perfect difficult and complex movements. Rhythmic gymnastics and gymnastics have excellent movements, fast speed, and many darts: if the strength is insufficient, the movements are fierce, and it is easy to cause local cumulative damage. The spinal muscles are rich and different in size and degree; a lack of strength or imbalance results in spinal deformities, such as cervical vertebral arch and thoracic scoliosis. Investigations have shown that the curvature of the spine in athletes is very pronounced and to varying degrees;

FIGURE 6: Damage nature.

FIGURE 7: Damaged tissue.

FIGURE 8: Injury site.

the deformation of the spine in turn affects the center of motion of the entire chain, and then a vicious circle begins, affecting most disciplines. In the past, spinal cord injury was much larger than knee joint and other joint injuries, accounting for 39.53% of the total injury, which promoted the solution of the prevention and treatment of spinal cord injury. The spine is the central axis and pillar of the human body and has the function of supporting the load; the spine is an arched structure with good elasticity, which plays the role of transmitting pressure and damping vibration. The lever is attached to this point. The nature of this phenomenon promotes the uneven development of muscle strength on

both sides of the spine, resulting in twisting of the spine, which in turn leads to a series of injuries to the bones, muscles, and fascia. This is a vicious circle that seriously affects the sports discipline and competition. The muscles on both sides of the spine are very rich and are critical to the balanced development of muscle strength in addressing spinal cord injuries. Core strength training reduces spinal cord strain, thereby reducing the damage to various spinal structures. While strengthening both sides, the weak side should be lifted, but the extension of strength should not be neglected. Deep muscles should be strengthened via exercise; the stability of the spine should be strengthened and the physiological structure of the spine should be normalized. In terms of recovery training, therapeutic treatment, spinal manipulation, spinal gun application, and extension, treatment, and rehabilitation methods are coordinated and intersected to achieve the purpose of spinal cord injury rehabilitation. The reason for ankle injuries is that rhythmic gymnastics is a sport based on dance equipment (rings, balls, sticks, belts, and ropes); standing movements are usually done by steps and by weight. In addition, when jumping, balancing, and turning around, the center of gravity of the human body changes, and the gravity falls on the outermost side of the foot, causing uneven force on the swinging part of the foot. The muscles and ligaments on the restless side are prone to cause ankle flexion and foot inversion, joint dislocation, and damage the lateral synovial joint and the anterior fibular ligament. If there is no systematic rehabilitation training, it is easy to hurt the ankle. The correct rhythm of gymnastics is to walk in “beauty” with both feet. Therefore, the form of external opening is necessary, which has a great relationship with the gymnastics rhythm, and the external rotation of the lower limbs must reach the maximum external hip. Herman’s axis is always in a straight line. However, “enlightened measures must be taken to grip the joint so that the inside of the foot touches the ground and ‘falls the foot.’” The high incidence of disc injuries in the foot cannot be underestimated and often affects whether a player is able to train and play. Important: A support band or ring can be applied to the swinging joint prior to exercise to reduce or prevent injury around the joint to be repaired. In addition to structural normalization, tissue rehabilitation must incorporate the complex functional capabilities of this part. The lower extremity is primarily fatigued (periostitis), often doing standing kicks and jumping exercises; fatigue is easily caused by the anterior osseous muscles, and these muscles are not easy to stretch and relax at will. Periostitis is a result of fatigue. The main reason is that there are too many technical jumps but insufficient knee muscle strength, difficult training, unreasonable technical movements, etc. In summary, we can clearly see that young gymnasts have limited physical ability and their physical ability is affected by fiber load. The coach must follow and guide patiently, train step by step, and try to avoid sports injuries.

4.4.5. *Sports Injury Factors.* See Figure 9. Among the injury factors, too long training time, improper training methods, and technical reasons are the main injury factors of sports

FIGURE 9: Causes of damage.

FIGURE 10: Treatment method.

injuries, and preparations for the athlete’s physiological and physical functions, medical monitoring, and follow-up care should be made at all times. The training volume, excessive training, and fatigue can make the athlete’s body more prone to injury. Coaches should have a more comprehensive understanding of each athlete and arrange training reasonably according to each athlete’s situation and should also work harder on the prevention of fatigue.

Fatigue and physical conditions can lead to injuries, suggesting the need to establish precautionary principles. In addition, the lack of preparation and laziness are also completely preventable causes of injury. Coaches should always remind athletes to prepare carefully and fully participate in warm-up exercises, so as to better protect their bodies and devote themselves to training.

4.4.6. Treatment and Prognosis of Sports Injuries. Injury cases in this investigation were treated by the following methods: massage, acupuncture, bandages, sealants, strength training, foot baths, stretching, cupping, ice compresses, scraping, repositioning, limbs, acupuncture, braking, nutritional medicine, and physiotherapy (mainly intermediate frequency current and ultrashort wave). From the above statistics, it can be seen that most injuries are

treated by traditional methods. Acupuncture and massage methods such as active position, tape, ice pack, physiotherapy, rehabilitation training, and other methods still account for a small proportion of the damage. A majority of the athletes who participated in the survey indicated that the treatment methods are effective in relieving pain from acute injuries, but injuries are likely to recur frequently. Complete rehabilitation of the injury site is important in addition to its anatomy to restoring normal tissue and tissue representation. The recovery of this part of complex functional ability requires muscle groups to restore the ability to work in coordination and precision work, and current injury treatments do not include rehabilitation training. It ignores the thorough treatment of the injured party. When this happens, repeat exercise can lead to the accumulation of injuries and gradually step into chronic injuries. Controlling the wearing of joint support belts through the necessary fastening techniques of support belts and the wearing of protective equipment is an important and effective method to protect knee joints and prevent joint injuries. Application of knee pads can protect the knee joint from the impact force after landing. The application of intramuscular action has a good effect on preventing muscle and joint damage. Therefore, it is necessary for us to increase the use of bandages in rhythmic gymnastics to reduce the occurrence

and aggravation of injuries. Strength training includes specific muscle strength training, small muscle group strength training, and core strength training. Core strength training can significantly alter the core stability of rhythmic gymnasts. However, access to scientific training requires good medical supervision. Support belts are used for damaged areas.

Taking preventive measures can help reduce the incidence of injuries, such as exercising before exercising, wearing protective equipment, and performing warm-up activities, which can help reduce the incidence of injuries. After training, athletes can completely relax in various ways, especially active stretching and athlete relaxation, which will not only allow athletes to relax completely, but also improve the flexibility of the athletes' whole bodies and make difficult movement skills go more smoothly; increase the standardization and differentiated treatment of technical gestures during training; effective treatment methods should be adopted in a timely manner after an athlete is injured. Another aspect of scientific training is to monitor the physiological and biochemical functions, and use scientific means to ensure the training level of athletes.

From this article, we can know that gymnastics injuries are mostly chronic injuries, and the treatment of chronic injuries is mostly massage. In sports injuries, we can see from Figure 10 that massage, acupuncture, and other treatments to restore body function are more effective.

5. Conclusion

Through the comparison of various studies and surveys of gymnastics, it can be concluded that the study of injuries in gymnastics is necessary and critical because injuries are inevitable when the general public and professional sportspeople engage in sports. By studying the force analysis of muscle mechanics, we can find the cause of injury during exercise, reduce the probability of injury, and also draw a more effective method of treatment. Our research can better allow the public to participate in gymnastics and reduce the risk of injury. Image recognition research also provides better research conditions for gymnastics sports injury research.

We provide a brief overview of the connotation and characteristics of data mining technology in the era of big data, analyze the feasibility of data mining technology in business management from the economic and technical perspectives, and propose specific application suggestions according to the content and requirements of business management. This paper describes in detail the principles and steps of using the weighted plain Bayesian algorithm and the decision tree algorithm to analyze students' performance; firstly, we need to obtain the plain Bayesian analysis model of college students' learning literacy in physical education and the C4.5 graduation literacy analysis model, and then use certain rules to combine the weighted plain Bayesian algorithm and the decision tree algorithm to obtain the WNB-C4.5 college students' learning literacy analysis model. In addition, in the prediction of financial risks, the classification scheme can be used in the judgment of violation of regulations, but the most used classification scheme is the decision tree. Experiments show that the effectiveness of this scheme in data mining for financial companies is increased by 2% compared to the benchmark method.

1. Introduction

With the rapid development of Internet, cloud computing, and Internet of Things (IoT) technologies in recent years, modern society has gradually stepped into the era of informatization and data-oriented environment [1]. In the development of enterprises, production and operation activities will generate a lot of data and the trend of explosive growth [2]. Comprehensive retrieval, analysis, and application of data can lay a good foundation for the formulation of scientific decision-making, and data information has gradually become an important factor affecting the development capacity of enterprises [3, 4].

With the continuous development of data mining technology, researchers have been expanding data mining technology, which makes its application research fields become more and more extensive [5]. At present, a large number of data mining techniques are successfully applied in many fields such as medical and health care, national

defense science and technology, education and teaching, enterprise applications, and communication industry, which are widely concerned by researchers [6].

For example, in the area of intelligent decision support system, few researchers [7, 8] researched and designed an intelligent decision support system based on data warehouse, OLAP, and data mining methods, and also researched and designed a new intelligent decision architecture framework. In terms of data warehouse applications, Liu et al. [9] researched and implemented a management system applicable to customer data analysis based on data warehousing and data mining techniques, and the combination of the two techniques reflects the advantages of analyzing historical data and is widely used in the mobile communication industry. Few researchers [10, 11] analyzed the intelligent financial decision support system of the ZT Group by combining three key mining techniques, namely association rules, fuzzy methods, and unstructured data mining techniques, and also adopted a function mapping approach to achieve improved

efficiency of operations in response to the shortcomings of the above three techniques. Similar analysis of intelligent decision support system based on data mining technology has many other worthy examples [12].

With the wide application of data mining techniques, most universities also apply the techniques commonly used in data mining to their daily educational teaching activities. Cui and Yan [13] designed and implemented an efficient grade analysis system based on data mining. The system adopts the grade analysis method of data mining, which can quickly and efficiently uncover valuable potential information hidden in a large amount of grade data and help university academic staff to comprehensively analyze students' grades. In [14], data mining technology is applied to the university reader borrowing query and analysis management system, the association rule mining technique is studied in depth, and the classical Apriori algorithm is analyzed, while the Apriori algorithm is improved, thus improving the efficiency of the algorithm to a great extent.

In the metrology business processing, the traditional metrology business often fails to extract valuable data information quickly and effectively when dealing with huge data, which restricts the metrology business management decisions [15]. The use of data mining technology, by building data mining models and data warehouses can effectively handle the huge amount of data generated in metrology business, thus reducing the errors in metrology business to within the standard range and improving the efficiency of metrology business. In [16], the application of data mining technology in WAP business operation is described. By analyzing and comparing the advantages and disadvantages characteristics of various data mining methods, the association algorithm is finally selected to mine the access logs generated by WAP, and some practical optimization solutions are proposed for the performance of data warehouse and data mining.

The deep application of data mining techniques is also widely involved in medical applications. Xu et al. [17] improved the Apriori algorithm by analyzing classical association rule mining algorithms such as AIS algorithm, FP-Growth, and Apriori algorithm, and proposed an array-based mining association rule DRA algorithm, which greatly improves the operation efficiency because the DRA algorithm does not need to generate candidate sets. In [18], a design idea of a data mining system for TCM cases with gastric pain was proposed, and the application of classical association algorithm in TCM cases with gastric pain was effectively verified by mining the medication pattern in 1221 cases for treating a certain disease using the Apriori algorithm.

From the above literature review, it is easy to find that data mining technology is now involved in almost every aspect of people's daily production life, and it is also used in intelligent decision support systems, higher education institutions, metrology business processing, mobile dream network data business, medical business, and other fields with increasing maturity [19, 20]. Based on the respective characteristics of classical Apriori association rule, clustering algorithm, and decision tree algorithm in data mining technology, we decided to use the above three data mining

algorithms to realize the analysis of the enterprise's financial data so as to uncover the potential value information in the enterprise's financial data and provide a reliable decision basis for the enterprise's leadership.

2. System Business Requirements Analysis

2.1. System Process Analysis. The system process analysis mainly describes the execution process of a core business in the main functional modules of the system. Since the financial management system has more functions and the accompanying business process is also relatively large, in view of this, this chapter will focus on analyzing the original financial card management process in the financial management system. The original financial fixed assets card management specification process is shown in Figure 1.

- Step 1: login to the system with the minimum open month.
- Step 2: enter the "Fixed Assets" management operation and enter the original card node; locate an original card at the same time and copy the original card operation.
- Step 3: select the fixed assets category.
- Step 4: enter the items of this fixed assets master card.
- Step 5: save the card.
- Step 6: select the attached card.
- Step 7: make changes to the selected supplementary card, add another supplementary card, and enter the contents again.
- Step 8: save the card.

Through the above eight steps, you can realize the original financial card data entry workflow.

The general ledger of enterprise assets is an accounting of enterprise fixed assets according to certain classification standards in a certain period of all economic operations, the original value of the assets, accumulated depreciation, net value (provision for impairment, net) in a three-column format of debit, credit, and balance of the summary to reflect the changes in their value of the pages of the account. The flow chart of general ledger management is shown in Figure 2.

The general ledger process includes the initial balance entry and after the trial balance, the initial accounts can be created. The general ledger manager can then create some account vouchers and documents based on the initial accounts, and by signing and stamping on the postpayment vouchers, eventually form transfer vouchers for year-end account review and audit role, and finally form bookkeeping methods for year-end transfer.

3. Data Mining Technology in the Era of Big Data

Big data mining technology is an important constituent element of knowledge discovery to analyze data with computer algorithms. In a large number of databases, the

FIGURE 1: Original financial card management process.

required data is obtained, and the data is appropriately transformed, mined, and utilized to obtain valuable information. Generally speaking, the object of big data mining is basically structured, semistructured, or other structured data. The process of data mining is mainly data selection \rightarrow data mining \rightarrow data analysis (see Figure 3).

4. Financial Analysis Method Based on Weighted Multiple Random Decision Trees

The classification problem of financial data is completed by adding a random decision tree scheme to the model, as shown in Figure 4.

The criticality of the attributes in the financial data warehouse varies under different mining objectives, so the criticality of each attribute should be analyzed quantitatively when establishing the decision tree. The current schemes that are often used to confirm the criticality of attributes are the discriminant matrix-based scheme and the information entropy-based scheme. In this study, we use the discriminant matrix scheme to evaluate the importance of attributes. In addition, since financial data are highly specialized, it is not possible to reflect the actual importance of an attribute by relying only on the discriminant matrix, so this project adds artificial weights to modify and intervene in the discriminant matrix to make the calculation of attribute weights more accurate [21, 22].

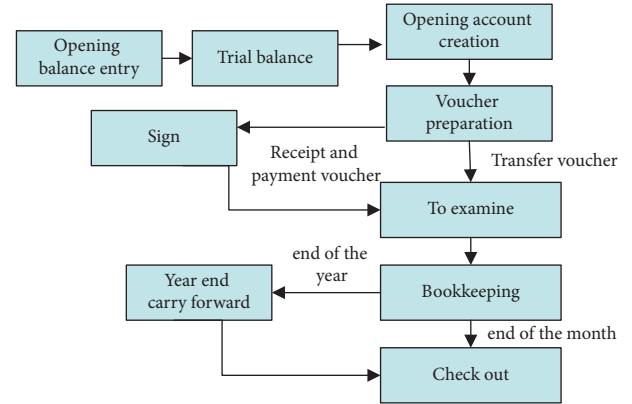

FIGURE 2: General ledger management process.

4.1. *Defining the Resolution Matrix.* A diagonal matrix of $|u| \times |u|$. Each of these terms is defined as

$$C_{ij} = \begin{cases} \{\alpha \in A | \alpha(x_i) \neq \alpha(x_j)\} d(x_i) \neq d(x_j), d(x) \in D \\ \phi \quad d(x_i) = d(x_j), d(x) \in D \end{cases} \quad (1)$$

The number of occurrences and the importance of the attributes in the discrimination matrix are positively correlated; and the shorter the data item with the attribute present, the more critical the attribute.

4.2. *Calculating Attribute Weights for Financial Data.* Initialize all $a_i \in A$ such that $w(a_i) = 0$.

For each term of the diagonal matrix in the resolution matrix C_{jk} calculate

$$w(a_i) = w(a_i) + |C_{jk}|, \quad a_i \in C_{jk}, 0 < k < j = |U|. \quad (2)$$

In the above equation, $|A|$ is the base of all attributes and $|C_{jk}|$ is the base of the discrimination matrix C_{jk} .

After the system presents the weights, it is possible to manually correct the weights in the system, so it is necessary to add the correction coefficients $w^l(a_i)$, $-1 < w^l(a_i) < 1$, if you want to increase the weight of a_i by setting $w^l(a_i)$ to a positive value, and the opposite by setting it to a negative value, then the weight of attribute a_i is $W_{ai} = w(a_i) + w^l(a_i)$.

5. Experimental Validation

This validation data are derived from the financial statistics of more than 1400 company customers who have worked with a commercial bank, and the period of validation data are uniform from 2013 to 2016. The financial information data tables are divided into attributes based on the bank's transaction database, so the financial information data tables provided by the bank can be transformed into 24 attributes that clearly show the financial situation of the company, as presented in Table 1.

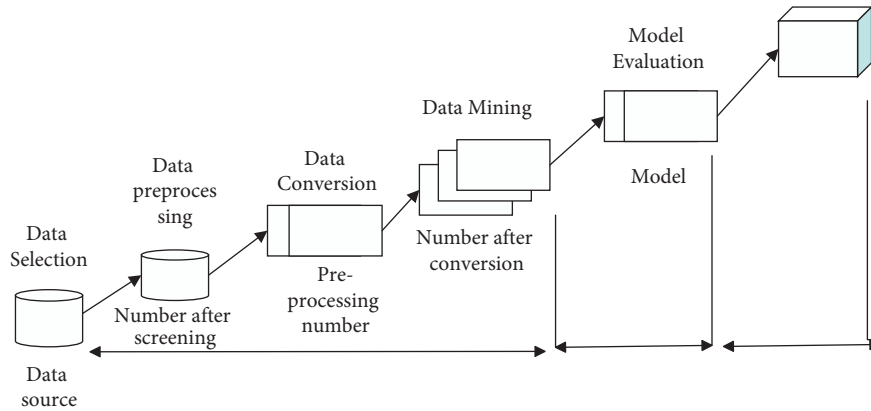

FIGURE 3: Flow of big data mining.

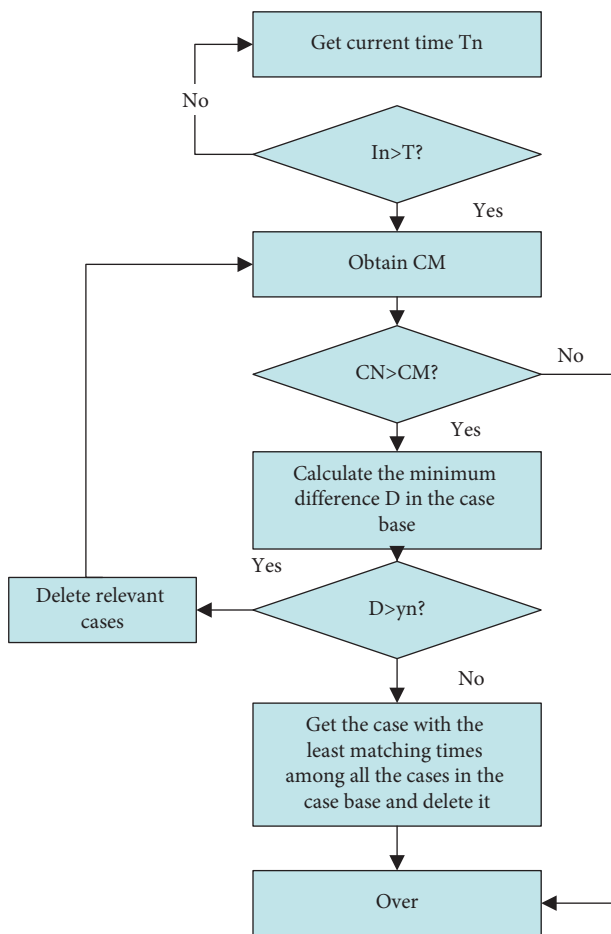

FIGURE 4: Case deletion process.

Due to the actual situation of the company in 2017 and the indicators related to the company, experts in finance classify the company risk into four categories: large, large, small, and small. In this case, companies with high risk are those that will go bankrupt from 2015 to 2017; companies with high risk are those that will default; companies with low risk are those that will not default but their financial situation will deteriorate, and companies with low risk have a

normal financial situation and will not default. The results of the study showed that the best way to apply the decision is to build 10 random decision trees. Therefore, in this study, a total of 10 randomized decision trees were built from the analyzed data because the decision trees were built in a randomized manner, and a total of 5 trials were conducted to verify the stability of the decision trees [23, 24].

The remaining 300 data are test data. The training data were used to build a random decision tree, and the completed decision tree was tested using the test data to finally document the classification accuracy of the decision tree. The experimental results are presented in Table 2 and Figure 5.

The results of the experiment show that this randomized decision tree algorithm classifies companies with large risk, large risk, small risk, and small risk with improved classification accuracy, which has been determined by bank staff to be a practical reference for predicting bank risk. However, because of the small number of large risk data in the training dataset, this branch is not sufficiently trained, making the stochastic decision tree algorithm less accurate than the other branches for large risk classification [25].

Each time, using the same training and validation data, the C4.5 algorithm is applied to classify the risk level, and the final results are presented in Table 3 and Figure 6.

The results of the experiments show that this randomized decision tree algorithm improves the classification accuracy for the risk level of large, risk level of large, risk level of small, and risk level of small by a considerable amount. Similarly, it can be seen that because the number of data with large risk level in the training dataset is relatively small, this class of branches is not trained sufficiently. The accuracy of the C4.5 algorithm is significantly lower for the risky branches compared to the other branches. This is shown in Figure 7.

From Figure 7, we can see that the accuracy of the randomized decision tree algorithm is higher than that of the C4.5 algorithm, which is about 10% higher.

In order to improve the correct rate, 300 data with high risk level are added to the training data set because the training of high risk level is not sufficient. The number of training data with large risk is ensured by replacing the

TABLE 1: Table of experimental attributes.

Attribute code	Attribute	Calculation formula
A1	Return on assets	$(\text{Total profit} + \text{finance costs}) / (\text{Total assets} + \text{total assets of the previous period}) * 2$

original random sampling with stratified sampling, in which the initial data are stratified by small, small, large, and large risk, and then random sampling is used for each stratum. The classification results using the stratified random sampling method are presented in Table 4 and Figures 8 and 9.

From the above figure, we can see that the correct rate of using the stratified sampling method with high risk is 10% higher than that of the random sampling method with high risk. The underlying reason is that 300 risky data are added to the training data set, which provides more samples for the stratified sampling. Therefore, the number of samples in the training data determines whether the decision tree classification is correct or not, and if the number of samples is

FIGURE 5: Comparison of the correct classification rate of multiple randomized decision trees.

large enough, the decision tree classification will be more correct.

6. Conclusion

In the era of big data, the content of enterprise financial analysis has increased and the complexity of work is higher. The reasonable application of data mining technology can reduce the work pressure of financial personnel and can improve the quality and efficiency of financial analysis, so it is recommended to promote the use. Good foundation to play the role of data support. During the enterprise cost efficiency accounting, data mining technology can be applied to analyze the association of a certain type of cost and another directly unrelated cost. If it has high correlation characteristics, it needs to be integrated into the process of project budgeting and decision-making to improve the accuracy of cost-benefit accounting.

With the rapid development of computer network technology, the advantages of virtual reality technology in the field of instant messaging are becoming more and more significant. Virtual reality technology plays an important role in communication networks, including enhanced resource utilization, device redundancy, immersion, interactivity, conceptualization, and holography. In this paper, we use the basic theory of Restricted Boltzmann Machine to establish a semisupervised spatio-temporal feature model through the animation capture data style recognition problem. The bottom layer can be pretrained with a large amount of unlabeled data to enhance the model's feature perception capability of animation data, and then train the high-level supervised model with the labeled data to finally obtain the model parameters that can be used for the recognition task. The layer-by-layer training method makes the model have good parallelism, that is, when the layer-by-layer training method makes the model well parallelized, that is, when the bottom features cannot effectively represent the animation features, such as overfitting or underfitting, only the bottom model needs to be retrained, while the top model parameters can be kept unchanged. Simulation experiments show that the design assistance time of this paper's scheme for animation is reduced by 10 minutes compared to baseline.

1. Introduction

Video communication in instant messaging systems usually requires high real time and stability; otherwise, it is prone to data delay, playback lag, and other instability [1]. Due to the influence of unstable network environment, the data is easily disturbed by various factors during transmission, resulting in the data not being broadcasted properly at the receiving end [2]. And the goal of this paper is to design a virtual video chat system combined with virtual reality, which needs to transform from the original transmission video data to the transmission user's face key point data based on the application scenario and handle the transmission abnormality [3]. At the same time, because the content of this paper is not based on video streaming instant messaging, but 3D virtual animation video chat, the user sees the expression animation of the virtual animation model during the chat, so the data format transmitted in the network is the data set of face keypoints and voice data, and this paper has high

requirements for noise reduction and echo cancellation of voice based on the actual application scenario, thus making the voice and animation [4]. Therefore, the synchronization of voice and animation and speech optimization become the urgent problem in the subject.

In recent years, the research on face keypoint localization has become more and more abundant and mature, and the research on deep learning has also made many breakthroughs, bringing better innovative methods and more opportunities for other related research fields [5]. Face keypoint localization is the basis of face recognition and other research, and the application scenarios are very broad. Researchers have proposed many algorithms for face keypoint localization and achieved good results in related fields, but in practical applications, faces are often affected by various internal and external factors such as expression, posture, illumination, and occlusion, making it very difficult to achieve accurate face keypoint localization, which is still a great challenge [6, 7]. This paper will address the design and

optimization of the face keypoint localization model and its application in mobile based on practical application scenarios [8].

Virtual reality technology is an important part of the computer field and has important applications in biochemistry, social entertainment, aerospace, and military industries [9]. However, virtual reality technology is less present in the current popular instant messaging-related research, which indicates that researchers in the field of instant messaging have paid less attention to virtual reality technology and have not well combined the two [10]. In this paper, we combine virtual reality technology and instant messaging, and the client drives the expression animation of 3D virtual model by parsing the key point data of human face to realize the virtual animation real-time communication [11].

In summary, the design of combining virtual reality technology with instant messaging and combining human-computer interaction with video chat will be a very important research direction in the future communication field [12].

2. Related Work

At present, domestic and foreign research in instant communication has made great progress, and communication among people has become more and more convenient and colorful [13]. At the same time, people are more and more willing to try various diversified and personalized instant communication methods, such as using 3D virtual animation models instead of real faces to communicate in real time, and the expression animation of 3D virtual animation models is driven by the real expressions of users in real time [14, 15].

In this paper, we combine deep machine learning-based face keypoint localization technology, virtual reality technology, and instant messaging to design and implement a more personalized instant messaging system [16].

2.1. Face Key Points. Face keypoint localization is the basis of face recognition and expression analysis and has a very broad development and application prospect. Researchers have proposed many face keypoint localization algorithms based on various methods. In [17], a fast face alignment method based on a layer-by-layer model is proposed, which converges after 8~10 iterations and the alignment time of each face image is tested within 40 ms on a Samsung I9300 smartphone. Reference [18] proposed a multitask cascaded convolutional neural network to achieve face detection while achieving face key point localization. Reference [12] et al. used a cascaded convolutional neural network-based method to achieve the localization of five key points of faces with an average localization error of 1.264 pixels, and it only takes 15.9 ms to process a face image. Reference [19] proposed a new cascaded deep design warp network, where the input of the previous cascaded neural network is a certain part of the image, unlike the previous ones, the input of each stage of the DAN (Deep Alignment Network) network is the

whole image, which can extract features from the whole image. The features can be extracted from the whole image to obtain more accurate localization. Reference [20] proposed an edge-aware face alignment algorithm based on the edge as the geometric structure of the face for localization of 98 key points of the face.

From the above studies, it can be seen that there are abundant studies on face keypoint localization techniques and many algorithms are able to achieve better results. In the task of this paper, we are more concerned with the real time of face keypoint localization and the accuracy of face keypoint localization under different postures and expressions.

2.2. Data Transmission and Sound-Image Synchronization. Currently, data transmission is moving in two directions: first, to pursue higher transmission performance at lower transmission rates, that is, to reduce the transmission BER as much as possible; second, to increase the transmission rate as much as possible while the BER meets the requirements. Reference [11] proposes a new method for synchronizing audio and video presynchronization: by designing a presynchronization module based on the RTP/RTCP timestamp in the receive buffer and a new working mechanism, a fast synchronization within the media is achieved, eliminating the intermediate layer bias and adding no additional end-to-end delay before unpacking the RTP packets. Reference [12] proposes a method that uses timestamps to store audio and video data with correlation in acquisition time into a fixed synchronization data structure and always synchronize and control them during acquisition, encoding, transmission, reception, decoding, and playback, which can well meet the demand of audio and video synchronization in application scenarios and has good engineering practice. Reference [15] implemented a virtual reality-based gaze sensitive social communication system for autistic patients, which can measure the gaze-related index of patients during their interaction with virtual companions, and this index can be mapped to their corresponding anxiety level. At the same time, the system can influence the patient's task performance and gaze-related index in response to the virtual companion's emotions.

Technologies such as speech coding and decoding, data transmission, and audio and video synchronization are the basis of research in instant messaging. In the task of this paper, more attention is paid to the effect of special environment on speech, such as external playback under mobile devices and the synchronization of speech with 3D animation models.

3. Animation Design Model Based on Two-Layer RBM

Aiming at the problem that there is often a semantic gap between the underlying features and the high-level semantics of animation capture data, a semantic recognition algorithm for animation capture data that incorporates a restricted Boltzmann machine generative model and a discriminative model is proposed by combining deep

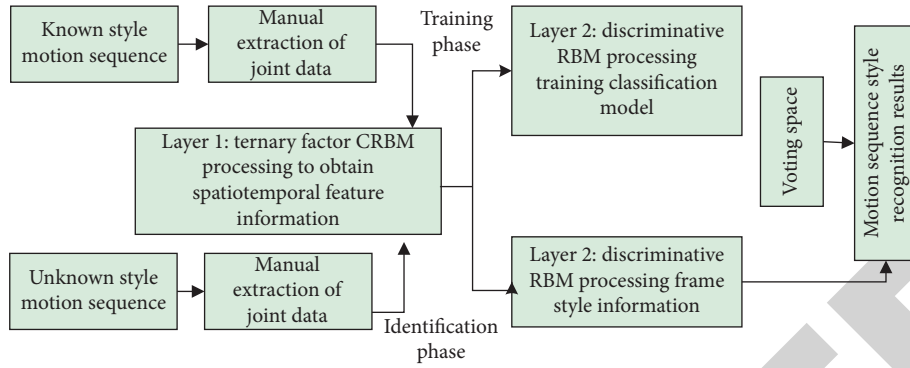

FIGURE 1: Flowchart of animation design based on two-layer RBM model.

learning ideas. The algorithm adopts a two-layer restricted Boltzmann machine to perform discriminative feature extraction (feature extraction layer) and style recognition (semantic discriminative layer) on animation capture data, respectively. Firstly, considering that the autoregressive model has excellent ability to express temporal information, a conditional restricted Boltzmann machine generative model based on single-channel ternary factor interaction is constructed for extracting temporal feature information of animation capture data; then, the extracted features are then coupled with the corresponding style labels as the input of the current frame data layer of the restricted Boltzmann machine discriminative model in the semantic discriminative layer for the training of single-frame style recognition; finally, on the basis of obtaining the parameters of each frame, the voting space is added to the top of the model to achieve the effective recognition of the style semantics of the animation capture sequence. The experimental results show that the algorithm has good robustness and scalability, can meet the needs of diverse animation sequence recognition, and facilitate the effective reuse of data.

3.1. Introduction to Recognition Models and Processes. As one of the representative models of deep learning, the RBM model has the ability to extract static frame features and build a CRBM model by adding autoregressive model constraints to the input layer, which in turn can obtain temporal feature information with contextual semantic scenarios. Reference [19] proposes a nonlinear mapping threshold CRBM binary hidden variable probabilistic model, which uses an unsupervised learning algorithm to extract not only the highly structured feature information that is available when transitions are transferred between video frame images, but also to portray the spatial relationships between each frame's own pixels. In this paper, a voting space layer is added on top of the label layer for animation design, and a segmentation layer with the ability to identify transition frames can also be added. The animation design process using the two-layer RBM model is shown in Figure 1.

3.2. Bottom Feature Extraction Layer. The generative model fully considers the distribution of data and can use joint probability to get the conditional probability from input data

to output data. Therefore, the RBM based on the generative model can reflect the generation process of the target object and the similarity between similar objects through the energy function and the activation state of the hidden layer neurons. The layer 1 generative RBM model developed in this paper takes advantage of the second property.

According to the autoregressive model algorithm, this paper splits the animation into 2 parts and constructs the bottom spatio-temporal feature layer: one part represents the previous n frames of the current animation frame, which is called the history frame; the other part has only one frame, which represents the current animation frame, which is called the current frame. In addition, the interaction factor layer is added to realize the information interaction control between the 2 input layers and the feature layer, aiming to map the latent information and spatio-temporal feature information in the animation data to the feature representation layer through the factor layer so as to obtain more accurate probability distribution of the data in the process of reverse estimation; meanwhile, the factor layer also has the function of reducing the model space complexity from $o(n^3)$ to $o(n^2)$, which is described as follows.

The representation of each neuron in the history frame based on the RBM feature learning is $p = (p_1, p_2, \dots, p_m)$, where $m = (f_r - 1)d$ is the total number of neurons, f_r denotes the length of the historical frame, and d denotes the frame data dimension. The neurons of the current frame are represented as $n = d$, with $v = (v_1, v_2, \dots, v_n)$ representing the total number of neurons of the current frame. The hidden layer neurons are represented as $h = (h_1, h_2, \dots, h_t)$, where t is the total number of hidden layer neurons set. For the convenience of description, p_i is the i th neuron of the history frame, v_j is the j th neuron of the current frame, b_j represents the bias of the j th neuron, h_k represents the k th neuron of the hidden layer, and c_k represents the bias of the k th neuron. c_k is the connection weight from the interaction factor layer to the history frame (directed connection), W_{if}^p is the connection weight from the interaction factor layer to the current frame (directed connection), and W_{if}^v is the connection weight from the interaction factor layer to the hidden layer (undirected connection). W_{kf}^H is the connection weight from the interaction factor layer to the hidden layer (undirected connection), which determines the model parameters and is denoted as $\theta_1 = (W_{if}^p, W_{if}^v, W_{kf}^H, b, c)$. Note

that the history frame and the current frame are both real-parameter visible neurons, while the hidden layer is a binary random hidden unit.

3.3. High-Level Semantic Discriminant Layer. The DRBM model can be considered as a two-layer model, where both the visible layer and the label layer are the input sample data, and the hidden layer can be used to sample the joint probability distribution and conditional probability distribution of the visible and label layer data. Since an animation belongs to only one style, the label layer can be coded as “single heat”; that is, the label layer is set as a binary neuron, and only the neuron corresponding to the label has a value of 1 and is active [21, 22].

The parameters are defined as follows: the label layer neuron is $L(L_1, L_2, \dots, L_o)$, where o represents the number of all styles of training samples, and the bias is $T = (t_1, t_2, \dots, t_o)$; the visible layer is the feature information extracted from the first layer, which is a real unit, denoted as $X = (x_1, x_2, \dots, x_k)$, and the bias is $Q = (q_1, q_2, \dots, q_k)$; the hidden layer is the unit that can represent the correspondence between the label layer and the visible layer, denoted as $Y = (y_1, y_2, \dots, y_n)$, and the bias is $R = (r_1, r_2, \dots, r_n)$. The connection weights of the visible and labeled layers to the hidden layer are W_{yx}, W_{yl} . Since this layer is used for classification rather than prediction of the probability distribution of the animated features, a hybrid discriminant method is used to train the second layer of the RBM, which is a linear combination of the optimal discriminant model

$p(l|x)$ and the generative model $p(l, x)$. The training algorithm is still a comparative scattering algorithm. The log-likelihood function of the function to be optimized takes the form

$$L_{\theta_2} = \sum_{i=1}^s \log P(l_i|x_i) - \alpha \sum_{i=1}^s \log P(l_i, x_i), \quad (1)$$

where s denotes the total number of categories. For the 2nd term, i.e., the generative model part, the parameters are updated according to the steps of the 1st level [23, 24]. For the first discriminant model, the conditional distribution can be calculated as proposed by Larochelle et al.

$$P(l|x) = \frac{e^{(t_l + \sum_j (\log 1 + e^{W_{jl}x_j + W_{jl} + r_j}))}}{\sum_{ls} e^{(t_{ls} + \sum_j \log(1 + e^j))}}. \quad (2)$$

In a sequence of frames, equation (3) represents the magnitude of the probability that each frame belongs to each label, where l is the category label notation to which the training frame belongs, $ls \in (1, 2, \dots, 0)$. Therefore, the conditional probability $p(l|x)$ can be solved by an optimization function using the gradient descent method such that the probability that the animation feature x belongs to the correct label l is maximized. Then, for a single frame of animation $x^{(t)}$ and the corresponding style label $l^{(t)}$, there are

$$\frac{\partial \log P(l^{(t)}|x^{(t)})}{\partial \theta_2} = \sum_j \text{sigmod}(S(x^{(t)})) \frac{\partial S(x^{(t)})}{\partial \theta_2} - \sum_{j,ls} \text{sigmod}(S(x)) P(ls|x^{(t)}) \frac{\partial S(x)}{\partial \theta_2}. \quad (3)$$

Among them, $S(x) = \sum_{i=1}^k W_{ji}x_i + U_{jl} + r_j$, $x^{(t)} \in x$. For label layer, bias update method is

$$\frac{\partial \log P(l^{(t)}|x^{(t)})}{\partial t} = 1_{y=y^{(t)}} - P(l|x^{(t)}), \quad (4)$$

where $1_y = y^{(t)}$ is the label layer neuron activated by the current label after the “single heat” encoding. The model parameters can be updated iteratively at each step by bringing equation (4) into the expression of the hybrid discriminative model in equation (3). The final DRBM model with classification function at layer 2 is trained [25, 26].

4. Experiment and Result Analysis

In order to verify the effectiveness of the two-layer model in animation design, the experiments are conducted on a PC with 3.30 GHz CPU and 8G memory, and the programming test environment is python3.7. In the generated model, the number of neurons in the historical and current frames as input data in the CRBM model is directly determined by the dimensionality of the input data. In the preprocessing, 53

dimensions of data were extracted for each frame, including 48 joint angular degrees of freedom, 3 animation directions, and 2 geodesic velocity data. The first 25 frames are used as the input vector of the history frame, and the 26th frame is used as the input data of the current frame so that the number of neurons of the history frame is 1325 and the number of neurons of the current frame is 53. The number of iterative updates is 250–500, and good feature information can be extracted.

4.1. Two-Layer Model Training. In this paper, we first eliminate the influence of spatial location of animation nodes on recognition and then retain the advantage of autoregressive model to build the first layer of ternary factor CRBM to extract temporal features and finally use the second layer of discriminative Boltzmann machine for classification. The two-layer model is trained to obtain a set of model parameters, including weights and biases, for each layer.

Since the layer 1 RBM uses a generative model, it contains reconstruction errors for the current frame animation data description. Using the reconstruction error, we

FIGURE 2: Total error of RBM reconstruction in layer 1 versus the number of iterations. (a) Dataset 1. (b) Dataset 2.

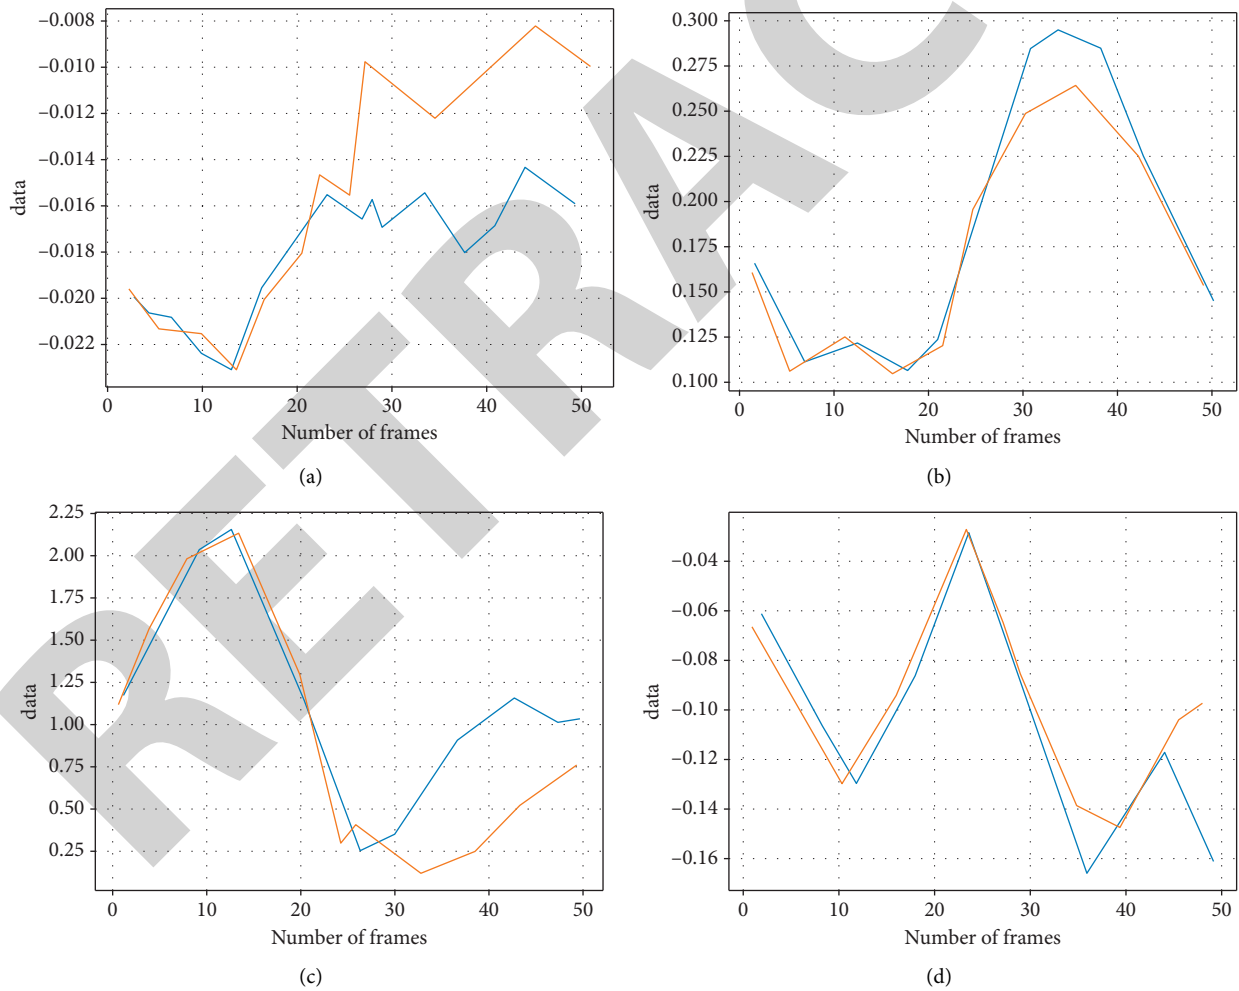

FIGURE 3: Effect of end effector reconstruction. (a) Left foot. (b) Right foot. (c) Left hand. (d) Right hand.

can roughly determine how well the model fits the current 26-frame data distribution. If the error is too large, the parameters are not set properly and the number of neurons

in the feature layer needs to be increased or the number of training sessions needs to be increased. Of course, the reconstruction error should not be too small, as overfitting will

FIGURE 4: Validation set error and energy change for 2 data sets. (a) Validation set error 1. (b) Free energy 1. (c) Validation set error 2. (d) Free energy 2.

occur if it is too small. In the later tuning process, the appropriate number of hidden neurons and other techniques can reduce the occurrence of overfitting. In general, the reconstruction error will be stabilized within a certain range after a certain number of training sessions, which is verified by relevant experiments.

Figure 2 shows the reconstruction errors of layer 1 of the model for the 2 data sets. It can be seen that the reconstruction error obtained from the RBM model based on layer 1 will gradually stabilize after a certain number of iterations. For example, after 200 iterations, the reconstruction error basically tends to a stable level, and the total error of 53 Euler angles per frame does not exceed 0.9. Therefore, it can be judged that the layer 1 model does not change the original characteristics of the animation, and the fitting effect is relatively good.

To verify the reconstruction effect of the model on the animation style, Figure 3 shows the reconstructed effect of the 1st layer generating model part on the 4 end effectors (left and right hands, left and right feet) of the 1st animation style JO (jogging) of data set 1. Analyzing the fluctuation magnitude, we can see that the degree of change of the

reconstructed data is similar to that of the original data animation style, which indicates that the data obtained by reconstructing using the first 25 frames and the model parameters are consistent with the style type of the current animation; that is, the hidden layer can effectively portray the style characteristics of the current animation.

The second semantic discriminative layer uses the RBM discriminative model to construct the mapping relationship between labels and each style animation feature, and the model parameters are updated according to the reconstruction errors of the input data in the label and feature layers. At the same time, a small number of samples are extracted from the training samples as the validation set to verify the accuracy of the model classification in each training cycle. Figure 4 shows the variation of the free energy of the RBM model at layer 2 and the recognition rate of the validation set in Dataset 1 and Dataset 2 as the number of training cycles increases. The free energy is closely related to the probability distribution of the model, and the trend is inversely proportional to the change in the probability distribution, as the energy decreases, the probability distribution becomes closer to the feature distribution, which

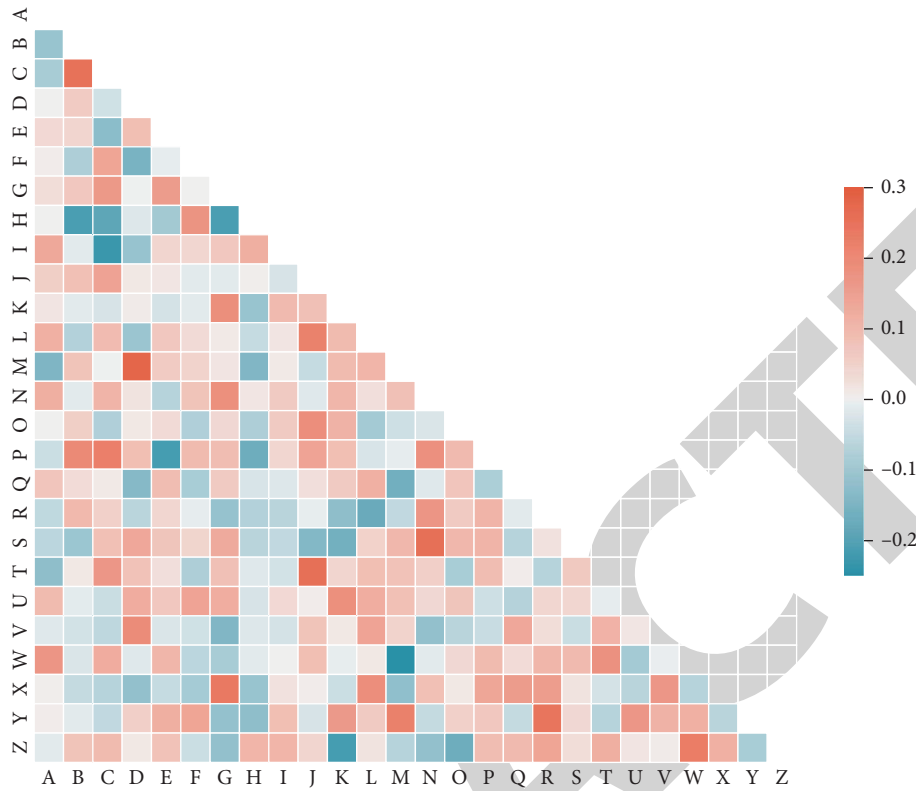

FIGURE 5: Animation style recognition confusion matrix.

also validates the theory that the system is most stable at the lowest energy. The effect of model energy release on the recognition rate can be clearly observed in Figure 4(b): as the system stabilizes, the frame classification error of the validation set is in a decreasing state and gradually tends to be smooth.

4.2. Comparison and Analysis of Experimental Results. In order to further verify the recognition effect of the two-layer RBM model on animation style, the recognition results of this paper’s algorithm are compared with the Adaptive Motion Codebook Classifier (AMCC) algorithm of [12] and the SVM recognition algorithm based on radial basis function, and the spatial locations of 23 nodes are selected as the data preprocessing method. The spatial position information of 23 nodes was selected as the data preprocessing method. From the experimental results of the three recognition algorithms in Figure 5, it can be seen that for simple animations, the two-layer RBM algorithm can also achieve good style determination results, such as JO, KF, and KS simple sequences, and its test discrimination rate reaches 100%. The main reason is that the AMCC and SVM algorithms mainly consider the spatial information of the body joints, which has the greatest influence on the animation style, for classification, and ignore the timing information. The two-layer RBM algorithm proposed in this paper can achieve better semantic discriminative effect, mainly because the first layer extracts discriminative spatio-temporal features for effective pose portrayal; the second layer of DRBM

FIGURE 6: Comparison of animation design rates.

model can effectively sample the conditional probability distribution of feature layer and class label data for semantic discriminative effect.

In terms of space storage efficiency, the AMCC algorithm needs to store the entire training set and build codeword templates for different classes of animation sequences, so the space occupation rate is large. In contrast, the depth model built in this paper only needs 2 sets of finite

FIGURE 7: Animation design process.

FIGURE 8: Animated character design.

parameters (1 set for each layer) to represent the sequence pose, and only some training samples are needed to learn the model parameters, so the storage space is relatively small. Therefore, the algorithm in this paper is suitable for the learning and modeling work of large data volume animation sequences. In terms of time efficiency, although the deep learning model established in this paper takes some time to learn the underlying features, once trained, the corresponding hidden units can be activated directly according to the model parameters and visible layer data, and the feature distribution of the current animation style can be obtained effectively. Therefore, the algorithm in this paper does not require additional similarity calculation, and in the MATLAB simulation environment, although the training time is long for 13 styles of animation, the recognition time is only

2.6 s. The speed of style recognition is comparable with existing algorithms, as shown in Figure 6.

5. Interactive Animation Design

In interactive animation design, the meaning of fast and slow rhythm is mostly reflected in the process of interactive experience. A fast rhythm can give immediate feedback to younger children. When children select options through the interactive buttons, as shown in Figure 7, the interactive buttons should change color and play corresponding music in an instant; for example, the button turns green with a celebratory tone when correct, and the mobile device vibrates and the button turns red when wrong. The immediate error feedback will provide a kind of error warning to the

younger children so that they can form a psychological gap and pay attention to the subsequent case explanation.

From Figure 8, it can be seen that Dynamic algorithm and this paper's algorithm each have advantages in different styles of animation design. Dyneme vector-based recognition algorithm is weaker in the four animation styles of jump, lie, sit, and stand, because the algorithm does not sufficiently consider the backward and forward timing relationship, such as sitting on the ground and standing up from the ground are inverse animations, but their forward difference vectors are similar to each other. The algorithm in this paper overcomes this drawback by using the past frame cell layer and the current frame cell layer in the visible layer, but the shortcoming is that RBM has transfer invariance, which leads to interference in recognizing animation styles like deposit (picking something up from the ground), jog (running in place), rotate (rotating both arms), and so on, where the animation joint changes are similar but the joint positions are different. Interactive animation design should also anticipate in advance, using the platform's error record to analyze the error-prone content of younger children and insert.

6. Conclusion

In order to meet the demand for spatio-temporal feature representation in human animation design, this paper adopts the two-layer RBM algorithm for animation feature representation and style recognition. The experimental results show that RBM has very good advantages in feature extraction and can extract more discriminative spatio-temporal features of animation sequences after adding autoregressive model constraints; meanwhile, it can achieve very good style recognition effect after introducing Boltzmann machine discriminative model, but the algorithm also has certain shortcomings, mainly because the number of neurons of its deep learning model is difficult to be determined well. Animators can create a moderate risky situation in the interactive animation design. Young children are under the care and attention of parents and lack of emotional catharsis, which leads them to subconsciously like to take risks. Therefore, moderate increase of adventure elements can stimulate their interest and let their playful emotional needs be satisfied put.

Based on the risk management of exposure to foreign exchange assets and liabilities and the application of financial derivatives, this paper provides an in-depth analysis of the financial and exchange rate risks of foreign-funded enterprises. Therefore, a method of evaluating the financial performance of listed financial enterprises based on principal component analysis and neural network model is proposed. First, principal components of alternative financial performance input-output indicators are extracted using principal component analysis. Subsequently, these principal components are used as input-output data for the DEA model to derive the relative validity evaluation results of the financial performance of individual financial enterprises and to provide a reference for decision making to improve the financial performance level of financial enterprises. Combined with the economic business data of the enterprises, an empirical test on exchange rate risk management is conducted and relevant suggestions are made on how foreign enterprises can reduce exchange rate risk losses. It has important theoretical value and practical significance for enterprise finance and exchange rate management.

1. Introduction

For a longer period of time in the future, it will also be difficult for the RMB to become a freely convertible currency on a global scale [1]. Moreover, on a global scale, as the world economy continues to develop, buyers dominate the trade market, which means that “in the settlement of foreign trade exports” [2]. Therefore, against the backdrop of the expected appreciation of the RMB, Chinese enterprises in a passive position are bound to face huge exchange rate risk losses [3]. As the manager of a company, whether the accountant is proficient in financial management will determine the future survival and development of foreign companies [4].

Financial accountants should be actively involved in the signing of foreign trade contracts, and the exchange rate should be taken into account to provide for a mutually acceptable risk ratio as an additional clause in the contract [5]. As foreign trade is a matter of bilateral transactions, both

parties to the transaction wish to reduce the exchange rate risk, and therefore, the choice of currency of denomination is likely to be contradictory [6]. The compromise options available to both parties to foreign trade are the party with the favourable currency of denomination is required to offer other concessions to the party with the unfavourable currency; a mix of soft and hard currencies for denomination, with both parties sharing the risk; and if both parties hold mutual claims and debts, the same currency may be chosen for denomination [7]. Although Chinese foreign companies are in a passive position in the international trade market, if accountants are able to take advantage of favourable contractual terms, they will be able to reduce their exchange rate risk losses to a large extent. As the financial manager of an enterprise, the accountant must not only be proficient in financial accounting but also, and more importantly, be knowledgeable and up-to-date with the relevant knowledge of international trade contract regulations. In the

negotiation of foreign trade contracts, accountants should grasp the elements of the contract terms and conditions and strive to achieve “watertightness” [8].

The use of the buy-sell position balancing method does not aim to completely eliminate foreign exchange risk [9] but to minimise foreign exchange risk losses. Enterprises can achieve a certain degree of balance in their buying and selling positions by adjusting the timing of export receipts and import payments and foreign exchange loan repayments [10]. The buy-sell position balancing method is the most basic method of foreign exchange risk management, and it is also the most effective and lowest cost method; therefore, in foreign exchange risk management, enterprises should first choose this method [11]. Cross-compensation risk refers to the cross-balancing of two different foreign exchange buying and selling positions to hedge foreign exchange risk. For example, if the Hong Kong dollar is linked to the US dollar, the two currencies can be cross-balanced. Cross-balancing risk is a low-cost method of managing foreign exchange risk, whereby companies first balance their buying and selling positions in the same currency and then seek to cross-balance their buying and selling positions [12].

Whether it is a financial enterprise or an enterprise performance evaluation, related research has made some progress, but on how to establish a financial performance indicator system reflecting the financial management level of financial enterprises and how to judge the level of financial performance, these studies are still relatively few. In view of this, this paper integrates the advantages of principal component analysis and data envelopment methods in dealing with the comprehensive evaluation of multiple indicators and proposes a financial performance evaluation method based on PCA-DEA for financial enterprises. Firstly, on the basis of comparing existing studies on financial performance evaluation index systems, principal component analysis is applied to preprocess alternative input-output indicators, i.e., to distil numerous input-output indicators into a few principal components with clear practical significance. Subsequently, these principal components are used as input-output data for the DEA model to derive the relative effectiveness evaluation results of the financial performance of each financial enterprise, which provides a reference for decision making to improve the financial performance level of financial enterprises.

2. Related Work

With the gradual acceleration of China’s economic restructuring, competition in the financial sector is becoming increasingly fierce and the rapid development of financial enterprises depends to a large extent on the level of their financial performance. Therefore, an effective evaluation of the financial performance of financial enterprises can provide a basis for decision making by decision makers and stakeholders and also create new value for the system and promote its healthy development.

Financial enterprises are characterised by high risk and high debt, and if problems arise, they will have a huge impact on the overall operation of the Chinese economy,

therefore, relevant research on financial enterprises has been a hot spot for scholars to focus on. The study in [13] constructed an index system and model for evaluating the symbiotic capacity of financial enterprise clusters, discussed the important factors affecting the symbiotic capacity of financial enterprise clusters; pointing out the direction for the development of financial enterprise clusters in China, the study in [14] constructing a support vector machine-based approach for the measurement of financial instruments and internal accounting control efficiency, which provides a new way for quantitative analysis and evaluation of internal accounting control efficiency of financial enterprises. In order to reduce the technological risk of Chinese financial enterprises, the study in [15] used a fuzzy comprehensive evaluation method to measure the degree of technological innovation risk of Chinese financial enterprises and obtain the risk weights of technological innovation risk provides a decision support for Chinese financial enterprises to carry out technological innovation management [16]. In order to verify whether there is a dynamic relationship between listed financial enterprises and the national macro economy, the study in [17] constructed three dynamic effect models to confirm that the effective introduction of monetary policy can play a significant role in the performance development of listed financial enterprises and provided a basis for the implementation of financial policies in China [18]. The results showed that the two were negatively correlated, and the higher the level of noninternationalisation of financial firms, the greater the negative impact of the degree of internationalisation on performance.

The evaluation of financial performance, which can reflect the operation of enterprises, has been the focus of scholars’ attention, and there are many relevant research results [17] that constructed a set of enterprise value evaluation index system based on the enterprise performance evaluation index system and conducted empirical research using grey clustering hair [18]. Based on the enterprise performance evaluation system promulgated by the Ministry of Finance, the hierarchical analysis method and correlation analysis method were used to evaluate the financial performance of Chinese real estate listed companies. Although these methods can achieve certain results, some evaluation models are not ideal, such as AHP, expert scoring, and other qualitative methods, and are highly subjective and cannot dynamically reflect the change pattern of financial performance data.

3. Corporate Financial Performance Indicator System

3.1. Sample Data. This paper mainly takes the listed financial enterprises in Shanghai and Shenzhen as the research sample, selects a total of 37 listed financial enterprises in the two cities, collects and collates the data of these listed financial enterprises that have passed the annual audit report in the CSMAR database in 2015, and selects the relevant data of the publicly disclosed financial indicators in the financial statements.

3.2. Selection of Indicators. This paper takes financial enterprises as the research subject, and the Ministry of Finance promulgated the measures for evaluating the performance of financial enterprises in 2016, which stipulates that the four dimensions of profitability, operating growth, asset quality, and solvency are required in evaluating the performance of financial enterprises. Therefore, based on these four dimensions and drawing on the financial indicator system constructed in the literature [18], this paper selects 26 common indicators that can measure the financial performance of listed financial enterprises at multiple levels and from multiple perspectives.

Due to the large number of financial indicators and the correlation between them, it is necessary to select the indicators that can best reflect the performance from many indicators. At the present stage, the most commonly used methods for selecting financial performance indicators are the expert consultation method and the hierarchical analysis method, but the evaluation results of these two methods are affected by the structure and number of experts and are highly subjective. Therefore, based on the existing research, this paper uses solvency and asset quality as input indicators and operational growth and profitability as output indicators. In particular, solvency reflects the level of debt burden, the ability to repay various debts and the debt risk faced by financial enterprises; asset quality reflects the efficiency of financial enterprises in utilising their operating assets, asset safety, and management level; operational growth reflects the level of operational growth and capital preservation and appreciation of financial enterprises; profitability reflects the quality of profitability and the level of input and output of financial enterprises within a certain period of time. The specific indicators are shown in Table 1.

The abovementioned indicator system evaluates the financial performance of financial enterprises from several aspects. Although it satisfies the principles of scientificity and diversity in establishing an indicator system, it does not meet the principles of streamlining and feasibility, especially the rules of DEA for input-output indicators.

To solve these problems, the following will use principal component analysis to perform dimensionality reduction in order to reduce the number of dimensions of these financial performance input and output indicators and to find from them the uncorrelated principal components that reflect the main information and subsequently use the values of the principal components as the original input-output variables for DEA model analysis.

3.3. PCA Treatment of Alternative Input Indicators. A factor analysis of the alternative input indicators gives a KMO value of 0.574 (greater than 0.5) and a chi-square statistic significance level of 0.000 after Bartlett's test, which implies that there are common factors among the input indicators and that they are suitable for factor analysis. In terms of the

amount of variance explained, the cumulative variance contribution of the five main components FAC1, FAC2, FAC3, FAC4, and FAC5 selected in the paper was 78.231%. Factor rotation was then performed using the variance maximisation method, and the results are shown in Table 2.

As can be seen from the factor loading matrix, the principal component FAC1 mainly contains information on two indicators, namely, accounts receivable to revenue ratio and accounts receivable to turnover days, reflecting the efficiency of capital recovery of financial enterprises; the principal component FAC2 mainly contains information on four indicators, namely, gearing ratio, net cash flow from operating activities/liabilities, operating debt ratio, and total asset turnover ratio, reflecting the level of indebtedness, riskiness, and ability to repay principal and interest on debt of financial enterprises; the principal component FAC3 mainly contains information on three indicators, namely, long-term capital indebtedness ratio, financial debt ratio, and return on investment, reflecting the long-term capital structure of financial enterprises and their ability to absorb savings; the principal component FAC4 mainly contains information on four indicators, namely, cash assets ratio, fixed assets ratio, consolidated leverage, and return on long-term capital, reflecting the liquidity of financial enterprises, the efficiency of asset utilisation, the impact of changes in sales volume on earnings per share, and the ability of capital profitability; the principal component FAC5 contains information on two indicators, namely, equity multiplier and accounts receivable turnover ratio, reflecting the ability of financial enterprises to achieve financial leverage and liquidity turnover speed.

3.4. PCA Treatment of Alternative Output Indicators. Similarly, a factor analysis of the alternative output indicators gives a KMO value of 0.573 (greater than 0.5) and a chi-square statistic significance level of 0.000 after Bartlett's test, which implies that there are common factors among the output indicators that are suitable for factor analysis. In terms of the amount of variance explained, the cumulative variance contribution of the four principal components FAC1, FAC2, FAC3, and FAC4 selected in the paper was 88.354%. Subsequently, the factor rotation was performed using the variance maximisation method, and the results are shown in Table 3.

As can be seen from the factor loading matrix, the principal component FAC1 contains information on five indicators, namely, the growth rate of total assets, the growth rate of net profit, the growth rate of comprehensive income, the net operating margin, and the growth rate of return on net assets, reflecting the growth scale of financial enterprises' assets, operating results, operating income to generate net profit, and profitability and growth capacity; the principal component FAC2 contains information on three indicators, namely, capital preservation and appreciation rate, return on assets (ROA), and net profit margin on total assets ,

TABLE 1: Financial performance evaluation indicator system for financial enterprises.

Input index	Name	Symbol	Output indicators	Name	Symbol
Solvency	Asset liability ratio	X1	Business growth	Rate of capital accumulation	Y1
	Net cash flow from operating activities/liabilities	X2		Growth rate of total assets	Y2
	Operating debt ratio	X3		Net profit growth rate	Y3
	Financial liability ratio	X4	Profitability	Growth rate of comprehensive income	Y4

Days sales outstanding	0.924	-0.0203	-0.195	-0.062	-0.047
Total asset turnover	-0.387	0.789	-0.082	0.058	0.035
Long term return on capital	-0.437	-0.051	-0.247	0.662	0.017
Return on investment	-0.388	-0.043	-0.097	0.150	-0.208
Accounts receivable turnover	0.245	-0.056	-0.112	0.178	0.768

TABLE 3: Factor loading matrix for output indicators after orthogonal rotation.

Input indicators	Component			
	FAC1	FAC2	FAC3	FAC4
Rate of capital accumulation	0.074	0.861	0.235	-0.167
Growth rate of total assets	0.793	0.247	0.387	-0.094
Net profit growth rate	0.748	0.557	0.192	0.167
Growth rate of comprehensive income	0.857	-0.025	0.338	-0.036
Sustainable growth rate	0.339	0.154	0.871	0.033
Return on assets	0.196	0.952	0.146	-0.070
Total assets net profit margin (ROA)	0.193	0.951	0.157	-0.065
Return on net assets	0.062	0.472	0.834	-0.176
Total operating cost rate	0.038	-0.154	-0.095	0.939
Return on net assets growth rate	0.847	0.080	0.081	0.345

reflecting the operational efficiency and safety of financial enterprises' capital, the efficiency of asset utilisation, and profitability; FAC3 contains the relevant total operating utilization ratio, which reflects the use of human resources in

the financial sector; the principal component FAC4 contains information on the total operating cost ratio, which reflects the overall situation of the financial sector and the position of the financial enterprise in the industry, and provides a

comprehensive understanding of the financial situation of the enterprise.

4. Predictive Modelling Based on Deep Belief Networks

4.1. Deep Belief Network Model. As an efficient deep learning algorithm, deep belief networks have gradually developed into a mainstream technological direction. A random neural network Boltzmann machine model based on statistical principles was generated, containing an implicit layer and a visible layer, as shown in Figure 1.

On these basis, the principle framework of the restricted Boltzmann machine is proposed, as shown in Figure 2.

Where $a = (a_1, a_2, \dots, a_{n_v})^T \in \mathbb{R}^{n_v}$ denotes the bias vector of the visible layer, $b = (b_1, b_2, \dots, b_{n_h})^T \in \mathbb{R}^{n_h}$ denotes the bias vector of the hidden layer and $W = (w_{i,j}) \in \mathbb{R}^{n_h \times n_v}$ denotes the weight matrix between the hidden and visible layers.

The restricted Boltzmann machine introduces a series of related probability distribution functions through the energy function. For a given set of neurons the state vector (v, h) is represented by an energy function, as in

$$E(v, h | \theta) = - \sum_{i=1}^{n_v} a_i v_i - \sum_{j=1}^{n_h} b_j h_j - \sum_{i=1}^{n_v} \sum_{j=1}^{n_h} h_j w_{i,j} v_i, \quad (1)$$

where v denotes the state vector of neurons in the visible layer, h denotes the state vector of neurons in the hidden layer, n_v denotes the total number of all neurons in the visible layer, n_h denotes the total number of all neurons in the hidden layer, and $\theta = \{a_i, b_j, w_{i,j}\}$ denotes the conditioning factor limiting the Boltzmann machine architecture.

With the energy function defined in equation (1), the joint probability distribution of the state (v, h) can be obtained as in

$$P(v, h | \theta) = \frac{1}{Z(\theta)} e^{-E(v,h|\theta)}, \quad (2)$$

where $Z(\theta)$ expressions, as in

$$Z(\theta) = \sum_{v,h} e^{-E(v,h|\theta)}, \quad (3)$$

where $Z(\theta)$ denotes the normalisation parameter. Let $P(v|\theta)$ be the probability distribution of the visible layer vector v . This can be calculated by $p(v, h|\theta)$ the edge distribution for $P(v|\theta)$, as in

$$PP(v|\theta) = \sum_h P(v, h|\theta) = \frac{1}{Z(\theta)} \sum_h e^{-E(v,h|\theta)}. \quad (4)$$

In the same way, we can obtain the probability distribution of the hidden layer vector h $P(h|\theta)$ as in

$$P(h|\theta) = \sum_v P(v, h|\theta) = \frac{1}{Z(\theta)} \sum_v e^{-E(v,h|\theta)}. \quad (5)$$

By analysing equations (4) and (5), it can be seen that in order to obtain $P(v|\theta)$ and $P(h|\theta)$, the key step is to calculate

the normalisation parameter $Z(\theta)$. However, equation (5) shows that its computational complexity is high. However, due to the special principle that restricts the Boltzmann machine model (the visible and hidden layers are conditionally independent), the probability of a neural unit being activated in the hidden layer can be calculated by equation (6) when the states of all neurons in the visible layer are known.

$$P(h_j = 1 | v, \theta) = \sigma \left(b_j + \sum_i v_i w_{i,j} \right), \quad (6)$$

where $\sigma(-)$ denotes the sigmoid activation function.

Because all neural nodes within the same layer are connectionless with each other, the relationship between the values taken by all neural nodes within the same layer and the values taken by a single node is as in

$$P(h|v) = \prod_{j=1}^{n_h} P(h_j | v), \quad (7)$$

$$P(v|h) = \prod_{i=1}^{n_v} P(v_i | h). \quad (8)$$

A randomized gradient algorithm is usually used to find the maximum value of $\sum_{i=1}^i \log P(v^{(i)}|\theta)$ in order to obtain the optimal conditioning factor θ in the network. A deep belief network model is used, as shown in Figure 3.

4.2. Deep Belief Network Training Process. The deep belief network training process is generally divided into 2 steps: a pretraining phase and a fine-tuning phase.

The loss function required for ageing in the fine-tuning phase is given in

$$L(x, y) = \|x - y\|_2^2, \quad (9)$$

where the symbol $\|\cdot\|_2$ denotes the 2-parameter reconstruction error, x denotes the input data, and y denotes the reconstructed data.

5. Corporate Financial Performance Evaluation Model

When the number of evaluation indicators increases to a certain level, it will not only increase the workload of the DEA model in data processing but also make the evaluation results meaningless due to the strong interrelationship between input and output indicators causing the validity of all decision units to be close. Therefore, in order to avoid the above problems, this paper proposes a combined evaluation model based on factor analysis and DEA to evaluate the financial performance of financial enterprises [21, 22].

Using the advantages of the PCA method in extracting the characteristics of indicators, the input and output data required by the DEA model are preprocessed, i.e., multiple indicators are synthesised into a few principal components that can cover their main information, in order to achieve

FIGURE 1: Boltzmann machine model.

FIGURE 2: Restricted Boltzmann machine model.

FIGURE 3: Depth generation model.

the purpose of dimensionality reduction of the indicators [23].

The processed input and output indicators are fed into the DEA model in order to calculate the relative efficiency of the financial performance of financial enterprises. This not only retains the complete information of each indicator but also reduces the degree of correlation between indicators, while satisfying the requirements of the DEA model, so that the model can adequately evaluate the relative effectiveness of the decision-making unit and ensure the accuracy and scientificity of the results. The process is shown in Figure 4.

6. Evaluating Model Validity Tests

As some of the principal components obtained above have negative values, they do not meet the DEA model's requirement of positive values for the input and output variables. Therefore, the principal components obtained in the above section were normalised to obtain new input and output data, which were fed into the DEA model to obtain the results, as shown in Table 4.

Technical efficiency can measure an enterprise's ability to allocate resources and its ability to use resources efficiently in

many ways and evaluate whether its industrial structure is in line with the overall requirements to enable the enterprise to maximise its economic efficiency. On the whole, these 37 listed financial enterprises operate well in terms of input-output efficiency in terms of financial performance, with an average value of 0.883 for technical efficiency, indicating that these listed financial enterprises have good capabilities in terms of capital allocation and efficiency of use.

As can be seen from Table 4, there are 24 financial enterprises with all three efficiency values of 1, accounting for 64.9% of the total sample, which are on the DEA efficiency frontier, indicating that these 24 financial enterprises are relatively efficient, achieving "maximum output with existing inputs" and "minimum input on top of existing output." The remaining 13 financial enterprises have achieved the best efficiency in terms of capital allocation and utilisation, with no waste of input resources and no shortfall in output. The technical efficiency of the remaining 13 financial firms ranged from 0.2 to 0.9, accounting for 35.1% of the total sample, indicating that the DEA of these financial firms was ineffective, with the dual problems of inefficient capital allocation and low capital efficiency. There are two main reasons for this: firstly, technical efficiency is 1 and

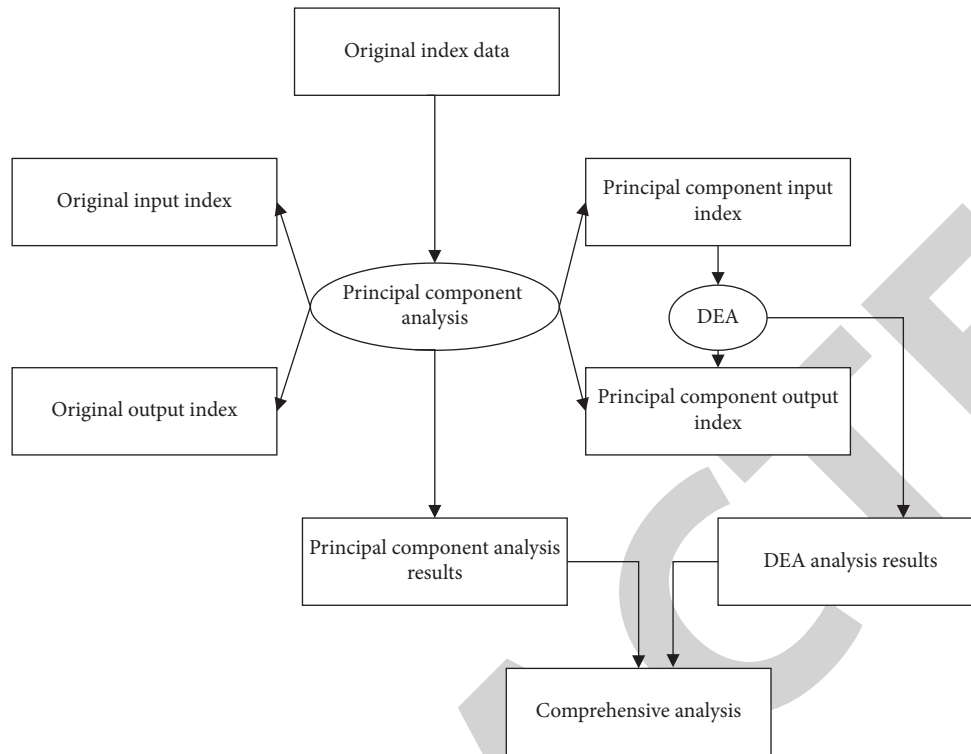

FIGURE 4: Financial performance evaluation process of the financial companies based on PCA and DEA.

scale efficiency is ineffective. For example, DUM19 technical efficiency is 0.452, technical efficiency is 1, and scale efficiency is 0.452. If we want to make this firm DEA effective, we need to increase the scale of investment and adjust to scale, and we can achieve relative optimality after increasing scale efficiency. Second, neither pure technical efficiency nor scale efficiency is 1, but both are at the stage of increasing returns to scale, indicating that it is advantageous for these financial firms to expand their scale at this stage. For example, the technical efficiency of DUM2 is 0.433, the technical efficiency is 0.448, and the scale efficiency is 0.967, which are in the stage of increasing returns to scale. If you want to make this enterprise reach DEA effective, you can adjust the scale of investment to improve the technical efficiency, but you cannot ignore the improvement in technology, and you need to make comparative improvements in both financial efficiency and input scale of the enterprise in order to reach relative optimization [24].

In terms of the value of pure technical efficiency, its overall sample mean reached 0.954 and the pure technical efficiency of the sample was 30, accounting for 81% of the total sample. For the remaining seven financial enterprises with ineffective DEA, they need to upgrade their technology and increase the scale of inputs in order to achieve relative optimality. For example, DUM2 with a pure technical efficiency of 0.448 and a scale efficiency of 0.967 has a low financial efficiency mainly due to a low level of financial management and technical inputs. Therefore, for these financial companies with relatively low values of pure technical efficiency, the management should further improve the scientific nature of their operational and investment

decisions and focus on managing the returns and risks of their investment projects [25, 26].

There are three types of returns to scale: constant returns to scale, diminishing returns to scale, and increasing returns to scale. Production with constant returns to scale is generally the most efficient. Increasing returns to scale indicate that each additional unit of resource input produces greater than one unit of output, while the opposite is true for decreasing returns to scale. In terms of scale efficiency coming to a value, the sample mean is 0.918, which indicates that only 0.82% of resources are underutilised at scale.

In terms of returns to scale, all financial firms are at the stage of constant or increasing returns to scale, indicating the huge potential and prospects for the development of the financial sector, when financial firms continue to increase their capital investment, which can lead to increasing output, thus contributing to the rapid development of the financial system as a whole. Twenty-four financial firms have an efficiency of scale value of 1. They are in a state of constant returns to scale, and their use of resources and scale of inputs are optimal and do not need to be improved. The remaining 13 financial firms, all of which have an efficiency of scale value less than 1, are in a state of increasing returns to scale despite their inefficient scale. For these financial firms, their pure technical efficiency and scale efficiency are inefficient, and in order to reach optimality, improvements must be made in both the input and output efficiency of financial resources.

For the purpose of analysis, assume that a foreign-owned company, Company A, has the following economic operations:

TABLE 4: Results of the 2015 financial performance evaluation of the listed financial companies.

1. On 4 January 2010, Company A enters into a trade contract with a foreign importer, Company B, which provides that over the next 12 months, with the 15th of each month being the shipment date, Company A will export to Company B goods valued at CNY72 million in 12 batches, with each batch being settled 60 days after the shipment date in the amount of CNY6 million.
2. On 5 January 2010, Company A launched a new domestic production line with a total project investment of CNY60 million, with an expected useful life of five years and a 30% increase in productivity, payable in 12 monthly instalments of CNY5 million from March 2010.
3. On 15 April 2010, Company A borrowed funds of CNY80 million from the Industrial and Commercial Bank of China to resolve its liquidity difficulties. Company A's foreign exchange exposure risk data (as shown in Table 5).

In the example above, the accountant did not apply any exchange rate risk management measures, and against the backdrop of a significant appreciation of the RMB, Company A, a foreign-owned company, suffered significant exchange rate risk losses. However, if the accountant had been able to use flexible foreign exchange exposure management, Company A's situation would have been different, as the price index CPI in China has been increasing since the

TABLE 5: Exposure data for Company A's foreign exchange exposure positions.

Date	Foreign exchange assets	Foreign exchange liabilities	Exchange rate	Open mouth
2010.01.15	USD6000000	2	6.8271	USD6000000

2010.10.15	USD6000000	5	6.4571	USD6000000
2010.11.15	USD6000000	6	6.5787	USD6000000
2010.12.15	USD6000000	8	6.5654	USD6000000

second half of 2010 and the central bank has adopted a tightening monetary policy, which means that the cost of financing for companies will increase. In contrast, due to the low economic boom in the United States, the Federal Reserve has adopted a quantitative easing monetary policy with lower lending rates in US dollars.

Therefore, Company A should choose a loan in US dollars to introduce advanced production lines from abroad and increase the rate of return of its project investment.

7. Conclusions

The rapid development of an enterprise depends largely on the level of its financial performance. An effective evaluation of its financial performance can create new value for the financial system continuously and promote the healthy development of the financial industry. This paper uses principal component analysis methods and data envelopment methods to conduct a comprehensive evaluation of the financial performance of the listed financial enterprises. While ensuring that the information on the indicators is retained intact, it can also provide a scientific and effective evaluation of the financial performance of financial enterprises and provide financial enterprises with the opportunity to make appropriate adjustments to their own resources or scale in order to achieve the optimal allocation of resources, thereby achieving an improvement in the overall financial performance level of financial enterprises.

Modern enterprise management is developing rapidly, and one of the most important components of enterprise management is enterprise digital management. In this paper, the research background of enterprise digital management system is firstly elaborated, current situation of enterprise digital management work in enterprises is elaborated, then the current situation of the system research and development at home and abroad is also analysed and outlined in detail, and finally, according to the actual enterprise digital management situation of enterprises, combined with the system method of software development and corresponding technology, the new system design requirements of enterprises based on Internet of Things are proposed. Simulations show that the overall design and module design of the system in this paper are well managed, a system interface diagram can be given, and the database table structure and entity class diagram are applied to elaborate the database design.

1. Introduction

Digital management is an important aspect of the management of modern enterprises, and the survival and development of enterprises is closely related to strengthening the protection of their digital resources [1]. Enterprises have been using traditional management methods for a long time, manually locating and retrieving digital files, and designing and printing hard copies of digital catalogues [2]. However, this traditional management approach requires human participation, leading to a variety of problems such as inefficiency and difficulty storing and securing documents [3]. In the course of an enterprise's daily operations, large numbers of digital documents are generated at all levels, and these documents all need to be archived [4]. The archiving of corporate documents is generally not undertaken in a timely manner. To meet the management requirements of modern enterprises, a digital enterprise management system should consist of six parts: scanning and entry, digital management, enquiry and statistics, loan management, approval management, and system management [5]. The rapid

development of Internet-based information technology systems has resulted in enterprises attaching increasing importance to digital information management [6]. The use of Internet technology is an important aspect of a digital information system, while the application of digital information resources provides support for the management and transformation of enterprises [7]. Therefore, it is necessary for each enterprise to build a digital management system that meets its specific requirements and enables it to keep up with the trend of increasing informatisation [8]. This study is based on the integration of the main activities of an enterprise with advanced management information system technology, and aims to improve the efficiency of enterprise management by designing a digital enterprise management system [9]. Based on the needs of enterprises, the digital enterprise management system is designed to facilitate information exchange and communication that overcomes problems such as poor information communication caused by inconvenient locations, incompetence, and operational distance, which can hinder the development of the enterprise [10, 11].

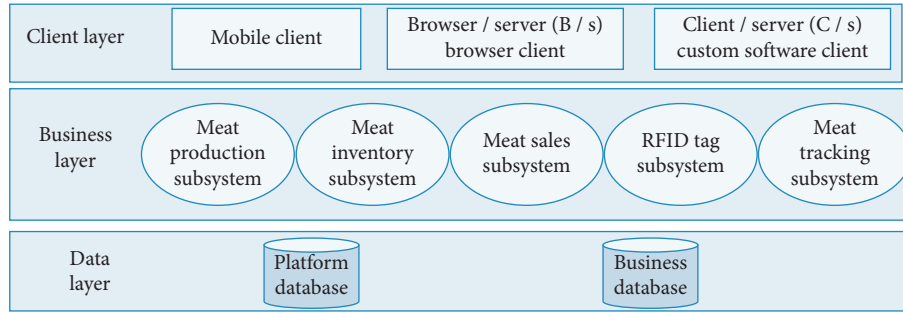

FIGURE 1: RFID-based enterprise digital management platform architecture.

FIGURE 2: Layout of RFID readers in the sales centre warehouse.

2. RFID-Based Enterprise Digital Management Platform Architecture

The architecture of the RFID-based enterprise digital management platform is shown in Figure 1 and is divided into a data layer, a business layer, and a customer layer. The data layer includes the platform database and the business database. The platform database provides the operational data of the basic platform, and the business database provides the business data [11]. The business layer provides the main functions of the system, which mainly consists of five subsystems: RFID tag subsystem, enterprise production subsystem, enterprise inventory subsystem, enterprise sales subsystem, and enterprise tracking and tracing subsystem. The client layer provides the interface for users to use the system in different ways, mainly divided into mobile phone clients, browser clients under the browser/server (B/S) structure, and custom software clients under the client/server (C/S) structure. Users are divided into 3 main categories: consumers, administrators, and supervisors.

The EPC system is mainly responsible for the collection and filtering of RFID data from each subsystem node, which

is transmitted via the network to the respective remote PML database for processing such as storage and query.

The lifecycle of an enterprise, from slaughter to the consumer, can be divided into several stages: slaughter, processing, inventory, transport, sales, and consumption. To achieve enterprise tracking and tracing, it is necessary to identify, record, manage, and track the information in these stages to form a complete enterprise lifecycle information chain [12]. Among them, the enterprise information tracking and tracing in the slaughtering and processing stage has already been discussed in this paper. This paper focuses on the tracking and tracing of information in the sales phase of the enterprise.

2.1. Analysis of Corporate Sales Tracking Systems. In a radio frequency identification (RFID)-based information system environment, the volume of information is so large that efficient RFID event detection and processing is difficult to achieve using existing database and data management technologies [14]. This system uses the stand-alone synchronisation equipment (SASE) event language of complex

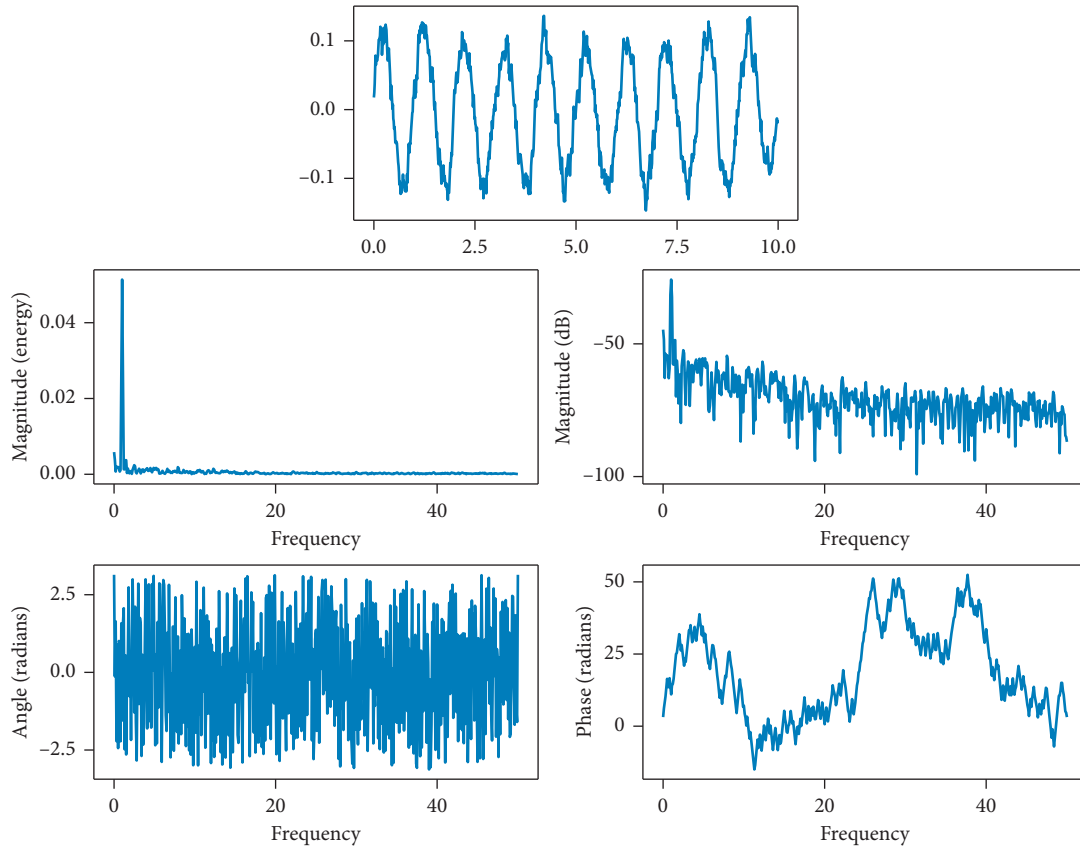

FIGURE 3: Frequency of use of different data information.

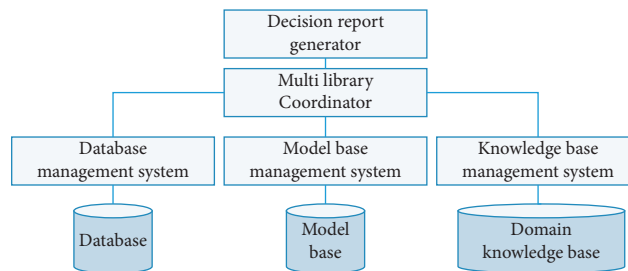

FIGURE 4: Overall structure of the decision support system.

event processing (CEP) technology to process the basic events formed by the filtered data [15]. CEP is an emerging technology for building and managing information systems [16]. CEP defines the basic information to be processed as events, which can be customised by the user, for example, as an event related to an operation in an enterprise application or as an event related to a data transfer on the network, depending on the user’s role and observation point [17]. There are various relationships between simple events, and multiple simple events can be combined to form a complex event. Further, multiple complex events can be combined to form a “more complex” event. The process of using CEP to analyse data is as follows. First, the layout of the RFID reader is designed based on the requirements of each node in the enterprise’s operations. Second, basic events are defined

based on the layout of the RFID reader. Finally, complex events are processed using the SASE event language [18, 19].

2.2. Operating mechanism of corporate sales tracking systems.

The following is an example of RFID data analysis of an enterprise’s inventory node to illustrate the process of RFID data analysis using CEP. 1) The enterprise’s regional sales centre is the main link in the circulation of the enterprise’s products and requires information about the enterprise’s sales, stock, and expired products. Based on an analysis of the functions required by the enterprise’s regional sales centre, it is clear that the information to be collected includes stock stored in the enterprise’s warehouse, sales through the regional sales centre, and expired stock in the enterprise’s

FIGURE 5: Effect of using company documents.

warehouse. Therefore, it is necessary to position RFID readers inside the warehouse, at the warehouse exit, and at the warehouse settlement point, as shown in Figure 2. 2). The three basic events in the warehouse inventory node are WAREHOUSE-READING, CHECK_OUT-READING, and EXIT-READING, where WAREHOUSE-READING represents the data from the RFID readers (R1, R2, R3, R4 in Figure 2) in the warehouse, CHECK_OUT-READING represents the data from the tags read by the checkout reader (Rcheck_out in Figure 2 when the enterprise ships stock, and EXIT-READING represents the data read by the warehouse exit reader (Rcheck_out in Figure 2 when the stock leaves the warehouse [20, 21] 3) Regarding the processing of complex events in the warehouse inventory node, the following is an example of how the SASE event language is processed. The complex event of enterprise sales is represented in the sales centre node model as follows. The stock arrives at the shipping checkout point and then arrives at the warehouse door, which is represented in the basic event set as a sequence of two basic events, CHECK_OUT-READING and EXIT-READING, and is completed within a defined time frame. When this complex event occurs, its EPC code and exit time are provided and this information is stored in the product exit table of the event database. In conjunction with the example shown in Figure 4, the complex event processing in relation to the sale of this stock involves checking that a label with the EPC code 86.0257A08.100167.20100608432 appears in sequence in the two basic events CHECK_OUT-READING and EXIT-READING with a time

interval of less than 1 h. If this is the case, the enterprise is considered to have completed the sale of the stock.

3. Establishment of Decision Support Systems

When the information accumulated by the system reaches a certain scale, advanced data mining technology can be used to intelligently identify information with potential utility from the data warehouse and provide decision support information to the leaders of relevant departments for the purpose of effective accident prevention. The system is designed with decision support interfaces included in both the data layer and the key service layer of the software. The decision support system is an independent subsystem, the overall structure of which is shown in Figure 3. The main functions of the decision support system are as follows. (1) Safety problem causation analysis for decision-making. The safety problem causation analysis decision support system assists managers in the analysis of the causes of safety problems and the assignment of responsibility for those problems. It analyses the internal and external environment in which safety problems arise, uses multidimensional analysis techniques to study the intrinsic connection of safety data, compares problems with similar problems that have occurred in the past, and completes a report on the causes of problems through human-computer interaction. (2) Accident prediction and decision-making. Predictive analysis is carried out using theories and methods such as fuzzy diagrams, grey systems, nonlinear

FIGURE 6: Effectiveness of digital management of companies with different solutions.

regression, stochastic processes, and safety system engineering. Correlations between factors affecting safe production and safety problems during production are obtained [19]. The applicability of various prediction methods is examined so that the results produced by the model provide a scientific basis for the prevention and management of safety problems. (3) Research on safety countermeasures. Safety information contains a wide variety of problem types. When the number and severity of problems are within specified limits, general management measures can be applied. However, when they reach or exceed those limits, safety improvements are required. This requires the identification of problem-prone units, lines, or

sections, as well as potentially problematic units, lines, or sections, and then the application of appropriate countermeasures. This mainly includes the identification of accidents, daily safety management countermeasures and safety engineering improvement countermeasures. (4) Safety warning mechanism. This involves the establishment of an assessment mechanism based on conditions such as problem level and unit type, which is then combined with historical data to enable a scientific assessment of the production safety status of each unit. A safety early warning mechanism is also established and regular safety early warning notices are issued in a targeted manner with the aim of preventing seasonal accidents.

4. Simulation Implementation

In summary, the RFID/GIS-based enterprise sales tracking and tracing system, which is a sub-system of the enterprise digital management platform architecture, needs to be integrated with other subsystems to enable the sharing of information. The frequency of data usage by the enterprise's employees is shown in Figure 4. Using the EPC codes of the products the enterprise buys, inputting these into the system through the reader on the traceability terminal and clicking on the product traceability function, it is possible to obtain the product circulation path from the manufacturer to the retailer. The relevant information regarding each product circulation node can be obtained from the GIS system. The digital enterprise management platform features hierarchical architecture containing a customer layer, a business layer, and a data layer. It is feasible to develop an enterprise sales tracking and tracing system using a unified enterprise digital management platform with hierarchical architecture. The enterprise sales link, which includes storage, transportation, sales, and other processes, does not require sales to be divided or combined with other activities, and is particularly suitable for the use of RFID tags. The system design proposed in this study was verified using enterprise documents, as shown in Figure 5. In the life-cycle management of the enterprise, based on the sales process key node RFID data collection and processing, the electronic product code system is used to develop an Internet of Things environment for enterprise information tracking and tracing. However, the system needs to ensure the validity of the data flow, and each key node in the business process must be connected to the entity tag language server of the producer to obtain the necessary information. If the data from one link cannot be updated, the integrity of the tracking and tracing information cannot be guaranteed. The effectiveness of various digital enterprise management solutions is shown in Figure 6. The good results obtained using the model proposed in this study can be attributed to the use of HF/UHF RFID technology, process optimisation and database backend control to ensure that the information is correctly collected and filtered. How to ensure stable operation of the equipment and fast, accurate data collection and processing is a challenging problem that requires further research.

5. Conclusions

In this study, we developed an enterprise information tracking and tracing platform based on GIS using three-tiered architecture. This platform is required to support multiuser and multiterminal devices, and thus requires the installation of the necessary GIS software in different terminals. The model proposed in this study uses process optimisation, database backend data control, and other measures to ensure that the data is safe and secure. However, the best way to ensure the security of information is to focus on the security of the RFID tags used in the front-end solution, which requires further research.

As a meta-heuristic algorithm based on swarm intelligence, the WOA algorithm has few control parameters and searches for the optimal solution by encircling the prey, searching for the prey, and attacking the bubble net. During the whole process, only two internal parameters A and C are utilized for the control of the exploration and development process. BWOA is simple to implement. In the process of algorithm execution, the initial population, global exploration, and local development stages have shortcomings. Therefore, it is necessary to optimize the WOA algorithm. Based on WOA, this study conducts a high-performance computing analysis and location selection of logistics distribution center space. It is concluded that: (1) by using the combination of direct logistics distribution and hierarchical logistics distribution, the WOA algorithm optimizes the cross selection strategy, the population fitness S-LO is improved, the quality of LA is guaranteed, and the chaotic S-LO mapping eliminates inferior individuals in the population. Direct distribution is carried out for bulky goods and important distribution customers, and hierarchical logistics distribution is used for customers in intensive logistics distribution destinations. (2) WOA uses the second reverse learning, chaotic mapping, and logistic chaotic mapping to improve the location update mode. The direct distribution method is mostly used for the logistics business with short journeys, fixed distribution points, and more goods delivered at one time, and logistics enterprises do not need to store and distribute goods. The uniform ergodicity of the Tent chaotic map and logistic chaotic map is improved. Ka adaptive inertia weights are a good complement to optimize the limitations of the Ao whale algorithm. (3) The inertia weight of the levy flight behavior can play a powerful role in balancing the global exploration ability and optimization performance of the intelligent algorithm. The long-term short-distance search of HED and the long-distance jump of KVAR are combined. Variant individuals undergo vector synthesis. It reduces the construction and operation costs of logistics sites and is suitable for logistics distribution under specific conditions.

1. Introduction

Whale Optimization Algorithm (WOA), as a new type of modern intelligent optimization algorithm, has been applied in research fields such as reactive power scheduling optimization, short-term load forecasting, logistics distribution calculation analysis, and location selection and has shown good results. Head whales surround the fish in a circular contraction [1–3]. At the same time, it will swim upward in a spiral upward manner to prey, and by following a “9” or “O”-

shaped path, it is constantly approaching its prey while generating unique bubbles. The position of each humpback whale in the whale algorithm represents a feasible solution. The advantages of this algorithm are that there are few adjustment parameters, simple operation, and strong local optimal ability. For each basic function, define the population size and variable range, run the improved whale optimization algorithm 30 times from randomly generated different populations, and calculate the average and standard deviation as the basis for judging the optimization effect of

the algorithm. In the whale algorithm, each whale can be regarded as a particle, and the position of each particle represents a decision variable. The shrinkage and encirclement mechanism will make the remaining whale individuals move closer to the current optimal whale, and the change in the absolute value of the coefficient will affect the judgment of the remaining whales based on the current position of the corresponding position of the optimal position at the next moment. The spiral update mechanism is based on the distance between the whale's real-time position and the current optimal position, simulating the whale's predation through a spiral trajectory to explore the trajectory range. This makes the population develop towards a single, prone to premature convergence. The optimal individual is mutated [4]. Individuals with high fitness before and after mutation can be used to expand the search range and improve population diversity [5–7]. The core idea of the WOA algorithm is to abstract the hunting mode of humpback whales into a mathematical model, which subtly solves the problem of finding the optimal value in most scenarios, but when faced with some more complex problems or high search space dimensions, in the WOA algorithm, there is insufficient global exploration ability and unsatisfactory convergence accuracy. It is easy to fall into problems such as local optimum [8–10]. In the process of algorithm execution, the initial population, global exploration, and local development stages have shortcomings. For the meta-heuristic algorithm based on group iteration, the quality of the initial population will directly affect the optimization ability and stability of the algorithm and the high-quality initial population with better diversity can lay the foundation for the global search of the group iterative algorithm. Since there is no prior knowledge of the global optimal value of the problem to be solved, the WOA algorithm uses random initialization to generate the initial whale population. The initialized population generated by the random method cannot guarantee the diversity of the population, and it is difficult to effectively extract the useful information of the solution space. To a certain extent, it will affect the convergence speed and optimization ability of the algorithm. The location update of whale individuals in the global exploration phase mainly depends on two parts: the randomly selected search individual location and the product of the coefficient vectors A and D . In the iterative process, A decreases from 2 to 0 and the proportion of A greater than 1 is very small, which leads to a very low probability of global exploration of the whale population, which further weakens the global exploration ability, and it is difficult to get rid of the constraints of local optimality, which leads to the algorithm Precocious and convergent.

As a key node in the express distribution process, logistics distribution sites have received more and more attention. Successful distribution site selection can speed up the circulation efficiency of products and reduce logistics costs, bringing convenience and economic benefits to suppliers and demanders. The development of social productive forces is promoted. Logistics and distribution need to deliver goods from suppliers to customers. For customers, logistics and transportation efficiency is an important determinants of customer experience. In the process of

logistics and transportation, storage, transportation, distribution, and processing are all indispensable. In the process of applying the whale algorithm to solve the optimization problem, since the convergence ability of the algorithm is closely related to the size and randomness of the population, the reasonable setting of the population is very important to the subsequent operation of the algorithm. The differential evolution algorithm performs mutation operations according to the differential strategy. The most prominent feature of the algorithm is its mutation operator. The method of selecting the parent in the mutation operator has an important impact on the search speed of the optimal solution of the differential evolution algorithm. Reasonable allocation of resources is suitable for demand distribution. It also needs to adapt to the overall function and spatial distribution pattern of the city [11–13]. Huge investment, recovery, and relocation are all difficult. The infrastructure of the logistics distribution center is coordinated and balanced with the overall logistics system in terms of spatial distribution, productivity, and technical capabilities. To control the impact of site selection on urban traffic is tried [14, 15]. The whale optimization algorithm has the characteristics of simple structure and easy implementation, but there is a problem of local optimality. It can be improved by simulating the mutation and selection operation of the differential evolution algorithm, so that the improved algorithm not only has the ability to quickly converge but also can optimize globally.

2. Logistics Model

2.1. Enterprise Logistics Distribution Network Model. The multilevel network distribution method is generally used in the logistics network distribution of e-commerce, and the logistics distribution is carried out by establishing a hierarchical logistics site. The current fitness value is calculated and the optimal individual is selected. Using the combination of direct logistics distribution and hierarchical logistics distribution, direct distribution is carried out for bulky goods and important distribution customers and hierarchical logistics distribution is used for customers in intensive logistics distribution destinations. According to the fitness value, the optimal individual of the newly generated population is selected, through the improvement of the whale position update method in the algorithm. The direct distribution method is mostly used in the logistics business where the journey is short, the distribution point is fixed, and there are many goods delivered at one time. The logistics enterprise does not need to store and distribute the goods. After the logistics enterprise obtains the goods from the supplier, it will be delivered directly to the customer, and in this way, the construction and operation costs of logistics sites are reduced, and it is suitable for logistics distribution under specific conditions. However, with the increase of modern logistics business demand, the distribution demand has become scattered and fragmented and most logistics enterprises no longer regard the direct logistics distribution method as the only distribution method of the enterprise but use it in combination with other distribution methods, as shown in Figure 1.

FIGURE 1: Enterprise logistics network.

2.2. Hierarchical Distribution Network. Hierarchical logistics distribution is divided into two logistics methods: for small and medium-sized cities, a two-layer logistics distribution network is established that includes a combination of a general distribution site and several regional distribution sites. When it is delivered to the customer by the regional distribution site and when returning the goods, the goods first enter the regional logistics site, and then the regional logistics site is merged into the general distribution site. For large cities, because there are too many logistics orders, a total distribution site is not enough to complete the distribution and collection of a large number of orders, so an intermediate distribution site will be built between the first and second level distribution sites to assist in the management of logistics, forming a three-level city logistics and distribution network. The transit station means that it is used in the distribution network of large cities, and the distribution network of small and medium-sized cities does not use intermediate distribution stations, as shown in Figure 2.

3. Whale Optimization Algorithm

3.1. BWOA [16–20]. Reactive power scheduling optimization,

$$\min p = \min \sum_{i \in X} L_i * M_i. \quad (1)$$

Short-term load forecasting,

$$x = \frac{\sum_{i \in X} L_i * M_i}{\sum_{i \in X} M_i}. \quad (2)$$

Logistics and distribution calculation analysis selection,

$$\min F = \sum_{i=1}^a \sum_{j=1}^b x_{ij} c_{ij}, \quad (3)$$

$$\min F = \sum_{i=1}^n \sum_{j=1}^m x_{ij} c_{ij} + \sum_{j=1}^m f_j.$$

Surround prey,

$$\min F = \sum_{i=1}^n \sum_{j=1}^m x_{ij} c_{ij} + \sum_{j=1}^m \sum_{k=1}^l h_{jk} x_{jk} + \sum_{j=1}^m v_j (w_j)^\sigma. \quad (4)$$

Bubble attack,

FIGURE 2: Logistics optimization distribution network.

$$F = \sum_{i=1}^k \sum_{x=1}^n a_{xi} d(x, i) + \sum_{i=1}^k \sum_{j=1}^m b_{xi} d(i, j). \quad (5)$$

Explore foraging,

$$W = \sum_{i=1}^k \left[\sum_{x=1}^n \max \left(g_{xi}, \frac{v_{xi}}{60} \right) C d(x, i) \right]. \quad (6)$$

Differential evolution algorithm,

$$\begin{aligned} \sum_1^n i &\geq 1, \\ \sum_1^n \partial_i &\leq 1. \end{aligned} \quad (7)$$

3.2. Rosenbrock [21–23].

$$\sum_{\theta=1}^n m_\theta \leq M. \quad (8)$$

Single population development,

$$\begin{aligned} \left[\sum_{j=1}^n g_{ij}, \sum_{x=1}^n g_{ij} \right] &\geq 0, \\ d(x, i, j) &\geq 0. \end{aligned} \quad (9)$$

Precocious astringent,

$$\left[\sum_{j \in D_i} j, \sum_{x \in D_i} x \right] \geq 1. \quad (10)$$

High-dimensional space search,

$$F = \sum_{i=1}^k \sum_{x=1}^n a_{xi}d(x, i) + \sum_{i=1}^k \sum_{j=1}^m b_{xi}d(i, j) + \sum_{i=1}^k \sum_{j=1}^m t_i g_j, \quad (11)$$

$$A = \{a_1, a_1, \dots, a_i\},$$

$$K_1 = \{K1_1, K2_1, \dots, K j_1\},$$

$$SSE_1 = \sum_{m=1}^j \sum_{a_{m1} \in Km_1} \|a_{m1} - Km_1\|^2.$$

3.2.1. Quartic [24–26].

$$K_2 = \{K1_2, K2_2, \dots, K j_2\}, \quad (12)$$

$$K j_2 = \text{mean}(a_{m1}).$$

Global exploration capability,

$$SSE_2 = \sum_{m=1}^j \sum_{a_{m2} \in Km_2} \|a_{m2} - Km_2\|^2, \quad (13)$$

$$\Delta SSE_2 = |SSE_1 - SSE_2|.$$

Local optimum,

$$\Delta SSE_2 \leq \delta. \quad (14)$$

Species diversity,

$$x(t+1) = x_{\text{best}}(t) + D * e^{bl}. \quad (15)$$

Differential evolution algorithm,

$$x(t+1) = x_{\text{rand}}(t) - A * C * x_{\text{rand}}(t) - x(t). \quad (16)$$

The overall coordination and balance of the logistics system are as follows:

$$p = \frac{|E_x - x|}{E_x}, \quad (17)$$

$$x_i^0 = (a_i - b_i)z_i + b_i.$$

4. Simulation Experiment

4.1. Individual Elimination Strategy. When the WOA searches immediately, it moves closer to a random position. Although this method can ensure the diversity of the population to a certain extent, it is easy to produce inferior solutions that deviate from the optimal direction, which affects the convergence speed. In the cross selection strategy of the genetic algorithm, after each iteration, the population is sorted according to fitness and equally divided into two parts, one part is relatively high-quality individuals and the other part is relatively inferior individuals, and the two parts are subjected to pairwise arithmetic crossover to generate a new one. The population of, where S-LO = 111, S-LA = 107, C-LO = 54, C-LO = 62, WT = 44, and VO = 10. A crossover between high-quality individuals and low-quality individuals can ensure the diversity of the population. The original

TABLE 1: Parameters of individual elimination strategy.

S-LO	S-LA	C-LO	C-LO	WT	Vo
99	116	78	77	28	3
119	102	62	56	27	9
90	111	74	71	20	9
96	111	68	60	28	9
110	94	86	75	46	3
94	107	72	65	22	9
99	96	67	54	42	8
114	102	73	90	31	10
92	109	63	81	40	8
105	117	90	65	48	9
111	107	54	62	44	10

population is merged, and the new population, sorted by fitness, eliminates inferior individuals in the merged population and lets the retained high-quality individuals enter the next iteration, and S-LO = 110, S-LA = 94, C-LO = 86, C-LO = 75, WT = 46, and Vo = 3. S-LA guarantees the high quality of the population. Chaos S-LO mapping can be used to generate chaotic sequences, and C-LO has a better effect than pseudorandom numbers in generating WT chaotic sequences in population initialization as shown in Table 1 and Figure 3.

4.2. Partial Development Stage. The chaotic sequence is added on the basis of secondary reverse learning. The more commonly used discrete chaotic maps are Tent chaotic map and logistic chaotic map, and Ka = 4.08, Ao = 4.47, Io = 4.22, IT = 4.04, To = 4.52, No = 4.47, and $\beta = 4.98$. It is proved that the Tent chaotic map has better uniform traversal properties than the logistic chaotic map. If the current optimum is close to the local optimum, then a small step search pattern around the local optimum will trap the algorithm in a local extremum, and Io = 4.44, IT = 4.78, To = 4.39, No = 4.97, and $\beta = 4$. It is difficult to get rid of the shackles of local extrema. The introduction of Ka adaptive inertial weights is a good complement to optimize the limitations of the Ao whale algorithm. In the local development stage, Ka = 4.68 and Ao = 4.97; an effective mutation strategy makes it difficult for the whale population to get rid of the shackles of local optimum. See Table 2 and Figure 4.

4.3. Levy Flight Strategy. Levy flight is a kind of random walk (Randomly walk) motion of living organisms; bats, fruit flies, cuckoos, people, lights, etc., all have this levy flight behavior. The inertia weight plays an excellent role in balancing the global exploration ability and optimization performance of the intelligent algorithm, and HED = 3.82, ND = 3.58, HDE = 3.45, DIR = 3.66, DIT = 5.51, LAD = 4.7, W = 2.63, and KVAR = 2.16 is used in a variety of algorithms. The walking performance of this mechanism is a combination of the long-term short-distance search of HED and the occasional long-distance jump of KVAR, which is characterized by directional variability. The mutation strategy in the differential evolution algorithm is to randomly select two different individuals in the population, and HDE scales the

FIGURE 3: Individual elimination strategy parameters.

vector difference and then performs vector synthesis with the individual to be mutated. See Table 3 and Figures 5 and 6.

4.4. Improvement Strategies. The whale optimization algorithm simulates the unique bubble network attack

mechanism of humpback whales. By calculating the fitness value of all search agents, the current optimal solution is selected, and then the circular contraction mechanism and the spiral up mechanism are selected. By calculating the fitness value of each whale, the optimal whale position bestX and its corresponding global optimal fitness value best f are

position and record the current global optimum value and optimum position at the same time. The selection of the circular contraction mechanism and the spiral up mechanism is performed (Figure 7).

As a meta-heuristic algorithm based on swarm intelligence, the WOA algorithm is the same as other meta-heuristic algorithms and has the advantages of fewer control parameters, simple implementation, and high flexibility. (1) Sphere

has few control parameters: test function = 0.6, algorithm = 0.03, optimal = 0.63, average = 0.84, and worst = 0.49. The WOA algorithm mainly simulates the predation behavior of humpback whales and searches for the optimal solution by encircling the prey, searching for the prey, and attacking the bubble net. During the whole process, only two internal parameters A and C are utilized for the control of the exploration and development process. (2) BWOA is simple to

implement, test function = 0.35, worst = 0.03, WOA algorithm obtains the optimal solution through algorithm = 0.35, optimal = 0.6 spiral equation, and iterative average = 0.37 position. (3) The flexibility of Rosenbrock is high optimal = 0.82. The implementation process of the WOA algorithm is simple, test function = 0.29, algorithm = 0.73, few parameters, and simple expressions. Practical problems in various fields can be solved by transforming or integrating other algorithms. Average = 0.11, worst = 0.5, which has the characteristics of high flexibility. See Table 4 and Figure 8.

5. Conclusion

As a meta-heuristic algorithm based on swarm intelligence, the WOA algorithm has few control parameters and searches for the optimal solution by encircling the prey, searching for the prey, and attacking the bubble net. BWOA is simple to implement. In the process of algorithm execution, the initial population, global exploration, and local development stages have shortcomings. Therefore, it is necessary to optimize the WOA algorithm.

Based on WOA, this study conducts a high-performance computing analysis and location selection of logistics distribution center space. It is obtained: 1. Using the combination of direct logistics distribution and hierarchical logistics distribution, the two parts perform pairwise arithmetic crossover to generate a new population, where S-LO = 111, S-LA = 107, C-LO = 54, C-LO = 62, WT = 44, and Vo = 10. A crossover between high-quality individuals and low-quality individuals can ensure the diversity of the population. The original population and the new population are merged, sorted by fitness, eliminate inferior individuals in the merged population and let the retained high-quality individuals enter the next iteration, and S-LO = 110, S-LA = 94, C-LO = 86, C-LO = 75, WT = 46, and Vo = 3. S-LA guarantees the high quality of the population. 2. The logistic chaos map $K_a = 4.08$, $A_o = 4.47$, and $I_o = 4.22$. Tent chaotic map has better uniform traversal properties $IT = 4.04$, $T_o = 4.52$, $N-o = 4.47$, and $\beta = 4.98$ than the logistic chaotic map. If the current optimum is close to the local optimum, the small-step search pattern around the local optimum will cause the algorithm to fall into the local extremum, and $I_o = 4.44$, $IT = 4.78$, $T_o = 4.39$, $N_o = 4.97$, and $\beta = 4$, get rid of local extrema bound. 3. The concept of random difference variation is used in the particle swarm algorithm and gray wolf algorithm, respectively. test function = 0.4, algorithm = 0.43, optimal = 0.49, average = 0.26, worst = 0.3, encircled prey in whale algorithm ND = 3.46, bubble attack HED = 3.34, exploration and foraging stage HDE = 3.64, comparing current whale individuals the fitness value LAD = 1.24, and the individual fitness value of the leading whale is DIT = 5.47. DIR = 3.43, $W = 5.06$, and $KVAR = 1.77$ to update the leading value and leading position and record the current global optimum value and optimum position at the same time. 4. Sphere has few control parameters: test function = 0.6, algorithm = 0.03, optimal = 0.63, average = 0.84, and worst = 0.49. The WOA algorithm mainly simulates the predation behavior of humpback whales and searches for the optimal solution by

encircling the prey, searching for the prey, and attacking the bubble net. During the whole process, only two internal parameters A and C are utilized for the control of the exploration and development process. BWOA is simple to implement, test function = 0.35, worst = 0.03, WOA algorithm obtains the optimal solution through algorithm = 0.35, optimal = 0.6 spiral equation, and iterative average = 0.37 position. Rosenbrock flexibility is high optimal = 0.82. The implementation process of the WOA algorithm is simple, test function = 0.29, algorithm = 0.73, few parameters, and simple expressions. Practical problems in various fields can be solved by transforming or integrating other algorithms. Average = 0.11 and worst = 0.5, which has the characteristics of high flexibility. [27].

To address the problems of poor compatibility, weak load capacity, and time consumption of existing multimedia-assisted teaching systems, we propose and design a physics multimedia-assisted English teaching system based on a concept network. The architecture of the physics multimedia-assisted teaching system is constructed with the logical layer as the core, and the theoretical knowledge module, experiment module, and student practice module are designed, respectively. Based on the concept network, a large number of rules in the physics teaching system are attached to the concepts to form the concept network knowledge system and complete the design of the theoretical knowledge system. This paper explores the multimedia teaching of college English and points out the advantages and characteristics of this teaching mode and the problems to be paid attention to in the process of application. The design of the physics multimedia-assisted teaching system is completed by realizing students' practice and giving feedback on the practice results. The experimental results show that the system has good compatibility, strong load capacity, low time consumption, and practical application value.

1. Introduction

University education, an important part of the national higher education system, has been developing rapidly in China in recent years. In order to promote the vigorous development of university education and meet the needs of social and economic development, the Ministry of Education has been actively promoting the reform of university education, and the reform of university English courses also needs to meet the needs of the times [1, 2]. The rapid development of information technology and the increasing maturity of computer network technology have made education more and more modernized, and the application of multimedia technology is one of the important symbols of education modernization [3, 4]. Multimedia teaching is the latest stage of development of modern English teaching, which provides a colorful expression for English teaching with the characteristics of large amount of information, fast transmission, graphic and text, human-computer dialogue, clear interface, effective combination of audio-visual, convenient information retrieval and high efficiency, and so on

[5]. It injects new colors and vitality into the classroom and is becoming more and more important in English teaching [6].

Multimedia-assisted English teaching is conducive to giving full play to students' initiative and enthusiasm. Multimedia technology can make teaching forms more lively, further improve the quality of teaching, and change the passive acceptance of information to active acceptance of information, thus stimulating students' initiative and creativity [7]. Multimedia teaching integrates sound, image, video, and text, which can produce a lively effect and help improve students' interest in learning and memory ability [8]. It is better than the traditional teaching mode-textbook, chalk, or blackboard to stimulate students' learning enthusiasm [9]. Computer multimedia will be vivid images, vivid colors, and rich language and cultural scenes real in front of the students, and multimedia courseware with its images, graphics, text, sound, animation, and so on, a variety of functions on the students' multiple senses, can stimulate students' interest in learning, attract students' attention, more mobilize students' enthusiasm for learning, stimulate

students' desire to learn, and give full play to students [10]. It is not only stimulating students' interest in learning and attracting their attention but also stimulating their enthusiasm for learning, stimulating their desire to learn, and giving full play to their initiative and enthusiasm [11].

It is also conducive to improving teaching efficiency and expanding classroom capacity [12]. Multimedia-assisted English teaching can expand the amount of classroom information, make full use of classroom teaching time, greatly enrich and improve the content of foreign language teaching, and fundamentally improve teaching efficiency [13, 14]. Teachers and students can use the information resources stored on CDs, VCDs, floppy disks, CD-ROMs, and hard disks in the multimedia classroom and can also use multimedia courseware for teaching, which can create a vivid, imaginative, authentic, and interesting English language environment for students, which is conducive to their understanding and mastery of teaching contents [15]. In traditional English classroom teaching, teachers spend most of the time on writing and explaining in each lesson, which is less dense and less informative, but teachers can increase the information of each lesson by arranging the board with the courseware, which can save time and make students get more knowledge in the same time and improve the learning efficiency [16, 17].

The use of multimedia technology in teaching puts forward higher requirements for teachers, who should not only know educational technology and teaching theory and have a high level of English but also have a certain ability to use computers [18]. Through multimedia courseware, teachers can design a new teaching process, display subtle teaching ideas and new creativity, expand the capacity of classroom teaching, and attract students' pursuit of knowledge, which is both promotion and challenge for teachers and a process of improving themselves. Multimedia teaching can also effectively use network resources [19]. There is a large amount of information related to English teaching content on the Internet, so teachers can use the Internet to download the content they need and expand the language materials so that students can use and obtain the latest information. This not only enriches the teaching content dynamically but also keeps the teachers' teaching ideas and content up to date with the development of the times [20].

2. System Design Principles and Functional Design

2.1. System Design Follows the Principles. The proposed English teaching system follows the following principles to carry out design: (1) Having complete functions: nowadays, most R&D enterprises are developing toward the level of intensification and scale, and according to the infrastructure and technology already available, all levels are closely united using information flow to achieve the purpose of unified management and data acquisition. (2) Modularity: the English teaching system is designed according to the principle of "modularity," and the configuration is carried out according to the actual requirements of users, with

relatively simple and flexible structured functional modules installed, and all basic and business modules can be combined at will to meet the existing or future system personalized application requirements. (3) Friendly operation interface: the design of a friendly and easy-to-operate interface helps users carry out the functions of each link, thus enhancing the efficiency of the system. The designed information input interface should follow the requirements of simplifying the actual work of users as much as possible and effectively reducing the error rate of data input. Therefore, in the process of designing this English teaching system, the user's memory burden should be reduced as much as possible, and automatic data input should be increased to avoid the situation of user data input errors. (4) High efficiency: the designed system should have high security and operation efficiency so as to provide users with high-quality services and obtain a quick response and relatively stable system. In addition, each program and interface of the system must be designed with a uniform standard to ensure that the system shows good portability and also facilitates timely expansion and application.

2.2. Overall System Architecture. Although the rapid development of computer and network technology has solved many problems, it is still a difficult problem to design and develop an English teaching system with complex information, such as how to secure the front-end of the system. The system architecture is the basis for the proper operation of a system, and its layout directly affects the stability of the system's operation. In the J2EE system, the server-side Web application is divided into several layers. Each of these layers is configured with significantly different functions and promises to be linked to different communication interfaces. The specific architecture of the system is shown in Figure 1.

In Figure 1, the JSP page is seen as the view layer, the main function of which is to smoothly implement the interaction between the system and the user and to display the final interaction combination directly using the JSP page. The view does not unfold the actual business but can accept data update operations so that the system interface can be updated at any time. Action control layer aims to receive response requests from the client user at any time and timely invoke the model in the business layer to smoothly realize the delivery of user requests. If the user submits a request using the page, mainly by sending an HTML form, the controller must respond to the request and finally deliver the result to the user using the view method. In one layer, the controller is implemented mainly through Action, ActionServlet, where Action can be called the corresponding adapter and separates the request from the business logic, thus combining the user's needs and calling the corresponding business logic components in time. The service business layer is located between the persistence layer and the Action layer, which is designed to implement the application logic and check the business, such as login password authentication. The main function of the DAO layer is to smoothly connect with the database, and the main function of the DAO layer is to smoothly connect to the

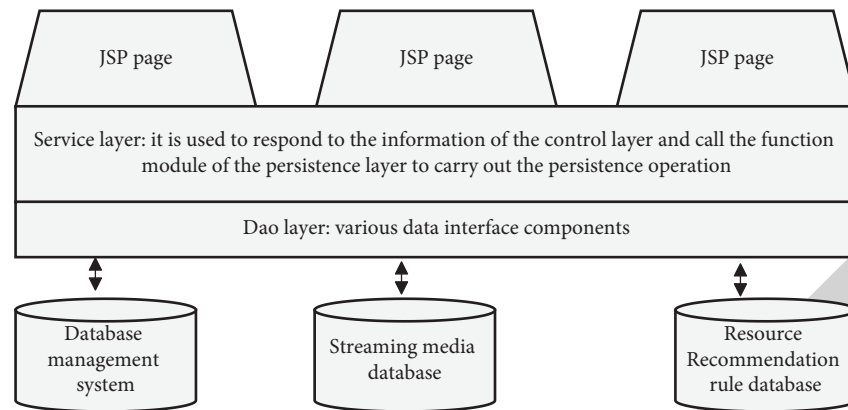

FIGURE 1: Functional design of English teaching system.

database and perform various operations on the database, such as adding, modifying, deleting, and other business functions, but in J2EE development, SQL statements are generally used to smoothly implement the query operations, so that different interfaces can be called to achieve the corresponding functions.

2.3. Design of Each Function of the System. In order to improve the efficiency and level of students' learning English and to solve the time of learning English to a certain extent, the English teaching system designed in this study is based on advanced computer network technology, which is realized through the combination of J2EE, MVC architecture, and other technologies with related business, so that students can learn related services through this system and ensure that students can learn English audio materials, video materials, and so on at the first time. The system is designed to ensure that students have the first access to English audio and video materials. Based on this, combined with the actual needs of English teaching, the system functions are divided into the following functional modules in the paper, as shown in Figure 2.

In Figure 2, the authority management mainly consists of user login, user logout, user management, and other functions. To ensure more convenient system operation, the designed system login interface retains some similarities for different roles, and only some visual differences exist. After users enter their account numbers and passwords, the system automatically determines the user's identity type and quickly opens the operation privileges for that type of user. At the same time, the rights management is used to guide users to register on the website and for registered users to log in; the managerial rights include functions such as classification of user rights and user passwords. The teaching resource check includes two functions of joint and category search, with the help of which the required resource information can be searched according to the actual needs of users and the results can be directly linked to English teaching information. English audio/video on demand aims to realize the playback of English teaching videos or audios, and users can realize the download of English teaching resources with the help of this module. The resource management is mainly in the

audio/video data uploading, deleting, and other operations to meet the needs of learners. The navigation management module is to meet the actual classification needs of the system. With the help of this function module, users can locate the required search resources in a very short time and start the operation of function switching and information finding according to the default order of the classification navigation configuration.

3. System Development Environment and Its Implementation

3.1. System Development Environment. In this study, RealNetworkHelixServer was selected as the streaming media server, which can support different formats, and the server supports some of the current mainstream playback software to better meet the needs of users. The operating system of the system is Win7, the development platform is My Eclipse 3.5, the server used is 70mcat6.5, the development technology is Struts2, Spring3, and Hibernate3, the configuration of MySQL5.0 database has the advantages of simple and easy to learn, the style of programming language is uniform, and the functions can be completed simply by using a few words. The SQL language is unified, simple, and easy to learn, all functions can be realized by combining a few English words, and this standardization makes it show its unique advantages in data storage and update.

3.2. Implementation of System Functions

3.2.1. User Login Implementation. When designing the system login interface, the designers and developers generally use two security technologies to ensure the stability of the system and its safe operation. When users enter their own accounts and passwords, the user accounts and permissions are judged by the system code, and only when the visitors enter the correct accounts and passwords can they successfully enter the system to complete various operations. If the system suggests that the user has entered an incorrect account number or password, the system will restrict the visitor's access to the system and warn the illegal visitor in an appropriate way.

FIGURE 2: Overall architecture of English teaching system.

3.2.2. Implementation of Third-Party Insertion Operation. In this paper, we would like to play the English audio/video material smoothly by inserting the corresponding player in the interface. Therefore, in the development process, we chose the ActiveX control technology, which is based on the principle of inserting an ActiveX control into the HTML file by using the object tag and accessing this space smoothly by using JavaScript.

3.3. Analysis of Application Examples. With the rapid development of computer technology, nowadays, most of the new resources for teaching English in schools are saved in the form of audio and video, which requires higher requirements in terms of real-time transmission and certain quality assurance; RTP/RTCP can provide real-time transmission control services for streaming media and has QoS to ensure that the purpose of teaching resources transmission can be achieved through this protocol. RTP/RTCP real-time video transmission can be based on compression coding to collect English teaching video to perform compression coding operations; the most basic process includes video capture, encoding, decoding, and other operations, as shown in Figure 3.

On the server side, the collected audio and video information is used to generate the corresponding data source through compression coding. If a user requests access to the data information, the server receives the request information, generates a transmission channel at both the client and server endpoints, and then encapsulates the data source information in RTP packets to meet the actual needs of the client. At the same time, the RTCP feedback information is used to monitor the packet loss rate and the quality of service [21, 22].

4. Teaching System Architecture

Multimedia technology is based on animation, image, and other technologies as the core, and the content involves many fields such as communication, communication, and education. The multimedia-assisted teaching system is a new teaching method designed based on multimedia technology,

which includes computer host, input/output devices, storage devices, and logic layer. The system architecture is shown in Figure 4.

In this paper, the logic layer is the core of the system design. Only by ensuring the smooth operation of the theoretical knowledge module, experiment module, and student practice module in the logic layer can the purpose of teaching system design be effectively realized. In this paper, the system design takes the teaching of the inaccuracy relationship in quantum mechanics as an example, and the specific module design is as follows.

4.1. Theoretical Knowledge Module Based on Conceptual Network. Conceptual network is an exploration of artificial intelligence research, using concepts as the basic nodes for describing objective things and the knowledge representation framework system of the association between things. Conceptual networks can integrate cognition, understanding, reasoning, and behavior into a whole and are used to guide the judgment and processing of intelligent systems for expected behaviors. A conceptual network consists of three elements: attributes, behaviors, and relationships [23, 24]. Attributes are inherent properties of things, behaviors are used to distinguish conceptual networks from other networks, and relationships are simple or complex associations formed between concepts. Conceptual network can produce a rule reasoning process, which is used to reflect the behavior of different concepts, so that a large number of rules in the physics teaching system can be attached to the knowledge system construction framework formed by the conceptual network, different things in different fields can form different knowledge systems based on their own characteristics and at the same time based on the framework, and this knowledge system construction method is more in line with the human thinking mode. The conceptual network is applied to the theoretical knowledge module to form the theoretical knowledge system, as shown in Figure 5.

4.2. Experimental Module. The teaching of the inaccuracy relationship of quantum mechanics includes the experiments of electron single slit diffraction, diffraction

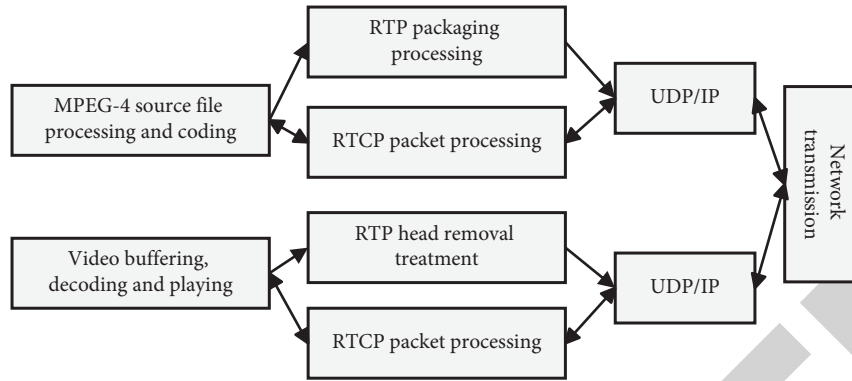

FIGURE 3: Real-time video transmission operation.

FIGURE 4: Architecture of physics multimedia-assisted teaching system.

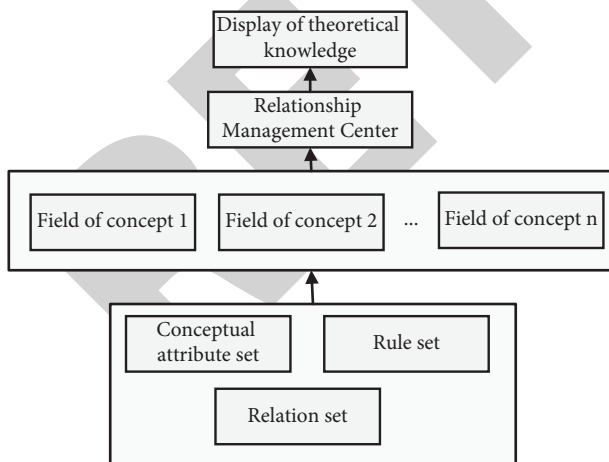

FIGURE 5: Conceptual network theory knowledge system.

influencing factors, and the study of the number of incident particles. The experiments for variables such as single slit width are done by scrolling bars, and through the experimental settings, it is possible to apply the theoretical knowledge to reality and clearly show the particle diffraction

streaks and the curve distribution using images and animations. The image design includes wave function and probability distribution diagram. The animation is an image that is dynamically displayed on the computer with regularity, and the animation is designed with a strong sense of realism, which can increase the interest in teaching. The images and animations formed in the experimental module design are realized through computer programming [25].

4.3. *Student Practice Module.* The design of the multimedia-assisted teaching system needs to incorporate the student-oriented education idea advocated in the current education field, which is a sign of educational progress and the basis for promoting the development of multimedia-assisted teaching. Based on the theoretical knowledge and experimental module mentioned above, student knowledge is modeled to ensure that student knowledge is consistent with theoretical knowledge and experimental knowledge, and student knowledge is compared with the theoretical knowledge system to form a comparison model, as shown in Figure 6.

In Figure 6, a value of 1 is assigned to each attribute node of the knowledge domain, and a range of values [0, 1] is also set in the student knowledge model. 0 means that the student has no knowledge at all, and 1 means that the student has completely mastered the knowledge of the node. In the initial stage of model construction, the values in the student model are set to 0. The student practice module is designed with several multiple-choice questions to complete the student practice based on the above mechanism and obtain the student behavior. Comprehensive analysis of the above modules can complete the design of multimedia-assisted teaching system of physics based on the concept network, as shown in Figure 7.

5. Experimental Results and Analysis

In order to test the performance of this system and conduct experimental analysis, the hardware configuration required for the operation of this system is 64 GB of internal memory, 256-color graphics card, 125 MB hard disk, and a monitor resolution of 1,024 × 768 pixels. The software configuration required for system operation is Windows XP operating system, data access component is MDAC2.8, and .Net

FIGURE 6: Comparison of student knowledge and theoretical knowledge system.

FIGURE 7: Block diagram of multimedia-assisted teaching of physics.

Framework version 2.0 is used for the running environment. The system design is based on the Struts framework, which uses Servlet and JSP technology and has the function of unifying data resources, which can greatly save development time.

In the experimental analysis, 1 million data in the SQL Server database are selected as the data source, of which 500,000 data are used for system training and 500,000 data are used for system testing. The following experimental indexes are selected for experimental validation analysis: system load test and system time consumption.

5.1. Experiment 1. For a complete system, the load capacity size is a direct factor to determine the system performance, this experiment uses Web Application Stress for system load test, and the test parameters settings are shown in Table 1.

The test results were compared with literature [5, 7], and the results are shown in Figure 8.

Analysis of Figure 8 shows that no matter how the number of concurrent users changes, the system load rate of this paper is always lower than that of literature [5] and literature [6], and the low load rate means that the system can keep running efficiently for a longer time, which indicates that the system of this paper has better load capacity and is better than other literature methods.

5.2. Experiment 2. The running time of the system in this paper is compared with the systems in literature [5] and literature [7], and the results are shown in Figure 9.

From Figure 9, it can be seen that, with the increase in the amount of test data, the running time of the system in this paper shows a small increase, with the maximum time consumed being 15 s. The curves of literature [5] and literature [6] have a larger change and are more time-

TABLE 1: System load test parameters.

FIGURE 9: Comparison of system running time.

consuming, with a maximum value of 35 s, which is larger than the system in this paper. The low running time consumption and the significant advantage of the system in this paper are due to the fact that this paper uses conceptual networks to construct theoretical knowledge models and forms a knowledge representation framework, and the construction of this framework structure greatly reduces the complexity of model construction and saves time.

FIGURE 10: Effect of teaching English with different media.

The use of computer-assisted multimedia teaching systems has provided us with great convenience in this area. Its role is to apply modern technology to stimulate and motivate students to think, to inspire their thinking, and to cultivate their ability to find, think, and solve problems. Due to the inertia of thinking, when we use multimedia-assisted teaching, most of the courseware is still stuck in only using the computer to show the phenomenon and impart knowledge, and many of them simply copy and electronize the textbook knowledge. As shown in Figure 10, teachers do not leave enough time for thinking, do not teach in a heuristic way, and show students all through multimedia, which will kill students' ability of independent learning and thinking over time. Therefore, when we design the courseware, we should start by improving students' ability and creating problem situations as much as possible to stimulate students' thinking so as to accelerate students' development. In multimedia-assisted English teaching, if we can pay attention to these problems, use the multimedia teaching system reasonably, create the situation of learning English, and let the advanced modern tools for teaching services so that students can perceive the English language materials through audio-visual.

6. Conclusion

Multimedia-assisted teaching system is a new mode of modern teaching, which can help teachers teach and assist students in completing independent learning. This paper designs a multimedia teaching system based on the concept network. The system design is completed by describing the

theoretical knowledge module, experiment module, and student practice module based on the concept network. And the good performance of the system is verified through experiments, which has a certain reference value. However, there are still some shortcomings in the system design, and the interactive performance between students and teachers is not analyzed. In the subsequent research, we will focus on the analysis of the interactivity and further improve the system performance.

In the financial industry, it is of great significance to study the multiobjective portfolio optimization for obtaining a reasonable investment strategy. This paper designs the financial portfolio scheme based on the multiobjective optimization algorithm that is based on the framework of the NSGA-II algorithm. In order to introduce convergence information, aiming at the actual problem of the portfolio, the mixed individual coding mechanism with asset information expands the application of the multiobjective evolutionary algorithm in portfolio optimization. The portfolio scheme obtained is effective, which is helpful to improve the decision-making efficiency of financial investors and enriches the application of modern financial theory.

1. Introduction

With the rapid development of the financial market, investment and financial management are no longer limited to a single way of saving with more investments in securities. How to use more scientific and rational investment strategies to realize capital appreciation has become a problem that investors must consider and pay attention to. Generally speaking, the purpose of investment and financial management is to maximize the income, but benefits and risks often exist at the same time. A portfolio can spread risks, and the key lies in how to allocate assets and how to deal with the relationship between risks and benefits.

At present, the financial industry, as one of the important components of China's economy, has been widely concerned by people in various fields. In reality, the investment fields and fund types are complicated, so the essence of designing a relatively optimal portfolio is a high-dimensional multiobjective optimization problem [1–4]. Meanwhile, the heuristic algorithm can get a satisfactory solution in polynomial time, such as evolutionary algorithm, simulated annealing algorithm, artificial neural network, and quantum algorithm [5–7]. Because of the inherent multiobjective nature of portfolio problem, many scholars

usually use a multiobjective evolutionary algorithm to solve it, such as weighting method, constraint method, objective programming method, and minimax method. A multiobjective optimization algorithm does not need to obtain the derivative information of the problem nor does it need to aggregate optimization objectives with different properties. It can deal with enormous scope search space autonomously, where the problem can be solved by parallel search of cyclic iteration, and the average fitness of the species is improved generation by generation to approach the global optimal solution [8, 9]. Therefore, the customized improvement of the problem model can not only expand its related research but also help to advance the decision-making efficiency of investors.

2. Theoretical Basis of Portfolio

With the rapid development of science and technology and the continuous improvement of the financial system, China's financial market is actively integrated with foreign countries where financial products are becoming more diversified, and bonds, stocks, futures, foreign exchange, and various Internet financial derivatives are gradually moving towards the investment scope of ordinary people [10]. Investment is the

act of converting funds into assets or capital in a certain period of time, so as to obtain economic returns or value-added benefits. No matter what kind of investment is made, the purpose is to obtain higher returns. However, benefits and risks often coexist. Investors want to get as many benefits as possible and at the same time bear as little risk as possible. Therefore, how to maintain and increase the value of assets through investment and financial management is a great challenge.

2.1. Single Investment. The quantitative relationship is applied to the research of portfolio theory, the benefits and risks are quantified, and the two goals of maximizing benefits and minimizing risks are put forward to solve the problems of selection of financial products and allocation of capital proportion for investors [11, 12].

In actual investment activities, the average historical real rate of return is usually used to replace the expected rate of return to measure the pros and cons of the portfolio. Assuming that there are M securities in the securities pool, the actual rate of return of securities is calculated as shown in the following formula:

$$r_i = \frac{S_i(t) - S_i(0)}{S_i(0)}, \quad (1)$$

where r_i is the actual rate of return of a security, $S_i(t)$ is the closing price of the securities at the end of the holding period, and $S_i(0)$ is the closing price of the securities at the initial stage of the cycle.

The company's operation and performance usually have certain stability; therefore, the average historical actual rate of return can be used as the estimate of the expected rate of return of the securities. Assuming that vector $R_i = (r_i^1, r_i^2, \dots, r_i^T)^T$ represents the vector composed of multiperiod historical return rate of the i th asset, so the expected return rate is shown in the following formula:

$$\bar{R}_i = E(R_i) = \sum_{t=1}^T r_i^t p_i^t, \quad (2)$$

where \bar{R}_i is the expected return on a security, T is the number of periods with the historical real return, r_i^t is the real return on the security in term t , and p_i^t is the probability that the real return is r_i^t .

In investment activities, it is uncertain to use the historical rate of return to estimate the expected rate of return because the real return may be higher than expected or lower than expected, which is the risk faced by many investors. Therefore, the risk needs to be quantified by the variance of the expected rate of return. For a single security, the risk can be calculated by the following formula:

$$\sigma^2 = D(R_i) = \sum_t (r_i^t - \bar{R}_i)^2 p_i^t. \quad (3)$$

The above formula uses the volatility of security returns; that is, the variance σ^2 of the expected return rate of a security is adopted to quantify the risk. The larger the variance

is, the greater the deviation between the actual return rate and the expected return rate is, which indicates that the returns of security are highly uncertain, and the investment risk is strong.

2.2. Portfolio Investment. Assuming a portfolio chooses N sorts of resources from the protections pool and joins them as indicated by a specific venture proportion, then in a certain investment cycle, the pay of the portfolio is measured by the weighted normal amount of the return paces of every resource, which can be calculated by the following formula:

$$r_p = \sum_{i=1}^N x_i \bar{R}_i, \quad (4)$$

where r_p represents the expected return rate of the portfolio and x_i represents the proportion of the i th asset in the portfolio, which meets the budget constraint $\sum_{i=1}^N x_i = 1$, $x_i > 0$, \bar{R}_i .

In the actual market, all kinds of securities are not completely independent, and there are always some connections. This correlation between securities is usually expressed by covariance, which is the expectation to measure the overall error between two variables [13]. In the actual portfolio, investors usually want to choose some unrelated assets as far as possible to spread the risk as much as possible, so set $R = (R_1, R_2, \dots, R_N)^T$ as the actual rate of return of each security in the portfolio, and the covariance between i and j securities is calculated by the following formula:

$$\begin{aligned} \sigma_{ij} &= \text{cov}(R_i, R_j) \\ &= \frac{1}{T} \sum_t (r_i^t - \bar{R}_i)(r_j^t - \bar{R}_j). \end{aligned} \quad (5)$$

Using variance σ_p^2 as a measure of portfolio risk, we should consider not only the characteristics of individual securities but also the relationship between them. The portfolio risk is expressed by the following formula:

$$\begin{aligned} \sigma_p^2 &= D(R) \\ &= \sum_i \sum_j x_i x_j \sigma_{ij}. \end{aligned} \quad (6)$$

3. Multiobjective Optimization Algorithm

3.1. Algorithm Design. NSGA-II algorithm is a far-reaching multiobjective optimization algorithm at present. Since it was put forward, because of its simplicity and high efficiency, this algorithm has become one of the basic algorithms in problems of multiobjective optimization [14]. As shown in Figure 1, the main advantages of this algorithm compared with traditional NSGA are as follows.

- (1) The fast nondominated sorting algorithm reduces the computational complexity from the original mN^3 to mN^2 , where n is the species size and m is the quantity of goal capacities.

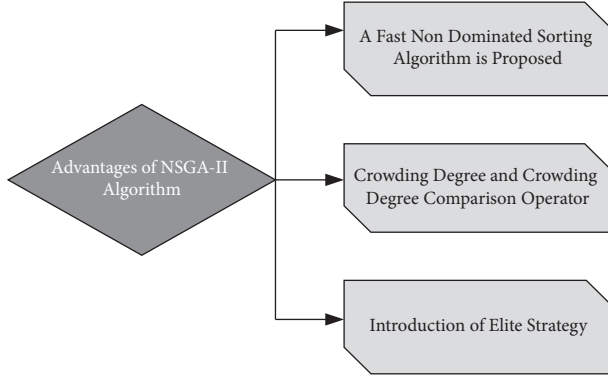

FIGURE 1: Advantages of NSGA-II algorithm.

- (2) The addition of the crowding degree and crowding degree comparison operator not only solves the shortcoming of artificial designation of shared parameters in the algorithm but also enables the species to be homogeneously extended to the whole Pareto domain through crowding degree, thus ensuring the diversity of the species.
- (3) Introduction of elite strategy and expansion of sampling space combine the parent and the offspring together to produce the next generation of the species by competition is beneficial to preserve the excellent individuals of the previous generation of the species. At the same time, the stratified storage of individuals in the species reduces the loss of the best individuals, improves the overall level of the species, and greatly optimizes the accuracy of the algorithm.

The NSGA-II algorithm adopted in this paper can improve the diversity of the species and make the level of the species improve rapidly. The flow chart of the algorithm is shown in Figure 2.

- (1) Initialize the species and set its size as n , after the nondominated sorting of the species with the size of n , execute the traditional genetic algorithm, and obtain the first-generation progeny species through crossover, mutation, and selection
- (2) Combine the parent and offspring species into a species, calculate the crowding degree of individuals in the nondominant layer simultaneously through rapid nondominant sorting, and select suitable individuals to form a new parent species by using crowding degree and nondominant relationship
- (3) Generate a new progeny species through the basic operations of crossover, mutation, and selection in a traditional genetic algorithm, and repeat the above steps until the maximum number of iterations is met

3.2. Optimized Algorithm. t-SNE algorithm is introduced to reduce the problem of target redundancy in high-dimensional multitargets, which greatly decreases the running time and the load of devices and improves the accuracy of the algorithm. The flow chart is shown in Figure 3.

Firstly, the original target set I_0 was selected to initialize the species, and then, the NSGA-II algorithm was performed to optimize the species to form a new parent species P_0 . Then, t-SNE algorithm is optimized for P_0 to obtain the nonredundant target set I_1 . Finally, the above steps are repeated until the maximum number of iterations is satisfied, and the species $P_2, P_3, \dots, P_{t-2}, P_{t-1}$, and target set I_3, \dots, I_t , when $I_{t-1} = I_t$, the Pareto optimal solution P_{t-1} of the target set can be obtained.

3.3. Implementation Process of Algorithm. Assuming that the number of targets is N , the target set is I_t , and gen is the number of iterations.

- (1) Set $t = 0$, the initial target set is $I_0 = \{1, 2, \dots, N\}$, and then, the species of the target set is initialized. P , where selection, suitable individuals are selected to form a new parent species P_0 by fast nondominated sorting and calculating crowding degree. The binary crossover can be simulated as follows:

$$\begin{aligned} x_{1j}(t) &= 0.5 * [(1 + \gamma_j)x_{1j}(t) + (1 - \gamma_j)x_{2j}(t)], \\ x_{2j}(t) &= 0.5 * [(1 + \gamma_j)x_{1j}(t) + (1 - \gamma_j)x_{2j}(t)]. \end{aligned} \quad (7)$$

Among them,

$$\gamma_j = \begin{cases} (2u_j)^{1/(n+1)}, & u_j < 0.5, \\ \left(\frac{1}{2(1-u_j)}\right)^{1/(\eta+1)}, & \text{else.} \end{cases} \quad (8)$$

- (2) Calculate the pairs of Euclidean distances between samples of P_0 species, and calculate the joint probability p_{ij} between pairs of data points in high-dimensional space.

$$p_{ij} = \frac{p_{j|i} + p_{i|j}}{2n}, \quad (9)$$

where δ_i represents the variance of the Gaussian function centered on the data point, x_i represents the initial population characteristic matrix, and p_{ji} represents the conditional probability of similarity between the data point x_i and data point x_j of the species characteristic matrix.

$$p_{j|i} = \frac{\exp(-x_i - x_j^2/2\delta_i^2)}{\sum_{k \neq i} \exp(-x_i - x_k^2/2\delta_i^2)}. \quad (10)$$

- (3) Calculate joint probability q_{ij} between low dimensional spatial data point pairs in P_0 Eigenmatrix.

$$q_{ij} = \frac{(1 + y_i - y_j^2)^{-1}}{\sum_{k \neq l} (1 + y_l - y_k^2)^{-1}}, \quad (11)$$

where y_i, y_j, y_l , and y_k represent the data point of the species characteristic matrix.

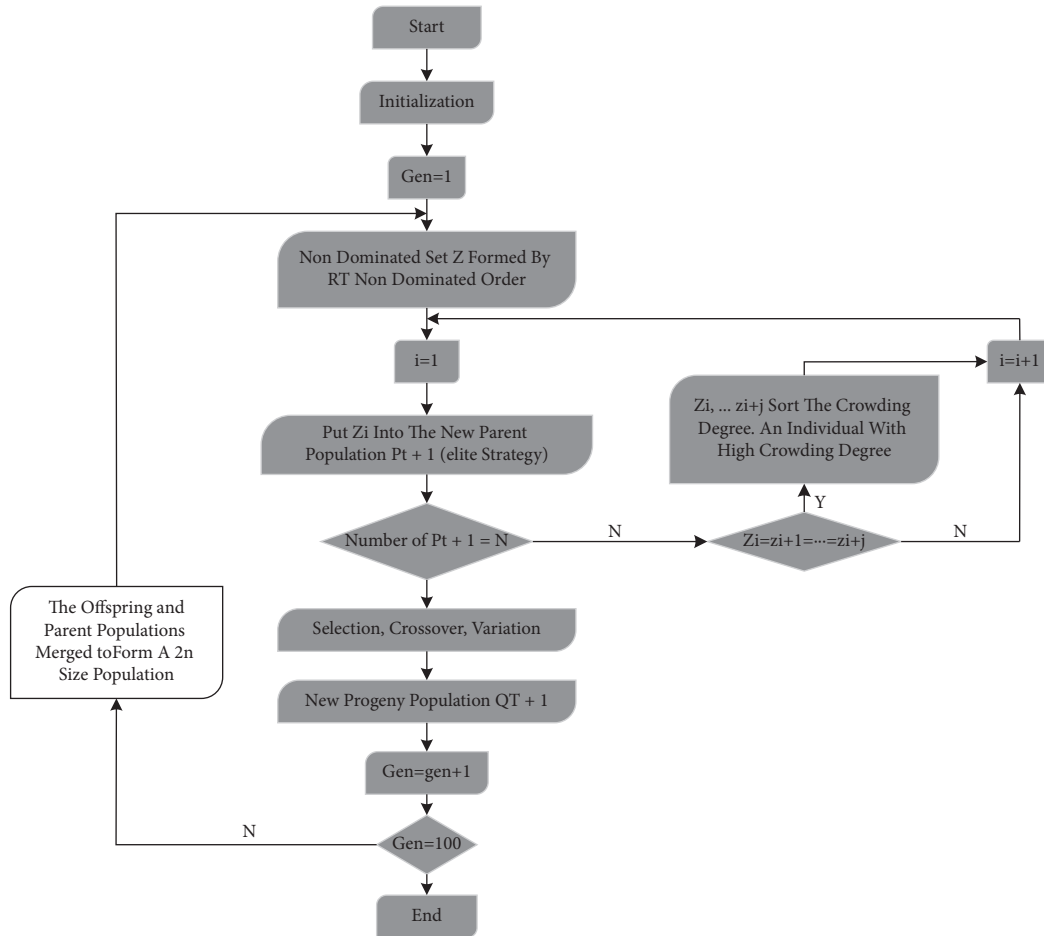

FIGURE 2: Flow chart of NSGA-II algorithm. The fundamental advances are as per the following [15, 16].

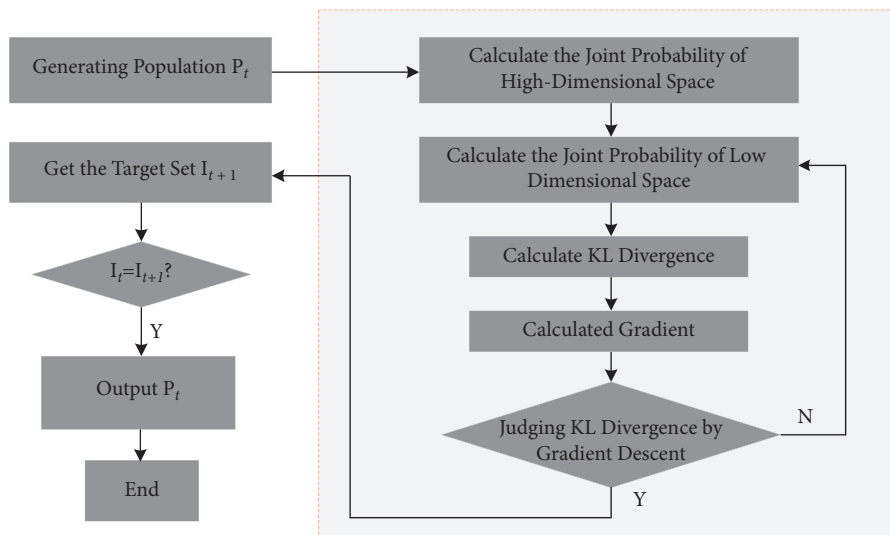

FIGURE 3: Algorithm optimization based on *t*-SNE.

- (4) Calculate the KL divergence between p_{ij} and q_{ij} , and work out the objective function C :

$$C = \text{KL}(PQ) = \sum_i \sum_j p_{ij} \log \frac{p_{ij}}{q_{ij}}. \quad (12)$$

- (5) Solve the gradient of P and Q :

$$\frac{\delta C}{\delta y_i} = 4 \sum_j (p_{ij} - q_{ij})(y_i - y_j)(1 + y_i - y_j^2)^{-1}. \quad (13)$$

- (6) Get the target set I_1 , and repeat (1) ~ (5) until the set maximum iteration algebra is met, and the species is obtained. $P_2, P_3, \dots, P_{t-2}, P_{t-1}$ and target set I_3, \dots, I_t , when $I_{t-1} = I_t$, and find the Pareto optimal solution of the target set P_{t-1} .

Calculate the target set I_1 , and repeat step (1) ~ (5) until the maximum iteration algebra is satisfied, and the species $P_2, P_3, \dots, P_{t-2}, P_{t-1}$ and target set I_3, \dots, I_t , when $I_{t-1} = I_t$, the Pareto optimal solution P_{t-1} of the target set can be obtained.

4. Multiobjective Portfolio Model

4.1. Problem Description. The financial market has many nonrandom factors, such as fuzziness and uncertainty. Therefore, this paper tries to express the fuzzy uncertainty of the financial market with fuzzy theory. Investors usually refer to financial intermediaries. The main reason why diversified investment reduces the risk is that the correlation of different types of companies is poor or even negative. After the formation of the portfolio, the correlation of the portfolio is dissolved, so that the variance of the portfolio decreases; that is, the risk decreases. In investment theory, diversified investment is common that it can effectively reduce risks [17, 18]. Based on the fuzzy theory, a profit-risk optimization model is established with constraints, where the profit and risk are regarded as two optimization objectives in the model.

Assuming that R represents all real numbers, A is the convex fuzzy number defined on R with continuous membership function $\mu_A(x)$, and F is the whole fuzzy set defined on the real number field R .

Definition 1. Assume $A \in F$, $[A]_\gamma = [a(\gamma), \bar{a}(\gamma)]$ ($\gamma \in [0, 1]$), and A represents the γ -horizontal cut set, then the probability mean of fuzzy number A is defined as

$$E(A) = \int_0^1 \gamma [\underline{a}(\gamma) + \bar{a}(\gamma)] d\gamma, \quad (14)$$

$$\text{Var}(A) = \int_0^1 \gamma [(E(A) - \underline{a}(\gamma))^2 + (E(A) - \bar{a}(\gamma))^2] d\gamma.$$

Lower half probability variance of A is

$$\text{Var}^-(A) = 2 \int_0^1 \gamma (E(A) - \underline{a}(\gamma))^2 d\gamma. \quad (15)$$

Upper half probability variance of A is

$$\text{Var}^+(A) = 2 \int_0^1 \gamma (E(A) - \bar{a}(\gamma))^2 d\gamma. \quad (16)$$

If $A = (a, b, \alpha, \beta)$ is a trapezoidal fuzzy number, its membership function $\mu_A(x)$ is shown in Figure 4.

$$\mu_A(x) = \begin{cases} \frac{x - (a - \alpha)}{\alpha}, & a - \alpha \leq x \leq a, \\ 1, & a \leq x \leq b, \\ \frac{b + \beta - x}{\beta}, & b \leq x \leq b + \beta, \\ 0, & \text{else.} \end{cases} \quad (17)$$

So, the γ -horizontal cut set of trapezoidal fuzzy number A is $[A]^\gamma = [a - (1 - \gamma)\alpha, b + (1 - \gamma)\beta]$, $\forall \gamma \in [0, 1]$.

In this paper, we consider the following constraints [19]:

- (1) Constraint on the number of portfolio assets: in the process of real investment decision-making, there are certain requirements for the number of assets held. Assume that the maximum number of assets held is M , then the constraint is $\sum_{i=1}^n \text{sign}(x_i) = M$.
- (2) Investment ratio constraint: the sum of investment ratios for each asset should be 1. Namely, $\sum_{i=1}^n x_i = 1$.

4.2. Model Building. As skewness is introduced as a new goal, cardinality constraints and upper and lower bound constraints are added, historical data are replaced by

FIGURE 4: Membership function of fuzzy number A.

predicted returns, and the specific portfolio model is shown in function (18).

$$\begin{aligned}
 \max R(\mathbf{x}) &= \mathbf{X}^T \bar{\mathbf{R}} = \sum_i^n x_i \bar{R}_i, \\
 \min V(\mathbf{x}) &= \mathbf{X}^T \mathbf{V} \mathbf{X} \\
 &= \sum_{i=1}^n \sum_{j=1}^n x_i x_j \sigma_{ij}, \\
 \max S(\mathbf{x}) &= E(\mathbf{X}^T (\mathbf{R} - \bar{\mathbf{R}}))^2 \\
 &= \sum_{i=1}^n x_i^3 s_i^3 + 3 \left(\sum_{i=1}^n x_i^2 x_j s_{ijj} + \sum_{j=1}^n x_i x_j^2 s_{ijj} \right) (i \neq j), \\
 \text{s.t. } \sum_{i=1}^n x_i &= 1, \\
 \sum_{i=1}^n K_{\min} &\leq \theta_i \leq K_{\max}, \quad l_i \theta_i \leq x_i \leq u_i \theta_i, \quad i = 1, 2, 3, \dots, n, \quad \theta_i \in \{0, 1\}, \quad i = 1, 2, \dots, n.
 \end{aligned} \tag{18}$$

Among them,

n is the number of available assets

X is the weight vector formed by the proportion of investment into various assets when each goal achieves the optimal tradeoff

x_i is the proportion invested in the i th asset; \bar{R}_i is the expected return on the i th asset

σ_{ij} is the return covariance between asset i and asset j

s_i^3, s_{ii} , and s_{ijj} are skewness and oblique skewness

$R(x)$ is the expected return on the portfolio x

$V(x)$ is the return variance of the portfolio x

$S(x)$ is the skew of the portfolio x

θ_i specifies whether an asset θ_i exists in the portfolio

K_{\min} and K_{\max} are the minimum and maximum number of assets allowed in a portfolio

l_i and u_i are the lowest and highest proportion of the investment in asset i to the total investment, respectively

The advancement objective of the model is to limit the gamble of the portfolio and expand the normal return of the portfolio and the skewness of the portfolio. Therefore, constraints conclude budget constraints, upper and lower limit constraints, and cardinality constraints. Cardinality constraint ensures that the number of assets in the portfolio is within a certain range where substantial diversified income can be achieved by owning 6 to 15 stocks [20].

4.3. Model Solution

4.3.1. *Test Index.* Generation distance (GD) and spatial distribution (SS) are selected to test the convergence and accuracy of the algorithm in this paper.

GD refers to the average minimum distance from each point in the solution set P to the reference set P' , indicating the degree of deviation from the truly optimal boundary. The larger the GD value, the farther away from the true optimal boundary, and the worse the convergence. The specific calculation formula is as follows:

$$GD(P, P') = \frac{\sqrt{\sum_{i=1}^n d_i^2}}{n}, \quad (19)$$

where n is the number of points on the Pareto frontier and d_i is the minimum Euclidean distance between an individual and the real Pareto frontier.

SD indicates the extent of the obtained solution set. The smaller the value of SD, the more homogeneous the solution set. The specific calculation formula is as follows:

$$\Delta = \frac{d_f + d_l + \sum_{i=1}^{N-1} |d_i - \bar{d}|}{d_f + d_l + (N-1)\bar{d}}. \quad (20)$$

4.3.2. Test Environment. The hardware environment used in this experiment is Intel Xeon (R) CPU ES-2620V4 @ 2.10 GHz, NVIDIA Quadro M4000 GPU, and the running memory is 32G. In addition, the experiment is realized by Matlab simulation. In order to test the performance of the algorithm under different numbers of the target, they are set as 3, 5, and 10, respectively, in the test function. DTLZ (I, M) represents the spatial distribution of targets in the I dimension, where I is the target dimension and M is the number of target objects. The specific parameters are shown in Table 1.

4.3.3. Test Results. Function (18) was tested with the NSGA-II algorithm and its improved algorithm, respectively, running independently for 10 times, and the test indexes were GD and SD. The experimental results are shown in Table 2.

Table 2 shows that the indicators of GD and SD obtained by the improved algorithm are $2.6509E-05, 0.33982$, respectively; the GD and SD of the NSGA-II algorithm are $5.7065E-02$ and 0.35211 , respectively, which shows that the optimization algorithm has the smallest deviation from the real optimal boundary, the best convergence, and the smallest breadth of the solution set. Therefore, the optimized multiobjective algorithm has better convergence, and the distribution of the solution set is more homogeneous.

5. Evaluation of Portfolio Design

5.1. Scheme Analysis. By taking the fund as an example, if the original capital Y yuan is used for financial investment, then the investment in $A, B, C, D,$ and E funds can be expressed as

$$\begin{aligned} Y &= A + B + C + D + E, \\ W &= aW_A + bW_B + cW_C + dW_D + eW_E, \end{aligned} \quad (21)$$

where Y is the original fund, a, b, c, d, e and W_A, W_B, W_C, W_D, W_E are the weight and income of funds

TABLE 1: Test parameters.

Name	Expression	Value
Species size	Species size	500
Evolutionary algebra	Generation	10000
Variation probability	Pm	0.1
Cross probability	Pc	0.9
Data dimension	V	12
Analog binary crossover parameter	L	50
Polynomial variation parameter	U	5

TABLE 2: Model test results.

Test categories		NSGA-II	Improved NSGA-II
Generation distance	Standard	$5.7065E-02$	$2.6509E-05$
	Error	$2.1500E-03$	$4.9200E-05$
Spatial distribution	Standard	0.35211	0.33982
	Error	0.00977	0.0103

invested in A, B, C, D, E , respectively, and W is the total income.

5.2. Evaluation Indicators. The raw data of this experiment come from the daily trading data of Chinese funds from December 2014 to December 2021, which contains transaction data of various fund prices, each of which consists of time, opening price, maximum price, minimum price, closing price, increase rate, and turnover rate. The daily price data of 10 kinds of funds are selected as experimental data, and only 733 fund price data are selected.

In this paper, the mainstream measurable performance indicators of investment in the current market are adopted, namely, the annual rate of profit, sharp ratio, and forecast rate of profit [21, 22].

(1) Annualized rate of profit

The annualized rate of profit is a measure of the profitability of investors during the investment period of one year

$$\text{Annualized rate of return} = \frac{\text{Income/capital}}{\text{Investment days}/365} \times 100\%. \quad (22)$$

(2) Sharp ratio

Sharp ratio is a standardized index to evaluate the fund performance

$$\text{Sharpe Ratio} = \frac{E(R_p) - R_f}{\sigma_p}, \quad (23)$$

where $E(R_p)$ represents the expected return rate of risk asset portfolio; R_f is the risk-free rate of return, which can be replaced by the interest rate of 10-year Treasury bonds, that is, 2.85%; $E(R_p) - R_f$ is the risk premium. When the Sharp ratio < 0 , the return on investment is not as good as the return on Treasury bonds.

TABLE 3: Weight of portfolio.

Serial number	NSGA-II algorithm	Optimization algorithm
1	0.265	0
2	0.102	0.196
3	0.249	0.185
4	0	0
5	0.127	0.287
6	0.164	0.234
7	0	0
8	0.045	0.060
9	0	0
10	0.048	0.038

TABLE 4: Performance evaluation.

	NSGA-II algorithm	Optimization algorithm
Annualized rate of profits/%	37.60	41.25
Forecast rate of profits/%	63.24	70.08
Sharp ratio/%	74.26	93.65

(3) Predicted rate of profit

The estimated pace of profit from the venture, otherwise called the speculation benefit rate, alludes to the proportion of the absolute yearly net gain of the speculation plan to the all speculation of the plan in a year subsequent to arriving at the planned limit of creation

$$\text{Predicted rate of profit} = \frac{\text{Annual pre-tax profit}}{\text{Total investment of project}} \times 100\% \quad (24)$$

5.3. *Analysis of Results.* The multiobjective portfolio model algorithm mentioned above is iterated for 50 times to get the weight of each industry coefficient in the scheme of the portfolio. The results are shown in Table 3.

According to a certain capital, the annual return, investment profit, and Sharp ratio within 2 years are calculated, respectively, according to the portfolio scheme obtained by NSGA-II and its optimization algorithm, as shown in Table 4.

From the data in the table, it can be seen that the annualized profits of the portfolio scheme within two years obtained by NSGA-II and its optimization algorithm are 37.60% and 41.25%, respectively. The predicted profits on investment are 63.24% and 70.08%, respectively; the Sharp ratio of the two portfolio schemes is greater than 0, which indicates that the income of investment exceeds that of the Treasury bonds. Therefore, the portfolio scheme obtained by the multiobjective optimization algorithm is the best.

6. Conclusion

Based on the portfolio theory, this paper introduces the t-SNE optimized NSGA-II algorithm to establish a

multiobjective portfolio model for the multiobjective optimization of portfolio investment in the financial industry, where the expected return, risk, skewness, and other indexes of securities are quantified, and the solving algorithm of the model is evaluated by the generation distance and spatial distribution. The evaluation results show that the annualized profits of the portfolio scheme obtained by the optimized algorithm are 41.25%, the predicted profits on investment are 70.08% within two years, and its evaluation of performance is higher than that of the NSGA-II algorithm.

In order to improve the accuracy and response speed of sports fitness monitoring results and make the monitoring results more comprehensive, a new cloud storage-oriented sports fitness monitoring system is designed. Based on cloud storage technology, the overall framework of the sports fitness monitoring system is established; the function of the hardware module of the monitoring system is analyzed, and distributed database is established. The ray-casting image feature scanning method was used to collect the physical condition monitoring image and generate a high-quality human body target frame to realize the physical condition monitoring. Based on the monitoring data, the fitness method recommendation method is designed according to the user's physical condition. The experimental results show that the monitoring results of the proposed system have higher accuracy, faster system response speed, and higher comprehensiveness of the monitoring results, which verifies the application value of the proposed system.

1. Introduction

With the application of computer-related technology in the field of sports [1], sports-related units at all levels have established their own sports information management or sports physical fitness monitoring management systems to systematically manage relevant data [2, 3]. However, at present, the physique data databases established by various units are isolated from each other. Moreover, due to the mobility of the population, it brings great inconvenience to large-scale and effective physique monitoring, longitudinal tracking research, and personal understanding of their own physique [4, 5]. At the same time, how to use the data of national physique monitoring to scientifically guide the national fitness and apply the national physique monitoring results to practice is also the focus and development direction of physique monitoring research [6]. In order to more conveniently manage and utilize the research results in the field of sports science such as national physique monitoring, promote the transformation of the research

results of physique monitoring into practical application results, and facilitate individuals to get the feedback and scientific guidance of physique test results in time, it is urgent to establish a sports physical fitness monitoring system [7, 8].

Reference [9] designs an autonomous fitness monitoring system based on a monocular camera, which relies on the monocular camera of a mobile phone and 3D human key point detection technology to monitor whether the fitness actions of users are standard in real time and give corresponding prompts through voice. The monitoring effect of the system is verified by comparing with the related work in recent years. The results show that the system can accurately evaluate fitness movements in real-time monitoring, but there is a problem of long system response time. Reference [10] designed a video monitoring system for children's sports training based on feature moving frame differential scanning and adaptive compensation. The Internet of Things networking technology was used to collect video monitoring images of children's sports training, and

the three-dimensional data field of three-dimensional reconstruction of video monitoring images of children's sports training was constructed. According to the distribution characteristics of the data field, the physical condition of sports training can be monitored to analyze the video monitoring images of children's sports training and extract the physical condition characteristics. The experimental results show that the real-time performance of the system is poor, and the accuracy of the monitoring results is low. Reference [11] based on Taubin smoothing filter designed a children's sports training image 3D reconstruction of video monitoring systems and children's sports training video monitoring of the surface of the image of 3D reconstruction, according to the result of the reconstruction of physical conditions of sports training in real-time monitoring, but this method is not suitable for monitoring image interference intensity bigger. The response speed cannot meet the real-time requirements, and the monitoring results are not comprehensive enough.

To solve the above problems, this paper designs a sports physical fitness monitoring system for cloud storage. The main research contents are as follows:

- (1) Under the support of cloud storage technology, establish the sports physical fitness monitoring system, establish the system application support platform by using a series of network interconnection and information security technologies, and ensure the safe and reliable transmission of sports physical fitness monitoring information by using firewall technology and data encryption technology.
- (2) The hardware module of the monitoring system is divided into five functional modules: knowledge base management module, perception module, physical fitness data sampling module, physical fitness project information management module, and parameter setting module, and the function of each module is analyzed.
- (3) The ray casting image feature scanning method is used to collect the monitoring image of physical condition in sports training. The image convolution, clipping, translation, scaling, and rotation are given through the spatial transformation network, so that the moving target has spatial invariance, and the image data can be automatically transformed in space to generate a high-quality human target frame to realize the monitoring of the physical condition.
- (4) After realizing the sports physical fitness monitoring, take the monitoring data as the basis, design the fitness mode recommendation method according to the user's physical fitness state, and improve the practical application value of the system.
- (5) Finally, simulation experiments are carried out to show the advantages of the proposed system in improving the sports physical fitness monitoring ability.

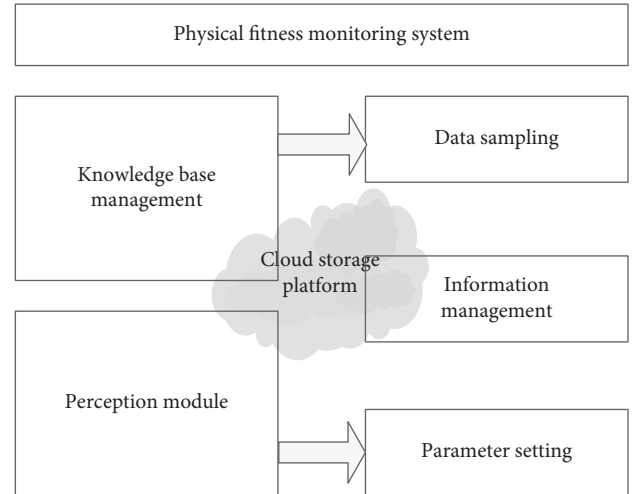

FIGURE 1: Schematic diagram of the overall architecture of the sports fitness monitoring system.

2. Design of Sports Physical Fitness Monitoring System

2.1. Overall Structure and Supporting Platform Design of Sports Fitness Monitoring System

2.1.1. Overall Structure of Sports Physical Fitness Monitoring System. Cloud storage technology [12, 13] is a networked storage concept rising in recent years. It is an emerging technology derived and developed on the basis of cloud computing [14, 15]. Cloud storage is a mode of online storage, that is, data are stored on multiple virtual servers usually hosted by a third party, rather than exclusive servers. Hosting companies operate large data centers. People who need a data storage and hosting can meet the needs of data storage by purchasing or renting storage space from them. According to the needs of customers, data center operators prepare storage virtualized resources at the back end and provide them in the form of a storage resource pool, so that customers can use this storage resource pool to store files or objects by themselves. In fact, these resources may be distributed on many server hosts, which is also the theoretical basis of cloud storage analysis. Combined with developed Internet technology, advanced cluster application, and mature distributed file system, this technology enables the massive types of storage devices in the network to work together to form an overall storage and computing structure model and jointly provide data storage and computing services and interface access functions. This paper transmits the collected data to the cloud platform through the wireless network to realize the cloud storage function [16], which can realize the storage and calculation of massive sports fitness monitoring data. In addition, compared with embedding the algorithm into the sensor terminal module program, the data processing algorithm stored on the remote cloud platform can be continuously optimized and updated in real time to ensure the accuracy and expansibility of the data [17, 18].

According to the characteristics of sports fitness monitoring, relying on cloud storage as the bottom end, through B/S and C/S multilayer architecture, realize the overall architecture design of the sports fitness monitoring system. The overall architecture of the system is shown in Figure 1.

According to Figure 1, based on the architecture of “optical fiber sensing terminal + data processing relay + cloud platform + heterogeneous application terminal” [19, 20], combined with cloud storage technology, the sports fitness monitoring system designs a system framework including sensing layer, cloud platform, management layer, data processing layer, and application layer.

2.1.2. System Application Support Platform. The network application support platform uses the TCP/IP protocol as the network communication protocol and is composed of network servers, communication equipment, security equipment, etc., and applies the latest, the most advanced network core technology also includes existing network application support systems and supports the operation of the upper-layer application software. Establish a safe, stable, reliable, and open network application platform, which is the cornerstone of establishing a comprehensive management environment for sports physical fitness monitoring information.

The network application support platform, based on open protocols and technical standards, is not limited to any hardware platform or network platform, spanning Unix, Windows NT, and other network operating systems and realizing multiplatform, multiprotocol, and multioperating system communication. This feature makes the comprehensive environment for sports physical fitness monitoring information management independent of the network environment, and the network application support platform is completely transparent to the application system to ensure a seamless connection between different systems.

The network application support platform adopts a series of network interconnection and information security technologies, uses firewall technology and data encryption technology to ensure the safe and reliable transmission of sports physical fitness monitoring information, and more importantly, makes full use of and shares various network resources such as existing public information networks by using virtual private network (VPN) technology. Users in different regions of the system can communicate with users in other regions of the system only by connecting with local public information network nodes, which saves investment. Virtual private network (VPN) has higher and stricter requirements for the security of network system and information. It comprehensively adopts appropriate technologies to establish separation around the internal network and external network, protect the internal network, and safely and stably protect the information platform through special firewall software, data encryption software, high-performance hardware, and comprehensive management measures.

2.2. Functional Module Design of Sports Physical Fitness Monitoring System. The sports physical fitness monitoring system can be divided into five functional modules:

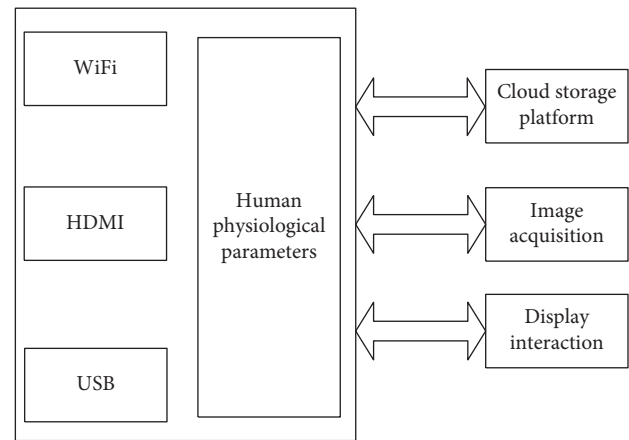

FIGURE 2: The working principle of the perception module.

knowledge base management module, perception module, sports fitness data sampling module, fitness project information management module, and parameter setting module. These functional modules are analyzed in detail below.

2.2.1. Knowledge Base Management Module. The knowledge and experience model of physical fitness analysis and evaluation experts is stored in the knowledge base, which is expressed by production rules. Production rule representation of. By analyzing the data of the inquirer, the system selects the corresponding knowledge base model and method and then generates the physical exercise methods and methods suitable for the inquirer according to the knowledge base [21, 22]. The knowledge base management system is responsible for the acquisition, retrieval, storage, and other functions of knowledge. The knowledge base also stores the technical action essentials, precautions, pictures, animations, videos of exercise methods, and diet adjustment recovered after exercise. The knowledge base is not only the organizer of sports prescription generation but also provides users with the basic knowledge and skills of physical exercise. Through learning and understanding, users can improve their interest in physical exercise, improve the quality of physical exercise, and finally achieve the effect of fitness.

2.2.2. Perception Module. The core chip used in the main control board of the perception module is RK3188 with a quad-core ARM Cortex-A9 architecture of Rockchip, with the main frequency of 1.8 GHz and is equipped with the Android 4.4 operating system. Different peripherals and interface circuits are built around the system functions, as shown in Figure 2.

According to Figure 2, the main control module exchanges data with the acquisition terminal through different transmission methods such as serial port, Bluetooth, and USB and realizes the reception and transmission of human physiological parameters such as bed rest state, heart rate, pulse and respiratory rate, and measurement instructions. GPIO can realize functions such as sound acquisition output and liquid crystal display interaction. It is equipped with

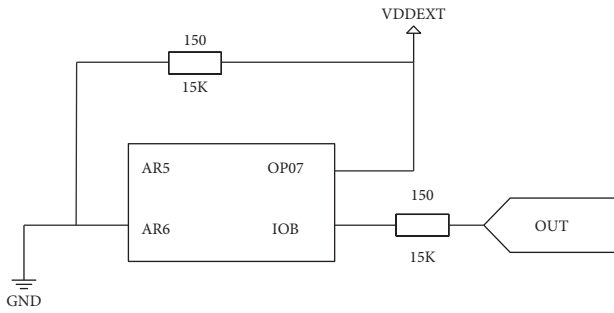

FIGURE 3: Circuit diagram of physical fitness data sampling module.

peripherals such as a liquid crystal display, touch screen, microphone, and speaker and uploads the monitoring data to the cloud storage platform in real time.

2.2.3. Physical Fitness Data Sampling Module. The physical fitness data sampling module realizes the acquisition of video image information of the physical fitness real-time monitoring system [23], and the DM9000 network module of DAVI-COM is used to design the radio frequency interface of the physical fitness real-time monitoring system in sports training. The real-time monitoring system for physical fitness in the design of sports training is divided into four layers, which are the process management layer, AD image processing layer, parameter calculation layer, and interface information interaction layer. The circuit diagram of the physical fitness data sampling module obtained is shown in Figure 3.

2.2.4. Physical Fitness Project Information Management Module. The entry of physical fitness measurement items is the preparation before sports physical fitness monitoring. The name, number, category, measurement unit, measurement instrument, measurement site, and other information of all items are recorded through the physical fitness item information management module. The system manager can view, modify, delete, and add new items at any time.

2.2.5. Parameter Setting Module. The user's personal information settings are shown in Figure 4.

According to Figure 4, the setting of the user's personal information needs to determine the user's name, photo, and source, as well as the user's age and sports level. The determination of the physical fitness index monitoring index is mainly combined with the competitive ability characteristics of users to reflect the advantages and disadvantages of users' physical reserves.

2.3. Database Design. The database is the carrier for storing all information. The database of this system is divided into three modules: basic information database, measurement data storage database, and measurement standard comparison database.

- (1) *Basic Information Database:* store the basic file data of users and the basic information of testers
- (2) *Measurement Data Repository:* record all measurement information, including the results and scores of measurement items
- (3) *Measurement Standard Comparison Library:* records the normal standards of various indicators formulated by the World Health Organization, which are used to compare with the performance of the measured person, so as to obtain the performance grade and physical fitness grade of the measured person

Since more databases will cause a certain burden on the operation of the system, the reconstruction method is adopted to create a distributed database [24, 25]. The reconstruction method is to re-establish a distributed database from the overall design, including the database on each site, according to the implementation environment and user requirements of the system [26], according to the design idea and method of distributed database, and from a unified point of view, as shown in Figure 5.

The advantage of the reconfiguration method is that it can consider various problems in the distributed database according to the unified idea and effectively solve the data consistency, integrity, and reliability of the distributed database.

This completes the design of the sports fitness physique monitoring system. The system is used to monitor people's body temperature, heart rate, and other physiological parameters during sports. At the same time, the data are uploaded to the cloud service center for data monitoring and analysis to prevent people from fainting, sudden death, and other accidents during sports. The application of the system not only provides an effective means for objectively evaluating the intensity of human sports but also promotes the scientific management of people's sports, which is of great significance to promoting sports.

3. Real-Time Monitoring Method of Physical Fitness Based on Video Image

3.1. Image Acquisition of Physical Condition Monitoring. In order to realize the real-time monitoring of physical fitness, it is necessary to reconstruct the three-dimensional contour and collect the sample pixels of the sports physical fitness monitoring image in sports training [27]. The ray-casting image feature scanning method is used to collect the physical condition monitoring image in sports training. The common spatial scanning methods of physical condition monitoring image in sports training are Cell Projection and Splatting. The ZigBee video monitoring network is designed in the environment of the Internet of things [28, 29]. The physical condition video image acquisition model in sports training is shown in Figure 6.

According to the image acquisition results in Figure 6, the sparse linear equations of fitness monitoring image template matching in sports training are obtained as follows:

FIGURE 4: User personal information settings.

FIGURE 5: Distributed database.

FIGURE 6: Image acquisition model of physical condition monitoring.

$$F(a, b) = h(a, b) * s(a, b) + l(a, b). \quad (1)$$

Here, $h(a, b)$ represents the disparity function of physical condition monitoring in sports training; the symbol $*$ represents the convolution. According to the pixel-level disparity function of sports physical fitness monitoring in sports training, information center pixel calibration and feature information adaptive weighting are performed to solve the parallax template function of physical fitness monitoring in sports training. The subpixel level matching is performed on the feature segmentation regions of the physical fitness monitoring images in sports training [30, 31], and the pixel disparity of the physical fitness monitoring image distribution in sports training is obtained as follows:

$$F(a, b) = \frac{s(a, b) + l(a, b)}{w(a, b)}. \quad (2)$$

Here, $w(a, b)$ represents the weight coefficient of physical condition monitoring in sports training [32]. The estimated value of edge pixels for physical condition monitoring is

$$\hat{s}(a, b) = R_k S(a, b) + \frac{1}{C_i} \phi^2. \quad (3)$$

Here, $S(a, b)$ represents the pixel value of the strong texture set of the physical fitness monitoring image in sports training about the scanning point (a, b) ; R_k represents the weak texture set of the sports physical fitness monitoring part; ϕ^2 represents the local variance; C_i represents the classification pixel set of the physical fitness monitoring image feature information in sports training. $s_1(x)$ and $s_2(x)$ are used to denote the gray value of the reconstructed image of the physical condition monitoring image in the exercise training of young children.

The spectral feature quantity of video surveillance is initialized, a real-time monitoring model is constructed, and combined with the 3D data distribution of the 3D reconstruction of the exercise training video image, the image reconstruction processing of the physical condition monitoring in the exercise training is carried out, thereby realizing the video image acquisition of the physical condition in the exercise training.

3.2. Physical Condition Monitoring. Because the human body's physical fitness target frame provided by the traditional method is not accurate enough, it is not suitable for the key point calibration of the physical condition monitoring image. The research shows that the slight movement of the human body target frame will seriously affect the key point calibration result. Therefore, this paper proposes to give the image convolutional cropping, translation, scaling, and rotation characteristics through the spatial transformation network, so that the moving target has spatial invariance, and the image data can be automatically spatially transformed to generate a high-quality human target frame.

Mathematically, the spatial transformation network can be regarded as a two-dimensional affine transformation [33, 34], which can be expressed as follows:

$$\begin{pmatrix} a_i^2 \\ b_j^2 \end{pmatrix} = [\alpha_1, \alpha_2, \alpha_3] \times \begin{pmatrix} a_i^f \\ b_j^f \end{pmatrix}. \quad (4)$$

Here, α_1 , α_2 , and α_3 represent two-dimensional vectors; (a_i^2, b_j^2) represents the coordinates before the transformation; (a_i^f, b_j^f) represents the coordinates after the transformation.

After the spatial transformation network, a human body physical fitness motion pose estimation network is formed, which is used to perform preliminary pose estimation of the human body target frame. At this time, the generated pose needs to be mapped to the original human body target frame image. Naturally, an inverse spatial transformation network is required to remap the estimated human pose back to the original image coordinates.

The spatial inverse transformation network performs inverse transformation by calculating the threshold value ϑ and generates a grid based on the threshold value ϑ . The calculation method can be expressed as follows:

$$\begin{pmatrix} a_i^f \\ b_j^f \end{pmatrix} = [\vartheta_1, \vartheta_2, \vartheta_3] \times \begin{pmatrix} a_i^2 \\ b_j^2 \end{pmatrix}. \quad (5)$$

Here, (a_i^f, b_j^f) and (a_i^2, b_j^2) are the coordinates before and after the spatial inverse transformation network transformation, respectively. Since the spatial inverse transformation network is the inverse process of the spatial transformation network, it can be derived as follows:

$$\begin{aligned} [\vartheta_1, \vartheta_2] &= [\alpha_1, \alpha_2]^{-1}, \\ \vartheta_3 &= -1 \times [\vartheta_1, \vartheta_2] \alpha_3. \end{aligned} \quad (6)$$

Then, a loss function $\partial(x)$ is set, which can be deduced as follows for α_1 and α_2 when back propagating in the spatial inverse transformation network:

$$\partial(x) = \frac{1}{\mu\alpha_1} + \frac{G_1((1/\alpha_2) + Y_1)}{G_2 + (1/\alpha_1) + Y_2}. \quad (7)$$

Here, μ represents the attitude error of the back-propagation center position of the space transformation network; G_1 and G_2 both represent the similarity between poses; Y_1 and Y_2 both represent the reference pose.

For α_3 , the equation can be derived as follows:

$$\partial(x) = \frac{\partial(x)}{\alpha_3} \times \frac{\lambda\alpha_3}{\lambda\vartheta_3}. \quad (8)$$

During network training, the spatial inverse transformation network and the single-person pose estimation network are fine-tuned together.

According to the above-given derivation results, the corner detection method is used to calibrate the characteristic key points of the video surveillance part of the motion training. The expression of the corner calibration is

$$\begin{cases} D_1 = \max(\tilde{z}_i - z_i), \\ D_2 = \min(\tilde{z}_i - z_i). \end{cases} \quad (9)$$

Here, D_1 and D_2 represent the image pixel difference feature quantity in the secondary matching template. The Harris corner detection method is used to locate the key feature points of the physical condition monitoring image in

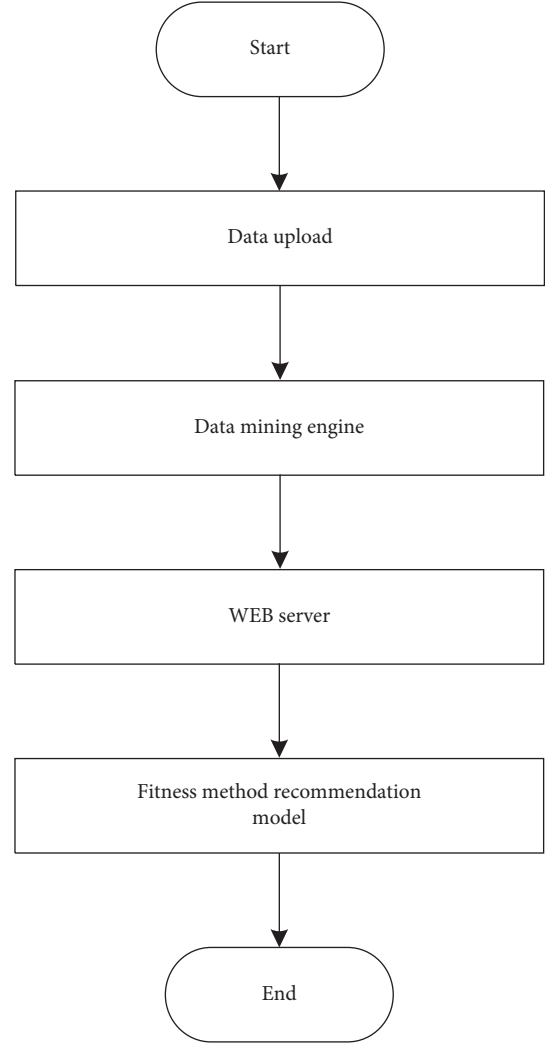

FIGURE 7: Fitness method recommendation process.

exercise training, and the positioning output vector is obtained as follows:

$$W_{ij} = \eta(a_i)\eta(b_j). \quad (10)$$

According to the dynamic distribution of the corners of the sports physical fitness monitoring images during exercise training, the sports physical fitness monitoring is realized.

3.3. Recommended Fitness Methods. After the sports physical fitness monitoring is realized, the monitoring data is used as the basis, and the fitness method recommendation method is designed according to the physical fitness state of the user [35, 36], so as to improve the practical application value of the system. The following are the recommended steps for specific fitness methods:

- (1) Use the browser as the interaction layer, provide a data input interface and data upload function, and transmit the physical fitness test data of individual users to the WEB server;

TABLE 1: Experimental parameter setting.

Number	Equipment or indicators	Model parameter
1	Monitoring system transformer	1500 kV
2	Monitoring system substation host	IdeaCentre K350
3	Rated voltage of monitoring system	380 V
4	Rated current of monitoring system	≤ 51 A
5	Monitoring system resistance	$6.8 \times 10^7 \Omega$
6	Total power consumption information storage of monitoring system	128 Gb

- (2) The server analyzes the physical fitness test data and transmits the physical fitness test indicators after the analysis to the data mining engine. During this stage, for the acquired physical fitness test indicators, in the background database, the data mining engine matches them with the fitness categories in the fitness mode recommendation model and generates the mining results of fitness mode recommendation;
- (3) Send the mining results to the WEB server;
- (4) Individual users will be able to view the mining fitness results through their browsers.

The design of embedding the fitness mode recommendation model into the service application platform focuses on the operation phase of importing the model into the data mining engine and background database.

Import the fitness recommendation model into the database: the model and rule set are processed in a certain format and imported into the database, or the model and the database are connected using a port. The physical fitness test sample data is mined through the data mining engine, and after completion, the mining results are matched with the background fitness method recommendation table to form a recommendation list, which is presented to individual users through the browser. In this way, different users and at different times, individual users see different content on their browsers. Therefore, the fitness mode recommendation based on the individual user's physical fitness test information is realized. Figure 7 is a flowchart of fitness mode recommendations.

4. Experimental Analysis

In order to verify the effectiveness of the cloud storage-oriented sports physical fitness monitoring system, an experimental study is carried out. Configure the relevant experimental parameters according to Table 1 to complete the construction of the basic experimental environment.

The storage space occupied by the compressed electric information can reflect the redundancy degree of information parameters. Generally, the smaller the storage space occupied by the compressed sports fitness monitoring system information, the lighter the redundancy degree of information parameters. At this time, the network host is more capable of eliminating redundant data.

4.1. Test Index Object Setting. Set the experimental test index object: take the autonomous fitness monitoring system based on a monocular camera (system 1) and the video

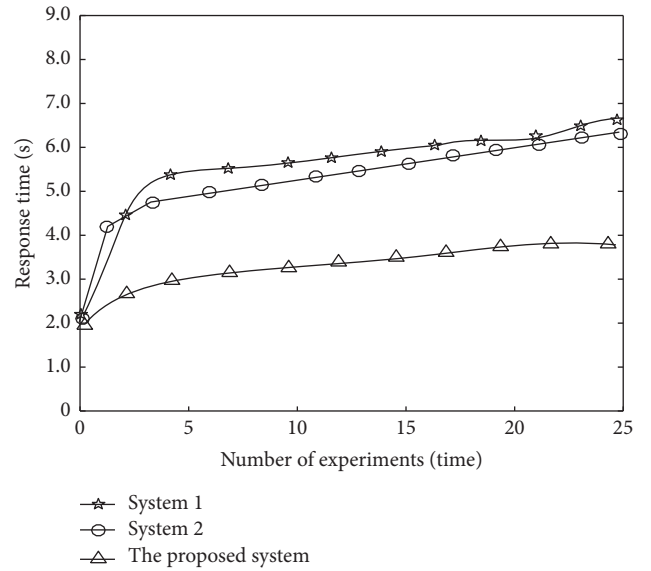

FIGURE 8: Response speed comparison results.

monitoring system for children's sports training based on feature moving frame difference scanning and adaptive compensation (system 2) as the comparison system to compare with the proposed system. In the system application performance test, the focus of the test is to verify whether the accuracy and response speed of the system monitoring results meet the actual use requirements of users and the comprehensiveness of the monitoring results.

4.2. Analysis of Test Results

4.2.1. System Response Speed. In order to verify the application effect of the monitoring system, the system response speed is used as an evaluation index. The faster the system response speed, the better the system application effect is, which indicates that the system can effectively meet the requirements of real-time monitoring of physical fitness status. Using system 1, system 2, and the proposed system to compare, the response speed comparison results of different systems are shown in Figure 8.

According to Figure 8, the response time of different systems increases with the increase of the number of experiments. When the number of experiments is 5, the response time of system 1 is 5.4 s, that of system 2 is 4.8 s, and that of the proposed system is only 2.9 s; When the number of experiments is 15, the response time of system 1 is 5.8 s, that of system 2 is 5.6 s, and that of the proposed system is

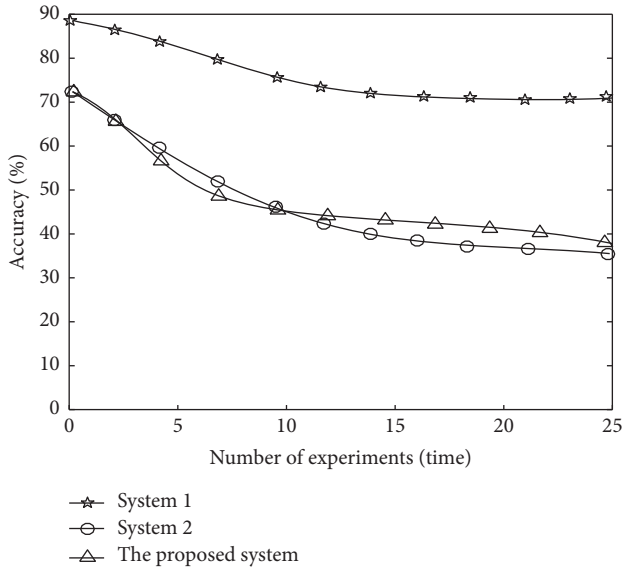

FIGURE 9: Comparison of accuracy of monitoring results.

only 3.3 s. Therefore, the monitoring time of the proposed system is less, indicating that the monitoring response of the proposed system is more timely.

4.2.2. Accuracy of Monitoring Results. In order to verify the monitoring effect of the proposed system, the accuracy of the monitoring results is taken as the evaluation index. The higher the accuracy of the monitoring results, it shows that the system can effectively meet the actual needs of sports physical fitness monitoring, obtain accurate monitoring results, and provide reliable data for the recommendation of fitness methods. Compare system 1, system 2, and the proposed system and get the monitoring results of different systems. The accuracy comparison results are shown in Figure 9.

According to the analysis of Figure 9, with the increase of the number of experiments, the accuracy of monitoring results of different systems decreases. When the number of experiments is 5, the accuracy of monitoring results of system 1 is 60% and that of system 2 is 57%. The accuracy of the monitoring results of the proposed system is 84%; when the number of experiments is 15, the accuracy of monitoring results of system 1 is 41%, that of system 2 is 44%, and that of the proposed system is 74%. It can be seen that the accuracy of the monitoring results of the proposed method is high, and more accurate monitoring results can be obtained.

4.2.3. Comprehensiveness of Monitoring Results. In order to further verify the monitoring effect of the proposed system, the comprehensiveness of the monitoring results is taken as the evaluation index. The index is expressed by numerical value, and the interval is $[0, 1]$. The larger the value is, the more comprehensive the monitoring results are. The monitoring results of different systems are shown in Table 2.

According to the data in Table 2, the highest comprehensive coefficient of the monitoring results of the proposed

TABLE 2: Comprehensive comparison of monitoring results.

Number of experiments/ time	The proposed system	System 1	System 2
2	9.6	7.5	8.0
4	9.4	7.3	7.9
6	9.2	7.2	7.8
8	8.9	7.6	7.5
10	9.0	7.9	7.4
12	9.0	7.1	7.5
14	8.7	7.0	7.3
16	8.7	6.8	7.1
18	9.1	7.0	7.0
20	9.3	7.0	6.9

system is 9.6, and the highest comprehensive coefficient of the monitoring results of system 1 and system 2 are 7.5 and 8.0, respectively. Through comparison, it can be seen that the comprehensiveness coefficient of the proposed system is higher, indicating that its monitoring results are more comprehensive.

To sum up, with the increase of the number of experiments, the monitoring time of the sports fitness monitoring system designed for cloud storage is less, and the monitoring response is more timely; the accuracy of monitoring results is high, and more accurate monitoring results can be obtained. The highest comprehensive coefficient of the monitoring results of the proposed system is 9.6, and the comprehensive coefficient is higher, indicating that the monitoring results are more comprehensive.

5. Conclusion

In order to improve the accuracy of sports fitness monitoring results, the response speed of the system, and the comprehensiveness of monitoring results, a sports fitness monitoring system for cloud storage is designed. Based on cloud storage technology, establish the overall architecture of sports fitness monitoring system, ensure the safe and reliable transmission of fitness monitoring information under the system application support platform, and improve the accuracy of testing results; analyze the function of the hardware module of the monitoring system and establish a distributed database to improve the comprehensiveness of the detection results; ray casting image feature scanning method is used to collect the monitoring image of physical condition, and a high-quality human body target frame is generated through the steps of image convolution, cutting, translation, scaling, and rotation to realize the monitoring of the physical condition. The following conclusions are obtained through the research:

- (1) The physical fitness monitoring system designed for cloud storage can improve the real-time response speed of monitoring
- (2) Based on the monitoring data, the fitness mode recommendation method is designed according to the user's physical condition, so as to improve the application value of the system

- (3) The monitoring results of the designed system are more accurate, the system response speed is faster, the monitoring results are more comprehensive, and the highest value reaches 9.6, indicating that the application value of the proposed system is higher

As a new type of electronic currency, bitcoin is more and more recognized and sought after by people, but its price fluctuation is more intense, the market has certain risks, and the price is difficult to be accurately predicted. The main purpose of this study is to use a deep learning integration method (SDAE-B) to predict the price of bitcoin. This method combines two technologies: one is an advanced deep neural network model, which is called stacking denoising autoencoders (SDAE). The SDAE method is used to simulate the nonlinear complex relationship between the bitcoin price and its influencing factors. The other is a powerful integration method called bootstrap aggregation (Bagging), which generates multiple datasets for training a set of basic models (SDAES). In the empirical study, this study compares the price sequence of bitcoin and selects the block size, hash rate, mining difficulty, number of transactions, market capitalization, Baidu and Google search volume, gold price, dollar index, and relevant major events as exogenous variables uses SDAE-B method to compare the price of bitcoin for prediction and uses the traditional machine learning method LSSVM and BP to compare the price of bitcoin for prediction. The prediction results are as follows: the MAPE of the SDAE-B prediction price is 0.016, the RMSE is 131.643, and the DA is 0.817. Compared with the other two methods, it has higher accuracy and lower error, and can well track the randomness and nonlinear characteristics of bitcoin price.

1. Introduction

Bitcoin is a decentralized, anonymous, exclusive ownership, and inflation-free currency [1]. Fry and Cheah [2] found that in view of the innovative characteristics of decentralization and traceability of bitcoin, bitcoin has attracted extensive attention from the media and investors. After the rise and fall of cryptocurrency prices in recent years, bitcoin is increasingly seen as an investment asset. Investors see bitcoin as a speculative investment, similar to the Internet stocks of the last century [3]. Bitcoin as a cryptocurrency, itself appears for a short time compared with the sovereign currency [4]. Unlike the sovereign currency, bitcoin is a decentralized digital currency without any government credit support, so the price of bitcoin is highly volatile. It produces much more volatility than sovereign currencies. Its price rose from zero value when

it was established in 2009, to about \$13 per bitcoin in January 2013, and then soared to about \$20000 per bitcoin in December 2017. Since bitcoin started trading, its highly unstable nature has been plaguing investors, and it may be a bubble, threatening the stability of the financial system. Therefore, it is necessary to make a good prediction of the price of the special currency. The possibility of predicting the price trend of bitcoin is a practical problem. It not only affects a country's economic policy at the macro level but also strongly affects investors' decision to buy and sell investment instruments at the micro-level. Matkovskyy and Jalan [5] found that the accurate prediction of bitcoin price can not only provide decision support for investors but also provide reference for the government to formulate regulatory policies.

Equally noteworthy are the factors that influence bitcoin prices. In addition to the internal factors such as block size,

hash rate, mining difficulty, trading volume, and market value of bitcoin, this study thinks that the factors should be more comprehensive: firstly, this study thinks that the Google and Baidu search index is an important factor affecting bitcoin because it is an important indicator to measure investors' attention and media hype and reflects the sentiment of the highly speculative cryptocurrency market [6]. Secondly, this study argues that the irrational factors such as major events and investor sentiment caused by economic policies will also affect the price of bitcoin [7]. Papadopoulos [8] shows that there is good interaction between bitcoin price and gold price. Dyhrberg [9] proved the similarity among bitcoin, gold, and the US dollar through the GARCH model. Therefore, this study takes the gold price and the dollar index as the influencing factors of bitcoin price. By selecting the above external factors, the problem of simplifying bitcoin price prediction is avoided.

The contribution of this study is as follows: compared with traditional financial asset price prediction, bitcoin price prediction is still in the early stage. Because bitcoin lacks seasonality, A. Greaves and Au [10] found that the machine learning model is applicable and useful. Similarly, Shah and Zhang [11] used Bayesian regression to predict the price change of bitcoin. At present, various popular machine learning algorithms such as SVM [12], RNN, LSTM, ARIMA [13], GA, and NARX [14] have also been applied to predict the price of bitcoin. Although the traditional machine learning model has obvious advantages in bitcoin price prediction, the imbalance and poor integrity of relevant data will lead to the problems of low accuracy, poor robustness, and easy to fall into the local optimum of deep network training. With the maturity of machine learning technology, deep learning has gradually become the mainstream of machine learning technology, and related algorithms and applications have also begun to flourish. And it shows strong ability in classification, feature extraction, and other non-linear modeling tasks. A deep denoising self-coding network is a widely used network model in deep learning. With fewer data samples and suitable classification and recognition algorithms, it can obtain higher classification ability and has strong feature extraction ability and robustness. The unsupervised pretraining of self-coding networks can effectively extract the internal features of bitcoin data and reduce the loss of typical features to the greatest extent [13, 15]. Therefore, this study proposes a deep learning ensemble

method (SDAE-B) to predict the price of bitcoin, which combines two technologies: one is the stacking denoising autoencoders (SDAE-B), which is used to simulate the nonlinear complex relationship between bitcoin price and its influencing factors. The other is a powerful integration method called bootstrapping, which generates multiple datasets for training a set of basic models (SDAES). Through the use of the SDAE-B method to compare the price of the special currency and get a good result.

The framework of this study is as follows: Section 2 introduces the methods proposed; Section 3 carries out empirical research and discusses the results; Section 4 gives the conclusion and describes the main contributions of the study.

2. Materials and Methods

2.1. Deep Learning Integration Method (SDAE-B). Stacking denoising autoencoders (SDAE) [16] is a popular DNN model. The results show that it has higher prediction accuracy in a series of classification problems than competitive machine learning models such as stacked autoencoders (SAE) and deep belief networks (DBN). SDAE is constructed by stacking several denoising autoencoders (DAEs), which is a special neural network structure. To illustrate SDAE, the autoencoder (AE) and the DAE are introduced.

2.1.1. Autoencoder (AE). Autoencoder(AE) is a single hidden layer neural network with equal input and output sizes. Firstly, an input vector $x \in [0, 1]^d$ is mapped to a hidden representation $y \in [0, 1]^d$ by a deterministic function:

$$y = f_{\theta}(x) = \phi_f(Wx + b). \quad (1)$$

$F(x)$ parametrization is $\theta = \{W, b\}$, W is a weight matrix of $d' \times d$, b is a bias vector, and $\phi_f(\cdot)$ is a nonlinear activation function. Then, y in the input space maps the return $z \in [0, 1]^d$ as the following equation:

$$z = g_{\theta'}(y) = \phi_g(W'y + b'). \quad (2)$$

With $\theta' = \{W', b'\}$. Therefore, each training $x^{(i)}$ is mapped to the corresponding $y^{(i)}$ and reconstruction $z^{(i)}$. The model parameters are optimized to minimize the average reconstruction error.

$$\theta^*, \theta'^* = \arg_{\theta, \theta'} \min \frac{1}{n} \sum_{i=1}^n L(x^{(i)}, z^{(i)}) = \arg_{\theta, \theta'} \min \frac{1}{n} \sum_{i=1}^n L(x^{(i)}, g_{\theta'}(f_{\theta}(x^{(i)}))), \quad (3)$$

where L is the loss function, which can be the traditional square error:

$$L(x, z) = \|x - z\|^2, \quad (4)$$

or reconstruction fork:

$$L_H(x, z) = H(B_x \bullet B_z) = - \sum_{k=1}^d [x_k \log z_k + (1 - x_k) \log (1 - z_k)]. \quad (5)$$

Vincent et al. [17] believed that the autoencoder (AE) is a self-monitoring algorithm, not an unsupervised algorithm.

It does not need to mark the training samples, and its label is generated from the input data. Therefore, it is easy to train a specific encoder for the input of the specified class without any new work. The autoencoder (AE) is data-related and can only compare data similar to training data. For example, the automatic encoder trained with face has poor performance in compressing other pictures, such as trees, because the features it learns are related to the face.

2.1.2. Denoising Autoencoder (DAE). Based on the autoencoder (AE), the denoising autoencoders (DAE) adds noise to the input data of the input layer to prevent the overfitting problem, which improves the robustness of the learned encoder. The core idea of DAE is to reconstruct a purified input from a corrupted version. First, the corrupted original input data x is randomly mapped $\tilde{x} \sim q_D(\tilde{x}|x)$ to \tilde{x} . Then input the noisy model \tilde{x} and get y by $y = f_\theta(\tilde{x}) = \phi(W\tilde{x} + b)$ mapping. Finally, the pair is mapped $z = g_{\theta'}(y)$ back to z . For the training set, the best parameters θ and θ' are obtained by minimizing the average reconstruction error between z and undamaged input x . The process is shown in Figure 1.

2.1.3. Stacking Denoising Autoencoders (SDAE). The idea of stacking denoising autoencoders (SDAE) is to stack multiple DAEs together to form a deep architecture. Only when the training is complete, the input will be added with noise. It follows layer-by-layer greedy training [18]: each layer of the self-coding layer carries out unsupervised training independently to minimize the error between the input (the input is the hidden layer output of the previous layer) and the reconstruction result. After the former k layer is trained, the $K+1$ layer can be trained, because the output of the k layer has been calculated by forwarding propagation, and then the output of the k layer is used as the input of $K+1$ to train $K+1$ layer.

Specifically, the first DAE uses the training set as the input for independent training and learns through $f_\theta^{(1)}$ mapping function. Then the second DAE uses the hidden representation y of the first DAE as input to train and learn by $f_\theta^{(2)}$ mapping function. All DAEs can train independently according to the same procedure. An independently supervised learning algorithm (such as FNN) is added to the structure, which uses the hidden representation of the last DAE as input. Finally, establish SDAE. Once the SDAE training is completed, its high-level characteristics can be used as the input of the traditional monitoring algorithm. Besides, the parameters of each layer of SDAE can be adjusted synchronously by gradient descent and other training algorithms. The process is shown in Figure 2.

2.1.4. Bagging. Bagging [19] is the abbreviation of bootstrap aggregating. It is a powerful integrated learning algorithm, which can be used for tasks such as two classifications, multiclassification, and regression. Its principle is to give a data set containing m samples, first, take a sample randomly and put it into the sampling set, and then put the sample back, so that the sample will still have the chance to be selected in the next sampling. So, after M times of sampling, we can get a

FIGURE 1: The architecture of DAE.

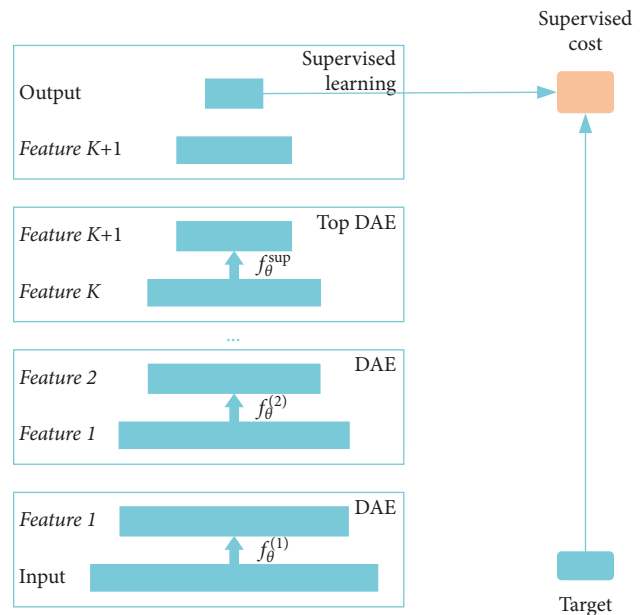

FIGURE 2: The architecture of SDAE.

data set with the same data amount of m from the original data set. Simply speaking, there are put back samples in the statistics and each sample. The probability of samples being taken is the same, which is one of the total samples.

Only when the basic learning algorithm is unstable, bagging can generate different basic models, which can be regarded as a method to improve the prediction accuracy by using this instability. The neural network model is unstable due to the random initialization process of weights, while the bagging neural network has strong robustness. It has been successfully applied in the field of finance and economy [20–22]. For these reasons, bagging can be used to construct an integration based on SDAES.

2.1.5. Multivariate Forecasting. Different from the time series model, the multivariate model not only considers the autoregressive effect of target series but also considers the influence of exogenous variables on the target series. The

multivariate model as a simple but very important method in the process of statistical analysis, it has been widely used in prediction in different fields. For example, Rombouts et al. [23] applied it in the field of option pricing. In recent years, scholars have applied multivariate model and deep learning technology to the field of prediction [24]. The results show that the multivariate model outperforms the univariate model for forecasting. It can be formalized as a function to simulate the relationship between dependent variables and independent variables:

$$y(t+h) = f(s(y), s(x_1), \dots, s(x_C)), \quad (6)$$

where $y(t+h)$ is the value of the dependent variable in $(t+h)$ and $s(x) = x(t), x(t-1), \dots, x(t-l_x+1)$ is a set of past values of exogenous variable x with a total of l_x . Therefore, the input quantity is $m = \sum l_y + l_{x_1} + l_{x_2} + \dots + l_{x_C}$.

2.1.6. The Overall Process of SDAE-B Approach. The main idea of the hybrid model is as follows. The deep learning model SDAE is used to extract useful information from the selected data and generate prediction. The powerful integration method bagging is used to combine the strength of multiple SDAEs to improve the prediction accuracy, so as to generate an integrated model with better performance.

SDAE-B forecasts bitcoin prices based on the following five steps. Figure 3 shows the flow chart of the whole process:

- (1) Data preprocessing: transform the original data into training samples and test samples.
- (2) Generate multiple training sets: generate K sample sets of training samples through the bootstrapping algorithm.
- (3) Training: each group of training samples trained K SDAE models, respectively.
- (4) Prediction: use SDAE models of K training to generate K predictions.
- (5) Result summary: take the average of K predicted values as the final result.

3. Results and Discussion

In this section, we compare the prediction ability of LSSVM and BP with that of SDAE-B. Firstly, the data description is given. Secondly, the model evaluation criteria are given. Then LSSVM, BP, and SDAE-B are used to compare the price of the special currency for prediction. Finally, the comparison results are given and analyzed.

3.1. Datasets. In this study, the data of bitcoin block size, hash rate, mining difficulty, number of transactions, and market capitalization are from Data.Bitcoinity.Org, Blockchain.com, and CoinMarketCAP. Baidu and Google search volume, respectively, come from Baidu Index and Google Trends. Relevant major events come from the review of the 11th anniversary of bitcoin by the blockchain media "Daily Star." Gold prices come from GOLDHUB. Dollar index from Investing.com. The data is from November 29, 2014, to March

30, 2020. This study selects nine indicators of bitcoin, including block size, hash rate, mining difficulty, trading volume, market value, Baidu, and Google search volume, gold price, dollar index, relevant major events (Table 1) as independent variables, and bitcoin price (trend as shown in Figure 4) as dependent variables to build the model, as shown in Table 2.

The reasons for choosing these variables are as follows. First, they are closely related to bitcoin prices. Secondly, the relationship between bitcoin price series and these factors is noisy, fluctuating, and nonlinear, but any of them may provide useful information about bitcoin price trends at a certain point in time. Therefore, we can extract more information through as many variables as possible. Finally, as a deep neural network model, SDAE has a very powerful function in high-dimensional data modeling. Using these variables, we can make full use of the advantages of SDAE to create an ideal environment for the modeling of the bitcoin price series.

Different from previous studies, except for the internal factors such as block size, hash rate, mining difficulty, trading volume, and market value of bitcoin, this study increases Baidu and Google search volume, gold price, dollar index, and relevant major events.

These variables are selected to model the price series of bitcoin for the following reasons: first, they are closely related to bitcoin prices and represent different drivers of bitcoin prices. Secondly, the relationship between bitcoin price series and these factors is noisy, unstable, and nonlinear, but any of them may provide useful information about the movement of bitcoin price at a certain time. Therefore, we can extract more information by including as many variables as possible. Finally, a large number of variables can be used to provide relatively complete bitcoin price change information.

To model, this study divides the data into two parts: the training sample contains the first 80% of the observation values of all series, and the rest is the test sample. For model training, bitcoin price and exogenous variables are pre-processed by the normalization method.

3.2. Model Evaluation Index. To evaluate the prediction performance of the model from different perspectives (i.e., direction prediction and level prediction), three frequently used indicators in recent years include direction accuracy (DA), mean absolute error (MAPE), and mean square root error (RMSE):

$$DA = \frac{1}{N} \sum_{t=1}^N a(t) \times 100\%,$$

$$MAPE = \frac{1}{N} \sum_{t=1}^N \left| \frac{y(t) - \hat{y}(t)}{y(t)} \right|, \quad (7)$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{t=1}^N (y(t) - \hat{y}(t))^2},$$

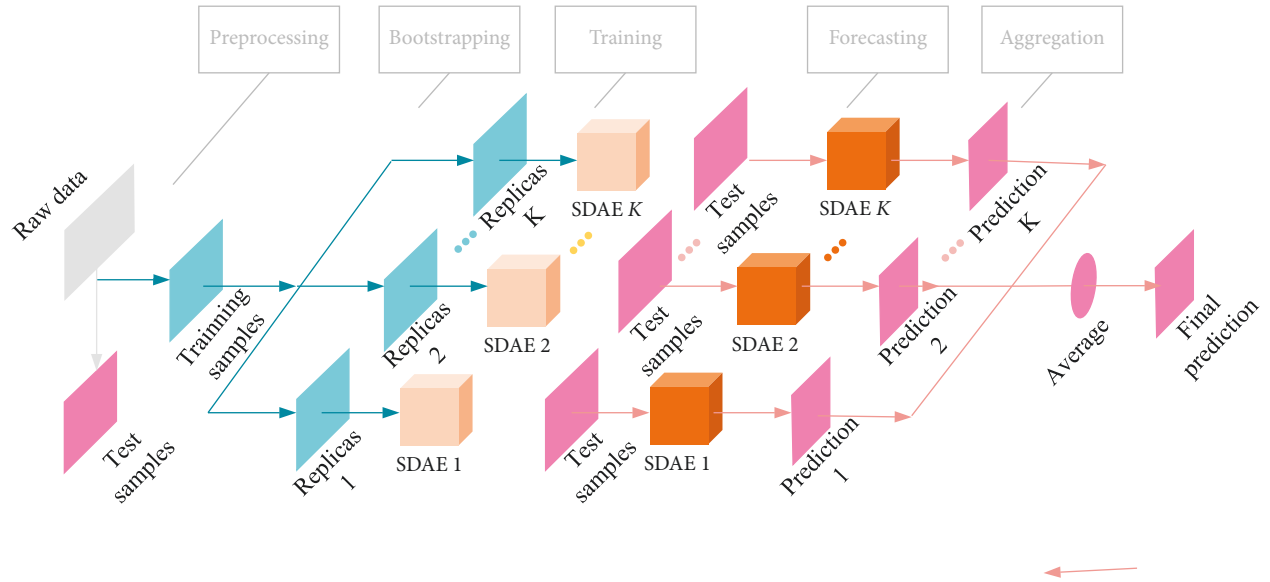

FIGURE 3: The prediction process of SDAE-B model.

TABLE 1: Features.

Future	Definition
Block size	The average block size in MB
Hash rate	The estimated number of tera hashes per second (trillions of hashes per second), the bitcoin network is performing
Mining difficulty	A relative measure of how difficult it is to find a new block. The difficulty is adjusted periodically as a function of how much hashing power has been deployed by the network of miners
Number of transactions	The number of transactions per day
Market capitalization	The total US dollar market value of bitcoin
Baidu and google search volume	The weighted volume for media coverage of the keyword “bitcoin”
Relevant major events	Major events in bitcoin from November 29, 2014, to March 31, 2020 (positive impact expressed as “1” and negative impact expressed as “-1”)
Gold price	XAU gold spot price in US dollars
Dollar index	An indicator that comprehensively reflects the exchange rate of the US dollar in the international foreign exchange market

where $y(t)$ and $\hat{y}(t)$ represent true value and prediction respectively when $(y(t+1) - y(t))(\hat{y}(t+1) - y(t)) \geq 0$, $a(t) = 1$; otherwise, $a(t) = 0$. N is the size of the forecast data.

3.3. Parameter Settings. SDAE model is a three-layer hidden neural layer network model. It stacks two DAEs and a supervised FNN on top of the architecture. According to the size of the feature space, set the number of nodes in the first to third hidden layers to 200, 100, and 10. Based on the trial and error method, the number of epochs for DAEs unsupervised pretraining, FNN supervised pretraining, and

global fine tuning are all set to 500. The noise type in DAEs is additive Gaussian noise. According to Vincent et al. [17], the noise ratio is 0.2. The numbers of K is set to 100. The choice of K number is actually a trade-off between computational complexity and accuracy. However, with the increase of K , the prediction error of SDAE-B quickly converges to a certain level, so it is not necessary to select a large number. The lagged order of all variables and bitcoin price in the multivariate prediction model is set to 1, i.e., to learn a function satisfying. Through this method, a short term nonlinear dependency can be learned between input/output data. The number of hidden layers of BP is 1, the network structure is [40, 20, 1] the activation function is sigmoid

FIGURE 6: Comparison of the true price of Bitcoin and predicted price based on LSSVM model.

FIGURE 7: Comparison of the true price of Bitcoin and predicted price based on BP model.

function, and the learning rate is 0.1. The Gaussian kernel function is selected as the kernel function of the LSSVM method. Matlab R2016a is used to perform all the computations in this study.

3.4. *Bitcoin Price Forecast.* With the help of MATLAB software, LSSVM, BP, and SDAE-B are used to compare the

price of special currency for forecasting. The results are shown in (Table 3). Also, the research results are shown in Figures 5–7.

The results show that SDAE-B has higher direction accuracy (DA), lower mean absolute error (MAPE), and lower mean square root error (RMSE), and has better prediction performance than LSSVM and BP. The possible reasons are as follows:

- (1) When dealing with data with various features, many traditional machine learning algorithms have a weakness. They cannot extract and organize different information from the data. Since it may be a difficult task to build a model of the relationship between bitcoin price and many variables, traditional models may not be able to learn useful representations, resulting in poor out of sample predictions. Instead, SDAE-B has a deep architecture. It can learn useful information from features by extracting multiple levels of representation, to obtain better prediction ability when the sample data are insufficient.
- (2) The performance of the integrated model is more stable than the traditional single machine learning model, because the traditional single machine learning model excessively relies on the sample data, underestimates the variance, and causes overfitting. The integrated model can reduce overfitting or generalization errors.

4. Conclusions

At present, bitcoin is a good stored value and safe haven, which is the most important use of bitcoin by all those who recognize it. In the long run, with the continuous development of blockchain technology and the recognition of bitcoin by more and more countries, bitcoin is likely to become a national strategic reserve resource like gold. Although the price of bitcoin is of great significance to market practitioners, the theoretical research in this field is very limited. In this study, a deep learning integration method named the SDAE-B is utilized to predict the price of bitcoin. Aiming at the complex relationship between bitcoin price and various factors, this study proposes LSSVM, BP, and SDAE-B to predict bitcoin price. In the data selection, through the analysis of internal and external factors, the limitations of the previous bitcoin price prediction methods, which only consider the historical data of bitcoin price are overcome. In empirical research, the first step is to obtain data, and then do data processing and model training. Through the training results, we can get a bitcoin price prediction based on deep learning and get good results. The SDAE-B model is better than the LSSVM model and BP model, which have higher accuracy and lower error. It shows that this method can be used as a promising tool for bitcoin price prediction.

Nevertheless, this study think there is still room for improvement. As we all know, unconventional factors such as political risk and investor psychology also have a great influence on the price fluctuation of special currency, but how to quantify the influence of these factors is quite challenging. This study believes that better predictions can be generated by quantifying these factors and using the information they provide. Finally, the prediction results of the SDAE-B model proposed in this paper have a certain lag, and the correction of postphenomenon is also the focus of future research.

Data Availability

In this study, the data of bitcoin block size, hash rate, mining difficulty, number of transactions and market capitalization are from Data.Bitcoinity.Org, Blockchain.com, and Coin-MarketCAP. Baidu and Google search volume, respectively, come from Baidu Index and Google Trends. Relevant major events come from the review of the 11th anniversary of bitcoin by the blockchain media "Daily Star.". Gold prices come from GOLDHUB. Dollar index from Investing.com.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the publication of this study.

The current English teaching mode focuses on the traditional offline teaching and online teaching. In order to solve the problems that some students are inefficient and cannot teach students according to their aptitude in the teaching process, this paper uses the big data analysis strategy based on a neural network algorithm. This paper studies the discrete dynamic modeling method of learner behavior analysis in English teaching. Firstly, it summarizes the current situation of English teaching and the research status of the hybrid application of discrete dynamic modeling technology. Secondly, combined with English teaching content and teaching objectives, through the analysis of various data of students' learning behavior, this paper evaluates students' English teaching quality from five aspects that affect the students' English teaching quality and puts forward a personalized English teaching quality evaluation model based on discrete dynamic modeling technology and learners' behavior analysis. Finally, through the practical teaching application in a university, the feasibility of the discrete dynamic English teaching model is verified. The results show that compared with the current innovative English teaching methods based on a dynamic iterative decision algorithm, the personalized discrete dynamic English teaching model based on learner behavior analysis significantly improves the quality of English teaching and students' academic performance.

1. Introduction

The mainstream English teaching still focuses on the traditional offline face-to-face teaching, supplemented by online network teaching, so the teaching mode is relatively single [1]. Since the teaching model innovation policies are promoted in different regions at this stage, the vigorous development of a variety of data analysis technologies has also triggered the innovative application of English Classroom Teaching [2]. Manufacturing computer-integrated manufacturing system CIMS, system scheduling, communication network system, database management system, military C3I system, and other systems are typical discrete event systems [3]. Therefore, customization and real-time have become important features of the College English classroom teaching system in China [4]. There are two kinds

of modeling methods for this kind: informal modeling and formal modeling. Informal modeling technology refers to modeling the system with the help of computer technology through graphical representation that people can easily accept and understand, and then converting it into computer language, and analyzing the system through programs [5]. Based on English teaching and the actual situation of learner behavior analysis, this paper studies the modeling and flexible recruitment strategy of the high-tech knowledge-based discrete dynamic system. English teaching behavior is deeply influenced by teaching values, which are usually formed under the guidance of learning theory [6]. In this context, this paper studies the discrete dynamic modeling technology based on a neural network algorithm and the innovative English teaching method of learner behavior analysis.

Compared with the current innovative English teaching methods with dynamic iterative decision-making algorithms as the mainstream, the innovation of this paper is to improve the efficiency of English teaching by combining discrete dynamic modeling technology and neural network algorithm. On this basis, it can make full use of each student's learning behavior, learning data, and test scores in the English classroom through real-time dynamic tracking. It can realize customized analysis, quantitatively describe the similarity and coincidence degree of each learning behavior and teaching strategy with behavior analysis factors, complete the influence ranking of English classroom teaching indicators with quantitative indicators, and effectively conduct multivariate analysis.

Aiming at the problems of low teaching efficiency and poor intelligence in English teaching, this paper studies the construction of a discrete dynamic modeling method for learner behavior analysis in English teaching. Chapter 1 briefly summarizes the background, innovation, and chapter arrangement of this study. Chapter 2 introduces the current research status of English teaching models and influencing factors at home and abroad. Chapter 3 analyzes the teaching classroom model. Based on Gaussian random function and Laplace feature recognition, a classroom teaching model is constructed. At the same time, the three-dimensional target matching analysis is carried out according to the students' classroom performance, and the quantitative characteristics are constructed. Chapter 4 sets up a correlation experiment to verify the relevant indicators of the English classroom teaching model constructed in this paper, analyzes the experimental results, and draws a conclusion.

2. Related Work

China has developed slowly in the mode of innovation and quality evaluation of English teaching, while some foreign developed countries have good basic and phased innovative achievements in the field of English Teaching [7]. It is very necessary and important to evaluate teachers' teaching behavior through the study of English learning theory and find deep theoretical roots for teaching practice, so as to carry out English teaching activities more scientifically in the future [8]. In addition, it is more suitable to analyze the learners' motivation and behavior of their learners [9, 10].

Based on this model, the strategy of a discrete dynamic system for learners' behavior analysis in English teaching is put forward, and the sufficient conditions for the asymptotic stability of the closed-loop system for learners' behavior analysis are analyzed. The designed strategy can ensure that each state of the actual discrete dynamic system tracks the desired state, and the simulation results verify the effectiveness of the discrete dynamic modeling strategy proposed in this paper [11]. The establishment of a reasonable discrete dynamic model and computer simulation has always been an indispensable research method, which has played a great role in reducing losses, saving funds, shortening the cycle, reducing costs, and improving product quality and service quality [12, 13]. With the help of the description and solution methods of learners' behavior analysis problems

provided by English teaching theory, the research on discrete dynamic modeling, analysis, control, and optimization of this kind of system has reached a quite mature and perfect state, at least in relatively simple branches such as linear time-invariant systems, and its effectiveness has been shown in practical applications [14]. According to the idea of neuron node association in neural network algorithm, researcher Zou et al. proposed a distributed parsing model for English teaching based on mixed contexts. The experimental results show that it has a strong speech discrimination ability [15]. Pejpichestakul et al. proposed that the Petri net modeling of discrete dynamic systems should be guided by scientific modeling methods and supported by powerful computer software. Deloitte & ToucheBakkenist of the Netherlands and Eindhoven University of Technology jointly developed ExSpect. The concept of domain model base and the design characteristics of supporting system analysis methods of this language make it a powerful modeling and simulation tool for complex discrete event dynamic systems [16]. Cao et al. proposal is more significant for basic systems such as large-scale computer and communication networks and airport traffic management systems. Therefore, the research on the modeling of discrete event dynamic systems is an urgent need for the current social production to achieve high efficiency and low fault operation [17]. Cao et al. proposed that when designing a feedback controller for modeling discrete dynamic systems, the time-varying perturbation of controller parameters may lead to the performance degradation of closed-loop systems, and even the stability will be destroyed. Therefore, the concept of elastic control was put forward. Elastic control in discrete modeling means that the control behavior can adapt to the changes in the internal conditions and external environment of the organization, and has a certain flexibility and anti-interference [18]. Deng et al. proposed that Petri net can describe the structure of a discrete dynamic modeling system well, and express the relationships of parallelism, synchronization, conflict, and sequence in the system, and the discrete dynamic combination model represented by graphics has the advantages of intuition, easy understanding, and easy use, and has its unique advantages in describing and analyzing concurrency phenomena [19]. Do et al. proposed that the use of the Petri net discrete dynamic model largely depends on the support of sufficient computer tools. To create, store, change, and analyze such discrete dynamic models with computers, it is necessary to choose a computer-friendly representation, which is called language [20]. Zheng et al. proposed to analyze the demand of enterprises for human resources through discrete dynamic modeling and gave a human resource planning scheme conducive to the development of enterprises. Note that most of these methods are based on discrete dynamic, static, and deterministic perspectives [21]. Santini et al. proposed to study and establish the m-sequence discrete dynamic test signal model according to the random characteristics of typical dynamic load, construct the electric energy measurement algorithm of the dynamic test signal, analyze and give the dynamic signal electric energy measurement error caused by the quantization error of IEC61850 protocol, and

provide the basis for testing and evaluating the dynamic error characteristics of all digital electric energy meter [22].

Dynamic iterative decision-making algorithms are mainly differentiated teaching methods, and rarely make effective analyses by combining learners' behavior habits [23]. It does not have a wide application, and rarely has a good construction of differentiated analysis model and discrete dynamic evaluation model [24]. Therefore, it is of great significance to study English teaching based on learner behavior analysis.

3. Methodology

3.1. Research Status of Discrete Dynamic Modeling of English Learners' Behavior Analysis. In this paper, the discrete dynamic modeling is studied under the analysis of English teaching learners' behavior. Teachers' intuitive judgments in the classroom of English teaching learners' behavior analysis are sometimes wrong [25]. Because those students who have introverted and retreating problem behaviors in English classes are often obedient, their behaviors are easily overlooked, and teachers' explanations and solutions to the discovered problem behaviors are not necessarily correct. The discrete dynamic modeling of the whole system under the analysis of English learners' behavior is a kind of discrete dynamic system, which is characterized by the continuous change of the system state caused by the interaction of discrete according to certain operating rules. In this sense, DEDS has the following two basic characteristics [26]: first, DEDS is driven by discrete events, which is the performance of its system attributes; secondly, the running rules of DEDS are all artificial rules, which are the performance of its artificial attributes. Besides, in the process of discrete dynamic modeling of behavior research in English teaching, it is sometimes difficult to find out the real cause of problematic behavior by the commonly used methods such as questionnaire survey and interview, because students' answers are often unwilling or unable to reveal their true inner situation because of face, anxiety, or other psychological factors. For these common problem behaviors of discrete dynamic modeling, teachers should take various countermeasures according to their judgments, and test whether these countermeasures are effective in classroom practice, so as to further improve their strategies and methods.

3.2. Modeling of Learner Behavior Analysis in English Teaching. The teaching behavior in line with the theory of "the essence of learning is trial and error" involved in sanddike's connection theory in the learning view of behavior school runs throughout the whole English teaching activities, especially in the oral training of students. English teachers often have to face the mistakes of students in language learning. This makes students inevitably make mistakes in practice. The usual practice is that no matter what mistakes students make in their expression, they will not interrupt directly, but write down the questions first. When summing up, all students are required to analyze

mistakes together and constantly encourage students to speak out first, which is the first step to success. For those students who are unwilling and unable to participate in classroom activities, teachers should create more opportunities for them to express themselves, but this opportunity is selective, that is, the tasks they are competent for. Modeling is actually an iterative process, which cannot be achieved overnight. The following figure describes the important process of modeling. There are several steps in the figure, which reflect that modeling is a spiral process, and its importance is obvious. Therefore, special attention should be paid to the implementation of these steps. That is, the layer-by-layer decomposition of the system and the use of reusable components. The data analysis process is shown in Figure 1.

Firstly, through image sensing equipment, the current English learning behavior of different types of professional students can be recorded online. It is used in computer language processing and converts it to multi-channel binary numbers. Then the teaching system is used to store students' learning data information in a multidimensional way. Vectorization analysis and feature extraction can be carried out for the first time. In this process, simulation analysis can be carried out on the data collected by different types of learners' behaviors. The results are shown in Figure 2.

As can be seen from Figure 2, with the increase in the number of iterative operations in the process of converting learning behavior information into data vector information dimension, the change law of the analysis error degree of learning behavior data information is also obvious. Different learning behavior analysis methods usually separate the learning process into independent behavior operation units. It is not conducive to grasping the process and analysis of online learning activities from the overall analysis. The time series and relationship between different learning behaviors aim to reveal the learning behavior characteristics of individuals and learning groups. Identify the behavioral differences of different learning groups, diagnose key learning events in learning activities, and predict learners' learning performance. Taking English teaching learners' behavior as the research object, the purpose of this group's English learning is more important to meet the needs of work and life, and their instrumental motivation is strong. However, the self-influence factors of English learners who are under the pressure of family and friends are relatively weak. Different from basic education English learners who are forced to study English full-time under the pressure of entering a higher school, the nature of this group's part-time study of English determines that the variables of second language learning experience related to the learning environment are less influential, but the variables of English learning attitude are relatively more important. According to its characteristics, it is divided into different English teaching center models. The simulation analysis results of customized teaching optimization are shown in Figure 3.

As can be seen from Figure 3, under the discrete dynamic modeling technology based on a neural network algorithm, with the increase in English teaching courses, the optimal customized teaching scheme has been optimized and

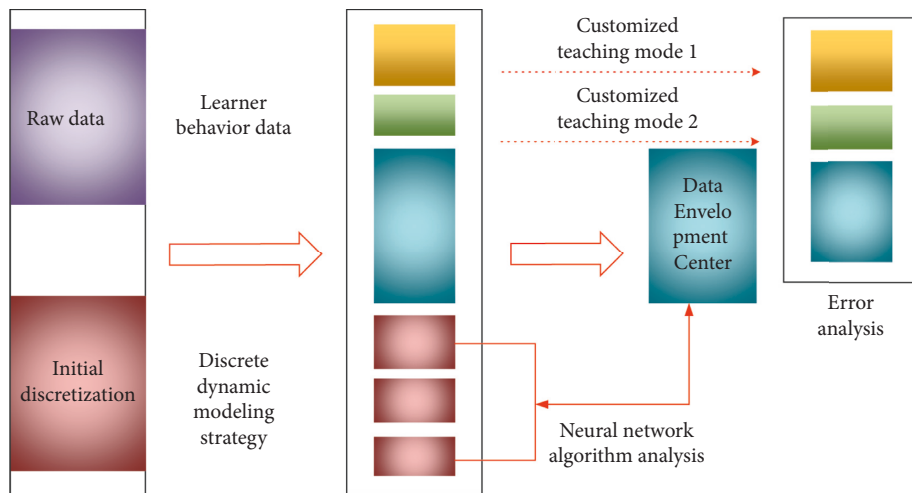

FIGURE 1: Discrete dynamic modeling method in the data analysis process of customized English teaching model.

FIGURE 2: Simulation analysis results of different types of learning behavior data.

FIGURE 3: Analysis error degree of customized teaching plan based on neural network algorithm discretization dynamic modeling technology.

improved to varying degrees, and shows a trend of gradual decline and then gradually stable. The improvement of students' learning enthusiasm will bring learning interest and satisfaction of success, and this cognitive internal motivation is the most important and stable motivation in classroom learning. Years of education and teaching practice have proved that students' learning enthusiasm has an obvious impact on the teaching effect. Cultivating students' learning enthusiasm is the premise and guarantee to improve teaching efficiency. The most fundamental driving force of learning comes from the enthusiasm for active learning. Therefore, due to the particularity of English learning, teachers' words and behaviors in English classes must be encouraged, and students' language output should not be criticized and attacked easily. They should adopt a tolerant attitude towards mistakes, and those students who have problematic behaviors should not be criticized and punished blindly. They must be more concerned about them

and find out the causes of their problematic behaviors! Then give them continuous help and guidance. In this process, the statistical results of 8 learning behavior types (A-H) under 12 simulation analyses are shown in Figure 4.

It can be seen from the changes of statistical data in Figure 4 that with more classification of learner behavior data information (A-H), the higher the proportion of special data information in the learner's behavior data information (A-H), the greater its role, and the internal differentiation is more obvious. Although the law trend is similar, there are also obvious differences, because of the process of calculation and recognition with high similarities. The process of completing the four stages of data association in turn is defined as "frame," that is, from the beginning of measurement sampling to the end of the physical operation and the beginning of new measurement sampling. At this stage,

FIGURE 4: The regular relationship between different types of learner behavior data sets and special data information under the discrete dynamic model.

let $x_i = (x_{i1}, x_{i2}, \dots, x_{ip})$ and $x_j = (x_{j1}, x_{j2}, \dots, x_{jp})$ be the observed values of English learning behavior of different students, then the similarity measure function $R(x)$ and correlation function $Q(x)$ between them can be characterized as

$$R(x) = \frac{\left[\sum_{k=1}^p (x_{ik} - \bar{x}_i)^2 \right] + \left[\sum_{k=1}^p (x_{jk} - \bar{x}_j)^2 \right]}{2}, \quad (1)$$

$$Q(x) = \sum_{k=1}^p (x_{ik} - \bar{x}_i)(x_{jk} - \bar{x}_j).$$

The corresponding dispersion function and $W(x)$ correlation function $T(x)$ are

$$W(x) = \frac{\sum_{k=1}^n x_{ki}^2 + \sum_{k=1}^n x_{kj}^2}{2}, \quad (2)$$

$$T(x) = \sum_{k=1}^n \frac{x_{ki} + x_{kj}}{2}.$$

The corresponding Fourier definite function $P(x)$ and European iterative function $Y(x)$ are

$$Y(x) = \sqrt{\frac{1 + (\sum_{k=1}^n x_{ki}^2 + \sum_{k=1}^n x_{kj}^2)}{n}}, \quad (3)$$

$$P(x) = \frac{1 + (\sum_{k=1}^n x_{ki} + x_{kj}/2)}{n}.$$

The corresponding square sum difference s^2 is

$$s_\delta^1 = \frac{1}{n} \sum_{k=1}^n \left[\sum_{k=1}^n x_{ki}^2 + \sum_{k=1}^n x_{kj}^2 \right]^2, \quad (4)$$

$$s_\delta^2 = \frac{1}{n} \sum_{k=1}^n \left[\sum_{k=1}^n \frac{x_{ki} + x_{kj}}{2} \right]^2.$$

3.3. Optimization Process of Discrete Dynamic Model Based on Neural Network Algorithm in English Teaching. In order to support the application of modeling in different fields, the concept of learner behavior analysis in English teaching is proposed. To a certain extent, this language library is similar to the professional language. The domain model library contains reusable components such as predefined system definition, mathematical function definition, and typical type definition. The use of these reusable components produces a high-level specification description of a discrete dynamic modeling system, that is, the specification and complexity of learner behavior analysis in English teaching description are reduced. Reusability is also a way to improve the efficiency of the modeling process. It can describe a discrete dynamic modeling system in less time. A discrete dynamic modeling system, which is different from a continuous dynamic system, has a large number of practical problems in the real world. The solution to such events is far from the maturity of the theory of a continuous dynamic system, which requires the further development of relevant theories. Another way is to modify the existing components in the discrete dynamic modeling system. In order to modify the existing components, users need to know the internal

behavior of the components. The process of a discrete dynamic modeling system is complex and cumbersome, and sometimes it has to go through many steps of derivation. For the data of 8 learning behavior types (A-H), after 12 groups of simulation analysis are carried out on the discrete dynamic model, the data analysis and processing process are shown in Figure 5.

As can be seen from Figure 5, with the increase in data analysis and processing groups, it can be found that within a certain range (1-12), the longer the unified standard processing time is, and it is relatively stable.

$$\begin{aligned}
 M(x) &= \frac{9x^7 + 9x^5 + 5x^3 + 3x^2 + 2}{7x^7 + 3x^5 + 5x^3 + 1}, \\
 L(x) &= \frac{\sum_{k=1}^n (x_{ik}\bar{x}_i/i + x_{jk}\bar{x}_j/j)}{\bar{x}_i + \bar{x}_j}, \\
 Z(x) &= \sqrt{\frac{\sum_{k=1}^n (x_{ik} - \bar{x}_i)(x_{jk} - \bar{x}_j)}{i + j}}, \\
 B(x) &= \frac{\sqrt{\sum_{k=1}^n (x_{ik}\bar{x}_i + x_{jk}\bar{x}_j)}}{i + j}.
 \end{aligned} \tag{5}$$

The information threshold R corresponding to the three functions is

$$\begin{aligned}
 R_L &= \frac{\sum_{k=1}^n (x_{ik}\bar{x}_i/i + x_{jk}\bar{x}_j/j)}{\sqrt{i^2 + j^2}}, \\
 R_Z &= \frac{\sum_{k=1}^n ((x_{ik} - \bar{x}_i)(x_{jk} - \bar{x}_j))}{\sqrt{i^2 + j^2}}, \\
 R_B &= \frac{\sqrt{i^2 + j^2}}{\sum_{k=1}^n (x_{ik}\bar{x}_i + x_{jk}\bar{x}_j/i + j)}.
 \end{aligned} \tag{6}$$

Based on the informal description of learner behavior analysis in English teaching, we distinguish the discrete dynamic modeling system entities involved, such as suppliers, customers, and transporters of the logistics system. We decompose the logistics system into subsystems until each subsystem is a basic material system, a basic information system, a control system, or a component. It has been widely used in many fields because of its strong ability for function distribution and function description. It is a powerful tool for modeling and performance analysis of asynchronous, discrete, and concurrent event dynamic systems. The simulation analysis is carried out, and the data processing process is shown in Figure 6.

4. Result Analysis and Discussion

4.1. Experimental Process of Discrete Dynamic Model for Learner Behavior Analysis in English Teaching. In order to verify the practicability of the English teaching model

constructed in this study, this study carries out practical teaching experiments combined with the actual English curriculum content, teaching process, and students' learning behavior data characteristics in Colleges and universities, and makes quantitative analysis according to students' classroom performance behavior. These external and controllable factors are attributed to the very few external and controllable factors. It shows that students' attribution tendency to their success in learning English has high stability. In foreign language learning, they generally work hard and can control their learning behavior. They believe that they can accept academic challenges. Even if they have unsuccessful experiences, they will not attribute their failure to their ability. This positive attribution will encourage students to actively summarize the experience, stimulate motivation, maintain motivation level, and help them succeed in subsequent learning activities. The simulation analysis results before the experiment are shown in Figure 7, and the results in the experiment are shown in Figure 8.

It can be seen from Figures 7 and 8 that in the discrete dynamic model based on the neural network algorithm, different types of learner behavior data have different characteristics. When determining the experimental data, with the improvement of the completion degree of data analysis times, the corresponding operation and analysis speed shows a changing trend of first decreasing and then increasing, whether in the process of simulation or experiment.

The data analysis times and completion degree of discrete dynamic model based on neural network algorithm increase, and the data operation rate of discrete dynamic model decreases and then increases. These are external controllable factors, which are caused by a very small number of external controllable factors.

Great changes have taken place in its internal relevance, and its changing laws are also different. The difference between the experimental process and the simulation process lies in the difference in minimum value. This is because different simulation data sets have different comprehensive solutions and correlation analyses.

4.2. Experimental Results and Analysis. This experimental study adopts different questionnaire contents. The questionnaire includes the following aspects: English learning habits, oral practice time, English reading habits, classroom student participation, types of homework completion, and English listening status. In the overall process of the experiment, 88.3% of the people have obvious effects, of which 62% are girls and 26% are boys. The error analysis results of the experimental results are shown in Figure 9 (1-10 represents ten groups of students who use discrete dynamic modeling to analyze English teaching, including 1357 groups for freshmen and sophomores, and 2468 groups for juniors and seniors).

It can be seen from Figure 9 that in the discrete dynamic model based on a neural network algorithm, after analyzing the learning behavior of freshmen, sophomores, seniors, and postgraduates (master and doctoral) of the University, the overall teaching quality is relatively good in the process of

FIGURE 5: Processing time required for discrete dynamic models under different data analysis and processing groups.

FIGURE 7: Experimental simulation analysis results.

FIGURE 8: Preliminary experimental analysis results.

FIGURE 9: The matching degree of the corresponding learning behavior of the discrete dynamic model with the customized English teaching under different operation analysis times.

customized English classroom teaching. Among the research variables, the average change rate of English learning attitude is the highest. Internalized instrumental motivation and ideal second language self-motivation do not produce strong learning motivation among adult English learners in open education, which shows that “the existence mode and degree of ideal second language self in various educational and learning situations are inconsistent, and there are great differences in the impact on learning behavior and learning feeling.”

5. Conclusion

This paper analyzes learners’ behavior in English teaching. In the discrete dynamic model of students’ English classroom teaching, students’ behavior is constantly changing, and the causes of problem behavior are also different. Based on the analysis of English learners’ behavior, a discrete dynamic model suitable for a general hybrid simulation system is established. Firstly, this paper analyzes and expounds on the current research status of English teaching. The application of dynamic modeling technology is analyzed. Secondly, combined with the English teaching content and teaching objectives, through various data analyses of students’ learning behavior, this paper evaluates students’ English teaching quality from five aspects that affect students’ English teaching quality and puts forward a customized English teaching quality evaluation model based on discrete dynamic modeling technology and learners’ behavior analysis. Finally, through the practical teaching application in a university, the feasibility of the discrete dynamic English teaching model is verified. The results show that compared with the current innovative English teaching methods dominated by dynamic iterative decision-making algorithms, the customized discrete dynamic English teaching model based on learner behavior analysis has significantly improved the quality of English teaching and the

improvement of students’ performance. In English teaching, they should also learn and understand the theories and research results of educational psychology, which can help teachers understand “problem-finding and problem-solving behaviors” from different aspects, fundamentally improve students’ interest and enthusiasm, and truly improve the efficiency and quality of behavior analysis of English teaching learners. However, this paper does not consider the personalized teaching model according to the actual situation of different students. Therefore, the model in this paper may deviate from the actual simulation. This requires further discussion in the future.

Data Availability

The data used to support the findings of this study are included in the article.

In order to effectively assist industrial designers in the color scheme design of cultural and creative products and output color schemes that meet users' image preferences, an interactive color scheme design method for cultural and creative products based on triangular fuzzy number is proposed. Through the group consistency decision based on triangular fuzzy number, an interactive genetic evolution of the color scheme population of cultural and creative products is performed to generate color schemes that satisfy the group consistency imagery preference and satisfaction, and the final selection scheme is calculated by color beauty. This paper verifies that the method can effectively integrate the imagery preferences of group users and help industrial designers to better design color schemes for cultural and creative products through the results of multiuser decision consistency.

1. Introduction

Cultural and creative products based on art paintings in the market are mainly divided into two categories based on a certain theme and cultural and creative products based on different artworks of a certain form [1]. For example, cultural creative products based on paintings of Van Gogh, Monet and Klimt, whose forms include functional artifacts such as mugs, mouse pads, scarves and coasters, belong to a series of cultural creative products based on a certain theme [2]. Cultural creative products based on a certain form with fixed forms, such as umbrellas and socks, with different famous paintings printed onto them [3]. To sum up, the current combination of paintings and cultural creative product carriers is rather rigid, without finding the proper entry point, not to mention the factor of personalization, which makes it difficult to win users [4].

The characteristics of cultural and creative products include shape, size, texture, material, color, graphics, and details, but aspects such as novelty style and personalized embodiment of products are not the characteristics of products, but the psychological reactions of people to products [5–7]. At the same time, design triggers emotional reactions in people, and Peter Dismert proposed five types of

emotions: instrumental, aesthetic, social, surprise, and interest [8]. Cultural experiences in products are entertaining, educational, aesthetic, and creative. Entertainment refers to the relaxation of the consumer during the experience, which is an enjoyable experience; education refers to the knowledge gained during the experience, such as understanding the shape and meaning of pottery, and the production process of pottery; aesthetics refers to the pleasure of the consumer immersed in the environment of something; creativity refers to the ability to create a product that is unique and based on a personal experience [9–13]. In this paper, an interactive color scheme design method for cultural creative products based on triangular fuzzy number is proposed. The process and basic principles of interactive genetic color scheme design are investigated, and the interactive genetic evolution of the color scheme population of cultural and creative products is carried out to generate color schemes that satisfy the consistent imagery preference and satisfaction of the group, and the final selection of the scheme is calculated by color beauty, which verifies that the method can effectively integrate the imagery preference of the group users and help industrial designers through the results of consistent multiuser decision making better design color schemes for cultural and creative products [14–16].

In this paper, based on triangular fuzzy number, an interactive genetic evolution of the color scheme population of cultural and creative products is performed to generate color schemes that satisfy the group consistency imagery preference and satisfaction, and the final selection scheme is calculated by color beauty.

2. Related Work

CNNs have been proposed to provide a new approach to image processing and have achieved remarkable success in the field of image recognition [17]. These were created on the basis of generative adversarial networks whose training data included more than 15,000 portraits from the 14th to the 20th century, and the system automatically generated several new works until it successfully fooled specialized tests to determine whether the work was created by a human or a machine. More recently, learned existing styles and aesthetics and were able to generate their own innovative images, and experiments found that 75% of people could not distinguish whether a painting was generated by AICAN or created by the artist [18].

A key issue in image generation is how to ensure that the generated images look realistic. To this end proposed a method for learning the shape of natural image streams directly from data using generative adversarial networks, a model that automatically adjusts the output so that all edits remain as realistic as possible and all operations are represented by constrained optimization. Deep convolutional GAN were developed in to produce some highly realistic images, but currently only for specific classes, such as faces, record covers, and room interiors. Zhang et al. [19] proposed generative adversarial networks to generate images based on text descriptions only, i.e., the model first acquires text descriptions about image synthesis, second learns and captures features in the text that describe important visual information, and then uses these features to synthesize realistic images that can fool people. Nilashi et al. [20] developed a set of image-to-image conversion algorithms and later proposed the CycleGAN framework to migrate the visual style of a set of images to other images. In addition, learning-based interactive coloring methods have been proposed [21].

Although these schemes have improved the color performance, the effect is still not good. Therefore, this scheme is more important for the performance of cultural and creative design.

3. Fuzzy Quantification of Color Imagery Preference

The color imagery of cultural and creative products reflects the users' psychological perceptions of the products, which are often expressed with the help of language and have ambiguity and uncertainty. The triangular fuzzy number helps to solve the problem that quantitative numbers cannot fully express the evaluation opinion, so this paper introduces the triangular fuzzy number to quantify the users' color imagery preference [22–24].

Let the set of comments $I = \{i_0, i_1, \dots, i_n\}$ represent an ordered set of linguistic evaluation values, where $i_m (1 \leq m \leq n)$ is a linguistic evaluation result in this linguistic set, then the triangular fuzzy number of this result can be expressed as

$$\bar{A} = (a^L, a^M, a^U) = \left(\frac{m-1}{n}, \frac{m}{n}, \frac{m+1}{n} \right). \quad (1)$$

In particular, when $m=0$, $\bar{A} = (0, 0, (m+1)/n)$.

The Likert five-level scale is used to determine the evaluation level of color imagery of cultural and creative products ($n=4$), and the corresponding triangular fuzzy numbers and scales are shown in Table 1.

4. Consensus Model of Group Imagery Preference

In order to make the color scheme design of tourism cultural and creative products better reflect the image preference of users, multiple user groups are used to participate in the interactive color scheme design process. The consistency of user groups' perception of the design scheme reflects the reliability of the color scheme design results. Through interactive genetic evolution of the color scheme group of cultural and creative products, generate a color scheme that meets the image preference and satisfaction of group consistency. Therefore, we constructed a consensus model to judge the consistency of group perception [25–27].

Let the set of users be $E = \{e_1, e_2, \dots, e_t\} (t \geq 2)$. According to (1) and Table 1, the triangular fuzzy number of users $e_i (1 \leq i \leq t)$ evaluating the color scheme of cultural and creative products is $a_i = (a_i^L, a_i^M, a_i^U)$, and the group evaluation matrix is

$$A = \begin{pmatrix} \bar{a}_1 \\ \vdots \\ \bar{a}_i \\ \vdots \\ \bar{a}_t \end{pmatrix} = \begin{pmatrix} a_1^L & a_1^M & a_1^U \\ \vdots & \vdots & \vdots \\ a_i^L & a_i^M & a_i^U \\ \vdots & \vdots & \vdots \\ a_t^L & a_t^M & a_t^U \end{pmatrix}. \quad (2)$$

The Euclidean distance is used to measure the difference of user groups' preference for color imagery of cultural and creative products, and the distance between the 2 sets of triangular fuzzy numbers $a_i = (a_i^L, a_i^M, a_i^U)$ and $a_j = (a_j^L, a_j^M, a_j^U)$ is calculated as

$$\frac{\|\bar{a}_i - \bar{a}_j\|}{\sqrt{(a_i^L - a_j^L)^2 + (a_i^M - a_j^M)^2 + (a_i^U - a_j^U)^2}}. \quad (3)$$

Then, the distance between the group evaluation matrices is

$$S = \sum_{i=1}^t \sum_{j=1}^t \|\bar{a}_i - \bar{a}_j\|. \quad (4)$$

Using the arithmetic mean ϕ aggregates all distances as

TABLE 1: Evaluation language sets.

Language evaluation variables	Triangular fuzzy number	Evaluation scale
I do not like it very much	(0, 0, 0.25)	0
Dislike	(0, 0.25, 0.5)	0.25
Commonly	(0.25, 0.5, 0.75)	0.5
Like	(0.5, 0.75, 1)	0.75
Like it very much	(0.75, 1, 1)	1

$$B = \varphi(S). \quad (5)$$

For a certain scheme of color scheme design of cultural and creative products, the consensus degree of imagery preference of user groups is

$$C_r = 1 - B. \quad (6)$$

5. Group Consensus-Driven Interactive Color Scheme Design

5.1. Interactive Color Matching Design Process. Interactive genetic algorithm is an evolutionary algorithm to simulate the superiority and inferiority of biological populations, evolving color schemes through selection, crossover and variation, generating color schemes that satisfy the consistent imagery preference and satisfaction of the population, and finally obtaining a satisfactory color scheme through color beauty calculation. Compared with traditional genetic algorithm, interactive genetic algorithm adds interactive evaluation with users and embeds implicit factors such as users' preferences and perceptions into the algorithm, which can obtain a satisfactory solution more in line with users' perceptions [27]. In this paper, we consider the problem of consistency of user evaluation in the population interactive genetic algorithm, and the process of interactive genetic color matching is driven by both the consensus degree of group opinion and satisfaction based on the quantification of user imagery preference, and its color matching design process is shown in Figure 1.

5.2. Color Matching Interactive Genetic Manipulation

5.2.1. Population Setting. The number of populations is set by the designer according to the actual demand. The individual coding method adopted in the color scheme is

$$D = \{(d_1, r_1, g_1, b_1), \dots, (d_x, r_y, g_y, b_y)\}, (x \geq y), \quad (7)$$

where x is the number of color partitions; d_i is the i -th color scheme of the product, $i = 1, 2, \dots, x$; y is the number of colors included in the product color scheme; r_j, g_j, b_j is the R, G, B color value of a color scheme, respectively, taking values between 0 and 255 [28, 29].

5.2.2. Generate the Initial Population. After obtaining the population individual code by (7), the initialized population is obtained by randomly generating the individual color by adopting the interactive genetic algorithm.

6. Color Beauty Calculation

In order to better reflect the quality of the output solution of interactive color scheme of cultural and creative products, color beauty is introduced to analyze the success degree of color scheme design. The color aesthetics includes the sense of order and the complexity of the color scheme, which is calculated as follows:

$$M = \frac{O}{C}, \quad (8)$$

where M is the degree of beauty, O is the order factor, and C is the complexity factor.

The order factor O is calculated as follows:

$$\begin{cases} O = \sum O_g \\ O = \sum O_h + \sum O_v + \sum O_c \end{cases}, \quad (9)$$

where O_g is the order factor when only uncolored grays are combined; $O_h, O_v,$ and O_c are the order factors determined by the color phase difference, lightness difference, and purity difference, respectively, when there are colors involved in the color scheme.

The complexity of color matching is obtained by calculating the total number of colors and the number of pairs with hue difference, lightness difference, and purity difference among all possible combinations of color pairs, thus obtaining the complexity factor C , as shown in (10).

$$C = C_m + C_h + C_v + C_c. \quad (10)$$

In which, C_m is the total number of colors in the color scheme; C_h is the number of color pairs with hue difference among all possible color pairs; C_v is the number of color pairs with lightness difference among all possible color pairs; C_c is the number of color pairs with purity difference among all possible color pairs. According to (9) to (10), the color order and color complexity are calculated, and the color beauty M is further calculated. When $M > 0.5$, the product color scheme is considered beautiful and conforms to the law of aesthetics, otherwise it is considered unattractive.

6.1. Example Application Results Analysis. The cloisonné tire making is used as an innovative design example for algorithm simulation and genetic algorithm is used as a comparison. The example process finds the specific substructure of cartoon expression modeling to satisfy the target maximum group, and the execution parameters of the algorithm in this paper are shown in Table 2. The execution process of

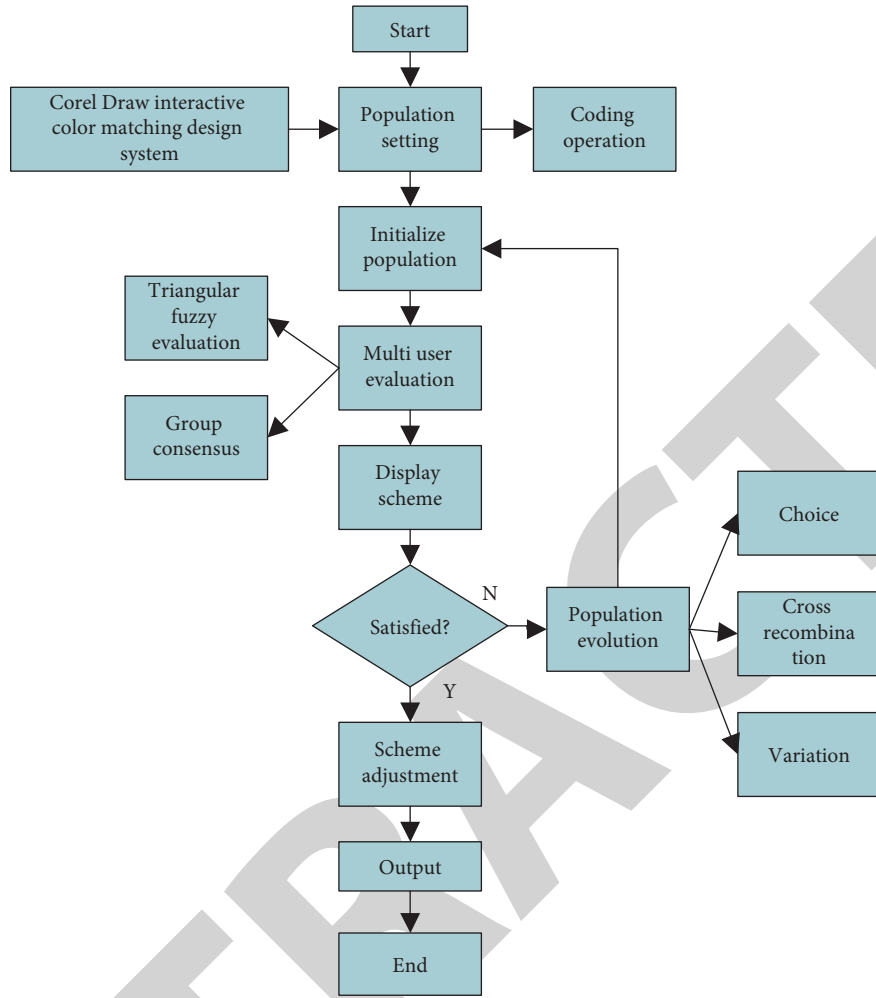

FIGURE 1: Color scheme operation flow.

TABLE 2: Implementation parameters of this paper.

Parameter	Numerical value
Initial temperature	1000
Termination temperature	0.1
Temperature variation coefficient	0.89
Function fitness	0

this paper is shown in Table 3, and the algorithm mining is executed 410 times.

6.2. Emoji Modeling Results. After reaching the target adaptation value of 0, the results of the optimized combination of cartoon expression modeling were obtained, of which the combination modeling results are shown in Figure 2. After the designer and user satisfaction survey, all the 9 cartoon expressions got 85 points (out of 100) or more, which verified the feasibility and effectiveness of the proposed method.

6.3. Cloisonné Making Session. The traditional cloisonné pattern making (tire making) is to cut out different shapes of purple copper sheets according to the drawings, and

TABLE 3: Implementation process of this paper.

Number of executions	Temperature	Fitness value
1	991	10
2	980.9	10
3	971.2	8
4	967.3	8
280	50.6	5
410	37.9	0

hammer them into various shapes of copper tires, then join the parts together and put on the solder, and after high temperature welding, they become the copper tire shape of the vessel [30].

In the process of cloisonné making, the traditional process is optimized through digital technology. Firstly, the traditional cloisonné vessels are measured and collected by laser scanning or photography to generate 3D model data of cloisonné tires, and the 3D scanning modeling is shown in Figure 3. Secondly, using deep learning and innovation engine to create 3D objects, AI achieves modeling of high-level data abstraction through image recognition technology, and deep neural network will analyze and learn from the

FIGURE 2: Cartoon expression modeling optimization results.

FIGURE 3: 3D scanning modeling.

stored traditional ware data to select 3D works that meet the requirements according to the cloisonné tire pattern specification and send them to online 3D printing platform for 3D printing. AI is useful in the model design, material selection, and product production of cloisonné 3D printing, realizing the intelligence of the whole process from design to copper tire forming. The intelligent creation of cloisonné body integrates AI with the “object,” which makes traditional craftsmen more accurate, time-saving, and labor-saving in the production of copper tires, and provides more possibilities for digital innovation design of cloisonné [31]. Taking cloisonné color scheme design as an example, it is verified that the proposed method can effectively integrate the imagery preferences of group users and assist industrial designers to better design the color scheme of cultural and creative products through the results of multiuser decision consistency.

When solving iteratively with Fluent, the flow field needs to be initialized. Still, an initial velocity is added to the liquid

FIGURE 4: Micro bubble generator printhead model speed vector distribution.

drip inlet plane and then the solution is solved iteratively (10 iterations). After solving, the simulation results are observed and analyzed. Figures 4 and 5 show the velocity field distribution vectors obtained after the simulation.

According to the velocity field distribution obtained from the simulation, Figure 4, the velocity field distribution of the main channel shows a decreasing trend, the further away from the drip channel, the smaller the velocity vector, but the velocity field distribution exists in all areas of the main channel, and the velocity vector is distributed in the order of $10\text{--}2\text{--}10^2$ cm/s. Figure 4 shows a partial enlargement of the printhead structure, which shows that the velocity field distribution also exists in the microchamber and capillary channels, with velocity vectors in the order of $10\text{--}2$ to 100 cm/s. This indicates that the velocity field distribution exists in all parts of the printhead in the presence of velocity pressure at the drip inlet [32].

7. Comparative Analysis of Mining Capacity

In addition, in order to evaluate the mining performance of the algorithm quantitatively, the similarity value index is used to compare the maximum cluster structure mining results of the genetic algorithm and the algorithm in this paper, and the similarity value index S is calculated as follows:

$$S = \frac{N_C}{N_s}, \quad (11)$$

where N_C denotes the number of triangular slices of the largest group structure and N_s denotes the number of triangular slices of the template structure. The average excavation index and time comparison of the 9 cartoon expression modeling results are shown in Table 4.

As can be seen from Table 4, compared with the genetic algorithm, the algorithm in this paper consumes less time and has less similarity between structures due to the controllable execution parameters and clear objectives, thus effectively improving the design efficiency while ensuring product diversity and quality.

FIGURE 5: Micro bubble generator printhead model velocity vector distribution (partial enlargement).

TABLE 4: Comparison of mining metrics and time.

Algorithm	Similarity (S)	Time (S)
Genetic algorithm	0.79	0.36
Simulated annealing algorithm	0.59	0.21

8. Conclusions

In this paper, an interactive color matching design method for cultural creative products with triangular fuzzy numbers is proposed. The user group's imagery preference is quantitatively described by using triangular fuzzy number, and the interactive genetic evolution of the color matching population of cultural creative products is operated by the group consistency decision based on the triangular fuzzy number. The proposed method is verified to be effective in integrating the imagery preferences of the group users by taking cloisonné color scheme design as an example.

In the era of big data, text as an information reserve database is very important, in all walks of life. From humanities research to government decision-making, from precision medicine to quantitative finance, from customer management to marketing, massive text, as one of the most important information carriers, plays an important role everywhere. The text data generated in these practical problems of humanities research, financial industry, marketing, and other fields often has obvious domain characteristics, often containing the professional vocabulary and unique language patterns in these fields and often accompanied by a variety of “noise.” Dealing with such texts is a great challenge for the current technical conditions, especially for Chinese texts. A clustering algorithm provides a better solution for text big data information processing. Clustering algorithm is the main body of cluster analysis, K-means algorithm with its implementation principle is simple, low time complexity is widely used in the field of cluster analysis, but its K value needs to be preset, initial clustering center random selection into local optimal solution, other clustering algorithm, such as mean drift clustering, K-means clustering in mining text big data. In view of the problems of the above algorithm, this paper first extracts and analyzes the text big data and then does experiments with the clustering algorithm. Experimental conclusion: by analyzing large-scale text data limited to large-scale and simple data set, the traditional K-means algorithm has low efficiency and reduced accuracy, and the K-means algorithm is susceptible to the influence of initial center and abnormal data. According to the above problems, the K-means cluster analysis algorithm for data sets with large data volumes is analyzed and improved to improve its execution efficiency and accuracy on data sets with large data volume set. Mean shift clustering can be regarded as making many random centers move towards the direction of maximum density gradually, that is, moving their mean centroid continuously according to the probability density of data and finally obtaining multiple maximum density centers. It can also be said that mean shift clustering is a kernel density estimation algorithm.

1. Introduction

Text detection is the fundamental step in many computer vision applications. This paper introduces a novel text detection technique, and we verify the utility of the method in the YouTube video text dataset and find that the method runs more than 2 times [1] of the classical method. This paper expounds the existing research work on the decomposition and inference of clustering algorithms based on text big data and points out the shortcomings of the existing research work [2]. Big data text analysis is the promoter of knowledge management. This paper believes that, through the big data text analysis, it not only can improve the quality of life of ordinary people but also can make various

enterprises for benign competition, so as to improve the quality of enterprises. This paper provides many different opinions, involving many aspects, from the daily life of ordinary people to different business functions of enterprises, from stock market to finance. Text big data analysis has become a shortcut and a leader of knowledge management [3]. Big data is used in various industries, which contains various value information, and text big data, as an important part of big data, carries countless human knowledge. This paper reviews the feature representation of text big data and finally discusses the future trend of large-text data content understanding [4]. Nowadays, the application of big data is not open in various fields, and the meaningful analysis and extraction of big data are needed in

many fields. In this paper, we study the cluster analysis process based on text big data and propose the whole process [5] from collecting big data to applying various clustering algorithms for cluster analysis. This paper uses K-means text clustering algorithm to analyze the big data talent recruitment information. The results show that big data jobs are concentrated in frontier cities. Most enterprises require undergraduate or graduate students, and a few enterprises see whether the applicant has many years of relevant work experience. There are wage differences between different types of jobs, and the higher the position, the higher the requirements for education and experience will be [6]. Discovering knowledge from text data in a high-speed and accurate manner is a major challenge in large-text data mining. This paper presents a new large-text data mining method, the random walk algorithm, which accurately extracts two basic and complementary words from numerous text data. We show that the proposed random walk algorithm is based on the aggregate relation and the combined relation [7] in recent decades, with the development of the Internet, it is almost normal for people to use mobile phones and computers, while the phenomenon of reading books decreases day and night. This also makes the storage and search of articles in the digital library reach an unprecedented height, but it is limited to indexing the text description of each pseudocode and cannot provide simple algorithm-specific information. Therefore, this paper proposes a set of algorithms to extract and search related information from text big data, and its efficiency is as high as 78% through practical verification [8] accurate. The K-means algorithm is an incremental clustering method. In this paper, we propose improvements of the algorithm to reduce the computational amount without significantly affecting the quality of the solution. It is also tested and showed that the improved K-means algorithm has better results than [9]. This paper presents a new algorithmic model, called the fuzzy c-mean clustering model (or FCM). FCM solves the problem [10] that objects in the dataset cannot partition significantly separated clusters. We discuss three main issues of traditional partitioning clustering, namely, sensitivity to initialization, difficulty determining the number of clusters, and sensitivity [11] to noise and outliers. In this paper, we propose an adaptive spatial fuzzy C mean clustering algorithm for the segmentation of 3D MR images in text big data. We verify the effectiveness of [12] through extensive segmentation experiments on simulation and real MR images and comparison with existing algorithms. Clustering algorithm plays an important role in analyzing the structure and function of biological network. In this paper, a fast local network clustering algorithm SPICI is proposed. It has the most advanced performance and can cluster all the test networks in a very short time. Experiments show that its success rate is the highest among other algorithms. Reference [13] in terms of the quality of the clusters it finds. In the data analysis methods, we often use the cluster analysis. In this paper, we propose K-means clustering algorithms and investigate the problem where the K-means clustering algorithm is limited to small-scale datasets. Finally, this paper presents a method to make the

algorithm more efficient and thus obtain better clustering [14] with reduced complexity. In text big data processing, K-means is our common partitioning clustering algorithm. However, the proposed algorithm is still unsatisfied in some professional fields, and many initialization methods have been proposed to solve this problem. In this paper, we demonstrate that popular initialization methods generally perform poorly, and that there are actually some powerful alternatives to these methods [15].

2. Text Big Data and Cluster Analysis

2.1. Text Big Data. Text big data refers to the document data, which is manifested in the form of documents and contains a large amount of information, fast speed, more types, and low data value. In big data, text big data is an important part of big data. Due to the rapid development of information technology, the growth rate of data sources increases through the media of mobile phones and computers. Text big data has three characteristics: diversity, large quantity, and fast speed. For the data collection technology, there are still huge challenges to ensure its accuracy and effectiveness.

2.2. Mining and Application of Big Data. Data mining refers to a process of searching for the information hidden in the data through algorithms, which is the process of analyzing the hidden and potentially valuable information contained in a large amount of data in a database. Data mining does not need manual operation, can automatically analyze the data of enterprises, can summarize the data, and then make reasoning, to help decision makers to adjust market strategies, reduce risks, and make correct decisions. The practical data analysis of big data can help people make judgments so as to take appropriate actions. Because of the popularity of the network and the convenience of big data application, the application of big data is more and more extensive such as answering customer questions, meeting customer service needs, helping to optimize business processes, improving health care and research and development, and so on. With the continuous innovation of big data in various industries, big data will gradually create more value for human beings. Text clustering is to cluster some documents with similar contents from many documents. Simply speaking, it is to find any two most relevant text information in the text information space and degenerate them into one text information, so as to reduce the amount of information.

2.3. Text Big Data Processing Method. Nowadays, our common text big data processing method is cluster analysis, which is a quantitative method. When processing text big data, clustering score is generally analyzed from two perspectives. First, from the perspective of data analysis, it is a multivariate statistical analysis method for quantitative analysis of multiple samples. Second, from the perspective of data mining, it can be divided into division clustering, hierarchical clustering, density-based clustering, and network-based clustering. Partition clustering is based on distance clustering, which effectively uses mean or center point and

small data. Hierarchical clustering is a very intuitive algorithm, as its name implies, it is to cluster layer by layer. Density-based clustering is to divide data into each category according to the connection of density around it. Grid-based clustering adopts multiresolution grid data structure, which can process data quickly.

2.4. Type of Clustering Algorithm

2.4.1. Cluster Analysis. Clustering is a technology of classifying data by computer, is also a classification of multivariate statistical analysis method, divides a data set according to a specific standard into different classes or clusters, and makes the similarity of the data object as big as possible, not the difference in the same cluster is as big as possible. Text clustering refers to the clustering of documents. Similarly, data with similar characteristics are gathered together as much as possible, and dissimilar data are separated as far as possible. Not only text can be clustered, but anything where features can be extracted. For example, e-commerce websites cluster goods according to features such as price and color, app stores according to the App's user age and downloads, and movie websites according to the theme and year of films. Machine learning including clustering can be performed simply by converting real-life objects into a vector in the mathematical world through feature extraction.

2.4.2. Clustering Algorithm. When dealing with text big data, we all have an algorithm bias, and we use different algorithms to deal with different problems. The following clustering algorithms are commonly used when we cluster data.

3. Cluster Algorithm Analysis

3.1. Definition of the Class

Definition 1. Set the positive number given by the threshold T , if the distance d of any two elements in the set G_{ij} . Everything meets

$$d_{ij} \leq T, \quad (i, j \in G). \quad (1)$$

It is called that G constitutes a class for the threshold T .

Definition 2. Let the threshold T be the given positive number, if each $i \in G$ in the set G satisfies

$$\frac{1}{n-1} \sum_{j \in G} d_{ij} \leq T \lim_{x \rightarrow \infty}, \quad (2)$$

where n is the number of elements in the set G and then G is said to form a class for the threshold T .

Definition 3. Let T and H ($H > T$) be two given positive numbers, if the average pairwise element distance in the set G meets

$$\frac{1}{n(n-1)} \sum_{i \in G} \sum_{j \in G} d_{ij} \leq T, \quad d_{ij} \leq H (i, j \in G), \quad (3)$$

where n is the number of elements in the set G and G is called a class of H for the threshold T .

Formula (2) shows that the average of the sum of distances between any two elements in the set G is less than a given threshold T . Similarly, formula (3) indicates that the average is less than T and less than H .

3.2. Characteristics of the Class. Let the sample contained by class G be $X_{(1)}, X_{(2)}, \dots, X_{(N)}$, where t is the sample of population G and its characteristics can be characterized from different angles. The barycenter of G , sample deviation matrix A_G , and sample covariance matrix S_G and D_G represent the diameter of class G as follows:

$$\bar{X}_G = \frac{1}{n} \sum_{t=1}^n X_{(t)}, \quad (4)$$

$$A_G = \sum_{t=1}^n (X_{(t)} - \bar{X}_G), \quad S_G = \frac{1}{n-1} A_G, \quad (5)$$

$$D_G = \sum_{t=1}^n (X_{(t)} - \bar{X}_G), \quad (X_{(t)} - \bar{X}_G) = \text{tr}(A_G), \quad (6)$$

$$D_G = \max_{i,j \in G} d_{i,j}. \quad (7)$$

3.3. Distance. If n samples are considered as n points in m -dimensional space, then the similarity between two samples is d_{ij} measure. For sample X_i , the distance of X_j , the general requirement is $d_{ij} \geq 0$, for any i, j , when $d_{ij} = 0 \Leftrightarrow X_{(i)} = X_{(j)}$; $d_{ij} = d_{ji}$, for any i, j ; $d_{ij} \leq d_{ik} + d_{kj}$, for any i, j, k (triangle inequality).

The common distances are as follows.

The Minkowski distance is represented as

$$d_{ij}(q) = \left[\sum_{t=1}^m |x_{it} - x_{jt}|^q \right]^{1/q}, \quad (i, j = 1, 2, \dots, n). \quad (8)$$

The first order Ming distance at V is expressed as

$$d_{ij}(1) = \sum_{t=1}^m |x_{it} - x_{jt}|, \quad (i, j = 1, 2, \dots, n). \quad (9)$$

The absolute distance, when X , is expressed as

$$d_{ij}(2) = \left[\sum_{t=1}^m |x_{it} - x_{jt}|^2 \right]^{1/2}, \quad (i, j = 1, 2, \dots, n). \quad (10)$$

Euclidean distance, when to Z , is represented as

$$d_{ij}(\infty) = \max_{1 \leq t \leq m} |x_{it} - x_{jt}| \quad (i, j = 1, 2, \dots, n). \quad (11)$$

That is, the Chebyshev distance.

The Mahalanobis distance is located.

In 1930s, Mahala Mahalanobis, a famous Indian mathematician, put forward Mahalanobis distance, which is

of great significance in data clustering. Σ is the covariance array of the indicator, $\Sigma = (\omega_{ij})_{p \times p}$, as shown in (12) and (13) among

$$\omega_{ij} = \frac{1}{n-1} \sum_{\alpha=1}^n (x_{\alpha i} - \bar{x}_i)(x_{\alpha j} - \bar{x}_j), \quad i, j = 1, 2, \dots, p, \quad (12)$$

$$\bar{x}_i = \frac{1}{n} \sum_{\alpha=1}^n x_{\alpha i}, \quad \bar{x}_j = \frac{1}{n} \sum_{\alpha=1}^n x_{\alpha j}. \quad (13)$$

When Σ^{-1} is present, it is Ma distance, which can be expressed as

$$d_{ij}^2(M) = (X_i - X_j)' \Sigma^{-1} (X_i - X_j). \quad (14)$$

The Mahalanobis distance from sample X factory to population G port is defined as

$$d^2(X, G) = (X - \mu)' \Sigma^{-1} (X - \mu). \quad (15)$$

Here, μ is the mean vector of the population.

The Lance and Williams Distance, also known as the Canberra Distance, is considered a weighted version of the Manhattan distance.

The Rand distance is a kind of distance given by Lance and Williams. The formula is calculated as follows:

$$d_{ij}(L) = \frac{1}{m} \sum_{t=1}^m \frac{|x_{it} - x_{jt}|}{x_{it} + x_{jt}}, \quad (16)$$

$$d_{ij}(L) = \frac{1}{m} \sum_{t=1}^m \frac{|x_{it} - x_{jt}|}{x_{it} + x_{jt}}, \quad i, j = 1, 2, \dots, n. \quad (17)$$

Jeffery and Matasta put forward the distance formula, but there is no related reference. The formula is calculated as

$$d_{ij}(J) = \left[\sum_{k=2}^p (\sqrt{x_{ik} - x_{jk}})^2 \right]^{1/2}. \quad (18)$$

Incline intersection space distance is defined as follows.

Since there are often different correlations between the variables, the distance of the orthogonal space calculates the sample space as variable.

You can use the oblique intersection space distance. The calculation formula is

$$d_{ij} = \left[\frac{1}{p^2} \sum_{n=1}^p \sum_{k=1}^p (x_{in} - x_{jn})(x_{ik} - x_{jk}) r_{hk} \right]^{1/2}. \quad (19)$$

3.4. Similarity Coefficient. To study the relationship between the samples, the similarity coefficient method was used here. First, the samples are classified, and then the relationship between the samples is studied by the similarity coefficient. C_{ij} represents the similarity coefficient between samples X_i and X_j , with $C_{ij} = \pm 1 \Leftrightarrow X_i = aX_j$; $|C_{ij}| \leq 1$, valid for any

i, j ; $C_{ij} = C_{ji}$ is true for any i, j . The closer the absolute value of C_{ij} is to 1 here, the more similar them X_i and X_j are. Conversely, the two are estranged. The common similarity coefficients are angular cosine:

$$c_{ij}(1) = \cos \alpha_{ij} \frac{\sum_{k=1}^n x_{ki} x_{kj}}{\left[(\sum_{k=1}^n x_{ki}^2) (\sum_{k=1}^n x_{kj}^2) \right]^{1/2}}. \quad (20)$$

When X_i and X_j are parallel, the angles $\alpha_{ij} = 0^\circ$ and $C_{ij}(1) = 1$ indicate that the two vectors are completely similar; when X_i and X_j are orthogonal, the angles $\alpha_{ij} = 90^\circ$ and $C_{ij}(1) = 0$ indicate that the two vectors are not correlated.

The correlation coefficient is expressed as

$$c_{ij}(2) = \cos \alpha_{ij} \frac{\sum_{k=1}^n (x_{ki} - \bar{x}_i)(x_{kj} - \bar{x}_j)}{\left\{ \left[\sum_{k=1}^n (x_{ki} - \bar{x}_i)^2 \right] \left[\sum_{k=1}^n (x_{kj} - \bar{x}_j)^2 \right] \right\}^{1/2}}. \quad (21)$$

I indicates the linear correlation of the two vectors.

3.5. K-Means Clustering Algorithm. The original mean clustering algorithm is different from the improved mean clustering algorithm. The specific steps of the original clustering algorithm are as follows: input data set $X = \{x_1, x_2, \dots, x_n\}$, cluster number K ; output K cluster C_j , $j = 1, 2, \dots, k$, make $I = 1$, and randomly select K data points as the initial cluster center $m_j(I)$, $j = 1, 2, \dots, k$. Of K clusters; calculate the distance between each data point and the center of the K cluster $d(x_i, m_j(I))$, $i = 1, 2, \dots, n$, $j = 1, 2, \dots, k$, if it meets

$$d(x_i, m_j(I)) = \min \{ d(x_i, m_j(I)), \quad j = 1, 2, \dots, k \}. \quad (22)$$

Then, calculating S new clustering centers satisfies

$$m_i(I+1) = \frac{1}{N_j} \sum_{i=1, x_i \in C_j}^{N_j} x_i, \quad j = 1, 2, \dots, k. \quad (23)$$

If $m_j(I+1) \neq m_j(I)$, $j = 1, 2, \dots, k$, then $I = I + 1$, return to step 2. Otherwise, the algorithm ends.

K-means clustering algorithm can also add clustering criterion function to terminate the iterative process; generally, the criterion function of sum of squares of clustering errors is adopted, that is, the sum of squares of clustering errors J is calculated in the fourth step of the above algorithm flow, and then judgment is added. If the value of J does not change obviously twice, it means that the value of J has converged, and the algorithm is ended. Otherwise, it is transferred to the second step to continue execution. Specifically, K clustering centers (m_1, m_2, \dots, m_k) are randomly designated as follows. Assign x_i , for any x_i , the nearest to it is divided into the same class. Recalculate the center of each cluster with formula H

$$m_i \frac{1}{N_i} \sum_{j=1}^{N_i} x_{ij}, \quad i = 1, 2, \dots, n. \quad (24)$$

The deviation is then calculated using formula F

$$J = \sum_{i=1}^k \sum_{j=1}^{n_i} \|x_{ij} - m_i\|^2. \quad (25)$$

If J converges, the return (m_1, m_2, \dots, m_k) algorithm ends; otherwise, proceed to the second step.

The idea of the original clustering algorithm is reflected in the above algorithm process, from which we can see that the selection of the initial cluster center point of each cluster is crucial to the final result of the clustering. In the above algorithm, the focus is on the iterative algorithm. In each iteration of the formula, the data points are divided into the cluster with the nearest cluster center and then recalculate the cluster center and then repeatedly iterate until each data point is no longer redivided. Simply put, K-means is a method of dividing data into K parts without any supervision signal.

4. Study on Text Clustering Algorithm

4.1. Improved Global K-Means Clustering Algorithm Analysis. In order to verify the real effect of clustering algorithm, the six data sets Iris, Wine, Soybean-small, Segmentation, Pima Indians Diabetes, and Pen digits are used for global clustering, fast global clustering, and improved clustering. By comparison of clustering time (T) sum of clustering error (E), we prove that the improved algorithm in this paper without seriously affecting the sum of squared of clustering errors. It greatly reduces the clustering time. Comparison of experimental results for the six sets of machine learning database data from UCI is shown in Table 1. Iris and Pen digits specifically refer to the data set of text big data in this paper.

From the above experimental results, compared with the other two algorithms, the improved algorithm obviously reduces the clustering time, without affecting the clustering error, right Soybean-small databases and databases greatly shorten the clustering time without seriously affecting the clustering errors. among Pen digits. It is particularly prominent in the big data sets. Thus, the present algorithm has a superior clustering performance.

In this paper, the improved global K-means clustering algorithm is tested by randomly generated artificial data sets with noise data to prove the anti-interference performance of the improved global K-means clustering algorithm against noise data. The randomly generated data are divided into three categories, each of which contains 120 two-dimensional samples, which conform to normal distribution. In class i , the mean value of abscissa x is μ_x^i , the mean value of ordinate is μ_y^i , and the standard deviation of class i is σ^i . Among them, a certain number of noise points are added to the second class, and the standard deviation of the noise points is expressed as σ^l . The effects of parameter category clustering for the three classes of randomly generated samples are shown in Table 2 and Figure 1. Figure 1 shows the clustering effect diagram of randomly generated three types of data, and its ordinate represents the time required for clustering the three types of data. The larger the value, the longer the time required.

These three sets of random data were tested using the above three algorithms, and the comparison of cluster time (T) and sum of cluster error (E) are shown in Table 3.

As can be seen from Table 3, these three algorithms have the same clustering effect on these three randomly generated data sets with noise points, but the improved algorithm in this paper has obvious advantages in clustering time, far superior to the other two kinds of algorithms. The steering results are shown in Figure 2. It can be seen from the table that the sum of squares of clustering errors of the three algorithms is the same, but the clustering time is gradually shortened, and the time required by this algorithm is the shortest, which also shows that this algorithm has obvious advantages in clustering time.

Visible from Figure 2, the global K-means algorithm, fast global K-means algorithm, and the improved global K-means algorithm in the three sets of randomly generated data sets with noise points has the same clustering effect, but this algorithm has obvious advantages in clustering time, far better than the global K-means algorithm and fast global K-means algorithm.

4.2. K-Means Original Algorithm and Improved Algorithm Analysis. In order to verify the effectiveness of the improved clustering algorithm, the Iris data set of the database was used for experimental test comparison. The comparative performance indexes are the accuracy and convergence rate (specifically the number of cycles of each test). First, the original and the improved algorithm were tested 10 random tests on the dataset, and the test metrics and accuracy comparisons are shown in Table 4 and Figure 3.

The original and the modified algorithms were sub-randomly tested on the dataset, and the results on the loop number index are shown in Figure 4.

Figures 3 and 4 present the results of the experiment: the clustering accuracy of the original algorithm fluctuates between 79% and 89% and 89%, and the number of cycles fluctuates between the second times, while the accuracy of the improved algorithm is always 92%, and the number of cycles is always 3 times. The horizontal and vertical coordinates in Figure 4 represent the number of tests and the number of bad cycles, respectively. The number of bad cycles refers to the number of times it is necessary to classify these data in the process of substituting data into the algorithm for clustering. When the original algorithm is used for clustering in the figure, the number of times to follow the bad is uncertain, which shows that the algorithm is imperfect and the accuracy is unstable. The improved algorithm can be seen in the graph is very stable, which will greatly shorten the clustering time.

To verify the effectiveness of the improved algorithm in practical applications, the original K-means algorithm and the improved algorithm were tested 5 times, respectively, with the dataset, and the metrics randomly run 5 times are shown in Table 5.

The five tests are shown in Figure 5 in terms of the overall accuracy of the algorithm and in Figure 6 in terms of cycle times.

TABLE 1: Comparison of the experimental results for several different clustering methods.

	The global K-means		Fast global K-means		The algorithm in this paper	
	E	T (s)	E	T (s)	E	T (s)

FIGURE 4: Comparison of the number of cycles of the original and improved algorithms.

TABLE 5: Five random runs of the original algorithm and the improved algorithm.

Test serial number	The original algorithm		Improve the algorithm	
	Precision	Follow the bad times	Precision	Follow the bad times
1	59	18	75	9
2	61	24	75	9
3	68	35	75	9
4	73	27	75	9
5	69	11	75	9

FIGURE 5: Accuracy comparison of the original and improved algorithm randomly run 5 times.

FIGURE 6: Comparison of cycle number for five random runs of the original and improved algorithms.

Figures 5 and 6 show the results of the experiment. The accuracy of the original algorithm fluctuates between times, and the cycle times fluctuate between the next times. Under the condition that the precision of the improved algorithm is unchanged, the number of cycles is unchanged, and the average time consumption is unchanged. Considering the experimental results, it is not difficult to see that the improved algorithm is better than the original algorithm in practice. At present, the automatic classification of text is widely used, such as Baidu news column display. For cluster analysis, category information is unknown and can automatically generate category information is not only critical for cluster mining count but also significant for subsequent data mining work.

5. Conclusion

Now, the data is explosive growth, and the data processing is particularly urgent. This paper studies big data processing, explains the concept and application of text big data, and introduces the processing method of text big data. This paper

studies the clustering algorithm for text-oriented big data and analyzes the sample point similarity measure method and clustering algorithm. In this paper, the K-means algorithm is the main object to solve the adaptive clustering algorithm to optimize the initial clustering center of the clustering algorithm, in order to solve the problems such as failure to handle large-scale data sets, low clustering accuracy, and unstable clustering results. And, the original K-means algorithm of the original algorithm and improved algorithm, global K-means, and fast K-means algorithm, through a large number of real data comparison experiment, demonstrates the proposed new algorithm can solve the problems in the actual problem. Experimental results show that the algorithm is higher, and clustering results are more stable. In the era of big data, text data is exploding every day, and how to deal with text big data quickly and efficiently has become a difficult problem. The scientific significance of this paper lies in the research of clustering algorithm, bringing forth new ideas and putting forward new text data processing algorithm. It makes clustering algorithm more convenient and efficient to deal with practical problems.

At present, e-commerce drives the logistics industry to develop greatly, but at the same time, there is a huge demand in this field, such as lower cost and higher efficiency. Facing the needs of logistics management development, it needs the blessing of intelligent technology, which involves countless fields at present. Intelligent logistics management has become a hot spot at present. What needs to be solved in this respect is how to shorten the transportation distance and save costs. To solve this problem, this paper proposes to introduce the shortest path algorithm. This paper compares the Dijkstra algorithm with the A* algorithm under the background of logistics management and finds that the latter is more suitable for this field with huge amount of information. In order to improve the performance of the A* algorithm, this paper introduces ant colony algorithm, which can better avoid obstacles. Combining these two algorithms, a *-ant colony algorithm is obtained. The algorithm absorbs the advantages of the two algorithms, while maintaining high efficiency and good stability. These characteristics are very satisfying in the field of logistics management. Through the performance test and simulation experiment, it is concluded that the algorithm has excellent optimization ability and can reduce the cost for this field.

1. Introduction

The awakening of e-commerce also awakens the development of logistics industry. At the same time, China pays great importance to logistics management. It is also the idea that the country wants to innovate and change to collide with the field of intelligent technology and logistics management. With the addition of intelligent technology, it can solve the shortest path problem well, thus reducing the cost. The shortest path algorithm is a good medicine to solve this problem. Under the test of the traditional shortest path algorithm, it is found that it can no longer meet the current problem, so it is necessary to innovate and change the algorithm. And, this is undoubtedly the mutual achievement of the two. The level of logistics management can be improved only when the two develop mutually.

In literature [1], the shortest path problem has penetrated into a wide range of fields. The Dijkstra algorithm is not perfect. First, its exit mechanism is not applicable to undirected graphs; second, the problem of adjacent nodes is

a great hidden danger; third, the problems of multivertex are not fully considered. In literature [2], the k -shortest path algorithm also has some defects in some aspects, and the alternative path obtained by the algorithm cannot be proved to be substantially different from the original path. In reality, network extension technology is usually used to solve the problems caused by turning restriction, but this method also has defects. Therefore, researchers introduce links to improve and solve this problem. The advantage of this model is to eliminate overlapping paths and find alternative paths, which can finally reduce similarity and only rely on its own nodes and links to complete the operation. In literature [3], distributed algorithm gives the shortest path problem a shot in the arm, the most important component of which is BHC. The related problems can be solved by calculating the time complexity. For example, each node can use multiple processors and how much time complexity can be calculated through these processors, so that this kind of problem can be well solved. In literature [4], the network shortest path problem is relatively simple to solve. The fact is that a single

objective function is incapable of describing problems appropriately in real life. While pursuing fast time, it may bring high cost. This is like a seesaw, but it still needs a way to balance the seesaw. The force that can balance the seesaw is Pareto. In literature [5], in the field of genes, this algorithm has also made some achievements. Dijkstra algorithm is like a good medicine to diagnose and treat gene-related problems. And, all genes in this path are candidate genes. Only a few genes were selected in the end. In literature [6], all objects have their own sizes and shapes, and researchers suggest that this algorithm has achieved little in motion planning. The idea of shape decomposition is put forward to solve this problem. Decomposition and iteration are a pair of enemies, and it is their choice to have more you and less me. Then, the geometric algorithm is the judge to judge whether there will be a war between them. If there is no hidden danger, the shortest path can be calculated by grass fire algorithm. In literature [7], researchers combine the graph algorithm with active contour restoration. Finding the global minimum is the trick of graph algorithm. Generally speaking, ordinary active contours cannot be run with three or more pixels in mind. Therefore, the researchers put forward a correct definition of deformable template and use the Dijkstra algorithm to track the contour. In literature [8], in order to study the relationship between user interface and satisfaction, the Dijkstra algorithm is used for experiments. Apple and Android are the two kings of mobile models. Students were recruited to conduct experiments on this. After testing, it was found that IOS was more useful than Android for Dijkstra algorithm. In literature [9], China has summarized all aspects of logistics. After analyzing the logistics demand, the researcher proposed to introduce relevant technical software support. For the problems related to the path, the relevant personnel and institutions decided to adopt logical data structure. In literature [10], the article agrees that intelligent technology is unshakable. Therefore, we can only find another way to change from a strategic perspective. At the same time, it shows that the addition of intelligent technology has brought many qualitative changes to this field. Compared with traditional methods, intelligent logistics application has been recognized as the best management method at present. In literature [11], the Internet of Things and cloud computing have propped up a sky, sheltering intelligent logistics from the wind and rain. In literature [12], in order to keep up with the development trend of intelligent logistics demand, it is necessary to shorten the cycle and cost while designing the system. In the whole process, there must be methods to implement both people and things. A series of technologies such as GPS have also been applied. Therefore, intelligent logistics will provide a good ascending ladder for e-commerce. In literature [13], in medical use, logistics management is also very important. Hospitals will encounter a series of problems when quoting a set of logistics management mode, which researchers need to analyze and popularize in hospitals after using the logistics management mode. At the same time, this model also needs to be improved. In this way, hospital consumables can be reduced, and costs can be reduced. In literature [14], it is recognized by most enterprises that production and

transportation become one. Cost and time are important factors in the whole process. If you want to taste the sweetness, you have to give up. This price is the control of information. For logistics management, the ultimate destination must be gradually networked and then set different frameworks according to different needs. In literature [15], Internet of Things has been the backbone of logistics development, which is the development trend of the times. Researchers need to analyze and predict the architecture, which will be a historic change.

2. Shortest Path Algorithm

As its name implies, the shortest path algorithm is a corresponding algorithm proposed to solve the shortest path problem, and the shortest path is the path with the minimum sum of the weights of edges in the process of starting from one vertex to another in a graph.

2.1. Dijkstra Algorithm. Dijkstra algorithm is a classical algorithm for solving the shortest path, and the core of its algorithm is the order of the length of the path. The main purpose of this algorithm is to choose the best route in the logistics transportation nodes.

The Dijkstra algorithm flow is shown in Figure 1:

The final shortest path length $D[j]$ is expressed as follows:

$$D[j] = \min\{D[i] | v_i \in V\}. \quad (1)$$

$D[i]$: shortest path length from shipment starting point to each receiving point. v : logistics starting point. v_i : end point.

After the shortest path is obtained, the shortest path length among the remaining paths is as follows:

$$D[j] = \min\{D[i] | v_i \in V - S\}, \quad (2)$$

$$S = S \cup \{v_j\}. \quad (3)$$

S : the shortest path set obtained. v_j : the shortest path end point of the remaining path starting from v .

At the same time, modify the shortest path that the remaining paths can reach v_k , and the formula is as follows:

$$D[k] = D[j] + arcs[j][k] \text{ if } D[j] + arcs[j][k] < D[k]. \quad (4)$$

2.2. A Algorithm.* The right-hand man of A* algorithm is not only the evaluation function but also the search direction. In the logistics system, in the process of finding the shortest path, there are 8 nodes around the starting point, and these nodes are adjacent to the starting point. With the help of his right-hand man, the node with the lowest value will soon be found out and given the search for the next extended node. Repeat the above operations, and the lowest cost path comes into being.

The A* algorithm flow is shown in Figure 2:

The formula of heuristic function is as follows:

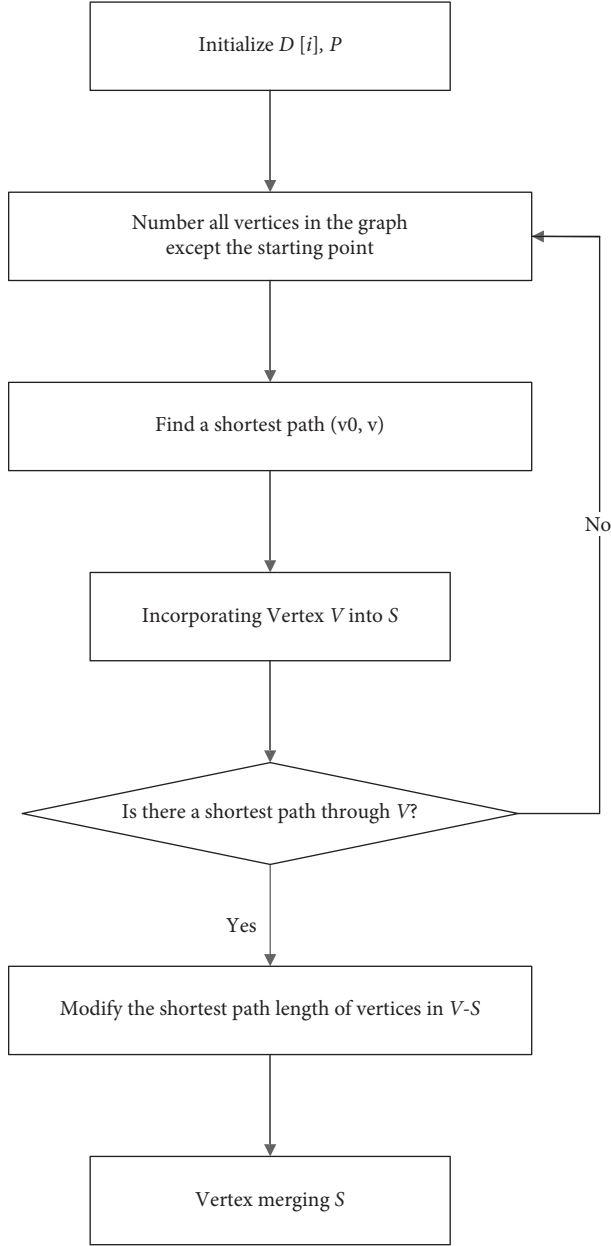

FIGURE 1: Flow chart of Dijkstra algorithm.

$$f(n) = g(n) + h(n), \quad (5)$$

$$g(n) = L_i + \sqrt{(x_n - x_i)^2 + (y_n - y_i)^2}, \quad (6)$$

$$h(n) = L_i + \sqrt{(x_n - x_T)^2 + (y_n - y_T)^2}. \quad (7)$$

$f(n)$: cost function of node n . $g(n)$: actual cost from starting point to node n . $h(n)$: estimated cost of node n to the end point. x_n, y_n : horizontal and ordinate values of node n . x_i, y_i : horizontal and ordinate values of current node i . x_T, y_T : horizontal and ordinate values of the end point. L_i : actual cost from the starting point to the current node i .

3. Optimization Algorithm

In logistics management, the above two algorithms can speed up this field. But even in terms of legal skills, there is still a gap between the two. When the digraph using Dijkstra algorithm has n vertices, the complexity of the algorithm is $O(n^2)$. Obviously, this algorithm is very efficient in solving single source path in directed graphs with all positive weighted edges, but it cannot combine more useful information to search, which is undoubtedly a fatal blow in logistics management with huge amount of information.

A* algorithm has the characteristics of Dijkstra algorithm mentioned above, and A* algorithm can maintain stability; at the same time, it has high-speed operation and accurate results. It can be seen from this that A* algorithm is more efficient in logistics management. But the A* algorithm still needs to be improved.

3.1. Improved A* Algorithm

3.1.1. Improved Node. There are n nodes in a single road section, and the search efficiency for n nodes one by one is too low, so this paper proposes to extract only the beginning and end nodes in a single road section, which greatly improves the search efficiency. Specific improvements are shown in Figure 3:

3.1.2. Improved Database. Logistics transportation usually takes each transfer point as a unit, and the amount of data in the network database of each transfer point is huge. General logistics management is to use direct reading means for data, but this is inefficient. Therefore, this paper puts forward the combination of database and memory and stores it in batches according to time. In this way, data can be obtained from the cache, thus greatly improving the efficiency of data query and search.

3.1.3. Improved Heuristic Function. In this paper, the evaluation standard of the evaluation function is travel time, while the heuristic function can be determined by the ratio of the distance between two nodes to the logistics speed. The formula of travel time estimation $h(n)$ is as follows:

$$h(n) = \frac{d(n, e)}{\bar{v}}, \quad (8)$$

$$d(n, e) = R \times \arccos \left[\cos \left(\frac{\pi x_n}{180} - \frac{\pi x_e}{180} \right) \cos \frac{\pi y_n}{180} \cos \frac{\pi y_e}{180} + \sin \frac{\pi y_n}{180} \sin \frac{\pi y_e}{180} \right], \quad (9)$$

$$\bar{v} = \frac{1}{m} \sum_{i=1}^m v_i. \quad (10)$$

$d(n, e)$: actual distance between node n and target node e . \bar{v} : average vehicle speed. R : radius of the Earth, with the value of. $6.37 \times 10^6 m$. v_i : speed on road section i . m : the

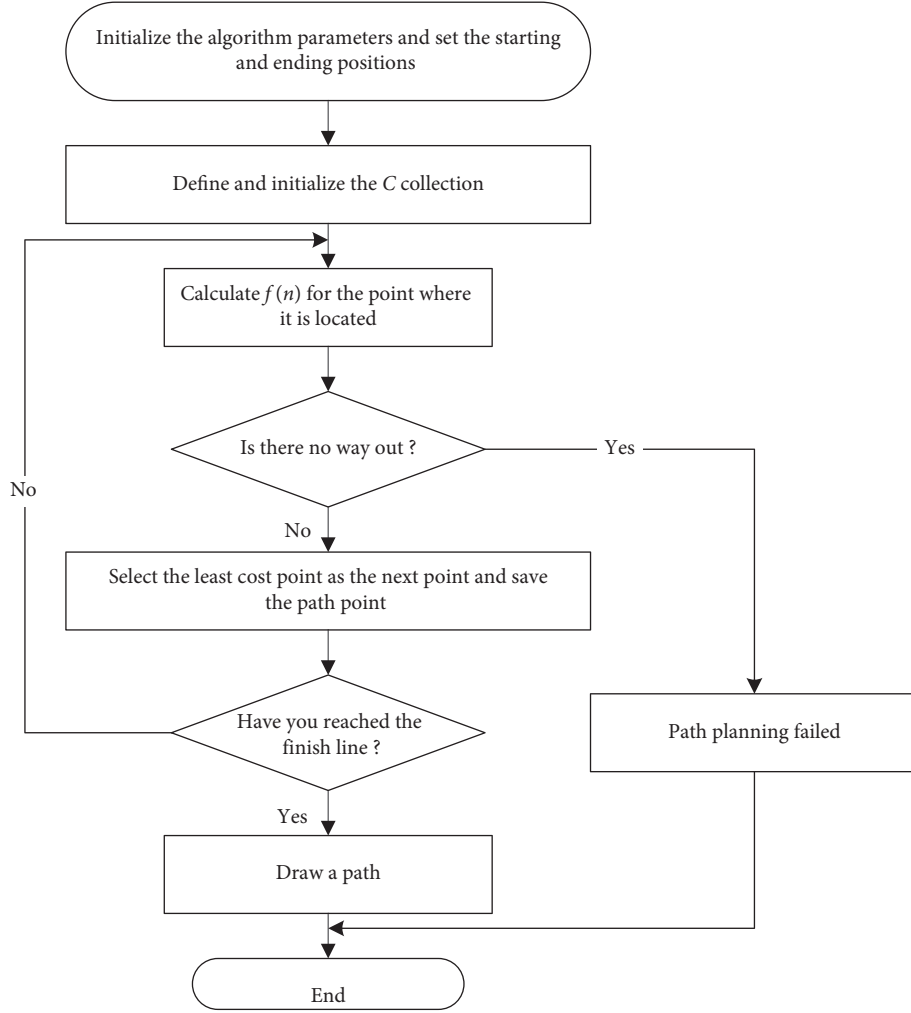

FIGURE 2: A* algorithm flow chart.

FIGURE 3: Node improvement diagram.

range involved in the formula is the total number of road sections in the logistics area.

3.2. Ant Colony Algorithm. The core content of the algorithm, Ant k , judges the choice path by pheromones and leaves pheromones for stacking. Finally, we can get the shortest path. The flow chart of ant colony algorithm is shown in Figure 4:

At first, when $\tau_{ij}(0) = \tau^0$, this means that ants do not understand the environment, and they need to determine the path by the transition probability $P_{ij}^k(t)$ from node i to j . The transition probability $P_{ij}^k(t)$ is expressed as follows:

$$P_{ij}^k(t) = \begin{cases} \frac{[\tau_{ij}(t)]^\alpha \cdot [\eta_{ij}(t)]^\beta}{\sum [\tau_{ij}(t)]^\alpha \cdot [\eta_{ij}(t)]^\beta}, & j \in a_k, \\ 0, & j \notin a_k, \end{cases} \quad (11)$$

$$\eta_{ij} = \frac{1}{d_{ij}}. \quad (12)$$

$\tau_{ij}(t)$: the pheromone left by ant k on path i, j at time t . $\eta_{ij}(t)$: distance heuristic factor. d_{ij} : distance between nodes i and j . α : relatively important factors about ant information trajectory. β : relative importance factor of heuristic function. a_k : a set of nodes to which goods k in the logistics are allowed to arrive next.

After ants move for a long time, pheromones remaining in the path will volatilize like alcohol. Therefore, the pheromone on the path should be updated after each cycle of ants. The pheromone update formula is as follows:

$$\tau_{ij}(t+1) = \rho\tau_{ij}(t) + \Delta\tau_{ij}(t, t+1), \quad (13)$$

$$\Delta\tau_{ij}(t, t+1) = \sum_{k=1}^m \Delta\tau_{ij}^k(t, t+1). \quad (14)$$

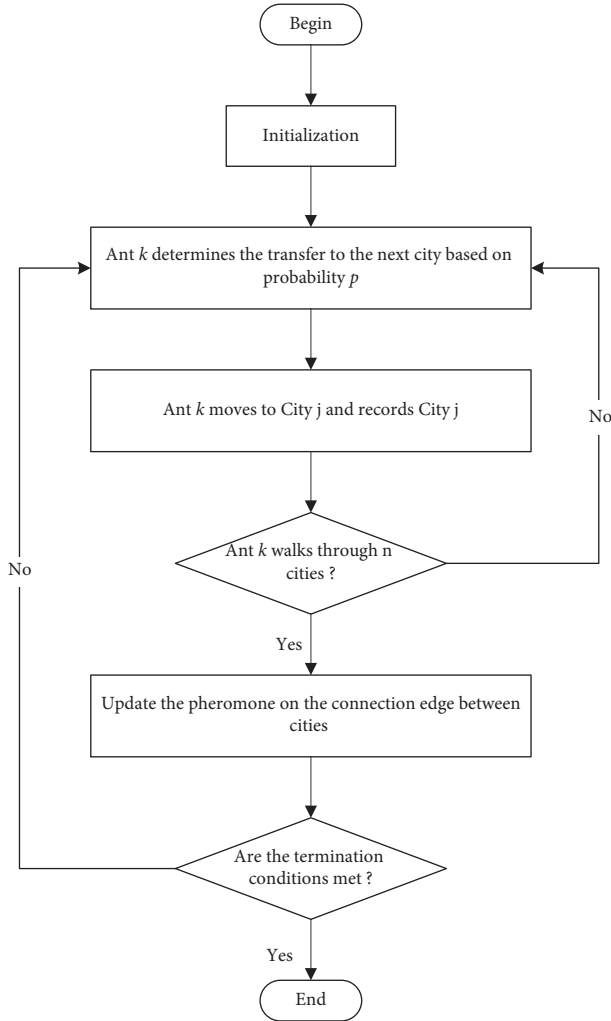

FIGURE 4: Flow chart of the ant colony algorithm.

ρ : pheromone volatilization coefficient. $\Delta\tau_{ij}^k$: pheromones left by ant k on paths i and j . $\Delta\tau_{ij}$: pheromone increment left by ants on paths i and j .

The three formulas for $\Delta\tau_{ij}$ are as follows:

$$\Delta\tau_{ij}^k(t, t+1) = \frac{C}{L_k}, \quad (15)$$

$$\Delta\tau_{ij}^k(t, t+1) = \frac{C}{d_{ij}}, \quad (16)$$

$$\Delta\tau_{ij}^k(t, t+1) = C. \quad (17)$$

L_k : path length of ant k once cycle. C : constant.

3.3. *A*-Ant Colony Algorithm*. A*-ant colony algorithm for logistics path planning is divided into global and local. The initial global planning is to use A* algorithm to calculate, with the passage of time to search for complex environment, the planning problems encountered by ant colony algorithm, which can effectively avoid obstacles and avoid local deadlock. The algorithm flow is shown in Figure 5:

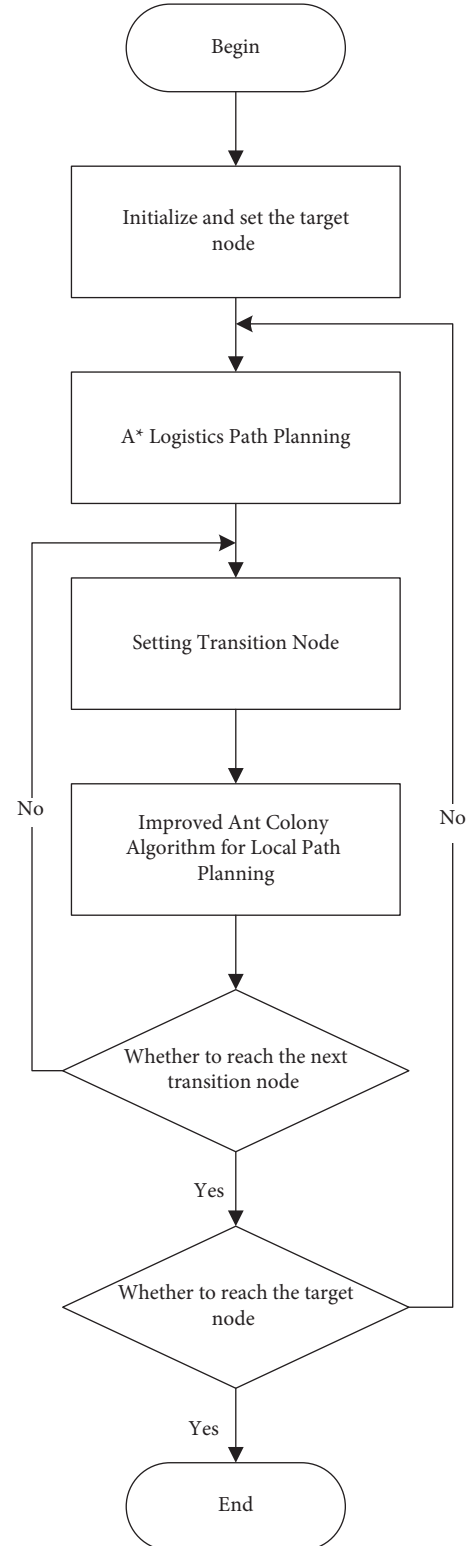

FIGURE 5: A*-ant colony algorithm diagram.

3.3.1. *Node Selection and Information Update*. However, ant colony algorithm also has some defects, such as the global search ability is not strong, convergence speed is not high, and a series of problems. This will make the whole algorithm appear a series of cases such as local optimum. Therefore, it is necessary to further improve the ant colony algorithm

before it can be merged with A* algorithm to obtain A*-ant colony hybrid algorithm.

Assuming that there are m goods to be transported by logistics in this area, the formula for m is as follows:

$$m = \sum_{i=1}^n b_i(t), \quad (18)$$

n : total number of target nodes in this area. $b_i(t)$: quantity of logistics goods at node i at time t .

The formula for the probability of goods k transported by logistics moving from node i to node j is as follows:

$$j = \begin{cases} \max\{\tau_{is}^\alpha(t)\eta_{is}^\beta(t)\}, & S \in a_k, r > \rho_0, \\ \text{choose } j \text{ according to } p_{ij}^k(t), & \text{otherwise,} \end{cases} \quad (19)$$

$$P_{ij}^k(t) = \begin{cases} \frac{\tau_{ij}^\alpha(t)\eta_{ij}^\beta(t)}{\sum_{S \in a_k} \tau_{ij}^\alpha(t)\eta_{ij}^\beta(t)}, & j \in a_k, \\ 0, & \text{others,} \end{cases} \quad (20)$$

$\max\{\tau_{is}^\alpha(t)\eta_{is}^\beta(t)\}$: the node of the path with the largest amount of information in the path set related to the node i .

When the whole iteration is completed, the best path, that is, the shortest path, will be selected, and the pheromones of each node on this path will be updated. The updated formula is as follows:

$$\tau_{ij}(t+1) = (1-\rho)\tau_{ij}(t) + \rho\Delta\tau_{ij}(t, t+1), \quad (21)$$

$$\Delta\tau_{ij}(t, t+1) = \frac{1}{L_i}. \quad (22)$$

L_i : the optimal path length of the whole search in this iteration.

4. Simulation Experiment

4.1. Algorithm Testing

4.1.1. Parameters and Environment Settings. In this test, the grid method is adopted, and 10×10 grids are divided, in which the white grid represents the logistics transportation area and the black grid represents the obstacles. Set the ant size to 50 and the maximum iteration number to 100.

$\alpha = 1$, $\beta = 5$, $\rho = 0.7$, $\tau_0 = 4$, and $Q = 2000$ for Dijkstra algorithm, A* algorithm, and A*-ant colony algorithm for path planning and experiment. The experimental results of Dijkstra algorithm are shown in Figure 6:

The experimental results of A* algorithm are shown in Figure 7:

The experimental results of A*-ant colony algorithm are shown in Figure 8:

The length and running time data of the path are shown in Table 1:

As can be seen from the above chart, for these three algorithms, in terms of time, A* algorithm has the shortest running time and the fastest search speed. But from the shortest path point of view, the shortest path found by the algorithm

proposed in this paper is better. From the combination of these two aspects, it can be concluded that the advantages of the A*-ant colony algorithm are not particularly prominent in the simulation environment, but the overall performance is still due to the other two. For the logistics management environment, the A*-ant colony algorithm can better play its advantages. For such a large environment as logistics management, there are much more nodes to search than tests. With iterative updating, the A*-ant colony algorithm can give full play to its advantages, while the first two algorithms are not suitable for such a large amount of data operations.

4.2. Simulation Experiment

4.2.1. Establishment of an Objective Function. This experiment will compare the three algorithms from the path length, cost, and speed.

The formula of the minimum cost is as follows:

$$F_i = \sum_{j \in J} C_{ij} X_{ij} + f_{ki} \quad i \in I, \quad (23)$$

$$\min F' = \sum_{k=1}^q \sum_{j=1}^n C_{kj} X_{kj}, \quad (24)$$

$$\sum_{j=1}^n X_{kj} \leq d_k, \quad (25)$$

$$\sum_{k=1}^q X_{kj} \geq b_j. \quad (26)$$

F_i : cost of transportation from node i . C_{ij} : management fee of goods transported from node i required by user j . X_{ij} : the quantity of goods transported from the node i required by the user j . C_{kj} : management fee of goods at outlet k required by user j . X_{kj} : the quantity of goods from the outlet k required by the user j . f_{ki} : the cost of setting the dot k in the experimental delimited area. d_k, b_j : maximum setting size of outlets and demand of users j .

4.2.2. Simulation Results and Experimental Analysis. Set a certain area as logistics transportation area and transform it into a 50*50 grid range. Suppose it needs to be delivered to 10 users for 10 times, and there are 8 outlets in total. Three algorithms are used to predict the shortest path length, find the shortest path time and transportation cost of these 10 times, and compare with the actual values.

The shortest path length data obtained through experiments are shown in Table 2:

The experimental data of finding the shortest path time are shown in Table 3.

The transportation cost data obtained through experiments are shown in Table 4.

The algorithm for the shortest path pair is shown in Figure 9.

The algorithm pair finds the shortest path time pair as shown in Figure 10.

The algorithm for transportation cost pairs is shown in Figure 11.

It can be seen from the above icon that, in terms of finding the shortest path and transportation cost, it is obvious that the algorithm proposed in this paper can better

TABLE 4: Data sheet of transportation cost.

FIGURE 11: Comparison of algorithm and transportation cost.

calculate and find the shortest path, which shows that the algorithm has been improved and greatly improved the optimization ability. In terms of running time, we can see that, in the early stage of running, the speed of the A* algorithm is still relatively fast, but with the increase of iteration times, the increasing number of nodes, and the continuous accumulation of information, the speed of A* algorithm cannot be well maintained, while the algorithm proposed in this paper is more consistent with the data in the later stage.

5. Conclusion

For the Dijkstra algorithm, facing a large amount of information, it does not have the ability to use it reasonably, which makes it and A* algorithm have a gap in logistics and transportation. This is also one of the reasons for choosing the A* algorithm in this paper. A* algorithm is really excellent in terms of running speed, but in terms of logistics and transportation, the algorithm proposed in this paper can provide stable development for later operation. At the same time, it can be found from the experiment that the performance of the algorithm is stable, and the high stability and accuracy can be combined with logistics and transportation. The logistics management in the future tends to be more intelligent, and the intelligent technology is constantly developing, which is a further excavation assistant for intelligent logistics management.

Physical education curriculum has been paid more and more attention by teachers and parents, and having a healthy body is the foundation. School sports competition is also more and more concerned by major researchers, and scholars have produced in-depth research and analysis of sports competition results prediction because prediction results can better let teachers carry out appropriate sports training for students, so as to achieve the best learning effect. The construction of the prediction model and whether the performance and universality of the model after construction are suitable for predicting sports competitions have also become a major research point. Deep neural network is a complex network method to analyze the structure of the human brain, which plays a core role in the field of sports planning and performance prediction and can know the future performance of athletes or students in advance in sports competitions. This paper establishes the autoregressive summation model prediction model, the complex neural network prediction model, and the improved complex neural network prediction model. It is concluded that only the improved BP neural network model has a remarkable effect on performance prediction, and the prediction value obtained by this prediction model can reduce the systematic error of prediction, so that it can better infer the performance prediction of sports competitions in China and plan which sports events are suitable for which prediction model.

1. Introduction

We live in the education by leaps and bounds in the environment, and our physical education curriculum content and structure of the construction is becoming more and more complete and having rapid development. Based on humidity, dew point, wind speed, and other meteorological parameters, a depth neural network (DNN) model is proposed to predict the minimum and maximum temperature. A particle swarm optimization algorithm is applied to select the correlation and important features of the data set to improve the prediction accuracy of the model. In the face of the multiobjective sinusoidal algorithm (MOSCA), the objective function is optimized [1]. The indexes of the optimized objective function are data rate, signal-to-interference-noise ratio (SINR), power consumption, and energy efficiency, and then the optimized objective function is allocated to a neural network for resource allocation [2]. It expounds a new deep neural network convolution layer-

variable convolution (vConv) layer, which learns the kernel length of data adaptively by its own cycle to realize the motif recognition of data sets with high throughput [3]. It proves the effectiveness of pretraining neural networks on different data sets and shows that in many practical cases, the convolution layer can be replaced by a smaller fully connected layer, and the accuracy degradation is relatively small [4]. In this paper, a machine learning (DL) method is proposed to accurately obtain the performance of components and obtain the key features of typical components, and the data set is prepared and trained based on the extracted indicators [5]. It introduces the method for fault damage. Because of its powerful feature extraction ability, this method can extract more advanced and abstract fault features from massive data. Experiments show that deep neural network has better feature learning and classification performance in the field of fault diagnosis [6]. This paper introduces the background of semantic segmentation, then divides the semantic segmentation methods based on deep learning into five

categories, and presents the advantages and disadvantages of each category [7]. The surrogate model is established by using polynomial chaotic expansion and a deep neural network, and the Sobol exponent needed to identify the influence of soil parameters on dam behavior is calculated [8]. In this paper, a new pruning-based DNNs model is proposed without affecting the expression ability of DNNs. By mining more compact structures and learning the effective weights, the computational overhead of DNNs is reduced [9]. We replace these empirical parameters with dynamic values of machine learning, which perfectly improves the accuracy of the extended model and uses complex neural networks to generate dynamic values to reproduce orbital energy and density based on density functional theory [10]. In this paper, the prediction ability of deep neural network relative to other machine learning technologies is established, and the future range of deep learning in multiparameter time series prediction is shown [11]. Our results are helpful to improve the estimation performance of structural variables of Arctic forests by using the concepts of image sampling and input features proposed in this paper [12]. This method also has the advantage of transfer learning; that is, DNN trained on one battery data set can use less training data to improve the curve estimation of other batteries running in different scenarios [13]. It will make a simple scientific overview of machine learning [14]. Learning-based computer generated holography (CGH) provides a fast way to generate holograms for holographic displays [15]. In REPAID, the multifocus image is first reconstructed from a single all-optical image and then up-sampled by a specially designed depth neural network suitable for real scenes, and finally, a full-focus image with the high spatial and temporal resolution is generated [16]. It introduces a regularized chain of deep and complex brain structure networks to handle classification tasks from multiple annotators [17]. A complex brain structure network for linear B cell epitope prediction is introduced [18]. The most relevant deep learning-based methods and the most advanced graphic page object detection in document images are discussed [19]. Materials informatics is an emerging field, which allows us to predict the properties of materials and has been applied to various research and development fields, such as materials science [20]. A new two-layer depth neural network structure is proposed, which can reconstruct the self-organized humanlike deformation shape from the depth framework by combining the inherent parameters of the camera [21]. Deep neural network for privacy protection becomes essential because of the need to maintain personal privacy and confidentiality of sensitive data and has attracted the attention of many researchers. With the wide application of neural network as a service in the unsecured cloud environment, the importance of privacy protection network is increasing day by day [22]. CNN is a new image recognition technology. Compared with the standard manual feature extraction method, it does not need explicit feature engineering and extraction and produces efficient results [23]. Its performance is satisfactory in both novelty detection and fault diagnosis, which is superior to other advanced methods. This study proposes a new fault diagnosis method,

which can not only diagnose defects of known types but also detect defects of unknown types [24]. We propose a new algorithm called depth feature selection, which is used to estimate sparse parameters and other parameters at the same time [25].

2. Concept and Characteristics of Complex Network Method of Brain Structure

2.1. The Concept of Artificial Neural Networks. Human brain is the most complex, perfect, and effective information processing system known by human beings in exploring unknown fields. It is the advanced product of biological evolution and the cornerstone of advanced spiritual movements such as language, thinking, and emotion of the human brain. At present, human beings have little knowledge of this field. For a long time, scholars have been studying neural networks through the analysis of a series of disciplines such as neurology, psychology, cognition, mathematics, electronics, and computational science and want to dissect the structure of the human brain and its massive information processing modes. Using the complex network structure characteristics of the brain, an intelligent system similar to the human brain, which can perform some functions, is designed to deal with massive information and solve the complex problem of blending different data. It is the core goal of the development of science and technology to replace part of the labor of the human brain with a machine structure composed of electronic parts. Computer is an information processing system which uses some electronic components to carry out some memory, calculation, and information processing functions of the human brain. The speed of every electronic component in modern computers is as high as nanoseconds, while the reflection time of every nerve cell in the human brain is only millisecond units. Therefore, the complex neural network method of the brain is only a neural network which can complete some ideal function after artificial construction and processing on the basis of cognitive understanding of the brain neural network. It is a mathematical network method close to the idealized human brain nerve structure, and it is also a data processing structure based on imitating the complex nervous system structure and function of the brain. In fact, it is a complex network structure constructed by a large number of simple components interconnected with each other, which has complex nonlinearity and can carry out complex logic operations and realize some curvilinear relationships.

2.2. Features of Artificial Neural Networks. Although an artificial neural network is an idealized network structure based on brain structure, the complex network structure of the brain is different from the current computer and artificial intelligence structure. It has many similarities with human intelligence: the performance of a single neural unit is relatively weak, but a large number of neurons converge into a network structure, which will have interoperability and

parallel processing functions and is very powerful. It has the following characteristics:

- (1) *Inherent Parallel Structure and Parallel Processing.* The similarity between an artificial neural network and the human brain in structure is parallel and interoperable, and the processing sequence is also parallel and simultaneous. Neurons in each layer process data at the same time. That is to say, the function of neural network processing data can be distributed and can be carried out simultaneously on multiple processing units.
- (2) *The Storage of Knowledge.* In the complex neural network model of brain structure, knowledge is not only stored in a fixed storage unit but all the memorized information is stored in the weights of interconnection between neurons. The content of stored information can not be seen from the weights of a single neuron, because the knowledge is stored in a distributed way.
- (3) *Strong Fault Tolerance.* The automatic death of brain cells every day will not affect our memory ability and thinking ability. Similarly, artificial neural networks have strong error tolerance; that is, local or partial neuron damage will not affect the subsequent and even global activity changes.
- (4) *Self-Adaptability.* Artificial neural network can acquire various abilities through learning. Input the input and ideal output modes into complex networks; the network adjusts the connection weights between neurons in each layer of the system according to the basic information extracted from the samples given by the original learning algorithm and stores these basic information in a specific system in the form of connection methods between neurons until the network reaches a stable state.

3. Sports Competition Prediction Algorithm

3.1. Traditional Statistical Methods

3.1.1. Determining the Time Series Prediction Model

- (1) *No Change Method.* The premise of this method is that the sports competition results in $T + 1$ period are the same as those in T period. Because this model is too idealistic, it may produce a higher prediction value for Chinese sports competition results with an obvious improvement trend.
- (2) *Proportional Change Method.* It is considered that the results of sports competitions change by a certain percentage with time. The expression is as follows:

$$C_{t+1}^A = C_t \left(1 + \frac{C_t - C_{t-1}}{C_{t-1}} \right). \quad (1)$$

- (3) *Moving Average Model Method.* That is, the average of observed values in the past several periods is used as the predicted value of the prediction period. The expression is as follows:

$$C_{t+1}^A = \frac{C_t + C_{t-1} + \cdots + C_{t-n+1}}{N} \quad (t \geq N). \quad (2)$$

- (4) *Weighted Moving Average Model.* Different weights are given according to the time when each data are away from the prediction period. It is generally believed that the closer the time is away from the prediction period, the greater the weight should be given because the recent prediction value has stronger prediction ability and accuracy. The expression is as follows:

$$C_{t+1}^A = \frac{a_0 C_t + a_1 C_{t-1} + \cdots + a_{N-1} C_{t-n+1}}{N} \quad (t \geq N). \quad (3)$$

- (5) *Exponential smoothing model*

It is a special weighted average method, which uses the weighted average of the previous observation value and the predicted value as the predicted value of the next period. The calculation formula is

$$C_{t+1}^A = a C_t + (1 - a) C_t^A. \quad (4)$$

3.1.2. Stochastic Time Series Model. This is the most commonly used method in the time sequential model method to find out the trend of sports competition results with a certain factor by regression method. The independent variable in the model can be any one of the influencing factors of sports competition results. People usually use time as the independent variable.

3.2. Evaluation Criteria of Sports Competition. The parameters of absolute average error, correlation coefficient, and reliability of output data are used to evaluate the model. Because they are neither affected by the size of the sample nor by the restriction of sample units on other different models, the comparability is strong. They can be obtained by the following formula.

Absolute mean difference:

$$\text{MAPE} = \frac{\sum_{i=1}^n |x_i - y_i| / y_i}{n} \times 100\%. \quad (5)$$

Correlation coefficient:

$$R = \frac{\sum_{i=1}^m (x_i \times y_i)}{\sqrt{\sum_{i=1}^m (x_i)^2 \times \sum_{i=1}^m (y_i)^2}}. \quad (6)$$

Data reliability:

$$Z = \frac{\sum_{i=1}^n j}{n} \times 100\%, \quad (7)$$

where $|x_i - y_i| / y_i \leq 0.15$, $j = 1$, otherwise $j = 0$.

3.3. *Artificial Neural Network Algorithm.* The expression of the input sum of neurons is as follows:

$$\text{net} = \sum_{i=1}^n P_i W_i. \quad (8)$$

Neuron output:

$$o = f(\text{net} - \theta). \quad (9)$$

Artificial neural network learning is carried out under the condition that the input mode and ideal output mode are known. Its comprehensive error often adopts the sum of squares of errors.

$$E_k = \frac{1}{2} \sum_j^Q (O_j^k - o_{kj})^2. \quad (10)$$

3.3.1. BP Neural Network

- (1) Calculate the output values of hidden layer and output layer nodes:

Hidden node output:

$$y_i = f\left(\sum_j w_{x_j} x_j - \theta_i\right). \quad (11)$$

Output node:

$$o_i = f\left(\sum_j T_{ij} y_j - \theta_i\right). \quad (12)$$

- (2) Calculate the error of output layer and hidden layer:

All sample errors:

$$E = \sum_{k=1}^P e_k \leq \varepsilon. \quad (13)$$

One sample error:

$$e_k = \sum_{i=1}^n |t_i^{(k)} - o_i^{(k)}|. \quad (14)$$

Output layer node error:

$$\delta_i = (t_i - o_i) \cdot o_i \cdot (1 - o_i). \quad (15)$$

Hidden layer node error:

$$\delta_i = y_i(1 - y_i) \sum_j \delta_j T_{ij}. \quad (16)$$

- (3) Correct the node weights and closed values of output layer and hidden layer:

Output layer node weight correction:

$$T_{ij}(k+1) = T_{ij}(k) + \eta \delta_i y_j. \quad (17)$$

Output layer node threshold correction:

$$\theta_i(k+1) = \theta_i(k) + \eta \delta_i. \quad (18)$$

Modification of node weight value in hidden layer:

$$W_{ij}(k+1) = W_{ij}(k) + \eta \delta_i x_j. \quad (19)$$

Hidden layer node threshold correction:

$$\theta_i(k+1) = \theta_i(k) + \eta \delta_j. \quad (20)$$

3.3.2. BP Algorithm Improvement

(1) *Additional Momentum Value Method.* The method is based on the back propagation method, adding a dynamic change quantity proportional to the last weight and threshold value to each change of weight and threshold value and generating new changes of weight and threshold value according to the back propagation method. The adjustment formula of weight and threshold value with additional momentum factor is as follows:

$$\Delta X(k+1) = mc \times \Delta X(k) + lr \times \frac{\partial E}{\partial X} \quad (0 < lr \leq 1). \quad (21)$$

(2) *Adaptive Learning Rate Method.* Adjusting the learning rate based on self-adaptation rules is beneficial to shorten the time. The learning rate is too small and the convergence rate is too slow; if the range of learning rate selection is too large, it may change too much, resulting in data dispersion. Therefore, a unique improved algorithm suitable for adaptive adjustment appears, and its weight and gap value update expression is

$$\Delta X = lr \times \frac{\partial E}{\partial X}, \quad (22)$$

$$\Delta X(k+1) = mc \times \Delta X(k) + lr \times mc \times \frac{\partial E}{\partial X}.$$

Adjustment formula of adaptive learning rate lr is as follows:

$$lr(k+1) = \begin{cases} 1.06lr(k)mse(k+1) < mse(k), \\ 0.6lr(k)mse(k+1) > 1.05mse(k), \\ lr(k). \end{cases} \quad (23)$$

(3) *Levenberg-Marquardt Optimization Method.* The weight and threshold update formula is

$$X_{k+1} = X_k - (J^T J + \mu I)^{-1} J^T e. \quad (24)$$

4. Experiment

4.1. *Simulation Experiment.* In order to effectively predict sports performance, 500 data samples of sports performance in a university were collected, of which 400 were used as training samples and 100 as test samples. 400 training samples are trained by a support vector machine algorithm,

TABLE 1: Comparison of forecast data of online computing platform.

Sports events	Prediction result (%)	Prediction error (%)	Actual result (%)
Running	98.7	0.21	98.5
High jump	96.5	0.38	97.2
Long jump	97.3	0.22	96.8

and the sports scores of 100 test samples are predicted by an online computing platform. The prediction results and prediction error curves obtained by the online computing platform are shown in Table 1 and Figure 1.

Through the above-given experimental results, we can see that using this model to test the sports performance prediction results are very ideal, the experimental results show that using this model can effectively predict sports performance.

The predicted results and actual results of the above-mentioned sports events are counted into a bar chart as shown in Figure 1.

Five groups of sports data are selected from the training sample data set to test and verify whether the improved BP neural network has good training. The error curve after inspection is shown in Figure 2.

4.2. Model Comparison. The error of predicting sports results by three models is compared, and the comparative data are shown in Table 2.

According to the experimental data in Table 2, we can get that the improved neural network model with complex brain structure has higher accuracy in predicting sports events. Is the prediction result of this model equally accurate for different types of sports events? We further compare and analyze the four kinds of sports: running, ball games, long jump, and improvement. For example, the experimental data are as follows.

Select the results of four kinds of sports events in a high school sports meeting to test the universality of the model.

The model performance indicators for running sports competitions are shown in Table 3.

The model index comparison data of the above-given experimental results are counted into a bar chart as shown in Figure 3.

Model performance indicators for ball games are compared and are shown in Table 4.

The model index comparison data of the above experimental results are counted into a bar chart as shown in Figure 4.

The model performance indicators for long jump sports are shown in Table 5.

The model index comparison data of the above experimental results are counted into a bar chart as shown in Figure 5.

Model performance indicators for high jump sports are shown in Table 6.

The model index comparison data of the above experimental results are counted into a bar chart as shown in Figure 6.

4.3. Contrast Experiment. Through the previous results, it is proved that applying the single prediction of various sports events, the prediction results superior to each single item can be combined, which can further effectively improve the prediction accuracy. Therefore, this study continues to use the improved neural network model construction method of complex brain structure to

establish a prediction model for all the data from 2018 to 2021 and predict the comprehensive evaluation index values in these years. The prediction results are shown in Table 7.

5. Conclusion

Through the preliminary establishment of the autoregressive summation model prediction model of sports competition development in China, the neural network prediction model of complex brain structure, and the improved network prediction model, it is concluded that the improved complex brain structure model prediction model has a remarkable effect, and its research results are as follows:

- (1) In both the neural network model and traditional regression model, a neural network with a complex brain structure is more inclined to predict the results of sports competitions
- (2) In the model comparison experiment, we predict the individual items of various sports events, and the

prediction effect of the improved prediction model is inconsistent

- (3) Among the four kinds of sports in the article, the prediction effect of running is the most obvious, while the prediction effect of the other three kinds is poor
- (4) The prediction error of the improved neural network model is reduced by about twice as much as that of the original model

With the advent of the information age, computer technology is also widely used in various fields. In the field of education, physical education teaching strategy has always been the focus of many educators. In order to optimize physical education teaching strategies and improve teaching quality, this paper proposes a new intelligent computing technology. This technology has excellent innovation in the engineering design field of physical education teaching strategy reform and innovation and combines Intelligent Computing with physical education teaching strategy to explore the feasibility and effectiveness of physical education teaching strategy reform and innovation. On the basis of intelligent computing algorithm, this paper analyzes the visualization strategy scheme brought by intelligent computing classroom to physical education teaching. This paper analyzes the feasibility of students' feedback after the reform of the physical education teaching strategy. Finally, the big data discrete dynamic modeling technology is used to dynamically model and analyze the students' learning behavior and effect after the reform and innovation of physical education teaching strategy. Combined with the analysis data and students' behavior feedback, this paper analyzes the feasibility of the physical education teaching strategy after the reform and innovation. The results show that the visualization scheme of physical education teaching strategy based on intelligent computing can help students understand theoretical knowledge and realize the transformation from static classroom to dynamic classroom. It enhances students' practical activities and perceptual knowledge and is of great help to students' physical education learning effect. In the discrete dynamic modeling analysis, the feasibility of physical education teaching strategy reform is very important.

1. Introduction

With the influence of examination-oriented education in China, the decline in students' physical quality in China is very serious (Wan et al. 2021) [1]. There are many diseases such as myopia, obesity, and weakness. Good physical education teaching can help students improve this situation. Therefore, the task of physical education teaching strategy reform in China is imminent (Jennina et al. 2021) [2]. Comprehensively improving students' physical quality and physical education achievements has become one of the teaching objectives of each university. More and more colleges and universities begin to pay attention to the reform of students' physical education teaching strategies. However, there are still many deficiencies in the actual process of teaching strategy reform and innovation. As a result,

students cannot give full play to their strengths and form good learning habits in sports activities (Hao et al. 2021) [3]. Among them, the factors affecting the reform of physical education teaching strategies include the low attention of schools. In carrying out sports activities, many colleges and universities do not pay enough attention to the impact of teaching itself (Yuchen et al. 2021) [4]. Physical education teaching is not only to improve students' physical performance but also to improve students' physical quality and comprehensive quality. Students need to improve their physical environment through physical education and physical exercise. Moreover, in school social communication, a good physical education teaching environment can help students change the introversion trend and expand communicative activities (Li et al. 2021) [5].

Most teachers only regard physical education courses as free activity time in physical education teaching, without clear teaching objectives (Liu et al. 2021) [6]. In the actual teaching process, I did not understand how to highlight the characteristics of sports and training direction. Teachers lack the combination of the theoretical basis and teaching activities, resulting in students' interest in sports cannot be effectively improved (Yang et al. 2021) [7]. The teaching mode of many colleges and universities is relatively backward, and the traditional physical education teaching method still exists in many schools. Teachers' teaching to students is mainly theoretical learning, supplemented by physical training [8]. This traditional teaching mode has a great impact on students' physical education development. In the learning process, it does not reflect that students are the main body of learning and lack of subjective initiative. With the combination of education and information technology, more and more physical education teaching strategies began to appear and achieved good results and teaching results (Lin et al. 2021) [9]. As a modern auxiliary teaching tool, intelligent computing can bring new opportunities for the physical education teaching environment. This method was originally used in the field of engineering and can simulate biological mechanism and evolution process with the help of a computer. It provides technical support for information acquisition and information processing. It has achieved good results in the fields of virtual modeling, image recognition, image processing, information processing, prediction analysis, and so on. Facing the single form of traditional physical education teaching strategy, this paper combines intelligent computing with physical education teaching to explore the reform, innovation, and feasibility analysis of teaching strategy.

Optimizing physical education teaching strategies and improving teaching quality are the main contents of the reform and innovation of physical education teaching strategies, including implementing the guiding principle of health first in teaching guiding ideology. In the relationship between teaching and learning, it emphasizes the equality between teachers and students, cooperation, and interaction, and students are the main body of teaching. In the concept structure of teaching, it emphasizes that teaching activities are the organic unity of three psychological activities: cognition, emotion, and behavior. Teaching design should create conditions for students' independent choice and active exploration in the teaching process, advocate teaching democracy, make students' learning an active and personalized process under the guidance of teachers, and emphasize the formation of students' self-study ability.

This paper is mainly divided into three parts. The first part is a basic understanding of the reform and innovation of physical education teaching strategies and puts forward the teaching strategies and teaching modes of intelligent computing. The research status of discrete dynamic modeling technology used in feasibility analysis is analyzed. The second part first studies the mode of Intelligent Computing physical education teaching strategy and analyzes the application of intelligent computing algorithm in the feasibility study. This paper studies the changes in students' behavior

after the reform of the Intelligent Computing physical education teaching strategy. Finally, the discrete dynamic modeling technology is used to analyze the feasibility of physical education teaching strategy reform and innovation. The third part analyzes the teaching environment after the reform of the physical education teaching strategy and the results of the feasibility study of the Intelligent Computing teaching mode.

2. Related Work

The reform of the physical education teaching strategy is a complex process and structure. Not only do schools need to pay more attention to physical education but also students need to form a good physical education classroom atmosphere (Liao et al. 2021) [10]. In the physical education teaching environment, teachers should give full play to their professional skills, analyze students' physical and mental characteristics, and formulate targeted teaching strategies (Bian et al. 2021) [11]. In the reform of physical education teaching strategy, we first need to solve the importance of this industry, make use of its own advantages to spread and influence in various aspects, improve people's understanding of sports, and use their spare time to help students take physical exercise. In the reform of teaching strategies, it needs to be formulated according to the physical and mental characteristics of students, and the time of sports activities cannot be reduced in order to meet the needs of examination-oriented education (Zhang et al. 2021) [12]. We use the characteristics of intelligent computing to improve physical education teaching strategies in order to explore the feasibility of this method. This paper uses big data discrete dynamic modeling technology to analyze the feasibility. Discrete dynamic modeling technology can quickly deal with the problem of excessive data in big data environment, which provides effective help for system operation and efficiency improvement. In the feasibility analysis, combined with the changes in students' own behavior, we study the dynamic changes before and after the improvement of the Intelligent Computing physical education teaching strategy. Finally, it provides accurate data sources for exploring the feasibility of teaching strategy reform and innovation. Next, we will briefly describe the application status of big data discrete dynamic modeling technology in various countries.

Japan does not pay much attention to the ecological environment. Therefore, with the progress and development of the times, they mainly study the protection and utilization of sustainable energy and renewable energy (Lin et al. 2021) [13]. Wind power generation has always been a large model in renewable energy. With the continuous bad changes in the ecological environment, they pay more attention to the research on the operation process of wind power generation. Wind turbines are prone to damage during operation. In order to effectively monitor the aging degree of components, they apply discrete dynamic modeling technology here to timely grasp the operation state of the motor and ensure stable operation.

Enterprise development in Korea has always been the main source of the national economy. With the

popularization of the Internet, the information system has also changed (Guan et al. 2021) [14]. Enterprises have been slow to use and accept big data. In order to improve this situation, they use big data technology to optimize and dynamically model enterprise management. Mainly combined with various factors affecting the enterprise environment, this paper constructs a dynamic model of data analysis and processing and finally realizes the purpose of optimizing the enterprise development process.

The United States is relatively advanced in the development of the military field. Their military strength is very strong, but computer technology is also a field that cannot be underestimated [15]. They have provided many effective achievements and research in the development of information technology. Military equipment operation system usually has minor faults, which is not conducive to their national security and guarantee. Therefore, they use big data technology to dynamically model and analyze the data source of equipment operation and build a prediction model to give early warning of possible fault factors in the system. Thus, the purpose of reducing maintenance cost and overhaul cost is realized. Based on the development status of discrete dynamic modeling technology in various countries, this paper studies the feasibility analysis of Intelligent Computing physical education teaching strategy reform.

3. Methodology

3.1. Feasibility Study on the Reform and Innovation of Physical Education Teaching Strategy Based on Intelligent Computing.

At this stage, most teaching methods in physical education teaching strategies have undergone basic reform and innovation. Traditional teaching mode and innovative teaching mode are parallel to each other. Most colleges and universities adopt traditional teaching, optional physical education, and free activity teaching. Through literature survey, we know that ordinary teaching methods have been relatively rare. The current physical education teaching mode has been basically improved in combination with modern educational technology. Traditional teaching strategies only appear in track and field, shot put, gymnastics, and other events. The physical education curriculum in most colleges and universities is also relatively single, and practical knowledge and teaching mode are relatively rare. This situation leads to the fact that the physical education curriculum in colleges and universities does not have its own characteristics and cannot attract students to study and stimulate interest. In the teaching strategy of intelligent computing, we use the efficient computer language program MATLAB as the core technology of visual teaching. It can process a large amount of data and information and realize analysis and sorting. It provides technical support in visual physical education teaching strategy. Visual teaching in physical education teaching strategy refers to the concretization of abstract actions by using simulation technology. In sports training, the most common observation methods are video observation and three-dimensional dynamic photography, which are established on the basis of science. Human motion simulation technology mainly

includes the establishment of the human model, the collection of more real physical reaction signals of the human body under specific conditions, the process of computer simulating human real motion, and so on. This technology is a major breakthrough of information technology in the process of sports. It can promote the development of sports and the development of three-dimensional dynamic simulation technology in sports, analyze and extract the theoretical knowledge from the essence, and show it intuitively. In traditional teaching, in addition to using body language to convey information, students can also perceive actions in virtual simulation. We apply MATLAB visualization technology to the teaching strategy of sports intelligent computing, which can enhance students' sensory understanding. In the process of studying the reform of Intelligent Computing physical education teaching strategy, it is necessary to complete three parts: theory teaching, actionability, and curriculum practice. We need to maximize the improvement of the physical education curriculum in a limited time. Compared with ordinary courses, this model has a shorter teaching time. In the reform and innovation of physical education teaching strategies, we need to pay more attention to students' thinking divergence ability and practical ability. Different from the traditional classroom, the optimized classroom can enrich students' ability to acquire knowledge. In Intelligent Computing physical education teaching, theory and practice need to be highly integrated. The traditional physical education teaching strategy only pays attention to the academic achievement and actual effect but does not pay attention to the teaching process. With the continuous development of educational ideas, in the process of education, we no longer only pay attention to the teaching of relevant knowledge and skills. At the same time, we also need to pay more attention to the awakening of students' self-spirit and constantly stimulate students' thinking of self-thinking and self-creation. When this phenomenon is fed back to the computer industry and artificial intelligence teaching, it is necessary to cultivate computing thinking in the process of basic computer knowledge teaching and skill training. Of course, due to the influence of traditional educational thought, the cultivation of computing thinking is relatively weak. However, intelligent computing course needs to cultivate students to combine theory with practice and be able to deal with technical problems by themselves. This cross-teaching strategy mode is shown in Figure 1.

As can be seen from Figure 1, this physical education teaching strategy includes theoretical teaching and innovation as well as practical exercises. It fully reflects the innovation and reform effect of teaching strategies and has a positive impact on students' physical education teaching activities. In order to explore the feasibility of physical education teaching strategy reform and innovation, we need huge data as the basis of analysis results. In dealing with massive data, intelligent computing algorithm can improve the running speed of the system on the premise of ensuring real time. Firstly, the feasibility analysis model is established, and the test values of data accuracy are as follows:

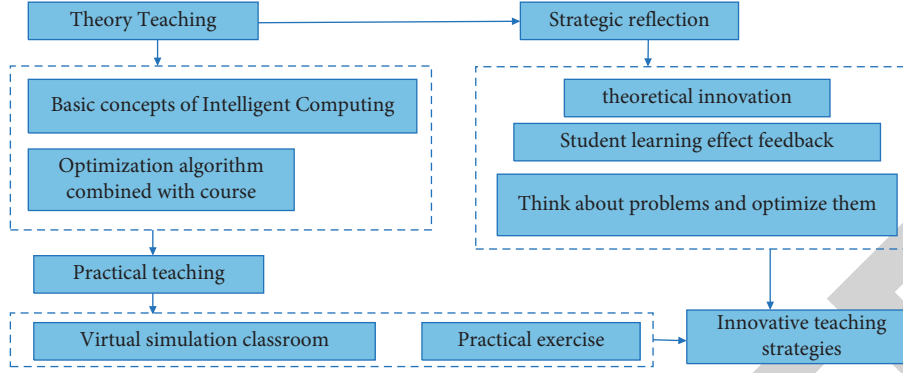

FIGURE 1: Cross-teaching strategy model.

$$M_{t+1} = M_t + w(m_t - M_t), \quad (1)$$

where M_t is the prediction data at each time and w is the weight coefficient. Set that the changes between adjacent data are equal, and the calculation formula is

$$\varepsilon = M_t - M_{k-1}. \quad (2)$$

In order to solve the error coefficient in data calculation, we will test the multiple prediction results in the way of average:

$$M = \frac{\sum_{k=1}^n M_k}{n}. \quad (3)$$

Judge the difference between the two coefficients to illustrate the changing trend of error rate when the current data increase with the number. In order to deal with high-dimensional data sets and prevent the fitting phenomenon, we need to classify and balance the data samples, increase the fault tolerance of the algorithm, and set the calculation formula of the sample characteristic index as follows:

$$G_m = \sum_{k=1}^{|k|} \sum_{k \neq k'} pmkpmk' = 1 - \sum_{k=1}^{|k|} p^2 mk. \quad (4)$$

In the formula, k represents the sample category and pmk represents the proportion of nodes and coefficients. Secondly, the importance of the eigenvector in the calculation node is expressed as follows:

$$VIM_{jm}^{(Gini)} = G_m - G_i - G_r. \quad (5)$$

In the formula, G_i and G_r , respectively, represent the relationship index in the node. If the eigenvalue is in the set state, the weight is

$$VIM_{jm}^{(Gini)} = \sum_{m \in M} VIM_{im}^{(Gini)}. \quad (6)$$

Assuming that there are multiple parent nodes in the algorithm, the formula is defined as follows when calculating the feasibility of characteristic data

$$VIM_i^{(Gini)} = \sum_{j=1}^n VIM_{ji}^{(Gini)}. \quad (7)$$

Finally, the calculated feasibility score is summarized by normalization as follows:

$$VIM_i = \frac{VIM_i}{\sum_{j=1}^m VIM_j}. \quad (8)$$

To sum up, the calculation can obtain the feasibility data of the reform model of physical education teaching strategy and provide accurate data support for the reform process of physical education teaching strategy. We summarize the flow of the intelligent computing model as shown in Figure 2.

As can be seen from Figure 2, first initialize the calculation parameters of the algorithm and arrange the factors affecting the data results. Finally, according to the adaptability of each data, the data are divided and processed uniformly. According to the feasibility results of physical education teaching strategy reform and innovation, the optimized physical education teaching model is more suitable for students' physical activities. The visual teaching of intelligent computing can also optimize the teaching according to the concept of combining theory with practice. With its own advantages of image, vividness, and intuition, visual teaching arranges a large amount of theoretical information into a collection. It is convenient for teachers to summarize teaching priorities and help students show their thinking through practical activities in combination with theoretical knowledge.

3.2. Feasibility Study on the Reform and Innovation of Physical Education Teaching Strategy Based on Discrete Dynamic Modeling Analysis. With the advent of the information age, information-based teaching mode and intelligent teaching mode have been gradually applied in the field of education. With the increasing demand for learning, it is necessary to study the theoretical knowledge that cannot be expressed by action in physical education teaching. We began to explore the practical application of information-based teaching methods in physical education. Intelligent computing visual physical education teaching strategy can make physical education technology and action clearly displayed in front of students. In traditional physical education teaching strategies, teachers can only teach movements through multiple demonstrations. This model is no longer applicable to today's environment. Therefore, a

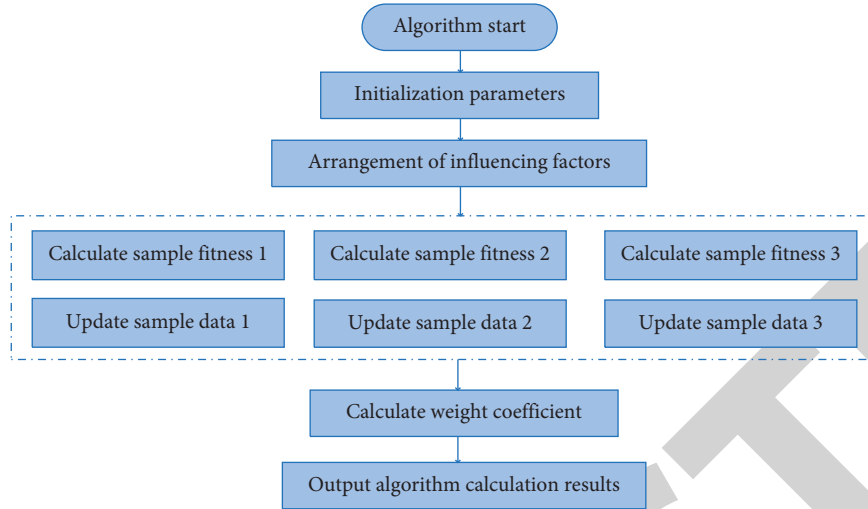

FIGURE 2: Process of intelligent computing model.

series of reforms and innovations have been carried out for physical education teaching strategies. In order to better explore the feasibility of reform and innovation, this paper uses big data discrete dynamic modeling technology to analyze the behavior of physical education learners. Because the work task and processing speed of the database in the big data environment are the main factors affecting the result judgment, the traditional data processing technology cannot face this dynamic and complex environment, so it is necessary to use discrete dynamic modeling to process the data set. In the selection of hardware system, make full use of the modern platform and combine the prediction model with historical experience to make the data processing model more intelligent. Be able to adapt to the changes in dynamic data and work content. Firstly, we reduce the error rate of data results based on Bayesian theory. The behavior of physical education learners is regarded as a feature vector. The eigenvalues are expressed by conditional coefficients. Define the main behavior of data in different categories and different sample characteristics, then

$$P(C_i|X) = \frac{P(X|C_i)P(C_i)}{P(X)}. \quad (9)$$

The assumed independence of the above formula is

$$P(X|C_i) = \prod_{j=1}^M P(X_j|C_i). \quad (10)$$

According to the above formula, we can divide the data processing into three parts. The first part is data mining and sorting, the second part is data visualization calculation, and the third part is to ensure the accuracy and independence of calculation. In learner behavior analysis, the correct rate and error rate of each behavior are different. A sports project needs a variety of learning behaviors to carry out a feasibility analysis. We mark the nodes in the behavior. When the value of the teaching strategy is a fixed value, we can obtain the learners'

learning state. If learners can master this sports skill in this teaching strategy, it can be expressed as

$$P(C_n = \text{false}|K_n = \text{true}),$$

$$P = \frac{\exp(-\sum_{j=1}^n \delta_j s_j^n + \gamma)}{1 + \exp(-\sum_{j=1}^n \delta_j s_j^n + \gamma)}. \quad (11)$$

In the formula, P represents learning efficiency and K_n represents accuracy.

If we cannot master this sports skill in learning, the coefficient of teaching strategy can be expressed by visual data. The calculation equation obtained by logarithmic regression expansion is

$$P(G_n) = P(C_n = \text{true}|K_n = \text{false}),$$

$$P(G_n) = \frac{1}{1 + \exp(-\sum_{j=1}^n \alpha_j s_j^n + \beta)}. \quad (12)$$

In the formula, α_j and s_j^n can represent the factors affecting the correctness and error of feasibility judgment, and β is the calculated deviation. Finally, the learning probability and mastery degree are expressed by the following probability formula:

$$P(K_{n+1} = \text{true}|K_n = \text{false}) = \frac{1}{1 + \exp(-\sum_{j=1}^n \alpha_j s_n^{(j)} + \beta)}. \quad (13)$$

According to the above formula, we can get the feasibility analysis results of discrete dynamic modeling technology on the reform and innovation of physical education teaching strategies. The teaching effect is known through the judgment of learners' behavior correctness and the mastery of sports skills. We will analyze the students' learning effect before and after the reform of the physical education teaching strategy as shown in Figure 3.

It can be seen from Figure 3 that after the reform and innovation of physical education teaching strategies, most

FIGURE 3: Analysis of students' learning effect before and after the reform of physical education teaching strategy.

students can improve their mastery of physical education skills. It has been well applied in sports.

4. Result Analysis and Discussion

4.1. Analysis of Feasibility Study Results of Physical Education Teaching Strategy Reform and Innovation Based on Intelligent Computing. The core content of optimization in the reform and innovation of physical education teaching strategy lies in the teaching mode. In traditional physical education, teachers are the main body and students are the object of imitation. Under this mode, students' own enthusiasm and initiative have been restrained, and their understanding of sports is not deep enough. Teachers' professional level and teaching content can affect students' learning interest to a certain extent. In order to improve this situation, this paper combines the visual teaching design in Intelligent Computing with physical education and puts forward a dynamic and innovative teaching strategy. In order to study the feasibility of physical education teaching strategy reform, we need formal modeling and intelligent calculation of learner evaluation. In the evaluation of physical education teaching, we should emphasize the task of physical education teaching and skill development. In testing, actions are often separated. What students learn are specific skills, which are often practiced under the condition of decomposition. Then, use standardized tests to test their ability to do these decomposition skills. Traditional evaluation methods cannot meet the current needs. We need to dynamically observe students' state and learning performance in sports activities. This demand brings some difficulties to the feasibility evaluation and analysis. We use the intelligent calculation algorithm to analyze the error of the student evaluation coefficient and test whether the evaluation results meet the accuracy requirements, which can be helpful for feasibility judgment. Next, we compare the accuracy changes of data before and after intelligent computing as shown in Figure 4.

It can be seen from Figure 4 that the information data processed by intelligent computing can ensure a certain accuracy in a massive range. According to the evaluation results, we want to intervene students' physical education teaching strategies and determine whether the current interaction state of students meets the expected effect.

FIGURE 4: Changes in data accuracy before and after Intelligent Computing.

According to the students' feedback, we know that the reform and innovation of physical education teaching strategies can have a positive impact on teaching activities. It has certain feasibility in the actual teaching effect.

4.2. Analysis of Feasibility Study Results of Physical Education Teaching Strategy Reform and Innovation Based on Discrete Dynamic Modeling Analysis. In the reform and innovation of physical education teaching strategies, we find that in order to mobilize students' interest in physical activities, this teaching model must be integrated with information skills, that is, integrated with auditory, tactile, and visual information to improve students' desire for exploration. The use of video or pictures in multimedia technology to explain sports movements separately is of great help to students' understanding and mastering skills. We found that after the reform and innovation of the physical education teaching strategy, it is very helpful for students to master knowledge points. Teachers only need to point out the wrong actions in training in time to help students exercise correctly. The traditional teaching strategy is only simple teaching according to the classroom form. Using the teaching strategy of information combination can make the physical education classroom more vivid in an intuitive and visual way. In the feasibility analysis of physical education teaching strategy reform and innovation, we use discrete dynamic modeling to predict and judge the results. Discrete dynamic modeling technology can quickly process a large amount of data information and ensure the accuracy of data. In terms of data feedback efficiency, discrete modeling technology also has good performance. We compare the feedback of the traditional prediction model with the discrete dynamic model as shown in Figure 5.

It can be seen from Figure 5 that the system model constructed by discrete dynamic modeling technology can stabilize the feedback efficiency when the data are increasing. Compared with the traditional prediction model, it has high applicability. In the reform and innovation of physical education teaching strategies, it can bring accurate judgment and rapid feedback to the calculation results. After feasibility

FIGURE 5: Comparison between feedback of traditional prediction model and discrete dynamic model.

analysis, we put forward some suggestions on the reform of the physical education teaching strategy. First, improve the teaching mode and set up physical education courses according to different types. For example, football, basketball, and yoga give full play to these professional advantages to the students. Let students drive students' learning and form a community model. Secondly, improving teaching facilities and sports environment can increase the atmosphere for students' sports activities. At the same time, it can ensure that students will not be injured due to sports conditions. Adding sports facilities can make students pay more attention to exercise. The last is to improve the level of teachers. A good physical education teaching strategy needs a qualified teacher to improve. PE teachers with professional and technical level can make students better understand sports activities and ensure the accuracy of posture in sports movement training.

5. Conclusion

With the improvement of the overall quality of the whole people, sports have become a necessary content in daily life. All colleges and universities have reformed and innovated the physical education teaching mode and strategy. Due to the defects of traditional physical education equipment and the influence of external factors, students' interest in physical activities is not high. Most students have poor physical quality in the examination-oriented education environment. More and more parents and teachers begin to pay attention to students' health. Therefore, it is imperative to reform and innovate physical education teaching strategies. The actual changes after the reform and innovation of physical education teaching strategies need further analysis and research. This paper analyzes the feasibility of physical education teaching strategy reform and innovation by using intelligent computing algorithm and big data discrete dynamic modeling technology. Firstly, according to the defects of physical education teaching strategies, this paper puts forward the ways and methods of reform and innovation. This paper briefly analyzes the application status of big data discrete dynamic modeling technology in various countries.

Combining the traditional classroom with the teaching method of intelligent computing, the teaching effect is analyzed by using the intelligent computing model. Finally, we compare the behavior characteristics of students before and after the reform and innovation of physical education teaching strategies, conduct discrete dynamic modeling analysis, and integrate the data results of dynamic analysis with students' learning attitude and effect to achieve the purpose of feasibility analysis. The results show that the reform and innovation of physical education teaching strategies can help students improve physical exercise activities and lay a foundation for the growth of students' interest in sports and help teachers improve the bad situation of students' sports activities and realize the concept of teaching integration and students' physical and mental growth.

With the continuous fermentation of the thought of intelligence, artificial intelligence has extended its tentacles into the field of artistic creation and has begun to try intelligent creation. Painting creation based on artificial intelligence is called “intelligent painting.” For oil paintings, the computational language is a relatively complicated description. How to correctly identify the computational language of oil paintings is essential for establishing a large oil painting database. This paper constructs a meaningful learning similarity measure and multiclassification model based on the CCNN model to realize the classification of oil painting language. A cropped CNN model is used to extract language features, and on this basis, oil painting works are cross-compared and multiclassified. This method realizes the classification of oil painting language and the corresponding painter and achieves superior accuracy. This paper constructs a data classification method based on small samples, measures similarity through cross-comparison, and provides a measuring approach for classifying the language of oil paintings. The CCNN model proposed combines the best classification results of oil painting language, which improves the accuracy of oil painting language classification. Moreover, it further enriches the methods of oil painting language classification and image recognition under computational intelligence.

1. Introduction

As a unique symbol of artistic expression, oil painting language conveys the artist’s understanding of the objective world and life and his feelings about life. It is a silent language, a bridge between the work and the audience’s appreciation, and the basic expression of oil painting [1]. Language category is an important aspect of the meaning of an oil painting. For example, a portrait of Pierre-Auguste Renoir (1841–1919) painted in heavy ink and color, or a beautiful landscape painting by Claude Monet, shows the meaning of the work and the painter’s thoughts. Famous artists often have their own unique language of their work, and understanding the language of art is crucial to artistic cognition. In order to better understand work of art, researchers put considerable effort into categorizing the language of work of art.

In computer vision research field, significant progress has been made in the classification of scenes in images and videos due to the improvement of machine learning algorithms and the improvement of image processing technology. Researchers have begun to try to automatically classify the language of work. Research on the use of machine learning methods to classify the language of work involves calligraphy, music, painting, etc. Among them, oil painting image classification can be regarded as two-dimensional signal classification.

Artistic language recognition in oil painting has their own characteristics in image features such as color, texture, and stroke thickness due to different painters [2]. They are hard to detect using traditional algorithms and objective characteristics. This research seeks to establish a CCNN-based oil painting language similarity measurement and classification method. The research done for this study in the

language classification of oil paintings will be a new attempt and possibility for image classification technology.

2. Literature Review

Different painting styles, tools, and materials are all important factors that affect painting recognition. The styles of painters in different eras are extremely different, which is closely related to the artistic movements carried out in different periods [3]. For example, Gauguin, the representative of Post-Impressionism, pays more attention to color harmony rather than contrast when painting. Van Gogh, who is also a postimpressionist, emphasizes the use of colors to highlight themes, and his paintings are always a carnival of colors and brushstrokes.

Painting language classification is a field that people take an interest in. It can apply to painted identification, style classification, and painting database search. The task of painter classification includes classifying a painting by its respective painter. The style classification is a matter of classifying artists based on art schools such as Cubism, Baroque, and Impressionism. Both tasks are expected to be extremely challenging, because even the same painter's work has extremely different styles. Image processing techniques are a quantitative analysis tool that can perform scientific statistics and evaluation of works of art [4, 5]. Stork's comments on this topic use low-level functions that encode colors, shadows, textures, and edges [6]. Lombardi proposed that the style of painting is regarded as a personal label for the artist. Different controlled and uncontrolled teaching methods were utilized to study artists' classification tasks [7]. Lee and Cha proposed using color-based statistical calculations to extract global features and to classify painting styles by segmenting painting objects to extract local features based on composition [8]. On the basis of extracting features, using SOM to classify and visualize painting work provides a new way for artistic quantification.

Research on oil painting language classification has not made much progress in recent years. The main reason is that there is no unambiguous definition of artistic style. Numerous studies have transformed the recognition of oil painting language into the analysis of oil painting's color, texture, composition, and other characteristics and analyzed these specific characteristics in the classification model [9]. However, the results achieved are not good. The definition of language is subjective, and there is no definite quantitative indicator for the language distinction of oil paintings, so it is difficult to say in which aspects the differences between the two works are manifested [10].

In traditional oil painting language classification research, researchers extract oil painting features and then classify the features by modeling. Lombardi developed a system to study the problem of artistic analysis. Quantitative method was used to analyze the characteristics of oil paintings using the work of Van Gogh and painters of the same period as research samples, which are Van Gogh's unique brushstroke language. This paved the way for science [7]. Saleh et al. proposed a measurement method for figuring out the impact of different paintings to evaluate by learning

how to optimize the primary functions of HOG [11]. Condorovici et al. studied the classification of Iranian paintings according to texture features. The characteristics of LBP, LPQ, and LCP oil paintings were extracted and input into KNN, SVM, and other models for classification. Recognition accuracy of painting language using SVM classifier is 96.24%, 96.42%, and 96.5% [12]. In the study of deep learning painting language classification, Bar et al. classified images according to the features obtained by the pretrained convolutional neural network for image classification tasks. A machine was designed to make aesthetically relevant semantic decisions. According to the existing consensus in the field of art history interpretation, predict painting language, genre and artist, and provide the best similarity measure [13]. In addition, 81449 images of 1119 artists were employed in the experiment, and the recognition accuracy reached 43%. In 2016, Tan et al. used neural network method to realize the automatic classification of oil painting language for the first time. They achieved an accuracy of 54.5% in the classification of more than 25 painting languages in Wiki-painting [14]. Lecoutre et al. suggested using deep residual nerve to solve the problem of discovering painting language, and the accuracy rate on the Wiki-paintings data set (for 25 different languages) reached 62% [15].

3. Methods

3.1. Convolutional Neural Networks (CNN). In recent years, in the field of large-scale image classification, CNN has significant advantages, so it has attracted people's attention in the computer vision field. CNN is composed of a collection of multilayer neurons, which process the input image hierarchically [16]. Each layer can be seen as a collection of image filters, where each filter extracts specific characteristics from the input image.

CNN's research history goes back nearly 50 years, from the concept of prescription drugs in biological research in the 1960s to the first model based on prescription drug yards in the 1980s [9]. In 1998, Lecun of New York University proposed that the LeNet-5 model PW has made breakthrough progress in handwriting recognition, which has promoted the process of CNN research [17]. In recent years, CNN research in the field of pattern recognition has come to peak [18]. The above model resulted in the machine recognition error rate of ImageNet gallery approaching 3%, which is equivalent to the error rate of human eye recognition [17, 19, 20]. Although these models' structure is getting more and more complex, the bases of these models are almost the same.

CNN model is composed of three layers, that is, convolutional layer, a pooling layer, and a fully connected layer [21]. The convolutional layer is composed of a series of filter banks, which is of some size. And the depth of the filter is equal to the depth of the input data. The initial parameters can be set randomly, and parameters are updated in the training process.

Most of the current CNN structures will have a pooling layer embedded in it. Generally, a pooling layer is inserted into the fixed structure after the convolutional layer [19]. The

pooling layer has a role of reducing the spatial size of the input data, so that it can reduce the possibility. The number of learning parameters greatly reduces the resource consumption of the computer and can also effectively control the overfitting of the training network [22].

Like a normal neural network, the neurons in the CNN are fully connected to input data of the former layer. The fully connected layer mainly maps the previously learned distribution features to the sample in the space; it plays a role of classification [23]. However, due to the parameter redundancy of the fully connected layer, some models (ResNet, GoogLeNet) have adopted other methods to replace the fully connected layer to avoid parameter redundancy and have achieved good results.

3.2. Information-Based Similarity (IBS). The IBS method combines classification methods based on information and word statistics and is a novel method for effectively classifying symbol sequences based on word frequency and rank statistics [24]. In the research of natural language, it is found that each writer tends to use certain high-frequency words in the word citations in his writing, and the high-frequency words preferred by different writers differ from each other [25]. In 2003, Yang et al. applied this concept to the study of heart rate signals and, for the first time, proposed a method for similarity measurement of two complex sequences [26], which is the prototype of the IBS method. At present, IBS has been successfully applied in various fields, including Interbeat (RR) interval analysis, SARS coronavirus classification, and literary work research [24, 27].

The IBS method is to quantify the degree of difference between two symbol sequences. This degree of difference can be measured by the comparability of repeated patterns, and then the “distance” between the two symbol sequences is defined by the degree of difference. The steps for measuring the degree of difference between two symbol sequences are as follows:

- (1) A sliding window of length m is applied to one of the symbol sequences Ψ_1 , and the sliding window divides the symbol sequence into a “word” of length m ;
- (2) Calculate the number of occurrences of each “word” and sort these words according to the number of occurrences. The more frequent the occurrence, the higher the ranking;
- (3) Step (1) and step (2) are applied to another symbol sequence Ψ_2 to obtain the sequence of the symbol sequence “words.” It can be seen that different symbol sequences correspond to different “words” sequence;
- (4) According to the distribution of the “words” of the two symbol sequences Ψ_1, Ψ_2 , the weight distance formula (1) is used to calculate the difference degree D_m of the two symbol sequences.

$$D_m(\Psi_1, \Psi_2) = \frac{1}{L} \sum_{k=1}^L |R_1(s_k) - R_2(s_k)| F(s_k). \quad (1)$$

In formula (1), s_k is a “word” of length m ; $R_i(s_k)$ is the rank of a specific word s_k in the symbol sequence Ψ_i ; L represents the type of a word of length m , which is 2^m for a two-dimensional symbol sequence; $F(s_k)$ represents the weighting factor of the word s_k .

When Yang et al. first proposed the similarity measurement theory [26], the weighting factor used is as shown in formula (2), and the weighting factor $F_0(s_k)$ represents the proportion of the occurrence probability of the word s_k in the two symbol sequences Ψ_1, Ψ_2 .

$$F_0(s_k) = \frac{p_1(s_k)p_2(s_k)}{z_0 \sum_{k=1}^L p_1(s_k)p_2(s_k)}. \quad (2)$$

In formula (2), $p_i(s_k)$ refers the probability of the occurrence of a specific word s_k in the symbol sequence Ψ_i . Z_0 is a normalization factor, which is used to ensure that the difference degree D_m takes a value in the interval [0,1]. The definition of Z_0 is as follows:

$$Z_0 = 2^m - 1. \quad (3)$$

In order to apply this difference index to the classification of more symbol sequences, Goldberger and Peng [24] proposed to use the Shannon entropy formula to redefine the weighting factor $F(s_k)$, as in formula (4), to obtain the difference, a new definition of the degree index.

$$F(s_k) = \frac{[-p_1(s_k)\log p_1(s_k) - p_2(s_k)\log p_2(s_k)]}{Z}. \quad (4)$$

The normalization factor Z is defined as

$$Z = \sum_{k=1}^L [-p_1(s_k)\log p_1(s_k) - p_2(s_k)\log p_2(s_k)]. \quad (5)$$

The steps for calculating the degree of difference between two sequences using the IBS method are as above. According to the definition of the degree of difference D_m , the more similar the two symbol sequences are in the order of words, the more similar the two sequences are. We can also visually reflect the “distance” between two symbol sequences by drawing a scatter diagram. If the words in the two sequences are more similar, the scatters are more concentrated near the diagonal. In some cases, the average deviation of the distance between these scattered points and the diagonal can be used to represent the “distance” between two sequences. The farther this “distance” is, the lower the similarity between the two sequences is.

Combining the distance measurement method of the IBS model and CNN, this research designs a CCNN model to measure and classify oil painting language.

3.3. Principles and Steps of CCNN. CCNN is built on CNN signal extraction and IBS distance measurement. The goal of CCNN is to determine the similarity of different images, so as to perform multi-image classification. The input data of CCNN are specific [28]. The algorithm uses deep-rolling neural network to extract features of images and generate a set of cross-probability maps through cross-comparison of

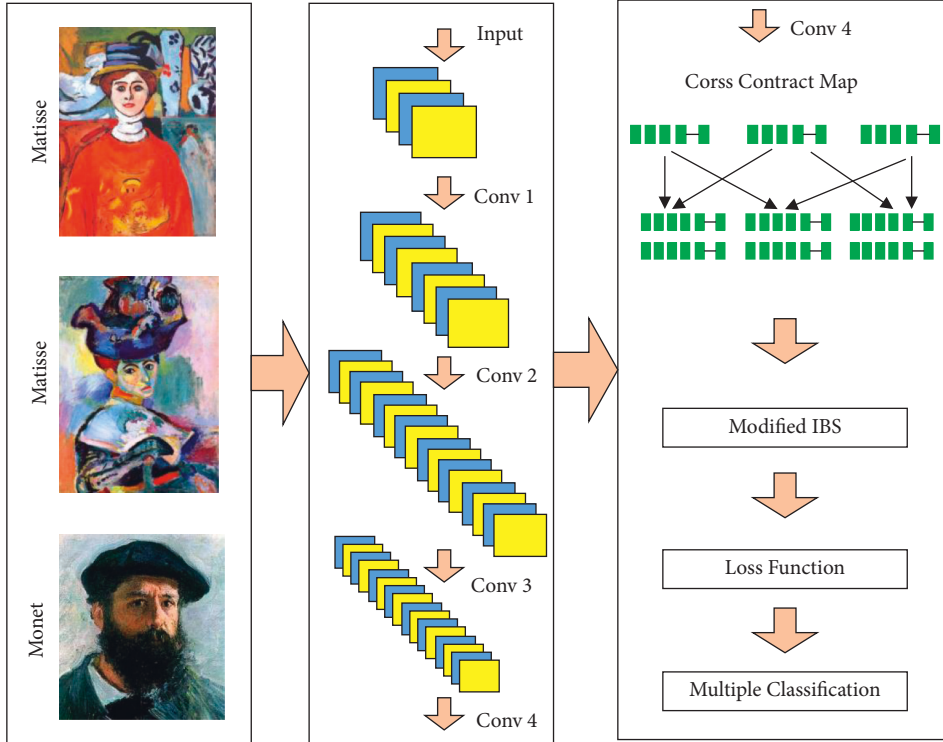

FIGURE 1: Schematic diagram of CCNN structure.

images. In addition, CCNN defines a ModLBS distance to represent the cross similarity between probability map vectors based on IBS. When the distance of ModLBS is 1, it indicates that the reorganized image languages are different. A value of 0 means that the languages are similar and come from the same painter.

CCNN extracts features by comparing the implicit information generated by the input image and obtains a set of cross-probability maps. The purpose of distance measurement is to determine the similarity between images. The two are related to each other, and together, they form a complete network [29]. As shown in Figure 1, the network uses cnN-tuned image extraction mode and ModLBS to measure the similarities between the two images.

3.3.1. Feature Extraction. First, introduce the part of the convolutional neural network used for feature extraction. The input image will be preprocessed before convolution and then pass through different layers of convolutional neural networks. The role of the convolutional layer is to do inner product operations, using multiple the convolution kernel operates on the pixels of a block. The convolution kernel is 3×3 , the step size is 1, and the padding is 1. The convolution output is activated by ReLU and then pooled. The kernel size of the pooling layer is 2×2 , so after the pooling layer, the input feature map will be cropped to $1/4$ of the original, and the output of the pooling layer is the compressed feature map (feature map). Table 1 shows the convolutional layer parameter changes in the convolution process, the ReLU layer is omitted in the table. It should be pointed out that, during the training and testing process, the

TABLE 1: VGGNet network structure of each level.

C-256-512	Conv 4-1	$28 \times 28 \times 512$

input is a single image rather than a pair. Therefore, this paper can load the trained weight to initialize the CCNN, and no need to perform parameters. Here, this paper uses parameters trained on the ImageNet dataset of VGG19 to initialize the model.

3.3.2. Cross-Comparison of Feature Images. After the convolutional neural network extracts the features, this paper will then perform cross-comparison and similarity measurement of the extracted features. First, it assumes that different convolution kernels correspond to different image features, and then the above output based on CNN feature extraction is a set of features.

The number of image features corresponds to that of convolution kernels. This paper first defines a threshold to

vectorize the output feature images. The $f(v)$ function is used to convert the output of the convolutional neural network into a probability distribution map, so that this paper can calculate the frequency of the feature represented by each convolution kernel. Here, Y is the i -th image of convolution filter in the j -th pixel value. N refers the number of image inputs. D represents the number of convolution kernels; K represents the output value of the last convolution layer.

$$\vec{p}_n = [p_1, p_2, \dots, p_i, \dots, p_D] \Big|_n, n \in [1, N],$$

$$p_i = f(v_i) = \frac{\sum_j \text{softsign}(\max(v_{ij}, 0))}{\sum_i \sum_j \text{softsign}(\max(v_{ij}, 0))}, \quad \begin{array}{l} i \in [1, D], \\ j \in [1, K]. \end{array} \quad (6)$$

This paper constructs feature vectors in the output feature images and then combines them into multiple sets of sample pairs, so that the output of the corresponding convolutional neural network can be converted into many feature vectors with dimensions of $(2, D)$. Figure 2 fully shows the cross-comparison structure. Among them, X_i is the i -th frame of a group of images; p_i is the probability. Combining the probability mapping pair, the pair label is set to 0 if both are in the same category; if they do not belong to the same category, the pair label is set to 1.

Therefore, N ($N \geq 2$) images can generate $C_N^2 = N \times (N - 1)/2$ sample pairs.

After constructing the corresponding feature vector, the language classification problem is transformed into how to measure and classify this group of feature vectors. In this way, an image classification problem is converted to a similarity measurement problem based on feature vectors. The CCNN model proposed in this paper focuses on the similarity of oil painting language, rather than the difference in exact image pixels. Therefore, when doing similarity measurement, in this model, value-sensitive Euclidean distance/Manhattan distance is not included. An improved IBS method is proposed to calculate the distance obtained by weighting information entropy. CCNN uses traditional IBS. Redefine it as NorlBS, and set a RevlBS value randomly.

3.3.3. Similarity Measurement. Based on the idea of IBS, this paper first defines a NorlBS distance. 5 cores are the sum of the entropy of the probability distribution of the two images. NorlBS tends to 0 if they are similar; when they are completely different, it is not positive for the upper limit. Analogous to the principle of IBS, if the two images correspond to the same filter, and the output feature maps are ranked similarly. The scattered points are located close to both sides of the diagonal. The greater the distance, the smaller the similarity. The improved IBS method is based on the following assumption: if a feature is randomly shuffled, and the corresponding ranking changes significantly, then the fluctuation of the feature mapping may not be random and may contain relevant structural information. So, it is necessary to set a cross probability. Assuming that, after random destruction, distribution is still discrete, then the

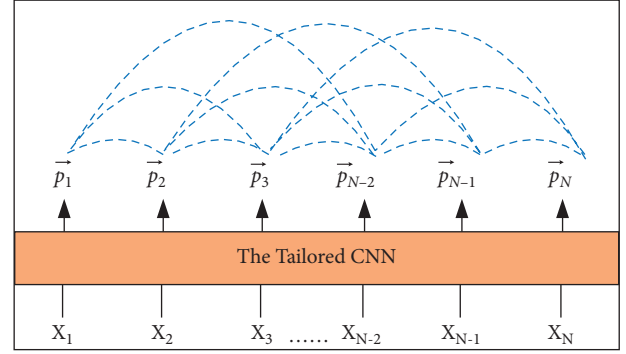

FIGURE 2: Schematic diagram of cross-contrast probability generation.

distance between the points after scrambling is defined as RevlBS.

$$\text{NorlBS} = \frac{\sum_i |R_{xi} - R_{yi}| SE_i}{D \sum_i SE_i},$$

$$SE_i = E_x(p_i) + E_y(p_i), \quad (7)$$

$$E(p) = -p \log p,$$

$$\text{RevlBS} = \text{NorlBS}(\text{random}(\vec{p}_x)).$$

For the two to work in different languages, that is, when the similarity category label is 1, the distribution before and after scrambling does not change much, so the corresponding ReslBS and NorlBS have not changed much. This paper can think that the difference between the two has a tendency to 0. And for two paintings of the same painter, the RevlBS value after scrambling is greater than NorlBS, and the difference between the two is greater than 0. Therefore, this paper defines a distance ModlBS as follows (8), where P is a coefficient, which is in 2~4. ModlBS is in 0~1. For ModlBS, when it tends to 0, the languages of the two works are similar. The value tending to 1 means that the languages of the two paintings are extremely different.

$$\text{ModlBS} = e^{-(\text{RevlBS} - \text{NorlBS}/\text{NorlBS})^P}. \quad (8)$$

Finally, this paper defines a loss function and establishes the optimization goal of the model in this paper to complete the construction of the model. The loss function is as follows, where y is the category similarity label, and $y=0$, indicating that the two oil paintings are the same painter, and vice versa, and $y=1$ means different.

$$L = \sum -[y \log(\text{ModlBS}) - (1 - y) \log(1 - \text{ModlBS})]. \quad (9)$$

3.4. Data Set. To train the model, the Wiki-paintings dataset is used. It is a large-scale image dataset collected by Karayev et al. of WikiArt [30]. The Wiki mapping dataset contains more than 85,000 images, which are divided into 25 languages/genres, such as Abstract Art, Abstract Expressionism, Baroque, Color Field Painting, Cubism, Early

TABLE 2: The number of different genres, painters and works.

Art genres	Painters	Train	Test	Total
Early renaissance	Sandro Botticelli	140	35	175
High renaissance	Leonardo da Vinci	69	17	86
Rococo	Jean-Baptiste Greuze	79	20	99
Baroque	Johannes Vermeer	43	9	52

FIGURE 3: Distribution of oil painting data sets.

Renaissance, and Expressionism. The styles of oil painting pictures from the Wiki-paintings dataset include Academicism, Baroque, Expressionism, High Renaissance, Low Renaissance, Impressionism, neoclassicism, Primitivism, Realism, and Rococo.

Some paintings can have similar content, but different languages. This paper selects 20 artists in different languages to form the “Selected-Wiki-Painting” data set of this paper.

The distribution of genres, artists, and the number of works is shown in Table 2.

Each artist contains more than 50 pictures. The specified train/test ratio is about 4:1. As can be seen from Figure 3, Renoir has the largest number of paintings in the data set, and the number of images drawn by Vermeer is drawn by these 20 artists. At least, in order to ensure that the model is based on the classification of the oil painting language, the

FIGURE 4: Accuracy and loss changes during the training. (a) The classification accuracy change. (b) The loss change.

selected images are all portraits, which guarantees the general similarity of the content.

4. Result and Discussion

4.1. Data Preprocessing. Data preprocessing has a greater impact on the quality of the model, and different data sets and different preprocessing methods should be used. Common image preprocessing methods in deep learning include the following three:

Zero mean: subtract the average value of each dimension of the original data of each dimension, and replace the original data with the result.

$$x_{\text{new}} = x - \mu. \quad (10)$$

Min-max standardization: it is a linear transformation of the original data in $[0,1]$ by mapping, and its mathematical expression is as follows:

$$x_{\text{new}} = \frac{x - x_{\min}}{x_{\max} - x_{\min}}. \quad (11)$$

Z-Score standardization: the data after Z-Score standardization conforms to the standard normal distribution.

$$x_{\text{new}} = \frac{\bar{x} - \mu}{\delta}. \quad (12)$$

In the CCNN-based oil painting language and artist classification process, data preprocessing mainly includes the following steps:

- (i) Crop the original image to a uniform size (224, 224, 3);
- (ii) Perform min-max standardization on the cropped image, and normalize the pixel value of the image to $[0,255]$;
- (iii) Zero-average processing is performed, and each pixel of the three channels of each image is subtracted from its corresponding RGB three-channel pixel average.

Zero-average processing can remove the average brightness value of the image and pay more attention to the

image language or content, and at the same time, data distribution with 0 center is also constructed, so that the gradient descent algorithm can effectively converge.

4.2. Model Training. This section conducts experiments on the data set selected, that is, Wiki-painting. VGG19 model pretrained on ImageNet is used to initialize the parameters. In addition, some related strategies are used, such as early stopping, learning rate, and index decay.

Implementation of the CCNN model is based on the TensorFlow framework. Model training includes image preprocessing, model initialization and training, parameter tuning, and other steps. Model training has two parts: forward propagation and backpropagation. In the back-propagation process, CCNN uses `tf.train.AdamOptimizer` provided by TensorFlow to update its parameters. Taking this into account, CCNN iterates the model parameters. The network gradually approaches the optimal solution and finally achieves the optimal goal. Here, the Adam method is a method founded on gradient descent. The `tf.train.AdamOptimizer` provided by TensorFlow can improve traditional gradient descent by using momentum, promote dynamic adjustment of hyperparameters, and accelerate model convergence. In addition, the CCNN model uses L2 regularization to prevent overfitting, and through loss, the sum of the squares of the parameter w is added to suppress the value of w and make the loss curve smoother, thereby reducing overfitting. The specific implementation of L2 in TensorFlow is `tf.add_n(tf.get_collection('losses'), weight)`. Extract all loss and use `total_loss` to train. In Figure 4, the accuracy and loss of the training set data are changing during the model training process ($lr=4.261487e-05$, $batch_size=21$).

Figure 5 shows the probability graph of similarity between two paintings by Matisse and a painting by Matisse and a painting by Monet. It is found that, in the initial stage, the probability distribution of the two paintings of different authors in the picture tends to be scattered. As the number of training increases, the degree of scatter increases. On the contrary, for the two paintings of the same artist, as the

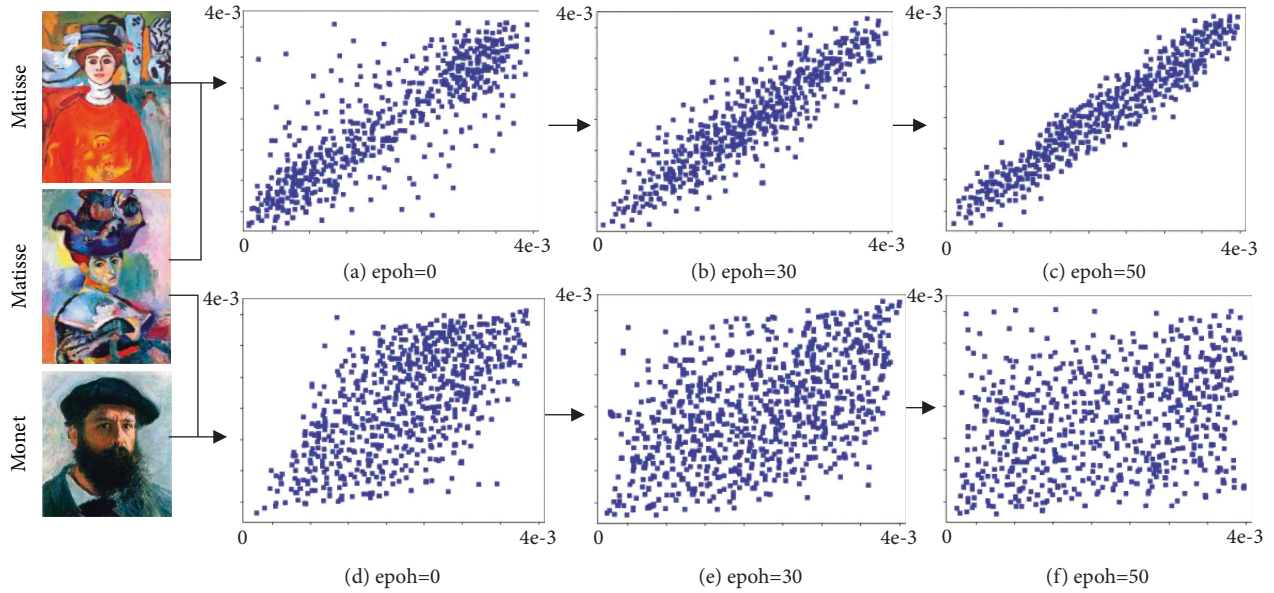

FIGURE 5: The probability distributions of different images.

training goes, it will be better distributed on both sides of the central axis. Observe the loss curve. As the training increases, the average loss is steadily decreasing, which indicates that the model training is converging in the expected direction.

4.3. Model Test. As can be seen from Figure 6, the test process of CCNN oil painting language classification is as follows. One test image and n training set images are combined into a set of inputs, and input into the trained model. 1 test image and 1 one training set image can get 1 ModIBS value, and n training set images can get n ModIBS values.

Three accuracy indicators are included in the model. Similarity accuracy (SA) is defined as the predictive accuracy of all pairs used to determine whether two images are similar, that is, two classifications. LVA is to select the category containing more label0 as the final classification result and calculate the accuracy rate. DVA is to select the category with the smallest average IBS modification value as the final classification. LVA and DVA aim to evaluate the classification accuracy of multiple classifications.

4.4. Classification Result. In the classification task, the goal is to find the similarity between two input images and realize its multiclassification. The model is applied to the identification and language classification of 20 painters. Results are presented in Table 3. Among them, in the classification of artists, the accuracy rate of similarity measurement is 97.95%. The DVA and LVA were 85.75% and 80.26%, respectively. The results of classification and recognition show that the model can effectively classify the two images. In other words, CCNN can estimate the structure from the contrasted images, copying the process of the human brain

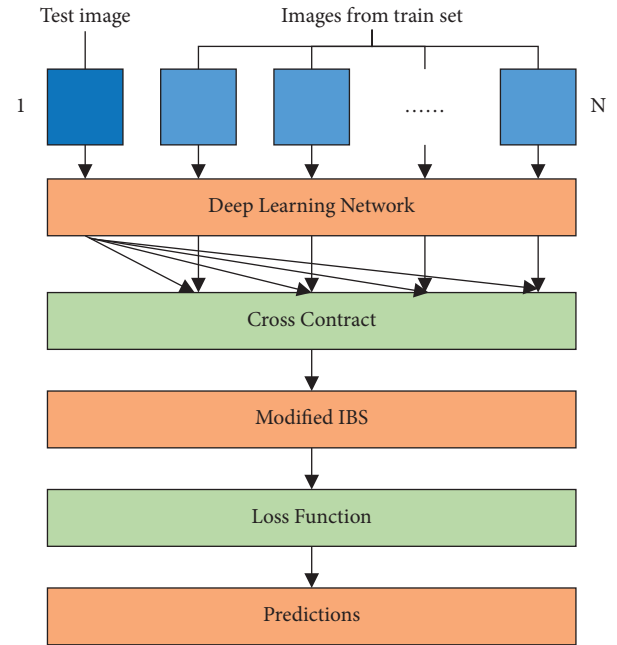

FIGURE 6: CCNN test method.

TABLE 3: Oil painting language classification results based on CCNN.

Classes	Artists/Style	SA (%)	DVA (%)	LVA (%)
13	Styles	86.96	52.77	47.76
20	Selected-wiki paintings	97.95	85.75	80.26

in measuring these images. In the classification of art genres, the accuracy rate of its 13 genres multiclassification is the highest 52.77%.

5. Conclusion

How to correctly identify the artistic language of oil paintings is essential for establishing a large oil painting database. The classification of artistic language cannot rely on any concrete characteristics, especially for those artistic works that are not representative. In response to the above problems, this paper proposes the CCNN model. The model performs well in the multiclassification task of oil painting language. This paper proposes a CCNN multiclassification method, which can measure the similarity and multiclassification of the language of oil painting work and the corresponding artists. Oil painting data set was constructed using the WikiArt library. The data set includes more than 2,000 works by 13 language styles and 20 artists. CCNN achieved an accuracy of 85.75% on the task of artistic classification. The CCNN model proposed dividing the 13 languages of the oil painting data set finds the best combination of the classification results and improves the accuracy of oil painting language classification. Although the CCNN model can be well applied to multiclassification tasks of small samples with obvious language features, its depth should be further expanded, such as extending ResNet for feature extraction.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the advent of big data, statistical accounting based on artificial intelligence can realistically reflect the dynamics of labor force and market segmentation. Therefore, based on the combination of machine learning algorithm and traditional statistical data under big data, a prediction model of unemployment in labor force based on the combination of time series model and neural network model is built. According to the theoretical parameters, the algorithm of the two-weight neural network is proposed, and the unemployment rate in labor force is predicted according to the weight combination of the two. The outcomes show that the fitting effect based on the combined model is superior to that of the single model and the traditional BP neural network model; at the same time, the prediction results with total unemployment and unemployment rate as evaluation indexes are excellent. The model can offer new ideas for assisting to solve the unemployment of the labor force in China.

1. Introduction

Unemployment is not only a comprehensive economic problem but also a complex social problem [1] which has turned into the focal point of consideration for all nations. Whether unemployment can be properly solved is related to the development of the country. In recent years, China's economy is facing a complicated international economic environment, such as RMB appreciation [2], prices rising of raw materials [3], and pressure increase of inflation input [4], which has led to the decline of export and economic growth, thus bringing about unemployment that deserves our attention. In addition, the government also attaches great importance to the development of a country, which depends not only on the country's economy, science, technology, military affairs, and the gap between the rich and the poor but also on the treatment results of unemployment. If countries with serious unemployment do not have effective policies and measures to ensure the survival of the unemployed labor force, it can easily lead to social instability, which will affect the development of a country in all aspects. Therefore, if the government can predict the number

and proportion of unemployed labor force in advance, they can formulate policies and measures to ensure the prosperity and development of the country according to these predicted data [5].

At present, with the advent of big data, some researchers try to use circumstantial big data to build indicators for measuring the dynamics of China's labor market [6–8]. For example, by using recruitment data on Internet [9], social media data [10], data of digital search [11], etc., to build economic indicators based on nonstatistical accounting methods, which can reflect the dynamics of the whole labor force and market segments in real time. However, these indicators lack a clear definition in the accounting sense, and their scientific and reliability are questioned. For the method of prediction, because the urban unemployment and unemployment rate in China are all differential stationary time series data, the neural network algorithm has been proved to have an excellent approximation ability to nonlinear relationship in theory [12, 13], so it is of practical significance to study a prediction model of unemployment in the labor force, so as to solve the actual unemployment.

Before 2018, the most important unemployment index released by the Chinese government was the registered

urban unemployment rate, which was quite different from the international definition of the unemployment rate, and the value remained stable at around 4% for a long time, so it was difficult to reflect the real unemployment level in China [14]. Since 2018, the Chinese National Bureau of Statistics has released the national urban survey of the unemployment rate on a monthly basis, which is a significant progress in the release of unemployment statistics. To make up for the long-term lack of China's four macro-economic indicators, the data have been generally recognized by all sectors of society. However, due to the limited sample size of the labor force survey, the unemployment rate in the urban survey is not representative of administrative regions at all levels below the provincial level [13]. In 2021, the Chinese National Labor Force Survey will conduct a new round of sampling according to the seventh national census and appropriately expand the sample size to meet the main index data, such as the urban unemployment rate, which is well representative of the country and provinces (autonomous regions and municipalities).

Therefore, in this paper, the above-mentioned combination model is established, and the unemployment situation of the urban labor force with the number of unemployed and unemployment rate as evaluation indexes to explore new ideas that are helpful to manage the urban unemployment in China.

2. Related Theories

2.1. Neural Network Model

2.1.1. BP Neural Network. First proposed by the Parallel Distributed Processing scientific research group represented by Rumelhart and McClelland in the United States, BP neural network is a multilayer perceptron feedforward network [15]. It has strong nonlinear adaptability, excellent nonlinear approximation, and good fault tolerance. Therefore, it can process large-scale data in parallel with outstanding self-organizing, self-learning, and self-adapting abilities, which are widely adopted in the fields of prediction, classification, and clustering. This back propagation algorithm makes multilayer perceptron has the ability to approximate any complex nonlinear function [16]. It is a feedforward neural network using the BP learning algorithm, and Figure 1 shows its topology.

It can be seen that the direction of data flow is that first the data of the input layer flow to the first hidden layer after weighting, then the data flow to the second hidden layer after further weighting, and so on until the output data of the last hidden layer flow to the output layer. The change function between the info and the result of neurons in each layer is known as the activation work. The universal approximation theorem has been proved [17, 18]. A three-layer BP neural organization with a secret layer can surmise any ceaseless capacity in a limited locale with erratic accuracy as long as there are an adequate number of stowed away hubs. The function corresponding to the i th neuron in a certain layer is shown in the following formula:

FIGURE 1: Topology of the BP neural network.

$$\begin{aligned} y_j &= f(W_j * X - \theta_j) \\ &= f\left(\sum_{i=1}^n \omega_{ij}x_i - \theta_j\right). \end{aligned} \quad (1)$$

In which, W_j is the weight in the BP neural network, X is the input vector, θ_j is the threshold, and F is the activation function.

2.1.2. RBF Neural Network. The radial basis function neural network (RBF) also belongs to feedforward neural network. It is widely used in function approximation and classification its straightforward design, simple preparation, quick learning combination, and the capacity to estimate any nonlinear combination [19]. Although RBF has only one hidden layer, it has the same excellent nonlinear approximation ability as BP neural network, and Figure 2 shows its topology.

The basis function of hidden nodes in RBF adopts the distance function, and the activation function adopts the Gaussian function. Since RBF has spiral evenness about a middle mark of N -layered space, and the farther the contribution of neurons is from the middle point, the less activated the neurons are. This characteristic is often called "local property" [20].

2.1.3. Two-Weight Neural Network. For the two-weight neural network, by changing parameters of neuron function, it can also be constructed not only as a higher-order neural network [21]. In addition, the neural of the double-weight neural network includes not only the weights of the BP neural network but also the core values (i.e., central data). The neuron function of the neural network is shown in the following formula:

$$y_j = f\left(\sum_{i=1}^n \left(\frac{\omega_{ij}(x_i - c_j)}{|\omega_{ij}(x_i - c_j)|}\right)^s \left|\omega_{ij}(x_i - c_j)\right|^p - \theta\right). \quad (2)$$

Among them, y_i is the output value of the j th neuron in a layer in the two-weight neural network model, f is the activation function, ω_{ij} is the weight of neuron, c is called the kernel value of neuron, x_i is the input value of neuron, θ is the threshold value of neuron, and s and p are two parameters.

FIGURE 2: Topology of RBF neural network.

In formula (2), when $C_j=0$, $S=1$, and $p=1$, it becomes the neuron function of the BP neural network; When $s=0$ and $p=2$, the function becomes the neuron function of RBF neural network. For the hidden layer, the neuron function of this layer only contains the direction weight but not the core weight. For the hidden layer of the RBF neural network, the neuron function of this layer only contains core weights but does not contain the direction weight; while for the hidden layer of the two-weight neural network, the neural function of this layer contains both the direction weight and the core weight. Therefore, when the parameters of the activation function take specific values, it has more excellent approximation ability for nonlinear continuous functions [22].

In view of this, the algorithm of the two-weight neural network is taken. To apply all training samples to the improved BP algorithm of weight adjustment (batch processing) in the neural network. The minimum mean square error criterion is selected to evaluate the learning rule and its objective function is defined as the following equation:

$$E^{(p)} = \frac{1}{2} \sum_{l=0}^{m-1} (d_l^{(p)} - y_l^{(p)})^2. \quad (3)$$

The total error of all input samples is

$$\begin{aligned} E_T &= \sum_{p=1}^P E^{(p)} \\ &= \frac{1}{2} \sum_{p=1}^P \sum_{l=0}^{m-1} (d_l^{(p)} - y_l^{(p)})^2, \end{aligned} \quad (4)$$

where P is the number of learning sample vectors, $d_l^{(p)}$ ($p=1, \dots, P$) is the expected output, and $y_l^{(p)}$ ($p=1, \dots, P$) is the actual output.

Generally, the gradient descent method is used to modify the weights. In this paper, the formulas for adjusting the weights and the core values are as follows:

$$\begin{aligned} \omega(t+1) &= \omega(t) - (1-\alpha)\eta \frac{\partial E_T}{\partial \omega(t)} + \alpha \Delta \omega(t), \\ c(t+1) &= c(t) - (1-\alpha)\eta \frac{\partial E_T}{\partial c(t)} + \alpha \Delta c(t). \end{aligned} \quad (5)$$

Among them, η represents the learning rate whose value is generally small, $\Delta \omega(t) = \omega(t) - \omega(t-1)$, $\Delta c(t) = c(t) - c(t-1)$, α is the momentum factor, and the value of α is

$$\alpha = \begin{cases} 0, & \text{SS}(t) > 1.04\text{RSS}(t-1), \\ 0.95, & \text{RSS}(t) < \text{RSS}(t-1), \\ \alpha, & \text{others,} \end{cases} \quad (6)$$

where $\text{RSS}()$ is the residual sum of squares of the output.

The learning of network is divided into two processes [23, 24]: one is to calculate the output of each layer by forward propagation from front to back and the other process is to correct the weight or core value of each layer by backward propagation from back to front. The Algorithm 1 steps are as follows:

2.2. Time Series Model. The time series of a random event usually refers to sequence $\{X_t\}$, formed by arranging the numerical values of an index observed at equal intervals in a certain period of time in sequence, which essentially reflects the trend that an index changes with time. The main purpose of time series analysis is to observe and study the existing data, mine the development law of these data with time, and thus analyze and estimate its future situation in the time series model [25]. The analyzed data are differential stationary time series in nonstationary time series. The so-called time series is a series of ordered data recorded according to the time sequence. In daily life, the data of time series can be seen everywhere, and most of these data are nonstationary time series, among which the ARIMA model, as a kind of nonstationary time series analysis, is widely used.

ARIMA (p, d, q) model has the following formula:

$$\begin{cases} (1 - \Phi_1 B - \dots - \Phi_p B^p) \nabla^d x_t = (1 + \theta_1 B + \dots + \theta_q B^q) \varepsilon_t, \\ E(\varepsilon_t) = 0, \text{var}(\varepsilon_t) = \sigma_\varepsilon^2, \\ \text{cov}(\varepsilon_t, \varepsilon_s) = 0 (s \neq t), \\ \text{cov}(X_s, \varepsilon_t) = 0 (\forall s < t). \end{cases} \quad (7)$$

The modeling steps can be summarized as [26, 27] follows:

- (1) Test the stationarity of the original sequence data. There are two most commonly used methods, one is the graph test, and other is the unit root test. If the sequence is stationary, the graph of data changing with time should show that most of the data fluctuate at a constant and its fluctuation range is similar, autocorrelation coefficient will quickly decay to zero. When the sequence is nonstationary, the corresponding characteristic equation contains characteristic roots. Therefore, the unit root test can also be used to verify whether the sequence is stationary. The commonly used ones are DF, ADF test, etc. If the sequence is not stationary, the difference operation will be carried out.
- (2) Test the white noise of the series. It is not meaningful for all stationary series models, but only for those series models that can influence each other.

- (3) Determine the model's order. The model to be established and its order can be determined according to the correlation coefficient diagram of stationary time series, and the order can also be determined according to the identification function.
- (4) Parameter estimation: The AIC criterion can be used to complete the process of order determination and parameter estimation simultaneously.
- (5) Model test. There are usually two types of tests: the significance test of model, whose purpose is to test whether the established model effectively and adequately extracts the information contained in the data. If the established model is effective, the residual has the characteristics of white noise data, and there is no available information; Otherwise, it means that the information in the data has not been extracted completely, and the significance test of the parameters remaining in the residual error is to confirm whether each parameter obtained is obviously different from zero to establish a simpler and more accurate model.

3. The Combined Model of Unemployment Prediction in Labor

Based on the above sample data, we first forecast the number of registered unemployed people and the registered unemployment rate in China by using the two-weight neural network and then forecast the data by using the time series method. Finally, the predicted results of the two methods are combined according to the corresponding weights as the predicted values of the combined model.

3.1. Two-Weight Neural Network Model. In this paper, the parameters in the neurons of the double-weight neural network are $s = 0$, $p = 1$, $\theta = 0$, and the BP algorithm is used. When taking two-weight neural network to analyze, it is important to standardize the information first. The normalization formula for the series of the number of unemployed and unemployment rate is:

$$x(i) = 2 \frac{x_0(i) - x_{0\min}}{x_{0\max} - x_{0\min}} - 1. \quad (8)$$

Among which, $X(i)$ is the i th value in the normalized sequence, $x_0(i)$ is the original data, $x_{0\min}$ is the minimum value, and $x_{0\max}$ is the maximum value.

A training sample is constructed with the normalized data of unemployed and unemployment rate, and the method of sample construction is shown in the following formula:

$$\begin{aligned} X_i &= (x(i), x(i+1), x(i+2)), \\ Y_i &= x(i+3). \end{aligned} \quad (9)$$

In which, X_i and Y_i are the samples i th group, and $x(i)$ is the i th value of the normalized data. The sample data of nearly 30 years are selected in this model, and Table 1 shows some normalized samples as follows:

Through the prediction method of two-weights neural network, the last expectation results are displayed in Table 2.

3.2. Time Series Model. Aiming at analyzing the data that changes with time, the time series analysis uses the time series model to analyze the unemployment and the registered unemployment rate in cities and towns. Because the data series of labor unemployment is nonstationary, it is necessary to make a first-order difference to the original series, and the series after the difference has a very strong short-term correlation. Therefore, the ARIMA model is selected for fitting.

The statistical samples are tested for significance level of $\alpha = 0.05$. The white noise test of the first-order differential sequence of unemployed shows that the P value of the statistics constructed after the sixth-order delay is 0.0122, which is less than 0.05, while for the unemployment rate, the P value is 0.0017 that less than 0.05. It can be considered that the differential sequence is a nonwhite noise sequence; that is, the related information of the differential sequence cannot be ignored and has yet to be extracted. The ARIMA model can be used to fit the differential stationary and nonwhite noise sequence.

After the difference sequence, the autocorrelation coefficient is trailing, so as the partial autocorrelation coefficient. After testing, when the ARIMA model with $p = 1$ and $q = 0$ is adapted to fit the data, the best results are obtained, and the upsides of AIC and SBC compared to the model are additionally the smallest. The results are shown in Table 3.

Under the significance test level of 0.05, the residual sequence test results are shown in Table 4.

The P values of the statistics constructed are far greater than 0.05, so it can be considered that the residual sequence no longer has the significance of extracting information. The results of the coefficient test and residual test show that the ARIMA (1, 1, 0) model implemented in this paper has a decent displaying impact on the sequence of unemployment.

According to the established model, the unemployment of the labor force is predicted, and the prediction results are shown in Table 5.

3.3. The Combined Model. In the previous part, the two-weight neural network model and the ARIMA model were used to analyze the number of unemployed and the unemployment rate in China. The two analysis methods are suitable for fitting the series of unemployed laborers and unemployment rate in China. The fitting values of the two models about the sample data are shown in Table 6:

Figures 3 and 4 describe the fitting situation between the number of unemployed and the unemployment rate under a single model. From the figure, it can be inferred that the fitting value of neural network model and time series model is higher than the actual value, but the curves of the three models are similar, showing that the fitting of single model is better. But for the unemployment rate, there is a certain deviation between the fitting curve and the actual curve.

- (1) Initialize the neural network weights;
- (2) Input P training samples in turn, and assuming that the currently inputted learning sample is the p -th training sample;
- (3) Calculate the output sequentially;
- (4) Solve the back propagation error;
- (5) Record the number that has been examined. If $p < P$, turn to (2), if $p = P$, continue to (6);
- (6) Revise the correction formula of the weight value of each layer or the right;
- (7) Recalculate the output of the hidden layer according to the new weight or core value, and if the maximum learning times are reached for each p and P , end the network learning.

FIGURE 3: Fitting chart of unemployment under single model.

According to the fitting results of the unemployment model, the sum of residual squares between the fitting value and the true value is solved, which is shown in Table 7:

Assuming that y_0 represents the true value, y_1 represents the fitting value of the neural network model, y_2 represents the fitting value of the time series model, W represents the residual value corresponding to the combination model, ω ($0 \leq \omega \leq 1$) represents the weight of the neural network model in the combined model, and $1-\omega$ represents the weight of the time series model in the combined model. The combined model is calculated by the following formula:

$$\begin{cases} W_{\min} = \sum_{k=1}^{i=1} (\omega y_1 + (1-\omega)y_2 - y_0)^2, \\ 0 \leq \omega \leq 1, \end{cases} \quad (10)$$

where k is the number of true values for calculating the residual sum of squares.

After calculation, when ω is 0.4267, the minimum residual error is 21353. Similarly, when ω is 0.598, the minimum residual error of the combined model is 0.6574, which

is smaller than the residual sum of squares fitted by neural network and time series model. According to this weight, the predicted value of the combined model for unemployment is shown in Table 8:

3.4. Other Comparison. Because the fitting effect of the combined model is better than that of the single model, which constitutes the combined model, it is still necessary to compare whether the fitting effect is better for other models. The BP neural network model, the most commonly used network model, is selected as the prediction model. For the number of unemployed, the minimum residual error of BP neural network model fitting is 25,673, and for the unemployment rate of labor force, the minimum residual error is 2.9760. Both of them are higher than the minimum residual error obtained by the combined model in fitting, which shows that in the model built in this paper, there are better fitting results and it seems to be more accurate to predict the unemployment in labor force.

4. Conclusion

An accurate prediction of unemployment in labor force is helpful to tackle the issue of metropolitan unemployment. In this paper, the data of unemployment obtained by the Chinese National Bureau of Statistics are taken as a statistical sample. A labor unemployment prediction model in light of the combination of the neural network model and time series model is built, while the situation about labor unemployment in China from 2022 to 2030, is forecasted. The results show that the fitting impact of the combined model is superior to that of the single model, which constitutes the combined model. The minimum residuals of the combined model for fitting and the unemployment rate are 21353 and 0.6574, respectively, which are lower than their single models. At the same time, the fitting condition of the combined model is better than that of the commonly used BP neural network model, which has an excellent impact. When the latter is fitted to the unemployed and unemployment rate, the obtained minimum residuals are 25673 and 2.9760, respectively, which are higher than the combined model. The prediction results of the combined model show that from 2022 to 2030, the number of unemployed labor force in China will fluctuate between 999.6992 and 1038.8520, and the unemployment rate will vary between 5.3406 and 5.8499.

In the era of rapid development of computer technology, piano music notation and electronic synthesis system can be established using computer technology, and the basic laws of music score can be analyzed from the perspective of image processing, which is of a great significance in promoting piano improvement and research and development, etc. In this paper, the Beaulieu analysis method is used to analyze the piano music notation and electronic synthesis system module. For piano sheet music, sheet music recognition is the main problem in the whole system. Through the digital recognition method, the piano sheet music feature matrix is extracted to get the piano sheet music multiplication frequency points and the envelope function needs to be extracted for better electronic synthesis of piano sheet music. The envelope function can represent the relationship between piano sound intensity and time change and finally achieve the recognition of the piano score. We extract the music information from the digital score, thus converting the music information into MIDI files, reconstructing the score, and providing an audio carrier for the score transmission. The experimental results show that the system has a correct rate of 94.4% in extracting music information from piano scores, which can meet the needs of practical applications and provide a new way for music digital libraries, music education, and music theory analysis.

1. Introduction

In the era of rapid development of computer technology, music and electronic synthesis are widely concerned by musicians, and the use of computer technology allows for the creation of piano music notation and electronic synthesis systems, which are important to promote the improvement and development of the piano, among other things [1]. With the advancement of electronic synthesis technology, computers are producing electronic synthesis scores, especially for the piano, which are very beautiful, and with electronic synthesis, more new scores will appear that perfectly demonstrate the uniqueness of the piano and its application to computer music composition. Computer technology for piano notation and electronic synthesis plays an important role in electronic music; however, computer technology is an important method to achieve piano music notation and electronic synthesis [2, 3].

Piano is a keyboard instrument used in various countries. The sound range of the piano is very wide, and the recognition

of piano music symbols is very important [4–6]. The design of the piano music score and the electronic synthesis system based on the improved linear modulation method is proposed. This method separates harmonic signals according to the edge tone of piano music, transmits the music score, analyzes the continuity of the piano music score signal, and completes the design of the piano music score and the electronic synthesis system, but the performance of this method is poor [7, 8]. The method proposes the design of the piano score setting and the electronic synthesis system based on the audio tampering method, extracts and measures the piano score, enhances the characteristic parameters of the piano score, classifies it, judges whether the score has been tampered, compares the authenticity of the score, and finds that the accuracy of this method for the piano score is low [9–12].

The rapid development and popularity of digital technology and network technology have provided material conditions for the conversion of paper sheet music into music sound dissemination; however, the key problem to be solved is

how to digitize the sheet music, convert the paper sheet music into digital sheet music, and automatically generate the corresponding digital audio to realize the dissemination of music on the Internet. Currently, there are two main methods to realize digital scores: one is to manually input the scores into computers by music professionals through music software (e.g., Cakewalk, etc.), which relies on professionals and has low work efficiency; the other is to use OMR (optical music recognition) technology for an automatic input [13, 14]. OMR integrates image processing, pattern recognition, artificial intelligence, MIDI, and other related technologies and can convert scores within seconds, which greatly improves the work efficiency and is widely used in digital media music libraries, large digital music libraries, reading and playing of robotic scores, computer music teaching, music teaching, and digitization of traditional Chinese scores [15–18].

2. Knowledge in the Field of Music Notation

Notation is a method of recording musical scores. In the course of music development, various notation methods have been created due to the different contents and needs of the music, such as the guqin score for the guqin, the gong score for the gongs and drums, and the five-line score, the short score, and the kongjue score used in our folklore [19]. Notation is very important for creation and performance. Notation must be able to record all aspects of musical activities, including the height, strength, length, musical notation, and expression marks. Notes are symbols that record the progression of notes of different durations [20]. A rest is a symbol that records the interruption of a note of different lengths. In western notation, the common notes and rests are shown in Figure 1.

3. Extraction of Musical Information from Digital Sheet Music Based on Mathematical Morphology

The workflow of digitizing paper sheet music and extracting music information based on the OMR system is shown in Figure 2.

The following is an example of a polyphonic piano score using mathematical morphology to process the digital image of the piano score and extract the musical information from the score. It is unrealistic to extract all the musical information of the score, and the purpose is only to get the sound corresponding to the score, so it is not necessary to identify the large number of performance cues in the score (the sound is originally the result of the performance). However, the basic note pitch, time value, and polyphony must be identified. By combining their information, the sound file (MIDI file) corresponding to this score is created, and the score can be reconstructed using the MI-DI file, as shown in Figure 3.

In the image preprocessing stage, because the background of the pentatonic image is single and the color used for recording music information is single, the binarization image processing technique can be used to transform the

paper pentatonic into a binary image, and at the same time, the pepper-like restless sound is removed by using the mathematical morphology of first erosion and then expansion operation [21, 22].

Let the image to be processed be A , its height be H , and its width be W .

In the music information recognition stage, the Y -projection technique (horizontal statistics) is used to obtain the information of the music score lines. The number of black pixels in each line is counted as a statistical unit, and the array $s[n]$, $1 \leq n \leq W$ is obtained. If the value of each element in $s[n]$ is considered as a grayscale value, the grayscale histogram, called the numerical histogram, can be counted. Obviously, there are two peaks in the numerical histogram, from which we can get the threshold value that divides the two peaks, denoted as f , find the elements in the array $s[n]$ that are greater than f , denoted as a total of m , get the sequence of subscripts of these elements, denoted as R_i , and satisfy $1 < R_i < W, 1 \leq i \leq m, S[R_i] > f$.

Let the width of the spectral line be k ; obviously, there is $k \geq 1$, and there is the property.

If $k = 1$, then $R_{i+1} - R_i \leq 1, 1 \leq i < m$; if $k > 1$, then, there exists i , which satisfies $R_{i+1} - R_i = 1, 1 \leq i < m, t, D$.

Note that there are t different i satisfying conditions $k > 1$ and $R_{i+1} - R_i = 1$.

The distance between spectral lines is defined as d :

$$d = \frac{\sum_{i=1}^{m-1} (R_{i+1} - R_i) - t}{m - t} \quad (1)$$

In this paper, a fragment of Beethoven's "Turkish March" (digital image A) was selected for processing, and the results are shown in Figure 3, where the digital image of the score is shown on the left, the corresponding part on the right is the result of Y -projection, and the numerical histogram is shown on the upper right.

The score and key number can be identified by using the hit and miss operation based on the position of the score line and the distance d from the score line.

The note can be identified using the erosion operation. Let $B1$ be a structural element consisting of black pixels of $(d - k) * (d - k)$, and using the erosion operation, the note head can be identified and the position information of the note head can be obtained. Figure 4 shows the result of the erosion of Tchaikovsky's "Four Little Swans," where the pitch of the note is determined based on the position of the score and the note head. Also, by setting $B2$ as a structural element consisting of $1 * [4 * d + 3 * k]$ black pixels, the stem and bar line of the notes can be obtained by the corrosion operation. Figure 5 shows the corrosion result of Beethoven's "For Alice" [23, 24].

The two operations $A \odot B1, A \odot B2$ can be performed in parallel, and the relationship between the note head position and the note stem position is used to design the structural elements E and F . Using these two structural elements, the temporal information of the notes can be obtained by hitting the hit-miss transformation of the score image.

FIGURE 1: Common notes and rests.

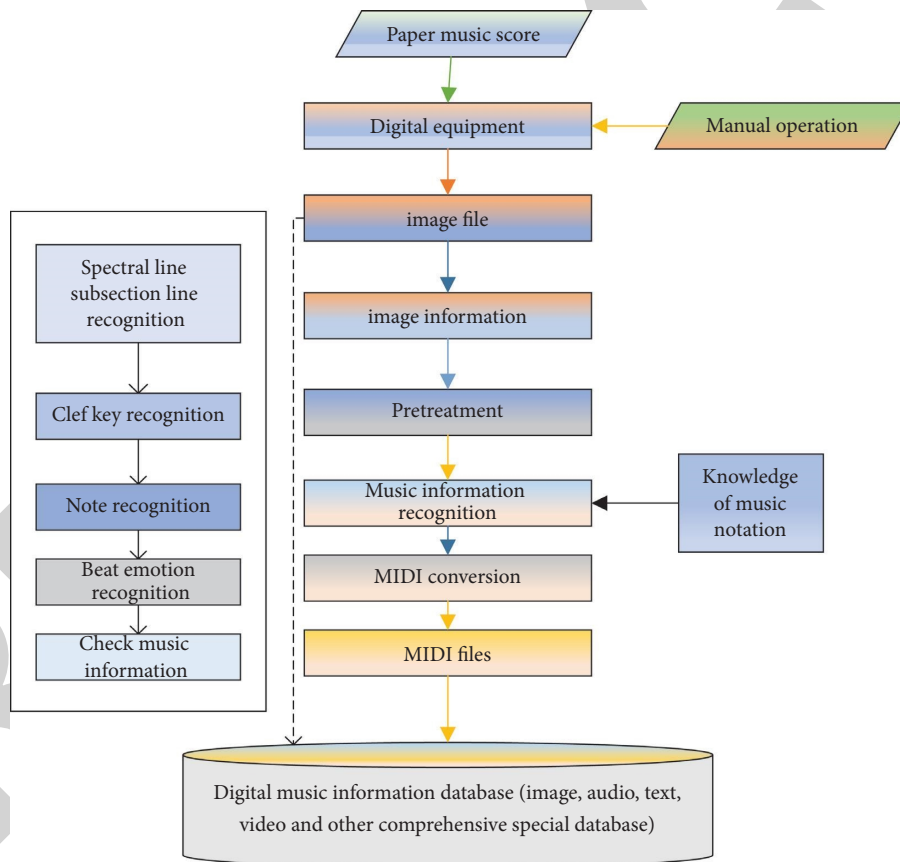

FIGURE 2: Music information extraction process based on the OMR system.

After getting the complete note information, all the notes are divided into bars by bars using bar lines, and each note belongs to one bar only, and the time values in all bars are calculated to determine whether they are equal or not.

Finally, the extracted music information is combined and converted into MIDI files according to the data structure of the MIDI 1.0 protocol.

4. DC-CNN-Based Music Notation Recognition Model

The reduction model proposed in this paper adopts a multilayer convolutional stacking and gate activation function model without a pooling layer similar to PixelCNN. The model is based on an extended causal convolutional

FIGURE 3: Example of Y-projection results and their numerical histograms.

FIGURE 4: The score (a) and the result of the corrosion operation of $A@B1$ (b).

FIGURE 5: The score (a) and the result of the corrosion operation of $A \otimes B2$ (b).

neural network (DC-CNN), and the reduction features are introduced by controlling the gate activation unit of each neuron in the neural network to achieve the reduction of electronic artifacts. The DC-CNN adopted in the model exists in causal convolution and expanded convolution, and the DC-CNN has achieved good results in the speech synthesis model WaveNet [25, 26].

4.1. Expanded Causal Convolutional Neural Network (DC-CNN). Generally, each neuron of a convolutional neural network (CNN) consists of a feature extraction layer responsible for extracting the local features of the previous neuron and a feature mapping layer consisting of multiple feature-mapping planes together required during the computation of that neuron.

As shown in Figure 6, the expanded convolution is combined with causal convolution to form an expanded causal convolutional neural network (DC-CNN). This network can control the speech data to be transmitted backward in an orderly manner in time order but also can expand the perceptual field without increasing the number of layers of the neural network and the size of the convolutional kernel, which makes it have excellent performance in processing speech signal data.

4.2. Structure of the DC-CNN-Based Music Notation Recognition Model. The speech signal x_T is predicted to be reduced by the input speech signal before time T with the reduction factor h . The multidimensional joint variable distribution of speech signal sequences $X = (x_1, x_2, \dots, x_T)$ over a period of time can be expressed as

$$P(X) = \prod_{t=1}^T P(x_t | x_1, x_2, \dots, x_{t-1}, h). \quad (2)$$

As shown in Figure 7, in order to make the music notation recognition sequence generated with the aforementioned conditional probability, the neural network body of the DC-CNN-based music notation recognition model is modeled with a multilayer stack of expanded causal convolutional blocks and a nonlinear mapping is achieved by introducing a gate activation function.

5. Experimental Analysis

A server with a Xeon(R) E5-2620 processor and an NVIDIA Quadro M4000 high-performance computing unit was used to train a reduced model with a 20-layer convolutional neural network. The 20-layer convolutional neural network is divided into 2 convolutional blocks, and the expansion coefficients in each block are (20, 21, 22, . . . , 29) in order. The size of the perceptual field in the reduced model is 128 ms, the number of connected channels in the leap layer is 256, and the initial learning rate is set to 10⁻³. 869 audio segments are selected for the training set, and the test set consists of 2 piano pieces and 503 English speech segments, all of which are sampled at 16 kHz and quantized at 16 bits [27–30].

The average training time per iteration was 5.0316 s for the piano piece and 3.7273 s for the English speech, and the average training time per 1 s speech was about 36.15 s.

5.1. Acoustic Features for Music Notation Recognition. The broadband speech spectrograms of the reduced piano piece and English speech are extracted, and the speech spectral envelope structure is observed, and the vocal pattern features are analyzed. As shown in Figure 8, the restored piano piece is weak in noise, with good audio continuity and a high restoration rate in the low-frequency part.

FIGURE 6: Schematic diagram of the expanded causal convolutional neural network.

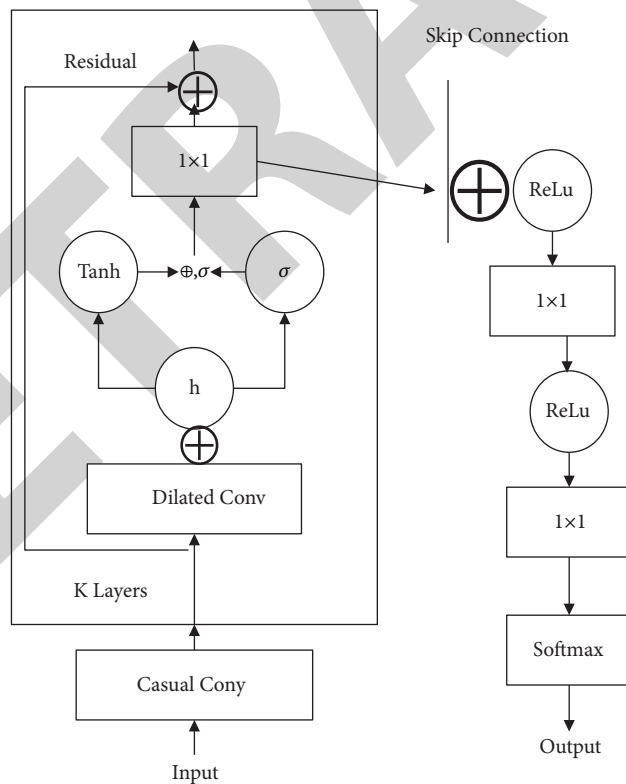

FIGURE 7: Structure of the DC-CNN-based music notation recognition model.

By comparing the broadband spectrograms of piano pieces with those of English speech, we can see that the broadband spectrograms of the model-reduced speech are clear, with obvious waveforms and high reduction rates.

5.2. *LPC Data Analysis for Music Notation Recognition.* Linear predictive coding (LPC) was first applied to speech analysis and synthesis by Itakura et al. in 1967 and has been widely used in speech signal processing technology since then.

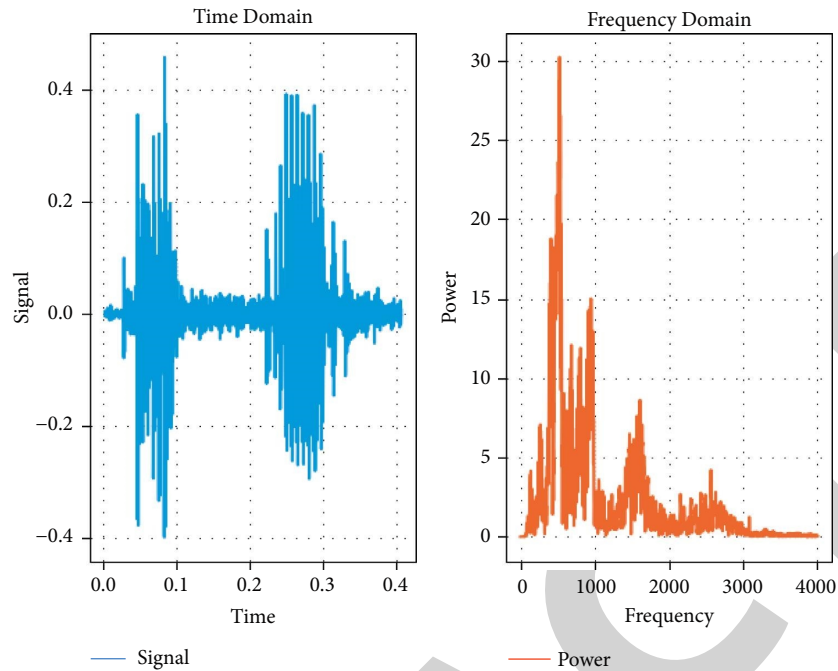

FIGURE 8: Broadband speech spectrogram of music notation recognition and original speech (partial).

As shown in Figures 9 and 10, LPC data were analyzed separately for the reduced piano music and English speech and the resonance peaks of the music notation recognition and the original speech were consistent with each other; the positions of the resonance peaks generally matched, with only deviations in the intensity of the sound. In Figures 9 and 10, the black solid line and gray solid line indicate the LPC data of music notation recognition and original speech, respectively.

The deviation between the arithmetic mean of music notation recognition and the arithmetic mean of the original speech was calculated for these main parameters. From Table 1, it can be seen that the center frequencies of the musical notation recognition of piano pieces and English speech are very close to their corresponding original speech, and the absolute average deviations of the two are 3.79% and 0.97%, respectively; the intensity of the sound is the second, and the absolute deviations of each artifact are within 13%. Only the bandwidth has a certain degree of deviation.

The analysis results prove that the proposed reduction model can achieve high-quality resonance peak waveform recovery; the overall reduction fit rates of the resonance peak parameters of piano music and English speech reach 79.03% and 79.06%, respectively, which are 44.03% and 44.06% higher than the 35% similarity ratio between the electronic artifact speech and the original speech, respectively.

5.3. Human Audiometric Identification of Sameness for Music Notation Recognition. In addition to the electroacoustic instrumentation, 15 volunteers were invited to conduct human ear audiometry to identify the identity of the electronic artifacts and music notation recognition of piano pieces and English speech, respectively, with their corresponding original

FIGURE 9: Graph of LPC data analysis of music notation recognition of piano pieces with original speech (partial).

speech. In the statistical results listed in Table 2, the percentage of identity between the musical notation recognition and the corresponding original speech for piano and English speech increased significantly compared with the percentage of identity between the electronic artifacts and their corresponding original speech, with a maximum increase of 46.67% and a minimum increase of 26.66%, indicating that the reduction model can effectively reduce the electronic artifacts in the speech and make the musical notation recognition closer to the original speech in terms of human ear primary observation.

Due to the influence of noise, the human auditory recognition results of music notation recognition differed

from the vocal pattern characteristics and LPC data analysis, so the percentage of volunteers judged the same source as the original speech during human auditory recognition for the noisy music notation recognition was low. In addition, the quality of the music notation recognition was affected by the μ -law compression and amplification conversion of the original speech and the auditory effect was not good, which made some of the audio less effective in the human auditory recognition experiment.

6. Conclusion

With the advancement of electronic synthesis technology, computer technology for piano notation and electronic synthesis plays an important role in electronic music but also in various musical themes. In this paper, we analyze and study the piano score and electronic synthesis system module using the Beaulieu analysis method. We extract music information from digital scores, thus converting music information to MIDI files, reconstructing the score, and providing an audio carrier for score transmission. The experimental results show that the system has a correct rate of 94.4% in extracting music information from piano sheet music, which can meet the needs of practical applications and provide a new way for music digital library, music education, and music theory analysis.

Music performance research is a comprehensive study of aspects such as emotional analysis and personalisation in music performance, which help to add richness and creativity to the art of music performance. The labels in this paper in collaborative annotation contain rich personalised descriptive information as well as item content information and can therefore be used to help provide better recommendations. The algorithm is based on bipartite graph node structure similarity and restarted random wandering. It analyses the connection between users, items, and tags in the music social network, firstly constructs the adjacency relationship between music and tags, obtains the music recommendation list and indirectly associated music collection, then fuses the results according to the proposed algorithm, and reorders them to obtain the final recommendation list, thus realising the personalised music recommendation algorithm. The experiments show that the proposed method can meet the personalised demand of users for music on this dataset.

1. Introduction

As an important vehicle to showcase the charm of music, music performance art can play a role in enriching the form of musical expression and enhancing the connotation of music performance art [1]. It is also an important vehicle for the expression of music and the enhancement of its connotation. The addition of modern music aesthetics to music performance art can, on the one hand, inject strong expressive power into the art and, on the other hand, bring audiences the ultimate visual and audio enjoyment [2]. The study of modern music aesthetics can contribute to the progress and innovation of music performance art and can also attract more people to the art of music performance, thus contributing to the overall development of the music industry. The study of contemporary music aesthetics is therefore important and needs to be implemented as soon as possible [3].

Music aesthetics has a long history and culture. As early as the ancient Greeks, Pythagoras and Plato noted the therapeutic effect of musical aesthetics on the human mood and how the good or bad character of music could make the

listener's soul beautiful or ugly [4]. However, they were constrained by their time to explain the reason for this, thus giving a strong mystical dimension to musical aesthetics [5]. As the times have developed, modern musical aesthetics is no longer unknown and has extended into two directions of study, psychological and social [6]. The psychological dimension of modern music aesthetics follows the same direction as that of the ancient Greeks, in that it relates to the psychological knowledge of people's reactions to listening to music in order to find the differences between the general mental activity and the psychological activity of music aesthetics [7]. The social dimension of modern music aesthetics is to relate music to social issues, for example, by analysing the social issues of the time in which the music was composed through the context in which it was written [8].

The art of music performance is a secondary activity of music creation. For the performer, it is a way of presenting the full range of musical achievements in the form of vocal, instrumental, and dramatic music, thus expressing the ideological content of the music [9]. For the listener, the art of music performance is not only an essential way of appreciating and understanding the content and form of music

but also a way of identifying and recognising the different interpretations of music by different music performers through the comparison of different performances. At the same time, different performance styles, genres, and techniques will enhance the audience's understanding of the music, thus giving them a sense of thought and emotional resonance [10].

With the development of information technology and the Internet, people are gradually moving from an era of information scarcity to an era of information overload. In this era, both information consumers and information producers have encountered great challenges: for information consumers, it is very difficult to find the information they are interested in from a large amount of information; according to the different technologies used, music recommendation systems can be broadly divided into three categories: content-based recommendation algorithms, collaborative filtering recommendation algorithms, and hybrid recommendation algorithms [11]. Content-based recommendation algorithms select appropriate items for recommendation based on the item's attribute associations, the location of the item, the item's metainformation (keywords describing the item, in the case of music, album, genre, artist name, lyrics, audio, etc. [12]), and the user's history [13]. However, the keywords used by the user do not correspond well to the item description tags, and converting audio information to digital information leads to increased computation and response time. This content-based approach also ignores the similarity of interests between different users and is therefore not well suited to community-based networks [14].

However, model-based algorithms are usually very time-consuming to build and update, and they do not cover all users as well as memory-based algorithms [15]. Collaborative filtering recommendation algorithms and content-based recommendation algorithms each have their own focus and shortcomings [16]. The main idea of the hybrid recommendation algorithm is to combine the above two recommendation methods in order to make full use of the information of users and resources. One of the most influential systems is the Fab [17] from Stanford University. There are also many research results in China in this area [18].

In order to achieve the recommendation of music that users may be interested in, this paper makes use of the information provided in social networks as much as possible and explores the intrinsic connection between users, tags, and items [19]. First, the two bipartite graphs of the user song and tag song are used to build the adjacency matrices of items and tags, respectively; then, the user vector is used to perform a restart-type random walk on the two adjacency matrices to obtain the list of related songs and related tags of the user; finally, the first N tags of the related tag list are selected. Finally, the top N tags of the relevant tag list are selected and the indirectly associated music set is mined from the tag-song relationship. The indirectly associated music set is used to adjust the ranking of the user's relevant song list and recommend the items with high scores to the user. Experimentation on the corpus collected by Last.fm shows that the proposed method performs better than the collaborative filtering algorithm [20].

2. Theory Related to Recommendation Algorithms

In traditional collaborative recommendation systems, users are required to give explicit ratings to indicate their liking of the item, and these ratings are generally limited and discrete. The memory-based algorithm can be divided into user-based and item-based collaborative filtering recommendation algorithms.

The user-based collaborative filtering algorithm is based on the assumption that if users rate some items similarly, they will also rate other items similarly. The algorithm approximates the target user's ratings of an item based on the ratings of the target user's nearest neighbours (the most similar users). Define the target user a and its unrated item i . Then, predict a 's rating of I as follows:

$$p_{a,i} = \bar{r}_a + \frac{\sum_{u=1}^K (r_{u,i} - \bar{r}_u) \omega_{a,u}}{\sum_{u=1}^N \omega_{a,u}}, \quad (1)$$

where $r_{u,i}$ denotes the rating of item i by the user u , \bar{r}_u and r_u denote the average rating of the user a and the user u , respectively, and $\omega_{a,u}$ denotes the similarity between the user u and the user a .

In contrast, the item-based collaborative filtering algorithm considers that there is similarity in users' ratings of different items, and when it is necessary to estimate users' ratings of an item, it can be estimated using users' ratings of several similar items of that item, as shown in the following equation:

$$p_{a,i} = \bar{r}_i + \frac{\sum_{k=1}^M (r_{a,k} - \bar{r}_k) \omega_{i,k}}{\sum_{k=1}^M \omega_{i,k}}, \quad (2)$$

where \bar{r}_k denotes the average score of the item I and $\omega_{i,k}$ denotes the similarity between the item i and the item k . In practical commercial applications, the user-based collaborative filtering algorithm is more efficient than the item-based one. In the corpus used in this paper, the number of songs is much larger than the number of users, and for efficiency, the user-based collaborative filtering algorithm is used as the comparison experiment in this paper.

Regardless of the method, the similarity between items and items or between users and users is calculated when predicting the score. There are many ways to calculate the similarity, but the most popular Pearson correlation coefficient is used in this paper, as shown in the following equation:

$$\omega_{a,u} = \frac{\sum_{i=1}^M (r_{a,i} - \bar{r}_a)(r_{u,i} - \bar{r}_u)}{\sqrt{\sum_{i \in I_a \cap I_u} (r_{a,i} - \bar{r}_a)^2} \sqrt{\sum_{i \in I_a \cap I_u} (r_{u,i} - \bar{r}_u)^2}}, \quad (3)$$

Obviously, in this algorithm, the more items the users rate together, the higher the similarity. However, assuming that both users only rate the same item, the similarity between the two users calculated by this method is very large, which is not reasonable. In order to reduce this situation, it is set that if the number of items jointly rated by two users, n , is less than the threshold $T\bar{r}$, then the similarity is multiplied by

a factor. In addition, this paper uses the k -nearest neighbour method to select similar users of the target user.

The dataset used in this paper is based on the number of times a user listens to a song to indicate how much the user likes a particular song, rather than an explicit rating of the item by the user based on their own liking. In order to fuse the label information, the similarity between users $\omega(UTr)_{a,u}$, u , and $\alpha\omega(UTr)_{a,u}$ is first calculated from the number of times a user listens to a song and the user's label, respectively, and the sum of the two is used as $\omega_{a,u}$, as shown in the following equation:

$$\omega_{a,u} = \alpha\omega(UTr)_{a,u} + \beta\omega(UTg)_{a,u}, \quad (4)$$

where $\alpha + \beta = 1$.

3. Music Recommendation Algorithm

We present the personalised music recommendation algorithm based on latent semantic mining in the user-tag item starting with the two-part diagram, followed by the latent semantic mining algorithm on the three-part diagram.

3.1. Correlation Matrix for Two-Part Diagrams. The relationship between a user and a song can be represented as a bipartite graph $G1 = \langle U, E1 \rangle$, where the set of vertices U represents the set of users in the recommender system, and if user u_i has listened to music Tr_j , then an edge Tr_j is created between u_i and the number of times the user has listened to the music. Similarly, the relationship between a user and a label can be represented as a bipartite graph $G2 = \langle U, E2 \rangle$, where an edge is created between the user and the label if there is a connection between the two. Then, the above two bipartite graphs are projected onto the dimensions of music and tag, respectively, and the weights of the edges between the node i and the node j after the projection represent the similarity between music (tag) i and music (tag) j . In this paper, the cosine method is chosen to calculate the node similarity, as shown in the following equation:

$$\omega_{i,j} = \frac{|\Gamma_i \cap \Gamma_j|}{\sqrt{|\Gamma_i| |\Gamma_j|}}, \quad (5)$$

where Γ_i is the set of neighbouring nodes of the node i before projection.

3.2. Recommendation Algorithms Based on Bipartite Graphs. The two-part graph-based recommendation algorithm estimates the relationship between users and items by ranking them. The algorithm represents a user node as a vector, and each dimension of the vector represents an item in the association graph, whose value in this paper records the number of times the user has listened to the music node or has used the tag, i.e., the user's interest in the song or tag. The algorithm uses the random walk with the restart model (RWR) to predict the interest of the user node u_i in node Tr_j or Tg_j . The random walk starts from the user node and traverses the whole graph. For any node, the traverser walks

with probability $1 - a$ to the node's neighbouring nodes and returns to the node with probability a to start the walk again. Each walk yields a probability distribution that describes the probability that each vertex in the graph will be visited. This probability distribution is used as input for the next walk, and the process is iterated over and over. The probability distribution of this point converges when the previous and next probability distributions are the same or essentially similar. After convergence, a stable probability distribution is obtained, which represents the closeness of the user node to the project.

For the bipartite graph composed of user music, definition \mathbf{U}_i^{tr} is a user query vector built from the record of songs listened to by user u_i in the training set, with playcount denoting the number of times the user listened to the j th song, and vector q_i is a normalized vector of \mathbf{U}_i^{tr} . Each dimensional element of \mathbf{U}_i^{tr} is defined as shown in the following equation:

$$\mathbf{U}_i^{tr} = \begin{cases} \text{playcount,} \\ 0. \end{cases} \quad (6)$$

The purpose of the algorithm is to obtain the music items that are most closely related to the user. If the association graph consists of N music nodes, the steady-state probability vector $\mathbf{S}_i^{tr} = [S_i^{tr}(1), S_i^{tr}(2), \dots, S_i^{tr}(N)]$ corresponding to u_i is the desired one. After experimental verification, \mathbf{S}_i^{tr} has reached convergence when the number of iterations $t = 10$.

3.3. Semantic Mining. Each user has their own interests, which are presented in the form of tags on their personal description page. When a user listens to music, social media allows the user to tag the item, and these tags reveal the user's perception of the item they are currently listening to. Over time, users' tags become richer and more sophisticated; in addition, a single item can be tagged by multiple users. For these reasons, there is a phenomenon in social media where different users have different perceptions of the same music item and where multiple tags for a music item may imply the same meaning. Therefore, we propose the following idea: a bipartite graph can be used to mine tags with the same meaning; the more tags an item and a user have in common (including similar meanings), the more the user is associated with the item. The workflow of a personalised recommendation system based on potential semantic mining in user-tag music is shown in Figure 1.

The same algorithm is applied to the user-tag bipartite graph to obtain a list of tags associated with the current user. $\mathbf{S}_i^{tg} = [S_i^{tg}(1), S_i^{tg}(2), \dots, S_i^{tg}(M)]$. The difference is that the list of tags obtained by this method does not exclude the tags used by the user itself, as these tags clearly indicate the interests of the user. Then, the N tags with the highest relevance to the user are selected and the music collection corresponding to these tags is extracted, which is defined as the "indirectly related music collection." Finally, the list of song recommendations is modified and reordered according to the song collection, and the final recommendation results are obtained. The weighting equation (7) is used to readjust the song weights:

FIGURE 1: Flowchart of the user-tag-music-based recommendation algorithm.

$$\omega'_{i,j} = \omega_{i,j} \times \left(1 + \frac{m}{p}\right), \quad (7)$$

where m denotes the number of occurrences of an identical song corresponding to different tags and p denotes the ranking position of the song in the intersection set (an intersection set is an ordered set of intersections between a collection of indirectly associated music and the original recommendation list by weight). It reflects two ideas: (1) the music corresponding to the tag that is more associated with the user is also more associated with the user; (2) multiple tags associated with the user correspond to the same music, which is more associated with the user. After adjusting the weights, the music is reordered in descending order of weights and top N is rerecommended to users. After counting the data in the dataset, the average number of tags per user is 10. Therefore, the number of relevant tags for a user should be more than the number of tags owned by the user itself, so as to obtain extended tags and more information. However, the more relevant the tags are, the more computationally intensive the algorithm will be and the efficiency of the algorithm will be reduced. Based on the above two points, 30 tags with high relevance to the user will be selected for the calculation in this paper [21, 22].

4. Analysis of Experimental Results

4.1. Last.fm Dataset. Last.fm is a musical social network that allows users to create their own personal pages, make friends, add tags, and record the names and times they listen

to songs. In 2008, the Computer Science and Technology Laboratory at the University of Glasgow collected and extracted a corpus from the music community site Last.fm and made it publicly available for scholarly research. The corpus contains 3,148 users, 30,520 songs, 12,565 tags, and 5,616 friendships among 3,148 users. This paper is a study of this corpus [23, 24].

For each user, all songs in the corpus are divided into three parts: the training set, which is 80% of the songs that the user has listened to; the test set, which is 20% of the songs that the user has listened to; and the set of songs that the user has not listened to.

4.2. Experimental Results and Analysis. In this paper, we compare the user-based collaborative filtering recommendation algorithm with the bipartite graph-based collaborative recommendation algorithm, where each set of experiments is designed to compare the recommendation algorithm with the simple model after adding the label information adjustment. The experiments using the user-music relationship and the experiments adjusted by adding user label information are denoted by UT_r and UT_rTg , respectively. The experiments use $P@N$ as the evaluation index, and for each method, $P@5$, $P@10$, $P@20$, $P@100$, and $P@200$ are calculated for the comparison experiments. Table 1 shows a comparison of the effectiveness of different recommendation algorithms using Last.fm as the dataset [25, 26].

As shown in the last row of Table 1, the two-part graph-based collaborative recommendation algorithm is significantly more effective than the user-based collaborative filtering algorithm in the same dataset, and the RWR algorithm with user labels is optimal. This is because the user-based recommendation algorithm only considers the relevance of the users and ignores the relevance between items.

As shown in Figure 2, after the user-based collaborative filtering algorithm is adjusted with the tag information, the overall recommendation effect does not improve, but the recommendation accuracy rate decreases. The reason for this is that although there are 12565 tags in the dataset, the average number of tags per user is 10 according to the experimental statistics. This means that there are very few edges in the user-tag bipartite graph, making the correlation between users obtained from this bipartite graph very small. When a simple weighted sum is applied to the user association matrix obtained from the user-music bipartite graph, the degree of association between users who are already closely related is reduced to some extent, resulting in a decrease in recommendation accuracy. This is a good algorithm if the density of user labels grows with time. In short, social tagging is still a hot topic and a focus of research.

For the improved bipartite graph-based collaborative recommendation algorithm, the accuracy of the recommendations was improved by adding label information and reordering the recommendations, but the effect was not very obvious. The user's browsing habits are mainly

TABLE 1: Comparison of the experimental results of the RWR and CF algorithms.

Method	Specific methods	MAP	P@5	P@10	P@20	P@100	P@200
CF	UT_r	0.031	0.142	0.124	0.091	0.047	0.035
	UT_rTg	0.021	0.1101	0.0801	0.0701	0.0385	0.0247
RWR	UT_r	0.1024	0.2415	0.3102	0.4412	0.3254	0.2091
	UT_rTg	0.1021	0.2102	0.3251	0.4127	0.3524	0.2021

FIGURE 2: Effect of different music recommendations.

focused on the first 20 items in the return list, and the items after that are rarely noticed by the user, so the main goal of this algorithm is to improve the accuracy of the first 20 items in the recommendation list. As can be seen from Figure 3, the algorithm in this paper mainly improves P@10. This is due to the nature of the dataset used. Last.fm has a large number of users and songs, but users rarely tag themselves and their songs, so there are even fewer suitable tags that can accurately locate users and songs. The density of user tags and music tags in the dataset is 4.6×10^{-4} and 3.2×10^{-4} , respectively, making the social tagging information sparse and inevitably mixed with some noisy tags. This makes the application of socially annotated information more difficult. Despite this, the proposed algorithm improves the recommendation results, and as time goes by and the user information and social labeling information become richer, personalised recommendations using community network graphs will be more in line with the interests of users.

As shown in Figure 4, in terms of computational efficiency, given the association matrix TR, the recommendation algorithm based on social annotation and bipartite graphs can obtain a recommendation in $O(n^2)$ time with a small number of iterations. However, one of the problems with this algorithm is that if one node in the association matrix TR is updated, the whole association matrix needs to be updated, which will consume $O(n^2)$ time.

FIGURE 3: Distribution of different levels of music appreciation.

FIGURE 4: Correlation matrix of different music recommendations.

5. Conclusions

The aesthetics of modern music is mainly presented through the art of music performance, which, on the one hand, allows the listener to gain knowledge of the music by learning about

its creator and the context in which it was created. On the other hand, music as an emotional carrier carries the full emotion of the music creator, and by listening to music, listeners can have a spiritual resonance with the music creator across generations. In this paper, the bipartite graph-based collaborative recommendation algorithm is further improved by mining the underlying semantics to make more accurate music recommendations. The results of the comparison with the user-based collaborative filtering algorithm and the bipartite graph-based collaborative recommendation algorithm on the same dataset show that this method is a good strategy for personalised recommendation, especially with the development of Web 2.0 and the increase of tags, this method will show a greater advantage.

The stable development of agriculture is related to the national economy, and the fragility and foundation of agricultural production determine the inherent requirements of the government for financial support of agriculture. Based on China's policy of agricultural subsidy, in this study, the basic characteristics and classification methods of agricultural subsidies are analyzed, and an evaluation model of agricultural subsidies is established based on a combined algorithm, where the attributes of agricultural subsidies are screened by analytic hierarchy process, and the evaluation process of agricultural subsidies is constructed by data envelopment approach. Moreover, the development level of regional financial subsidies for agriculture is measured by relative efficiency value, and the implementation direction of financial subsidies is evaluated, to enhance the administrative benefits of government finance and deepen the supply-side reform of agricultural financial subsidies, which promote the sustainable development of agricultural insurance and agricultural production.

1. Introduction

Agriculture is the foundation of human existence, which provides necessary conditions for all production activities, and is the foundation of social stability and economic development. However, agricultural production is restricted by the natural environment with inherent weakness, low efficiency, and high risk. At the same time, with the marketization of China's socialist economy, the problem of "agriculture, rural areas, and rural residents" has become increasingly prominent [1–3]. Therefore, in recent years, the Central Committee of the Communist Party of China has issued a series of policies to strengthen agriculture and benefit farmers, where the financial support and protection for agriculture, rural areas, and rural residents have been continuously enhanced. A subsidy is the way that the government provides transferred payment to the production, circulation, and trade of agricultural products through administrative means [4, 5]. It helps to support and protect

the agricultural field, which plays a very important role in promoting agricultural development, healthy operation of national economy, and protecting farmers' interests, and occupies an important position in the economic policies in the world.

However, there are many outstanding problems of supply-side structural contradictions in China's agricultural development at present. Although the total amount of grain is increasing continuously, due to the change in social demand, the imbalance of supply, and demand structure of agricultural products, the costs of agricultural production has been rapidly increased, and the comparative benefits and internal motivation of agricultural development are obviously weakened [6–8]. For a long time, China's cultivated land resources have been relatively short. Under the condition of overexploitation of cultivated land and serious pollution, the pressure on agricultural resources and environment has become greater. In addition, some policies of agricultural subsidy are biased in pertinence due to

imperfect guiding mechanism, which leads to the continuous weakening of agricultural subsidies.

The performance evaluation of agricultural subsidies refers to the use of a method or model to measure the efficiency of agricultural financial subsidies and to measure the achievement of government performance in the process of agricultural financial subsidies or the governance efficiency of government in the process of agricultural development participation [9, 10]. Through the results of performance evaluation, the shortcomings can be found in the process of government administration, which provides guidance for the improvement and stable implementation of the follow-up agricultural financial subsidies.

2. Basis of Agricultural Subsidies

Agricultural subsidies are part of financial subsidies, by implementing specific financial support for some specific projects, and according to certain subsidy basis and standards, the supply and demand structure of agricultural products and agricultural means of production is changed, thus generating the income effect and substitution effect, which is a kind of transfer expenditure of the government with guiding function.

2.1. Basic Characteristics of Agricultural Subsidies. From the connotation of the abovementioned agricultural subsidy policy, it can be known that the characteristics of agricultural subsidy policy mainly include the following points [11–14]:

- (1) The main body of agricultural subsidy policy is the government. No matter what kind of agricultural subsidies are adopted, the subsidy funds will ultimately come from fiscal revenue.
- (2) Agricultural subsidy belongs to the government's transfer expenditure; that is, it is a unilateral and unpaid transfer of funds given by the government to agricultural producers, consumers, or operators. Agricultural producers, consumers, or operators who get agricultural subsidies will inevitably get certain benefits that are not equivalent. A subsidy is a kind of pure benefit increase or cost decrease, so agricultural subsidy must be a behavior of transfer payment.
- (3) The policy objectives of agricultural subsidies are often diversified and phased. There are three main objectives of agricultural subsidy policy: ensuring food security; raising farmers' income level; and realizing the sustainable development of agriculture and rural economy, which will be adjusted correspondingly with the changes in economic development level, industrial structure, and other related economic variables.
- (4) Agricultural subsidies are diversified and flexible. The diversified characteristics of agricultural subsidy policy inevitably require that agricultural subsidy methods have both diversity and flexibility.

2.2. Classification of Agricultural Subsidies. As shown in Figure 1, according to different classification standards, agricultural subsidy policies can be classified in many different ways. In the light of different links of agricultural production, subsidy policies can be divided into productive subsidies, circulation subsidies, and income subsidies, while according to different payment methods, agricultural subsidy policies can be divided into direct subsidy and indirect subsidies [15–17]. Meanwhile, according to different subsidy objects, it can be divided into producer subsidy, consumer subsidy, and operator subsidy.

According to the functional mechanism of agricultural subsidies, this study divides them into four types: income-based agricultural subsidies, cost-based agricultural subsidies, technology-based agricultural subsidies, and price-based agricultural subsidies, as shown in Figure 2.

2.2.1. Income-Based Agricultural Subsidies. It refers to the agricultural subsidy policy that directly subsidizes farmers to increase their income, thus affecting the total expenditure of farmers' agricultural budget. Hook grain direct subsidies and Hook comprehensive agricultural resources subsidies belong to income-based agricultural subsidies, while unhook grain direct subsidy generally takes the taxable farmland or taxable regular production as the basis of grain direct subsidy, where whether farmers actually plant or not, there is subsidy when there is contracted land, which is a kind of inclusive subsidy and belongs to income-based agricultural subsidy policy. The way and mechanism of unhook agricultural comprehensive subsidies are similar to those of unhook grain direct subsidies, so unhook agricultural comprehensive subsidies also belong to income agricultural subsidies.

2.2.2. Cost-Based Agricultural Subsidies. By reducing the cost of grain production, it can mobilize farmers' enthusiasm for growing grain, which promotes the increase in grain production and increases farmers' income level. Unhook direct grain subsidies and unhook comprehensive agricultural subsidies are cost-based agricultural subsidies. Hook grain direct subsidy means that the grain direct subsidy is linked to the current agricultural production and planting situation; that is, linked grain direct subsidy is subsidized according to the actual grain planting area of farmers, and the amount of direct grain subsidy is linked to the planting area. Hook grain direct subsidy can reduce the cost of grain production, mobilize farmers' enthusiasm for growing grain, and thus promote the increase in grain production and farmers' income, so it is a cost-based agricultural subsidy policy. The same argument, hook comprehensive agricultural subsidies also belong to the cost-based agricultural subsidy.

2.2.3. Technology-Based Agricultural Subsidies. It refers to the policy that advances the agricultural production mode through new products and technologies, thus improving the production efficiency of agricultural products. Improved varieties' subsidy, farm machinery purchase subsidies, etc.,

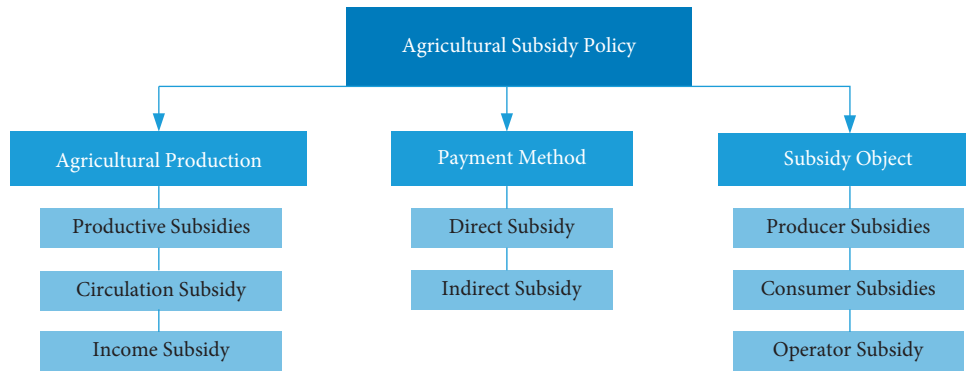

FIGURE 1: Classification of agricultural subsidies.

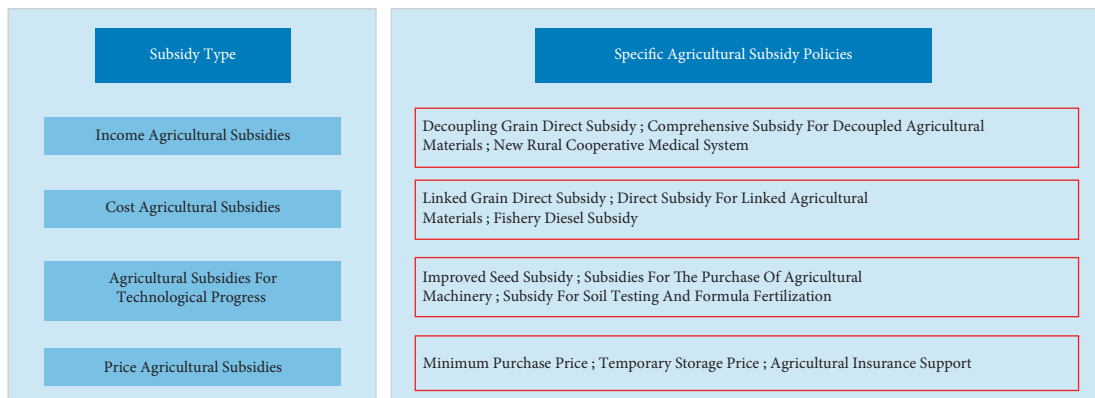

FIGURE 2: Classification of agricultural subsidies based on mechanism of action.

are technology-based agricultural subsidies. Improved varieties’ subsidy is a subsidy given by the government to farmers who use high-quality seed, which guides farmers to adopt new varieties and technologies and improves the output and quality of agricultural products, while farm machinery purchase subsidy is a subsidy given by the government to farmers who purchase farm machinery within the scope specified in the catalogue, which encourages and supports farmers to use advanced and applicable farm machinery, improves the mechanization process, and thus increases the output of agricultural products. Therefore, it belongs to the technology-based agricultural subsidies.

2.2.4. *Price-Based Agricultural Subsidies.* It refers to the policy that promotes the development of grain production, protects farmers’ enthusiasm for growing grain, and guarantees farmers’ income from growing grain by stabilizing or influencing the prices of agricultural products, where the minimum purchase price, temporary purchasing and storage price, etc., are price-based agricultural subsidies.

3. Evaluation Model of Agricultural Subsidy Based on Combined Algorithm

3.1. *Screen of Agricultural Subsidy Attribute Based on AHP.* Analytic hierarchy process (AHP) is a process of modeling and quantifying the decision-making thinking process of

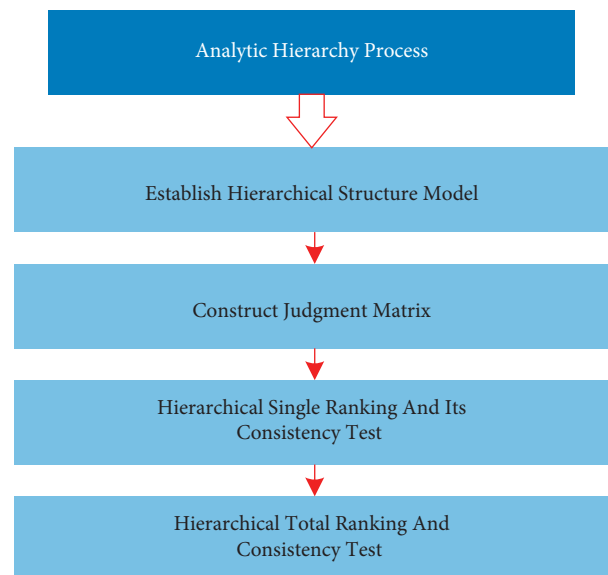

FIGURE 3: Steps of AHP based on classification of agricultural subsidies.

decision-makers on complex systems, which is a hierarchical weight decision analysis method combining qualitative and quantitative analysis, where the decision-maker points out the standard weight of each decision scheme and calculates the ranking of the alternatives using the weight of each decision

FIGURE 4: AHP hierarchy.

scheme [18]. According to the classification of subsidy mentioned above, the analytic hierarchy process adopted in this study is divided into the steps as shown in Figure 3.

3.1.1. Establish a Hierarchical Structure Model. The targets, factors, and objects are divided into target level, criterion level, and scheme level according to their relationships, and the hierarchical structure is shown in Figure 4.

The decision-makers point out the weight of each scheme and then adopt the weight to calculate the ranking of the advantages and disadvantages of each alternative scheme. When there are many factors at a certain level, the layer can be further divided into sublayer orders of the next order [19].

3.1.2. Construct a Judgment Matrix. The judgment matrix compares each other between pairwise, which is to reduce as little as possible the difficulty of comparing various factors due to different nature, thus improving the accuracy of the decision-making model. Assume that the elements of the judgment matrix are a_{ij} , which is generally given by the Saaty 1–9 scale method, where i and j are horizontal and vertical coordinates, respectively. When using the numerical ratio with practical significance, the construction of the judgment matrix can express the importance degree between pairwise.

3.1.3. Hierarchical Single Sorting and Its Consistency Test. The judgment matrix established in the second step is solved. The formula for characteristic root is as follows: $\bar{A}W = \lambda_{\max}W$. The eigenvector of W is obtained, the hierarchical single sort is solved, and the consistency of hierarchical single sort is checked. Here, you can define the consistency index formula (CI). The formula is as follows, where n is the order of the judgment matrix.

When solving the characteristic root of judgment matrix \bar{A} , which has been established in the second step, the eigenvector W can be obtained in the formula $\bar{A}W = \lambda_{\max}W$. Then, the consistency test of a single order of levels is

implemented; here, the consistency index formula CI is defined as follows, where n is the order of the judgment matrix:

$$CI = \frac{\lambda_{\max} - n}{n - 1}. \quad (1)$$

The consistency ratio (CR) is defined, and its calculation formula is as follows:

$$CR = \frac{CI}{RI} \quad (2)$$

When the consistency ratio $CR < 0.1$, it is considered that the degree of inconsistency of hierarchical single sorting is within the allowable range, and the result has satisfactory consistency; otherwise, the scoring matrix should be reconstructed [20].

3.1.4. Hierarchical Total Sorting and Consistency Test. In this study, it is assumed that the upper level A contains m factors, which are A_1, A_2, \dots, A_m , respectively, and then, the total sorting weights of these elements are a_1, a_2, \dots, a_m , respectively. In addition, it is assumed that the next level B of the elements in the upper level contains n factors, which are B_1, B_2, \dots, B_n , and then the single sorting weights of these elements for factor A_j , including $b_{1j}, b_{2j}, \dots, b_{nj}$ (if B_k and A_j are not related, $b_{kj} = 0$).

If in hierarchy B the consistency index of the hierarchical single ordering of element A_j of some factors is CI_j , then the average random consistency index corresponding to these elements is RI_j , and the calculation formula of the random consistency ratio of the total ordering of element B is shown as follows:

$$CR = \frac{\sum_{j=1}^m a_j CI_j}{\sum_{j=1}^m a_j RI_j}. \quad (3)$$

3.2. Process of Agricultural Subsidy Evaluation Based on Data Envelopment Analysis. As shown in Figure 5, the experimental process of data envelopment method can be divided into four modules [21, 22].

FIGURE 5: Experimental flow of data envelopment method.

3.2.1. Define Data Variables. It consists of two parts: “determine the evaluation target” and “select the decision-making unit.” The evaluation target of this study is to realize performance evaluation of the government’s agricultural financial subsidy policy, whose experimental process mainly refers to DEA, where the input and output of different subsidy categories are selected as decision-making units, including income subsidies, cost subsidies, technology subsidies, and price subsidies.

3.2.2. Determine the Objective Function. It is mainly to establish input and output target system, which is mainly based on a decision-making unit of the module, where the input target and output target systems are based on the selection of AHP indicators, and the indicators in data envelopment method are established as shown in Figure 6.

The determined index system takes the per capita net income of rural residents, the proportion of agricultural employees, the average household population, the per capita common cultivated land area, the amount of chemical fertilizer used per acre, and the effective irrigated cultivated land area as the input indexes of decision-making unit in DEA and takes the agricultural development status, cultivated land endowment, rural labor force, and production factors as the output indexes of DEA decision-making unit.

3.2.3. Choose DEA Model. CCR model is selected as the performance evaluation model of agricultural insurance financial subsidy. CCR model assumes that the production

technology of the decision-making unit is constant to scale return and determines whether the decision-making unit is DEA effective by constructing production front.

3.2.4. Establish Constraints. This module is the regulating variable in the whole performance evaluation process of agricultural financial subsidies, which controls whether the evaluation results are recognized by evaluators or relevant agricultural participants. Model participants can set constraint thresholds according to the existing experience of agricultural subsidies policies. If the evaluation results are accepted, the effectiveness of the DEA evaluation model is recognized and the model evaluation can be implemented. Otherwise, Step 3 is returned, the evaluation model is replaced or the AHP algorithm is adjusted to alter the evaluation index system, and then Step 4 is restarted.

3.3. Evaluation Model of Agricultural Financial Subsidies Based on Combination Algorithm. As shown in Figure 7, the evaluation model of agricultural financial subsidies proposed in this study is mainly divided into two modules: AHP module and DEA module, in which the main function of AHP module is to determine the evaluation index of DEA module; and DEA module establishes the evaluation target system according to the results of AHP, thus determining each decision-making unit and then evaluating agricultural financial subsidies.

The third-order hierarchical model of evaluation index is constructed as shown in Figure 8, in which the first-level index is the evaluation index system of agricultural financial subsidy policy that is also the target level of this evaluation index, the second-level index system includes scale index, efficiency index, influence index, and sustainability index, and the third-level index is the basic index related to the evaluation of agricultural financial subsidy.

The hierarchical total sorting of all judgment matrices is carried out by the index weight values under the single sorting of each level through the consistency test, and the results of the hierarchy total sorting are checked for consistency, as shown in Table 1.

4. Results and Discussion

The decision-making units in this study included income subsidies, cost subsidies, technology subsidies, and price subsidies. According to the results in Table 1, in the ranking of three-level indicators, four indicators with a comprehensive score greater than 0.1 are selected: the amount of financial subsidies, regional per capita income, economic development density, and economic development depth, and the amount of financial subsidies is taken as the input index of DEA decision-making unit, while regional per capita income, economic development density, and economic development depth are taken as the output indicators of DEA decision-making unit. Therefore, the settings of each unit are shown in Table 2.

Relative efficiency is the performance of agricultural insurance financial subsidies related to input index and

Price-based subsidy	2794.05	25.97	72.82	0.24

TABLE 3: Calculation results of relative efficiency.

	Input weight vector		Output weight vector		Relative efficiency
	Amount of financial subsidy	Regional per capita income	Economic development density	Economic development depth	
Income-based subsidy	60.89	0.0034	0	0	0.9832
Cost-based subsidy	135.45	0.0075	0	0	0.9583
Technology-based progress subsidy	79.42	0.2190	0	0	0.9023
Price-based subsidy	46.05	0	0.0218	0	0.9345

output index, which can be used as a significant evaluation index to measure the effect of agricultural insurance fiscal subsidies in a certain region. According to the relevant data on agricultural fiscal subsidies provided by the Department of Finance (2015–2021), the input weight vector and output weight vector are calculated and the relative efficiency is calculated according to the evaluation input index and decision unit setting. The results are shown in Table 3.

The above results show that the relative efficiency of agricultural financial subsidies in this region is relatively high, and its comprehensive efficiency exceeds 0.9. Among them, the comprehensive efficiency of income subsidies is the best, which is 0.9832, while that of technological progress subsidies is lower, which is 0.9023. From the relative efficiency index of financial subsidies, the progress of related technologies has effectively promoted the improvement of agricultural productivity. In addition, according to the result of input-output efficiency value, the region still needs to strengthen the innovation of agricultural financial subsidy system, adjust the allocation structure of financial subsidy funds, and improve the allocation management of financial subsidy funds to make

up for the lack of scale efficiency. Moreover, with the implementation of the financial subsidy policy, the stable development of subsidies has better compensated for the economic losses in the process of agricultural production and ensured the healthy production of agriculture.

It can be seen that China is in the new normal period of economy, the market puts forward higher requirements for the quality and safety of agricultural products, and the contradiction between market constraints and resources and environment faced by the development of agricultural industry is prominent, so it is urgent to promote the structural reform of agricultural supply side. Meanwhile, we should strengthen the implementation of technical subsidy policies and advance the rapid development of key agricultural technologies.

5. Conclusion

The evaluation of agricultural subsidies can improve China's agricultural management and promote the agricultural production with sustainable, healthy, and stable

development. Therefore, this study establishes an evaluation model of agricultural subsidies based on a combined algorithm and measures the development level of regional agricultural financial subsidies with relative efficiency value. The evaluation result shows that in the hierarchical total sorting, the comprehensive score of financial subsidy amount, regional per capita income, economic development density, and economic development depth is greater than 0.1, which can be used as the decision-making unit of this model. The relative efficiency of agricultural financial subsidies in this region is relatively high, and its comprehensive efficiency exceeds 0.9. Among them, the comprehensive efficiency of income subsidies is the best, which is 0.9832, while the efficiency of technology-based subsidies is lower, which is 0.9023. The government should adjust the allocation structure of financial subsidy funds and strengthen the implementation of technical subsidy policies, to ensure the healthy production of agriculture.

The relationship between financial development and economic growth has become a hot topic in recent years and for China, which is undergoing financial liberalisation and policy reform, the efficiency of the use of digital finance and the deepening of the balance between quality and quantity in financial development are particularly important for economic growth. This paper investigates the utility of digital finance and financial development on total factor productivity in China using interprovincial panel data decomposing financial development into financial scale and financial efficiency; an interprovincial panel data model is used to explore the utility of digital finance on total factor productivity. This involves the collection and preprocessing of financial data, including feature engineering, and the development of an optimised predictive model. We preprocess the original dataset to remove anomalous information and improve data quality. This work uses feature engineering to select relevant features for fitting and training the model. In this process, the random forest algorithm is used to effectively avoid overfitting problems and to facilitate the dimensionality reduction of the relevant features. In determining the model to be used, the random forest regression model was chosen for training. The empirical results show that digital finance has contributed to productivity growth but is not efficiently utilised; China should give high priority to improving financial efficiency while promoting financial expansion; rapid expansion of finance without a focus on financial efficiency will not be conducive to productivity growth.

1. Introduction

The role of financial development in promoting economic growth has been unanimously recognised by scholars at home and abroad [1–3] and it was found that the scale and function of finance can effectively stimulate long-term economic growth as well as total factor productivity growth through their studies. The main emphasis is on a kind of guiding effect of financial development on supply, that is, with the growth rate of economic development as well as the complexity of economic structure, social demand for financial aspects will further stimulate the development of the economy, and financial development and economic growth are causally related to each other [4–6].

A vector error correction model is used to separately verify the existence of a significant positive relationship between financial development and total factor productivity.

There is a large body of research literature, both domestic and international, on the utility of digital finance for economic growth [7]. An endogenous growth model based on digital finance argues that digital finance, as the main carrier of knowledge products, is an alternative to knowledge and innovation. The existence of digital finance overcomes the constraint of diminishing marginal returns to factors and makes long-term economic growth possible [8, 9]. The study points out that the long-term growth rate of the economy is directly proportional to the long-term growth rate of basic knowledge, that the ultimate variable determining the long-term growth rate of basic scientific knowledge is the stock of digital finance in the economy, and that digital finance is the real source of economic growth. Paper [10] concluded that higher education in the eastern, central, and western regions all contributes significantly to the GDP growth rate, but the contribution is distributed in a gradient from higher to lower.

The measurement of total factor productivity growth can be broadly grouped into two categories: the growth accounting approach and the econometric approach [11]. The econometric approach uses various econometric models to estimate total factor productivity, taking into account the effects of various factors in a more comprehensive manner, but the estimation process is more complex [12]. One type of econometric method is the potential output method, also known as the frontier production function method, which has been widely used in current research. These methods use changes in inputs and outputs and the displacement of the frontier production function to measure total factor productivity growth, the key to which lies in the estimation of the frontier production function and the measurement of the distance from observations to the production frontier [13]. Depending on the method of estimating the frontier production function and the distance function, the frontier production function method can be divided into two categories: First, the stochastic frontier analysis (SFA) method, of which the more popular methods are Hildreth and Houck's random coefficient panel models [14] (this is more problematic for empirical studies with small sample sizes); secondly, nonparametric data envelopment analysis (DEA).

2. Data Acquisition and Processing

There is a lot of noise and missing values in all types of real data, which are detrimental from the point of view of training algorithmic models. It is important to carry out the necessary preprocessing before using the data information to improve its quality and make the training of the model smoother, which is important for data mining purposes [15].

2.1. Feature Engineering. For machine learning, feature engineering is required to improve the performance of a model. The original dataset is the input and the relevant dataset used in the future model training process is the output, which can be used to select more desirable training features and thus achieve good results in simple structural models. The current work will address the general process of feature construction and processing, feature selection, and analysis.

Steps are as follows:

- (1) First find the minimum (min) and maximum (max) of the original sample data X .
- (2) Calculate the coefficients k by expressing them as follows:

$$k = \frac{100}{(\max - \min)}. \quad (1)$$

- (3) The data normalized to the interval [0, 100] is obtained y^* as follows:

$$y^* = k(X - \min). \quad (2)$$

In this paper, the data on the number of public cars per 10,000 people ($\times 18$), urban disposable income per capita

($\times 19$), and rural disposable income per capita ($\times 20$) are normalized so that these data become continuous variables in the range of [0, 100].

2.2. Feature Selection. Once the analysis, construction, and processing of the relevant features have been completed, feature selection is performed. Those features that have a high correlation with the target variables are selected and those that are not are eliminated [16]. The selected feature subsets are identified as the input to the model training process, resulting in a significant increase in model accuracy and performance and a corresponding decrease in training time costs.

Fitting a series of features together gives a better fit than fitting individual features, resulting in a significant increase in the predictive power of the model. However, this does not mean that more features will give better results. Random forest is an integrated learning algorithm consisting of multiple decision trees, which is easy to implement, is computationally compact, and has high performance in classification and regression and is one of the representative techniques in current integrated learning technology [17]. If the relevant features are selected by the random forest algorithm, the problem of overfitting caused by a large number of features can be effectively solved on the one hand, and the relatively minor features can be filtered out to make the prediction results more accurate on the other hand.

The key function of the random forest algorithm is to accurately calculate the importance of each feature variable. The basic principle of importance measurement is to calculate the specific contribution of each feature in each tree, to obtain its mean value, and to compare the contribution of different features [18]. The error rate of out-of-bag data is often used as an important metric for evaluation. The importance of each feature is used as an aid in the feature selection process, so that the robustness of the model is increased and the dimensionality of the features is reduced. The actual out-of-bag error rate (i.e., OOB) of each feature allows us to calculate the specific importance of the feature. The specific algorithm is described in equation:

$$FIM_j = \frac{\sum (\text{errOOB2} - \text{errOOB1})}{N}. \quad (3)$$

Here, err OOB2 is the out-of-bag correlation error size when noise is added to feature j in a random way; errOOB1 is the out-of-bag correlation error size under normal conditions; N is the total number of trees in the random forest; j is feature j ; and FIM is the actual rating of the importance of the feature. If noise is added to feature j , it significantly reduces the out-of-bag accuracy level, which means that the final outcome of the prediction is significantly influenced by feature j , and the importance of the feature is high.

3. Estimation of Total Factor Productivity Growth

3.1. Estimation Methodology. This paper draws on the nonparametric DEA-Malmquist index method of [19] to

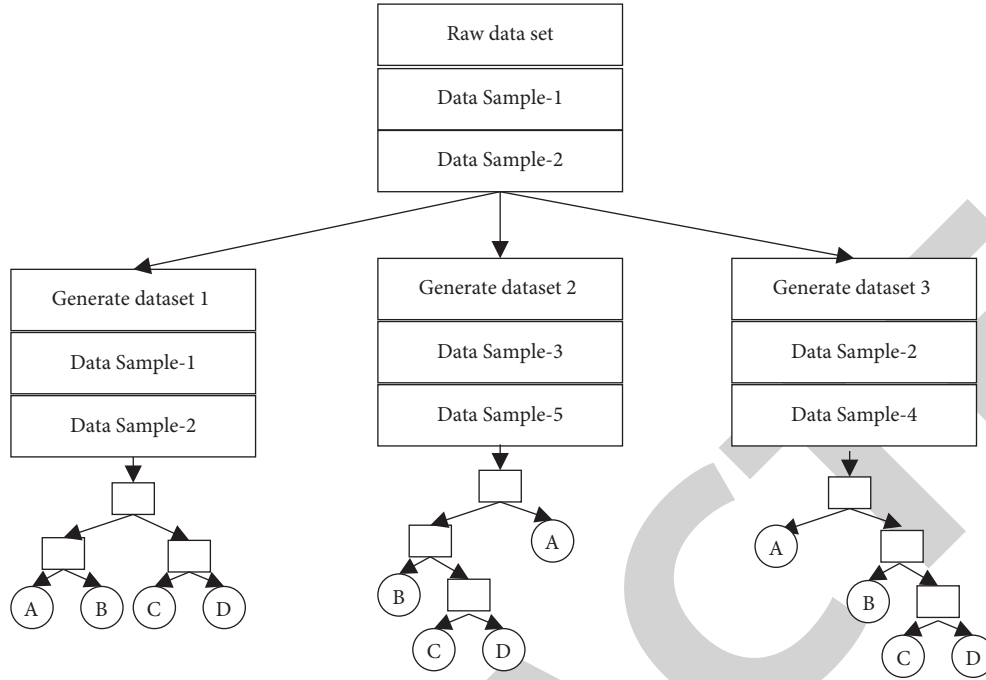

FIGURE 1: Random forest regression model construction process.

estimate total factor productivity growth in China's provinces. Assume that there are H agents, where the input of the h th agent in period t is $x'_h = (K_{ht}, L_{ht})'$, K_{ht} is the capital stock input, and L_{ht} is the labour input. Then the Malmquist index of total factor productivity growth in period $t+1$ for the h th subject is

$$M_h^{t+1}(x'_h, y'_h, x'^{t+1}_h, y'^{t+1}_h) = \left[\frac{D'_h(x'^{t+1}_h, y'^{t+1}_h)}{D'_h(x'_h, y'_h)} \frac{D_h^{t+1}(x'^{t+1}_h, y'^{t+1}_h)}{D_h^{t+1}(x'_h, y'_h)} \right]^{1/2},$$

$$h = 1, \dots, H.$$
(4)

When the total factor productivity growth index is greater than one, it means that total factor productivity growth is positive, while the opposite means that total factor productivity growth is negative.

The Malmquist index has two advantages over traditional growth accounting methods: it eliminates the need for factor price information and economic equilibrium assumptions; and it provides more comprehensive information on total factor productivity growth by decomposing it into two components: efficiency change and rate of technological progress. This method is only applicable to panel data.

4. Construction of a Random Forest Regression Model

The following procedure is involved in the construction of this type of model.

- (1) Samples are randomly drawn from the initial data set in a put-back and unweighted manner, so that each decision tree will be generated from its training set.

- (2) Decision tree can be constructed from each training set; no pruning is required at this point.
- (3) A series of decision trees together form a random forest. The prediction mean of each decision tree forms the final prediction result.

Figure 1 details the modelling process.

4.1. Data Sampling. For each decision tree, it corresponds to a particular training set, so the original dataset is used as the basis for forming the relevant subset of data (so that both have an equal number of decision trees) and thus the random forest is constructed. The corresponding dataset is obtained through a random sampling technique. This technique covers two different types of sampling methods: reverse and one-way.

A specific set of samples is taken from a dataset and not put back when the samples are collected; this is called nonreturn sampling. These include the random number method and the lottery method. The former is the sampling of a data set by means of a random number formation or table. In the case of nonreturn sampling, the initial dataset will continue to get smaller during the sampling process, so that there will be no duplication of samples in the subdataset. In the latter case, the entire data is numbered, the data set is homogenised, and the relevant subsets are extracted by a random method (with a capacity of n). Although the latter method is relatively straightforward, the difficulty of homogenisation increases when there is a large dataset, making the resulting sample unrepresentative.

4.2. Constructing Decision Trees. When constructing a decision tree, it is crucial to choose the random feature

variables appropriately. The basic attributes associated with node splitting are called random feature variables. They are selected in order to reduce the correlation between decision trees and to improve the performance of the random forest algorithm. The random feature variables can be generated by combining input variables or by random selection. The selection process involves a number of indicators, including the Gini index, information gain ratio, and information gain. The CART algorithm is based on the Gini impurity index, which is used as the basis for determining the classification scale for effective selection.

The above process results in a number of decision trees that together form a random forest. The final result of the model is the mean of the predicted values of all the decision trees.

5. Empirical Analysis

5.1. Model Setting. Based on the claim that the level of digital finance can facilitate access to technology, the following equation for total factor productivity growth is proposed:

$$\Delta a_{it} = c + gh_{it} + m \left[\frac{h_{it}(y_{\max t} - y_{it})}{y_{it}} \right] + \theta i, \quad (5)$$

where $y_{\max t}$ represents output per capita in the technologically advanced region and y_{it} is output per capita in period t in region i . h_{it} represents digital finance in period t in region i , a_{it} represents total factor productivity, and i represents individual provincial fixed effects, which are included to control for possible variability between provinces [19, 20]. In this model, total factor productivity growth depends not only on the level of digital finance in the current period, but also on the interaction term between digital finance and the difference in technology levels in technology-led regions. Based on this model, the following model is developed to analyse the utility of digital finance and financial development on total factor productivity growth:

$$a_{it} = c + gh_{it} + m \left[\frac{h_{it}(y_{\max t} - y_{it})}{y_{it}} \right] + \alpha \text{fin}_{it} + \beta_j \text{ctrl}_{jit} + \theta i + \varepsilon_{it}. \quad (6)$$

Among them, fin_{it} is the level of financial development. According to the research of [21–23], the effect of financial scale and financial efficiency on the economy is different. The effect of financial scale and financial efficiency on the economy through the growth of total factor productivity should also be different. Therefore, this paper divides the level of financial development into financial scale and financial efficiency, to explore its role in the growth of total factor productivity. c is the control variable, which is the government intervention, the degree of economic activity, and the degree of opening to the outside world. ε_{ij} is the random disturbance term. Empirical analysis is carried out according to model (4).

Endogenous growth theory holds that digital finance is an important reason to explain total factor productivity. It has a significant impact on total factor productivity through influencing technological innovation ability, technology spillover absorption ability, and other channels.

It can be seen from Table 1 that the statistics of Kao test are statistically significant at the 1% level; that is, the original assumption that there is no cointegration relationship cannot be accepted at the 1% level. Therefore, it is considered that there is cointegration relationship between the two variable systems and regression analysis can be carried out [24, 25].

5.2. Empirical Results. In this paper, fixed and random effects panel data models are used. Table 2 presents the model estimation results, where columns (1) and (2) present the utility analysis of digital finance and financial size on total factor productivity growth, and columns (3) and (4) present the utility analysis of digital finance and financial efficiency on total factor productivity growth. Hausman test p values are 0.9641 and 0.8420, respectively, which are both greater than 0.10; therefore, at the 10% level the original hypothesis that individual effects are correlated with explanatory variables cannot be rejected at the 10% level, so it is decided that a random effects model should be chosen instead of a fixed effects model [26, 27].

From there, the analysis is based on the model estimation results in columns (2) and (4).

The analysis focuses on the core variables to be explored in this paper, digital finance lnhit , the interaction term between digital finance and technology level differences lnhmaxit , and the impact of financial development indicators lnfscit and lnfeft on total factor productivity growth.

Column (2) presents the estimated results of the regression of digital finance and financial scale on total factor productivity growth. From the estimated results, the estimated coefficient of digital finance on total factor productivity growth is 0.0427, which is statistically significant at the 5% level; i.e., when the level of digital finance increases by 1, it will contribute to an increase in total factor productivity growth by 0.0427. Therefore, strengthening education efforts and increasing the level of digital finance are conducive to promoting an increase in total factor productivity growth, which in turn will contribute to economic growth. The interaction term between digital finance and technology level difference is negative (−0.0000984) and statistically significant at the 5% level; i.e., technology level difference shows a negative effect in the effect of digital finance on total factor productivity growth; the greater the technology level difference, the more negative the effect of the utility of digital finance on total factor productivity growth, but this negative effect is relatively small; it can be seen that the use of digital finance in China is relatively inefficient and the ability to learn new technologies is weak. The estimated coefficient of the effect of financial size on TFP growth is −0.177, which is statistically significant at the 1% level, suggesting that every 1 increase in financial size will contribute to a 0.177 decrease in TFP, possibly because state-owned enterprises receive most of the incremental financial resources due to implicit government guarantees, but do not use them effectively or even have idle funds, while the private economy, which operates more efficiently, faces a chronic shortage of capital, and the

expansion of credit is also inflationary, leading to a recession [28, 29].

Column (4) presents the estimated results of the regression between digital finance and financial efficiency on total factor productivity growth. The estimated coefficient is 0.0564, which is statistically significant at the 1% level. The elasticity of financial efficiency to total factor productivity growth is 0.289, which is statistically significant at the 1% level, indicating that an increase in financial efficiency can contribute to an increase in total factor productivity growth, and an increase of 1 in financial efficiency will increase total factor productivity growth by 0.289. In addition, the contribution of financial efficiency in China (0.289) is greater than the inhibiting effect of financial size (0.177), so China should continue to carry out institutional reforms to promote financial efficiency in order to promote economic growth.

For the control variables, the results in columns (2) and (4) are generally consistent. The estimated coefficient of government expenditure on total factor productivity growth is positive, which shows that increased government expenditure is conducive to economic growth and that appropriate government intervention is conducive to healthy economic development. The estimated coefficient for investment is negative and statistically significant at the 1% level, indicating that continued higher investment is not

conducive to increased efficiency in the Chinese economy, thus showing a declining trend in the marginal return to capital. The two variables of foreign development—total exports and imports and FDI—both have negative regression results in column (2), while the estimated coefficients of total exports and imports are positive and FDI remains negative in column (4), and neither is statistically significant, which is somewhat inconsistent with the fact that, according to [14], exports and imports may inhibit firms through the following channels. Firstly, domestic exporters face a latecomer disadvantage in R&D innovation in international markets, with internationally available technologies creating strong patent barriers and barriers to domestic firms’ innovation, which cannot be applied unless domestic firms have a practical innovation. Secondly, international dominant enterprises suppress and control the R&D behaviour of China’s export enterprises, resulting in serious “capture effect” and “lock-in effect,” which will eventually lead to a “ceiling effect” on the technological progress of export enterprises.” Therefore, the impact of international trade on total factor productivity depends on the outcome of the game between positive and negative forces, and only when the technology spillover effect is greater than the “barrier effect” can it significantly contribute to total factor productivity growth. For FDI, some scholars point out that, in places where resources are more scarce, FDI firms as dominant firms may seize the production and market resources of domestic firms, thus causing the decline of domestic firms. Therefore, FDI may have a dampening effect on total factor productivity.

5.3. Comparison of Model Results. The current work has used RF, SVR, and MLR methods in comparative studies. In this work, the bias of the random sampling process is effectively reduced by means of a tenfold cross-validation method, which requires the calculation of the mean value to obtain the relevant indicators for the prediction assessment. In general, the metrics used are RMSE, MSE, and MAPE. The results are given in Table 3.

In the regression models presented in the previous section, the parameters are the default parameters in the computational library and are compared with each other for the same conditions. A detailed analysis of the prediction results shows that these algorithms have generally consistent prediction results, in the following order: MLRRFSVR. The middle of the range of errors was obtained by the random forest method with an error of 22.58%, and the larger error value was obtained by the multiple linear regression method (about 38.98%). Compared to linear regression, prediction by nonlinear regression has relatively better results. It can be found that if a multiple regression correlation model is used, it will have a high training efficiency and convenience, but relatively poor nonlinear learning ability. The random forest approach (based on regression trees) has better prediction results, and the support vector machine regression approach would have better prediction results. In the current work, with a relatively small dataset and a small number of features, the advantages of the random forest approach are difficult to realize, and the factors that affect carbon

productivity in practice are complex, including consumption structure, energy efficiency levels, and differences between cities (regions). By increasing the number of features, the advantages of random forests are highlighted and the accuracy of the prediction results is increased.

The current work uses the best values of the parameters as its input and then compares them with the default parameters, as shown in the data in Table 4.

Here, RF_opt and RF_def are the random forest regression model with optimal and default parameters, respectively. A detailed comparison of the above evaluation metrics shows that, for the case of optimal parameters, the errors of MAPE and RMSE are reduced by about 17.23% and 7.72%, respectively, which means that the prediction results are better than those with default values. The current work is based on the commonly used parameters of interest, and the best values are obtained by a grid search algorithm and optimised, which greatly increases the accuracy.

6. Conclusions

The study points out that the long-term growth rate of the economy is directly proportional to the long-term growth rate of basic knowledge, that the ultimate variable determining the long-term growth rate of basic scientific knowledge is the stock of digital finance in the economy, and that digital finance is the real source of economic growth. The role of financial development in promoting economic growth has been unanimously recognised by scholars at home and abroad. This paper examines the utility of digital finance and financial development on total factor productivity in China using interprovincial panel data. The results show that digital finance has contributed to the improvement of total factor productivity, but there is still a problem of inefficient use of digital finance in China; to this end, this paper proposes a random forest regression model with a related optimisation process. First, a training set is generated using random sampling, and a number of decision trees are constructed using a series of operations to obtain a random forest. The final result of the model is the mean of the predicted values of all the decision trees. The model is then used as the basis for regression. In the current work, the main parameters of the regression function are adjusted in order to optimise the prediction model and improve its accuracy. China should give high priority to improving financial efficiency while promoting financial expansion,

which is detrimental to the growth of total factor productivity, the source of economic growth.

Aiming at the problem that the loss distribution balance control effect of high-power photovoltaic grid-connected inverter is poor due to the complex loss factors, this paper proposes a loss distribution analysis and balance intelligent control method for high-power photovoltaic grid-connected inverter. The topology structure of high-power photovoltaic grid-connected inverter is constructed and the overall control scheme is designed. The loss of inductance, resonant frequency, harmonic attenuation, and damping resistance in the circuit of PV grid-connected inverter is analyzed, respectively. On this basis, a two-stage loss control model of high-power PV grid-connected inverter is constructed, and the generalized linear decision rule is adopted to schedule PV power supply and fluctuating load. A two-stage loss control model for high-power photovoltaic grid-connected inverter was established and the optimal loss control value was obtained. Experimental results show that the proposed method can accurately suppress voltage and current losses of grid-connected photovoltaic inverters and has strong resonance resistance and robustness.

1. Introduction

In recent years, photovoltaic power generation has accounted for an increasing proportion of the installed capacity in the power system. As a kind of distributed generation, photovoltaic power generation has also been widely studied. According to different needs and applications, photovoltaic grid-connected power generation systems have different structures and power levels, from a single photovoltaic module to a million-level photovoltaic module [1]. With the continuous improvement of requirements for grid-connected voltage level, efficiency, and grid-connected current quality of photovoltaic grid connected inverter, multilevel photovoltaic grid-connected inverter is bred [2–4]. The multilevel conversion technology can avoid the direct series connection of power switching devices. It has the advantages of high output voltage, low harmonic content, small switching stress, low voltage change rate, and low switching frequency. It can be applied to the fields of medium voltage high-power AC speed regulation, high-voltage DC transmission, static var generator, and new energy

power generation [5–7]. When the large-scale photovoltaic power generation system is connected to the grid, the impact on the power quality of the power grid and the operation conditions such as the separation speed of the power grid in case of failure of the photovoltaic power generation system itself has become an important focus [8]. The research on the intelligent control method of loss distribution balance of high-power photovoltaic grid-connected inverter has become the main research content in the current field.

At present, relevant scholars have made research on the loss distribution of high-power photovoltaic grid-connected inverters and proposed an intelligent control method for the balance of loss distribution of photovoltaic grid-connected inverters. Reference [9] presents a control method for a two-stage single-phase grid-connected cascaded H-bridge photovoltaic inverter based on a hybrid control strategy of optimal third harmonic injection and limited power maximum power point tracking. The optimal third harmonic injection can improve the modulation range; limited-power maximum-power point tracking algorithm can limit the power of the photovoltaic module of the unit where the

maximum modulation ratio is located under the condition of exceeding the third harmonic compensation range, so that it can continue to meet the grid-connected operating conditions. Reference [10] proposes a direct power control method based on nonlinear disturbance observer. In the photovoltaic grid-connected power generation system, when the output power of photovoltaic panels suddenly changes, the DC side bus voltage fluctuates greatly. If the control is improper, it will directly affect the normal operation of the system. This method does not need to add additional sensors. The disturbance observer is used to observe the output power of the photovoltaic panel in real time, and it is added to the inner power loop as a feedforward value, so that the given power inner loop contains the input power information. For the power inner loop, the control input is redefined, and the synchronous rotation coordinate transformation is omitted. The design process of the observer and the power inner loop is introduced in detail, and the parameter tuning method of the inner and outer loops is given.

The above methods all provide a certain theoretical support for the control of high-power photovoltaic grid-connected inverters, but the above methods do not fully consider the loss distribution of high-power photovoltaic grid-connected inverters, and the control effect on the loss of photovoltaic grid-connected inverters is relatively low. Difference. For this reason, this paper proposes an intelligent control method for the loss distribution balance of high-power photovoltaic grid-connected inverters, fully analyzes the inductance, resonant frequency, harmonic attenuation, and damping resistance losses in the photovoltaic grid-connected inverter circuit, and a two-stage loss control model is proposed, and the intelligent control of loss distribution balance of photovoltaic grid connected inverter is realized.

2. Topology Structure and Overall Control Scheme of High-Power Photovoltaic Grid-Connected Inverter

2.1. Topology. The function of the high-power photovoltaic grid-connected inverter is to convert the DC power output by the high-power photovoltaic panels into the AC power of the same frequency and phase of the large grid voltage. In order to study the intelligent control method of the loss distribution balance of the high-power photovoltaic grid-connected inverter, this paper chooses a typical two-stage high-power photovoltaic grid-connected inverter topology; its topology is shown in Figure 1.

As shown in Figure 1, U_d represents the output voltage of the high-power photovoltaic array; C_d represents the filter capacitor on the input side; (S_{a+}, S_{a-}) , (S_{b+}, S_{b-}) , and (S_{c+}, S_{c-}) represent the switch tubes that constitute the key components of the inverter; R_l represents the missed filter R_d represents the grid resistance of the large grid; C_l represents the inverter capacitance; N represents the neutral point of the large grid, which is used as the potential reference point [11, 12]. The core of the topology structure of the high-power photovoltaic grid-connected inverter is the realization of the

FIGURE 1: Topological structure of high-power photovoltaic grid-connected inverter.

control theory, so the requirements for the topology structure of the high-power photovoltaic grid-connected inverter are relatively high. The voltage space vector control which is easy to digitize is adopted, which has the effect of improving the utilization rate of DC voltage and has the characteristics of many voltage steps of output voltage, so it has small voltage harmonic component, meeting the needs of topology design of high-power photovoltaic grid-connected inverter.

In order to construct the mathematical model of the high-power photovoltaic grid-connected inverter, its switching function is defined [13], as shown in the following formula:

$$\begin{cases} d_1 = \begin{cases} 1 & S_{a+} & \text{turn on} \\ -1 & S_{a-} & \text{shut down} \end{cases} \\ d_2 = \begin{cases} 1 & S_{b+} & \text{turn on} \\ -1 & S_{b-} & \text{shut down} \end{cases} \\ d_3 = \begin{cases} 1 & S_{c+} & \text{turn on} \\ -1 & S_{c-} & \text{shut down} \end{cases} \end{cases} \quad (1)$$

In formula (1), S_{a+} , S_{b+} , and S_{c+} represent the inverter coefficient in the open state, and S_{a-} , S_{b-} , and S_{c-} represent the inverter coefficient in the closed state. The inverter output voltage is the voltage between the inverter output phase and the neutral point plus the neutral point voltage [14]. According to the balance theory and the characteristics of capacitance and inductance on voltage and current, the mathematical model of high-power photovoltaic grid-connected inverter is derived as

$$\dot{x} = Ax + Bi. \quad (2)$$

In formula (2), \dot{x} represents the phase voltage of the inverter output filter; x represents the large grid voltage; A and B represent the coefficient matrix; i represents the inverter output filter current.

2.2. Overall Control Scheme of Photovoltaic Inverter. The adoption of the photovoltaic inverter carrier phase-shift control strategy can avoid the state where the voltage of

the photovoltaic inverter integrated circuit is zero, so that the modulation index $n > 0.462$ in the phase-shift control system can be optimized in the photovoltaic inverter optimization control system to stabilize the control modulation area below 0.462 [15]. Under such conditions, the DC voltage u_b of the photovoltaic inverter integrated circuit drops to 1. If the photovoltaic inverter carrier phase-shift control scheme needs to be adopted in the area of $n < 0.462$, the current in each circuit will have a certain peak value, which reduces the utilization rate of photovoltaic inverters [16, 17]. When n is the domestic standard value of 0.5, the carrier amplitude of the three output terminals of the PV inverter carrier phase-shift control is 2 V, the period is T_2 , the carrier signal reaches the peak value, the sine wave first falls and then rises, and the number of carrier switches increases to 2. Second, the zero state is in a small variation range and lasts for a short time. So the photovoltaic inverter always works under the current light and temperature. In the process of optimizing the modulation strategy of the modulation control system, the level of the differential mode filter supplements the energy in the back-shifted state and is equivalently exchanged with the zero-state voltage of the circuit, thereby effectively improving the mutation of the phase-shifted carrier and maintaining the switching. The number of times does not change. The low-level state appearing in the pulse transformation is regarded as the zero state of the integrated circuit, which is equivalent to the carrier pulse transformation in the equivalent state [18–20]. The carrier pulse translation process is shown in Figure 2.

According to Figure 2, it can be seen that if the pulse signal sine wave is distorted at the intersection of the rectangular wave, the duration of the zero state of the circuit will be prolonged. When the potential of the intersection of the triangular wave is reduced to the lowest point, the duration of the zero state of the integrated circuit is significantly shortened, and the high level jumps. The trigger pulse signal is variable, so when setting the zero state of the photovoltaic inverter integrated circuit, the change of the pulse width causes the output voltage to be uneven to a certain extent, so that the differential mode properties of the pulse are frequently switched, and it needs to be compensated in the shortest time because the voltage bump changes the pulse energy, the pulse modulation strategy of the photovoltaic inverter changes the position of jump and shift, and the number of pulse switches of the photovoltaic inverter is retained [21].

3. Loss Distribution of High-Power Photovoltaic Grid-Connected Inverters

3.1. Basic Current Formula. Since the loss of the switching device has a direct relationship with the current flowing through it, the relationship between the voltage and current of the intermediate bus in the circuit is deduced [22], and the influence of the photovoltaic grid-connected inverter on the current is deduced according to the inverter harmonic circuit model.

$$G_n = \frac{I_{A-n}(s)}{U_{A-n}(s)}. \quad (3)$$

In the above formula, G_n represents the influence of the photovoltaic grid-connected inverter on the current; $I_{A-n}(s)$ represents the phase current harmonic under the n harmonic; $U_{A-n}(s)$ represents the phase voltage harmonic of the grid under the n harmonic.

To sum up, as the harmonics of photovoltaic grid-connected inverters increase, the current harmonics increase rapidly. It can be seen that the quality of photovoltaic grid-connected inverter is extremely sensitive to inverter harmonics, which will cause the power supply quality to fail to meet user needs [23].

3.2. Loss Analysis of Photovoltaic Grid-Connected Inverters

3.2.1. Inductance. According to the L-type filter standard, the total inductance is analyzed for the suppression of harmonics in the low input voltage inverter. According to the grid-connected standard, the harmonic amplitude of each order current in the inverter is set to $i_g(n)$, and the filter is calculated by the following formula. The inductance value of the device Z is

$$Z = \max \left[\frac{u(n)}{n \times \theta_{s0} \times i_g(n)} \right]. \quad (4)$$

In the above formula, $n = 2, 3, 4$ and θ_{s0} represents the fundamental angular frequency; $u(n)$ represents the harmonic amplitude of each order phase voltage output in the inverter.

When calculating the current harmonic amplitude $i_g(n)$ of each order, the parasitic resistance existing in the inductor is not considered:

$$i_g(n) = \frac{u(n)}{\theta_{s0} \times [(Z_1 + Z_2) - Z_1 Z_2]}. \quad (5)$$

In the above formula, Z_1 and Z_2 represent the grid-side inductance and the inverter-side inductance, respectively.

On the basis of the above formula, the inductive loss value Z_{eq} of the n -th current harmonic output in the LCL filter is obtained:

$$Z_{eq} = (Z_1 + Z_2) \times \left(1 - \frac{n\theta_{s0}}{\theta_{res}} \right). \quad (6)$$

In the above formula, θ_{res} represents the resonant angular frequency.

3.2.2. Resonant Frequency. When resonance occurs, the LCL filter with zero impedance resonance point will affect the stability of the power grid control system, resulting in a decrease in power quality and distortion of the output current [24].

Regardless of the parasitic resistance existing in the inductance, the parallel branch of inductance Z_1 on the series inductance side, the inverter inductance Z_2 , and capacitor C , for the midpoint of the bridge arm, the voltage

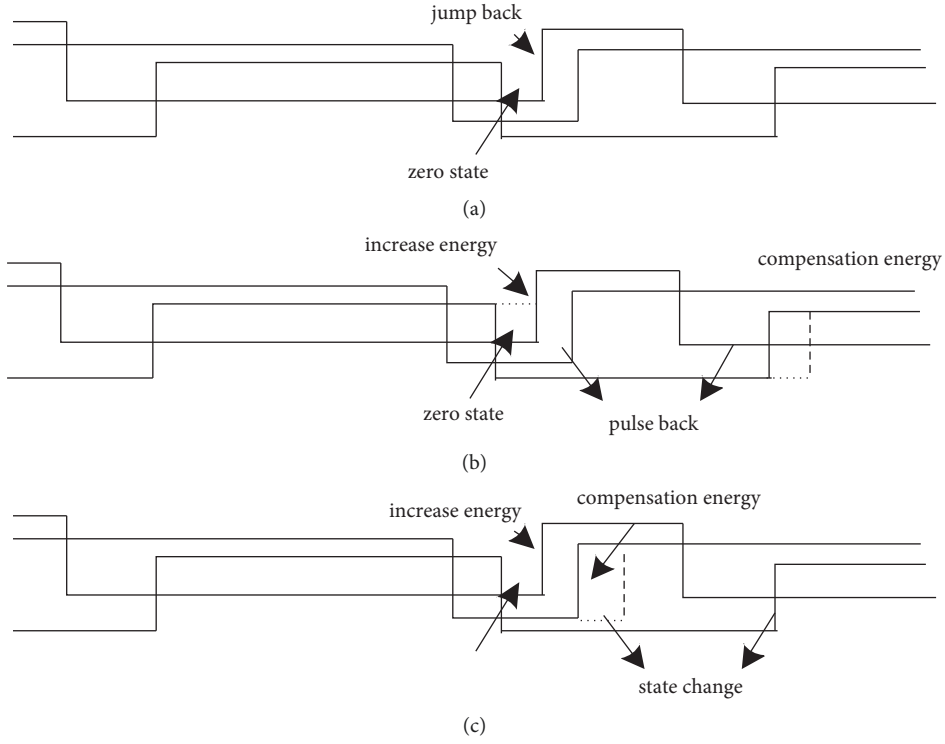

FIGURE 2: The translation process of the carrier pulse of photovoltaic inverter (Jump backward), (Pulse backward), and (State change).

transfer impedance X_1 generated by the output current of the inverter can be calculated by the following formula:

$$X_1 = j\theta(Z_1 + Z_2 - C\theta^2). \quad (7)$$

Set the inverter inductance Z_2 to zero, and calculate the resonant frequency g and the resonant corner frequency θ by

$$\begin{cases} g = \frac{1}{2\pi} C \sqrt{\frac{Z_1 + Z_2}{Z_1 Z_2}}, \\ \theta = C \sqrt{\frac{Z_1 + Z_2}{Z_1 Z_2}}, \end{cases} \quad (8)$$

3.2.3. Harmonic Attenuation. According to the relationship between the output current and the input current of the LCL filter, the current harmonic attenuation of the filter is designed, and the relationship between the output current i_0 and the input current i_i is described by the following transfer function $H_i(s)$ combined with the topology of the filter:

$$H_i(s) = \frac{i_0(s)}{i_i(s)}. \quad (9)$$

Express the above transfer function $H_i(s)$ in current form:

$$i(n) = i_0(n) \left| 1 - \left(\frac{n\theta_0}{\theta} \frac{Z_1 + Z_2}{Z_1} \right) \right|. \quad (10)$$

Solve the above equation to obtain the corner frequency g' of the LCL filter:

$$g' = \frac{1}{2\pi} \sqrt{\frac{2}{Z_2 C}}. \quad (11)$$

If the corner frequency g' is lower than the harmonic current frequency existing in the output current of the low input voltage inverter, after processing by the LCL filter, attenuation will occur. Therefore, the current harmonics whose frequency is higher than the turning frequency have higher suppression ability. However, when the LCL filter is used to process the current harmonics whose frequency is lower than the corner frequency g' , it is easy to reduce the waveform quality and cause the waveform to be distorted. Therefore, when designing the harmonic attenuation of the LCL filter, it is necessary to reduce the corner frequency g' .

3.2.4. Damping Resistor. In order to avoid resonance in the low input voltage converter, it is necessary to introduce a damping resistor to improve the stability. At the same time, it is necessary to consider the influence of the damping resistor and the stability requirements. Adding a damping resistor to the inverter will increase its power loss. By reducing the resistance value of the damping resistor to reduce the power loss of the low input voltage inverter, the resonance suppression effect is not ideal at this time; increasing the resistance value of the damping resistor in the inverter

can improve the stability of the inverter, but, at the same time, it will increase the power loss, which will affect the bypass effect of high-order current harmonics. When suppressing high-frequency harmonics, the ability of the LCL filter is reduced [25].

4. Loss Control of High-Power Photovoltaic Grid-Connected Inverters

4.1. Construction of a Two-Stage Loss Control Model for High-Power Photovoltaic Grid-Connected Inverter Losses. The front-stage DC-DC conversion of the photovoltaic power generation inverter is to track the control of the maximum power. The power output of the photovoltaic cell has a maximum value and a minimum value. By tracking the power change, the required maximum power is output. Under different temperature and illumination conditions, the power of photovoltaic power generation will be affected differently, so the tracking of the maximum power is necessary for the research and control of the utilization rate of the photovoltaic power generation system and the equipment.

The poststage AC converter stabilizes the DC bus voltage between the front and rear stages to achieve the balance between the output power of photovoltaic power generation, the input power of the grid, and the power of the energy storage device; to control the output current of the system; and to control the waveform. The quality is optimized so that the output current can track the voltage of the grid.

In order to make the system reach the maximum power point voltage as soon as possible and avoid the power loss caused by the system searching for the area far from the maximum power point during the startup process, the compound MPPT method of constant voltage tracking method and disturbance observation method is adopted.

In addition, referring to the idea of intermittent scanning method, the photovoltaic array periodically changes the array voltage and works at this point. Since the actual situation is that the operating point of the array does not change much in a short period of time during the operation of the day, the system uses the method of starting MPPT every 500ms. This method does not require the grid-connected inverter to be in the search state all the time, does not generate oscillation, and avoids the power loss caused by other schemes due to the need for real-time search, and it has proved to have almost no impact on accuracy.

The system has the problem of cooperation between MEPT and MPPT. In the stable stage, MEPT is embedded in MPPT due to the large difference in the disturbance time between the two. Different from the ordinary disturbance observation method, in order to make the system perform MEPT as soon as possible in the startup phase to achieve the maximum efficiency, this paper adds a step change counter in the system startup phase; that is, after each disturbance, it is judged whether the disturbance step size has changed. When a change occurs, the counter is incremented by 1. If the step size changes for the first time, it means that the photovoltaic array operating point has

crossed the vertex of the photovoltaic curve; when the second step size changes, it means that the operating point has completed crossing the vertex of the photovoltaic curve twice, and the next beat works. The point will move towards the apex, at which time the array must work near the apex of the photovoltaic curve and oscillate near the apex. The value of the counter is equal to 2, wait for one beat, and trigger the start of MEPT. After the system startup process is over, the design method is the same as the ordinary disturbance observation method.

4.1.1. Calculation of Two-Stage Loss Control Objective Function. Aiming at minimizing the losses of photovoltaic grid-connected inverters, the two-stage loss control objective function is calculated. It is determined that, during the operation of the distribution network, its reactive power is compensated locally, and the structure does not change. Only the optimal scheduling of active power is taken into account, and the photovoltaic power supply and fluctuating load are regarded as the uncertain random variables of loss control. An uncertainty set contains all uncertain random variables in the fluctuation range [26]. In the first stage of optimal scheduling, the predicted values of uncertain random variables, that is, the active power of photovoltaic power sources and loads, are selected as the decision variables of this stage. There is a certain error between the predicted value and the actual value, and the actual value is unknown [27]. The first-stage loss control objective function is

$$C_1 = \sum_{t=1}^N (U_t + A_t + B_t + R_t)t. \quad (12)$$

In the above formula, C_1 is the schedulable operation cost of the first stage, N is the loss control scheduling cycle, U_t is the photovoltaic energy scheduling cost at t time, A_t is the fluctuating load scheduling cost at time t , B_t is the energy storage scheduling cost, and R_t is the distribution network loss cost [28]. In the second stage of optimal dispatching, the load loss and light rejection are taken as decision variables. At this time, the actual value of the uncertain random variable is known, and its loss control objective function is

$$C_2 = \sum_{t=1}^N (H_t + K_t). \quad (13)$$

In the above formula, C_2 is the schedulable operation cost of the second stage, H_t is the reduced penalty cost of light abandonment, and K_t is the reduced penalty cost of load loss. Taking formulas (12) and (13) as the objective functions of loss control, the random variables in the uncertain set can also minimize the total expected cost of the distribution network in the worst case. So far, the calculation of the two-stage loss control objective function has been completed.

4.1.2. Calculation of Two-Stage Loss Control Constraints. When the random variable in the uncertain set takes any value, calculate the various constraints contained in it, obtain the extreme bad scene of the uncertain random

variable, and optimize the objective function. The expression of the first-stage loss control equation constraint is

$$\begin{cases} P = P_1 + P_2 + P_3 - P_4 - P_5, \\ \frac{P^2 + Q^2}{V^2} = I^2. \end{cases} \quad (14)$$

In the above formula, P is the power flow distribution, P_1 is the predicted photovoltaic power output value, P_2 is the maximum fluctuation difference of the active power output value, P_3 and P_4 are the charging and discharging capacities of the distribution network, P_5 is the load active power, and V is the active power of the branch; Q and I are circuit resistance and current, respectively [29–31]. By formula (15), the branch power flow constraint is carried out on the objective function of the first stage. According to the electricity conservation of the distribution network and the limit of charging and discharging power, the loss control is constrained by inequality, and the expression formula is

$$\begin{cases} P_{\min} \leq P_1 \leq P_{\max}, \\ S_{\min} \leq S_1 - S_2 \leq S_{\max}. \end{cases} \quad (15)$$

In the above formula, P_{\min} and P_{\max} are the lower limit and upper limit of the active power of the photovoltaic power supply, S_{\min} and S_{\max} are the lower limit of the discharging power and the upper limit of the charging power, and S_1 and S_2 are the charging power and the discharging power, respectively [32]. The first stage of loss control is used as the reference value to determine the fluctuation range of photovoltaic power output and load. The second stage adopts distributed loss control theory to further reduce the fluctuation of photovoltaic output and load. It provides reactive auxiliary services [33]. Since this process will produce abandoned light, the PV inverter reactive power auxiliary constraint is carried out for the second stage, and the expression is

$$F = \frac{\lambda}{G}. \quad (16)$$

In the above formula, F is the apparent power of the photovoltaic inverter, λ is the binary variable during reactive auxiliary service, and G is the maximum power of the access node. According to the recourse cost, the second-stage loss control is constrained by inequality, and the expression is

$$\begin{cases} 0 \leq \frac{D}{a} \leq D_{\max}, \\ 0 \leq \frac{V}{b} \leq V_{\max}. \end{cases} \quad (17)$$

In the above formula, V is the loss of load, V_{\max} is the maximum loss of the loss of load, D is the amount of abandoned light, D_{\max} is the maximum loss of the amount of abandoned light, and a and b are the penalty coefficients of the loss of load and the amount of abandoned light, respectively [34]. Traverse all the nodes connected to the photovoltaic inverter, set the voltage of node j to U_j , set the

maximum voltage and the minimum voltage of the node to U_{\max} and U_{\min} , respectively, and impose voltage constraints on the uncertain set. The formula is

$$U_{\min} \leq \sum_{j=1}^{\delta} U_j \leq U_{\max}. \quad (18)$$

In the above formula, δ is the number of nodes connected to the PV inverter. Through the objective function and constraints, the loss control scheduling results under the worst distribution of uncertain random variables are expressed. At this point, the calculation of the constraints is completed and the model construction is realized.

4.2. Solving the Two-Stage Loss Control Model of High-Power Photovoltaic Grid-Connected Inverter Losses.

Using generalized linear decision rules, the two-stage loss control model of high-power photovoltaic grid-connected inverter losses is solved, and photovoltaic power sources and fluctuating loads are dispatched. The principles followed in the process of establishing the model are as follows. The first is the simplification principle: the actual model is a multivariable and multilevel complex model, and the establishment of the model requires the necessary simplification of the prototype. Therefore, the model establishment process should be the “simplest” model. The second is the derivation principle: a series of definite conclusions can be deduced through the study of the model. If the model cannot be mathematically deduced and the result of the application prototype cannot be determined, the model will be meaningless. The third is the similarity principle: the model is a form of numerical expression, which needs to have “similarity” with the actual prototype. The key to modeling is to reasonably use the mathematical formula and analytical graphics “similar” to the prototype. The established environment should use new independent variables or existing variables as environment settings. An auxiliary variable is introduced to simulate the change of an uncertain random variable through an affine function to obtain the probability distribution information of the random variable [35]. The calculation formula of auxiliary variable e is

$$e = \frac{f(v)}{E}. \quad (19)$$

In the above formula, v is the random variable in the uncertain set, $f(v)$ is the affine function of the random variable, and E is the random value function of the random variable. The loss control model is solved recursively. Through mixed-integer linear programming, e is transformed into the first-stage auxiliary variable o_1 and the second-stage auxiliary variable o_2 . The transformation formula is

$$\begin{cases} o_1 = \frac{(y_1 - y_2)cP}{h_{\max} - h_{\min}}, \\ o_2 = q(e - o_1). \end{cases} \quad (20)$$

In the above formula, y_1 and y_2 are the adjustment power of the photovoltaic inverter reactive power and active power,

c is the correction coefficient, p is the power of the abandoned light, q is the compensation capacity of the inverter access node, and h is the compensation capacitor. Through auxiliary variables, a fuzzy upper bound is applied to the objective function of the two stages, and the global optimal value in the worst scenario is obtained, the value of the uncertain random variable is continuously updated iteratively, and the set of decision variables which satisfies the expected cost minimization is selected to obtain optimal decisions for two-stage loss control scheduling [36]. So far, the solution of the two-stage loss control model of the high-power photovoltaic grid-connected inverter loss has been completed, and the design of the two-stage loss control scheduling method for the loss of the high-power photovoltaic grid-connected inverter has been realized.

5. Experimental Analysis

5.1. Experimental Environment. In order to verify the overall effectiveness of the intelligent control method of loss distribution balance of high-power photovoltaic grid-connected inverters, it is necessary to carry out relevant tests. An active distribution network is selected as the optimization object of the four methods. The distribution network is a combined electricity-heating type, the installed photovoltaic capacity is 1 MW, the rated capacity of the cogeneration unit is 2500 kW, the rated capacity of the electric energy storage is 2300 kWh, and the photovoltaic capacity is 2300 kWh. The output is fluctuating, and the peak load is taken as the power per unit value. The distributed power and daily load curves are shown in Figure 3.

According to Figure 3, the standard value of distribution network load is 2.95 MW and the PV unit value is 3.02 MW. When the design method is connected to the photovoltaic inverter, the DC voltage source and the controlled current source are, respectively, used to replace the front stage and the rear stage. The key parameters of the power circuit of the photovoltaic inverter are shown in Table 1.

Based on the key parameters of photovoltaic inverter in Table 1, the simulation results of intelligent control of loss distribution balance of high-power photovoltaic grid-connected inverter under the condition of severe uneven sunlight are studied by simulation experiment. The simulation time is 3 s, and the photovoltaic units keep the light intensity at 800 W/m². The corresponding high-power photovoltaic grid-connected inverter output voltage, output current, and loss control effects are given. The antiresonance capability of the high-power photovoltaic grid-connected inverter is analyzed.

5.2. Analysis of Experimental Results. According to the simulation parameter settings, test the waveforms of the output voltage and output current of the high-power photovoltaic grid-connected inverter before and after the application of the method in this paper, and test the regulation effect of the method in this paper in turn. The results are shown in Figures 4 and 5.

It can be seen from Figures 4 and 5 that, after the method in this paper regulates the joint operation of high-power

FIGURE 3: Daily operation curves of photovoltaic grid and load.

TABLE 1: Key parameters of PV inverter.

Parameter	Numerical value
Number of PVs installed in the node	8
Inverter rated capacity	4000 kW/h
Maximum charge and discharge power	450 kW
Inverter total capacity	4500 kW/h
Distribution grid voltage	220 V
Output filter inductor	7mH/0 Ω
Reactive power compensation range	-100~300 kvar
DC bus capacitance	2500 uF
DC bus voltage	450 V
Distribution network frequency	60 Hz
Inverter remaining capacity threshold	6.0kVA
Operating frequency	40 kHz
DC boost inductor	5 mH

photovoltaic grid-connected inverters in the power grid, the output voltage waveform can be optimized and the current fluctuation can be suppressed, which verifies the effectiveness of the method in this paper for loss control.

The proposed method, the method of [9], and the method of [10] are used to track the grid-connected current of the high-power photovoltaic grid-connected inverter, and the tracking results are shown in Figure 6.

Analysis of Figure 6 shows that, under the same environment, there are errors in the method of [9] and the method of [10] when tracking the incoming current, and the tracking results of the proposed method are basically consistent with the actual current waveform, indicating that the proposed method has better performance and tracking effect.

Change the inductance value of the grid-side point, and continue to use the proposed method, the method of [9], and the method of [10] to track the incoming current in the above test environment, and the tracking results are shown in Figure 7.

Analysis of Figure 7 shows that when the grid-side inductance of the proposed method changes, the tracking

— after application
 --- before application

FIGURE 4: Waveform diagrams before and after the output voltage is applied.

— after application
 --- before application

FIGURE 5: Waveform diagrams before and after the output current is applied.

results are still basically consistent with the actual grid-connected current, indicating that the proposed method has high robustness. Changing the grid-side inductance can be regarded as an external disturbance, so the loss affecting the high-power photovoltaic grid-connected inverter was analyzed before the proposed method to control the grid-connected current. On this basis, a two-stage loss control method was designed to control the grid-connected current. Therefore, for the external disturbance in the control process, the proposed method shows good robustness.

FIGURE 7: Grid current tracking results with changing grid-side point inductance.

A trace disturbance signal of 1000 rad/s is introduced into the control process of the double closed-loop grid-connected current of the inverter, and the antiresonance capabilities of the proposed method, the method in [9], and the method in [10] are compared, as shown in Figure 8.

It can be seen from Figure 8 that, after the introduction of microdisturbance signal, the network access current control curve obtained by the proposed method is relatively smooth, and there is no resonance peak, indicating that the proposed method has strong antiresonance capability. However, after the introduction of microdisturbance signal, there are multiple resonance peaks in the network current control curve and the surface smoothness is low, which shows that the resonance peaks of microdisturbance signal noise cannot be eliminated when the methods in [9] and [10] are used to control the loss of high-power photovoltaic grid-connected inverter. Compared with the proposed method, the network current control effects of the methods in [9] and [10] are poor, with weak antiresonance capability.

To sum up, the output voltage waveform can be optimized and the current fluctuation can be suppressed at 0A after the joint operation regulation of high-power

FIGURE 8: Antiresonance capabilities of different methods.

photovoltaic grid-connected inverters in the power grid. Under the same environment, the tracking results of the proposed method are basically consistent with the actual current waveform. When the network side inductance changes, the tracking result is still basically consistent with the actual network current. After introducing micro-disturbance signal, the control curve of network access current obtained by the proposed method at 0A is relatively smooth, there is no resonance peak, and the proposed method has strong antiresonance capability.

6. Conclusion

The control of photovoltaic grid connection is a necessary condition for photovoltaic system power generation and a key technology related to the utilization of new energy. It is very important for the intelligence, efficiency, and popularization of microgrid in the future. This paper proposes an intelligent control method for the loss distribution balance of high-power photovoltaic grid-connected inverter. Based on the analysis of the loss distribution of high-power photovoltaic grid-connected inverter, a two-stage loss control objective function is proposed. In the first stage, the scheduling costs such as photovoltaic energy and fluctuating load are selected, and, in the second stage, the penalty costs of light abandonment and load loss are selected, which are limited by branch power flow and charging and discharging power of distribution network. A two-stage loss control model of distribution network is built and the optimal solution of the model is searched. Finally, through experiments, the correctness and feasibility of the loss analysis and loss control strategy of photovoltaic grid-connected inverter are verified, which reflects the effectiveness of this method for loss control, good tracking effect, strong robustness, and strong antiresonance capability.

In industry, sensor-based monitoring of equipment or environment has become a necessity. Instead of using a single sensor, multi-sensor system is used to fully detect abnormalities in complex scenarios. Recently, physical models, signal processing technology, and various machine learning models have improved the performance. However, these methods either do not consider the potential correlation between features or do not take advantage of the sequential changes of correlation while constructing an anomaly detection model. This paper firstly analyzes the correlation characteristic of a multi-sensor system, which shows a lot of clues to the anomaly/fault propagation. Then, a multi-sensor anomaly detection method, which finds and uses the correlation between features contained in the multidimensional time-series data, is proposed. The method converts the multidimensional time-series data into temporal correlation graphs according to time window. By transforming time-series data into graph structure, the task of anomaly detection is considered as a graph classification problem. Moreover, based on the stability and dynamics of the correlation between features, a structure-sensitive graph neural network is used to establish the anomaly detection model, which is used to discover anomalies from multi-sensor system. Experiments on three real-world industrial multi-sensor systems with anomalies indicate that the method obtained better performance than baseline methods, with the mean value of F1 score reaching more than 0.90 and the mean value of AUC score reaching more than 0.95. That is, the method can effectively detect anomalies of multidimensional time series.

1. Introduction

Internet of Things (IoT) is an extended network based on the Internet, which supports more intelligent physical object management. In recent years, a rapid growth of the IoT has been witnessed, and the number of connected IoT devices is estimated to exceed 500 million by 2030 [1, 2]; therefore, IoT-based services will appear on a large scale in different application domains [2]. In the era of “Industry 4.0,” digital twin, which is a “fusion of the real and the virtual entities,” has begun to use data such as sensors, physical models, and

operational histories to represent the entire life cycle processes of physical entities [3]. In the actual production process, the digital twin entity is commonly established by monitoring one or more important, interdependent physical entities through sensors [4]. In general, the function of the sensor is relatively single, so a single sensor cannot fully reflect the physical world [5]. A multi-sensor system is a system that contains multiple sensors. A digital entity constructed by a multi-sensor system can reflect the entity and its behavior more comprehensively and can provide richer data for different kinds of analysis [6].

Hawkins [7] defined anomalies as data that are distinctive in a dataset, which is suspected not to be derived from random deviations but generated by a totally different mechanism. Anomaly detection refers to identifying anomalous data using various data processing models and techniques and is a prerequisite part for fault diagnosis [4]. Anomalies in the equipment or the environment, which reflect production problems, usually cause failures and economic losses and can even lead to catastrophic consequences [8]. Taking the electric power system as an example, we find that abnormal real-time monitoring of electric power and electrical equipment not only can obtain the running state of the equipment, but also will diagnose the fault in time. Therefore, finding anomalies can help to better ensure the safe and stable operation of a power and electrical equipment. On the contrary, failure to discover the anomalies implied in the sensing data will be unfavorable to the timely detection of problems of physical entities and may cause unnecessary losses. Thus, multi-sensor systems which can achieve data monitoring of complex equipment or an environment throughout its whole life cycle have become the main approach in the field of anomaly detection.

The collected data of a multi-sensor system is represented by multivariate time-series data, and different dimensions of the multivariate time-series data originate from different features of sensors. In complex industrial systems, anomalies are not always isolated. Due to the fuzzy physical interaction, small anomalies might spread between different sensors and gradually deteriorate into serious anomalies in some devices [9]. Taking the thermal power plant as an example, there are two devices: coal feeder and coal pulverizer. A coal feeder is responsible for conveying the coal to the coal pulverizer for crushing. In normal conditions, when the amount of coal conveyed by the coal feeder increases, the working load of the coal pulverizer also needs to increase accordingly in time, which indicates that the coal quantity of the coal feeder and the current of the coal pulverizer maintain a stable correlation. On the contrary, if the coal pulverizer is not adjusted within the allowable time range, it will cause coal blockage and insufficient output and even cause equipment damage and production interruption. That is, the complex correlation between sensors is closely related to anomalies.

In recent years, deep learning-based techniques have been used for the anomaly detection of multi-sensor systems. However, the potential relationships between sensors, which are helpful for finding anomalies, are not explicitly learned. That is, when the stable correlation is destroyed, it may indicate the occurrence of anomalies. Therefore, it is necessary to obtain the correlations between sensors in a multi-sensor system, and the main challenge of using these correlations in anomaly detection is that the functions of sensors vary greatly and the relationship between sensors changes dynamically, which requires dynamic discovery, representation, and detection of correlations. Hence, this paper proposes a correlation-based anomaly detection method of a sequential multi-sensor system, which learns a set of temporal correlation graphs from sensors and detects the deviations of these correlations. The proposed method involves two main stages. (1) Correlation-based graph model is constructed: Firstly, the

time-series data generated by the multi-sensor system is divided according to the time window. Nodes and edges are, respectively, used to represent the features and the correlations between pairs of features. Then, temporal correlation graphs are constructed to represent the fluctuation of correlations between features in a sequential multi-sensor system. (2) Graph-based anomaly detection learns the anomaly detection model with a structured-sensitive graph neural network and then identifies the deviations from the learned correlations in the temporal correlation graphs.

To summarize, the main contributions of this work are as follows:

- (i) This paper is a novel attempt to propose and construct the concept of temporal correlation graph by obtaining the correlation between the features in a multi-sensor system.
- (ii) A structured-sensitive graph neural network is used to learn the information in the temporal correlation graph, including attributes such as points, edges, and structure of the graph, and classify the graph based on the collected information for anomaly detection.
- (iii) The accuracy and stability of the proposed method are compared with baselines by conducting numerous experiments on several datasets, and hence accuracy and stability have proven better than those of the baselines.

The rest of this paper is organized as follows. Section 2 briefly introduces the related work of anomaly detection. Section 3 analyzes the correlation characteristics of the sensor data acquired by a multi-sensor system, defines the research problem, and describes the correlation-based anomaly detection method for multi-sensor system. The performance evaluation is given in Section 4, and Section 5 is the conclusion.

2. Related Work

An overview of the current state of anomaly detection is first presented. Then, the data-driven anomaly detection methods are reviewed. Since the proposed method is a deep learning method, the related work of machine learning methods and deep learning methods is also summarized.

2.1. Anomaly Detection. The most important aspect of quality monitoring in the industry is anomaly detection. With the application of multi-sensor systems in the industry, anomaly detection is starting to target more than just outliers. The data acquired by multi-sensor systems is reflected as high-dimensional time-series data with characteristics such as continuity and correlation. Therefore, the anomalies of physical entities characterized by multi-sensor systems are no longer reflected as a single outlier or small number of outliers, but through multiple anomalies of data with certain continuity. Currently, methods for anomaly detection can be broadly classified into two types, i.e., non-data-driven methods and data-driven methods [10].

2.2. Non-data-Driven Methods. The non-data-driven anomaly detection methods include physical model-based methods and signal processing-based methods. The former focus on obtaining the data signals on the system to be tested and analyzing the data processing results with the initially established model in order to obtain the abnormal diagnostic situation. The latter aims at investigating the techniques and methods of highlighting abnormal feature information.

However, the above methods require a priori knowledge and relevant equipment or environment knowledge.

2.3. Data-Driven Methods. The data-driven anomaly detection method can be used without having a priori knowledge such as the physical model of the system. That is, the monitored system data is analyzed to extract information about features and can be combined with historical data to diagnose anomalies in the system. This approach does not require extensive domain knowledge, relevant expert reasoning mechanisms, or establishment of accurate complex system models. This has become an important tool in the field of anomaly detection in the context of IoT and Industry 4.0. Traditional data-driven anomaly detection methods refer to anomaly detection for outliers and can be classified into four types, namely, statistical-based methods [11, 12], distance-based methods [13, 14], density-based methods [15, 16], and clustering-based methods [17, 18]. Statistical-based methods are model-based methods where a model is first created for the data and evaluated based on how well the object fits the model. For example, Laurikkala et al. [10] used box-line plots to identify outliers in the dataset while Kasliwal et al. [16] used a hybrid model of G-LDA which combines Latent Dirichlet Allocation (LDA) and genetic evolution techniques to detect anomalies in the network traffic. Distance-based methods consider a point anomalous if it is far from most of the points, because for the distance measurement, there are various ways. For example, Zhang et al. [17] used Mahalanobis distance for anomaly detection of hyperspectral images while Laxhammar and Göran [19] used Hausdorff distance for phase dissimilarity measure for multidimensional trajectories of arbitrary length. Density-based methods consider outliers as objects that are in low-density regions. Density is commonly defined by proximity. Huang et al. [20] solved the problem of adaptive anomaly detection based on the Local Outlier Factor (LOF) algorithm while Celik et al. [21] discovered the anomalies present in temperature data based on the Density-Based Spatial Clustering of Applications with Noise (DBSCAN) algorithm. Clustering-based methods treat those data that do not belong to any class as anomalies by clustering them into classes. Münz et al. [22] proposed an anomaly detection approach based on the K-means algorithm for detecting anomalies in network monitoring data while Chitrakar and Chuanhe [23] proposed a hybrid method to solve the anomaly detection problem by combining Naïve Bayes classification and k-Medoids clustering method.

Since this paper aims to perform anomaly detection on a multi-sensor system based on extracting and analyzing

potential correlations between features, the above methods do not match the goal of this paper.

2.4. Machine Learning Methods. As a typical representative of data-driven methods, machine learning can comprehensively analyze and mine potential anomalies in the high-dimensional time-series data generated by multi-sensor systems. Rauber et al. [24] designed a raw feature vector based on a set of statistical and signal characteristics and then used Support Vector Machine (SVM) to identify bearing faults. Chine et al. [25] calculated several feature parameters and used Artificial Neural Networks (ANN) for fault diagnosis of photovoltaic (PV) systems.

Although machine learning models, such as SVM [26], ANN [27], clustering algorithms [28], genetic algorithms [29], and fuzzy inference [30], can partially meet the needs of anomaly diagnosis and identification, changes in mechanical equipment load during operation can also affect the generalization ability of the models.

2.5. Deep Learning Methods. Deep learning is a branch of machine learning, and it can automatically discover features to meet the requirements of adaptive feature extraction for mechanical anomaly diagnosis. It effectively overcomes the shortcomings of traditional manual extraction of features, such as poor generalization ability and poor robustness, and reduces the uncertainty of traditional anomaly detection methods in the process of manual design and extraction. In recent years, different deep learning models, such as Deep Belief Networks (DBN), Stacked Autoencoder (SAE), Recursive Neural Network (RNN), and Conventional Neural Network (CNN), have received increasingly wide attention in intelligent anomaly detection [31]. Zhao et al. [32] proposed an approach for multi-sensor fault detection based on DBN, using deep learning models for the classification and prediction of sensor faults. Li et al. [33] used DBN for fault classification of bearings to reduce the manual operations in the detection process and to achieve intelligence in fault detection. Lei et al. [34] proposed a deep learning-based health monitoring method for mechanical equipment using frequency-domain signals as training data for Deep Neural Networks (DNN), completing adaptive feature extraction and intelligent health condition identification without the need for fault feature extraction through signal processing. Wan et al. [35] proposed a function-aware anomaly detection approach, in which both single function and short sequence patterns are considered as the function control characteristics, and a Wavelet Neural Network- (WNN-) based behavior model is established to detect function control misbehaviors caused by cyber intrusions in industrial automation. Kumar and Hati [36] proposed a CNN-based fault detection method for squirrel cage induction motor, in which small convolutional kernel and adaptive gradient optimizer were used to verify the performance of CNN model. Wilson et al. [37] proposed a deep learning-based fault diagnosis method for ship turbines using a deep bidirectional Long Short-Term Memory (LSTM) model for fast detection of turbines. Khorram et al. [38] investigated a

Convolutional Recurrent Neural Network- (CRNN-) based fault diagnosis method, where the authors fused CNN and LSTM to form a Deep Neural Network for end-to-end fault diagnosis. Deng and Hooi [39] proposed an anomaly detection method based on GDN (Graph Deviation Network) in multivariate time series, in which the relationship between sensors is firstly found by GNN (graph neural network). The expected behavior of time series is then predicated, and the anomaly is finally identified by judging whether the predicted data violates the correlation. It considers the correlation as the scoring and judgment basis of whether the prediction data is abnormal.

In a nutshell, all the methods do not consider the potential correlation between features in a multi-sensor system, except for the method proposed in [39], which only uses the correlation as a threshold to judge whether the prediction data is abnormal and does not fully consider the dynamic and continuous characteristics of correlation to directly construct an anomaly detection model. In a multi-sensor system, sensors cooperate with each other to reflect the state of an entity, and the features used to describe the same entity are usually relevant. In general, the correlation is related to the physical characteristics of the entity, so the correlation is relatively stable, and if the correlation is broken, there may be an anomaly. Therefore, it is necessary to introduce correlation into anomaly detection for the purpose of finding potential anomalies caused by feature dependencies. Moreover, due to the time stability of the correlation, using the correlation between features which are obtained by time window for anomaly detection can effectively avoid the wrong detection results caused by discrete noisy data.

3. The Proposed Method

3.1. Correlation Characteristic of Multi-sensor System. Sensor data is generally considered to be the data collected by sensors for continuous sensing of the physical world. A multi-sensor system consists of several or even plenty of sensors. These sensors are used jointly to reflect the physical world. Except for continuity [40] and high dimensionality [41], the sensor data acquired by a multi-sensor system has several correlation characteristics, discussed as follows.

3.1.1. Spatiotemporal Correlation. Sensor data is always applied to collect information about the physical world. Therefore, the sensor data can be correlated with the physical world it senses, especially in terms of time and space. In other words, there is a similarity between sensor data collected by similar sensors located in analogous time and space ranges. For example, multiple air quality monitors set up in the same environmental monitoring station at the same moment detect the same environmental indicators. Therefore, if sensor data is anomalous, the sensor data with which it has spatial-temporal correlation is more likely to be anomalous as compared to other sensor data [40].

3.1.2. Data Similarity. If the sensor's monitoring objects are similar in behavior, the sensor data which is used to portray

their behaviors should also have similarities. Take the power system as an example; the electricity meter data of household users with similar electricity consumption patterns are also approximately similar. It can be assumed that there are similarities between the data collected by similar sensors under similar behavioral, temporal, or spatial conditions. If sensor data is anomalous, the sensor data with which it has data similarity is more likely to be anomalous. That is, sensor data that disrupt data similarity may be anomalous. In a real-life production environment, monitoring data are relatively stable in most cases [42]. When a special event happens, the surrounding sensors usually monitor the situation and obtain data at the same time [43].

3.1.3. Data Correlation. There may be correlations between the collected data of different sensors monitoring the same physical entity, including positive correlation and negative correlation. For example, the current and voltage collected by smart meters are correlated with power while the line loss is positively correlated with the current in the transmission system. When this correlation fluctuates, it may mark an anomaly of the physical entity; therefore, the correlation between different sensor data can also be used as a basis for determining anomalies. In fact, sensors always work together. Even if single sensor data is normal, it might be anomalous when it is calculated jointly with other sensor data [44].

3.2. Problem Statement. In a multi-sensor system, the training data usually consists of multiple sensors' data, that is, multivariate time-series data with M features from N sensors. The multivariate time-series data is expressed as the following formula:

$$S_{t,w} = (s^1, s^2, \dots, s^m)^T \in R^{m \times w}. \quad (1)$$

In (1), t denotes the current timestamp, w denotes the size of the time window, and m denotes the feature dimension of the temporal data. Moreover, s^i ($i = 1, 2, \dots, m$) denotes the column vector composed of the values of feature i in the dataset over the time window from timestamp t to timestamp $t + w - 1$, and $S_{t,w}$ denotes a fragment of the time series. Using $s^k = (s^k_t, s^k_{t+1}, \dots, s^k_{t+w-1})^T \in R^w$ denotes the value vector of the k th feature within a time window.

The goal of this paper is to identify anomalies in physical entities characterized by multivariate time-series data generated by the same sensors but over a different time slice. The output of the proposed method is a group of labels used to show the result of anomaly detection for each time window; i.e., $\text{label}_t \in \{-1, 1\}$, in which $\text{label}_t = 1$ indicates that the time window t is normal, and $\text{label}_t = -1$ is the opposite.

3.3. Method Overview. The goal of the proposed correlation-based anomaly detection method is to capture the temporal correlations between sensors and then identify whether the normal temporal correlation patterns between sensors are violated. As shown in Figure 1, the proposed method mainly

involves two parts, namely correlation-based graph model construction and graph-based anomaly detection.

3.3.1. Correlation-Based Graph Model Construction. It represents the unique characteristics of the multiple sensors for each time window with multivariate time-series data, and these multidimension time series are converted into a set of graph structures.

3.3.2. Graph-Based Anomaly Detection. It trains an anomaly detection model with a structured-sensitive GNN and then identifies deviations from the learned temporal correlations.

3.4. Correlation-Based Graph Model Construction. Data captured by a multi-sensor system are represented as multivariate temporal data; i.e., there are temporal correlations between different sensors. To represent and analyze the correlations, these multidimensional time-series data can be transformed into a set of temporal correlation graphs $G = (V, E)$ according to the time window. A temporal correlation graph is an undirected graph, where the nodes represent features in the multi-sensor systems while the edges represent the correlation between these features.

3.4.1. Construction of Nodes. Each feature of the multi-sensor system is considered as a node in the temporal correlation graph, and the node information consists of $s^i = (s^i_p, s^i_{t+1}, \dots, s^i_{t+w-1})^T$, where $i = 1, 2, \dots, m$, where m is the total number of nodes.

3.4.2. Construction of Edges. The edges in a temporal correlation graph are defined as the temporal correlations between nodes. Take the example of constructing an edge between node V_i and node V_j ; the edge is depicted as a row vector $e = (corr_1, corr_2, \dots, corr_k)$ consisting of k kinds of correlation coefficients between node V_i and V_j on the time series $S_{t,w}$. To comprehensively measure the correlation between nodes, this study fuses multiple correlation coefficients to constitute the edge information, including Manhattan distance, Euclidean distance, Chebyshev distance, Pearson correlation coefficient, and Spearman correlation coefficient.

By calculating the inter-feature correlation coefficients of each pair of features, the corresponding inter-feature correlation coefficient matrix for a time window can be obtained, as shown in Figure 2(a). If the inter-feature correlation coefficient matrices of continuous-time windows are combined, a group of multidimensional temporal correlation matrices are built, as shown in Figure 2(b).

3.4.3. Construction of Temporal Correlation Graphs. To identify the fluctuation of correlations between features, the proposed method converts each matrix array into a temporal correlation graph. Subsequently, the correlation strength between pairs of features is calculated according to the correlation coefficient. Then, the value of correlation

coefficient is further analyzed; if it is within the threshold of the correlation coefficient in the normal mode, the edge is reserved; otherwise, the edge is removed from the graph. That is, a temporal correlation graph can be an incomplete graph, and the structures of different temporal correlation graphs may not be the same, as shown in Figure 3.

When the multidimensional time series are converted into a set of temporal correlation graphs, these graphs are used as an input for the graph-based deep learning algorithm. Besides, the proposed method is still a supervised one; the correlations among features always have high stability. Since anomalies in a multi-sensor system are usually reflected as non-single outliers and the significant fluctuations in the correlations between features in different time windows may exist, a label is assigned to each temporal correlation graph, which is used to mark whether the time series is abnormal or not. If anomalies exist, the graph label is set to positive; otherwise, it is set to negative.

3.5. Graph-Based Anomaly Detection. The method uses temporal correlation graphs to represent features and the correlations between them. Changes in the graph structure, point, and edge attributes can reflect changes in the degree of dependency between features. Therefore, an anomaly detection of multi-sensor systems can be converted into a binary classification problem based on the GNN model.

3.5.1. Construction of Graph-Based Anomaly Detection Model. Figure 4 shows the network architecture of the anomaly detection model.

The correlation between features is also a kind of time-series data, whose fluctuation is universal. In this paper, the edges of temporal correlation graph are conducted based on the strength of correlation between features. If the correlation is very low or even does not exist, there is no edge between features. That is, the temporal correlation graphs are heterogeneous. Therefore, a structure-sensitive graph convolution neural network, GIN (Graph Isomorphism Network), is applied to the temporal correlation graphs by encoding feature and the correlation between features according to the requirements of GIN. Then, Global Add pooling (GAP) which refers to the default pooling function `global_add_pool` in `torch_geometric` maps the features of different samples to the same size and the pooled features are output to the Softmax classifier for classification after being mapped to the sample label space by the fully connected (FC) layer. In addition, for this model, cross-entropy loss is selected as the training loss function, and Adam is used to optimize the neural network.

3.5.2. Anomaly Detection. Figure 5 shows the workflow of graph-based anomaly detection. The multidimensional time series is firstly transformed into a set of inter-feature correlation matrices, and then the corresponding temporal correlation graphs are established. The graph-based anomaly detection model treats these graphs as input and produces output based on the binary classification.

4. Evaluation

4.1. Experimental Setting. Dataset: In order to evaluate the validity of the proposed method, this paper conducted extensive experiments on three industrial datasets. These datasets are described in detail as follows:

Dataset 1: Air Quality1 is from the air quality online detection and analysis platform (<https://www.aqistudy.cn/historydata/>). The platform contains air quality and meteorological data collected hourly in more than 300 cities from December 2013 to December 2021. Dataset 1 selected the historical data from January 2014 to December 2018 in Air Quality1, including AQI, $PM_{2.5}$, PM_{10} , CO, NO_2 , SO_2 , and O_3 . Among them, AQI is used to measure air quality based on the standard of “Technical Regulation on Ambient Air Quality Index (on trial)” [45]. The data description of other features in Dataset 1 is shown in Table 1, in which the unit of each feature is $\mu g/m^3$.

Dataset 2: Air Quality2 is from Kaggle (<https://www.kaggle.com/amritpal333/tps-july-2021-original-dataset-clean>). The installation is in a heavily polluted area of an Italian city, and the data are collected through an embedded air quality chemical multi-sensor unit containing five metal oxide sensors’ data and other relevant data. The five metal oxide sensors’ data refer to carbon monoxide, total nitrogen

oxides, non-methane hydrocarbons, NO_2 , and benzene. Air Quality2 is accumulated according to the “Ambient Air Quality Standards” [46]. The dataset contains six kinds of air quality data from March 2004 to February 2005, with data collected hourly. After data cleaning, a total of 827 time points were included. To ensure the scale, Dataset 2 was constructed by replicating Air Quality2, and the expanded dataset contains data of 414327 time points. The data description of Dataset 2 is shown in Table 2, in which the units are, respectively, mg/m^3 , $\mu g/m^3$, $\mu g/m^3$, $^{\circ}C$, %, and g/m^3 .

Dataset 3: The gas chromatography data was obtained from the industrial dataset of power enterprises, consisting of the dissolved gas content of insulating oil of oil-filled power equipment. It is the basis for power generation and supply enterprises to judge whether there are latent overheating, discharge, and other faults of oil-filled power equipment in operation. Moreover, it is also the necessary data for oil-filled electrical equipment manufacturers to carry out factory inspection of their equipment. Dataset 3 is time-series data consisting of transformer oil chromatography data, containing six data items, namely, H_2 , CH_4 , C_2H_4 , CO, C_2H_6 , and total hydrocarbons, containing 20128 time points. Based on the “Guide to the Analysis and the Diagnosis of Gases Dissolved in Transformer Oil” [47] issued by the National Energy Administration, if the gas

evaluate the validity of the proposed method, it is essential to conduct experiments on datasets with different anomaly distributions. Therefore, a data enhancement algorithm whose framework is described in Algorithm 1 is used to inject anomalies into the original data. The method of data augmentation is as follows: For each passing step, an attribute is selected, and the original time-series array is modified by the data augmentation sequence array within the data augmentation window.

The distribution of anomalies for the datasets is listed in Table 4.

Baselines: The following algorithms are selected for comparison for the sake of verifying the effectiveness of the proposed method. The detailed description of these comparison algorithms is as follows.

Decision Tree: The purpose of decision trees is to build a model which can forecast the value of a specified variable according to a set of decision rules extrapolated from the

Algorithm 1 : Data augmentation in the dataset.

ALGORITHM 1: Framework of data augmentation in the dataset.

data characteristics. It can be used as a nonparametric supervised algorithm for classification.

Logistic Regression: Logistic regression is used to evaluate the possibility of a particular event by settling binary classification problems through the machine learning method.

Naïve Bayes: As a supervised algorithm, Naïve Bayes is a simple and effective classification algorithm based on Bayes' theorem.

Quadratic Discriminant Analysis: Quadratic Discriminant Analysis (QDA) is a classifier that makes classifications according to the difference in covariance, which is particularly useful for many features.

Support Vector Machine: Support Vector Machine (SVM) is a binary classification algorithm that maps the feature vector of each entity to a point in the space and classifies these space points by finding an optimal separating hyperplane.

Convolutional Neural Networks: As a deep learning model, Convolutional Neural Network (CNN) is a feed forward neural network based on convolution calculation, which can classify the input information according to the hierarchical structure.

Evaluation Metrics: Although anomalies are common, the proportion of anomalies in a dataset is not high, so most of the data used for anomaly detection are unbalanced data. In the classification problem of balanced data, accuracy is a common evaluation metric. In the classification of unbalanced data, F1 score and AUC (Area Under Curve) score are common evaluation metrics. Thus, F1 score and AUC score are used to measure the performance of the proposed method.

F1 Score: Precision focuses on evaluating the proportion of real positive data in all data predicted as positive, while

TABLE 4: Detailed information of datasets in the experiments.

Dataset	Positive samples	Negative samples	Negative ratio (%)
Dataset 1	4142	6807	37.82
Dataset 2	1562	256	85.90
Dataset 3	898	3126	22.30

TABLE 5: Settings of hyperparameters.

Hyperparameter	Dataset 1	Dataset 2	Dataset 3
window_size	5	5	5
threshold_1	0.25	0.25	0.05
threshold_2	2	2	3
learning_rate	0.01	0.01	0.01
batch_size	10	10	10

recall focuses on assessing how much of all the positive data has been successfully predicted as positive. F1 score is a harmonic mean of precision and recall. In general, the value of F1 score will be high only when both precision and recall are good.

AUC Score: Facing the unbalanced data, ROC (Receiver Operating Characteristic) curve ignores the imbalance of samples and only considers the classification ability of the model. That is, when the proportion of positive and negative samples changes, the discrimination ability of the model remains unchanged, and the shape of ROC curve will not change. However, ROC is not intuitive enough, so AUC which refers to the area under the ROC curve becomes a way to reflect the classification ability expressed by the ROC curve. Since AUC score is robust to the data with heterogeneous distribution of positive and negative samples, this

CNN	0.90	0.005	0.86	0.027	0.95	0.005
Proposed method	0.92	0.006	0.90	0.031	0.95	0.004

Bold font is to highlight the results of the proposed method.

paper uses AUC score as a metric for performance evaluation, and the larger the AUC, the better the effect.

Environments: A XenServer virtual machine is used to conduct these experiments, and its configuration is as follows: CentOS7.3, one Intel Core i5-1135G7 processor, 16.00 GB RAM, 500 GB hard disk. The proposed method and the baselines are all implemented in Python and PyTorch 1.6.0.

Hyperparameter Settings: The model in this paper involves five hyperparameters, which are *window_size*, *learning_rate*, *batch_size*, correlation coefficient-related parameter *threshold_1*, and feature value anomaly-related parameter *threshold_2*. *window_size* is the size of the sliding window, which can collect data on the time series according to the specified length; *learning_rate* and *batch_size* are the parameters used to train the deep learning model; *threshold_1* is the upper limit of the inter-feature correlation coefficient fluctuation; *threshold_2* is the upper limit of feature value anomalies within the sliding window. Table 5 gives the setting of these hyperparameters in the experiments.

In addition, the model setting for the structure-sensitive GNN is as follows: the model was trained for 300 epochs with a learning rate of 0.01 and a batch size of 10.

4.2. Experiments

4.2.1. Experiment on Accuracy. The mean and standard deviation are two relevant statistical indicators whose combined use can describe the overall characteristics of the data more comprehensively. The former indicator shows the concentration tendency of the data, while the latter indicator shows the off-center tendency of the data. In other words, the smaller the standard deviation, the better the representativeness of the mean. Table 6 shows the accuracy of anomaly detection by listing the mean and standard deviation of F1 scores of the proposed method and the baselines in three datasets.

As shown in Table 6, the standard deviation values of the F1 score in the three datasets are, respectively, 0.006, 0.031, and 0.004. The two standard deviation values of CNN are 0.001 lower than or equal to those of the proposed method, while the other 16 values are not as good as those of the proposed method. This result shows that the F1 score of the proposed method is more concentrated and the proposed method is more stable. The mean values of the F1 score in the

three datasets are, respectively, 0.92, 0.90, and 0.95. Among all the mean values of F1 score, only the value of the decision tree on Dataset 3 is 0.02 higher than that of the proposed method. This proves that the proposed method outperforms all the other baselines. In addition, all the three mean values of the F1 score of the proposed method are more than 0.90, while the baselines failed to do so. Overall, the F1 score of the proposed method is low for off-center tendency and high for concentration tendency. F1 score is a comprehensive evaluation of the precision and recall of a method. The results indicate that the method proposed in this paper achieves well balanced precision and recall, which shows that both precision and recall are good.

4.2.2. Experiment on Classification Ability. In Table 7, the classification ability of different anomaly detection methods in terms of the mean value and standard deviation of AUC score on the three datasets is given.

As shown in Table 7, the standard deviation values of the AUC score in the three datasets are, respectively, 0.005, 0.009, and 0.005. Only three standard deviation values are, respectively, 0.001, 0.001, and 0.002 lower than those of the proposed method, while the other 15 values are not as good as those of the proposed method. This result indicates that the mean value of the AUC score of the proposed method is quite concentrated. The mean values of the AUC score in the three datasets are, respectively, 0.96, 0.98, and 0.95. Except that the value of the decision tree on Dataset 3 is 0.01 higher than that of the proposed method, the proposed method outperforms all the baselines. The mean values of the AUC score of the proposed method on the three datasets all exceed 0.95, while the other methods do not reach this value. AUC score reflects the classification ability of the models. Therefore, the results illustrate that the method proposed in this paper is superior to the baselines in the classification ability on all the three datasets no matter whether the datasets are balanced or not.

In view of the above experiments, it is found that the method based on the neural network has better performance. Meanwhile, the decision tree method also has good results on Dataset 3. The reason is that Dataset 3 is the actual measurement data of the substation equipment of the National Grid, and the original dataset does not contain anomalies, while the injected anomalies are more obviously different from the normal data. Since the decision tree uses a tree structure, it is easier to decide if the two categories are

TABLE 7: Classification ability of anomaly detection in terms of AUC score, on three datasets.

Method	Dataset 1		Dataset 2		Dataset 3	
	Mean	Standard deviation	Mean	Standard deviation	Mean	Standard deviation
Logistic regression	0.90	0.006	0.98	0.008	0.95	0.008
Decision tree	0.90	0.006	0.89	0.051	0.96	0.012
Naïve Bayes	0.93	0.007	0.96	0.010	0.84	0.025
QDA	0.92	0.009	0.91	0.030	0.92	0.020
SVM	0.75	0.012	0.81	0.022	0.68	0.042
CNN	0.96	0.004	0.96	0.007	0.93	0.006
Proposed method	0.96	0.005	0.98	0.009	0.95	0.005

Bold font is to highlight the results of the proposed method.

completely different when binary classification is performed, so its classification results become better. However, the F1 score and AUC score of the decision tree in Dataset 1 and Dataset 2 are not as good as the proposed method. That is, the stability of the decision tree is lower than that of the proposed method. In brief, the experimental results of the proposed method on all three datasets illustrated that the method introduced in this paper is a better classifier than the baseline methods by combining the two metrics, especially for the anomaly detection problem in which unbalanced data may exist.

5. Conclusion

For the anomaly detection problem of multi-sensor systems, this paper proposes an anomaly detection method which innovatively makes use of the correlation between features and transforms the anomaly detection of multivariate time-series data into graph classification problem. Since the correlation of features fluctuates with time, the concept of temporal correlation graph is firstly proposed, and the method in which both the feature and the correlation between features are, respectively, encoded into nodes and edges is given to construct the temporal correlation graph. Subsequently, the graph classification model is established for the constructed graph structure data which may have structural differences by the structured-sensitive GNN. Finally, the anomalies of the multi-sensor system are identified by determining whether the graph data are anomalous. The results of the experiments show that the mean values of F1 score and AUC score of the proposed method exceed 0.90 and 0.95, respectively, which are better than those of other baseline methods. That is, the proposed method achieves well balanced precision and recall and is a better classifier which provides better discrimination. Therefore, the proposed method can effectively identify the physical entity anomalies reflected by multidimensional time series in multi-sensor systems. Future research will focus on conducting more abundant experiments to analyze the influence of graph-related attributes and labels on the classification effect and to study more domain-targeted anomaly detection methods for multi-sensor systems.

Data Availability

Dataset 1 and Dataset 2 used to support the findings of this study are included within the article. Dataset 3 used to

support the findings of this study was supplied by China State Grid under license and so cannot be made freely available. Requests for access to these data should be made to the corresponding author for an application of joint research.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

With the steady growth of the global economy, the communication between countries in the world has become increasingly close. Due to its translation efficiency and other problems, the traditional manual translation has gradually failed to meet the current people's translation requirements. With the rapid development of machine-learning and deep-learning related technologies, artificial intelligence-related technologies have affected various industries, including the field of machine translation. Compared with traditional methods, neural network-based machine translation has high efficiency, so this field has attracted many scholars' intensive research. How to improve the accuracy of neural machine translation through deep learning technology is the core problem that researchers study. In this paper, the neural machine translation model based on generative adversarial network is studied to make the translation result of neural network more accurate and three-dimensional. The model uses adversarial thinking to consider the sequence of emotion direction so that the translation results are more humanized. We set up several experiments to verify the efficiency of the model, and the experimental results prove that the proposed model is suitable for Chinese-English machine translation.

1. Introduction

Since the twenty-first century, the economic level of all countries in the world has been greatly improved. In the context of economic globalization, cross-language communication between people of all countries has become more and more frequent. Different nations have their own customs and cultures, and there are great differences in language expression. How to communicate effectively across languages is a problem that must be faced and solved. Due to its translation efficiency and other problems, the traditional manual translation has gradually failed to meet the current people's translation requirements. Therefore, many people turn their attention to Machine Translation, which is an important branch of natural language processing. Machine translation is to generate the target language with the semantics of the source language unchanged through relevant computer and algorithm and other techniques. That is, to achieve equal conversion from one natural language to another [1, 2].

In the initial stage of machine translation research, the implementation of translation is mainly through the use of rule-based methods. Linguists manually compile translation rules between source language and target language, that is, rules that enable conversion between two natural languages, and then input these formulated translation rules into the system [3]. Although the method that generate conversion rules between source and destination languages has made great progress, this method almost completely depends on the quality of language rules established by linguists, and it has certain limitations in practical application. Moreover, due to the problems such as its too extensive coverage and the direct relationship between language and national culture, it is difficult to list the translation rules between source language and target language. Therefore, the failure to obtain a complete set of language rules [4, 5] is the main problem faced by rule-based machine translation. IBM put forward the Statistical Machine Translation model in 1993. Statistical Machine Translation mainly adopts the way of word alignment between source language and target language.

Statistical Machine Translation mainly obtains the conversion rules between two natural languages by learning the corpus, without the need to make conversion rules manually. However, there are still many problems in Statistical Machine Translation [6]. It relies too much on the learning of the model in the corpus and has high requirements on the accuracy of the processing steps such as word alignment, word segmentation, and translation rule extraction [7].

In recent years, with the continuous maturity of artificial intelligence technology and the rapid development of machine learning and deep learning-related technologies, deep learning has gradually been combined with different fields. How to improve the accuracy of neural machine translation through related deep learning technology is also a problem that researchers have been studying [8, 9]. Deep learning techniques are used to deal with natural language problems so that some problems faced in natural language processing have been well solved and good results have been achieved. The application of deep learning technology provides many ideas and methods for improving the accuracy and efficiency of machine translation. At present, deep learning technology is mainly used in two models in the machine translation [10]. The first is the Statistical Machine Translation model framework, which adopts neural network to improve and optimize the language model, sequencing model, and other key modules in the model framework. The second method is to construct the encoder and decoder through neural network, and use the end-to-end neural network machine translation model to realize the translation and conversion from source language to target language [11, 12]. With the deepening of research, more and more neural network machine translation algorithms are proposed.

2. Related Work

2.1. Rule-Based Machine Translation. With the birth of computers in the middle of the last century, machine translation began its exploration [13]. In 1954, IBM used the computer to translate several simple Russian sentences into English for the first time. Its translation system consists of six translation rules and 250 words [14, 15]. This experiment shows that the process of machine translation can be realized by using the method based on dictionaries and translation rules. Although it was only a preliminary success, it aroused the enthusiasm of machine translation research in the Soviet Union and other European research institutions. It greatly promoted the research progress of early machine translation. However, machine translation was completely rejected in 1966 by a report titled LANGUAGE AND MACHINES, and machine translation research suffered a setback at that point [16, 17]. With the increasingly close exchanges between countries, the communication barriers between different languages become more and more serious, and people's demand for machine translation is more and more intense. At the same time, the development of corpus linguistics and computer science has provided new possibilities for machine translation. Since then, Machine Translation has entered a period of rapid development. After decades of evolution, it has formed three stages from Rule-based Machine

Translation to Statistical Machine Translation and then to Neural Machine Translation [18–20].

The earliest machine translation method is rule-based machine translation, which realizes the conversion between source language and target language by making relevant translation rules. The process of rule-based machine translation mainly includes three steps: source language parsing, language conversion, and target language generation [21]. The first step is to parse the input source language to obtain the structural representation of the source language. The second step is language conversion. Transform the structural representation of the source language into the structural representation of the target language through the formulated translation rules. In the third step, the representation of the target language is generated into the target language by processing the corresponding rules. Early rule-based machine translation methods require manual transformation rules. Although they have high-translation accuracy for a small number of sentences, their coverage is limited, the system robustness is poor, and is very sensitive to noise in rules. The rule-based machine translation method can perform machine translation to a certain extent, but its application is very limited. This translation method almost completely depends on the language rules established by linguists, which has certain limitations in practical application. Moreover, due to the extensive and profound language, it is difficult to list all the rules contained in various kinds of language. Therefore, the inability to obtain a complete set of language rules is the main problem facing rule-based machine translation research.

2.2. Machine Translation Based on Statistics. In order to solve the problems of rule-based machine translation, statistical machine translation has become the representative method of machine translation research. A landmark event was the launch of Google's free online automatic translation system, also known as Google Translate [22], which really brought the "high-flying" technology of machine translation into people's lives. Statistical machine translation is a data-driven approach that designs probabilistic models on large-scale parallel corpora to achieve automatic translation from source language to target language. Early statistical machine translation was word-based, learning model parameters from words in the corpus. Later, phrases were used as the basis to learn model parameters, and now syntax is used as the basis to build syntactically based statistical machine translation model to further improve translation accuracy. Statistical machine translation model is one of the most widely used machine translation models. This is because statistical machine translation models have excellent translation results in machine translation in unbounded domains.

Statistical machine translation model is to obtain the parameters required by the relevant translation model through the statistical analysis and learning of a large number of parallel corpus, and then to construct the statistical translation model, and then to use the model for translation. Koehn et al. took words as the basic unit of

statistical machine translation model, extracted corresponding words of original language and target language from corpus, and proposed phrase-based statistical machine translation model [23]. Och and Ney proposed statistical machine translation based on the maximum entropy model and constructed the machine translation model through the log-linear model [24]. Later, the processing unit of the translation model is extended to include words, and a phrase-based statistical machine translation model is proposed [25]. All of the above statistical machine translation methods are syntactically based and take syntactic structure as the basic translation unit to construct translation models. Although the basic organizational structure of a sentence can be displayed through the syntax tree, the specific semantic information of the sentence cannot be expressed, which makes it difficult for the final translation to correctly represent the original sentence semantics. People gradually turn their attention to the semantic understanding of source language and target language in machine translation. In order to increase the differentiation of translation rules, Aziz et al. integrated the semantic information generated by the source language as a feature into the existing translation model, and marked the nonterminal symbols in the syntactic translation model to a certain extent through the semantic role information [26]. Wu and Fung preprocessed the translation process to realize the utilization of semantic information, reordered the candidate translation list, and marked semantic information with semantic roles [27]. Zhai et al. [28] through the predicate meta-structure made the statistical machine translation model maintain the semantic information of the original text to the maximum extent, made the semantics of source language and target language more similar, and established a semantic translation model based on the transformation of predicate meta-structure.

The charm of language lies in the fact that different words have different meanings in different situations. However, in the process of translation, these traditional machine translation models ignore the influence of contextual information on sentence semantics, ignore the context in which the sentence exists, and only focus on the translation of the sentence, which results in the lack of structural rationality and semantic coherence. Therefore, many researchers conduct machine translation research based on the whole article as a translation unit. Xiong et al. [29] proposed a statistical machine translation model based on topic transformation in order to improve the quality of discourse-level statistical machine translation. Gong et al. maintained semantic consistency of the same words and phrases in the whole document through semantic caching technology based on cohesive properties [30]. Tu et al. made a preliminary exploration of the discourse translation framework model based on discourse and proposed a statistical machine translation model that takes the rhetorical structure of discourse as the basic translation unit [31]. Statistical machine translation also has some problems. The independent parameter model structure makes the parameters of the translation model independent, which leads to the situation that the translation model cannot consider the relevance between words, leading to the existence of

sparse problem. The process of parameter optimization and training of translation model is independent and not unified. Since learning is carried out in a corpus, statistical machine translation is dependent on the corpus, and the quality of the corpus will directly affect the final translation result. Without in-depth analysis of the source language, if the model does not deal with syntactic and semantic components, it ignores the connection between words and context, which results in the inability to deal with long-distance dependence, resulting in semantic incoherence and unreasonable semantics [32].

2.3. Neural Network Machine Translation. With the development of deep learning theory, researchers have found that deep learning-related technologies can better solve these problems in statistical machine translation. Neural machine translation technology originated from the neural network probabilistic language model proposed by Bengio et al. in 2003 [33]. It represents discrete characters into continuous dense distributed vectors through neural networks, which effectively alleviates the problem of data sparsity. In 2013, Kalchbrenner and Blunsom et al. [34] from Oxford University constructed an encoder-decoder structure by using CNN and RNN. As an encoder, convolutional neural network (CNN) can obtain historical information and process variable length strings. As a decoder, recurrent neural network (RNN) can directly model translation probability. In earlier studies, deep neural network was only used as an auxiliary method for language modeling, while their study was completely composed of deep neural network, which marked the independent application of deep learning methods in machine translation. Subsequently, Sutskever et al. in Google team proposed RNN-RNN model on the basis of the former, which became the general Sequence-to-Sequence model later. The model uses recurrent neural network as the backbone network of an encoder and a decoder. Cho et al. [35] proposed that Gated Recurrent Unit (GRU) could replace LSTM to handle machine translation tasks. GRU is actually an optimization of LSTM, which simplifies the internal structure, reduces training parameters, and improves training efficiency. Sequence-to-sequence structure, understood abstractly, generates a semantic space. Source language and target language are mapped to this semantic space through neural network training. The more semantically similar words are, the closer they are in the semantic space. In 2014, Bahdanau of Youngor University in Germany proposed attention mechanism, which effectively solved this problem and brought machine translation to a new height [36]. They gave the “S-S” model ability to distinguish, so that it pays attention to the more relevant input information. The attention mechanism is essentially a small neural network trained at the same time as the S-S network. Luong et al. from Stanford proposed many variations of attention mechanism, which further enhanced the representational ability of attention mechanism. After the attention mechanism is introduced, the long-distance dependency problem can be better dealt with. The influence of the previous word on the current word can be obtained

through the attention weight, and the representation vector of the current word can be better generated.

With the proposal of attention mechanism [37] and the rapid development in the field of image, attention mechanism is gradually combined with natural language processing. Especially in machine translation, attention mechanism is introduced between the current state of the target language sequence and the hidden layer state of the source language sequence. The matching degree of these two states is measured by attention weight, so as to obtain a better representation vector of the target language. The problems of long-distance dependence and incomplete representation of vector information are effectively solved [38]. Mi et al. used punishment to improve the translation effect. If the completed part of the translation received too much attention, it would be punished and reward the unfinished part of the translation [39]. In order to obtain better translation results, Tang et al. selected the required rules through the attention mechanism in the translation process, but it also caused high-time complexity [40]. Researchers have never stopped improving the neural machine translation model and have made some achievements in improving the memory capacity of the model and expanding the depth of the translation model [41].

Although neural machine translation has surpassed statistical machine translation in many publicly evaluated translation tasks, its actual translation quality is far from the level of human expert translation, and the model of neural machine translation still needs to be optimized. Compared with phrase-based or rule-based statistical machine translation, neural machine translation lacks the basis of theoretical explanation, because deep learning itself is a “black box” approach. Besides, the complex network structure and the large number of parameters mean the need for large-scale and high-quality parallel corpus pairs. However, high-quality parallel corpus pairs are often missing among many less-popular languages. From the cyclic neural network based on attention mechanism to the convolutional neural network based on attention mechanism to the current mainstream Transformer model based on self-attention mechanism, Transformer’s parallel input combined with the self-attention mechanism makes the actual distance between the input words as 1. It effectively alleviates the long-distance dependence problem. At the same time, the computing speed is greatly improved. However, this also leads to inferior representational ability of local information as RNN and CNN, and damages relative location information. In addition to the Transformer model, there is still a lot of room for improvement in the neural machine translation model.

3. Network Framework

Bi-LSTM and Transformer are widely used in various fields of artificial intelligence. How to further improve the translation effect of Bi-LSTM and Transformer neural machine translation models which introduce attention mechanism that is the focus of this paper and also the innovation of this paper. In this paper, the generative adversarial network is added to the neural machine translation model. The

generator adopts Bi-LSTM and Transformer neural machine translation models, respectively. The discriminator uses convolutional neural network to discriminate the translation results and generates feedback to act on the generator. Through the idea of generating antagonism, the effect of generator is improved, that is, the final translation effect of the machine translation model is improved. Language is an important means of expressing emotions. Confrontational training methods can judge positive or negative emotions, and such translation results have emotional effect also.

Based on the end-to-end neural machine translation model, the neural machine translation model adopts the encoder-decoder framework structure. Encoder-decoder model framework is used to encode and decode variable sequences of input and output. In the frame of the model of the encoder and decoder, the decoder corresponds to the output sequence, and the encoder corresponds to the input sequence. The decoding stage decodes the whole target language sequence by maximizing the probability of prediction sequence, and the coding stage encodes the whole source language sequence into a vector. The encoder-decoder framework mainly realizes the probability prediction of target language through the encoding and decoding process of encoder and decoder. Assuming that the source language sequence is $X \in [x_1, x_2, \dots, x_n]$ and the target language sequence is $Y \in [y_1, y_2, \dots, y_m]$, the probability calculation of generating the target language is shown in formula (1). The generation probability of each target language vocabulary is calculated by softmax function as shown in formula (2).

$$P = (y_1, y_2, \dots, y_m | x_1, x_2, \dots, x_n) \quad (1)$$

$$= \prod_{t=1}^{t=m} P(y_t | c, y_1, \dots, y_{t-1}),$$

$$p(y_t | x, y < t; \theta) = \frac{\exp(\phi(y_t, x, y < t, \theta))}{\sum_{y \in Y} \exp(\phi(y, x, y < t, \theta))} \quad (2)$$

$$= \frac{\exp(\phi(v_{y_t}, c_s, c_t, \theta))}{\sum_{y \in Y} \exp(\phi(v_y, tc_s, n, qc_t, h, \theta))},$$

where C is the vector used to represent the source language sequence, contains the relevant information of the source language sequence, and is the vector with fixed dimensions generated by the encoder stage. The ϕ function defines the possibility of generating the current target language term y_n from the source language as well as the generated target translation. The purpose of introducing the softmax function is to generate the probability distribution of the target word and to ensure that the function value satisfies the probability distribution. c_s represents the source language context vector representation, c_t represents the target language context vector representation, Y represents the target language, and v_y represents the word vector representation of the target language. The known source language sentences and generated target language sentences are used to predict the current probability of the target word. Since the source language sentences and generated target language sentences are very sparse, neural machine translation uses continuous

representation to model the conditional probability of the current word in the target language.

3.1. RNN Neural Translation Model. Owing to the network structure of Recurrent Neural Networks, which perfectly fits the sequence problem, it can process the input sequence of any length in theory. In the process of processing the sequence problem, Recurrent Neural Networks can store the time sequence information and store the historical information of the time sequence through the implicit state. Therefore, the structure of cyclic neural network is generally adopted to deal with sequence problems. The output of the recurrent neural network is a hidden layer state, which is used when the current layer processes the next layer, and each layer outputs to the next layer. This structure enables the recurrent neural network to process the input sequence data well, and to process the data samples with contextual dependencies. The hidden layer state at each moment is a functional representation of all the hidden layer states at the previous moment. According to the time sequence, the schematic diagram of the cyclic neural network is shown in Figure 1.

As shown in Figure 1, the input in the network at time t consists of the hidden layer state h_{t-1} at the previous moment and the input x_t at the current moment. The hidden layer state h_t at the current moment can be calculated by h_{t-1} and x_t . The hidden layer state h_t is computed repeatedly until all inputs are complete. In general, the zero vector is used to represent the initial state of the hidden layer. If the neural network contains only one hidden layer, the activation function of the hidden layer will generally adopt sigmoid function, which is represented by σ . For a batch data with n samples, assuming that the length of the hidden layer is h and the dimension of the feature vector of the sample data is X , the output representation of the hidden layer is shown in formula (3):

$$H = \sigma(XW_{xh}^T + b_h), X \in (R^{n \times x}), \quad (3)$$

where b_h, w represents the bias vector parameters and weights of the hidden layer, respectively. In the neural network, the output of the hidden layer is taken as the input of the output layer. Assuming that the dimension of the output vector corresponding to each sample is y , the final output representation is shown in formulae (4) and (5):

$$\hat{y} = \text{softmax}(HW_{hy} + b_y), \quad (4)$$

$$\text{softmax}(x_m) = \frac{e^{x_m}}{\sum_k e^{x_k}}. \quad (5)$$

3.2. Transformer Neural Network Translation Model. Attention mechanism is used for machine translation tasks. Encoder or decoder layers are directly used for attention, which reduces the transmission path of information. In addition, this attention approach can directly mine the semantic combination relationship between words inside sentences, and treat it as a semantic whole, making better use

FIGURE 1: Expansion diagram of RNN internal structure.

of word combination and even phrase information in translation, and better encoding semantic matching target language words. The final experimental results show that with the reduction of computation and the improvement of parallel efficiency, the translation result is also improved. Transformer is the encoder and decoder, respectively. The encoder maps the natural language sequence into a hidden layer, that is, the mathematical expression containing the natural language sequence. The decoder is responsible for remapping the hidden layer to a natural language sequence. First of all, text is typed in Transformer for embedding. That is word embedding processing. Text information is transformed into high-dimensional real vector. In order to identify the sequential relationship between statements, position embedding is introduced, and linear transformation of sine and cosine functions is used to provide position information for the model.

In the encoder of Transformer, $N=6$, that is, there are six layers, and each layer includes two sublayers, as shown in Figure 2. The first sublayer refers to the multihead self-attention mechanism, which is mainly used to calculate the self-attention value. The second sublayer is a simple fully connected network. Residual networks are added to each sublayer, and the output of each sublayer is shown in the equation (6):

$$\text{LayerNorm}(x + \text{Sublayer}(x)), \quad (6)$$

where $\text{Sublayer}(x)$ represents the mapping of input x by the sublayer. To ensure dimension consistency, all sublayers and word embedding layers have the same output dimension. Transformer decoder is also composed of $N=6$ layers, each layer includes three sublayers. The first sublayer is masked multihead self-attention, which is also used to calculate self-attention. However, because it is a generation process, there is no result at time i greater than i , and only at time less than i , so mask processing is required. The second layer is the encoder input, related to attention calculation. The third sublayer is also a fully connected network, the same as encoder's sublayer fully connected network. The encoders and decoders of the Transformer model do not contain cyclic neural networks or convolutional neural networks, so it is impossible to capture sequence information. For example, if K, V are scrambled in line, the result will be the same after attention. However, the sequence information is very important, representing the global structure of the sequence, so the relative or absolute position information of each word of the sequence must be used.

3.3. Generative Adversarial Network. The core idea of generative adversarial network is derived from the Nash

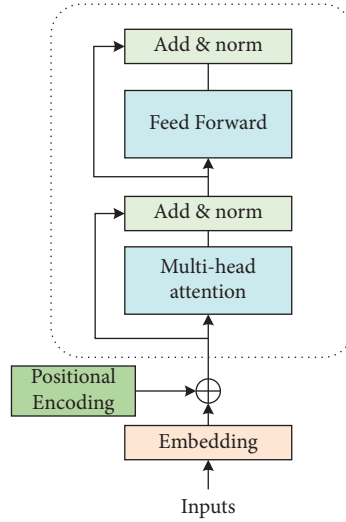

FIGURE 2: Transformer encoder structure diagram.

FIGURE 3: Generate an adversarial network diagram.

equilibrium of game theory, which is a two-player game in which the sum of the interests of both sides is a constant. The generation problem is regarded as the competition and game between generator and discriminator networks: the generator generates synthetic data from a given noise (generally evenly distributed or normally distributed), and the discriminator distinguishes the generator's output from the real data [42]. The former tries to produce more realistic data, while the latter, in turn, tries to better distinguish real data from generated data. Thus, the two networks make progress in the confrontation and continue to fight after progress. Then the data obtained from the generative network is more and more perfect, approaching the real data, so that the desired data can be generated. The antagonistic network judges that the text belongs to positive or negative emotion, and the final output results include that the emotional state that is more consistent with the language characteristics. The overall architecture of the model is shown in Figure 3.

The left half of Figure 3 is made up of generator G and discriminator D . Among them, G is our neural machine translation model, which generates target sentences. D discriminates between the sentences generated by G and the artificial translation sentences, and generates feedback results. The right part carries out strategy gradient training for G , and the final feedback is provided by D and Q , where Q is

BLEU value. The model of generator G is similar to the model of neural machine translation. Generator G defines the method of generating the target sentence y , given the source statement x . The generator uses exactly the same architecture as the neural machine translation model. It is noteworthy that we do not assume a specific model structure for generator G . In order to verify the effectiveness of the proposed method, the generator adopts Bi-LSTM and Transformer. Since the length of the target sentence generated by the generator is not fixed, the discriminator model CNN fills the generated sentence to a certain extent and converts the target sentence into a sequence with fixed length T , which is the maximum length of the output target sentence of the generator. Given the source sentence sequence $[x_1, x_2, \dots, x_T]$ and the target sentence sequence $[y_1, y_2, \dots, y_T]$, the source matrices for the source sequence and the target sequence are, respectively, established as shown in the following expressions:

$$\begin{aligned} X_{1:T} &= x_1; x_2; \dots; x_T, (x_t \in R^k), \\ Y_{1:T} &= y_1; y_2; \dots; y_T, (y_t \in R^k). \end{aligned} \quad (7)$$

When l words undergo convolution operation, a series of feature graphs are generated, as shown in the formula (8):

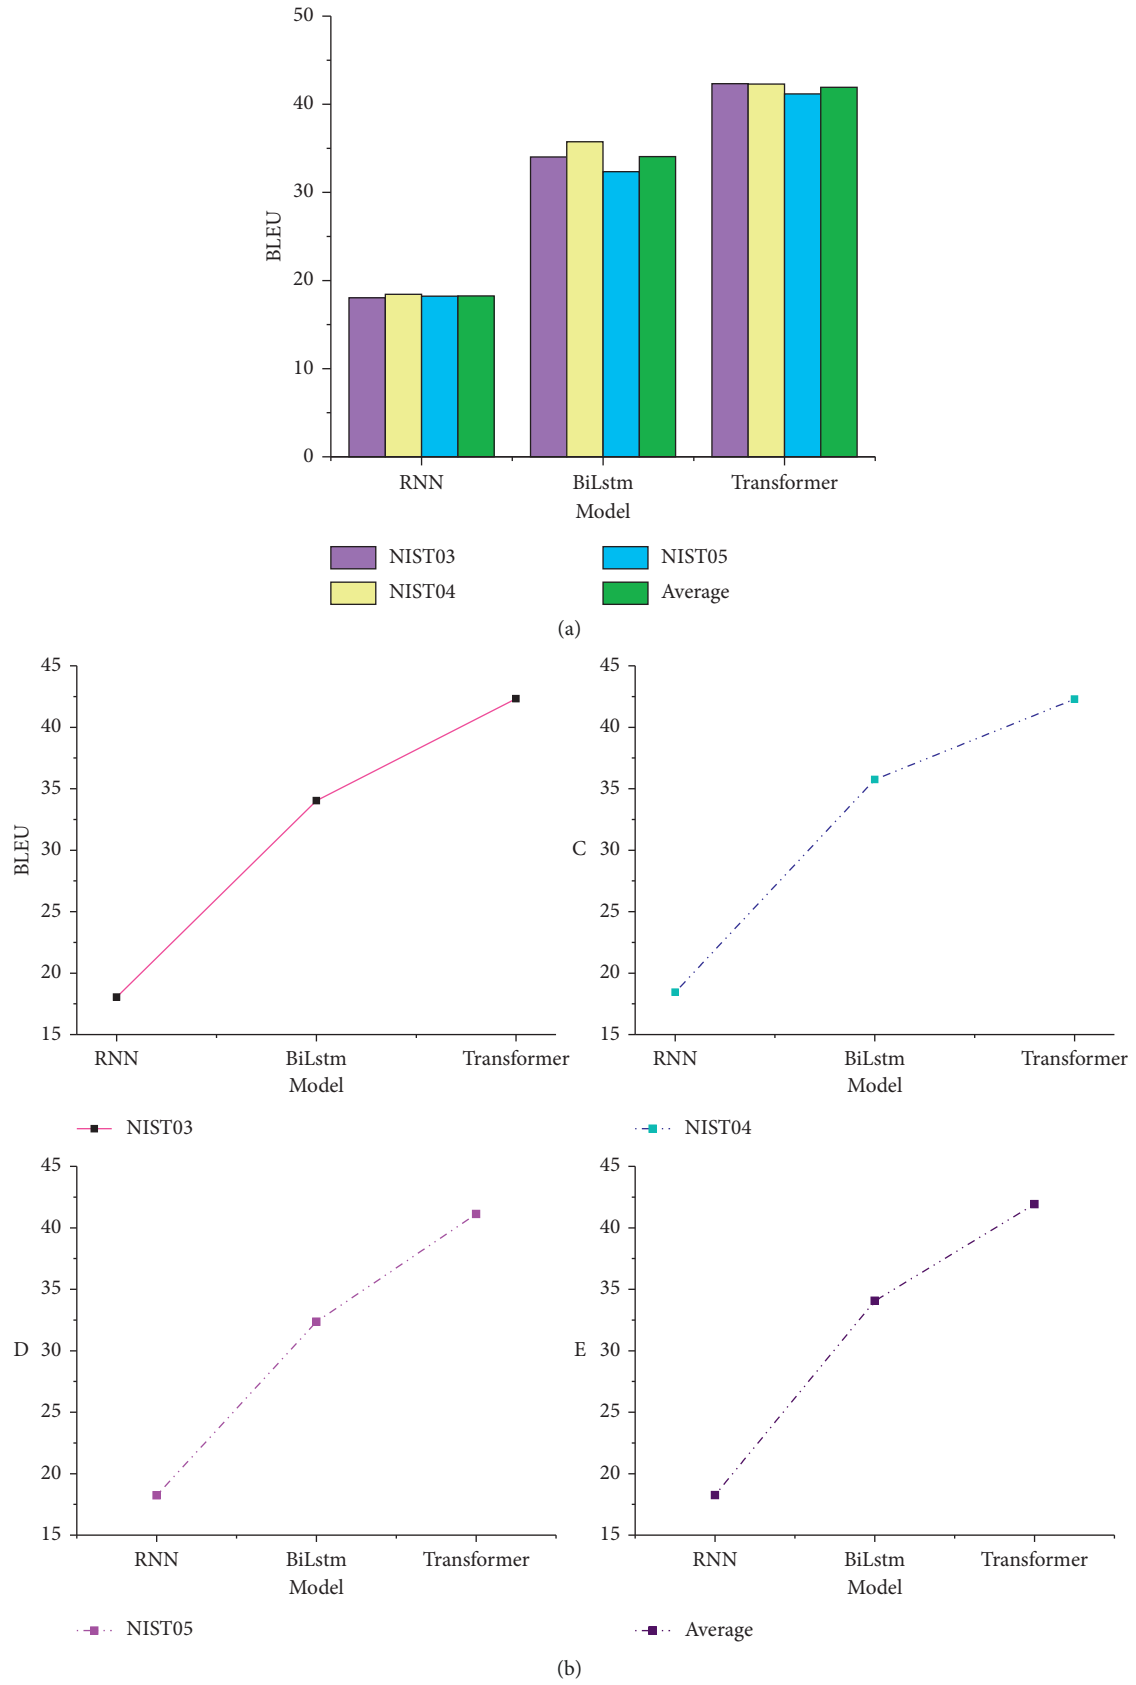

FIGURE 4: BLEU value diagram of baseline experiment. (a) Baseline model BLEU histogram. (b) Baseline experimental grouping diagram.

$$c_{ji} = \sigma \left(BN(w_j \otimes x_{i:i+1} + b) \right), \quad (8)$$

where \otimes represents the sum of principal element multiplications, b is the offset term, and σ is the activation function. Apply the BLEU value to the generator as a specific target. For the target sequence y_g generated by the generator and the real target sequence y_d , by calculating the n-element syntax accuracy of the generated target sequence y_g , the calculated result $Q(y_g, y_d)$ is used as the feedback of the final generation. In order to facilitate the fusion of D and Q , the value range of $Q(y_g, y_d)$ is 0–1, the same as the output of the discriminator. The objective of generator G is defined as maximizing the expected feedback from the beginning state of the generated sequence, and the objective function is shown in the formula.

$$J(\theta) = \sum_{Y_{1:T}} G_\theta(Y_{1:T}|X) \cdot R_{D,Q}^{G_\theta}(Y_{1:T-1}, X, Y_T, Y^*), \quad (9)$$

where θ is the parameter in generator G , $Y_{1:T} = Y_1, Y_2, \dots, Y_T$ is the target sequence generated by generator, x is the source sentence sequence, Y^* is the real existing target sentence sequence. The action value function from the source sentence sequence X given by $R_{D,Q}^{G_\theta}$ to the target sequence indicates that the generated feedback is accumulated from the state. The action value function is calculated by combining the actual probability estimation output of discriminator D with the output of BLEU objective function Q as feedback.

4. Experimental Analyses

The experimental models were done on the Tensor Flow framework and then run on the GPU. When the model ran ten evaluation tests on the test set and the model performance did not improve, we stopped training the model. BLEU value is used as the evaluation index of translation results. In order to ensure the fairness of the experiment, 1 million sentence pairs are randomly selected from the LDC corpus as training data, and the source and target statements are encoded by byte pair encoding, respectively. About 36,000 words are generated in the source language and 32,000 words in the target language. Select NIST04 as the test set and NIST02 as the verification set. The hidden neural units of both the encoder and decoder are set to 512, and the dimension size of word embedding is also set to 512 dimensions.

For the Transformer translation model, the basic structure of the model is used without any changes. We set the dimension size for word embedding to 512 dimensions, Dropout to 0.1, and multiple to 8. Both encoders and decoders have a six-layer network structure. For Bi-LSTM translation model, the number of hidden units of encoder and decoder is set to 512, and the dimension size of word embedding is also set to 512 dimensions. Dropout is not used to train the Bi-LSTM translation model.

4.1. Baseline Experimental. It can be clearly seen from Figure 4(a) that the BLEU score of RNN model is low,

FIGURE 5: Experimental results of Bi-LSTM + GAN.

indicating that the translation effect generated by the original RNN is not very good. This is because in the original RNN translation model structure, the Encoder needs to compress the whole source language sentence into a fixed dimension vector, and then the Encoder-Decoder decodes the whole target language sentence from it. This requires that the fixed dimensional vector contain all the information of the source language sentence, which is obviously difficult to achieve, so it becomes the performance bottleneck of the original RNN as a machine translation model. Although Bi-LSTM and Transformer models are better than traditional RNN models, the effect is still not ideal.

Bi-LSTM model, due to the internal bidirectional time extraction of features, has a stronger timeliness of features, so it reaches the highest 35.74 in NIST04, and the average BLEU value is 34.06. Transformer, due to its own attention mechanism, well explores the potential connection between different time points, and the features obtained have stronger internal connection, and the overall effect is significantly improved. In order to clearly show the changes of the three groups of experiments, we used another way to express the experimental results, as shown in Figure 4(b).

4.2. Generative Adversarial Network Model Experiment. According to the basic experiment, we select Bi-LSTM and Transformer, two models with better performance, to join the generative adversarial network. Experimental results were grouped according to the size of training parameters λ of generating adversarial network (0, 0.7, 0.8, 1.0). As can be seen from the experimental results in Figure 5, when the parameter λ of generating adversarial network is 0.7, the Bi-LSTM model achieves the best effect and the highest average value is 35.88. According to the changes of four curves, the experimental model in this paper conforms to objective laws.

Transformer is the most outstanding model in all fields of artificial intelligence at present, and has been greatly

FIGURE 6: Experimental results of transformer + GAN.

improved after the introduction of GAN. As can be seen from Figure 6, the lowest BLEU introduced by Transformer model into generative adversarial network is 41.4, higher than the average of other models. When the parameter λ value of generated admission-network is 0.8, the model achieves the best result of 43.14 and the average value of 42.73. From the overall experimental results, BLEU values of Bi-LSTM and Transformer models have basically the same change rule with parameter λ , both of which are nonlinear changes. It is important for our subsequent improvement. As an expression mode closely related to culture, language deserves more features and models.

5. Conclusion

With the development of economic globalization, communication between countries, industries, and people of all countries are becoming more frequent and closer. Language is the tool of communication between people. How to quickly and accurately realize the free conversion between different languages is vital. Machine translation is an important research direction in natural language processing, and the development of deep learning related technologies has improved the methods and performance of machine translation. Machine translation as an efficient tool for language conversion, is of great practical significance in translating different languages into equivalent languages while preserving original semantics. Aiming at common neural machine translation models, this paper combines generative adversarial network with machine translation and improves the translation effect of translation models through adversarial training of generative adversarial network. In this paper, classic neural network model and attention-based Transformer model are studied. Then, Bi-LSTM model and Transformer model are added with generative adversarial

network, respectively. Through the addition of generative adversarial network, the newly constructed model is analyzed and studied. Through the adversarial idea of generative adversarial network, certain feedback is obtained from discriminator D and acted on generator G to improve the translation effect of the translation model, get two emotional attributes of opposite polarity, and the effectiveness of the improved analysis method is verified through the final experiment. There are many hidden forms of emotion in language, and it is difficult to find the deep meaning of language by ordinary models, which is also the biggest advantage of the model in this paper.

The contradiction between limited network resources and a large number of user demands in vehicle environment will cause a lot of system delay and energy consumption. To solve the problem, this paper proposes an efficient resource management optimization scheme for Internet of Vehicles in edge computing environment. Firstly, we give a detailed formulation description of communication and computing cost incurred in the resource optimization process. Then, the optimization objective of this paper is clarified by considering the constraints of computing resources, and system delay and energy consumption are considered comprehensively. Secondly, considering dynamic, random, and time-varying characteristics of vehicle network, the optimal resource management scheme of Internet of Vehicles is given by using distributed reinforcement learning algorithm to optimize total system overhead to the greatest extent. Finally, experiments show that when bandwidth = 40 MHz, the total system cost of the proposed algorithm is only 3.502, while that of comparison algorithms is 4.732 and 4.251, respectively. It is proved that the proposed method can effectively reduce the total system overhead.

1. Introduction

In recent years, the automotive industry has developed rapidly, and intelligence and networking have become an important trend in the future development of automotive industry [1]. On the one hand, these technologies enable communication and information exchange between Vehicle to Vehicle (V2V) and Vehicle to Infrastructure (V2I), helping to build safe, collaborative, and intelligent transportation systems. On the other hand, this in turn generates a large amount of data, and at the same time, the demand for computing, communication, and content increases significantly [2–4]. With the development of Internet of Vehicles (IoV) and intelligent connected vehicles, in-vehicle infotainment applications such as road safety, intelligent navigation, autonomous driving, and in-vehicle entertainment continue to emerge. This promotes the development of intelligent transportation and brings a great improvement to driving experience [5–7]. Due to the particularity of the

physical location of vehicles and cloud servers, the backhaul link capacity is limited. Such a high content demand of the Internet of Things will bring a huge burden to the core network [9]. At the same time, they also pose a major challenge to support massive content delivery and meet the low-latency requirements of IoT [10–12].

The introduction of mobile edge computing (MEC) technology makes up for the network instability and delay limitations of cloud computing in IoT scenario and is more suitable for low-latency, high-reliability task computing on IoT requirements [13–18]. The cloud server located in core network is far away from vehicles, and vehicles need to rely on a large base station for multi-hop transmission to offload tasks to the cloud server for processing. However, it is prone to network fluctuations and transmission interruptions and is unreliable for in-vehicle applications, especially safe driving applications [19, 20]. Therefore, using distributed MEC services to replace traditional cloud computing services can effectively solve the resource management optimization problem in IoT [21].

The main factors that affect the decision of computing offloading are the execution delay and energy consumption of task. Thus, optimization goals usually include solutions such as reducing delay, reducing energy consumption, and weighting between delay and energy. Reinforcement learning can capture the hidden dynamics of environment well, so it is often used to optimize resource allocation algorithms. Liu et al. [22] proposed a resource allocation strategy based on deep reinforcement learning (DRL). Zhan et al. [23] designed a strategy optimization method based on DRL by using game theory. Huang et al. [24] studied the wireless charging MEC network and proposed an online decision-making method based on DRL. Hui et al. [25] proposed a content dissemination framework based on edge computing. Combining the selfishness and transmission ability of vehicles, the authors designed a two-level relay selection algorithm to reasonably select relay vehicles to meet different transmission needs. Su et al. [26] used the vehicles parked around the street and the vehicles driving along the road to communicate the vehicle social community through V2V and used the content cached in the parked vehicles to reduce the delay of content download. Zhao et al. [27] proposed a caching strategy in V2V scenario with information as the center and designed a dynamic probabilistic caching scheme. Zhang et al. [28] proposed a MEC scenario computing resource allocation scheme based on DRL network, which avoids falling into the disaster of dimensionality. Zhang et al. [29] proposed a joint optimization scheme of IoT content caching and resource allocation based on MEC in high-speed free-flow scenario, which reduced data acquisition latency. Li [29] proposed a resource allocation strategy for computing unloading in vehicle Internet based on DRL. However, in the case of limited network resources and a large number of user demands, the above research has the problems of excessive resource delay consumption and large energy consumption. Therefore, the optimization of IoT resource management in the MEC system scenario is a challenging problem.

Based on the above analysis, in view of delay and energy consumption caused by the contradiction between limited network resources and a large number of user needs in vehicle environment, this paper proposes an efficient resource management optimization scheme for IoT in edge computing environment. This method takes minimizing the weighted sum of system delay and energy consumption as the optimization goal and constructs a communication model and task offloading optimization model in IoT edge computing scenario. Moreover, a solution algorithm based on distributed reinforcement learning is used to optimize the total system overhead.

2. System Model and Problem Modeling

2.1. System Model. The system model is shown in Figure 1. J road side units (RSUs) are evenly distributed on the road, and all have MEC services configured, denoting MEC server as me_{c_j} , $j \in \{1, 2, \dots, J\}$. Each of C randomly distributed vehicles performs multiple computing tasks. Suppose the sum of computing tasks of all vehicles is N , and the computing

FIGURE 1: IoT system model.

tasks are denoted by L . b represents the size of input data, w represents the task computation amount, and t^{\max} represents the task deadline. If the task processing exceeds the time limit, it means that the task processing fails, and R_L represents MEC cell carried by vehicle-mounted terminal to which the task belongs. ω represents the importance of computing task to distinguish the task is a secure computing task and a common computing task. Therefore, the computational task can be denoted as $L = \{b, w, \omega, t^{\max}, R_L\}$. Let i represent the number of onboard terminals offloading the computing task to MEC server, and $x = 0$ indicates that the task is executed locally. The offloading strategies of N computing tasks constitute the offloading strategy vector set $X = \{x_1, x_2, \dots, x_N\}$.

2.2. Communication Model. When task i chooses to perform computing offloading, a corresponding offloading decision needs to be made to decide which MEC server to offload to and which channel to select to upload data. When the offloading decision vector \mathbf{d} of all users is given, data transmission rate $R_n^m(\mathbf{d})$ on the n channel between user u_i of offloading decision $d_n^0 > 0$ and the j RSU can be obtained. The maximum information transfer rate V is

$$V = W \log_2(1 + \text{SNR}), \quad (1)$$

where W is the channel bandwidth and SNR is the ratio of average power of signal transmitted in the channel to noise power in the channel, that is, the signal-to-noise ratio. Its calculation is

$$\text{SNR} = \frac{p_i g_i^h}{\gamma^2 + \sum_{i \in V} p_i g_i^h}, \quad (2)$$

where p_i represents the transmission power of users, that is, the transmit power of user equipment; g_i^h represents the channel gain of communication channel selected by users; and γ^2 represents the white Gaussian noise power.

The data transfer rate $V_{i,j}^h(d)$ is

$$V_{i,j}^h(d) = B \log_2 \left(1 + \frac{p_i g_i^h}{\gamma^2 + \sum_{i \in V} p_i g_i^h} \right). \quad (3)$$

2.3. Computing Offloading Model

2.3.1. Local Computing. Assuming that task i is only calculated locally, only the calculation delay is considered. e^{loc} represents the computing capability of vehicle terminals. The processing delay of local tasks and the energy required for local computing are expressed as

$$t_i = t_{\text{loc}} = \frac{w_i}{e_{\text{loc}}^{\text{mec}}} \quad (4)$$

$$E_i = t_i P_{\text{loc}}.$$

When MEC server resources are insufficient, the system unloads the task to other servers.

2.3.2. Local Server Computing. When the vehicle communicates directly with the local server, the vehicle will unload the computing task to the server in the cell. After the server completes the execution, the result will be returned to the vehicle immediately. The total task delay includes upload delay, server calculation delay, and return delay. Let $t_{i,j}^{\text{mec}}$ denote the task execution delay, $e_{i,j}^{\text{mec}}$ denote the computing resources, and $v_{i,j}$ denote the wireless transmission rate:

$$t_{i,j}^{\text{mec}} = \frac{w_i}{e_{i,j}^{\text{mec}}} \quad (5)$$

$$t_{i,j}^{\text{trans}} = \frac{b_i}{v_{i,j}}$$

Since the return rate is much higher than the upload rate, the return delay of the calculation result can be ignored. The total time delay of unloading calculation is

$$t_{i,j} = t_{i,j}^{\text{trans}} + t_{i,j}^{\text{mec}}. \quad (6)$$

The energy consumption for unloading calculation is

$$E_{i,j} = P_{\text{loc}}(t_{i,j}^{\text{trans}} + t_{i,j}^{\text{mec}}), \quad (7)$$

where P_{loc} represents the energy consumption per unit cycle of local CPU.

2.3.3. Other Server Computing. When the MEC server in the cell where the vehicle is located is overloaded, the computing task is unloaded to other cell servers. Communication between MEC servers is generally performed through wired communication links such as optical fibers. Assuming that the average task transmission delay on the wired link is t_w and c represents the number of wired link hops between computing tasks offloaded to other servers, the task processing delay at this time is expressed as

$$t_{i,j}^o = 2ct_w + t_{i,j}^{\text{trans}} + \frac{w_i}{e_{i,j}^{\text{mec}}}. \quad (8)$$

Then, the energy consumption of other servers' offloading computing is

$$E_{i,j}^o = P_{\text{loc}} \left(2ct_w + t_{i,j}^{\text{trans}} + \frac{w_i}{e_{i,j}^{\text{mec}}} \right). \quad (9)$$

2.4. Problem Modeling. τ is the calculated weight, and the weighted sum of the total delay is

$$t_{\text{all}} = \sum_{i=1}^N \left(\tau t_i + (1 - \tau) \sum_{j=1}^J t_{ij} \right). \quad (10)$$

The total energy consumption is

$$c_{\text{all}} = \sum_{i=1}^N \left(\tau C_i + (1 - \tau) \sum_{j=1}^J t_{ij} \right). \quad (11)$$

Considering delay and energy consumption, the total cost of local calculation is

$$C_{\text{all}} = \gamma t_{\text{all}} + (1 - \gamma) c_{\text{all}}, \quad (12)$$

where γ is the weight.

The optimization problem can be formulated as

$$\min(C_{\text{all}}). \quad (13)$$

In order to ensure that the task is completed on time, the calculation task is required to complete the task before the vehicle leaves the MEC unit, and the following conditions shall be met:

$$t_i^{\text{stay}} = \frac{S_i}{v_i}, \quad (14)$$

$$t + \frac{w_i}{e_{i,j}^{\text{mec}}} \leq \min[t_i^{\text{max}}, t_i^{\text{stay}}].$$

Computing tasks unloaded to other servers should meet the following conditions:

$$2ct_w + t_{i,j}^{\text{trans}} + \frac{w_i}{e_{i,j}^{\text{mec}}} \leq \min[t_i^{\text{max}}, t_i^{\text{stay}}]. \quad (15)$$

The computing resources required to complete computing tasks are

$$e_{i,j}^{\text{mec}} \geq \max \left\{ \frac{w_i}{\min[t_i^{\text{max}}, t_i^{\text{stay}}] - t_{i,j}^{\text{trans}}}, \frac{w_i}{\min[t_i^{\text{max}}, t_i^{\text{stay}}] - 2ct_w - t_{i,j}^{\text{trans}}} \right\}. \quad (16)$$

The total computing resources required for computing tasks are

$$e_j = \sum_{i=1}^N \sum_{x_i=j} e_{i,j}^{\text{mec}}. \quad (17)$$

The constraints are as follows:

$$\text{C1: } x_i \in \{0, 1, 2, \dots, j\}, \forall i \in N,$$

$$\text{C2: } y_i \in \{0, 1\}, \forall i \in N, \quad (18)$$

$$\text{C3: } e_j < E_j, j \in \{1, 2, \dots, J\}.$$

C1 indicates that a computing task can only be offloaded to one edge server and cannot be offloaded to two or more at the same time. C2 means that the computing task adopts binary offloading, which can choose not to offload or offload entire task at the same time, that is, the task is indivisible. C3 indicates that computing resources required by computing tasks offloaded to edge server cannot exceed the total resources of edge servers.

3. Solutions Based on Reinforcement Learning

3.1. Problem Solving Based on Distributed Reinforcement Learning. In view of dynamic, random, and time-varying nature of in-vehicle networks, artificial intelligence algorithms are more suitable for resource management and task scheduling than traditional mathematical methods. In comparison, Q-learning needs to maintain Q-table and is not suitable for networks with many states. Deep deterministic policy gradient algorithms need to use an experience replay mechanism to eliminate the correlation between training data. For experience playback mechanism, the agent consumes more resources for each interaction with the environment. The off-policy learning method adopted can only be updated based on the data generated by the old policy. Therefore, consider using the actor-critic algorithm to reduce the overhead required for algorithm execution, while providing optimal offloading decisions and resource management based on real-time network environment. Modeling the environment of system with an actor-critic algorithm requires determining its state space, action space, and reward function.

The state space, S , consists of computing resources and cache resources of in-vehicle network, $S = \{F_1, F_2, \dots, F_M, S_1, S_2, \dots, S_M\}$, where F_i and S_i represent the computing capacity and storage capacity of road side unit i , respectively.

The action space consists of offloading decisions of vehicles, caches of road side units, and computing resource management, $A = (x_i, w_i, f_i)$, where $x_i = \{x_{i0}, x_{i1}, \dots, x_{iM}\}$, $w_i = \{w_{i1}, w_{i2}, \dots, w_{iM}\}$, and $f_i = \{f_{i1}, f_{i2}, \dots, f_{iM}\}$ represent the set of vehicle i offloading decision, road side unit storage, and computing resource management, respectively.

Reward Function. The goal of reinforcement learning training is to maximize long-term cumulative reward. According to the objective function of this paper, the reward function is designed as

$$r_{i,t} = 1 - \frac{C_{i,j}}{\max\{C_{i,j}\}}. \quad (19)$$

The public neural network in actor-critic algorithm consists of multiple threads, and each thread has the same 2 modules as public neural network: the policy (actor) network and the critic (critic) network. The actor network is used to optimize the policy $\pi(a_t|s_t; \delta)$ with parameters δ ; the critic network tries to estimate the value function $V(s_t; \delta)$ with parameters δ_v . At time t , the actor network performs action a_t based on current state s_t , gets a reward r_t , and enters the next state s_{t+1} .

Use the advantage function $A(a_t, s_t)$ to represent the difference between the action value function $Q(a_t, s_t)$ and state value function $V(s_t)$:

$$A(a_t, s_t) = Q(a_t, s_t) - V(s_t). \quad (20)$$

To speed up convergence, approximate $Q(a_t, s_t)$ with k step sampling:

$$Q((a_t, s_t)) \approx \sum_{i=0}^{k-1} \gamma^i r_{t+i} + \gamma^k V(s_{t+k}; \delta_v), \quad (21)$$

where γ is the discount coefficient, r_{t+i} represents the instant reward, and $V(s_t)$ is obtained through critic network.

Taking the parameter δ as a variable, differentiate the policy loss function to obtain

$$\nabla_{\delta} f_{\pi}(\delta) = \nabla_{\delta} \log \pi(a_t|s_t; \delta) A(a_t, s_t) + \beta \nabla_{\delta} H(\pi(s_t; \delta)), \quad (22)$$

where H is the entropy of policy and β is the coefficient.

For the value loss function, there are

$$f_v(\delta_v) = (R_t - V(s_t; \delta))^2. \quad (23)$$

Based on RMSProp algorithm, the gradient estimate can be expressed as

$$g = ag + (1 - a)\Delta\delta^2, \quad (24)$$

where a represents momentum and $\Delta\delta$ represents the cumulative gradient of loss function.

The update parameters of RMSProp algorithm are

$$\delta \leftarrow \delta - \eta \frac{\Delta\delta}{\sqrt{g + \varepsilon}}. \quad (25)$$

3.2. Algorithm Flow. The proposed offloading strategy flow based on distributed reinforcement learning is shown in Algorithm 1.

4. Example Verification and Result Discussion

4.1. Simulation Settings. This section uses Python to simulate and verify resource management optimization scheme for IoT and evaluate the pros and cons of different algorithms by comparing the impact of each algorithm on the total system overhead with the number of vehicles, the number of tasks, and the bandwidth. The simulation parameters are set as shown in Table 1. Due to the existence of small-scale fast fading and the mobility of mobile devices in established model, the results of each run are random. Therefore, the mathematical method of statistical averaging is used to obtain average value as the final result. The computer configuration information used for the simulation is Windows Server 2019, Intel(R) Xeon(R) 2.6 GHz processor, and 16 GB RAM.

4.2. Convergence Performance Analysis. Figure 2 describes the convergence of algorithm in this paper under different learning rate scenarios. It can be found from the figure that when the learning rates of actor and critical networks are $L_a = 1 \times 10^{-3}$ and $L_b = 1 \times 10^{-2}$, respectively, although the learning speed of algorithm is very fast, it will degrade the final convergence performance of system. When the learning rate is too small ($L_a = 1 \times 10^{-3}$, $L_b = 1 \times 10^{-2}$), the learning speed will drop sharply. Therefore, the learning rate is set to $L_a = 1 \times 10^{-4}$, $L_b = 1 \times 10^{-3}$ in the follow-up experiment.

4.3. Comparison of Accumulated Average Rewards under Different Schemes. Compare the average reward value of the

Input: actor network, actor target network, critical network and critical target network, learning rate α , discount rate γ , attenuation factor λ .
Output: computing task offloading policy π' .
 Initialize the critical network parameter δ^c and actor network parameter δ^a .
 Initialize the status of experience playback pool and task vehicle s_0
For $t \leq T$ **do**
 Observe the environment status s_t and select actions a_t based on the current policy
 Execute the action a_t , get the reward r_t , and transfer to the state s_{t+1}
 Save array (s_t, a_t, r_t, s_{t+1}) to experience playback pool
 If the memory bank is full, but the stop condition is not met, a small batch of arrays (s, a, r, s') is randomly sampled from the experience playback pool.
 Update critical network parameters, actor network parameters, and target network parameters
End
End

ALGORITHM 1: Resource management algorithm based on distributed reinforcement learning.

TABLE 1: System parameters.

Parameter	Value
Number of concurrent tasks of a single vehicle	2~7
Number of vehicles	5~15
Calculation capability of onboard terminal	5 MHz
Vehicle transmission power	1.5 W
Vehicle speed	30~80 KM/h
Gaussian white noise power	-80 dB
MEC computing power	$[2 \times 10^8, 9 \times 10^8]$ Hz
System bandwidth	10~50 MHz

FIGURE 2: Performance comparison under different learning rates.

proposed scheme with the following schemes: (1) all-local strategy; (2) random strategy; (3) all-MEC policy. During DDPG training, there will be violent shocks. Thus, this section observes the convergence of neural network by calculating the cumulative average value of system reward. Figure 3 shows the comparison of cumulative average rewards for different caching schemes. With the increase of training times, it can be seen that all-MEC and random schemes can gradually converge to a stable cumulative

FIGURE 3: Comparison of average rewards under different schemes.

average. All-local strategy behavior is not encouraged, so the reward value is the lowest. Because the proposed algorithm needs to consider the road conditions of adjacent areas, increases the dimension of system state, and improves the complexity, it has poor performance at the beginning of training and obtains the highest average reward value after convergence. Therefore, the proposed resource optimization management scheme for IoT can make full use of communication resources and effectively improve the effectiveness of the system.

4.4. Performance Comparison under Different Algorithms.

In order to prove the advantages of the proposed algorithm, the algorithms in [28–29] are compared with the proposed algorithm under the same experimental conditions. Figure 4 shows the impact of the number of vehicles on the delay. It can be found that the delay of system task processing increases with the increase of the number of vehicles. This is mainly due to the increase of processing tasks and the limitation of computing resources. Among all algorithms, The reference [29] algorithm has the largest delay.

FIGURE 4: Influence of vehicle number on delay of different algorithms.

Compared with the reference [29] algorithm and the proposed algorithm, the vehicle will undertake more tasks. Due to the limitation of the vehicle's own computing resources, processing tasks alone will cause greater delay. Due to the limitation of vehicle computing resources, processing tasks alone will cause large time delay. The proposed algorithm considers the cooperation of terminal, edge, and cloud, improves the utilization efficiency of resources, and minimizes the system delay.

The change of total system overhead with bandwidth under different algorithms is shown in Figure 5. Figure 5 shows that with the increase of bandwidth, the total system overhead of three algorithms shows a downward trend, but the total system overhead of the proposed algorithm is always lower than that of other two algorithms. When bandwidth = 40 MHz, the total system overhead of the algorithm in [28] is 4.732, and the total system overhead of the algorithm in [28] algorithm is 4.251, while the total system overhead of the proposed algorithm is only 3.502. Further analysis shows that when the cloud computing ability of comparison algorithm is relatively weak, most of computing tasks will be completed at the edge node, which cannot make good use of the cloud edge system. Therefore, it produces high total system overhead. Compared with the other two algorithms, the proposed algorithm can achieve the lowest total system overhead because the proposed algorithm considers the dynamic, random, and time-varying characteristics of vehicle network to optimize system performance to the greatest extent.

The change of total system overhead with the number of tasks is shown in Figure 6. With the increase of the number of tasks, the total cost of the three algorithms shows an upward trend. However, the total system overhead of this algorithm is less than that of the algorithms in [28, 29]. This is because the algorithm can collect the state and action information of the whole system and make better decisions according to the global information, so the total cost of the system is low. The comparison algorithm does not fully analyze the state and action information of the system, and

FIGURE 5: Variation of total system overhead with bandwidth under different algorithms.

FIGURE 6: Changes of total system overhead with the number of tasks under different algorithms.

the multi-vehicle game increases the energy consumption, resulting in the increase of the total cost of the system.

5. Conclusion

Aiming at the problem of delay and energy consumption caused by the contradiction between limited network resources and a large number of user needs in vehicle environment, this paper proposes an efficient resource management optimization scheme for IoT in edge computing environment. The proposed algorithm builds a communication model and task offloading optimization model in IoT edge computing scenario and solves them based on distributed reinforcement learning to maximize the system performance.

In the future, we will study the content acquisition decision combined with micro-traffic data and the

prediction of vehicle mobility to further improve algorithm performance. Besides, a dynamic situation will be considered, that is, devices may leave the current edge server during computing offloading. In this case, it is necessary to set up a more effective mobile model for devices. In addition, the current blockchain technology provides a powerful solution for the unloading of secure computing tasks in the IoV. In view of the contradiction between the high real time of IoV applications and the low real time of blockchain, we can take advantage of the differences of participants in IoV in terms of security level, computing power, and communication ability to design a hierarchical blockchain structure matching the cloud IoV structure to solve it. It is of great significance to use the blockchain technology to build a secure Internet of Vehicles computing task unloading platform.

With the gradual advancement of informatization and industrialization, the safety and controllability of industrial Internet of things (IIoT) have attracted more and more attention. Aiming to improve the security of industrial IIoT, a detection method using stacked sparse autoencoder network model is proposed. In this method, the basic units of the network model have been simplified and sparse, and some of basic features are combined with obtaining a higher-level abstract expression, so as to solve the problem of unbalanced network traffic data. The cascaded network structure is adopted to stack its sparse autoencoder network model, so as to improve the data ability of the detection model. In addition, the incorporation of Softmax classifier realizes the dynamic adjustment and optimization of the whole network parameters, which further ensures the efficiency of the detection method. The simulation experiment is based on NSL-KDD dataset. The experiment has proved that the proposed method has excellent network attack identification and detection performance. Its accuracy index is about 95.42%, and the detection time is about 3.42 s.

1. Introduction

The essence of Internet of things (IoT) is the integrated development of industrial automation and interconnection of all things technology [1–3]. The Industrial Internet of things (IIoT) has realized the unprecedented combination of subsystems such as production, monitoring, and management. Different systems can process all kinds of industrial data more efficiently under the unified management of the control center [4, 5]. Its high complexity and openness increase the network security risk faced by the industrial IIoT.

Typical network attacks in industrial control systems are common [6]. In July 2010, the first virus “Stuxnet” targeting the Supervisory Control and Data Acquisition (SCADA) system attacked Iran’s nuclear facilities. In 2012, the “Flame” virus paralyzed Iran’s oil industry network. Since then, the incidents of hacker attacks on industrial control systems have been reported all over the world, and the frequency and impact have shown a rapid upward trend year by year. Industrial control security has become a complex of “network security, equipment security, control security,

application security, and data security” [7]. Therefore, it is particularly urgent to propose an accurate and efficient network intrusion detection method.

Intrusion detection system is widely used in traditional industrial control system and modern industrial IIoT, and it has attracted more and more attention [8, 9]. In [10], the authors detect attacks on the industrial IIoT based on BiLSTM-RNN and use the UNSWNYB15 dataset to train a multilayer neural network. In [11], the authors designed a network intrusion detection system for the SCADA system based on CNN to protect the IIoT from conventional network risk such as DDoS and specific network attacks against SCADA. In [12], the authors studied the power theft attack in the smart grid and proposed a detection method using the multilayer network. However, it should be pointed out that when facing the current high real-time, high-capacity and complex multidimensional data in industrial IIoT, the above methods often need a complex training process, and the accuracy needs to be improved [13].

Deep network can not only obtain the maximum reward from the high-dimensional and massive network data

environment but also have the exploration function and automatically mine more valuable information in the network environment [14–16]. Therefore, many scholars have carried out research studies and analyses using deep learning network. In [17], the authors used a context adaptive intrusion detection system, which realizes the accurate detection of network attacks through the mutual assistance of multiple agents. The IIoT detection model in [18] combines feedforward neural network and long-term and short-term memory network. In [19], the authors used an IIoT detection model based on intelligent algorithm and multilayer network, which can achieve better detection efficiency. In [20], the authors proposed a new multiagent confrontation reinforcement learning model for IIoT detection system to realize steady-state support for the network environment. However, it should be noted that the industrial IoT data has unbalanced characteristics. The current deep learning intrusion detection method cannot achieve accurate data feature extraction in the network data with too many feature dimensions, and it is difficult to support efficient and accurate intrusion attack-type mapping. At the same time, due to the deeper network structure, the deep network model also has the problem of time-consuming in intrusion detection.

Aiming at the above problems, based on the improved autoencoder (AE), a detection method for IIoT is proposed. The main innovations are as follows:

- (1) In this study, the network structure unit of the multilayer network is sparse. By adding sparsity constraints to the hidden layer, some neurons are suppressed, and the problem of industrial network intrusion detection with unbalanced network traffic data is solved, so as to learn more accurate and efficient feature expression.
- (2) The cascade form is used to combine the sparse autoencoder (SAE) network and construct the stacked sparse autoencoder (SSAE) network model, which can realize the continuous deep feature extraction of industrial IoT network data, so as to support the high accuracy of intrusion detection network.

2. Standard Autoencoder Model Learning Algorithm

Industrial control system network dataset presents the characteristics of more normal data, less abnormal data, and uneven data distribution [21]. Algorithms including traditional artificial neural network cannot effectively classify and identify unbalanced data.

AE network is an unsupervised feature detection model, which can learn a feature representation of input data. This model belongs to artificial neural network and is optimized by backpropagation algorithm.

The essence of the algorithm of self-encoder network is an unsupervised training and learning method. In order to make the target value input directly, it introduces the data

FIGURE 1: Autoencoding network structure.

processing model of backpropagation to maintain the consistency of data.

In addition to being used as the construction module of deep neural network, the AE network can also be used to extract discriminant features with lower dimension than input, so as to solve the dimension disaster.

The standard AE is a multilayer feedforward network, which expects the input and output to be consistent. It can be used to learn identity mapping and extract unsupervised features. Figure 1 is a network structure of a single-layer autoencoder, in which only one hidden layer is used to encode the input and reconstruct the input at the output through decoding. The part from the input layer to the middle layer is called encoder, and the part from the middle layer to the output layer is called decoder. Autoencoder is an unsupervised feature detection model, which can learn another feature representation of input data. Autoencoder learns to generate a hidden layer representation from the input and reconstructs the output as close to the input as possible from the hidden layer representation.

As can be seen from Figure 1, the AE network model is composed of the input layer, the hidden layer, and the output layer. Specifically, the purpose of the self-encoder is to make the output value of the model equal to or as close to the input value of the model as possible with the help of an identity function. $x_i = e_i$.

Encoding refers to the process of mapping input $x \in R$ to implicit representation $h(x) \in R$. The calculation form is

$$h(x) = \alpha_h(Wx + b), \quad (1)$$

where $W \in R$ is the encoding weight matrix, $b \in R$ is the encoding offset vector, $\alpha_h(x)$ is the vector value function, and in the case of nonlinearity, $\alpha_h(x)$ is taken as Sigmoid function.

Decoding refers to mapping the implicit representation $\alpha_h(x)$ to the output layer e , so as to reconstruct the input x . The calculation form is

$$e = \alpha_e(Wh(x) + b'), \quad (2)$$

where $W' \in R$ presents the decoding matrix, $b' \in R$ presents the decoding vector, and $\alpha_e(x)$ is similar to $\alpha_h(x)$.

FIGURE 2: Intrusion detection model for IIoT.

3. Intrusion Detection Model of IIoT

Excessive feature dimension is the reason for the low efficiency of industrial control safety anomaly detection [22, 23]. Dimension reduction can be achieved by reducing high-dimensional and nonlinear attribute features. Through the sparse expression of features, a small number of basic features are combined to obtain a higher-level abstract expression.

Therefore, based on the standard AE network, this study adds sparsity constraints to the output of the hidden layer so that most neurons are suppressed and constructs a attacked sparse autoencoder (SSAE) network model.

The SSAE network is used to establish the intrusion detection model of the IIoT. On the premise of maintaining the accuracy of detection, the calculation speed and calculation memory are improved, so as to learn better feature expression.

3.1. Overall Architecture. The proposed overall architecture is shown in Figure 2.

From Figure 2, the identification of industrial IoT intrusion by this model mainly includes the following three steps:

(1) Data preprocessing: build an industrial IoT environment and capture real-time network data, including source address, target address, connection attributes, and other relevant information [24, 25]. The data are preprocessed and transformed into a format that can be processed by the stacked noise reduction convolutional autoencoder. In this study, data preprocessing is divided into three parts:

- ① Attribute mapping: convert character data into numerical data
- ② Data normalization: normalize the data to within 0 to 1 to solve the problem of dimensional inconsistency, which affects the accuracy
- ③ Regional adaptive oversampling algorithm: generate new samples at the algorithm level for minority samples, handle the imbalance of data distribution properly, and then carry out the next operation to optimize minority data

3.2. Stacked Sparse Autoencoder Network. SAE network suppresses most neurons by adding sparsity constraints to the output of the hidden layer, which can learn better feature expression, so as to solve the problem of industrial network

intrusion detection with unbalanced network traffic data. The specific way is to add a sparse penalty term, that is, the function of the average output activation value of neurons.

The goal of SAE is to make the output fit the input features, which is similar to AE, but SAE imposes sparsity restrictions on the middle layer in order to avoid simple mapping output to input.

The simple understanding of sparsity restriction is that when the output of neuron in each layer is 0, it indicates that the state of neuron is inhibited; when the output of neuron is 1, it indicates that the state of neuron is active, and the sparsity restriction makes the state of neuron inhibited most of the time.

The mean activation degree of hidden layer neuron i is defined as follows:

$$\hat{\tau}_i = \frac{1}{n} \sum_{p=1}^n [c_i^{(2)}(v^{(i)})], \quad (3)$$

where n indicates the total number of data sample sets and $c_i^{(2)}$ is the activation parameter of the middle layer neuron i when v is used as input. To get the sparse representation of the middle layer neuron, it should make the activation mean $\hat{\tau}_i$ of the middle layer neuron i as 0 as possible. If making $\hat{\tau}_i = \tau$ as a sparsity parameter, τ should be a decimal close to zero. By introducing a penalty factor into the solution of the objective, those scenarios that $\hat{\tau}_i$ and τ are significantly different are punished, so as to realize such sparsity limitation and continuously optimize the value of the objective function. There are many ways to construct penalty factors. Here, the Kullback–Leible (KL) is used to regularize the network so that the average activation degree $\hat{\tau}_i$ is equal to τ as much as possible:

$$KL(\tau \parallel \hat{\tau}_i) = \tau \log \frac{\tau}{\hat{\tau}_i} + (1 - \tau) \log \frac{1 - \tau}{1 - \hat{\tau}_i}. \quad (4)$$

The penalty factor formula is as follows:

$$\sum_{i=1}^{z^2} \tau \log \frac{\tau}{\hat{\tau}_i} + (1 - \tau) \log \frac{1 - \tau}{1 - \hat{\tau}_i}, \quad (5)$$

where z^2 is the sum of neuron. The above penalty factor can also be expressed as $\sum_{i=1}^{z^2} KL(\tau \parallel \hat{\tau}_i)$.

It can be seen that the loss function of the detection network is

$$\theta_{sparse}(W, b) = \theta_E(W, b) + \mu \sum_{i=1}^{z^2} KL(\tau \parallel \hat{\tau}_i). \quad (6)$$

Usually, in order to avoid the overfitting problem, the L_2 weight penalty is introduced to the objective function; then,

$$\theta_{SAE}(W, b) = \theta_{sparse}(W, b) + \frac{\gamma}{2} \sum_{i=1}^{s_q} \sum_{p=1}^{s_q+1} \sum_{q=1}^{s_q-1} (u_{pi}^{(q)})^2, \quad (7)$$

where γ represents the regularization parameter, q represents the current layer, and s_q and $s_q + 1$ are the sum of neurons.

The formula of descent optimization is as follows:

$$W_{pi}^{(q)} = u_{pi}^{(q)} - \psi \frac{\partial}{\partial u_p^{(q)}} \theta_{SAE}(W, b), \quad (8)$$

$$b_{pi}^{(q)} = b_{pi}^{(q)} - \psi \frac{\partial}{\partial b_p^{(q)}} \theta_{SAE}(W, b), \quad (9)$$

where ψ is the learning rate. The optimal W and b can be obtained by back propagation using the SGD optimization method.

The training process of SSAE network is shown in Figure 3.

The first SAE contains layers x , m_1 , and \hat{x} , uses formula (6) to learn the representation of features in an unsupervised manner, and then obtains U_1 and c_1 through formulae (7) and (8) training. The second SAE contains layers m_1 , m_2 , and \hat{m}_1 . The training method of the second SAE is similar to that of the first SAE, and U_2 and c_2 are obtained through training. By repeating the above training steps, all the parameters in the stacked sparse autoencoder network can be obtained.

The way of weight assignment of neural network through pretraining is better than that of random weight assignment of neural network, and it is conducive to convergence. In the training process, the number of neurons decreases gradually, and finally, the deep sparse feature is obtained.

3.3. Detection Model Training. Softmax classifier is added in the last layer of SSAE network, and the trained parameters are used as the initial optimization parameters of the model, and then, the parameters of the whole network are fine tuned. This layer-by-layer greedy process is proved to produce a better local extremum than random initialization weights and achieves better generalization performance in some tasks.

The proposed detection model used the SSAE network model is as follows (Algorithm 1).

4. Experiment and Result Discussion

4.1. Simulation Environment. Tensorflow and OpcnAlGym are the mainstream machine learning training platforms and environments. We choose them as the software environment for simulation experiments. Meanwhile, the experimental hardware environment is CPU model: AMD Ryzen 7, CPU: NVIDIA GeForce RTX2080Ti, and RAM: 32 GB.

4.2. Data Preprocessing. At present, the public datasets of industrial IoT intrusion mainly include KDDCup99, NSL-KDD, GasPipeline Datasets, WaterDatasets, and UNSW-NB15. These datasets have the problems of redundancy and repetition of data and attributes. This study selects NSL-KDD dataset as the experimental benchmark data.

NSL-KDD dataset solves the problem of redundant data in KDDCup99 dataset. Its original training set

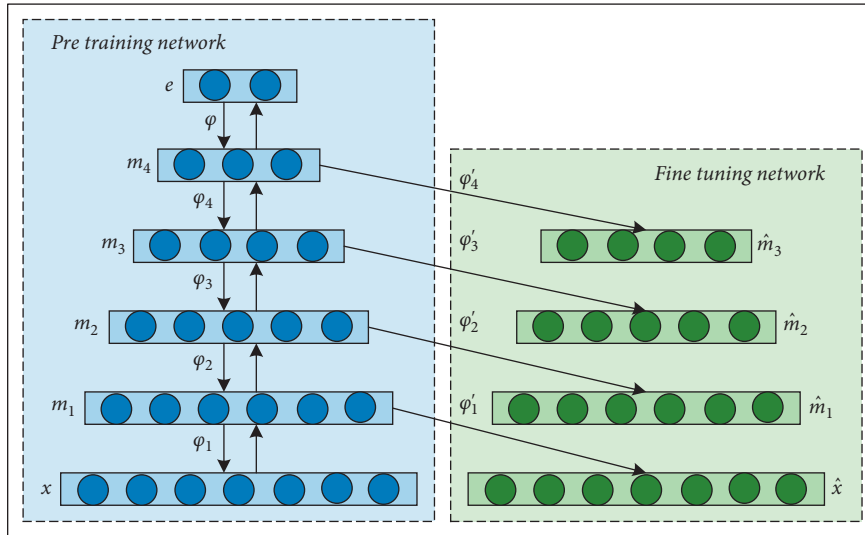

FIGURE 3: Stacked sparse autoencoder network training process.

Input: 256 dimensional data x after high-dimensional mapping and normalization, data \hat{x} with a certain noise proportion κ .

Output: optimal network parameter values $\varphi_1, \varphi_2, \varphi_3, \varphi_4$, and φ_5 .

Step 1: the feature extraction model based on SSAE network takes the training data x as the input. Through the SGD descent method, the input data are analyzed and processed to obtain the network parameters of the hidden layer. Finally, the output m_1 of the first hidden layer is calculated by using the original data x and parameters φ_1 .

Step 2: then, combined with m_1 and φ_1 , the output parameter φ_2 and output m_2 of the hidden layer can be obtained through the calculation and analysis of the second layer.

Step 3: repeat step 1 and step 2, and get the weight parameters $\varphi_1, \varphi_2, \varphi_3$, and φ_4 by layer-by-layer training. With the help of the calculation and analysis of the classifier, the parameter m_5 is obtained.

Step 4: through the above calculation, we can obtain the network parameter $\varphi_1 - \varphi_5$ of the detection model. By introducing random noise, we input it as training data, calculate the loss function between the predicted value and the target, and use various optimization methods to calculate the parameters near the minimum value.

ALGORITHM 1: Training algorithm of intrusion detection model based on SSAE network model.

KDDTrain contains 125973 data and the original test set KDDTest contains 22544 data. In this study, KDDTrain+20% of 25192 data are selected as experimental data.

4.2.1. Character-Type Mapping Numeric Type. “O, tcp, ftp_data, SF, 491, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 1, 0, 0, 150, 25, 0.17, 0.03, 0.17, 0, 0, 0, O.OS, O, Normal” is a piece of data in the dataset. According to the analysis, the values in dimension 2, 3, and 4 of the data are character types and need to be converted into numerical types. For example, there are 3 types in dimension 2 (TCP, UDP, ICMP), 70 types in dimension 3 (“auth,” “bgp,” “courier,” etc.), and 11 types in dimension 4 (“OTH,” “REJ,” “RSTO,” etc.), which are processed according to the one-hot coding in Figure 4 and finally convert the 32 dimension into 256 dimension attributes.

4.2.2. Numerical Normalization. Because data order of magnitude and corresponding value range of different feature attributes are obviously different, in order to

facilitate the analysis of experimental results, the Min-Max standardization method is used to uniformly map the numerical data to the $[0, 1]$ interval so that the data is in the same order of magnitude:

$$x_{\text{normal}} = \frac{x - x_{\min}}{x_{\max} - x_{\min}}, \quad (10)$$

where x is the original eigenvalue of data, x_{\min} and x_{\max} represents the minimum and maximum values in the data respectively, and x_{normal} represents the new feature value after normalization of each data.

4.2.3. Low-Frequency Sample Processing. Although current industrial IoT attacks show a rapid growth trend, the individual attack categories still belong to the low-frequency category compared with the normal data flow, which makes it difficult to capture their feature records. Moreover, most AI models have obvious classification bias because they aim at the overall classification accuracy of the largest sample. Therefore, this study improves the sampling algorithm and introduces the Regional Adaptive Synthetic Oversampling algorithm (RASmote) to

FIGURE 4: One-hot coding digitization.

incrementally process low-frequency samples. The algorithm formula is as follows:

$$\begin{aligned} \eta &= |X_n - X_l| \\ &= \sqrt{\sum_{k=1}^n (X_{nk} - X_{lk})^2}. \end{aligned} \quad (11)$$

Euclidean distance is used to calculate the distance of low-frequency samples in the nearest neighbor radius. n is the nearest neighbor radius, X_n is the nearest neighbor sample set, X_l is the low-frequency sample, and X' is the new sample set:

$$\begin{cases} X' = 0, & 0 \leq \eta \leq \frac{n}{2}, \\ X' = X + \mu(0, 1) \left(\left(\frac{1}{n - \eta} \sum_{i=1}^n X_i \right) - X \right), & \frac{n}{2} < \eta < n, \\ X' = X, & \eta = n, \end{cases} \quad (12)$$

where $(1/n - \eta \sum_{i=1}^n X_i)$ is a low-frequency sample.

4.3. Evaluation Index. The performance of the SSAE intrusion detection model can be evaluated from two aspects: model comparison and classification detection. The model comparison is mainly compared with traditional intrusion detection technology. The main indexes of system detection include accuracy Acc, precision Pre, recall Re, and F1-score F_1 . It should be noted that, for these four indexes, the higher the value, the better the detection performance:

TABLE 1: Distribution of dataset.

Data type	Training set	Test set
Normal	9415	4034
Dos	6500	2734
Probe	1603	786
R2L	145	64
U2R	8	3

TABLE 2: Identification result of different types of network attacks.

Data type	Accuracy (%)
Dos	97.34
Probe	96.81
R2L	91.32
U2R	88.23

FIGURE 5: Intrusion detection analysis under different methods.

$$\begin{aligned} \text{Acc} &= \frac{|T_P| + |T_N|}{|T_P| + |F_P| + |T_N| + |F_N|}, \\ \text{Pre} &= \frac{|T_P|}{|T_P| + |F_P|}, \\ \text{Re} &= \frac{|T_P|}{|T_P| + |F_N|}, \\ F_1 &= 2 \times \frac{\text{Pre} \times \text{Re}}{\text{Pre} + \text{Re}}, \end{aligned} \quad (13)$$

where T_N is true negative rate, F_P is false positive rate, F_N is false negative rate, and T_P is true positive rate.

4.4. Experimental Analysis. KDDTrain+20% data are used as the experimental data, 70% as the training set, and 30% as the test set. The data distribution is shown in Table 1.

Firstly, based on the experimental dataset, the detection, analysis, and research of industrial IoT under different network attacks are carried out for the proposed model. The

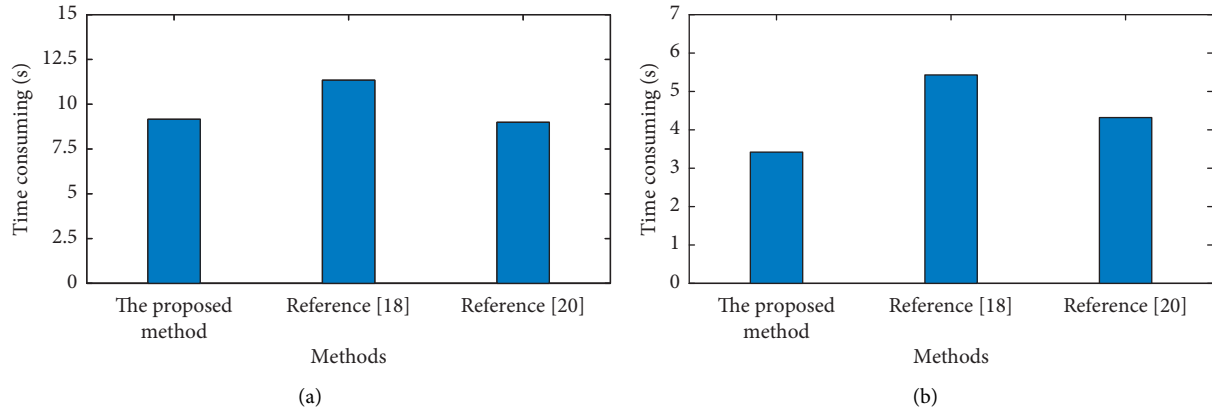

FIGURE 6: Comparison of intrusion detection time under different methods. (a) Training set time consuming. (b) Test set time consuming.

identification results of attacks are displayed in the under table.

From Table 2, we can see that the proposed model can better complete the task of network defense, and the detection accuracy of Dos and Probe attacks is more than 95%. For R2L and U2R attacks, because of the small volume of training data, the identification accuracy is lower than that of the first two attacks, but it is still more than 85%.

In order to further verify the performance of the proposed model, the authors [18, 20] are used as comparison methods to detect KDDTrain+20% datasets, respectively. Figure 5 shows the attack identification results under different intrusion detection methods.

From Figure 5, we can see that the proposed method is better than other comparison methods in terms of network performance. The evaluation indexes of the proposed method are as follows: the accuracy Acc is 95.42%, the precision Pre is 93.14%, the recall Re is 90.29%, and the F1-value F_1 is 92.35%. The accuracy of intrusion detection in [18, 20] is less than 95%, which is less than the detection performance of the proposed method.

The reason is that the proposed model simplifies the network and enhances the autonomous ability and can realize better feature extraction and expression of the network. Meanwhile, with the introduction of Softmax classifier, the detection network parameters can be dynamically adjusted to support accurate network attack identification and analysis. In [18, 20], LSTM network as the benchmark model is taken for modeling and analysis, without considering the imbalance of data, which is not enough to achieve more accurate and efficient intrusion identification analysis.

At the same time, the attack detection efficiency is also compared and evaluated. Figure 6 shows the analysis of detection time under different methods.

As shown in Figure 6, due to the simplification of the network unit, the unit structure of the proposed method needs more autonomous learning time to realize the accurate extraction of data features. Therefore, the training time is 9.16s, which is 0.17s more than that in [20]. Moreover, the time-consuming of the proposed method for

network intrusion detection is only 3.42 s and that of [18] is 5.43 s and that of reference [20] is 4.32 s.

To sum up, while ensuring the accuracy of detection, the proposed method can improve the efficiency of intrusion identification and analysis and reflect its overall efficient performance.

5. Conclusion

This study proposes an intrusion detection method based on stacked sparse autoencoder network. This method constructs an intrusion network model based on autoencoder network, which can effectively improve the feature extraction of industrial Internet data. The autoencoder network is simplified and cascaded, and a small number of basic network units are used to obtain more efficient feature expression. In addition, the introduction of Softmax classifier ensures that the parameters of the detection network can be fine-tuned and optimized, which can further improve the processing and computing efficiency of the network while improving the accuracy of industrial IoT attack recognition. The experimental analysis based on NSL-KDD dataset shows that the proposed method can realize accurate and fast intrusion attack identification and can meet the safe and controllable operation requirements of industrial IoT.

Although this method improves the solution of IIoT intrusion detection, the essence of the proposed model is a centralized processing and computing model. Aiming to support the detection research in the actual complex network environment, the next step will be to study the intrusion detection method of distributed architecture mode.

Brand image assessment is a key step to reasonably quantify the value of a brand and has far-reaching significance for improving the competitiveness of an enterprise. With the rapid development of Internet technology, traditional questionnaires can no longer meet the current needs of brand image assessment. In this environment, the huge amount of fragmented consumer topic data provides a rich data resource and new research ideas for brand image assessment. Therefore, a brand image assessment method based on consumer sentiment analysis is proposed. First, a topic-based brand image cognitive label extraction method is proposed by setting language rules, aggregation rules, and ranking rules according to the characteristics of online topic data. Then, the fusion of cognitive labels and deep features is performed by fusing the deep features extracted from word vectors. Finally, a supervised learning support vector machine is selected as the sentiment classification model. The experimental results show that based on the obtained important cognitive labels, enterprises are able to better understand the unique attributes that consumers have for the brand; the feature fusion approach is better evaluated and can accurately reflect consumers' views on brand image and quantified as brand score.

1. Introduction

With the rapid development of the global market, various brands are becoming more and more colorful, but the trend of product homogeneity is intensifying, leading to increasingly fierce competition among enterprises. For an enterprise to gain lasting vitality, it must have a clear and superior brand image. Brand image assessment is a key step in understanding brand image and is the first step in improving brand quality and developing brand communication strategies. Enterprises need a way to objectively assess their brand image. This will enable companies to better grasp consumers' psychological perceptions and thus develop precise marketing strategies that vary from person to person and can provide support and more insight into future decisions. Internet technology has broken the traditional ecology of information dissemination and changed the previous way of information delivery. The traditional brand evaluation method based on a questionnaire survey can no longer meet the current demand for brand image evaluation.

In the new information communication ecology, user-generated content brings unprecedented opportunities and challenges for brand image mining [1–3]. Based on user-generated data, social networks can improve the feasibility, operability, and flexibility of brand image assessment. Analyzing the sentiment tendency of texts through natural language processing techniques for user-topic texts is a new trend in brand image assessment and has a very practical application value [4–8]. The task process of sentiment analysis includes sentiment feature extraction and sentiment classification. The first task of sentiment feature extraction is to find the words (features) that represent the user's point of view and then classify the features for sentiment tendency [9–11]. From a psychological perspective, the brand image refers to the sum of consumers' psychological feelings about the brand's products and services. Brand image is divided into two main dimensions, one that is the user's perception of the functional attributes of the brand and one that reflects the emotional value of the brand.

Consumer perception of a brand is the overall impression of the consumer of the brand [12]. The most basic

element of brand image assessment is brand perception. The explosive growth of topic texts provides a massive source of data for brand perception analysis. Therefore, this paper focuses on brand research through topic text sentiment analysis techniques, so as to extract the attributes of brands that consumers pay attention to. It also quantifies consumers' attitudes toward brands into brand scores, so that companies can understand consumers' views more intuitively and objectively, understand the strengths and weaknesses of brand images, and provide them with decision support for resource allocation and product strategy adjustment.

The rest of the paper is organized as follows: In Section 2, the related research is studied in detail, while Section 3 provides the detailed methodology of brand image cognitive label extraction. Section 4 provides the detailed brand image evaluation method based on a weighted fusion model. Section 5 provides the results and discussion. Finally, the paper is concluded in Section 6.

2. Related Research

Brand image theory was first proposed in the United States in the 1960s. After that, brand image theory has been developed continuously, and brand image is gradually interpreted as a collection of consumers' perception of various elements and concepts of a brand. Brand image in general can be divided into two categories, one from the image visual perspective and one from the psychological perspective.

The visual image of a brand refers to the visual design and communication elements that are visible to the user. As the differences between products become less and less, brands are anthropomorphized. Rehman et al. [13] mapped consumers' personality traits vaguely to the brand image. Consumers and brands are closely linked, and consumption can interact and communicate through brands. Portal et al. [14] described brands anthropomorphically and considered brands as having their own independent personalities. The relationship between the consumer and the product is also an interpersonal relationship. These early definitions of anthropomorphism were vague until the concept of the brand image became clearer by using the Big Five personality theory to construct a brand personality theory.

From a psychological perspective, the brand image refers to the sum of consumers' psychological feelings about a brand. Psychological image is divided into two main dimensions, one that is the user's perception of the functional attributes of the brand and one that reflects the emotional value of the brand. The perception of functional attributes refers to the ability of the brand to satisfy functional needs [15]. For example, a car can fulfill the function of a substitute, and coffee can refresh the mind. Currently, defining brand image at the psychological level has been dominant in the field of related research. Sentiment analysis from a psychological perspective consists of two components: feature selection of texts and feature-based sentiment classification models. Early sentiment analysis was mainly based on a rule-based feature approach to classification. Recently, many researchers have started to study machine

learning classification for sentiment analysis methods. Suhasini et al. [16] used a fusion of machine learning and rules for sentiment classification of microblog data with good results and solved the problem of sentiment classification of fuzzy words by combining rules and statistics. Kang et al. [17] compared plain Bayes, support vector machine (SVM), and Rocchio (ROC) classification models, where the second classifier effect is the best performance among the three. The above findings suggest that machine learning-based classification methods are more scalable, while rule-based classification methods need to be constrained by the corpus.

In this paper, we analyze massive topic sentiment data for brand evaluation and set language rules, aggregation rules, and ranking rules to extract consumers' cognitive label (CL) of the brand. This cognitive label is used to achieve a shallow portrait of the brand. Meanwhile, the feature selection method incorporating deep features improves the evaluation effect of the classification model. Finally, a supervised learning support vector machine is selected as the sentiment classification model.

The main innovation points and contributions of this paper are as follows.

- (1) A topic sentiment-based brand image cognitive analysis method is proposed to extract the features of topic text and improve the effect of the sentiment recognition algorithm. By regularizing the topic data (constraint rules), consumers' cognitive labels of brands are extracted.
- (2) In order to make up for the defect that shallow features cannot obtain complete semantic information, this paper introduces the method of fusing deep features, fusing shallow learning features with deep learning features to solve the problem of recognizing a large number of nonentity words in the text, enriching the set of features used by the classification algorithm, and improving the correct rate of text classification.

3. Brand Image Cognitive Label Extraction Based on Topic Sentiment

The effect of sentiment classification is crucial with feature selection, and this paper proposes a rule-based cognitive feature extraction method and aggregates cognitive labels with the help of a synonym dictionary and Jaccard similarity. Finally, the TF-MF model is applied to calculate the importance of cognitive labels.

3.1. Language Rules for Cognitive Label Extraction. Definition of cognitive label: users' knowledge and understanding of brand connotation. For example, the Redmi Note, which positions itself in the low and midrange market, users' cognitive labels of its brand are "within one thousand dollars," "teenager," "big screen," "good pixel," "lagging," etc. In this paper, w is used to denote the cognitive labels.

Let the corpus set $T = \{t_1, t_2, \dots, t_n\}$, where t_i denotes a corpus instance. Different users use different lengths of utterances to express their feelings or experiences about a brand. In general, a single phrase may contain several aspects of a user’s perception of a brand. However, one aspect of the user’s perception of a brand is usually not in several phrases, but in a single phrase. For example, “It’s really good! The system is smooth, the screen is good, the performance is good, but unfortunately there is no transparent case. [Big Love] It’s really good!” In this corpus, the idea of “no transparent case” can only be expressed in one phrase. However, the phrase “smooth system, good screen, and good performance” contains the perceptions of “smooth system,” “good screen,” and “good performance.” The corpus is partitioned using the dot mark set $D = \{, ; : ? !\}$ to obtain a set $S = \{s_1, s_2, \dots, s_m\}$ of phrases, where $m > n$. We choose phrase s_i as the basic unit to extract the candidate cognitive labels.

After splitting the input text into a series of phrase collections S , the traditional feature extraction view is to deal with adjectives. However, in addition to adjectives, nouns, adverbs, and verbs are often used to express opinions and perceptions. For example, “big” as an adjective is often used to modify nouns. If “big brand” is the user’s perception of the brand, then this noun phrase can be regarded as the user’s perception label. Similarly, verbal and adverbial phrases such as “stuck” and “trustworthy” are also user awareness, reflecting the user’s perception of a particular aspect of the brand. After splitting and deactivating s_i , the speech chain rule set $R = \{r_1, r_2, r_3, r_4, r_5, r_6\}$ is used to extract candidate cognitive labels w , as shown in Table 1.

The distance between the first word and the last word in the label is L . There are too many interferences in the labels extracted by the lexical chain rule, so we need to use the distance principle to filter the interferences. In the corpus “The phone is very comfortable to operate,” after pre-processing, the corpus becomes “phone/n, operate/vn, very/d, comfortable/a.” We may extract the label “phone comfortable.” At this point, “phone” is in position 1, and “comfortable” is in position 4. Using the principle of closest modification, we design a word spacing constraint. The label extraction is constrained by using the label distance L to improve the readability of the cognitive labels. After the above steps, a series of candidate cognitive tag sets $W = \{w_1, w_2, \dots, w_p\}$ are obtained from the corpus T . The processing schematic is shown in Figure 1.

3.2. Aggregation Strategies for Cognitive Label Extraction.

The initial extracted cognitive labels appear to be messy and voluminous because users freely choose their own terms when expressing their opinions and views. Therefore, we need to further aggregate the initial cognitive labels extracted in the previous section. Although users are free to use words when expressing their perceptions, in most cases, users’ perceptions of a certain side are often near or opposite words. Therefore, we use Jaccard similarity [18–20] to cluster the extracted tags based on a lexicon of near-sense words. For the candidate tags w_i and w_j of the same length, the similarity between them is

TABLE 1: Speech chain rules in label extraction.

Rules	Speech chain	Example
r_1	n + d + a (noun + adverb + adjective)	Cost very effective
r_2	n + h + a (noun + prefix + adjective)	Logistics super-fast
r_3	a + n (adjective + noun)	Smooth system
r_4	d + v (adverb + verb)	Very much like
r_5	d + n (adverb + noun)	Very youth
r_6	d + a (adverb + adjective)	Really good

FIGURE 1: Sketch map of candidate labels extracting based on language rules.

$$\text{SIM}(w_i, w_j) = \frac{|w_i \cap w_j|}{|w_i \cup w_j|}. \quad (1)$$

When a pair of elements in a phrase appears in pairs in the list of near-synonyms, we consider them to be the same word. For example, $A = \text{“Beautiful appearance,“}$ $B = \text{“Pretty appearance,“}$ $C = \text{“Fast logistics.“}$ Obviously, A and B have a high similarity. The words “Beautiful” and “Pretty” are a set of near-synonyms, so $\text{SIM}(A, B) = 1$ and $\text{SIM}(A, C) = 1/5 = 0.2$.

Based on the Jaccard similarity and synonym dictionary, we can get the similarity between any two words, which in turn clusters the initial cognitive labels. The word w with the highest frequency in this cluster is selected as the representative of this cluster. At this point, the new set of cognitive labels $W^* = \{x_1^*, x_2^*, \dots, x_k^*\}$, $k \leq p$ is obtained, as shown in Figure 2. For example, after the aggregation of “good endurance, great endurance, OK endurance,” the cognitive label “good endurance” is extracted.

3.3. Importance Ranking of Cognitive Labels. In order to understand the importance of the acquired cognitive labels in the minds of consumers, the importance of the cognitive labels needs to be ranked. The entire corpus set is T , and the set of tags appearing in this corpus is w^* . The elements in the initial tag set W are replaced by representative elements in the same tag cluster. f_{w^*} denotes the number of occurrences of the word w^* in the corpus set T , and B denotes the number of corpus containing the word w^* in the corpus set. Considering that w^* is already a label with actual meaning, the importance of the label w^* can be calculated according to the TF-MF model.

$$\text{TFMF}(w^*) = \frac{f_{w^*}}{\sum_{W^*} f_{w^*}} \times \log\left(\frac{B}{|T|} + 1\right). \quad (2)$$

An example of the TF-MF model is given as follows. Suppose the corpus set T has five different corpora

FIGURE 2: Candidate labels aggregation diagram.

t_1, t_2, t_3, t_4, t_5 . Two cognitive labels w_1^* and w_2^* appear in the corpus, and the specific distribution is shown in Figure 3.

The importance of the two was calculated by the TF-MF model.

$$\begin{aligned} \text{TFMF}(w_1^*) &= \frac{5}{10} \times \log\left(\frac{3}{5} + 1\right) = 0.102, \\ \text{TFMF}(w_2^*) &= \frac{5}{10} \times \log\left(\frac{5}{5} + 1\right) = 0.151. \end{aligned} \quad (3)$$

Although the two labels w_1^* and w_2^* appear equally in the corpus in total, the label w_2^* is more important than w_1^* . This coincides with the fact that in practice the more people pay attention to it the more it deserves attention.

4. Brand Image Assessment Method Based on Weighted Fusion Model

The previous section proposed to extract features by cognitive labels, but cognitive labels only address the importance of brand attribute features and cannot explain the meaning of a large number of noncognitive labels. To complement this deficiency, this paper then introduces fusion features to supplement the feature vectors based on the results of deep learning word vector models.

4.1. Features Based on Word Vector Model. Since the implicit meaning of some words can be obtained using deep model parameter passing, this paper uses the CBOW (continuous bag of words) model [21] to train the word vector model. The CBOW model uses the context before and after the target word to predict the probability of occurrence of the target word. We used a three-layer word vector model for training to obtain the word vector representation.

Firstly, a lexicon matching and hidden Markov model-based lexicographer are used to split the text. Then, the lexicon numbers are extracted from the split text, and the numbers are used to convert the training text utterances into id representations. Finally, the word2vec tool [22] is called, and the word vector model is trained according to the belonging parameter settings. The dimensionality of the word vector is set to 200, and the sliding window size in the

FIGURE 3: Example of TFMF model.

training model is 5. The output results in a vector set of floating-point numbers and the vector values are normalized.

4.2. Emotion Classification Model with Feature Fusion. We fuse shallow cognitive label extraction and deep feature filtering to improve the accuracy of feature selection and optimize the classification results. Then, the training text is trained for classification using an SVM classifier, which we call CL-C-SVM.

The processing of text content in sentiment analysis can be reduced to the processing of a vector of a certain length. For the extracted cognitive labels, they can be represented in the form of one-hot. Each cognitive label represents a dimension, and a sentence may be represented by thousands of dimensions. The position of words that have appeared in the sentence is filled with 1, and the position corresponding to words that have not appeared is filled with 0. This allows the text data to be represented by a high dimensional 0-1 vectorization. The extracted cognitive labels and the word vectors from the training output are fused to generate new feature files, and the flow of feature fusion is shown in Figure 4.

4.3. Definition of Brand Image. For a brand, which contains a lot of products, products at the same time contain a lot of models, different models of goods in the e-commerce site, and a large number of sellers, thus generating a large number of topic comments data. The good or bad topic comments can represent the brand's reputation to a certain extent. According to the principle of statistics, in the context of big data statistics, good or bad user word-of-mouth can be used as a standard for a high or low brand image, so the brand assessment given in this paper is defined as

$$\text{score} = \sum_{i=0}^m w_{ij} - \sum_{i=0}^n w_{ij}, \quad (4)$$

where m denotes the number of positive comments and n denotes the number of negative comments. w_{ij} denotes the ranking of each cognitive label j in the sentence i .

5. Experiment and Result Analysis

5.1. Data Selection and Preprocessing. Two competing cell phone brands, <Huawei mate50> and <Samsung Galaxy S22>, were selected for the experiment. Records about these two brands were searched on three online platforms, namely B2C e-commerce cell phone category comment information, Sina Weibo and Zhongguancun Online, and 10,000 records

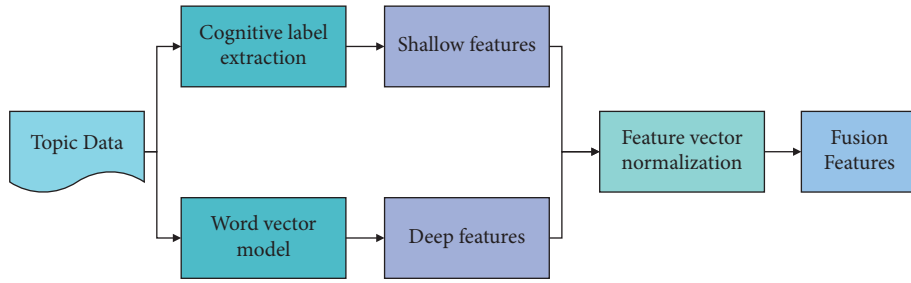

FIGURE 4: The process of feature fusion.

(a)

(b)

FIGURE 5: Short sentences' length distribution. (a) Huawei Mate 50. (b) Samsung Galaxy S22.

each were randomly selected as the experimental data set. Each corpus was segmented with the dot as the separator to obtain the basic unit phrases for label extraction. The NLPiR system was used for word segmentation and lexical

annotation, and the deactivated words in the records were removed using a deactivated word list. The Huawei mate50 dataset has 27575 phrases, with a maximum of 163 words and a minimum of 1 word in the phrase, and an average

length of 5 words. The Samsung Galaxy S22 dataset has 34563 phrases, with a maximum of 195 words and a minimum of 1 word, and each phrase has an average of 5 words. The overall distribution is shown in Figure 5.

5.2. Cognitive Labeling Analysis. Using the speech chain rule, the initial set of cognitive labels is obtained, and the results are shown in Table 2.

The above table shows that the initial cognitive labels extracted at this point are cluttered and disorganized. Next, critical information needs to be obtained through linguistic aggregation and importance ranking methods. Based on Jaccard similarity and synonym dictionary to calculate the similarity between tags, the initial cognitive tags are aggregated, the tags are ranked using TF-MF rules, and the top 5 tags are taken, as shown in Table 3.

From Table 3, it can be seen that the method in this paper can effectively extract the cognitive labels of consumers, so as to obtain the key elements of users' perception of brand image. Through the method in this paper, it can help companies recognize their image in consumers' mind and discover the most and least satisfied areas of users, thus providing strong support for subsequent brand image evaluation.

5.3. Classification Performance. The dataset was annotated manually and labeled with the review data sentiment classification as positive or negative reviews. The labeled data were divided into a training set and a test set in the ratio of 9:1. The classical IG (information gain)-SVM model was selected as the comparison algorithm to compare with the proposed CL-SVM and CL-C-SVM classification algorithms to verify their effectiveness. The metrics for evaluating the algorithms were chosen as accuracy rates commonly used in the field of natural language. The accuracy comparison of the different classification models is shown in Figure 6.

From the accuracy comparison shown in Figure 6, it is clear that the CL-C-SVM algorithm proposed in this paper has the best sentiment classification effect. By analyzing the data, the reason can be obtained that the choice of IG, CL, or feature fusion by the feature extraction algorithm leads to a large difference in the actual results. The fused features are more comprehensive and compensate the problem that shallow features cannot explain the meaning of a large number of non-CL words. Combining the shallow filtered CL with deeper features that contain more hidden meanings can improve the accuracy of feature selection.

5.4. Brand Image Evaluation Experiment. For the two cell phone brands, the results of brand image assessment using the CL-C-SVM model are shown in Table 4.

In order to conduct a manual and subjective assessment of brand image ratings, this paper adopted a user questionnaire + ranking approach. For the above two cell phone brands, 1000 online questionnaires were randomly distributed at the entrance of a large supermarket. The target audience was consumers who had used these two cell phone brands, and they were asked to rate these two cell phone brands. A score of

TABLE 2: The distribution of candidate cognitive label in the speech chain.

Candidate label type	n+d+a	n+h+a	n+a	d+a	d+v	d+n	Total
Huawei Mate 50	2954	27	1171	587	3124	2358	10221
Samsung Galaxy S22	4067	55	1466	794	3458	2783	12623

1 was set as a passing score, and the higher the score, the better the brand's psychological impression on users. The scores and the number of people were multiplied to obtain the average score and normalized to within 1000, and the final results were obtained as shown in Table 5. The comparison of brand scores for different methods is shown in Figure 7.

The scores of different brands are shown in Figure 7, and it is found that the brand scores calculated by the CL-C-SVM model have the best fit with the scores of the user questionnaire. The brand scores derived from the CL-SVM

FIGURE 7: Comparison of brand scores.

model are slightly less effective but better than those calculated by the IG-SVM model. The practical value of the CL-C-SVM model was verified by comparing the results with those of the manual questionnaire.

6. Conclusions

In this paper, a brand image cognitive analysis method based on topic sentiment is proposed to extract features of topic text and improve the effect of the sentiment recognition algorithm. At the same time, the feature selection method incorporating deep features makes up for the defect that shallow features cannot obtain complete semantic information and enriches the set of features used by the classification algorithm. The experimental results show that the proposed cognitive label extraction method can effectively obtain the key elements of users' brand image and discover the most and least satisfied areas of users. In addition, the CL-C-SVM model can accurately quantify consumers' brand scores on brand image, and the results are almost consistent with the manual questionnaire approach. However, the extraction of cognitive labels does not take into account the influence of unexpected events, resulting in the assessment of the model failing to reflect the real-time changes in corporate image, which is important in practical applications. Therefore, further work on this issue will be conducted in subsequent studies.

Data Availability

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Conflicts of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as potential conflicts of interest.

Solfeggio is an important basic course for music majors, and audio recognition training is one of the important links. With the improvement of computer performance, audio recognition has been widely used in smart wearable devices. In recent years, the development of deep learning has accelerated the research process of audio recognition. However, there is a lot of sound interference in music teaching environment, which leads to the performance of the audio classifier that cannot meet the actual demand. In order to solve this problem, an improved audio recognition system based on YOLO-v4 is proposed, which mainly improves the network structure. First, Mel frequency cepstrum number is used to process the original audio and extract the corresponding features. Then, try to apply the YOLO-v4 model in the field of deep learning to the field of audio recognition and improve it by combining with the spatial pyramid pool module to strengthen the generalization ability of data in different audio formats. Second, the stacking method in ensemble learning is used to fuse the independent submodels of two different channels. Experimental results show that compared with other deep learning technologies, the improved YOLO-v4 model can improve the performance of audio recognition, and it has better performance in processing data of different audio formats, which shows better generalization ability.

1. Introduction

Music is an abstract art form with sound as its means of expression. In the process of music teaching, solfeggio can strengthen students' musical memory ability, enable students to accurately identify music works, and thus obtain better "musical perception." As an important link in solfeggio, audio recognition training is very difficult for junior students. This is because students need to master all kinds of clefs, distinguish the length and duration represented by different notes, and the pitch difference between different notes.

Audio signal analysis based on embedded intelligent devices has attracted more and more researchers' attention [1–7]. Intelligent wearable devices with audio recognition function can help students solve the above problems and realize music teaching assistance. The task of audio

recognition needs to preprocess the collected audio signals first, extract useful features for distinguishing music scores from them, and finally classify them according to these features. Classification is a very important method of data mining [8–10]. Classification refers to generating a classification function according to certain rules on the basis of training set data. This function can map the data of the test set to one of the given categories, thus realizing the category prediction of unknown data. At present, common classifiers include decision tree, logistic regression, support vector machine (SVM), Naive Bayes, k -nearest neighbor algorithm (KNN), BP neural network, and deep learning [11–13].

The previous machine learning methods often need to manually extract the features that can represent the original data as the input of the classifier. However, deep learning can automatically extract the high-dimensional features of samples (without manual feature extraction), as long as the

input data cover the information of the original data as much as possible, which is suitable for large-scale data. The deep learning method can realize specific audio recognition tasks with the help of a large amount of audio data collected by intelligent devices. The convolutional neural network (CNN), as a kind of deep learning architecture, is widely used in image classification, speech recognition, natural language processing, and other fields because of its superior performance in local feature learning [14]. Different from other neural network models (such as Boltzmann machine and recurrent neural network), the CNN characterized in that core operation is convolution operation. The YOLO network draws lessons from the CNN classification network structure and shows good advantages in the field of image recognition, which has attracted the attention of many researchers.

Therefore, this study tries to apply the YOLO-v4 model to the field of audio recognition and improves its network structure. In addition, the stacking method in ensemble learning is used to fuse two independent submodels of different channels, and the classification performance of the fused system is further improved compared with the single submodel.

2. Related Works

Nowadays, with the emergence of a large number of smart devices, the excellent computer performance and the development of deep learning technology have jointly promoted the research process in the audio field. Combined with the main research contents of this study, the current research status will be introduced from two aspects: convolutional neural network and audio recognition.

The convolutional neural network structure originated from a study by Yann LeCun in 1998 is called the Le Net-5 artificial neural network. The convolutional neural network, like other neural networks, can be trained by the back propagation algorithm [15]. In 2012, Alex Krizhevsky and others adopted CNN technology for the first time in complex computer vision tasks. By using 3 fully connected layers, 5 convolution layers, and Softmax classifier, a convolutional neural network with 8 layers is constructed, which is named AlexNet. AlexNet uses ReLU activation function, and at the same time, it also uses regularization (dropout) to prevent overfitting. In 2014, the Google' computer vision team puts forward the GoogLeNet network [16], with a network depth of 22 layers, which contains a new structure, incident. It integrates the features of different depths and the same scale, and the detection accuracy is improved. On the basis of the GoogLeNet network, YOLO and SSD algorithms appeared. Both methods are based on a single end-to-end network, which can complete the input from the original image to the output of the object position and category.

In the aspect of audio recognition, Yang and Zhao [17] proposed an acoustic scene classification method based on the support vector machine (SVM), which enhanced the sound texture to improve the classification accuracy. Greco et al. [18] proposed a voice recognition system based on the heuristic deep learning method. Demir et al. [19] proposed a

new pyramid cascade CNN method for environmental sound classification. Zhu et al. [20] proposed an improved YOLO-v4 algorithm for sound imaging instruments, which effectively improved the accuracy of acoustic phase cloud image detection. The above methods all show excellent performance in dealing with audio recognition tasks in a single acoustic scene, but there are many sound disturbances in the music teaching environment, and it is necessary to deal with a variety of different audio format data.

Therefore, this study proposes an audio recognition system based on the improved YOLO-v4 network model. The main innovations and contributions include the following: (1) try to apply YOLO-v4 network architecture, which is excellent in the field of deep learning, to the field of audio recognition, and improve it by combining the spatial pyramid pool module. The improved YOLO-v4 network architecture effectively utilizes the spatial information in audio files, thus strengthening the generalization ability of data in different audio formats. (2) The stacking method in ensemble learning is used to fuse two independent submodels of different channels, and the classification performance of the fused system is improved.

3. Extraction and Processing of Audio Features

Extracting the best parameter representation of audio signal is one of the important tasks to produce better recognition performance. The feature extraction in this stage is very important for the classifier classification in the next stage because it will directly affect the classification efficiency.

In the classification task, especially the audio classification task, the Mel frequency cepstrum coefficient (MFCC) which describes the spectral shape has a long history. Although the MFCC extraction process will cause lossy compression of data, its classification and recognition effect are quite available even when the data rate is very low. In addition, compared with other classification features, MFCC is widely used because it is more in line with the auditory frequency response curve of human ears.

The reason why human beings can judge different environments in complex sound environment lies in the credit of the cochlea. The cochlea can be seen as a filter bank to help people filter 20-20 kHz audio. The problem is that the sensitivity of the cochlea to frequencies in the auditory range is not linear, but there is a mapping relationship. MFCC can simulate the frequency response of the human ear. MFCC feature extraction consists of seven steps, and the whole process is shown in Figure 1.

Common audio signals have the phenomenon that the low-frequency energy is large, but the high-frequency energy is small. If it is transmitted directly, it will lead to high signal-to-noise ratio at low frequency and insufficient signal-to-noise ratio at high frequency. In order to make up for this loss of audio signal during transmission, preemphasis is introduced to compensate the input signal, so that the high-frequency characteristics of audio signal can be highlighted. Preemphasis is usually achieved by means of a high-pass filter [21–23].

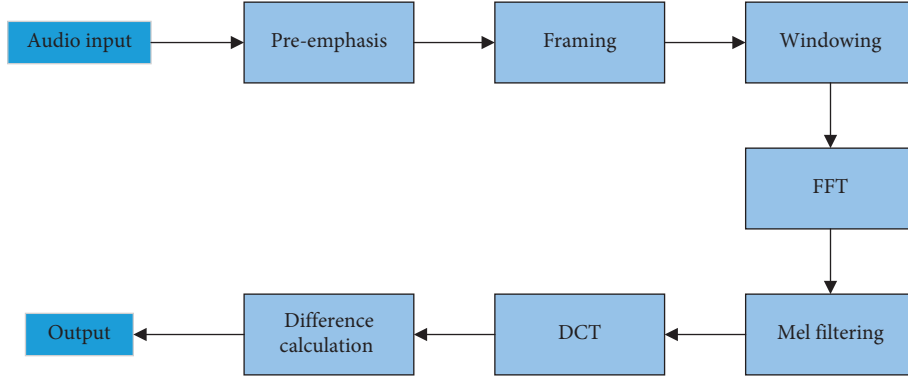

FIGURE 1: MFCC feature extraction steps.

Let the voice sample value at the n^{th} time be $X[n]$, and the result after preemphasis is

$$Y[n] = X[n] - aX[n-1], \quad (1)$$

where a is the preemphasis coefficient, usually within 0.9-1.0.

Framing divides audio samples obtained from analog-to-digital conversion (ADC) into small frames with a length in the range of 20-40 milliseconds. After preemphasis and framing are completed, it is necessary to add a Hamming window to each frame. Windowing is to control the amount of data processing, and only the data in the window are processed at a time. The frequency range in the fast Fourier transform spectrum is very wide, which leads to the speech signal not following the linear scale [24-26]. Therefore, it is necessary to pass the Mel scale filter bank as shown in Figure 2.

Figure 2 shows a set of triangular filters, which are used to calculate the weighted sum of the spectral components of the filters, so that the processed output approximates Mel scale. The amplitude-frequency response of each filter is triangular. The Mel spectrum of a given frequency f is calculated as follows:

$$F(\text{Mel}) = 2595 \cdot \log_{10} \left(1 + \frac{f}{700} \right). \quad (2)$$

Discrete cosine transform (DCT) transforms the Mel spectrum into time domain. The result of the transforms is called Mel frequency cepstrum coefficient. The coefficient set is called acoustic vector. Therefore, each input is converted into an audio vector sequence.

In order to improve the signal recognition performance, the differential spectrum based on the static characteristics of audio signals is used to describe the dynamic characteristics of audio signals. 13 first-order difference features and 39 second-order difference features are introduced. The frame energy of signal x in the window from time t_1 to t_2 is as follows:

$$\text{Energy} = \sum_{t=t_1}^{t_2} X^2(t). \quad (3)$$

13 first-order differential features represent the changes between frames of cepstrum in MFCC features, while 39 second-order differential features represent the changes between frames in first-order differential features. The first-order difference is calculated as follows:

$$d(n) = \frac{c(n+1) - c(n-1)}{2}, \quad (4)$$

where $c(n+1)$ represents the cepstrum coefficient at time $n+1$.

4. SPP-YOLO-v4 Network Structure

4.1. Spatial Pyramid Pool (SPP) Module. SPP can avoid information distortion caused by scaling, stretching, clipping, and other operations and provide output that is not affected by the input size, which cannot be achieved by sliding window pooling technology [27]. Second, SPP can pool with multiple scales, while sliding window pooling only uses one window scale. The basic structure of the SPP module is shown in Figure 3. It can be seen that because the input size is flexible, SPP can combine the features of data in different audio formats. The dimension of the transformed feature vector is the same as that of the fully connected layer, while alleviating the generalization problem.

4.2. SPP-YOLO-v4. YOLO-v4 is a high-precision real-time single-stage detection algorithm integrating YOLO-v1, YOLO-v2, and YOLO-v3. YOLO-v4 constructs the CSP cross-stage partial network (CSPNet) in the residual module, in which the feature layer is the input and the feature information of the higher layer is the output. This shows that the learning objectives of YOLO-v4 in the ResNet module are different between output and input. Therefore, residual learning is realized, and the model parameters are reduced, so the feature learning ability is enhanced. Considering the application environment of music teaching, some changes are made on the basis of the original network, and the final network structure is shown in Figure 4.

First, the feature layer is convolved three times, and then, the input feature layer is maximally pooled by using the maximum pooled cores of different sizes. After convolution and upsampling, different feature layers are connected in

FIGURE 2: Mel scale filter bank.

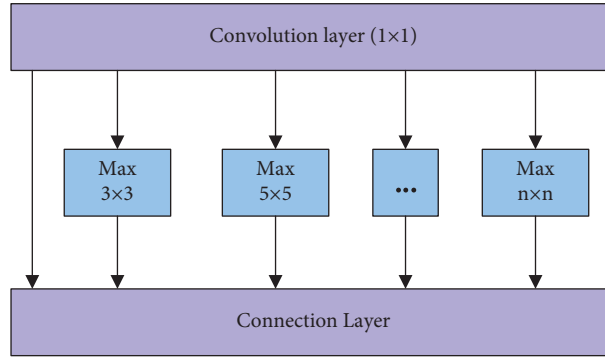

FIGURE 3: Basic module structure of SPP.

series to realize feature fusion. Then, perform down-sampling, compress height and width, and finally stack with the previous feature layer to realize more feature fusion (5 times). The classification module uses the features extracted from the network to make classification judgment. Take the 13×13 grid as an example, which is equal to dividing the input Mel spectrogram into 13×13 squares; then, each square will be preset with three prior frames. The classification results of the network will adjust the positions of these three prior boxes and finally filter by the nonmaximum suppression (NMS) algorithm [28], so as to get the final classification results.

5. Audio Recognition System Based on SPP-YOLO-v4

5.1. System Architecture. As shown in Figure 5, after audio input, the proposed audio recognition system first divides the audio sequence data into two parts. The first part comes from stereo channel, while the second part is compressed into mono. The audio signals of the two channels are extracted by MFCC spectrogram and input into the SPP-YOLO-v4 model as features. Then, two groups of SPP-YOLO-v4 models are integrated, and the stacking method is adopted in the

integration. After the integrated learning of the two models, the audio classification results are finally output. The details of the SPP-YOLO-v4 model are shown in Figure 4.

5.2. Stacking Integrated Learning. As shown in Figure 5, the system uses ensemble learning technology to get the final classification result. The basic idea of ensemble learning is to form a strong classifier through the combination of several weak classifiers. Even if some weak classifiers make wrong predictions, they can be corrected by other weak classifiers with correct predictions, thus achieving the effect of improving the system performance.

Assuming that x is an input, m_i ($i = 1, 2, \dots, k$) is a group of classifiers and the output of the classifiers is the probability distribution $m_i(x, c_j)$ of each class c_j ($i = 1, 2, \dots, k$), the final output $y(x)$ of the integrated classifier can be expressed as

$$y(x) = \operatorname{argmax}_{c_j} \sum_{i=1}^k w_i m_i(x, c_j), \quad (5)$$

where w_i is the weight of classifier m_i . Ensemble is a method to calculate the best weight of each classifier according to the

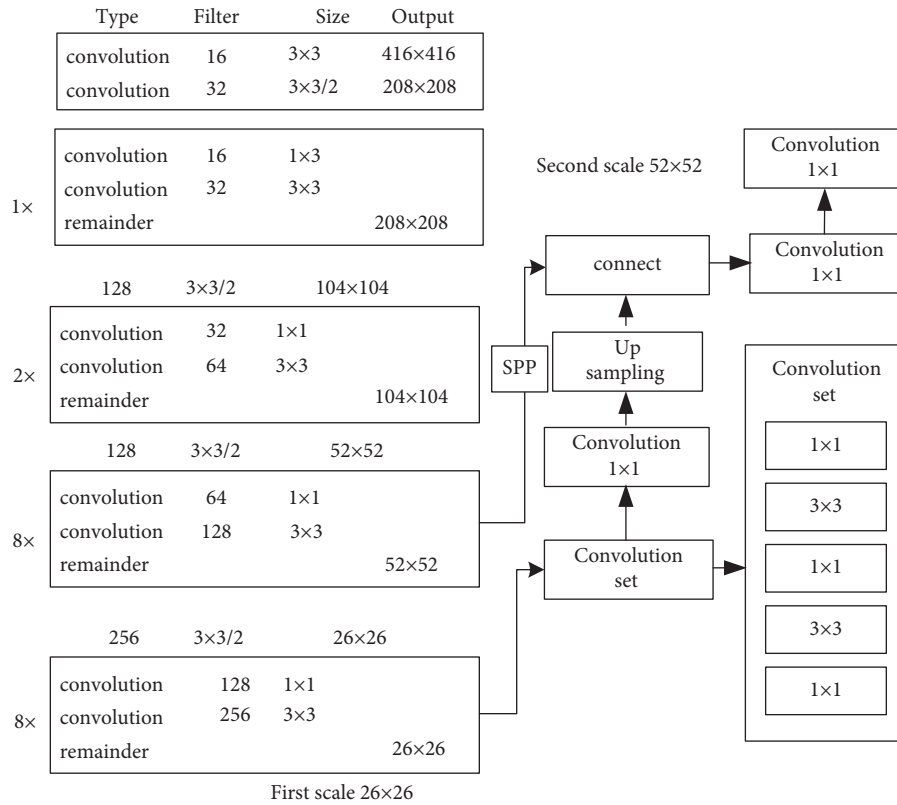

FIGURE 4: SPP-YOLO-v4 network structure.

FIGURE 5: Overall architecture of the audio recognition system.

classification target. At present, popular ensemble learning algorithms include stacking, bagging, boosting, ensemble selection, and so on. The ensemble learning algorithm selected in this study is the stacking method.

Stacking is a process of second-order learning with the output of the first-order learning process as input, also known as “meta-learning.” The stacking method has become a popular ensemble learning method, not only because its implementation is quite simple but also because it can significantly improve the generalization ability of the system, which is very consistent with the purpose of this study. The basic principle of the stacking method is shown in Figure 6.

6. Experiment and Result Analysis

6.1. Experimental Environment and Dataset. The hardware platform of this study is Intel Core i3-M350 CPU@ Dual-core 2.20 GHz, 8 GB of DDR2 memory, Nvidia RTX2080Ti GPU, and 11 GB of video memory. The PyCharm integrated

development tool is developed in Python 3.5.0 language. The YOLO annotation framework written in Python is used to convert the numerical format, so that it can be read by YOLO. The comparison methods are the Gaussian mixture model (GMM), CNN, and R-CNN.

The experimental dataset is recorded audio files in the real teaching environment. The dataset consists of audio types of four different labels (D1, D2, D3, and D4). All audio files are cut into 30-second clips. There are 12 audio file formats including MPEG, MP3, and WMA. Each recording is performed at a different location, and the average recording duration is 3–5 minutes. The recording equipment includes two-channel Soundman OKM II Classic/studio A3 in-ear microphone and Roland Edirol R09 waveform recorder with 44.1 kHz sampling rate and 24 bit resolution.

The used dataset contains 1404 audio files, and the number of audio files of each type is 351. About 70% of the data is used for training the audio recognition model, and the remaining 30% is used for testing. The system settings are given in Table 1.

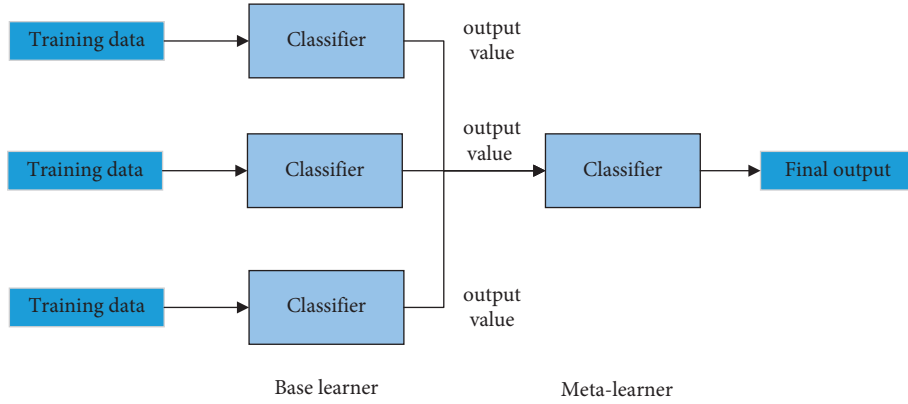

FIGURE 6: Basic principle of the stacking method.

TABLE 1: The system settings.

Settings	Parameter
Audio channel	Single channel
Audio type	MFCC
Audio window length	40 ms
Audio frame shift	20 ms
Feature vector	Static MFCC + first-order + second-order
Feature vector length	60

6.2. *Evaluation Criteria.* The mean accuracy (mAP) is calculated as follows:

$$\text{mAP} = \int_0^1 p(\tau) d\tau, \quad (6)$$

where $p(\tau)$ is the accuracy of audio classification.

Precision and recall are defined as follows:

$$\text{Pr} = \frac{\text{TP}}{\text{TP} + \text{FP}}, \quad (7)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}},$$

where TP is the positive alarm rate, FP is the false alarm rate, and FN is the missed alarm rate.

F1 score is the harmonic value of precision and recall rate. The higher the value, the better the performance. It is defined as follows:

$$\text{F1} = 2 \frac{\text{Recall} \times \text{Pr}}{\text{Recall} + \text{Pr}}. \quad (8)$$

6.3. *Verification of SPP-YOLO-v4 Performance.* In order to verify the promotion effect of the proposed improved YOLO-v4 (SPP-YOLO-v4) on generalization ability, it is compared with the traditional YOLO-v4 model. In the experiment, 3 of 12 audio file formats were selected: MPEG, MP3, and WMA. The generalization ability of SPP-YOLO-v4 is given in Table 2.

From Table 2, it can be found that the overall accuracy of SPP-YOLO-v4 is higher than that of traditional YOLO-v4, which verifies its generalization ability for data in different

TABLE 2: Generalization ability analysis of SPP-YOLO-v4.

Model	Audio file format	Accuracy				
		1	2	3	4	Average
YOLO-v4	MPEG	0.931	0.914	0.901	0.933	0.919
	MP3	0.889	0.961	0.894	0.880	0.906
	WMA	0.921	0.910	0.900	0.913	0.911
SPP-YOLO-v4	MPEG	0.951	0.969	0.961	0.959	0.956
	MP3	0.889	0.982	0.911	0.889	0.918
	WMA	0.937	0.989	0.919	0.938	0.945

audio formats. This is because compared with the original method, SPP of SPP-YOLO-v4 contains more layers, but it also increases the processing time.

6.4. *Comparison of Test Results.* Table 3 provides the results of training loss, mAP, and so on for all categories after 8000 rounds of training. It can be seen that the training model of the proposed method can effectively identify audio types. It has certain advantages in accuracy, recall rate, and F1 score, and its loss value is also the lowest of all methods, only 0.0122. Therefore, the stability and accuracy of the proposed method are better. This is mainly due to the high resolution and receptive field (RF) of SPP-YOLO-v4, and the addition of SPP module in the connection layer retains the advantages brought by SPP. In terms of training time, SPP-YOLO-v4 is only slightly more than GMM. The CNN needs to train a lot of convolution operations, so its training time is longer.

Finally, the experiment uses data of 12 different audio formats to test and compare the four methods. Table 4 provides the values of test accuracy and test time. It can be seen that the average accuracy of the method proposed in this study is 99.0%, and the average detection time is 0.449ss. Therefore, the proposed method achieves better performance among the four methods compared. It can be concluded that the upsampling and maximum pooling of SPP-YOLO-v4 brought significant benefits. Maximum pooling selects the maximum value from adjacent areas to slightly delete some maximum frequency noise in the audio sequence. Therefore, convolution subsampling can be better operated in the subsequent sampling layer. Through these advantages, SPP can improve the performance of the backbone network.

7. Conclusions

This study presents an audio recognition system suitable for music teaching environment. Use SPP to improve YOLO-v4 network architecture, that is to say, use SPP to select local areas on different scales of the same convolution layer to learn the characteristics of the multiscale system. In addition, the stacking method in ensemble learning is used to fuse independent submodels of two different channels. The experimental results show that the proposed method can improve the recognition accuracy of audio types and has better performance for different audio file formats. Due to the limitation of audio recording conditions, there are few audio types in the experimental dataset and the classification performance of audio files recorded by different devices has yet to be verified. More tests will be conducted on these two issues in the future.

In cloud and edge computing, senders of data often want to be anonymous, while recipients of data always expect that the data come from a reliable sender and they are not redundant. Linkable ring signature (LRS) can not only protect the anonymity of the signer, but also detect whether two different signatures are signed by the same signer. Today, most lattice-based LRS schemes only satisfy computational anonymity. To the best of our knowledge, only the lattice-based LRS scheme proposed by Torres et al. can achieve unconditional anonymity. But the efficiency of signature generation and verification of the scheme is very low, and the signature length is also relatively long. With the preimage sampling, trapdoor generation, and rejection sampling algorithms, this study proposed an efficient LRS scheme with unconditional anonymity based on the e-NTRU problem under the random oracle model. We implemented our scheme and Torres et al.'s scheme, as well as other four efficient lattice-based LRS schemes. It is shown that under the same security level, compared with Torres et al.'s scheme, the signature generation time, signature verification time, and signature size of our scheme are reduced by about 94.52%, 97.18%, and 58.03%, respectively.

1. Introduction

In most scenarios involving data transmission, including blockchain, cloud computing, edge computing, etc., the sender of data usually wants to be anonymous, while the receiver of data always expects the data to be reliable. Ring signature (RS) proposed by Rivest et al. [1] is a good technology that can meet the above requirements. RS has two essential security properties: (1) unforgeability, which requires the verifier is able to verify whether the signature was signed by a reliable signer; and (2) anonymity, which requires the verifier could not identify the real signer from a group of users. Similar to group signature [2, 3], RS is group-oriented. However, different from group signature, in RS, the group is formed spontaneously, that is, there is no special manager, and the setup and revocation procedures are not required. Any user can select a group of ring members and sign any message with his own private key and the public keys of other members without their consent. And the verifier only can verify whether the signature comes from a member in the ring without knowing which member the signer is.

Due to the anonymity of RS, it is widely used in anonymous tip off, e-cash [4], and other fields. It is worth noting that while protecting the anonymity of signers, RS also brings a new problem, that is, the same signer can sign multiple times without being detected.

In 2004, Liu et al. [5] introduced an extended property called linkability to RS, and the corresponding primitive is now known as linkable ring signatures (LRS). LRS not only satisfies the properties of ordinary RS (such as correctness, unforgeability, and anonymity) but also can be used to judge whether two different signatures are signed by the same signer (linkability). LRS is useful in situations where anonymity and nonrepeatability are required. For example, in the system of blockchain [6], if some user signs the same amount of money twice, LRS will help the verifier detect it and the verifier will deny the second signature, thus avoiding the so-called “double spending” problem. In smart grid systems [7], the electricity consumption data of users are automatically collected by the smart meter, and specific electricity consumption information is fed back to the service provider. Thus, malicious attackers can infer the life and rest rules of the user from the large amount of electricity

consumption data recorded by the smart meter. LRS can not only conceal the specific information of the meter user but also eliminate the redundant data of the same meter and provide the system with abnormal user monitoring and tracking functions.

In 2013, Liu et al. [8] constructed an unconditional anonymous linkable ring signature (UALRS) scheme, which addressed the open problem that RS could not have linkability and strong anonymity simultaneously and made it more secure. RS schemes have two types of anonymity: computational anonymity and unconditional anonymity. Computational anonymity refers to the protection of anonymity under certain number theory problems. The anonymity of RS is destroyed if this potential problem can be solved by an adversary. By contrast, unconditional anonymity means that the probability that any adversary with unlimited computing power and time knows the actual signer of a given RS is no better than random guessing. In other words, assuming that there are l users in RS, the probability of any adversary with unlimited computing power and time correctly indicating the public key of the actual signer is no more than $1/l$.

It is not difficult to design a RS scheme with unconditional anonymity. In fact, most traditional RS schemes can satisfy unconditional anonymity [1, 9–16]. However, it is not an easy work to construct a UALRS scheme. The difficulty lies in the following two aspects. First, in a computational anonymous linkable ring signature (CALRS) scheme, the linking tag can always be designed as a pseudorandom function about the private key of the signer based on some mathematical problem. But unconditional anonymity means that the adversary has unlimited computing power, that is it can calculate out the solution of any NP-hard problem, such as NTRU-SIS, large integer factorization, discrete logarithm, and the preimage of a given hash value. Therefore, only designing the linking tag using mathematical problems is not enough, and it should consider more skills. Second, in order to achieve unconditional anonymity, the generation and verification of a linking tag are often more complex, which may increase the length of public and private keys and signatures, as well as reduce the computational efficiency of the scheme. In fact, from 2004 to 2013, only the LRS scheme proposed by Liu et al. [8] can achieve unconditional anonymity.

The above schemes are all constructed based on classical number theory problems, that is, discrete logarithm and the decomposition of large integer problems. With the development of quantum computers, cryptosystems under classical number theory problems are faced with severe challenges. Shor [17] constructed a quantum algorithm in 1994 to solve the problem of large integer factorization in polynomial time under quantum computing conditions, and this algorithm made most existing public key cryptosystems no longer secure under quantum attacks.

In this case, post-quantum cryptography began to be studied by scholars in the field of cryptography. In the alternatives, lattice-based cryptography appeals to scholars because of its high efficiency, simplicity, high parallelizability, and strong provable security guarantees. In 2016,

Libert et al. [18] constructed a lattice-based RS scheme based on zero-knowledge proofs and accumulators. Thereafter, other lattice-based RS schemes have been proposed [19–21]. In 2017, Yang et al. [22] proposed a lattice-based LRS scheme based on weak pseudorandom functions, accumulators, and zero-knowledge proofs. In 2018, Baum et al. [23] proposed the lattice-based one-time LRS scheme based on the module-SIS problem (a variant of SIS problem) and module-LWE problem (a variant of LWE problem). In the same year, Alberto Torres et al. [24] proposed a lattice-based one-time LRS scheme based on the ring-SIS problem. Subsequently, Zhang et al. [25] proposed a LRS scheme over ideal lattice based on the homomorphic commitment scheme and Σ protocol. In 2019, Liu et al. [26] proposed a lattice-based LRS scheme supporting stealth addresses under the module-SIS and module-LWE problems. In 2020, Beullens et al. [27] constructed a LRS scheme whose signature size scales logarithmically with the ring size from isogeny and lattice assumptions.

However, in the above lattice-based LRS schemes, only Alberto Torres et al.'s scheme [24] satisfies unconditional anonymity. By analyzing Torres et al.'s scheme, it is found that in order to achieve unconditional anonymity, the linking tag of Torres et al.'s scheme is generated using an m -dimensional polynomial vector over a polynomial ring. Since the linking tag is so large, Torres et al.'s scheme generates signatures m times longer than a normal CALRS scheme over a polynomial ring, and its efficiency in generating and verifying signatures is also significantly reduced.

Hoffstein et al. [28] proposed the NTRU lattice-based cryptosystem in 1996. Considering that it only involves multiplication on polynomial rings and small integer modulo operations, the NTRU-based cryptosystem usually requires smaller public and private keys and is more efficient compared with that on the general lattice. Therefore, it has received extensive attention from scholars. In 2016, Zhang et al. [29] proposed an efficient RS scheme on NTRU lattice whose security can be reduced to the e-NTRU problem (a variant of the SIS problem on NTRU lattice) in the random oracle model. In 2019, Lu et al. [30] constructed Raptor, a practical NTRU lattice-based LRS scheme based on a variant of chameleon hash functions. In 2021, Tang et al. [31] constructed an identity-based LRS scheme over NTRU lattice by employing the technologies of trapdoor generation and rejection sampling. The security of this scheme relies on the small integer solution (SIS) problem on NTRU lattice.

1.1. Our Contribution. To reduce the signature size, as well as promote the efficiency of signature generation and verification of lattice-based UALRS scheme [24], in this study, a LRS scheme is reconstructed on NTRU lattice, and its architecture is shown in Figure 1. The main contributions of this article are as follows:

- (1) In the key generation stage, the public and private keys of the LRS scheme are generated by the trapdoor and the preimage sampling algorithms on NTRU lattice. Then, the linking tag is produced by the public and private keys of the signer, and a LRS

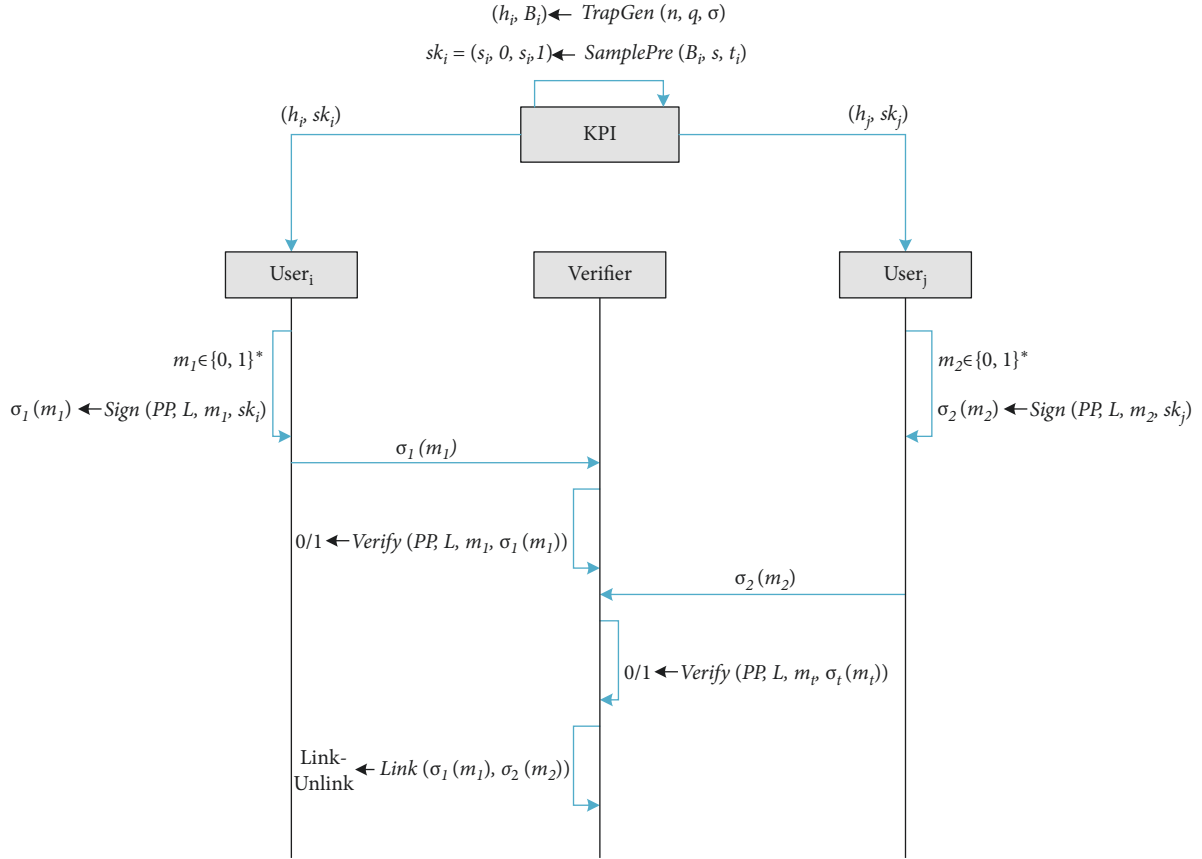

FIGURE 1: Linkable ring signature on NTRU lattice.

is generated based on the signature algorithm of Zhang et al. [29] combined with the rejection sampling algorithm.

- (2) In terms of security analysis, strict security proof is conducted based on the security model of UALRS proposed by Liu et al. [8]. The result of the proof shows that the unforgeability and linkability of the proposed scheme can be reduced to the difficulty of e-NTRU problem under the random oracle model, and, meanwhile, the proposed scheme satisfies unconditional anonymity.
- (3) In terms of performance analysis, the proposed scheme is compared with the latest and efficient lattice-based LRS schemes in [23, 24, 26, 27, 30], and a detailed analysis is given. The possible parameter settings of the proposed scheme are also analyzed and provided under the premise of ensuring the security of the proposed scheme.
- (4) We implement our scheme and Torres et al.'s scheme [24], as well as other four efficient lattice-based LRS schemes [23, 26, 27, 30], and it is shown that under the same security level, the signature generation and verification time of the proposed scheme are respectively reduced by 56.61% and 65.18%. Especially compared with Torres et al.'s scheme, the signature generation and verification time of the proposed scheme are respectively reduced by 94.52% and

97.18%, and the signature size of the proposed scheme is reduced by 58.03% on average.

1.2. Paper Organization. In Section 2, we introduce some definitions, lemmas, difficult problems, and related algorithms which we will use to construct the scheme. We introduce the definition of LRS and the relevant security model in Section 3. Section 4 contains the construction and correctness statement of the LRS scheme and the proof of correctness. Section 5 contains the security statements of the proposed scheme and the proofs of unforgeability, unconditional anonymity, and linkability. In Section 6, we discuss the parameter settings and post-quantum security of the proposed scheme. Finally, in Section 7 and Section 8, we respectively give the performance analysis and experimental results of the proposed scheme and the lattice-based LRS schemes of [23, 24, 26, 27, 30] and also make a comparison between them.

2. Preliminaries

2.1. Symbol Definition. Descriptions of the used notations are listed in Table 1.

2.2. Related Definitions of NTRU Lattice

Definition 1 (lattice). Lattice Λ generated by m linearly independent vectors $\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_m \in \mathbb{R}^n$ is the set of linear

TABLE 1: Symbol description.

Notations	Explanation
\mathbb{R}	Set of real numbers
\mathbb{Z}	Set of integers
\mathbb{Z}_q	Set of integers modulo q
\mathbb{Z}^m	Set of m -dimensional column vectors over \mathbb{Z}
$\mathbb{Z}_q^{n \times m}$	Set of matrices of n rows and m columns over \mathbb{Z}_q
R	Polynomial ring $\mathbb{Z}[x]/(x^n + 1)$
R_q	Polynomial ring $\mathbb{Z}_q[x]/(x^n + 1)$
\mathbf{A}	Matrix
\mathbf{x}	Vector
$\mathbf{x} \leftarrow D$	Randomly choosing vector \mathbf{x} from probability distribution D
$\ \mathbf{x}\ $	Euclidean norm of vector \mathbf{x}
$f \cdot g$	Multiplication of polynomials
$negl(n)$	Negligible function about n
$g(n) = \omega(f(n))$	$g(n) > f(n)$

combinations of all integer coefficients of the m linearly independent vectors, namely

$$\Lambda = L(\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_m) = \left\{ \sum_{i=1}^m a_i \mathbf{b}_i \mid a_i \in \mathbb{Z} \right\}, \quad (1)$$

where m and n are the rank and dimension of lattice Λ , respectively, and $\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_m$ is called a basis of lattice Λ .

Definition 2 (convolutional polynomial ring). Let $R = \mathbb{Z}[x]/(x^n + 1)$ be an ordinary polynomial ring. If the addition operation remains unchanged and the multiplication operation is replaced by a convolution operation on R , then R is called a convolution polynomial ring. Similarly, given a prime number q , the modulus convolution polynomial ring is $R_q = R/qR$.

Let $f = \sum_{i=0}^{n-1} f_i x^i, g = \sum_{i=0}^{n-1} g_i x^i \in R_q$, then the two operations on R_q are defined as follows:

(i) Addition operation $+$:

$$f + g = \sum_{i=0}^{n-1} (f_i + g_i) x^i \bmod q \in R_q. \quad (2)$$

(ii) Convolution operation $*$:

$$f * g = f \cdot g \bmod (x^n + 1) \bmod q \in R_q. \quad (3)$$

Definition 3 (anticirculant matrix). Let the coefficient vector of polynomial f be $(f_0, f_1, \dots, f_{n-1})$. Then, the coefficient vector of polynomial $x \cdot f$ is $(-f_{n-1}, f_0, \dots, f_{n-2})$ and the coefficient vector of polynomial $x^{n-1} \cdot f$ is $(-f_1, -f_2, \dots, f_0)$. The anti-circulant matrix defined by polynomial f is as follows:

$$\mathbf{A}_n(f) = \begin{bmatrix} f_0 & f_1 & \cdots & f_{n-1} \\ -f_{n-1} & f_0 & \cdots & f_{n-2} \\ \vdots & \vdots & \cdots & \vdots \\ -f_1 & -f_2 & \cdots & f_0 \end{bmatrix} = \begin{bmatrix} f \\ x \cdot f \\ \vdots \\ x^{n-1} \cdot f \end{bmatrix}. \quad (4)$$

Definition 4. (NTRU lattice). Let a positive integer $q \geq 2$, n is a power of two and $f, g \in R_q, f^{-1} \in R_q$ be the inverse of $f, h = g * f^{-1} \bmod q$. The NTRU lattice corresponding to q and h is as follows:

$$\Lambda_{q,h} = \{(u, v) \in \mathbb{R}^2 \mid u + v * h = 0 \bmod q\}. \quad (5)$$

Apparently, lattice $\Lambda_{q,h}$ is a $2n$ -dimensional full-rank lattice, and $\mathbf{A}_{q,h} = \begin{pmatrix} -\mathbf{A}_n(h) & \mathbf{I}_n \\ q\mathbf{I}_n & \mathbf{O}_n \end{pmatrix} \in \mathbb{Z}_q^{2n \times 2n}$ is a set of basis matrices. $\mathbf{A}_{q,h}$ can be uniquely determined by the polynomial $h \in R_q$, whereas the others can be compressed during storage. Thus, the storage space required is relatively small. However, in NTRU lattice-based cryptographic schemes, $\mathbf{A}_{q,h}$ cannot be used as a trapdoor basis because it has poor orthogonality.

Definition 5. (discrete gaussian distribution) [32]. For any $\sigma > 0$ and m -dimensional integer lattice Λ , the discrete Gaussian distribution on integer lattice Λ with vector $\mathbf{c} \in \mathbb{R}^m$ as the center and σ as the parameter is defined as follows:

$$\forall \mathbf{x} \in \Lambda, D_{\Lambda, \mathbf{c}, \sigma}^m(\mathbf{x}) = \frac{\rho_{\mathbf{c}, \sigma}^m(\mathbf{x})}{\rho_{\mathbf{c}, \sigma}^m(\Lambda)}, \quad (6)$$

where $\rho_{\mathbf{c}, \sigma}^m(\mathbf{x}) = \exp(-\pi \|\mathbf{x} - \mathbf{c}\|^2 / \sigma^2)$. When $\mathbf{c} = 0$, let ρ_{σ}^m and $D_{\Lambda, \sigma}^m$ be abbreviated as ρ_{σ}^m and $D_{\Lambda, \sigma}^m$, respectively. And throughout the article, $D_{\mathbf{c}, \sigma}^m$ denotes the discrete Gaussian distribution over \mathbb{Z}^m .

2.3. Hardness Assumption

Definition 6 (NTRU small-integer solution, NTRU-SIS) [33]. For a polynomial $h = g * f^{-1} \bmod q \in R_q$ and a real number $\beta > 0$, to find two nonzero polynomials $(u, v) \in R_q^2$ such that $u + v * h = 0 \bmod q$ and $\|u\|, \|v\| \leq \beta$.

Definition 7 (extended NTRU, e-NTRU) [29]. Given N polynomials $h_i = g_i * f_i^{-1} \bmod q \in R_q, i \in \{1, \dots, N\}$, where $N \ll q$, to find a tuple of short polynomials $(u_i, v_i) \in R_q^2, u_i, v_i \neq 0 \bmod q, i \in \{1, \dots, N\}$ such that

$$\sum_{i=1}^N (u_i + v_i * h_i) = 0 \bmod q, \|u_i\|, \|v_i\| \leq \beta, i \in \{1, \dots, N\}. \quad (7)$$

Theorem 1 (see [29]). *Let integer $k > 0, n = 2^k, q = 1 \bmod 2n$ and integer $N \ll q$, then the e-NTRU problem is polynomially equivalent to the NTRU-SIS problem.*

2.4. Related Algorithm

Lemma 1 (see [34]). *Let an integer $n = 2^k$ for $k > 0$, a prime number $q = 1 \bmod 2n$, and a parameter $\sigma = 1.17\sqrt{q/2n}$. Then, a probabilistic polynomial time (PPT) algorithm TrapGen(n, q, σ) can output a sample matrix $\mathbf{B}_{f,g} \in \mathbb{Z}_q^{2n \times 2n}$ from (a distribution close to) $D_{h, \sigma}^{2n \times 2n}$ and a polynomial $h = g * f^{-1} \bmod q \in R_q$ on the NTRU lattice $\Lambda_{h,q}$.*

Lemma 2 (see [34]). *Given a matrix $\mathbf{B}_{f,g}$ and a parameter $s = 0.585/\pi\sqrt{q} \ln(2 + 2/\eta)$ for $\eta = 2^{-\lambda}/2n$, where λ is the security parameter. For any polynomial $t \in R_q$, a PPT algorithm $\text{SamplePre}(\mathbf{B}_{f,g}, s, t)$ may output $\mathbf{z} = (z_1, z_2) \leftarrow D_{h^{\dagger+c,s}}$, such that $z_1 + z_2 * h = t$, $\|\mathbf{z}\| \leq s\sqrt{2n}$.*

Definition 8 (rejection sampling algorithm) [35]. In 2012, Lyubashevsky proposed rejection sampling technique for the first time and gave the first signature scheme without trapdoor on lattice with this technique. It can be applied to the signature system and can make the distributions of the signature and private key independent of each other. Thus, it can effectively prevent the leakage of the private key.

Lemma 3. *Let $V = \{\mathbf{v} \in \mathbb{Z}^m : \|\mathbf{v}\| < t\}$, $\sigma = \omega(t\sqrt{\log m})$, and $h: V \rightarrow \mathbb{R}$ is a probability distribution. Then, for constant $M = O(1)$, the statistical distance of output distributions of Algorithms 1 and 2 is less than $2^{-\omega(\log m)}/M$.*

Algorithm 1. $v \leftarrow h$, $\mathbf{z} \leftarrow D_{\mathbf{v},\sigma}^m$, output (\mathbf{z}, v) with probability $\min(D_{\sigma}^m(\mathbf{z})/MD_{\mathbf{v},\sigma}^m(\mathbf{z}), 1)$.

Algorithm 2. $v \leftarrow h$, $\mathbf{z} \leftarrow D_{\sigma}^m$, output (\mathbf{z}, v) with probability $1/M$.

Furthermore, the output probability of Algorithm 1 is at least $1 - 2^{-\omega(\log m)}/M$.

3. Security Model

In this section, we present our security model and define related security concepts.

3.1. LRS Definition. A LRS scheme consists of the following five PPT algorithms:

- (1) **Setup**(1^λ): On input a security parameter λ , it outputs system public parameters PP .

- (2) **KeyGen**(PP): On input the public parameters PP , it outputs a public/private key pair (pk_i, sk_i) . We denote by SK and PK the domains of possible private and public keys, respectively.
- (3) **Sign**(PP, L, m, sk_k): On input the public parameters PP , a public key list L , a message $m \in \{0, 1\}^*$, and private key sk_k , it outputs a signature $\sigma(m)$, which contains a linking tag I .
- (4) **Verify**($PP, L, m, \sigma(m)$): On input the system public parameters PP , a public key list L , a message $m \in \{0, 1\}^*$, and a signature $\sigma(m)$, if $\sigma(m)$ is valid, it outputs “1”; otherwise, it outputs “0.”
- (5) **Link**($\sigma(m_1), \sigma(m_2)$): On input two signatures $\sigma_1(m_1), \sigma_2(m_2)$, where $\sigma_1(m_1)$ and $\sigma_2(m_2)$ are the signatures of different messages m_1 and m_2 under the same ring, which contain linking tags I_1 and I_2 , respectively. It checks whether $I_1 = I_2$ and outputs “Link” if $I_1 = I_2$; otherwise, it outputs “Unlink.” “Link” means that the two signatures are generated by the same signer, and “Unlink” means that the two signatures are generated by different signers.

Definition 9 (correctness). Correctness for LRS contains verification correctness and linking correctness simultaneously.

- (i) **Verification Correctness:** For a valid signature $\sigma(m)$, the probability of the algorithm $\text{Verify}(PP, L, m, \sigma(m))$ outputting “0” is negligible.
- (ii) **Linking Correctness:** For two valid signatures $\sigma_1(m_1), \sigma_2(m_2)$ generated by using the same private key, the probability of the algorithm $\text{Link}(\sigma(m_1), \sigma(m_2))$ outputting “Unlink” is negligible. The formal definition of the correctness of the LRS scheme is shown in the following expressions:

$$\Pr \left[\begin{array}{l} \text{“0”} \leftarrow \text{Verify}(PP, L, m, \sigma(m)) \\ (pk, sk) \leftarrow \text{KeyGen}(PP) \\ \sigma(m) \leftarrow \text{Sign}(PP, L, m, sk) \end{array} \right] \leq \text{negl}(\lambda). \quad (8)$$

$$\Pr \left[\begin{array}{l} \text{“Unlink”} \leftarrow \text{Link}(\sigma(m_1), \sigma(m_2)) \\ (pk, sk) \leftarrow \text{KeyGen}(PP) \\ \sigma(m_1) \leftarrow \text{Sign}(PP, L_1, m_1, sk) \\ \sigma(m_2) \leftarrow \text{Sign}(PP, L_2, m_2, sk) \end{array} \right] \leq \text{negl}(\lambda). \quad (9)$$

3.2. Security Model. Generally, a LRS scheme should satisfy three security properties, namely unforgeability, anonymity, and linkability. According to the security model of UALRS proposed by Liu et al. [8] in 2013, this study uses a series of games between an adversary A and a challenger S to describe the security model of LRS. Supposing there are l

members in the ring, these three properties are described as follows:

Before defining unforgeability, anonymity, and linkability, we consider the following oracles, which together simulate the adversary’s ability to break the security of the scheme.

JO (Joining Oracle): A inputs member index k , and S outputs the corresponding public key $pk_k \in PK$ to A

CO (Corruption Oracle): A inputs a public key $pk_k \in PK$, which is a query output of *JO*, and S returns the corresponding private key $sk_k \in SK$

SO (Signing Oracle): A inputs a public key list $L = \{pk_i\}_{1 \leq i \leq l} \in PK$, and a message $m \in \{0, 1\}^*$, and S returns a valid signature $\sigma(m)$

In addition, in the random oracle model, a random oracle model *HO* is provided for users to query.

3.2.1. Unforgeability. It means that users outside the ring cannot successfully forge a legal signature under the ring. That is, if there is no private key of a member in the ring, even if the adversary obtains multiple valid message signature pairs, the probability of the adversary forging a valid signature successfully is negligible. Unforgeability for the LRS scheme is defined by the following game between an adversary A and a challenger S , in which A is given access to oracles *JO*, *CO*, *SO*, and *HO*:

- (i) The system public parameters PP are generated by challenger S and given to A
- (ii) A can access the oracles adaptively
- (iii) A gives S a list $L = \{pk_i\}_{1 \leq i \leq l}$ of public keys, a message $m \in \{0, 1\}^*$, and a signature $\sigma(m)$

A wins the game if

- (i) $\text{Verify}(PP, L, m, \sigma(m)) = "1"$
- (ii) All public keys in L are obtained by querying *JO*
- (iii) Any public key in L has not been input to *CO*
- (iv) $\sigma(m)$ is not obtained by querying *SO*

We express it as

$$\text{Adv}_A^{\text{Unf}} = \Pr[A \text{ wins the game}]. \quad (10)$$

Definition 10 (unforgeability). If the advantage $\text{Adv}_A^{\text{Unf}}$ of any PPT adversary A to win the unforgeability game is negligible, then the LRS scheme is unforgeable.

3.2.2. Unconditional Anonymity. It means that given a ring signature, no one can guess the real signer. In other words, given the public keys of all the members of the ring, it is impossible for anyone to tell the public key of the actual signer with a probability larger than $1/l$, where l denotes the cardinality of the ring, even the adversary has unlimited computing time and resources. The unconditional anonymity of LRS is described by the following game between an adversary A and a challenger S , where A is granted access to oracle *JO*:

- (i) The system public parameters PP are generated by challenger S and given to A ;
- (ii) A can access the oracle *JO* adaptively;

(iii) A gives S a public key list $L = \{pk_i\}_{1 \leq i \leq l}$, which are query outputs of *JO*, and a message $m^* \in \{0, 1\}^*$. S randomly samples $b \in \{1, \dots, l\}$, uses the signature key sk_b corresponding to pk_b to run algorithm $\text{Sign}(PP, L, m, sk_b)$, and generates and gives A the signature $\sigma(m^*)$; and

(iv) A returns the guess value $b' \in \{1, \dots, l\}$.

We express it as

$$\text{Adv}_A^{\text{Anon}} = |\Pr[b' = b] - 1/l|. \quad (11)$$

Definition 11 (unconditional anonymity). If the advantage $\text{Adv}_A^{\text{Anon}}$ of any unbounded adversary A to win the anonymity game is negligible, then the LRS scheme is called to be unconditional anonymous.

It is worth noting that though only *JO* is given to A , since A has unbounded computation power, it can calculate out the solution of any NP-hard problem, such as NTRU-SIS, large integer factorization, discrete logarithm, as well as the preimage of a given hash value. Therefore, unconditional anonymity in fact requires that in this case, A is still unable to reveal the public key of the actual signer of a RS with a probability higher than $1/l$.

3.2.3. Linkability. It means that two signatures generated by the same ring member can be linked. That is, an adversary who has less than two members' private keys in the ring cannot generate two valid signatures determined by the linking algorithm as "Unlink." The linkability of a LRS scheme is described by the following game between an adversary A and a challenger S , where A is granted access to oracles *JO*, *CO*, *SO*, and *HO*:

- (i) The system public parameters PP are generated by challenger S and given to A
- (ii) A can access the oracles adaptively
- (iii) A gives S two sets $L_1 = \{pk_i\}_{1 \leq i \leq l_1}$ and $L_2 = \{pk_i\}_{1 \leq i \leq l_2}$, messages $m_1, m_2 \in \{0, 1\}^*$, and signatures $\sigma(m_1)$ and $\sigma(m_2)$, where $\sigma(m_1)$ and $\sigma(m_2)$ contain the corresponding linking tags I_1, I_2 , respectively

A wins the game if

- (i) All public keys in $L_1 \cup L_2$ are query outputs of *JO*
- (ii) For $i = 1, 2$, $\text{Verify}(PP, L_i, m_i, \sigma(m_i)) = "1"$ such that $\sigma(m_i)$ is not an output of *SO*
- (iii) *CO* has been queried less than two times
- (iv) $\text{Link}(\sigma(m_1), \sigma(m_2)) = \text{"Unlink"}$

We express it as

$$\text{Adv}_A^{\text{Link}} = \Pr[A \text{ wins the game}]. \quad (12)$$

Definition 12 (linkability). If the advantage $\text{Adv}_A^{\text{Link}}$ of any PPT adversary A to win the linkability game is negligible, then the LRS scheme is linkable.

4. Scheme Construction

- (1) Setup($1^\lambda, 1^n$): On input the security parameter λ and integer $n = 2^k$, where $k > 0$, a ring of $l = \omega(\log n)$, a prime $q = 1 \bmod 2n$, two parameters $\sigma = 1.17\sqrt{q}/2n$ and $s = 0.585/\pi\sqrt{q \ln(2 + 2/\eta)}$, where $\eta = 2^{-\lambda}/2n$, choose a collision-resistant hash function $H: \{0, 1\}^* \rightarrow \{0, 1\}^n$, and output $PP = (q, \sigma, s, H)$.
- (2) KeyGen(PP): On input the system public parameters PP , the following steps should be performed:
 - (i) Run the trapdoor generation algorithm $\text{TrapGen}(n, q, \sigma)$ to generate $\{h_i \in R_q, \mathbf{B}_i \in \mathbb{Z}_{2n \times 2n}^q\}$;
 - (ii) Randomly choose $t_i \in R_q$, and let $sk_i = (s_{i,0}, s_{i,1}) = \text{SamplePre}(\mathbf{B}_i, s, t_i)$ such that $s_{i,0} + s_{i,1} * h_i = t_i$, $\|(s_{i,0}, s_{i,1})\| \leq s\sqrt{2n}$; and
 - (iii) Output a public key list $L = \{h_i\}_{1 \leq i \leq l}$ and the private key for the member i : $sk_i = (s_{i,0}, s_{i,1})$.
- (3) Sign(PP, L, m, sk_k): On input the system public parameters PP , the public key list $L = \{h_i\}_{1 \leq i \leq l}$, a message $m \in \{0, 1\}^*$, and a private key $sk_k = (s_{k,0}, s_{k,1})$, the member k performs the following steps:
 - (i) Compute linking tag
$$I = s_{k,0} + s_{k,1} * h_k. \quad (13)$$
 - (ii) For $1 \leq i \leq l$, sample random vectors $\mathbf{r}_{i,0}, \mathbf{r}_{i,1} \leftarrow D_s^n$.
 - (iii) Let
$$\mathbf{v} = H\left(\sum_{1 \leq i \leq l} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i), L, m, I\right). \quad (14)$$
 - (iv) If $i \neq k$, compute
$$\mathbf{z}_i = (\mathbf{z}_{i,0}, \mathbf{z}_{i,1}) = (\mathbf{r}_{i,0}, \mathbf{r}_{i,1}). \quad (15)$$

if $i = k$, compute

$$\mathbf{z}_k = (\mathbf{z}_{k,0}, \mathbf{z}_{k,1}) = (s_{k,0} * \mathbf{v} + \mathbf{r}_{k,0}, s_{k,1} * \mathbf{v} + \mathbf{r}_{k,1}). \quad (16)$$
 - (v) Continue with probability $\min(D_s^n(z_k) / MD_{s^*v,s}^n(z_k), 1)$, where $M = O(1)$; otherwise restart.
 - (vi) Output signature $\sigma(m) = (m, (\mathbf{z}_i)_{1 \leq i \leq l}, \mathbf{v}, I)$.
- (4) Verify($PP, L, m, \sigma(m)$): On input the system parameters PP , the public key list $L = \{h_i\}_{1 \leq i \leq l}$, a message $m \in \{0, 1\}^*$, and a signature $\sigma(m) = (m, (\mathbf{z}_i)_{1 \leq i \leq l}, \mathbf{v}, I)$, output “1” if and only if the following conditions are true; otherwise, output “0”:
 - (i) $\mathbf{v} = H\left(\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v}, L, m, I\right). \quad (17)$
 - (ii) For $1 \leq i \leq l$, $0 \leq \|\mathbf{z}_{i,0}, \mathbf{z}_{i,1}\| \leq s\sqrt{2n}. \quad (18)$
- (5) Link($\sigma(m_1), \sigma(m_2)$): On input two signatures $\sigma(m_1)$ and $\sigma(m_2)$, which contains linking tags I_1 and I_2 ,

respectively, the following steps should be performed:

Verify whether $I_1 \stackrel{?}{=} I_2$. If $I_1 = I_2$, then return “Link”; otherwise, return “Unlink.”

Theorem 2 (correctness). *The proposed LRS scheme satisfies correctness.*

Proof. Assuming $\sigma(m) = (m, (\mathbf{z}_i)_{1 \leq i \leq l}, \mathbf{v}, I)$ is a signature generated by a member of the ring according to the algorithms under public key set $L = \{h_i\}_{1 \leq i \leq l}$, then the following equation holds:

$$\begin{aligned} & \sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v} \\ &= \mathbf{z}_{k,0} + \mathbf{z}_{k,1} * h_k - I\mathbf{v} + \sum_{1 \leq i \leq l, i \neq k} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) \\ &= (s_{k,0} + s_{k,1} * h_k)\mathbf{v} + \mathbf{r}_{k,0} + \mathbf{r}_{k,1} * h_k - I\mathbf{v} \\ & \quad + \sum_{1 \leq i \leq l, i \neq k} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i). \end{aligned} \quad (19)$$

Given that $s_{k,0} + s_{k,1} * h_k = I$, we have

$$\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v} = \sum_{1 \leq i \leq l} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i). \quad (20)$$

Hence,

$$\mathbf{v} = H\left(\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v}, L, m, I\right). \quad (21)$$

By using the rejection sampling algorithm described in Definition 8, the distribution of $(\mathbf{z}_{i,0}, \mathbf{z}_{i,1})$ is close to $D_s^n(\mathbf{z}_i)$ for $1 \leq i \leq l$. Thus, by Lemma 3, we have $\mathbf{z}_i = (\mathbf{z}_{i,0}, \mathbf{z}_{i,1})$ satisfies $\|\mathbf{z}_i\| \leq s\sqrt{2n}$ with a probability at least $1 - 2^{-\omega(\log n)}$. Therefore, the proposed scheme satisfies verification correctness.

Assume member k calculates the linking tags of messages m_1 and m_2 as I_1 and I_2 , respectively. In the proposed scheme, $I_1 = s_{k,0} + s_{k,1} * h_k$ and $I_2 = s_{k,0} + s_{k,1} * h_k$ are generated by the signer’s public and private keys, and thus this scheme satisfies linking correctness. This completes the proof. \square

5. Security Analysis

Theorem 3 (unforgeability). *Under the random oracle model, when the e-NTRU problem is intractable, the proposed LRS scheme is unforgeable.*

Proof. Setup Phase: To solve the e-NTRU problem, S gets an instance $(h_i)_{1 \leq i \leq l}$

Query Phase: Adversary A is allowed to access oracles JO , CO , SO , and HO , and S responds as follows:

- (i) H : A inputs $((\mathbf{r}_{i,0}, \mathbf{r}_{i,1})_{1 \leq i \leq l}, L, m, I, k)$, S first checks whether there is the relevant record in the list $list_H$. If so, then the same query result is returned to A . Otherwise, S randomly picks and gives A an integer

\mathbf{v} , and adds the tuple $((\mathbf{r}_{i,0}, \mathbf{r}_{i,1})_{1 \leq i \leq l}, L, m, I, \mathbf{v}, k)$ to the list $list_H$.

- (ii) *JO*: Suppose A can only access the oracle JOI' times at most, where $l' \geq l$. S selects a subset X_l with l random indexes. S assigns $(h_i)_{1 \leq i \leq l}$ to these l indexes as their public keys, respectively. Moreover, for these l indexes, S does not know the corresponding private keys. We use $l+1, \dots, l'$ to denote other indexes. With regard to other $l' - l$ indexes, S obtains the public and private keys according to the algorithm $KeyGen(PP)$. A inputs index j to query, and S outputs the corresponding public key.
- (iii) *CO*: A inputs a public key $pk_i = h_i$, S checks whether i belongs to X_l . If so, then S stops; otherwise, S outputs the corresponding private key.
- (iv) *SO*: A inputs a ring public key set $L = \{h_i\}_{1 \leq i \leq l}$ a public key h_k , where $k \in \{1, \dots, l\}$, and a message $m \in \{0, 1\}^*$. S performs as follows:

- (1) If h_k does not correspond to any element in the subset X_l , then S knows its private key and generates the signature according to the signature algorithm $Sign(PP, L, m, sk_k)$. Otherwise, we assume that h_k is obtained by JO .
- (2) S checks the list $list_H$ to find the record $((\mathbf{r}_{i,0}, \mathbf{r}_{i,1})_{1 \leq i \leq l}, L, m, I, \mathbf{v}, k)$ corresponding to the index k . Then, S randomly chooses $\mathbf{z}_{i,0}, \mathbf{z}_{i,1} \leftarrow D_s^n$ and sets the output of $H(\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v}, L, m, I)$ to \mathbf{v} .
- (3) S returns a signature $\sigma(m) = (m, (\mathbf{z}_i)_{1 \leq i \leq l}, \mathbf{v}, I)$ with probability $\min(D_s^n(z_k)/MD_{s_k * v, s}^n(z_k), 1)$, where $M = O(1)$.

Forgery Phase: After the simulation, A gives signature $\sigma(m^*) = (m^*, (\mathbf{z}_{i,0}^*, \mathbf{z}_{i,1}^*)_{1 \leq i \leq l}, \mathbf{v}^*, I^*)$ about $\{PP, m^*, L\}^*$ to S satisfying the following conditions:

- (i) $Verify(PP, L^*, m^*, \sigma(m^*)) = "1"$
- (ii) All of the public keys $pk_i = h_i$ in L^* are query outputs of JO
- (iii) A did not query *CO* about the public keys in L^*
- (iv) $\sigma(m^*)$ is not a query output of *SO*

Analysis. Assuming the signature $\sigma(m^*)$ is a valid signature, the following shows how S can solve the e-NTRU problem using the forged results of A . We will consider the following two situations:

- (i) If \mathbf{v}^* appears in the *SO*, and assume that $\sigma(m) = (m, (\mathbf{z}_{i,0}, \mathbf{z}_{i,1})_{1 \leq i \leq l}, \mathbf{v}, I)$ is a query output of *SO*. Given that the signature is valid, it satisfies

$$\mathbf{v}^* = H\left(\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v}^*, L, m, I\right). \quad (22)$$

Given that A successfully forged the signature, there is

$$\mathbf{v}^* = H\left(\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0}^* + \mathbf{z}_{i,1}^* * h_i) - I^* \mathbf{v}^*, L^*, m^*, I^*\right). \quad (23)$$

When the function H collides, S aborts (Abort I). Otherwise, from (22) and (23), there is

$$\begin{aligned} L^* &= L, m^* = m, I^* = I, \\ \sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} + \mathbf{z}_{i,1} * h_i) - I\mathbf{v}^* &= \sum_{1 \leq i \leq l} (\mathbf{z}_{i,0}^* + \mathbf{z}_{i,1}^* * h_i) - I^* \mathbf{v}^*. \end{aligned} \quad (24)$$

$$\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} - \mathbf{z}_{i,0}^*) + (\mathbf{z}_{i,1} - \mathbf{z}_{i,1}^*) * h_i = 0 \text{ mod } q. \quad (25)$$

Therefore, $[(\mathbf{z}_{i,0}^* - \mathbf{z}_{i,0}), (\mathbf{z}_{i,1}^* - \mathbf{z}_{i,1})]_{1 \leq i \leq l}$ is a solution to the e-NTRU problem.

- (ii) If \mathbf{v}^* appears in the H query and is stored as $((r_{i,0}, r_{i,1})_{1 \leq i \leq l}, L, m, I, \mathbf{v}^*, k)$ in $list_H$, then,

$$\mathbf{v}^* = H\left(\sum_{1 \leq i \leq l} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i), L, m, I\right). \quad (26)$$

When the function H collides, S aborts (Abort II). Otherwise, from (23) and (26), there is

$$\begin{aligned} L^* &= L, m^* = m, I^* = I, \\ \sum_{1 \leq i \leq l} (\mathbf{z}_{i,0}^* + \mathbf{z}_{i,1}^* * h_i) - I^* \mathbf{v}^* &= \sum_{1 \leq i \leq l} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i). \end{aligned} \quad (27)$$

S performs the following: when $i \neq k^*$, let $\mathbf{z}_{i,0} = \mathbf{r}_{i,0}$ and $\mathbf{z}_{i,1} = \mathbf{r}_{i,1}$; when $i = k^*$, let $\mathbf{z}_{k^*,0} = \mathbf{r}_{k^*,0} + \mathbf{v}^* I$ and $\mathbf{z}_{k^*,1} = \mathbf{r}_{k^*,1}$. Then, we have

$$\begin{aligned} \mathbf{v}^* &= H\left(\sum_{1 \leq i \leq l} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i), L, m, I\right) \\ &= H\left(\sum_{1 \leq i \leq l, i \neq k^*} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i) + \mathbf{z}_{k^*,0} \right. \\ &\quad \left. - \mathbf{v}^* I + \mathbf{z}_{k^*,1} * h_{k^*}, L, m, I\right) \\ &= H\left(\sum_{1 \leq i \leq l} (\mathbf{r}_{i,0} + \mathbf{r}_{i,1} * h_i) - \mathbf{v}^* I, L, m, I\right). \end{aligned} \quad (28)$$

Given (23), (27), and (28), we have

$$\sum_{1 \leq i \leq l} (\mathbf{z}_{i,0} - \mathbf{z}_{i,0}^*) + (\mathbf{z}_{i,1} - \mathbf{z}_{i,1}^*) * h_i = 0 \text{ mod } q. \quad (29)$$

Thus, the solution to the e-NTRU problem is $[(\mathbf{z}_{i,0}^* - \mathbf{z}_{i,0}), (\mathbf{z}_{i,1}^* - \mathbf{z}_{i,1})]_{1 \leq i \leq l}$.

Probability Analysis. The challenger S fails when Aborts I and II occur. The probability of H colliding is $1/2^n$. Assume A can successfully forge the signature with probability ξ ,

then the probability of S solving the e-NTRU problem is $\xi - 1/2^n \times 2 = \xi - 1/2^{n-1}$. This completes the proof. \square

Theorem 4 (unconditional anonymity). *The proposed scheme satisfies unconditional anonymity.*

Proof. The anonymity proof of the signature is completed by the following game between adversary A and challenger S . If the signature distributions of l different members in the ring are computationally indistinguishable to adversary A , then this scheme satisfies anonymity.

Query Phase: A is allowed to access JO , and S responds as follows:

JO: A inputs an index j to query. S runs the algorithm $\text{KeyGen}(PP)$ to generate the public key $pk_j = h_j$ and returns it to A .

Challenge Phase: A inputs a public key list $L = \{h_i\}_{1 \leq i \leq l}$ and a message $m^* \in \{0, 1\}^*$. S randomly chooses $b \in \{1, \dots, l\}$, then runs $\text{Sign}(PP, L, m^*, sk_b)$ to generate the signature $\sigma(m^*) = \text{Sign}(PP, L, m^*, sk_b)$ and gives it to A , where sk_b is the private key corresponding to index b .

Guess Phase: A gives a value $b' \in \{1, \dots, l\}$ as a guess for b .

Analysis. Suppose A is an adversary with unlimited computing power. Next, we will show the advantage $\text{Adv}_A^{\text{Anon}}$ of A in winning the anonymous game is negligible. We need to prove that the distributions of signatures generated with the private keys of different users are computationally indistinguishable.

First, even A is an adversary with unlimited computing power, from the JO query, or from the challenger signature (which contains a linkability tag), A still cannot deduce the private key, as well as the corresponding index. That is because the randomness of the algorithms TrapGen and SamplePre makes each public key h_b correspond to multiple pairs $(s_{b,0}, s_{b,1})$, and which one is the actual private key of member b cannot be determined. Moreover, given a linking tag $I = s_{b,0} + s_{b,1} * h_b$, to know which member generated the linking tag I , it is no better than random guessing for the adversary. In addition, it should be noticed that the signature $\sigma(m^*)$ is generated by using not only a private key $(s_{b,0}, s_{b,1})$ but also a set of random numbers. Lemma 3 guarantees that the distributions of $(z_{b,0}, z_{b,1})$ and $(z_{i,0}, z_{i,1})_{i \neq b}$ are indistinguishable, and the distribution of $(z_{b,0}, z_{b,1})$ is independent of $(s_{b,0}, s_{b,1})$. That is, in the view of the adversary, the signature $\sigma(m^*)$ is independent of the index b of the actual signer. Hence, we can conclude that even an unbounded adversary cannot guess the index b with a probability greater than $1/l$.

We can infer that when A is a normal adversary, that is, A has limited computing power and time, obviously it cannot destroy the anonymity of the scheme. This completes the proof. \square

Theorem 5 (linkability). *Under the random oracle model, if the proposed scheme is unforgeable, then for any PPT adversary A , the proposed scheme is linkable.*

Proof. We will show that if the proposed scheme satisfies unforgeability, then it will satisfy linkability. The linkability proof of the scheme is completed by the following game interaction between an adversary A and a challenger S .

- (i) S generates the system public parameters PP and public and private keys $(pk_i, sk_i)_{1 \leq i \leq l}$, and then sends PP to A
- (ii) A can access JO , CO , SO , and HO , and the process of accessing JO , CO , SO , and HO in the linkability game is the same as that in the unforgeability game
- (iii) Suppose A outputs two signatures $\sigma_1(m_1) = (m_1, (z_{i,0}, z_{i,1})_{1 \leq i \leq l}, v_1, I_1)$ and $\sigma_2(m_2) = (m_2, (z_{i,0}, z_{i,1})_{1 \leq i \leq l}, v_2, I_2)$ under public key set L , which satisfy the following conditions:
 - (1) All public keys in L are outputs of JO
 - (2) For $i = 1, 2$, $\text{Verify}(PP, L, m_i, \sigma_i(m_i)) = "1"$ such that $\sigma_i(m_i)$ is not an output of SO
 - (3) A accesses CO once at most

Analysis. Assume A can generate two signatures $\sigma_1(m_1)$ and $\sigma_2(m_2)$ with a nonnegligible probability η while holding only one private key sk_k , and $"1" \leftarrow \text{Verify}(PP, L, m_i, \sigma_i(m_i))$ for $i = 1, 2$. Given that the proposed LRS scheme is unforgeable, these two signatures can be validated by the Verify algorithm if and only if A honestly generates signatures $\sigma_1(m_1)$ and $\sigma_2(m_2)$ using his private key sk_k . In other words, we have $I_1 = s_{k,0} + s_{k,1} * h_k$ and $I_2 = s_{k,0} + s_{k,1} * h_k$. And since there is also only one public key corresponding to this private key, that is, $h_k = h'_k$, we have $I_1 = I_2$. This indicates that the algorithm $\text{Link}(\sigma_1(m_1), \sigma_2(m_2))$ returns "Link" when given two signatures $\sigma_1(m_1)$ and $\sigma_2(m_2)$. Hence, the advantage $\text{Adv}_A^{\text{link}}$ of A is negligible. This completes the proof. \square

6. Discussion

6.1. Parameter Selection. The security of the proposed scheme is based on the e-NTRU problem, which is reduced to the NTRU-SIS problem. The NTRU-SIS problem is to find two polynomials $(u, v) \in \mathbb{R}_q^2$ that satisfies $u + v * h = 0 \text{ mod } q$ and $\|u\|, \|v\| \leq \beta$ in the NTRU lattice, which is in turn reduced to γ -Ideal-SVP problem. Similar to [34, 36], we use the "root Hermite factor γ " which measures the hardness of γ -Ideal-SVP problems to select the parameters.

If we look for a polynomial v in an n -dimensional lattice, which is greater than the n -th root of the determinant, then the associated γ is

$$\frac{\|v\|}{\det(\Lambda)^{1/n}} = \gamma^n. \quad (30)$$

According to [37], if we look for a small-size polynomial v in the NTRU lattice, the associated γ is

$$\frac{\sqrt{n/(2\pi e)} \cdot \det(\Lambda)^{1/n}}{\|v\|} = 0.4\gamma^n. \quad (31)$$

From the results in [36, 38], if the value of γ is approximately 1.007, to find the polynomial is at least 80 bits

TABLE 2: Parameter settings.

Parameter	Recommended choice	
λ	80	192
γ	1.0069	1.0040
n	256	512

TABLE 3: Comparison of time costs and difficult assumption.

hard. If the value of γ is less than 1.004, to find the polynomial is at least 192 bits hard.

The methods to attack the proposed scheme are mainly to attack the ring member's public key and the signature.

The public key of the member i is a polynomial $h_i = g_i * f_i^{-1} \text{mod } q \in R_q$. The attack on h_i is to find two nonzero small-size polynomial $(u_i, v_i) \in R_q^2$ that satisfies $u_i + v_i * h_i = 0 \text{mod } q$. By Lemma 1 we know, $\|(u_i, v_i)\| \leq \sigma\sqrt{2n}$. So using (32) to calculate the value of γ , we have $\gamma = (\sqrt{n}/1.368)^{1/2n}$. When $n = 256$, $\gamma \approx 1.0048$, it is at least 80 bits hard to attack the ring member's public key, and when $n = 512$, $\gamma \approx 1.0027$, it is at least 192 bits hard to attack the ring member's public key.

The attack on the signature of the member i is to find a vector $(\mathbf{z}_{i,0}, \mathbf{z}_{i,1})$ passing the verification algorithm without member i 's private key. It can be seen from Lemma 3, $\|(\mathbf{z}_{i,0}, \mathbf{z}_{i,1})\| \leq s\sqrt{2n}$. Since $s = 0.585/\pi\sqrt{q} \ln(2+2/\eta)$, where $\eta = 2^{-\lambda}/2n$, there is $s = 1.4708\sqrt{q}$ for $n = 256$ and $s = 2.2089\sqrt{q}$ for $n = 512$. So, computing the value of γ by (28), we have

$$\frac{\sigma\sqrt{2n}}{\sqrt{q}} = \gamma^{2n} \implies \begin{cases} \gamma = (2.080\sqrt{n})^{1/2n}, & n = 256 \\ \gamma = (3.124\sqrt{n})^{1/2n} & n = 512 \end{cases}. \quad (32)$$

When $n = 256$, $\gamma \approx 1.0069$, to attack the ring member's signature is at least 80 bits hard, and when $n = 512$, $\gamma \approx 1.0041$, to attack the ring member's signature is at least 192 bits hard. The recommended choice of the parameters is shown in Table 2.

6.2. Post-Quantum Security. The proposed scheme is based on the hard assumption over lattice which is generally recognized to provide anti-quantum security. The security proof of the proposed scheme is unlikely to be extended to the Quantum Random Oracle Model [39] (QROM): in the security proof (Theorems 3 and 5), we use the adaptive programming of random oracle (RO) H , and this proof technique is inherent in the structure to some extent.

We note that other schemes built on QROM, such as [40, 41], also use the form of RO programming (even if not

TABLE 4: Comparison of communication costs.

adaptive). In addition, although Fiat–Shamir seems unlikely to be proved in QROM, to the best of our knowledge, there are no attacks on the protocols using these proof technologies, which stems from the use of RO.

7. Performance Analysis

In this section, the proposed LRS scheme is compared with the schemes [23, 24, 26, 27, 30] in terms of efficiency. We mainly compare these schemes in terms of elapsed time and storage space.

Comparison terms in Table 3 include signature generation cost, signature verification cost, unconditional anonymity, and difficult assumption. Comparison terms in Table 4 include public and private key, as well as signature size of each user. In Tables 3 and 4, n is the degree of polynomials, $q = 1 \text{mod } 2n$ is a large prime number, l represents the cardinality of the ring, and k and v are integers. The time cost for the discrete Gaussian sampling algorithm and the rejection sampling algorithm running once are represented by T_{SD} and T_{RS} , respectively. In general, $T_{SD} > T_{RS}$. The time cost for polynomial-polynomial multiplication is represented by T_{Mul} , and $T_{Mul} > T_{SD}$. The time overhead of hash, matrix-matrix addition, and polynomial-

polynomial addition is ignored because these operations take less time. We mainly focus on time-consuming operations, such as matrix-matrix multiplication and polynomial-polynomial multiplication.

In terms of signature generation cost, the proposed scheme mainly uses the Gaussian sampling algorithm $2l$ times, the polynomial-polynomial multiplication l times, and the rejection sampling algorithm once, respectively. Hence, the signature generation cost is $2nlT_{SD} + nlT_{Mul} + 2nT_{RS}$. In terms of signature verification cost, since the proposed scheme primarily runs polynomial-polynomial multiplication l times, the signature generation cost is about nlT_{Mul} . From Table 3, due to $T_{Mul} > T_{SD} > T_{RS}$, compared with the four schemes of [23, 24, 26, 30], the proposed scheme has higher signature generation and verification efficiency. The signature generation and verification time of the proposed scheme is linearly related to the number of ring members l , while that of the scheme of [27] has a logarithmic relationship with l . Therefore, when l is large, the signature generation and verification efficiency of the scheme of [27] is better than that of the proposed scheme. But when l is small, the proposed scheme is more efficient by the settings of relevant parameters. In addition, only Alberto Torres et al.'s scheme [24] and our scheme can achieve unconditional anonymity, while other four schemes only have computational anonymity. And the efficiency of signature generation and verification of our scheme is obviously higher than that of Torres et al.'s scheme.

In the proposed scheme, the public key of the member in the ring is a small polynomial $h_i \in R_q$ generated by the trapdoor generation algorithm TrapGen, and the private key corresponds to two small polynomials in R_q . Therefore, the public and private key lengths of the proposed scheme are $n \log q$ and $2n \log q$, respectively. As shown in Table 4, the public and private key lengths of [23, 24, 26, 27, 30] are $(kn \log q, n \log q)$, $(n \log q, kn \log q)$, $(3kn \log q, kn \log q)$, $(kvn \log q, vn \log q)$, and $(n \log q, 9n \log q)$, respectively. Hence, in terms of public key size, the public key size of the proposed scheme is similar to that of [24, 30] and smaller than that of [23, 26, 27]. With respect to private key size, the private key size of the proposed scheme is larger than that of [23] and they are both smaller than that of [24, 26, 27, 30]. For signature size, the signature size of the scheme [27] has a logarithmic relationship with l , while that of the other five schemes including the proposed scheme has a linear relationship with l . But the growth rate of signature size of

[23, 30] and the proposed scheme is obviously slower than that of [24, 26].

8. Implementation and Evaluation

We implemented and evaluated the proposed LRS scheme on a typical laptop configured with a Windows 8.1 system, an Intel(R) Core(TM) i5-4210U CPU@1.70 GHz processor, and a 4.00 GB running memory. We selected parameters to make the proposed scheme secure, and detailed parameter settings are given in Table 5. We ran the signature generation and verification algorithms for 1000 times. And at security level $\lambda = 80$, the average running time of these algorithms of the five schemes under different numbers of ring members is shown in Table 6. It can be seen from Table 6 that the signature generation and verification of [24] take the longest time among the six schemes, while the signature generation and verification time of the proposed scheme is shorter than that of [23, 24, 26, 30]. Compared with [27], when $l \leq 256$, the proposed scheme has higher signature efficiency, but when $l \geq 512$, the signature efficiency of the proposed scheme needs to be improved. On average, compared with the other five schemes, the signature generation and verification time of the proposed scheme is reduced by about 56.61% and 65.18%, respectively. Especially compared with [24], which also has unconditional anonymity as ours, the signature generation and verification time of the proposed scheme is reduced by about 94.52% and 97.18%, respectively.

At security level $\lambda = 80$, the comparison between the proposed scheme and the other five schemes on public/private key size and signature size under different numbers of ring members is shown in Table 7. As for the public key size, the public key size of the proposed scheme is equal to that of [24, 30] and smaller than that of [23, 26, 27]. With respect to private key size, the private key size of the proposed scheme is larger than that of [23] but is significantly smaller than that of [24, 26, 27, 30]. In the case of signature size, the signature size of the proposed scheme is larger than that of [23] but is significantly smaller than that of [24, 26, 30]. When $l \geq 64$, the signature size of the scheme in [27] is shorter than that of the proposed scheme. However, the scheme of [27] only has computational anonymity, while the proposed scheme has unconditional anonymity. Especially compared with [24], the signature size of the proposed scheme is reduced by 58.03% on average.

In addition, in the above experiment, we only completed the proof-of-concept work and did not consider potential

optimization algorithms, such as the polynomial-polynomial multiplication based on FFT.

9. Conclusions

Based on the e-NTRU problem, this study constructed a LRS scheme on NTRU lattice by combining preimage and rejection sampling techniques. Under the random oracle model, the security of our LRS scheme was analyzed in detail. The analysis results show that our scheme satisfies the requirements of correctness, unforgeability, and linkability based on the intractability of the e-NTRU problem in the random oracle model. In particular, our scheme can achieve unconditional anonymity. The efficiency of the proposed scheme was analyzed in detail, and the optional parameter settings of the proposed scheme that meet the security requirements are given. Finally, the proposed scheme and other five latest lattice-based LRS schemes are implemented, which shows that under the same security level, the proposed scheme has higher signature generation and verification efficiency as well as shorter signature size compared with other five LRS schemes.

The elderly group is a unique social phenomenon in China. This study analyzes the typology of psychological changes in the elderly group based on the analysis of deep learning techniques and also combines crisis intervention theory to study the intervention strategies of social workers in different stages of emotional changes in the elderly group. A questionnaire survey of the elderly was conducted using the survey method, in which 10,948 valid questionnaires were screened from the Psychological Condition Self-check Scale and 11,040 valid questionnaires were screened from the Mental Health Survey Questionnaire for the Elderly. The degree of negative emotions of the elderly group in public emergencies was not related to age, but significantly correlated with age (p value < 0.05), and there was a tendency that the higher the age, the deeper the degree; in addition, elderly people of different professions also showed significant differences ($p < 0.05$); elderly people of different regions also showed significant differences ($p < 0.05$). In crisis intervention, social workers mainly provide services such as initial diagnosis, primary intervention, secondary intervention, and assessment for the caseworkers. The practical study found that social workers need to use strategies such as short-term focal solutions, avoiding guiding clients with their own values; crisis intervention programmes should be flexible, proactively helping clients to rebuild their support network, developing clients' self-solving skills, and implementing inter-professional teamwork and whole-person rehabilitation services.

1. Introduction

As the first generation of only-child parents move into old age, more and more problems are emerging for the elderly parents of only children. According to some scholars, nearly 100 million only child have been born in China over the past 30 years [1]. Most of the young couples who responded strictly to the national family planning policy and had only one child are now in their middle and old age. If they lose their only child, they become China's new generation, the "lost generation" [2]. Although there are no official statistics on the number of older people, demographic survey data and reports show that the number of older people is increasing and cannot be ignored. As they are past their child-bearing years, many of them are

facing great trauma, with problems such as the breakdown of their family of origin and the inadequacy of the social security system causing them to suffer both physical and psychological blows, and they may face problems such as "no one to rely on, no one to turn to, no one to defend their rights, no one to interact with, no one to seek medical treatment for their illness, no one to support them in their old age, and no one to send them to their death" [3].

At present, both the government and civil society are still not paying enough attention to this group. Social workers can, to a certain extent, help this group to effectively integrate multiple resources, repair the broken social network, and rebuild social support, thus restoring and enhancing their ability to adapt to their environment [4].

There are three main perspectives in the study of older people in China. One is the study of the number and growth trend, which is a macrolevel study by scholars, but lacks consideration of the microlevel of the single-parent group [5]. The second is the perspective of family-planning policy risks, where scholars have mainly explored the interrelationship between family planning policies, but lacked research on practical services for different family risks [6]. Thirdly, from the perspective of research on protection mechanisms, academics have studied the issue of social assistance for older people at the external levels of material and spirituality, but not enough research has been conducted on crisis interventions for older people to cope with risks and their ability to live independently [7]. Crisis intervention aims to help older people deal with emotional crises that they cannot cope with, provide them with social resources to avoid further harm, and help them return to the good state they were in before the crisis, in the process promoting their growth and improving their ability to cope [8]. Overseas research on the problems associated with only children focuses on the education and psychological aspects of growing up as an only child and comparisons with non-only children, but little research has been conducted on the issue of “lost children.” In addition, children need to become self-reliant as adults and are thus removed from the parental relationship [9]. In response to the lack of research on practical interventions for older people, this study attempts to answer the following questions: what are the aspects of the emotional crisis of older people, what are the practical theoretical foundations of crisis intervention, how to apply crisis intervention theory in the process of serving older people, what are the strategies and techniques of crisis intervention, how to reflect on the practice of crisis intervention, and so on [10].

The elderly population is a special group that is easily affected during major public emergencies. The primary reason for this is that the elderly population is in a stage of rapid physical and mental development and change, with a high degree of instability; secondly, as the lifestyle of the elderly is inclined towards cerebral activities, their inner world has a relatively complex. Thirdly, as the lifestyle of older people is inclined towards mental activities, their inner world has a relatively complex nature [11]. As a result, the overall psychological needs of older people are high and may lead to psychological crises in times of social change, family conflicts, and setbacks in personal development [12]. As a result, the psychological crisis of the elderly population is the most important issue in the event of a major public emergency. The increasingly fierce competition in contemporary society and the gradually accelerating pace of life are bound to have an impact on the academic life of older people [13]. From a historical perspective, the great abundance of material conditions means that people will gradually face less stress in life and have less capacity to cope with unexpected events. There are numerous contemporary cases of psychological crises among the elderly due to various problems, and universities are paying more and more attention to mental health education for the elderly [14]. Therefore, it is of great importance to establish a perfect

psychological crisis intervention mechanism for the elderly, to cultivate a positive psychological concept among them, to provide them with correct mental health education, and to guide them to face possible psychological crises by using strong will qualities, appropriate achievement motivation, and correct attribution methods, both for maintaining the life safety of the elderly and for building a harmonious society [15].

2. Practical Theory of Emotional Crisis Intervention for the Elderly

2.1. Theoretical Foundations. Lindemann, one of the founders of crisis theory, began with his study of the grief reactions of refugees and families of those who died in the Boston fire of 1943 and divided crisis intervention into four stages [16]: disruption of equilibrium, short course therapy or grief intervention for the client, overcoming the crisis or coming out of discomfort, and regaining equilibrium (see Figure 1).

This theory suggests that the longer an older person is in a state of severe depression, especially in bereavement, the higher the risk of falling into excessive grief, leading to a loss of balance and a state of crisis. The social worker should help the client to get out of the emotional crisis as soon as possible by giving them adequate support and linking them to resources to restore their pre-crisis state of equilibrium [17].

The Kubler–Ross model, which describes the emotional reactions that people experience when facing their impending death, has since been widely applied to the study of grief following the loss of a loved one. Figure 2 shows the extended crisis theory model.

First is the period of denial. When people hear news of a terminal illness or death of themselves or a family member, they will first feel shocked and numb and psychologically deny the truth of the information they receive about the death. Second is the period of anger. After the shock and numbness have passed, the case worker becomes very angry, lashing out at those around him or her and blaming himself or herself or others for the death. Third is the bargaining period. During this period, the caseworker enters a period of self-deception, hoping for another chance to make up for what was not accomplished in the past. The caseworker will bargain with God for a series of things in exchange for or to prolong life. Fourth is the depression phase. During this phase, the caseworker has two depressive tendencies, reactive depression, which is an ineradicable emotional reaction, and preparatory depression, which is an internal emotional preparation to give up on everything. Fifth is the period of acceptance. After going through the whole grief journey, the caseworker begins to accept the status quo and shows a state of calmness, but this phase is the most melancholic period.

As with bereavement in general, older people who have lost someone go through this series of emotional changes, but not everyone will go through every stage, some will skip certain stages and some will stay at a certain stage. Older people who have lost someone may take longer to move

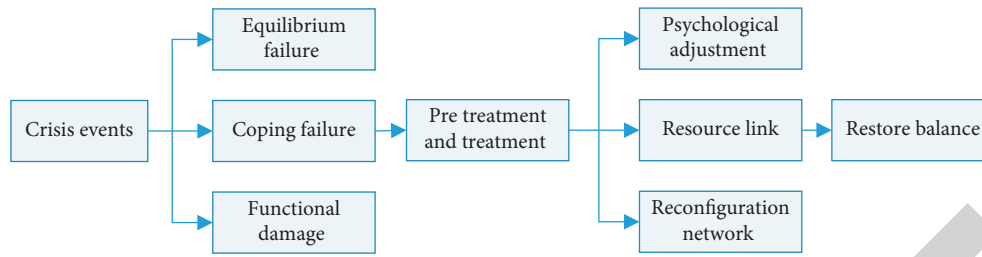

FIGURE 1: Lindemann crisis theory model.

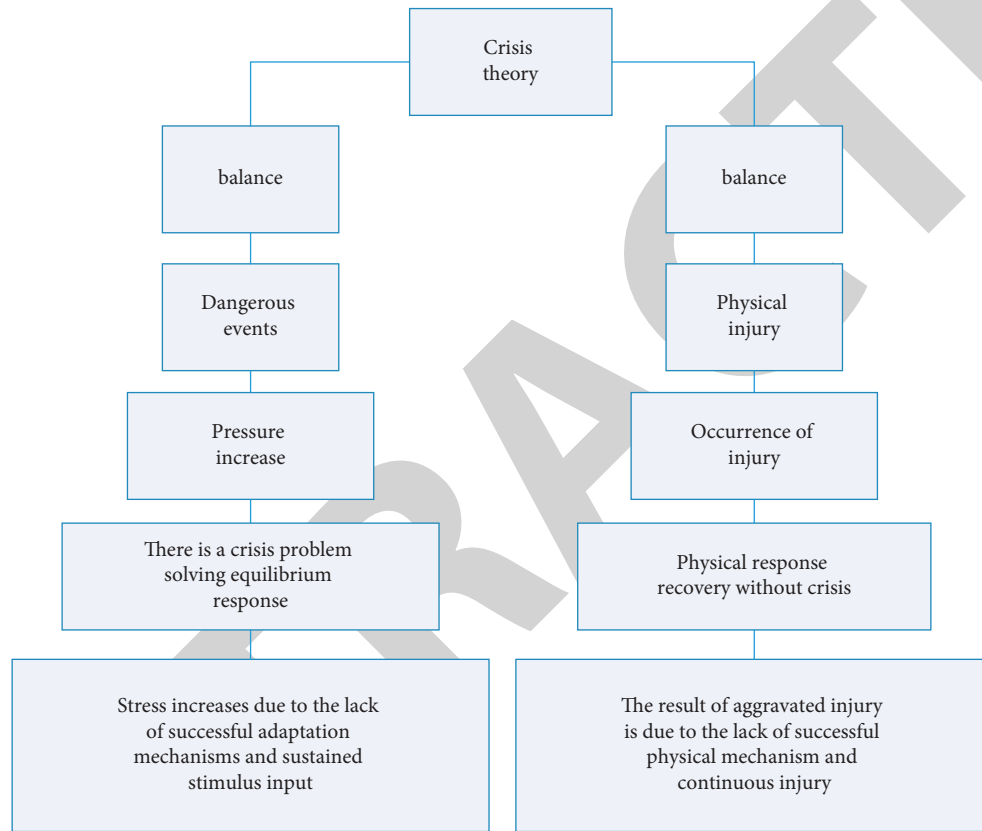

FIGURE 2: Extended crisis theory model.

through each stage of emotional change than at other ages or other bereavement events.

Without grief counselling from professionals, it can be difficult for the bereaved elderly to get out of their situation on their own. Moreover, feelings of self-blame and irrational emotions will be more pronounced in the elderly who have lost a parent, and the worse their physical and mental state, the greater the likelihood of depression.

2.2. Support Network Rupture and Reconstruction: A Case Intervention in an Emotional Crisis. Crisis assessment requires the identification of the client’s crisis situation, the planning of crisis intervention services, and a specific diagnosis of post-traumatic stress disorder [18]. The assessment is generally done in a funnel style, moving from an assessment of the client’s wider social environment to a

focused assessment of the core issues, which is a subjective and uncertain process (see Figure 3).

This case is an emotional crisis and a developmental crisis. Through crisis management strategies, the social worker helped the client to cope with the internal or external stress caused by the loss of her son (see Figure 4). In the intervention, the principles of immediate response, time limitation, focus on the crisis structure, problem solving, self-determination of the client, and social network connection were followed.

3. Modelling Mental Health Status Calculations

3.1. Data Collection. This study used a self-developed online experiment platform to collect data from Sina Weibo users (Figure 5). During April 2012, a total of 563 Sina Weibo users volunteered to participate in the experiment. In order to

FIGURE 3: Hierarchy of prognosis in a funnel.

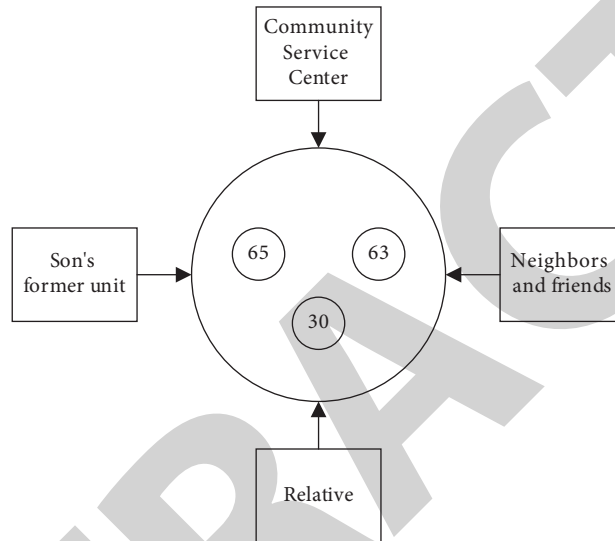

FIGURE 4: Ecological map of the case owner's family.

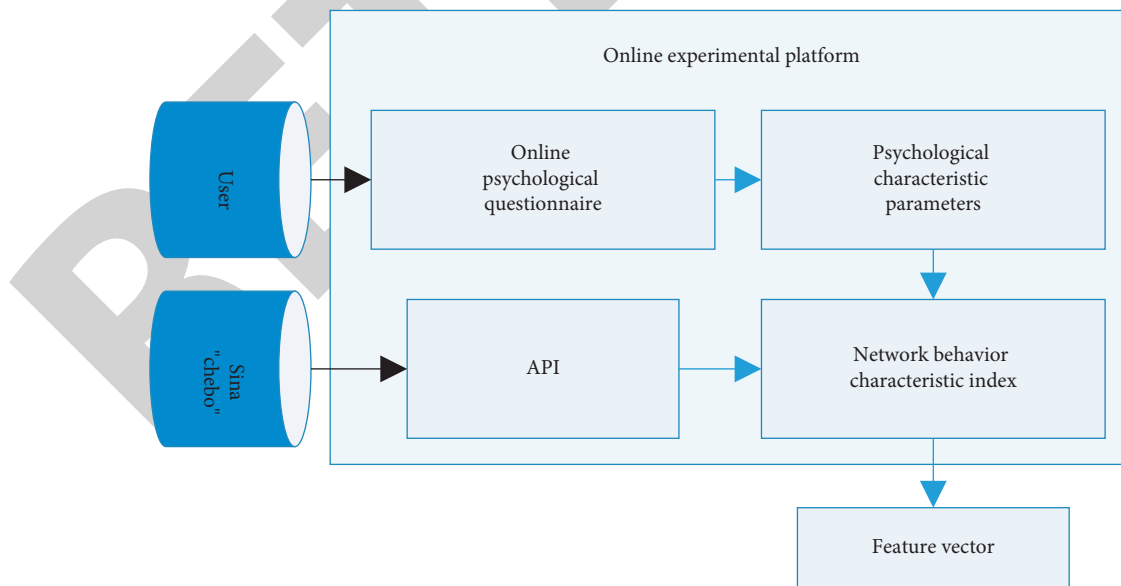

FIGURE 5: Subject data collection process.

ensure a sufficient amount of online data for the subjects, active users were selected from the recruited users with requirement that they had posted at least 500 tweets before

the experiment and that the latest tweet was posted within 3 months before the experiment, thus effectively eliminating inactive users from the data. In order to ensure the quality of

the psychological characteristics of the subjects, the subjects were required to fill in the online psychological questionnaire according to the standard. In this study, subjects who failed to answer the questionnaire were excluded [19]. After the screening process, 444 subjects (171 males and 273 females, average age 23.8 years old) remained, and their education level was mainly undergraduate (43%) and college (24%). The monthly per capita disposable income of the subjects was concentrated in the range of 1000–2000 RMB (25%) and 2000–5000 RMB (22%). Data from eligible subjects were used for subsequent model training.

3.2. Data Measurement

3.2.1. Mental Health Status. In this study, the Symptom Checklist 90 (SCL-90) [20] was used to measure the depression and anxiety levels of the subjects. The SCL-90 is a widely used international instrument for measuring mental health status, with good reliability and validity [21]. The questionnaire consists of a series of mental health symptoms, and subjects are asked to rate the severity of each mental health symptom on a 5-point Likert-type scale (0 being never and 4 being severe). The number of questions measuring depression and anxiety was 13 and 10, respectively, with higher scores indicating more severe mental health problems.

3.2.2. Online Behavioural Characteristics. In this study, based on the common types of online behavioral characteristics, we designed four categories of online behavioral characteristics based on the functions and data format of Sina Weibo, and the characteristics of the modeling target (mental health status). Based on the features of Sina Weibo, we designed 45 online behavioral characteristics in 4 categories [22]. Among them, (1) user information features describes the basic personal information of the subjects (e.g., gender and place of origin), (2) self-presentation features describe how the subjects create a virtual personal image on the online platform and present it to other users (e.g., whether to use the system's default virtual avatar), (3) privacy settings' features describe the subjects' preferences for personal privacy protection (e.g., whether to allow strangers on their personal pages), (4) privacy settings' features describe the subjects' preferences for privacy protection (e.g., whether to allow strangers on their personal pages), and (5) social network characteristics describe subjects' interpersonal interactions on online platforms (e.g., number of "followers" and number of "mutual followers"). For the Boolean features, they were binary coded, while for the floating-point features, the original values were retained.

3.3. Data Modeling. Mental health includes a range of different mental health dimensions (e.g. depression and anxiety), which are related to each other to a certain extent. The effectiveness of data modeling can be improved if common information between different mental health dimensions is

taken into account when building a computational model for a specific mental health dimension.

The basic idea of the multitask regression approach is that there are assumed to be T tasks and N instances, each with a training dataset $\{(x_{tn}, y_{tn})\} (t = 1, 2, \dots, T; n = 1, 2, \dots, N)$. Each instance can be represented as $x \in \mathbb{R}^d$ and $y \in \mathbb{R}^T$ (with feature number d) and matched with a multidimensional output vector (e.g., depression and anxiety dimensions), with the aim of finding a $T \times d$ matrix of coefficients, e.g.,

$$\mathbf{W} = \arg \min \{L(x, y, \mathbf{W}; 1:T) + \lambda \Omega(\mathbf{W})\}. \quad (1)$$

In this study, $L(x, y, \mathbf{W}; 1:T)$ is denoted as the empirical loss function, $\Omega(\mathbf{W})$ is denoted as the regularizer, and λ is denoted as the tradeoff constant [23]. In this study, $L(x, y, \mathbf{W}; 1:T)$ is set as the least square error, and $\Omega(\mathbf{W})$ is set as the Frobenius norm. That is,

$$\begin{aligned} L(x, y, \mathbf{W}; 1:T) &= \mathbf{Y} - \hat{\mathbf{Y}} = \sum_{t=1}^T \sum_{n=1}^N (y_{tn} - \hat{y}_{tn})^2 \\ &= \sum_{t=1}^T \sum_{n=1}^N \left(y_{tn} - \sum_h w_{th} x_{nh} \right)^2, \end{aligned} \quad (2)$$

$$\Omega(\mathbf{W}) = \|\mathbf{W}\|^2 = \text{tr}(\mathbf{W}^T \cdot \mathbf{W}). \quad (3)$$

Substituting (2) and (3) into equation (1), i.e.,

$$\mathbf{W} = \left(\lambda \mathbf{I} + \sum_n \mathbf{x}_n \mathbf{x}_n^T \right)^{-1} \left(\sum_n \mathbf{x}_n \mathbf{y}_n^T \right). \quad (4)$$

For the selection of λ , a bias-variance decomposition method was used to minimize the expected loss of [(error)+variance]. In view of this, the multitask regression method [24, 25] was used to develop models for depressive and anxiety states based on network data analysis. This study also used linear regression and feedforward neural network to develop the same mental health state model, which was used as a baseline model to evaluate the effectiveness of the multitask regression method.

4. Study Results

After tuning the model parameters, the learning rate of the feedforward neural network method was set to 0.9 and the parameter λ of the multitask regression method was set to 1.70 ($\ln(\lambda) = 0.53$). The correlation coefficients between the results of the mental health state model and the psychological questionnaire are shown in Table 1, and the network behavioral characteristics that were significantly correlated with depression and anxiety are shown in Table 2. For the same modeling target (depression or anxiety), the results of the mental health state model based on different modeling methods were different [26]. It is noteworthy that the correlation coefficient between the results of the mental health state model and the results of the psychological questionnaire was the highest among the three different

TABLE 1: Calculated results of the mental health state model and the results of the psychological questionnaire: correlation coefficients between the results of the mental health model and the results of the psychological questionnaire.

	Linear regression	Feedforward neural network	Multitask regression
Depressed	0.12	0.26	0.41
Anxious	0.14	0.21	0.34

TABLE 2: Correlation coefficient values for selected online behavioural characteristics and mental health dimensions.

Features	Depressed	Anxious
Gender	-0.137	-0.148

modeling approaches for both the depression and anxiety dimensions.

Analysis of the data showed no significant gender differences in anxiety and depression during major public events, anxiety $t = -0.865$, $p = 0.387$; depression $t = -0.011$, and $p = 0.991$; but regionally, significant differences were shown, anxiety $F(31, 10\ 916) = 1.713$, $p = 0.008$, and depression $F(31, 10\ 916) = 3.687$, $p = 0.000$; unexpectedly, the region with the highest levels of both anxiety and depression among older people was Guangxi (M (anxiety) = 9.38, $SD = 3.264$, and M (depression) = 12.05, $SD = 4.011$). The data showed that the levels of anxiety and depression among older people in this major public event differed between groups of older people, with anxiety $F(9, 10\ 938) = 3.757$, $p = 0.000$, and depression $F(9, 10\ 938) = 3.840$, $p = 0.000$, and the differences were highly significant. It is noteworthy that there were no significant differences in anxiety and depression between ages, but there were significant differences between ages, with anxiety $F(2, 10\ 945) = 5.495$, $p = 0.004$, and depression $F(2, 10\ 945) = 5.117$, $p = 0.006$, and it is easy to see from the images that, as age increases, the levels of anxiety and depression caused by major public events increased significantly and linearly with age, see Figure 6.

TABLE 3: Test of variance for each dimension of the Older People’s Mental Health Survey questionnaire.

Dimension	F	Sig
Growth experience	0.66	0.517
Personality traits	4.646	0.01
Life events	69.206	0
Social support	8.688	0

However, significant age differences were found in only some of the older adult groups. Again, not all regions showed significant age differences, with the most significant differences being in Inner Mongolia, where $F(2, 1,147) = 5.221$, $p = 0.006$, and in depression, $F(2, 1,147) = 4.997$, $p = 0.007$. Anxiety was $F(2, 231) = 3.966$, $p = 0.020$, and depression was $F(2, 231) = 6.034$, $p = 0.003$.

The analysis of the results of the mental health questionnaire for older people showed results that were largely consistent with the results of the Psychological Status Self-Assessment Scale [27]. There were no significant differences in total questionnaire scores by age, but there were significant differences by age, $F(2, 11,037) = 4.916$, $p = 0.007$. Tests of variance for each dimension of the Psychological Screening Questionnaire for Older People showed that the

most significant differences between ages were for life events, followed by social support and personality traits, see Table 3.

5. Conclusions

By collating and analysing the results of psychological assessments conducted on older people through big data, we can accurately identify groups with potential psychological crises and develop psychological support programmes to promote psychological resources to groups in greater need, which is of great guidance in helping counsellors to complete psychological crisis screening, effectively improve the timeliness of psychological counselling work, and improve the directionality of psychological support and psychological construction. Combined with the results of big data analysis, the construction of a complete psychological crisis intervention system will help to give full play to the important role of cadres and counsellors of the elderly, form a four-level crisis prevention and intervention system of schools, psychological centres, counsellors of elderly groups, and class-level psychological members, monitor the psychological dynamics of the elderly in real time, carry out psychological health education, improve the response rate when facing psychological crises, and effectively help the elderly cope with potential psychological crises arising from major emergencies.

Blockchain technology can build trust, reduce costs, and accelerate transactions in the mobile edge computing (MEC) and manage computing resources using the smart contract. However, the immutability of blockchain also poses challenges for the MEC, such as the smart contract with bugs cannot be modified or deleted. We propose a redactable blockchain trust scheme based on reputation consensus and a one-way trapdoor function in response to the problem that data on the blockchain, which is an error or invalid needs to be modified or deleted. The scheme calculates each user's reputation based on their currency age and behavior. The SM2 asymmetric cryptography algorithm is used as the one-way trapdoor function to construct a new Merkle tree structure, which guarantees the legitimacy of the modification or deletion after verification and vote. The simulation experiments show that the modification or deletion does not change the existing blockchain structure and the links of blocks. Furthermore, the consensus verification accurately passes after the modification or deletion operations, which indicates the proposed scheme is feasible.

1. Introduction

The mobile edge computing (MEC) reduces latency and network load by consolidating computing resources that are close to mobile users in edge networks. However, there are problems in system security and resource management. The security and privacy of MEC have been a concern in recent years, and blockchain can provide the best solution. Blockchain technology is one of the revolutionary emerging technologies in recent years. The immutability of blockchain technology facilitates it to establish a consensus in a trustless environment [1]. Furthermore, blockchain has the advantages of decentralization, distrust, anonymity, and data incorruptibility, and makes the transmission of secret information in the MEC more secure [2]. Therefore, it has broad development prospects. The smart contract can realize the decentralized resource management and ensure the security of system data. Using the decentralized characteristics of blockchain to perform task allocation and scheduling in mobile edge computing can effectively eliminate the attack behavior to the central server and ensure the correctness of data transmission.

Blockchain brings benefits to the MEC but also challenges. The immutability ensures the information security of the computing devices on the chain. It also means the wrong or invalid information cannot be modified or deleted and will be permanently stored in the blockchain. The smart contract can facilitate the intelligent management of MEC devices. Still, bugs in the smart contract will lead to irreparable damage, as in the well-known DAO attack. However, illegal information has been maliciously uploaded to the blockchain time and again since the creation of blockchain, providing opportunities for criminals to disrupt the order of the blockchain network for benefit. The current research and application of blockchain emphasize the security of storage and transmission of data on the blockchain, while ignoring the security of data contained on the blockchain from the perspective of information regulation [3]. Data on the blockchain can only be appended, not deleted or modified [4]; the storage burden of the entire blockchain increases due to the increasing amount of data on the blockchain, which cannot be deleted or altered, which is not conducive to maintaining. The General Data Protection Regulation

(GDPR) mandated by the European Union in 2018 sets new standards for collecting, storing, protecting, and using users' data. Companies need to ask for each user's permission before collecting their personal data. The user has the right to be forgotten, and the data controllers must ensure that personal data are accurate and kept up to date. It means that users can withdraw their permission at any time and ask companies to modify or delete their personal data. Therefore, the blockchain system applied in this context must provide users with a convenient way to modify or delete. The decentralization of blockchain does not mean that the system data cannot be modified, but the data on the blockchain can be modified with the approval of the majority of the system users, and the modification operation is performed by the system users, which does not violate the concept of decentralization. Therefore, the study of redactable blockchain technology under specific conditions is of great research significance.

After Satoshi Nakamoto proposed "Bitcoin: A Peer-to-Peer Electronic Cash System" in 2008 [5], blockchain came into the public eye. As the core technology of blockchain, the consensus mechanism determines blockchain's security, scalability, decentralization, and other essential characteristics [6]. It solves the Byzantine problem so that communication between untrustworthy nodes is possible and makes the distributed data of blockchain consistent. A suitable consensus mechanism improves the performance and efficiency of a blockchain system, provides a robust security guarantee, and supports complex application scenarios [7]. The initial Bitcoin blockchain used the Proof-of-Work (PoW) mechanism, which relies highly on the HashRate of nodes, to ensure the consistency of the distributed data. However, PoW proved to be a severe waste of resources and an inefficient transaction. The Proof-of-Stake (PoS) consensus created by Peercoin solves the problem of waste of resources of PoW. However, it cannot resist the permanent divergence. It may lead to polarization, widening the gap between rich and poor nodes, and a low level of decentralization is detrimental to currency circulation [8]. Liu proposed a new consensus mechanism based on reputation in 2019 (Proof of Reputation, PoR) [9]. It distributes a reputation value to each node and determines who has the right to create a new block according to the reputation value. The PoR consensus mechanism does not waste the HashRate or power resources; it has a low computational cost and is more efficient compared with the PoW consensus mechanism. The PoR also does not lead to polarization compared with the PoS consensus mechanism. The reputation value is logarithmically proportional to the amount of currency. The reputation value increases with the increasing amount of currency, but the growth rate decreases. It allows moderately wealthy nodes to create a new block for rewards.

Krawczyk H proposed the chameleon hash function in 2000 [10], which has a trapdoor that can construct a hash collision. The Accenture company applied for a patent of redactable blockchain that having a trapdoor can modify the block data without changing the block's hash value. Still, the scheme is not secure because the trapdoor is controlled by only one party, and the scheme is highly centralized. Li

proposed a study of redactable blockchain technology based on chameleon hash functions and verifiable secret sharing in 2018 [11]. Li's scheme solves the problem of high centralization, with N nodes cooperating to perform modification operations. Still, most of the blockchains are mainly based on traditional collision-resistant hash functions, so the application value of Li's scheme is low. Ren proposed a redactable blockchain scheme based on Proof-of-Space consensus and collision-resistant hash functions in 2020 [12], using one-way trapdoor functions to modify the data on the blockchain. The blockchain structure of Proof of Space is different from Proof of Work and Proof of Stake, due to the features of Proof-of-Space consensus, and this scheme [13] is only limited to Proof-of-Space consensus, which has substantial limitations; the modification involves the inverse operation of Q users. The more users there are in the blockchain network, the larger the Q is, and the lower the efficiency is. Therefore, the Proof of Reputation has many advantages compared with Proof of Space. First, the Proof of Reputation selects a Leader to create a new block according to user's reputation value, and it does not waste the HashRate resources compared with Proof of Space; second, the efficiency of Proof of Space will decrease with the increasing number of Q users in the network, there are Q inverse operations, and the efficiency of Proof of Reputation will not decrease because there is only one inverse operation.

This paper uses a collision-resistant hash function to implement a redactable blockchain scheme based on the Proof of Reputation consensus mechanism (PoR). We propose a new Merkle tree structure using a one-way trapdoor function. As a result, legitimate modification of invalid or error information could be performed after verification without changing the existing blockchain structure; all users can verify the validity of modified data [14].

2. Basic Knowledge

2.1. One-Way Trapdoor Function. A one-way trapdoor function contains two features: a one-way function and a trapdoor. The one-way function is irreversible. For a one-way function $y=f(x)$, it is easy to calculate y given x but is computationally infeasible to compute x given y . There exists a z such that we can easily calculate $x=f^{-1}(y)$ if we have z and y . The function $y=f(x)$ is called one-way trapdoor function, and z is called the trapdoor. The character of the one-way function determines its computational complexity, and the character of the trapdoor determines that z will be the key to cracking the one-way function.

2.2. PoR Consensus-Based Blockchain. A new consensus mechanism based on Proof of Reputation (PoR) was proposed in [9]. The PoR consensus mechanism has certain merits in energy-saving and computation efficiency compared with PoW. Furthermore, PoR can avoid the waste of resources caused by PoW and create a secure network atmosphere.

As shown in Figure 1 [9], the block structure of the PoR consensus mechanism has three parts: block header,

FIGURE 1: Block structure [9].

transaction sub-block, and reputation sub-block. Detailed contents of the three parts are as follows:

- (1) Block header: contains block height, version, timestamp, signature of the block header, hash of the previous block (only hash the block header), transaction Merkle root, and reputation Merkle root.
- (2) Transaction sub-block: contains transactions stored as a Merkle tree. The root of Merkle tree in the transaction sub-block links to the transaction Merkle root in the block header.
- (3) Reputation sub-block: contains the vote information. As shown in Figure 2, the vote information includes explicitly: the voter’s public key, reputation value, opinion of agreement or disagreement, signature, and the block hash. The vote information, stored as a Merkle tree, is used to verify the legitimacy of the created block. The Merkle root links to the reputation Merkle root in the block header.

In the PoR consensus mechanism, the highest reputation node can create a new block. The factors that affect a node’s reputation are as follows: currency age R_s ; transaction activities with other nodes R_a ; and contribution to consensus R_c . The currency age is the product of currency amount and time; transactions with other honest nodes and participation in consensus validation voting will increase a node’s reputation value, and the reputation values of each participating node will change when each block is published, whether the block is approved or rejected by the network. The following equations computing the constituting components, R_s , R_a , and R_c , of the reputation values are formulated in [9].

FIGURE 2: Details of a vote information.

$$R_s(S_i, t) = \alpha \log(S_i t), \quad (1)$$

$$R_a(A_k, V_k) = \sum_{k=1}^j A_k \log(V_k) S(k), \quad (2)$$

FIGURE 3: Process of creating new blocks [9].

$$R_c(N_i) = \gamma_1 N_{ic} T_{\text{total}} - \gamma_2 N_{ie} T_{\text{total}} \quad (3)$$

In (1), the S_i denotes the currency amount of the i^{th} node; the t represents the time length that node i has owned this currency, $S_i t$ is the currency age, and α is a conversion factor. The PoR consensus mechanism uses the logarithmic formula to calculate reputation value. The reputation value growth rate decreases as the wealth increases; this reduces the gap between the rich and the poor so that people of moderate wealth also have the opportunity to create new blocks for reward of increasing its reputation value.

The j in (2) is the number of transactions related to node i . With the appropriate settings of the weighting factor A_k and the scaling factor $S(k)$, nodes would prefer to trade with other high reputation nodes to achieve or maintain their high reputation status.

The R_c in (3) incentivize nodes to frequently make positive contributions to consensus voting to increase their reputation values.

The reputation value R_i for each node in the network can be calculated using the following (4) from [9], where β_1 , β_2 , and β_3 are weighting parameters. Readers are referred to [9] for a more detailed description of each of the parameters in following equations:

$$R_i = \beta_1 R_s(S_i, t) + \beta_2 R_a(A, V) + \beta_3 R_c(N_i). \quad (4)$$

There is also a positive causal connection between the system currency and the reputation values; the high reputation nodes are likely responsible for the system's security because system security is inseparable from their wealth.

The process of creating a new block is as follows.

- (1) Select a Leader to create a new block. As shown in Figure 3, an initial reputation ranking block is generated during the system initialization. The highest reputation node of the initial reputation ranking block is selected as the Leader to create

blocks 0 and 1. Then, reputation ranking blocks 0 and 1 are built according to the blocks 0 and 1 created by the Leader. The highest reputation node of block 0 creates block 2, the highest reputation node of block 1 creates block 3, and so on. After creating a new block, the Leader needs to sign and broadcast it to the network and wait for the other nodes in the network to vote on it.

- (2) Votes on the new block. The validation group consists of high reputation nodes, and the sum of their reputation values is over 80% of the system's total reputation values. The nodes in the validation group are usually in the top 20% of the highest reputation nodes. All nodes in the network can verify whether the transactions and signature are legitimate and then vote on it. The Leader needs to collect the voting information and store it in the reputation sub-block as a Merkle tree. The block will be uploaded to the blockchain when (i) more than 2/3 of the validation group nodes vote in favor; (ii) the sum of the YES voters' reputation values exceeds 1/2 of the system total reputation value. The block is rejected in the opposite scenario.
- (3) The other nodes in the blockchain network verify the new block. Other nodes verify the newly released block and update their local blockchain data for consistency.

3. Redactable Blockchain

We propose a redactable blockchain based on the blockchain structure of PoR, using a new Merkle tree and a one-way trapdoor function. The specific transaction in the *Request* can only be legitimately modified when the nodes who agree to perform the requested modification have more than 1/2 of the whole reputation value in the network, so the

FIGURE 4: Structure of redactable block.

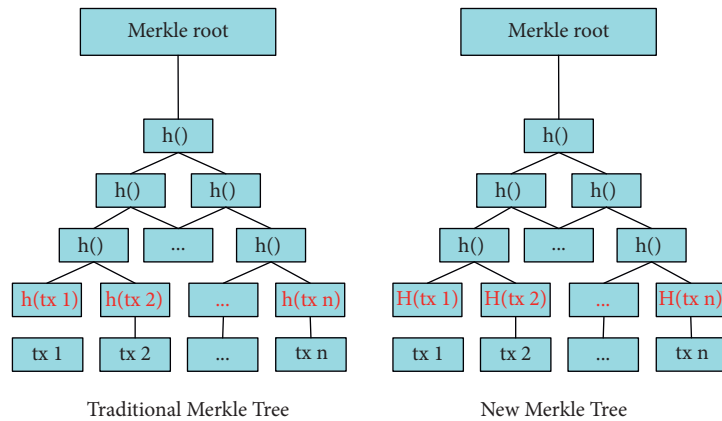

FIGURE 5: Traditional Merkle tree and new Merkle tree.

amendment represents the system’s will. Furthermore, the blocks’ link and other data remain unchanged after the amendment. Thus, the proposed redactable blockchain prevents illegal or malicious modifications. We first introduce the redactable blockchain structure and then analyze the modification principle and security.

3.1. Structure of Redactable Blockchain. As shown in Figures 4 and 5, the structure of the redactable block uses a new Merkle tree that incorporates the XOR operation $H(tx)$ on the one-way trapdoor function and the hash function. This operation ensures that the transaction Merkle root, the signature, and the hash value of the block header will remain unchanged after the modification, keeping the links of blocks intact.

The difference between the traditional Merkle tree and the new Merkle tree is in the hashing of the leaf nodes.

In the traditional Merkle tree, the value of each leaf node is the $SHA256$ hash $h(tx)$ of a transaction tx . The parent node’s value is the hash of two hash values, $h(tx1)$ and $h(tx2)$, of the two children nodes, and this hashing process is repeated until the transaction Merkle root is generated. Therefore, we can detect any tamper of transactions according to the Merkle root to ensure the transaction data’s integrity [15]. If a transaction is tampered with, its hash value and the transaction Merkle root will also change; therefore, the transactions on the blockchain cannot be modified without being detected at the Merkle root.

In the new Merkle tree structure, the value of the leaf node is $H(tx)$, which is the XOR of the hash value $h(tx)$ of the

transaction tx and the one-way trapdoor function $g(x)$ (the calculation process of the other nodes remains unchanged):

$$H(tx) = h(tx) \oplus g(x). \quad (5)$$

x is the Leader's exclusive random number, automatically generated when the public and private keys are created and recorded as a common parameter. $g(x)$ is the result of encrypting the random number x with the public key. When the transaction tx is modified to tx_{new} , the block Leader can use its private key to compute a new number $x' = g^{-1}$, ($h(tx) \oplus g(x) \oplus h(tx_{new})$), to satisfy the formula:

$$h(tx) \oplus g(x) = h(tx_{new}) \oplus g(x'). \quad (6)$$

Although the transaction is modified, with the calculated number x , the transaction Merkle root, the signature, and the other data in the block header remain unchanged; the block header's hash is also intact, therefore maintaining the links of blocks. Thus, the new Merkle tree can still achieve the functions of the traditional Merkle tree as follows:

- (1) Providing a Merkle proof. *Light nodes* can verify whether a transaction exists by Merkle proof with the help of *full nodes*, even if only the block header is stored (a *full node* has all transactions in the network, while a *light node* only has transactions related to itself).
- (2) Verifying whether a transaction has been modified. Suppose an attacker wants to change a transaction maliciously. Because only the Leader owns the trapdoor, an attacker cannot calculate the number x' to ensure the transaction Merkle root is unchanged. So, we can judge whether a transaction is modified according to the different transaction Merkle root.

3.2. The Principle of Redactable Blockchain. In a redactable blockchain, the data on the blockchain can be legitimately modified in the interest of the system if nodes with more than 1/2 of the system total reputation value agree the modification. Furthermore, the modification does not break the links between the blocks. The following section describes how to implement modification operation and ensure it is legal.

3.2.1. Implementing Data Modification

(1) *Legitimacy Verification of a Modification Request.* When a node has a valid reason to modify a transaction, the node can send a modification *Request* to the network. All nodes in the network could vote on whether the *Request* is legitimate. The *Request* is approved if the sum of the yes voters' reputation values is greater than 1/2 of the system's total reputation value; otherwise, the *Request* is rejected if the voting result is in the opposite. The modification *Request* information includes the height of the block to be modified, the serial number of transactions, the reason of redaction, and the set after redaction.

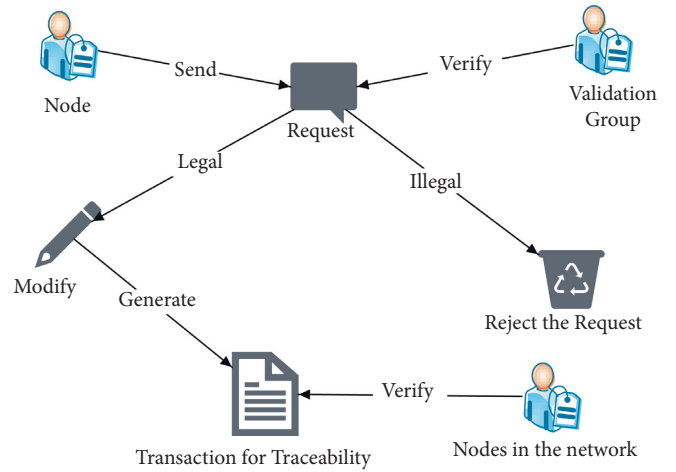

FIGURE 6: Process of data modification.

$$\text{Request} = \{\text{Height, ID, Action, data}_{\text{new}}\}. \quad (7)$$

The requirement of high reputation yes voters' sum of reputation values is more than 1/2 of the system's total reputation values ensures the "legality" of the modification *Request*, and prevent malicious nodes in the network from destroying the modification operation. Higher reputation nodes are more likely honest nodes, so these nodes are entrusted with more decision-making power.

(2) *Process of Implementing Data Modification.* The Leader needs to calculate a new number $x' = g^{-1} (h(tx) \oplus g(x) \oplus h(tx_{new}))$, to guarantee that the Merkle root and the data in the block header remain unchanged after the transaction modification. Hence, the links of the blocks are not affected, and there is no need to adjust the data of the subsequent blocks. Furthermore, all nodes in the network can verify the legitimacy of the data at any time.

(3) *Update of System Status.* The Leader generates a new transaction message called $txorg$ for traceability after the modification operation is executed. The content of $txorg$ is as follows:

$$txorg = \{\text{id, Height, ID, Action, data}_{\text{new}}, x, x', \text{Pubkey}_{\text{leader}}, \text{time, rt_set}\}. \quad (8)$$

The contents of the $txorg$, in sequential order, are as follows:

- (i) The serial number of the $txorg$, id
- (ii) The height of the block, $Height$
- (iii) The serial number of transactions, ID
- (iv) The reason of redaction, $Action$
- (v) The set after redaction, $data_{\text{new}}$
- (vi) The Leader's random number, x
- (vii) The calculated new number, x'
- (viii) The Leader's public key, $\text{Pubkey}_{\text{leader}}$
- (ix) The time of modification, $time$

(x) The voting record to the Request, rt_set

All network nodes can verify the modification's legitimacy according to *txorg* and update their local blockchain data for the consistency of the chain.

Figure 6 illustrates the data modification process.

First, the node sends a transaction modification *Request*.

Second, all nodes send in the network vote on the legitimacy of the *Request*. The *Request* is considered legitimate if the favorable votes come from nodes whose sum of reputation values is more than 1/2 of the system's total reputation values. Then, the Leader executes the legitimate modification *Request* by calculating a new number x' so that the links of blocks are not affected after the modification. Otherwise, reject the modification *Request* and vastly reduce the reputation value of the node sent the *Request*.

Third, the Leader issues a transaction for traceability, and the nodes of the whole network verify whether the executed modification is legitimate and update their local blockchain data.

3.2.2. Ensuring the Legality of Modification. The redactable blockchain does not compromise blockchain security while addressing the limitations of immutability. Because only legal changes voted and verified through by the network's nodes can be performed, the "redactable" blockchain can still ensure the data's security, guaranteed by the characteristics of the one-way trapdoor function and our scheme.

We can only adjust the number x' to match the modification of transactions, which guarantees that data and the links of the blocks remain unchanged after the modification. The property of the one-way trapdoor function determines that only the node knowing the trapdoor can find the only number x' that can match the transaction change to execute the modification. In this paper, the trapdoor is the Leader's private key, so only the Leader can calculate the new number, and only the Leader can execute the modification authorized by the network.

Specifically, we choose the SM2 asymmetric cryptography algorithm as the one-way trapdoor function. In essence, the Leader encrypts its selected random number x with its *public key*. According to the one-way trapdoor function properties, all nodes can use the Leader's *public key* to calculate $g(x)$ given x . However, only the Leader can do the reverse calculation, that is, calculate x given $g(x)$, with the corresponding *private key*. Therefore, the Leader's private key is the trapdoor generated by one-way trapdoor function. Furthermore, the blockchain modification request needs to be approved by the nodes in the network before execution and verified by all other nodes after implementation. Therefore, the modification operation represents the will of the system and is legitimate.

3.2.3. Security Analysis of Data Modification. To illustrate the security of the redactable blockchain scheme, we simulate the attacks of a malicious adversary on modifying block transactions. The adversary can take the following methods:

- (1) Modify the target block data, modify the data of all blocks on the chain from the targeted block up to the latest block, and keep the links of blocks unchanged
- (2) Calculate a new number for the modification so that the new Merkel tree root is unchanged after modifying the targeted block data

Attack scenario 1 is not feasible because only the block Leader can modify the block. Furthermore, the Leader of each block on the path from the targeted block up to the latest block may be different. The Leaders of each block on the block path are all high reputation nodes. A high reputation node is likely trustworthy because its wealth is closely related to the system's security. According to the principle of maximum wealth, high reputation nodes will not damage the system, negatively affecting their wealth. So, the adversary cannot perform all modification operations from the targeted block up to the latest block. Therefore, the adversary's attack is not feasible.

The attack scenario 2 is also infeasible because only the Leader knows the trapdoor of the new Merkel tree, so only the Leader can calculate the unique number to keep the Merkel root unchanged after the transaction modification. And the Leader with a high reputation is more likely to be honest because blockchain security is closely related to its wealth. However, suppose the Leader does not faithfully execute the modification request in the network. In that case, the unauthorized modification cannot pass the verification of the other nodes, and the modification operation cannot complete. The Leader's reputation value is also significantly reduced as a consequence. In this way, the attacker cannot obtain benefits but loses his wealth, violating the principle of attack. Therefore, the scheme is safe. In conclusion, the redactable blockchain scheme is safe and effective.

4. Experimental Simulation

Smart contracts can be used for computing devices management in MEC. However, if a smart contract with bugs is released in MEC, and the bugs can cause devices to fail to alert potential warning conditions, it can cause irreparable damage. In this scenario, the proposed redactable blockchain scheme can modify the uploaded buggy smart contract to prevent damage that the buggy smart contract can cause. For easier understanding, the information in the buggy smart contract can be treated as transaction data in the system blockchain to implement the modification. Furthermore, the proposed redactable blockchain also facilitates companies' compliance to GDPR, the EU law on data protection and privacy. For example, in a blockchain-based electronic health record system, the medical institute should ensure that customer's personal data are accurate and up to date, and be able to modify customers' personal data or completely erase a customer's health record at the customers' request. In these scenarios, the customers' health records can be treated as transaction data modified or deleted.

TABLE 1: Node information.

We simulated the data modification on a blockchain under the PoR consensus mechanism. The experiment uses Python as the language, PyCharm, as the compiler and imports the encrypted package of gmssl.sm2 for the encryption, decryption, and signature operations.

4.1. Competition of Bookkeeping Rights. Table 1 shows the information of the nodes in the initial system. There are no transactions and validation votes in the initial system, so the reputation values are only related to the nodes' wealth.

The system converts the amount of currency into a reputation value using the conversion formula in equation (1), that is, $R_s(S_i, t) = \alpha \log(S_i t)$, and generates an initial ranking of reputation value, as shown in Table 2. We set the conversion factor α as 1/2. The initial reputation value is only related to currency amount because no transactions have been generated yet.

Figure 7 shows the nodes' reputation values.

The consensus mechanism selects the highest reputation node as the Leader to create a new block. Then, other nodes

in the network vote on the legitimacy of the new block, and all nodes can verify the legitimacy of the new block.

4.2. Generation of New Blocks. The system sets each block to pack four transactions. The initial reputation ranking determines that node 1 is the Leader to create blocks 0 and 1. The Leader collects four transactions in the transaction pool, packs them into a block, and releases it to the network with a signature. All nodes in the network vote on the legitimacy of the transaction and verify the signature. If passing the validation, the block is uploaded as block 0, and a new reputation ranking table 0 is generated. The highest reputation node in reputation ranking table 0 generates block 2. Similarly, the highest reputation node in reputation ranking Table 1 generates block 3, and so on. Figure 8 shows the detailed structure of blocks 0 and 1.

Let's use block 1 as an example to introduce the computation of the transaction Merkle root.

- (1) Block 1 contains four transactions, and node 1 is the Leader of block 1. The one-way trapdoor function $g(x)$ can be calculated using SM2 encryption on the Leader's exclusive random number x using the public key of the Leader (node 1). The $g(x)$ is at least 776 bits in length. We calculate the $SHA256(tx)$ of each transaction first and then pass the value of $SHA256(tx)*3$ to the first 768 bits of $h(tx)$, and padding the remaining bits of $h(tx)$ with zero to make $h(tx)$ and $g(x)$ equal in length. Then, calculate the hash value $H(tx)$ of each leaf node.
- (2) After calculating the $H(tx_i)$ of each Merkle tree leaf node i , we compute the hash value of the parent node of two leaf nodes by performing $SHA256()$ hashing of the concatenation of their hash values. These steps

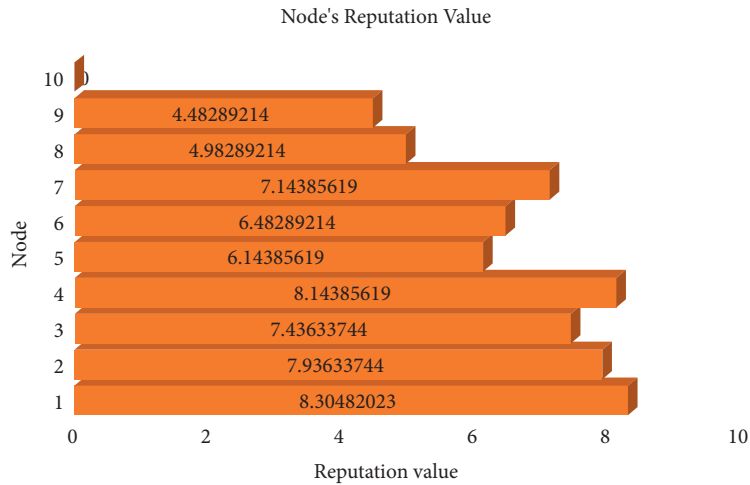

FIGURE 7: Nodes' reputation values.

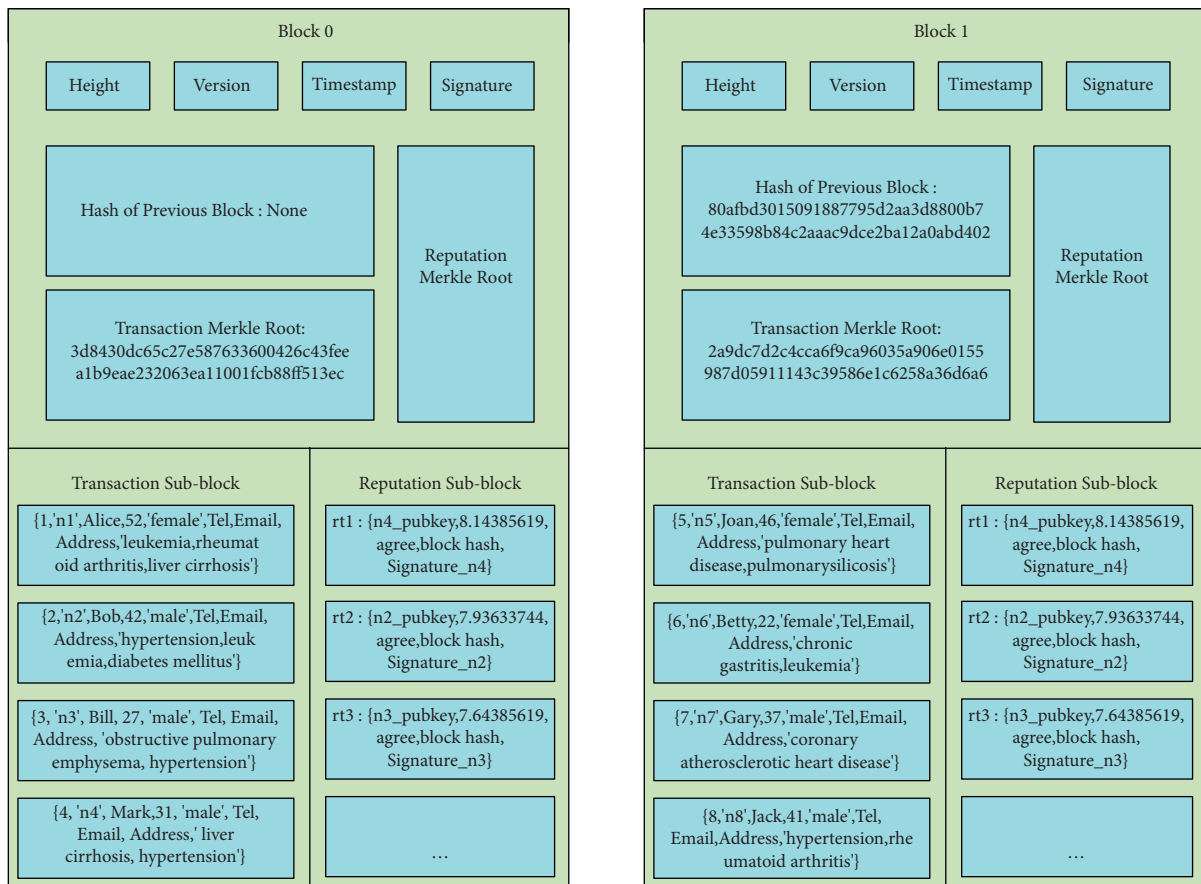

FIGURE 8: Blocks 0 and 1.

are repeated until the transaction Merkle root is generated.

$$\text{Merkle root} = \text{SHA256}(\text{SHA256}(H(tx1)\|H(tx2))\|\text{SHA256}(H(tx3)\|H(tx4))). \tag{9}$$

TABLE 3: Hash of transactions.

FIGURE 11: Program result.

The block Leader (node 1) publishes the packaged block and signature to the network. Then, all nodes in the network vote on the legitimacy of the transactions and verify the signature in the block. Next, the block Leader (node 1) collects the vote information and stores it in the reputation sub-block. After the nodes finish the validation and vote in agreement for the block, block 1 is officially uploaded. After block 1 Leader (node 1) uploads block 1, the rest nodes in the network verify the legitimacy of block 1 and update their local blockchain data to achieve the consistency of the distributed data if passing the verification.

4.3. Modification of Block Data. Suppose a blockchain-based health record system needs to update a customer’s personal data in compliance with GDPR at the customer’s request. Under the EU General Data Protection Regulation (GDPR), Bob as a customer is entitled to demand his personal data be accurate, be up to date, or be deleted. For example, Bob can request that his contact information be updated after he has changed a phone number or moved to a new address. For example, Bob informs his hospital that he has moved home. His hospital is obliged to update Bob’s personal information, and the hospital can send an “Address change” Request to the medical blockchain system with Bob’s ID.

FIGURE 12: Details of transaction record *txorg*.

$$\text{Request} = \{ 'Height : 0', 'ID : 2', 'Action: customer changed address, Address : 78 some street, zheng zhou' \}. \quad (14)$$

All nodes (participating hospitals) in the blockchain-based health record system validate whether the modification request is legitimate. If they approve the modification request, the Leader of block 1 performs the modification as shown in Figure 10 to update this customer's personal record. Block 1 Leader (node 1) can calculate a new number x'

$$\text{SHA256}(tx_{2_{\text{new}}}) = 5f03ca15f22bf2faebea168783fdb976a740e00744eb9b7b7240b6586b8b1269. \quad (15)$$

The value of $g(x')$ is as follows:

$$g(x') = 7a9299a80e5a161b37de114f81c5f959211c65b1e8c0599e26507593bed1087aa51279ee003fbce2012241b491ca9f67a904294fcff534c0ad938659f3b310fb7c960664d08424e53a1ff72ee1d6b59976f2a1b11153d6b3ff6414d43f82876aa5df14ec. \quad (16)$$

Decryption to calculate the new number is as follows:

$$x' = 1183451931(468a0b1b). \quad (17)$$

Figure 11 shows the result of the program. We can calculate the result of XOR operation. Therefore, the transaction Merkle root is the same after updating this customer's health record.

The signature and the hash of the block header will not change if the transaction Merkle root does not change after the modification, so the links of blocks are not affected. After completing the modification, block 1 Leader (node 1) generates a new transaction record called tx_{org} and publishes it to the network, as shown in Figure 12, for legitimacy verification by the rest nodes in the network.

The other nodes in the network verify whether the modification is legal according to tx_{org} , and update their local blockchain data if the amendment is legitimate, which completes the modification operation.

After the modification, both the transaction Merkle root and the block header's hash are unchanged; the links of blocks are not affected, so the modification operation is feasible.

5. Conclusion

A redactable blockchain scheme based on the PoR consensus mechanism is put forward in this paper to address the problem of amending or removing erroneous or sensitive data on blockchains of MEC applications. The proposed Merkle tree structure uses the one-way trapdoor function characteristics, which ensures the Merkle root does not change after modifying a transaction, so the links of blocks are not affected. Although only the block Leader node with the trapdoor can legally perform the modification operation, the modification operation also needs to be validated and

to execute the amendment without affecting the transaction Merkle root and the links of blocks.

The new number $x' = g^{-1}(h(tx) \oplus g(x) \oplus h(tx_{\text{new}}))$ is calculated, which satisfies (6).

The hash of $tx_{2_{\text{new}}}$ is as follows:

agreed upon by the nodes of the whole network to ensure the integrity and security of the blockchain.

Aiming at the problems that the existing video captioning models pay attention to incomplete information and the generation of expression text is not accurate enough, a video captioning model that integrates image, audio, and motion optical flow is proposed. A variety of large-scale dataset pretraining models are used to extract video frame features, motion information, audio features, and video sequence features. An embedded layer structure based on self-attention mechanism is designed to embed single-mode features and learn single-mode feature parameters. Then, two schemes of joint representation and cooperative representation are used to fuse the multimodal features of the feature vectors output by the embedded layer, so that the model can pay attention to different targets in the video and their interactive relationships, which effectively improves the performance of the video captioning model. The experiment is carried out on large datasets MSR-VTT and LSMDC. Under the metrics BLEU4, METEOR, ROUGEL, and CIDer, the MSR-VTT benchmark dataset obtained scores of 0.443, 0.327, 0.619, and 0.521, respectively. The result shows that the proposed method can effectively improve the performance of the video captioning model, and the evaluation indexes are improved compared with comparison models.

1. Introduction

With the rapid development of the mobile Internet and the rapid popularization of intelligent devices, from “Internet + Plus” to “AI + Plus,” the process of human informatization has entered a new stage. As a new type of user-generated content, short video has widely appeared on various social platforms. While people interact through video, some unhealthy videos such as terrorist violence and pornography take advantage of it, which seriously endanger the physical and mental health of young people. Therefore, the audit of short video content is of great significance. Most of the existing video auditing methods use manual means, but manual auditing has poor real-time performance and low efficiency. Using the deep learning for video content auditing can not only improve the accuracy of the audit but also support the video screen, text, and speech for multi-dimensional audit. Therefore, how to obtain the main information from short videos and convert it into natural language, analyze, and understand it has become a hot research topic in the field of text expression of video content. Video captioning is a cross-modal, cross-disciplinary

research, and has been a challenging research topic in the computer and multimedia fields [1, 2]. The video captioning aims at expressing the objects, attributes, and mutual relationships presented in the video in natural language. The research has broad application prospects, including helping visually impaired people to understand visual content such as movies and short videos, and helping existing video social platforms to identify the objectionable content.

The early work of video captioning is based on the fixed template structure [3–5], which mainly includes two phases, content recognition, and sentence generation from template. The content recognition stage is to visually recognize and classify the main objects in the video. The stage of generating sentences according to the template is to match the entities identified by the content with the categories required by the template, such as subject, predicate, object, and location. However, the method relies too much on the preset template, resulting in poor flexibility in generating descriptions and the simplex sentences. Inspired by the machine translation direction encoder-decoder framework, the current mainstream methods of video captioning use convolutional neural networks (CNNs) [6–8] in advance, which are widely

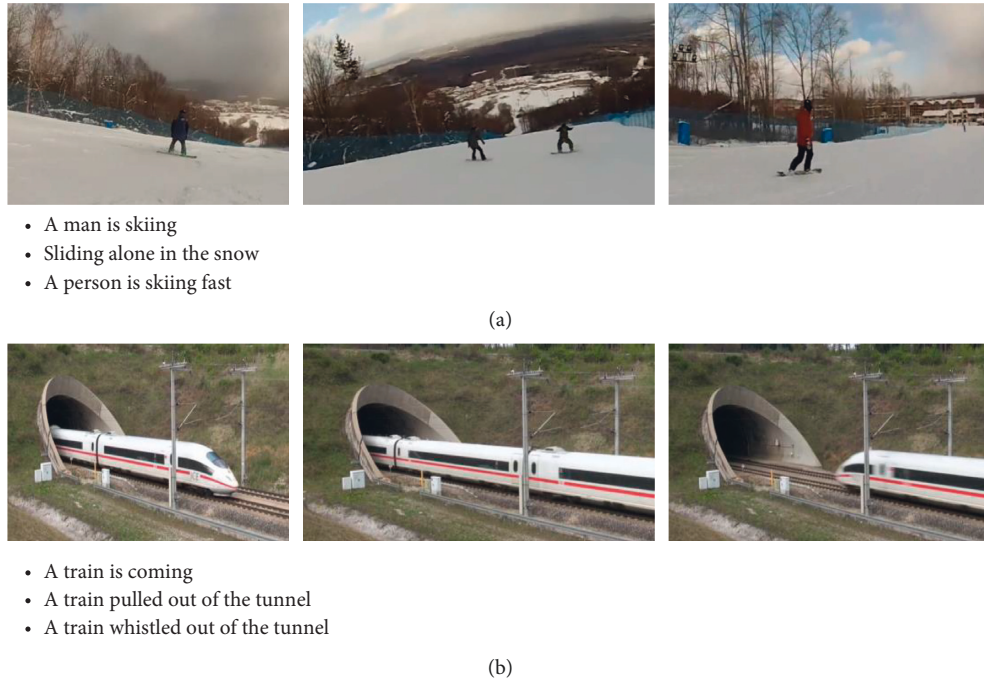

FIGURE 1: The video contains not only physical objects, but also features such as sound. When we pay more attention to these supplementary features, the generated text will be more complete. (a) Video example of fast skiing. (b) Video example of a train honking out of a tunnel.

used in the field of object recognition and detection, to obtain visual information and generate vision representation vector, and then use recurrent neural networks (RNNs) [9–11] that have made great progress in natural language processing as the encoder to receive the visual representation vector for encoding, generate the intermediate hidden vector, and send it to the decoder composed of RNN so as to generate serialized natural language expression. For example, literature [12] uses CNN to extract the image features of each frame in the video, sends it to the RNN encoder for encoding in time sequence, generates the intermediate hidden vector, and sends it to the decoder to generate the description text of the video. Literature [13] improves the performance of the video description text network by adding explicit high-level semantic attributes of images and videos, but these attributes are extracted from a single modality, which is not enough to fully understand the video. The actual video is constructed from a number of different modal contents, which contains not only a single image information, but the information such as the motion of the object in the video, the audio in the background, and the timing of the context, and the information of different modalities. There is a high degree of correlation and complementarity between them, and these modalities cooperate with each other to provide complete information. As depicted in Figure 1(a), the example video can be described as “a person is skiing fast,” in which “fast” is highly related to sports information; in Figure 1(b), the example video can be described as “there is a train whistling out of the tunnel,” in which “whistling” is closely correlated to the audio information.

Video is a recording carrier based on static pictures, but it is a higher expression than static pictures. With the movement of the object and the camera, the composition

structure and plot focus of the video screen will change accordingly, and the perspective relationship of the objects in the video will also change. This change is called the motion feature of the video; the optical flow graph of video has apparent feature invariance and contains coherent motion trajectory information. The accuracy of optical flow at the boundary and small displacement has a strong correlation to the capture of video motion information. The audio signal carried by the video is also of great significance to the video. Video dubbing can explain the main points and themes of the video in the form of sound. For example, applause and whistle can only be captured from audio information. Aiming at the problem of low accuracy of video captioning based on a single visual feature, and the high correlation and complementarity between different modal information, this article uses the fusion of multiple complementary modal information to train the video captioning model. Firstly, each frame of video in the dataset is converted into a single JPEG image, and the audio information of each extracted video is stored as an audio file in wav format. Then, the representation information of static image, audio, motion, optical flow, and other modes is extracted from the extracted modal data to cross-modal information fusion, and to generate a richer and more accurate video captioning. The main work of the research is as follows:

- (1) According to different video modal information, various models pretrained by large-scale datasets are used to extract static, dynamic, and audio information in video, which improves the accuracy of the text expression of the video content.
- (2) An embedded layer based on self-attention mechanism is designed to embed the single-mode

eigenvector and learn the network parameters needed in sentence generation. The complementary information between different modes can be fitted better when encoding.

- (3) Two schemes of joint representation and collaborative representation are used for cross-modal feature fusion, and it is verified that the collaborative representation strategy has better experimental results in this model when fusing multiple complementary video modal information.

2. Related Work

The video captioning aims at analyzing, understanding, and expressing the content displayed in the video through the use of natural language. At present, the mainstream methods of video captioning are based on the “coding decoding” architecture, which can be divided into three types: methods based on visual feature mean/maximum, video sequence memory modeling, and three-dimensional convolution features.

The method based on the mean/maximum value of visual features extracts the visual features by employing the mean value or the maximum value, and then encodes the features and decodes them to generate the natural language text. Venugopalan et al. [14] adopted an LSTM-MY model that uses mean pooling to extract visual features, and its performance is improved compared with the template-based method. Dong et al. [15] proposed the ruc-uva model to solve the problem of insufficient relevance of generated text and video content. This model extracts video keywords by combining the video tagging method and then combines the keywords and video frame features as the input of the decoder, which effectively improves the accuracy of the generated text. However, these methods are difficult to capture the time-series characteristics in video clips, which could cause the loss of dynamic features easily.

The method based on video sequence memory modeling effectively solves the problem that time-series features in video clips are difficult to capture. Literature [16] adopted a temporal attention (TA) model for video data preprocessing, which combines attention mechanism in the time dimension, generates text from the resulting feature input decoder, and selects the frame with the greatest correlation with the content to be generated in a time step to make the generated sentences more adaptable. Literature [17] applies the sequence-to-sequence model to the video to text task to solve the problem of variable length of video to text, and realizes the end-to-end video description of video frame sequence input and text sequence output. Although this type of model can realize the time-series feature extraction and end-to-end training of the language module, the CNN feature could easily lead to the destruction and loss of the spatial information in the video frame after the sequence transformation.

The method based on 3D convolution features can mine the static and temporal dynamic features of video at the same time by encoding the spatiotemporal features of video. In literature [18], the proposed model uses the 3D convolutional network to extract the three-dimensional features of

different video segments, calculates the average value of multiple three-dimensional feature vectors, and then combines them with the average value of the CNN feature extracted from the video frame as the feature representation of the video. The features extracted by the 3D convolution network contain some dynamic information of video, which improves the performance of the model to a certain extent. Literature [19] proposed the M^3 – inv3 model that jointly models visual information and language information by extracting the 2D and 3D features of the video frame, which better solved the problem of the long-term dependence of multimodal information and semantic dislocation in LSTM. Literature [20] proposes a hierarchical LSTM with the adaptive attention method for image and video captions, which uses spatial or temporal attention to select regions to predict related words. Literature [21] presents a grammar prediction action module that combines the region target features with the spatial location information of the corresponding region to form a new region target feature to guide the description generation. To further selectively integrate semantic features into the description generation model, Ryu et al. (2021) [22] used semantic alignments to establish the correlation between a word phrase and a video frame and used semantic focusing mechanism to group semantically related frames. The visual and semantic features are then passed to the codec to generate the description.

The proposed model does not fully utilize the extracted single-mode representation information and take into account the audio information carried by the video to the model. Therefore, considering the complementarity between single-mode feature parameter learning and video multimodal representation information, the semantic attributes expressed by each mode are obtained by extracting the representation information of multiple modes of video, so as to improve the performance of the video captioning model.

3. Video Captioning Model

3.1. Model Structure. The structure of the cross-modal video captioning model based on multilayer attention is shown in Figure 2. It mainly includes four parts: video preprocessing, single-modal feature extraction, coding (single-modal information embedding, multimodal information fusion), and decoding. Among them, the video preprocessing module mainly extracts the video frame and the video audio information. The single-mode feature extraction module uses the improved ResNet network [23], FFmpeg, two-stream inflated 3D convolution network [24] (I3D) to extract 2D frame features, audio MFCC features, and optical and 3D motion features of the video after increasing channel attention. The designed embedded layer is composed of a self-attention mechanism [25] and a two-layer LSTM network [26], and the encoder takes the feature vectors of the frame, motion, and audio modes as input, feeds different modal features into the embedded layer for single-mode modeling, and finally codes them into three hidden vectors $\{h_v, h_{I3D}, h_{audio}\}$ and maps the information of multiple modes together to a single multimodal vector space V_{multi} through collaborative representation. The decoder receives

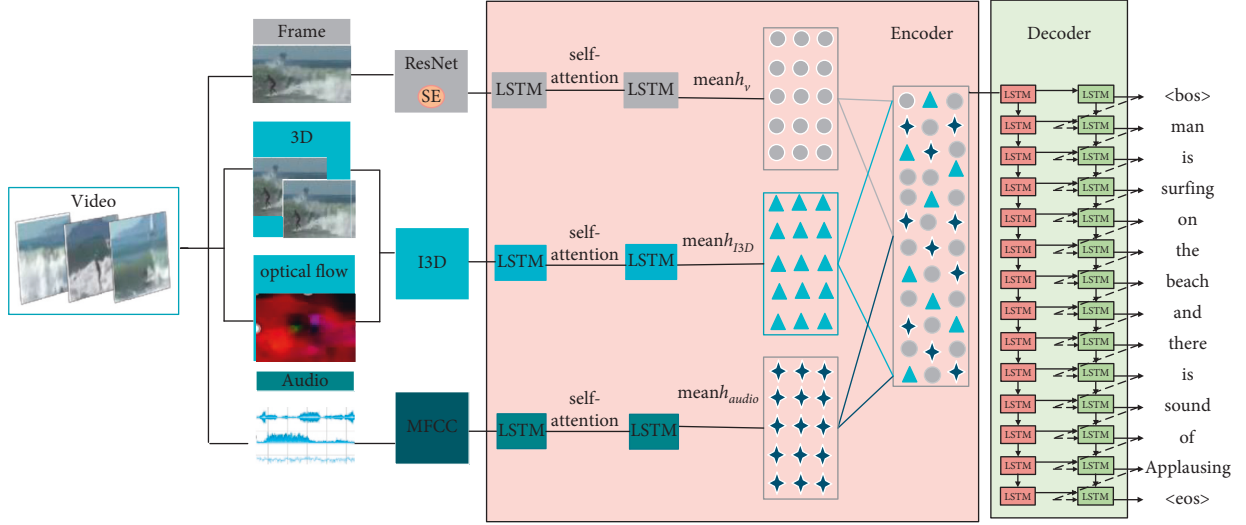

FIGURE 2: The architecture of the MM-V2T (multimodal video content text generation model). Specifically, the MM-V2T is composed of three parts as follows: video preprocessing, single-modal feature extraction, coding (single-modal information embedding, multimodal information fusion), and decoding.

V_{multi} for decoding, predicts the hidden state of the current time, outputs the probability distribution vector of each time step in turn, and uses the greedy search algorithm to take the word with the highest probability at each time step at the decoding time as the predicted output result. The word probability model of time T is shown in

$$P_t(Y)_t = \arg \max(\text{softmax}(h_t, Y_{t-1}, V_{multi})), \quad (1)$$

where h_t is the current hidden state, Y_{t-1} is the result of the last time step, V_{multi} is a unified multimodal vector space, softmax is a normalized exponential function, mapping the result to (0,1) as a probability value, and $P_t(Y)_t$ represents the probability distribution of each word in the current time step. When all probability distributions are calculated, the greedy search algorithm is used to extract the word with the highest probability in each time step at the decoding time as the prediction output until the output is $\langle eos \rangle$ and the decoding is completed.

3.2. Feature Extraction. Video data differ from picture data in that video is multiframe snapshot, which makes video more suitable for describing continuous actions or pictures. Meanwhile, the video is attached with corresponding real-time sound information, so that the video can record an event more stereoscopically and vividly. Compared to a single image, the video contains not only spatial features but also temporal features, as well as audio and motion features. Because the continuous frame structure in the video conveys a wealth of information, it is difficult to determine in the context of the more significant content to accurately describe. For this reason, we use multimodal features of video to express video content text.

For the static feature extraction of video frames, a channel attention framework unit squeeze and excitation (SE) proposed in literature [27] is added to the residual

network ResNet152 network [28] to extract frame-level 2D features.

For the extraction of dual-stream 3D features of video, the two-stream inflated 3D convolution network (I3D) proposed by the DeepMind team is adopted [29]. This network structure adds the idea of dual stream into 3D convolution, which can make the network better extract the spatiotemporal information of video and capture fine-grained temporal features.

For the extraction of audio information in the video, FFmpeg is used to extract the Mel frequency cepstral coefficient (MFCC) of the voice signal.

3.2.1. Channel Attention. The attention mechanism in deep learning draws lessons from the human visual system. For example, the human visual system tends to focus on the key information that assist judgment in the image and ignore the irrelevant information [30]. Therefore, the attention mechanism is essentially similar to the human selectivity mechanism. Attention in deep learning refers to the weight of learning parameters. The core task is to select the information more related to the current model goal from the extracted information. The extraction of video frame-level features actually extracts different information from each frame picture in different channels, so adding channel attention can give greater weight to important features. In the SE module [27], the interdependence between channels is explicitly modeled and the channel-type feature response is adaptively recalibrated. Through this mechanism, the model can learn to use global information to selectively emphasize important features and suppress redundant features. SE module realization and its structure are shown in Figure 3.

In the SE module, there are three key operations: squeeze, excitation, and reweight. In Figure 3, (a) network input matrix X is given, and its characteristic channel is C' .

FIGURE 3: SE network structure.

After a series of convolution and other operations, a characteristic diagram with the number of characteristic channels of C is obtained. Then, the three operations of the SE module are used to recalibrate the previously obtained feature map U .

The first is the squeeze operation. This operation compresses the feature map U along the spatial dimension. The two-dimensional information of each characteristic channel is compressed into a real number Z_C , which has a global receptive field to a certain extent. Z_C represents the global information of the response on the characteristic channel. Formally, the statistic Z_C is generated by reducing the space dimension ($H * W$) of the characteristic graph U , so the c th element of z is calculated in the following:

$$Z_C = F_{sq}(U_c) = \frac{1}{H \times W} \sum_{i=1}^H \sum_{j=1}^W u_c(i, j). \quad (2)$$

In order to take advantage of the information gathered in the squeeze operation, the second important operation exception is carried out. The exception is similar to the design of the gate in the cyclic neural network structure. This operation aims at capturing the channel dependence completely. The excitation operation is implemented with two fully connected (FC) structures to reduce the model complexity and to improve the model generalization ability. The first FC layer reduces the C channel into c/r channels, and the dimension reduction factor r is a super parameter. The second FC layer is used to restore the original dimensions of the feature map. Finally, a weight coefficient S is obtained, which is calculated as in the following equation:

$$S = F_{ex}(z, w) = \sigma(g(z, w)) = \sigma(w_2 \delta(w_1 z)), \quad (3)$$

where σ represents the sigmoid function and δ represents the ReLU function, $w_1 \in R^{c/r \times c}$, $w_2 \in R^{c \times c/r}$

Finally, the reweight operation is performed. The weight output from the previous operation is weighted to the previously obtained feature map U channel by channel, and the recalibration of the original feature on the channel dimension of the feature map is completed to obtain the final attention feature \tilde{X}_C . The calculation of \tilde{X}_C is shown in the following equation:

$$\tilde{X}_C = F_{scale}(u_c, s_c) = s_c \cdot u_c, \quad (4)$$

where F_{scale} refers to the channel multiplication between the attention weight s_c and the feature map u_c .

The SE module finally performs an attention or gating operation in the channel dimension. This attention mechanism allows the mode to pay more attention to the channel features with the largest amount of information and suppress the unimportant channel features.

3.2.2. Feature Extraction of Video Frame. For the video frame feature extraction part, the SE (squeeze and excitation) module is added to the improved ResNet152 network structure and used as the video frame feature to extract the network. As shown in Figure 4, the SE module is embedded in the ResNet152 network to readjust the important features extracted by the network, so that the global information can be used to measure the importance of each feature and obtain the correlation between two channels, so as to assist in the recalibration of features. In order to simplify the complexity of model parameters, a $1 * 1$ full connection layer is adopted at both ends of the ReLU activation function of the SE module [31]. The advantages of this approach are as follows: (1) making the network more nonlinear and better fitting the complex correlations between channels; and (2) promoting useful features and suppressing features that are of little use to the current task.

Each video in the dataset is preprocessed into fixed frames, and 80 of them are taken as sample frames at equal intervals. Then, these sample frames are sent to the SE-ResNet model pretrained on the large-scale image dataset ImageNet to extract the feature information of the frames and obtain a high-dimensional feature vector of $80 * 2048$.

3.2.3. Feature Extraction of Two-Stream I3D. Two-stream inflating 3D convolution network [29] I3D is one of the latest 3D convolutional networks proposed by the deep mind team. Since two-stream can capture action information simply and effectively, this network structure adds the idea of dual stream to construct an I3D network in 3D convolution. One 3D structure is used to receive RGB information, and the other is used to receive optimized smooth optical flow information. These two 3D convolution structures are derived by improving the 2D convolution structure Inception v1, as shown in Figure 5(a). The convolution kernel parameters in the 2D structure are repeated in the time dimension to form the parameters of the 3D convolution kernel, and then, the parameters are divided by N to ensure that the network output is the same as the 2D convolution.

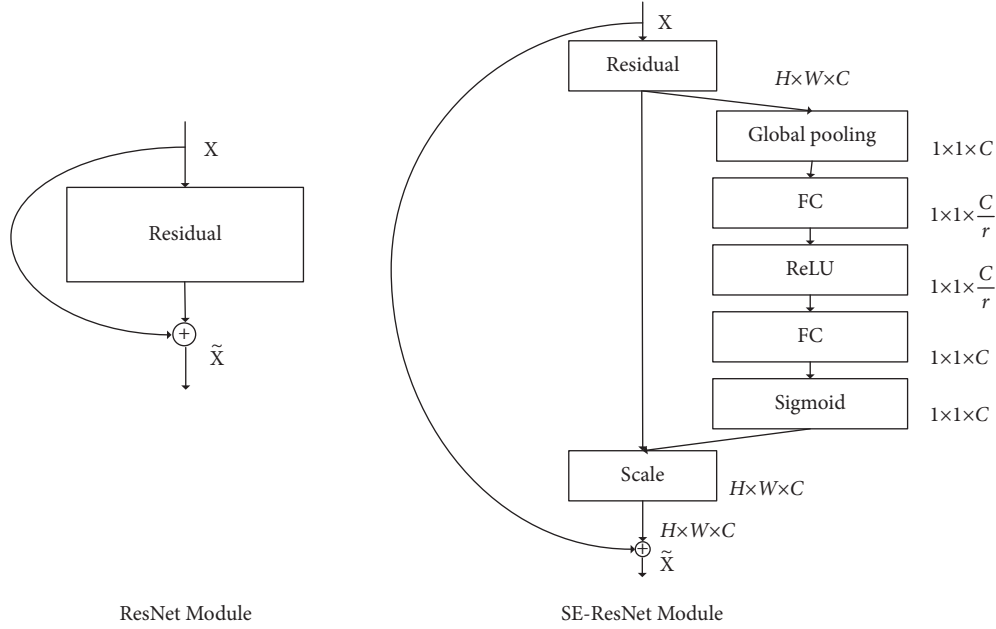

FIGURE 4: ResNet original structure and ResNet structure embedded with SE module.

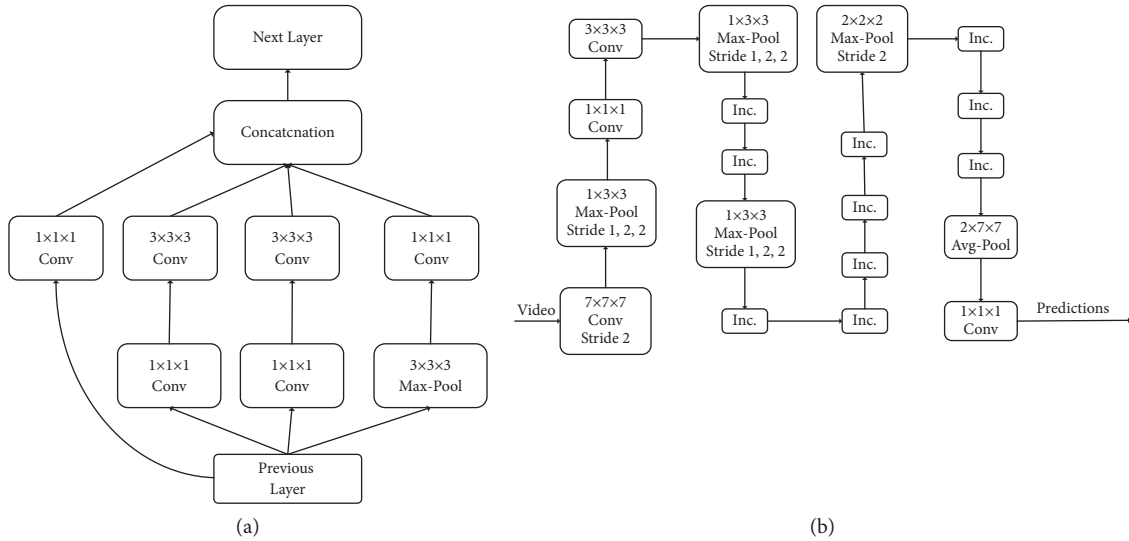

FIGURE 5: Three-dimensional convolution and two-stream expansion 3D convolution network structure. (a) 3D Inception V1. (b) I3D.

Therefore, the convolution kernel and pooling increase the time dimension, and other nonlinear layer structures remain unchanged. The network connection details are shown in Figure 5(b). Although 3D convolution can learn the time features of a video directly, it only performs pure forward propagation, and the optical flow algorithm provides some iterative ideas in it, the recognition accuracy of the network can be improved by adding optical flow.

Each video in the dataset is preprocessed into a $224 * 224$ fixed frame and sent it to the I3D model pretrained on the large-scale image dataset ImageNet and the video dataset kinetics to extract the dynamic features of the video to obtain a feature vector.

3.2.4. Feature Extraction of Audio MFCC. At present, the commonly used speech feature extraction methods include linear prediction cepstral coefficient extraction method [32], linear predictive cepstral coefficient (LPCC), and Mel frequency cepstral coefficient extraction method [33], and Mel frequency cepstral coefficient (MFCC). MFCC was proposed by Stevens, Volkman, and Newman in 1937. MFCC is mainly based on human nonlinear auditory mechanism to simulate the function of the human ear for speech frequency analysis, so as to better extract speech signal features. Mel is the measurement unit of perceived tone or tone frequency, and 1 Mel is 1/1000 of the tone perception degree of 1000 Hz. The specific definition is shown in the following equation:

$$f_{mel} = 2595 \log_{10} \left(1 + \frac{f_{Hz}}{700} \right), \quad (5)$$

$$f_{mel} = 1125 \ln \left(1 + \frac{f_{Hz}}{700} \right),$$

where f_{Hz} is the actual linear frequency and f_{mel} is the Mel frequency standard.

The cepstrum parameter feature of the Mel filter plays an important role in speech feature extraction. Its calculation is simple, and its discrimination ability is prominent. The feature parameter extraction principle of MFCC is shown in Figure 6.

First, the audio signal extracted from the dataset is preprocessed, such as pre-emphasis, framing, and windowing, and then, the corresponding discrete Fourier

transform is performed on the single frame signal after framing to obtain the frequency-domain data, as shown in the following equation:

$$X_i(k) = \sum_{n=1}^N x_i(n) \text{ExponentialE} \left[\frac{-j^2 \pi n k}{N} \right]; \quad 1 \leq k, n \leq N, \quad (6)$$

where $x(k)$ represents the time domain signal; $x_i(k)$ is the data of the i -th frame; and K represents the k th spectral line in the frequency domain.

Secondly, the frequency-domain data obtained above are filtered by W Mel frequency filters, and the spectrum, Mel filter banks, and frequency envelope are extracted. The frequency-domain response of the filter $H_w(k)$ is in the following equation:

$$H_w(k) = \begin{cases} 0, & k < f(w-1) \\ \frac{2(k-f(w-1))}{(f(w+1)-f(w-1))(f(w)-f(w-1))}, & f(w-1) \leq k < f(w) \\ \frac{2(f(w+1)-k)}{(f(w+1)-f(w-1))(f(w)-f(w-1))}, & f(w) \leq k \leq f(w+1) \\ 0, & k > f(w+1) \end{cases}, \quad (7)$$

where $\sum H_w(k) = 1$; $f(w)$ is the center frequency of the filter.

Then, the logarithm of the processed energy spectrum is taken so that the amplitude multiplication in the Fourier transform is converted into addition to obtain the logarithmic energy, which is calculated in the following equation:

$$S_i(w) = \ln \left(\sum_{k=0}^{N-1} |X_i(k)|^2 H_w(k) \right); \quad 0 \leq w < W, \quad (8)$$

where i is the i -th frame and k is the k -th spectral line in the frequency domain.

Finally, it is substituted into the discrete cosine transform (DCT) to obtain the MFCC coefficient, which is calculated in the following equation:

$$MFCC(i, n) = \sum_{w=0}^{W-1} S(w) \cos \left(\frac{\pi n (w + 0.5)}{W} \right), \quad (9)$$

$$0 \leq w < W, n = 1, 2, \dots, L.$$

where W is the w -th Mel filter, i is the i -th frame, and n is the spectral line obtained after DCT.

The audio extracted from each video in the dataset is divided into 1120 frames, and the MFCC signal of 20 dimensions is extracted from each frame and stored as an $1120 * 20$ high-dimensional audio feature matrix.

3.3. Feature Fusion. The information fusion of different modes is a key point in multimodal research, which integrates the information extracted from different modes into a stable multimodal representation. There are two multimodal feature fusion strategies [34]: joint representations and coordinated representations.

Joint representation is shown in Figure 7; this method maps the information of multiple modes together into a unified multimodal vector space. After multiple modal features x_1, \dots, x_m are obtained, the characteristic $X = f(x_1, \dots, x_m)$ is obtained by splicing and fusing. When the splicing vector dimension is high, principal component analysis (PCA) dimensionality reduction operation is carried out to form a multidimensional feature vector space $F = PCA(X)$.

Collaborative representation is shown in Figure 8. Instead of seeking fusion, this method models the correlation among various modal data but maps the information of

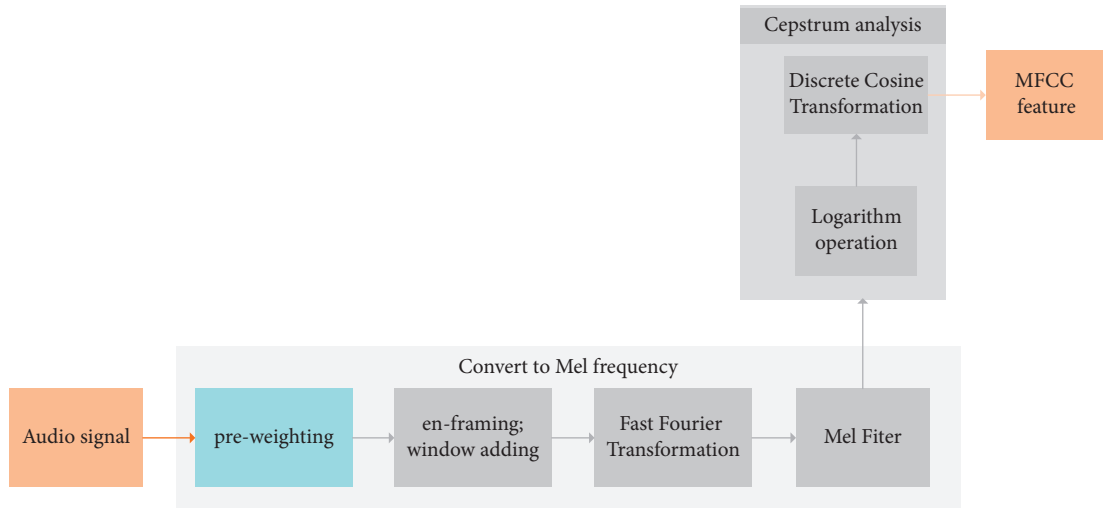

FIGURE 6: MFCC feature parameter extraction.

FIGURE 7: Joint representation.

FIGURE 8: Collaboration representation.

multiple modalities to a collaborative space, which is expressed as $f(x_1) \sim f(x_n)$, where \sim represents a collaborative relationship. The goal of network optimization is to optimize the cooperative relationship.

As shown in Figure 2, the various modal features extracted from the pretraining model are input into the embedded layer based on the self-attention mechanism for

single-mode parameter learning. Then, the extracted multimodal feature vectors are fused by the above two fusion methods. As shown in Table 1, in the ablation experiment results, it is found that for the field of video captioning, the performance of cooperative representation and fusion of multimodal features is better than joint representation. The joint representation structure retains

the independent representation space of multiple modes, which is more suitable for applications with only one mode as input, such as cross-modal retrieval and translation. However, the cooperative representation structure pays more attention to capture the complementarity of multimodes and obtains multimode representation X by fusing multiple input modes X , which is more suitable for multimode as input.

4. Experimental Design and Result Analysis

4.1. Experimental Hardware Platform. In this experiment, the server CPU is 48-core Intel(R) Xeon(R) Gold 5118, the running memory is 128G, the GPU card is NVIDIA Tesla V100, the video memory is 32G, and the operating system is Ubuntu18.04. NVIDIA CUDA 11.3, cuDNN V8.2.1 deep learning acceleration library, and PyTorch deep learning framework supporting GPU acceleration are installed.

4.2. Datasets

4.2.1. MSR-VTT. MSR-VTT [35] is a large public dataset released by Microsoft in 2016 for research into video-

generated text. We used the updated MSR-VTT from the 2017 competition, which contains 10,000 training video clips and 3,000 test video clips for a total of 41.2 hours. On average, each clip contains 20 natural language tags, 200000 statements in total. The dataset contains the most comprehensive and representative video content that consists of 257 popular categories from 20 representative categories (including cooking and movies) of the real video search engine, which is conducive to enhance and verify the generalization ability of the video semantic description algorithm. The content distribution of the dataset is shown in Figure 9. The x -axis is the video category, a total of 20 categories, and the y -axis is the total number of videos under each category.

4.2.2. Large-Scale Movie Deion and Understanding Challenge Dataset. The large-scale movie description challenge LSMDC dataset is based on the joint presentation of MPII Movie Description Dataset (MPII-MD) [36] and Montreal Video Annotation Dataset (M-VAD) [37]. The dataset contains more than 128K sentence fragment pairs and 158-h video. The training, validation, public, and blind test sets contain 101079, 7408, 10053, and 9578 video clips,

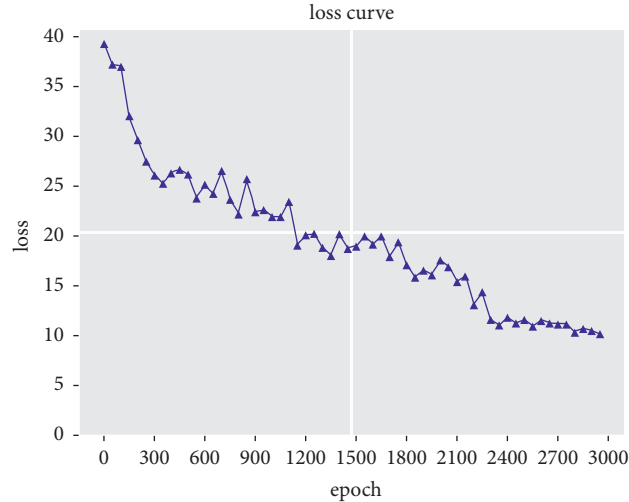

FIGURE 10: Decline curve of the training loss value.

respectively. Since the vocabulary used to describe action movies may be quite different from those used in comedy movies, this division balances the types of movies in each group, making the data more evenly distributed.

4.3. Evaluation Metrics. For model performance evaluation, four algorithms widely used in the field of video caption, namely, consensus-based image description evaluation (CIDEr) [38], Metric for Evaluation of Translation with Explicit Ordering (METEOR) [39], Recall-Oriented Understudy for Gisting Evaluation Longest Common Subsequence (ROUGEL) [40], and Bilingual Evaluation Understudy (BLEU) [41], are used as evaluation indicators to calculate evaluation scores for the model in this article and the comparison model, thereby objectively evaluating the effect of the model's sentence description generation.

4.4. Experimental Parameters and Result Analysis

4.4.1. Experimental Parameter Settings. Scaling the extracted original frame size to $256 * 256$ pixels before the model reads each frame. When extracting features, perform 15° random rotation on each frame of the image, which is needed firstly, and then perform random clipping to obtain an image with the size of $224 * 224$ pixels. Summarize and count the text vocabulary after the word segmentation, and then form a vocabulary list that consists of the words that are larger than the low-frequency threshold, and remove the vocabulary below the low-frequency threshold. Finally, select the vocabulary threshold as 5 and get 16860 words.

In the training phase of the model, Adam's algorithm [42] is used to optimize the parameters of the model. The parameters of the optimizer are $\alpha = 0.9$, $\beta = 0.999$, $\epsilon = 10^{-8}$. The initial learning rate of the model is 0.001, and the learning rate decay rate is 0.8. The model is trained with a learning rate decay of 0.8 for 50 consecutive rounds without loss, and the negative log-likelihood loss function is used to measure the distance between the labeled statements of the

dataset and the generated statements of the model, and the batch size is set to 128. The single-mode embedding layer adopts a two-layer LSTM network, and the numbers of LSTM layers of the fusion feature encoder and decoder are set to 1, 2, and 3.

4.4.2. Analysis of Experimental Results. During the training of the model, the average loss value is kept every 50 rounds. The curve of the loss value is shown in Figure 10. The initial loss decreases obviously. After 2300 rounds of training, the overall loss value tends to be stable.

To verify the validity of the model and the impact of specific parameters on the model, two-mode $V_f + V_{I3D}$, $V_f + V_{audio}$ and three-mode $V_f + V_{I3D} + V_{audio}$ video captioning models were trained for static frame feature V_f , motion feature V_{I3D} , and MFCC feature V_{audio} of the video. On the basis of each mode combination, the number of layers of LSTM network is set as 1 layer, 2 layers, and 3 layers for the single-mode embedded module and encoder module, and the model training experiments are carried out, respectively. The model comparison experiment is carried out under the MSR-VTT dataset, and the experimental results are shown in Table 1. Through nine sets of experiments, it can be seen that the monomodal embedding-multimodal fusion video captioning model constructed in this study can optimize the model by learning the parameters of monomodal information and fusing the representation information of multiple complementary modalities. The performance of the model also proves that there is a high degree of correlation and complementarity among different modal information. According to the data in the table, when the number of LSTM layers is fixed, the fusion of three complementary modal information including 2D frame features, I3D features containing 3D and optical flow information, and MFCC features of audio have the highest evaluation score for the model. When the mode is fixed, selecting 2 layers of LSTM layers in the embedded layer and encoder module is the best for the experiment. In the case of fixed modes and the number of layers of the LSTM network,

the model trained by cooperative representation has a higher test score than that obtained by joint representation, which proves that the effect of modal information fusion by cooperative representation in the video captioning is better. The experimental results show that the joint representation structure retains independent representation space of multiple modes and is more suitable for applications with only one mode as input, such as cross-modal retrieval and translation. The cooperative representation structure pays more attention to capture the multimode complementarity, fusing multiple input modes x_1, \dots, x_m to obtain the multimode representation $X = f(x_1, \dots, x_m)$, which is more suitable for multimode as input.

First, three modal features are fed into the embedded layer structure to learn the parameters that related to the single mode. Then, the multimodal information is fused through the joint representation and fed into the encoder-decoder. The ablation results show that the performance of the model is improved by fused audio information compared with single-mode and dual-mode cases. Compared with the single-mode fusion score evaluation indexes BLEU4, METEOR, ROUGEL, and CIDEr increased by 0.137, 0.072, 0.102, and 0.130, respectively. Compared with dual-mode fused score evaluation index, BLEU4, METEOR, ROUGEL, and CIDEr are improved by 0.084, 0.113, 0.016, and 0.124, respectively.

This study is compared with the top five model structures in the second MSR-VTT challenge, and the results are shown in Table 2.

This article also compares the results with the representative research work in the field of video captioning, as shown in Table 3.

As can be seen from Tables 2 and 3, in the evaluation indexes such as BLEU4, METEOR, ROUGEL, and CIDEr,

TABLE 4: In this article, the model is compared with the experimental results of the large-scale film description challenge in the LSDC dataset.

the model improved 0.139, 0.114, 0.125, 0.315, respectively, compared with the top five models in the MSR-VTT challenge. Compared to the authoritative models in this field, the proposed model improves 0.158, 0.090, 0.099, and 0.171, which verifies the performance improvement of the video captioning model and the superiority of the proposed model.

This article also conducts experiments based on the latest large-scale movie description challenge (LSMDC) dataset. Table 4 shows the comparison of the METEOR results of the model on the LSMDC public dataset.

The model extracts multiple modal information of the video and uses it to train the model so that the model can obtain more complementary and diversified characterization information, making the model more robust and adaptable to multiple types of video clips. The text description is more specific and accurate, which further proves that the different modal information of the video has a high degree of correlation and complementarity.

In the split test set from the MSR-VTT dataset, different categories of video were selected. Figure 11 shows the effect of the text generation of the video content under four different categories, and each dataset selected the first five true

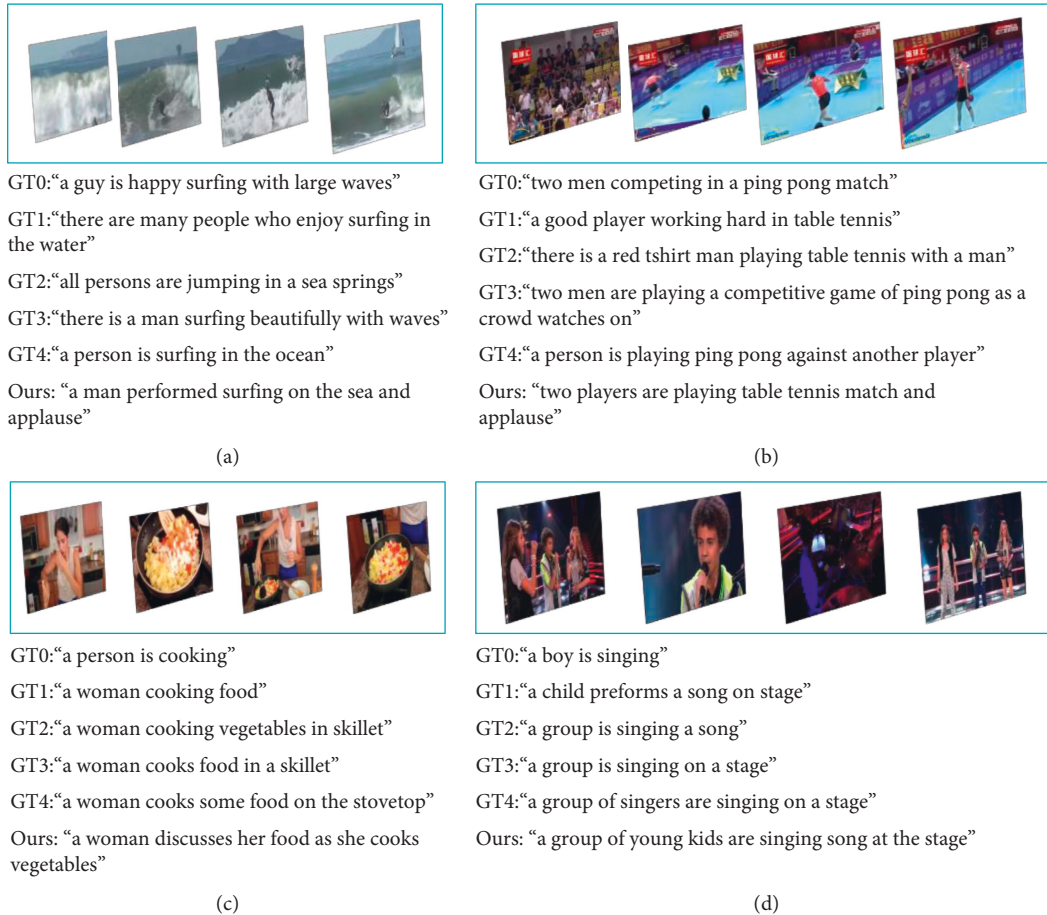

FIGURE 11: Dataset test visualization case.

markup statements (ground truth, GT), from which the visual model is generated to improve the accuracy and richness of video content text generation, and it shows that the performance of the model is improved by the fusion of multiple complementary modes.

5. Conclusion

In this article, a single-mode embedding multimode fusion video captioning model is proposed. Through a variety of efficient pretraining models, various modal representations contained in the video are effectively extracted, and static frame information, dynamic 3D, optical flow information, and audio information are complementary. The embedded layer based on self-attention is designed to learn the characteristic parameters of a single mode, which can enhance the complementarity of each mode better. Provide comprehensive and plentiful representation information for video generation text. And make the model generate more rich and accurate natural language. The above methods are verified by a series of ablation experiments and comparative experiments on MSR-VTT and LSMDC datasets. The experimental results show that the performance of the proposed model is significantly better than other models, and the generated text is more accurate.

In the later research work, we will make further improvements on the method of cross-modal information fusion and the complementarity of modal information. Combined with the attention mechanism to do further improvement work, make the alignment of various modal information with the text more accurate, and make the model obtain more accurate and rich representation information, so as to generate high-quality text and ensure the lightweight of the model.

Due to the narrow range of route search and the single choice of the optimal route during the peak period of tourists' tourism, resulting in a long walking time and relatively high route cost, an intelligent tourism information service model considering tourists' experience is proposed in the environment of Internet of things. Firstly, the overall architecture of the Internet of things environment is designed to obtain the characteristic data of the carrying capacity of scenic spots, including tourism resources, psychology, ecology, and economic carrying capacity, based on which the tourist perception experience model is constructed; different service functions such as in-depth mining of Web content, personalized information push, and data information conversion under the environment of Internet of things and the construction of intelligent tourism information service model are realized. The experimental results show that the passenger flow prediction error of the designed model is small and has a good prediction effect of tourist attraction selection demand.

1. Introduction

Driven by the rapid development of information technology and Internet technology, tourism has ushered in a golden period of rapid growth. With the gradual development of the national economy and the increase in leisure time and disposable income, tourism has become an important way of entertainment for residents [1]. Because ecotourism has the characteristics of objectivity, dynamics, and management, it is difficult to measure its environmental carrying capacity. There are still great disputes on the selection of indicators and influencing factors [2]. In the open Internet of things environment, the total amount of data information shows a geometric growth, which causes great resistance to the rapid retrieval service of data information [3]. In the Internet of things environment, it is impossible to quickly confirm the current location and return to the specified node. Secondly, due to the limited receiving and holding capacity of information users, it is difficult to correctly understand and apply information [4,5]. Although the emergence of various

search engines has satisfied the basic needs of information users to a certain extent, the quality of information retrieved is poor due to the huge amount of Internet information and the existence of information overload [6, 7]. Considering the tourist experience, the intelligent tourism information service model is established, which not only has the function of fast retrieval and collection but also integrates the Internet of things retrieval functions such as personalized database, favorites, and hyperlinks, which significantly improves the information retrieval efficiency.

Reference [8] presents an assessment of the comparative advantage shown by Ukraine's export of tourism services to the EU. For those countries where tourism is an important source of national income and a job-creating activity, the question of tourism and the revitalization of the tourism sector become urgent following the devastating consequences of the pandemic. Tourism stimulates the development of small- and medium-sized enterprises, has great potential for a creative economy, enables rapid recovery of costs, has a significant environmental impact, and enables a

high degree of social inclusion, including the use of women and youth labour. Reference [9] proposed the impact of applied quality standards on improving environmental tourism services in nature reserves in southern Jordan. The study population included tourists from all nature reserves in southern Jordan. Descriptive analysis was used to conduct a field survey of 600 visitors to a nature reserve in southern Jordan, selected by a simple random method, through questionnaires. Using statistical analysis of social science statistical procedure according to the results, in the south of Jordan nature reserves, tourist service quality standards to improve the environment have a significant statistical effect, and the study suggested southern Jordan nature reserve management department to make a plan, through continuous application of quality standards, to ensure to improve its ecological tourism services.

Although the above research has made some progress, there is less consideration of tourists' experience. Therefore, an intelligent tourism information service model considering tourists' experience in the Internet of things environment is proposed to adapt. The overall architecture of the Internet of things environment was designed to obtain the characteristic data of tourist attractions' carrying capacity, and based on this, the tourist perception experience model was constructed. Different service functions such as in-depth mining of Web content, personalized information push, and data information conversion can be realized in the Internet of things environment, to adapt and meet the personalized information retrieval and use needs of tourists in the Internet of things environment.

2. Intelligent Tourism Information Service Model considering Tourist Experience in the Environment of Internet of Things

2.1. Overall Architecture of Internet of Things Environment. The overall architecture of the Internet of things environment can be divided into four main levels of "cloud management edge end."

2.1.1. Cloud Level. The "cloud" layer can realize the functions of intelligent tourism information service terminal connection, system deployment, data decoupling, and so on, which meets the conditions of high-speed response to the demand for tourism information service and intensive system operation and maintenance [10].

2.1.2. Pipe Level. This layer uses the system of the integration of remote communication network and local communication network to meet the needs of intelligent tourism information service through channel IP, network protocol, and resource self-description.

2.1.3. Edge Level. The architecture of "unified hardware system + edge operation + business software" is used to integrate the functions of network, computing, and storage, combined with edge computing to improve the real-time processing performance and reduce the computing pressure; the terminal

is defined according to the software to realize the flexible deployment of intelligent tourism information service [11].

2.1.4. End Level. This level can collect information such as the operation of intelligent tourism information service, equipment, and environmental status and can execute decision-making commands to realize timely communication with tourists. The overall architecture of the Internet of things environment is shown in Figure 1.

2.2. Obtain the Characteristic Data of Carrying Capacity of Scenic Spots. From the perspective of tourists' experience and keeping the tourism demand and tourism supply of the scenic spot in a relatively ideal state, the transportation carrying tools of tourists and the facilities or space occupied by them in a specific time are determined through the combination of quantitative and qualitative methods, to obtain the characteristic data of the carrying capacity of the scenic spot, including the carrying capacity data of tourism resources, tourism psychological carrying capacity data, tourism ecological carrying capacity data, and tourism economic carrying capacity data [12,13]. The specific contents of data acquisition are shown in Table 1.

For the data of tourism resource carrying capacity, the calculation formula is as follows:

$$R_j = \frac{T_a}{T_1} \times \frac{S_a}{S_1} \quad (1)$$

In formula (1), R_j represents the actual limit daily capacity of resources, T_a represents the opening time of tourist destination every day, T_1 represents the actual visiting time of each tourist, S_a represents the resource area, and S_1 represents the minimum space standard of each tourist.

For the data of tourism psychological carrying capacity, the calculation formula is as follows:

$$C_{zl} = \frac{T_a}{T_1} \times k \times S_a \quad (2)$$

In formula (2), C_{zl} represents daily psychological capacity and k represents reasonable capacity per unit area of space.

For the data of tourism ecological carrying capacity, the calculation formula is as follows:

$$S_{tc} = \frac{\sum_{i=1}^n S_i T_i + \sum_{i=1}^n Q_i}{\sum_{i=1}^n P_i} \quad (3)$$

In formula (3), S_{tc} represents the daily ecological capacity, n represents the specific number of pollutants, and S_i represents the specific number of i pollutants absorbed and purified by the ecological environment, T_i represents the specific purification time of each pollutant, Q_i represents the amount of Q_i pollutants treated manually every day, and P_i represents the actual amount of pollutants (type i) produced by each tourist every day.

For the data of tourism economic carrying capacity, the calculation formula is as follows:

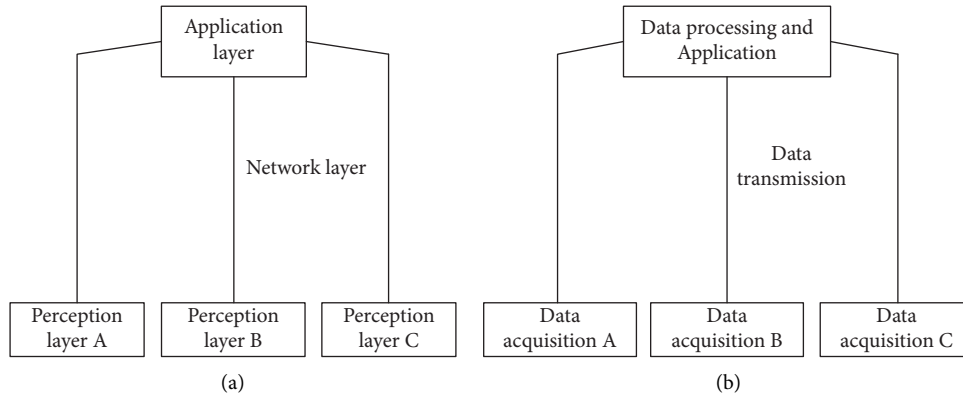

FIGURE 1: Overall architecture of Internet of things environment.

TABLE 1: Specific contents of data acquisition.

Serial number	Data type	Specific content of data
1	Tourism resources carrying capacity	Actual limit daily capacity of resources
2	Tourism psychological carrying capacity	When tourists can get greater satisfaction, the maximum tourism activity capacity that the region can carry
3	Tourism ecological carrying capacity	The ability to treat tourism pollutants through artificial methods and ecological environment absorption and purification methods
4	Tourism economic carrying capacity	It refers to the reception capacity of basic tourism facilities, related facilities, and industrial supporting facilities, represented by the actual supply capacity of entertainment and accommodation facilities

$$\begin{cases} T_e = \frac{\sum_{i=1}^m D_l}{\sum_{i=1}^m E_l} \\ T_h = \sum_{i=1}^{n_l} B_j \end{cases} \quad (4)$$

In formula (4), T_e represents the daily carrying capacity of food supply tourism, m represents the specific types of food consumed by tourists, D_l represents the supply of l kinds of food per day, E_l represents the l food demand per person per day, T_h represents the daily carrying capacity of accommodation bed tourism, B_j represents the specific number of accommodation beds in class j tourism areas, and n_l represents the actual types of accommodation facilities.

2.3. Tourist Perception Experience Model. Tourism activities involve many factors, not only taking tourists as the main participation but also taking the image of the scenic spot as the main behavior. Scenic spots attract tourists with specific resources and carry out relevant activities. Whether tourism resources have a certain tourism attraction depends not only on the tourism resources of the scenic spot but also on the comprehensive object environment of the scenic spot [14, 15]. The tourism environment is an important carrier of tourism activities. The tourism environment is one of the important factors for tourists to consider whether the scenic spot is worth traveling. For example, the quality of the natural environment often affects the experience of tourists

in this process. If the scenic spot has good tourism resources, but it rains or earthquakes frequently all year round, then tourists will not come to visit. It can be seen that tourism environmental factors are very important.

Tourists bring economic benefits, promote employment, promote the protection of ecological environment and traditional culture, and inevitably bring many negative effects caused by their own lifestyle and behavioral habits to the scenic spot. Therefore, it is of great practical significance to study tourism information services from the perspective of tourists [16].

ACSI represents the core concept and architecture of tourism motivation, purchase policy, tourism, and tourism process when tourists play. As a dynamic and continuous experience process, the end of tourism can establish a tourist perception experience model through the dynamic process of tourists' comprehensive experience [17, 18]. The specific content is shown in Figure 2.

As can be seen from Figure 2, the tourist perception experience model is built on the basis of tourist resettlement experience. Tourist perception experience is a kind of social perception that tourists perceive the impact of tourism, including the perception of economy, social culture, environment, self, interpersonal relationship, and social role. Tourism experience is generated in every link of tourism product consumption, from landscape appreciation to the acquisition of various services, and the quality of service in each link will affect the quality of tourist experience [19,20]. The accuracy, safety, comfort, and reliability of information transmission determine the service quality of each element.

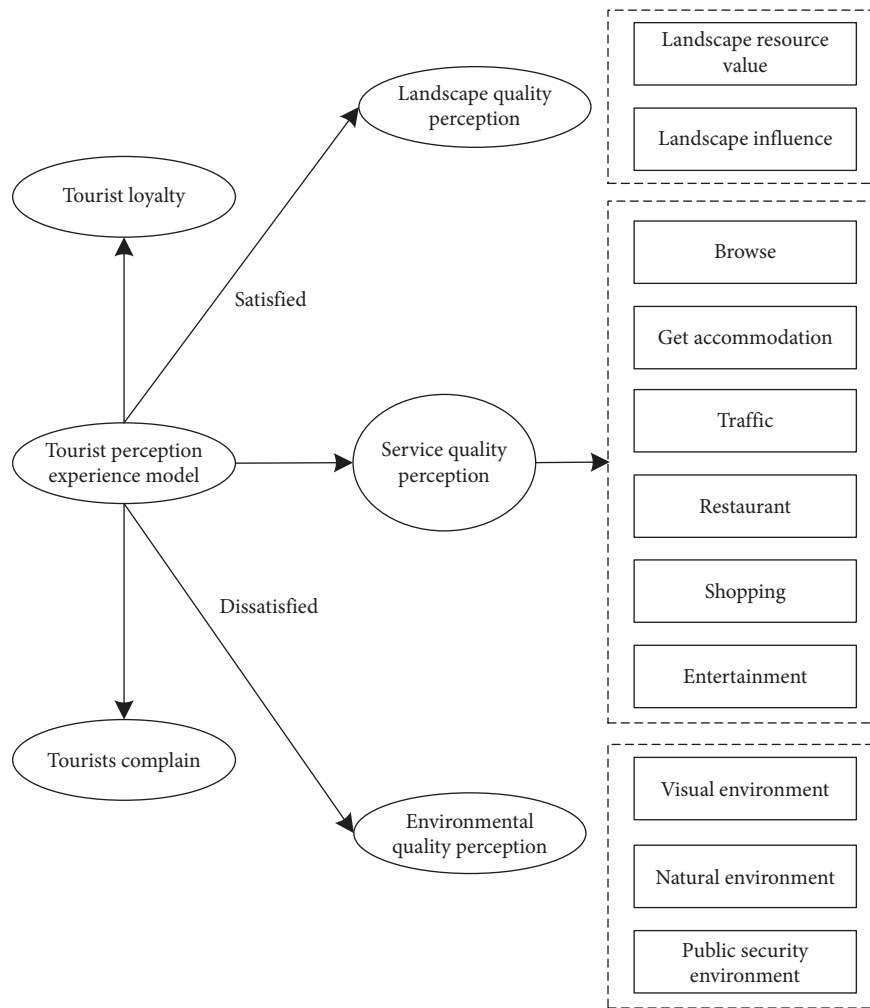

FIGURE 2: Tourist perception experience model.

Therefore, tourists can obtain more accurate comprehensive perception experience through the perception of tourism landscape quality, service quality, and environmental quality.

3. Realize the Design of Intelligent Tourism Information Service Model considering Tourist Experience

3.1. Design of Information Service Function Module. Consider intelligent tourism information service model of tourist experience, which is divided into four modules, respectively, as tourism information module, the network data retrieval module, push module, and database module, to realize the Internet environment, the depth of the Web content mining, data conversion and other personalized information push service function, the structure of the model, and the main function module design, as shown in Figure 3.

- (1) *Visitor Module.* The intelligent tourism information service model based on multimode takes tourists as the service center. The functions of the tourist module include basic information management and customized management of tourists' information needs. All personal information and account

information of tourists are stored in the module. After authorization, you can enter the account and password to log in to the system. After entering the system, tourists can add, edit, and modify tourist information by themselves after being authorized by the system administrator; through this module, tourists can put forward specific tourism information retrieval needs, customize the database list, and select the retrieval and classification query methods of tourism information. The module has the function of automatic storage and retrieval, and the historical retrieval content can be queried through keywords.

- (2) *Network Data Retrieval Module.* This module is the core module of the tourism information service model, through which tourists can retrieve and customize the content of interested weblogs [21]. To adapt to the compound multi-data transmission mode, a data retrieval network is designed. The network has good compatibility and supports different modes such as static data transmission and dynamic data transmission. The bus matrix can process 64 bit data input and output in parallel, with four I/O interfaces. The network data retrieval module can deeply mine and

FIGURE 3: Structure diagram of main functional modules of intelligent tourism information service model.

analyze the contents of the network log and actively switch the mode of tourism information retrieval according to the use habits and preferences of tourists, to obtain the retrieval habits of tourists and store keywords and characteristic words in the database, to facilitate the subsequent data call of tourists.

- (3) *Tourism Information Push Module*. The tourism information push module includes the specific functions of pushing tourism information management, tourism information generation, and tourists' use feedback. The total amount of tourism information in the network is huge, and the total amount of data information collected according to tourists' habits and preferences is huge. Push management is to preprocess and classify this redundant and wrong tourism information first, retain useful tourism information, and eliminate interference information [22,23]; through the classified retrieval of customized tourism information for tourists, the most economical tourism information transmission mode is selected in the Internet of things environment, the tourism information categories required by tourists are generated, and directional and regular push is realized [24]. The tourism information push module has a two-way information interaction function; that is, on the one hand, it transmits basic tourism information to tourists, and on the other hand, it also receives tourists' feedback, to optimize each module of the system and continuously improve the database [25].

- (4) *Database Module*. According to the above three modules, the list category of the database is divided into tourist basic tourism information data, tourist search tourism information table, and personalized data table, as shown in Tables 2–4, respectively.

Other forms in the database are extended and expanded on the basis of the basic form and connected with the basic form through the primary key field, which is convenient for tourists' retrieval and query.

3.2. Realize Intelligent Tourism Information Service Model. The Internet of things is taken as the goal of tourists' experience perception, an intelligent tourism information service model is established through intelligent perception, a large number of tourism-related real-time information are mined through the Internet of things, such as scenic spot tickets, accommodation places, weather, and meteorology, this information is gathered and analyzed, and the tourism information available for service is summarized [26,27].

To establish an intelligent tourism information service model, we need to take the big data of the Internet of things as the goal and use multi-agent technology to divide the establishment of the model into multiple modules, namely data acquisition, data perception, data decomposition, data storage, data integration, central control, and data display modules. Among them, data acquisition is responsible for the input of the model, collecting the tourism big data of the Internet of things through the compiled crawler program,

Ind	Data	Flo	10	Yes	No

making preliminary selection and filtering, and submitting the data to the data decomposition module after completing the preliminary processing; the data decomposition module decomposes the collected data into multiple parts through extraction, filtering, decomposition, and other operations and submits them to the perception module [28]; after sensing the tourism information, the perception module in the platform selects the tourism data with service value in a unified format through weighted calculation and normalization processing and then integrates this data information with service value into independent data through the data integration module, which is stored in the data storage module, managed storage, and provided to the data display module, and the data are displayed in front of tourists.

The central control module is responsible for connecting each module in the perception model, controlling the information exchange of each module, and the processed request link queue established by the manager in the process of obtaining the tourism data of the Internet of things, so that the whole platform can effectively process the tourism big data and communicate information [29].

In the above, the data collection is mainly realized through the Web page analysis algorithm, which is not simply judged according to whether all the text of the Web page is related to the given subject. This judgment method lacks certain reliability. In the process of establishing the intelligent tourism information service model [30], the data

collection is mainly based on the theme relevance of the parent Web page of the Internet of things. The correlation between the current Web page and the theme and the location of the Web page link is comprehensively determined. The final result may be a continuous value between 0 and 1. The closer the value is, the higher the correlation between the collected data and tourism service information, which proves that the collected data are the target data of the platform [31,32].

Assuming that the 0/1 mode is used to represent whether tourists have been to the scenic spot, the check-in times of tourists correspond to the degree of interest of tourists in the scenic spot. Therefore, the similarity between tourist interest points is solved using the check-in times of tourists in the scenic spot, and the expression is as follows:

$$X_{qd} = \frac{\left(\sum y_{i,j} \times y_{k,j}\right)}{\sum y_{i,j}}. \quad (5)$$

In formula (5), $y_{i,j}$ represents the check-in frequency of a tourist $y_{i,j}$ in scenic spot j and $y_{k,j}$ represents the check-in frequency of another tourist in scenic spot j .

The first N' tourists with the greatest similarity are selected according to the similarity between tourists. These tourists are used to form a set U_I , and the possibility that tourists will go to the scenic spot without checking in is solved according to the collaborative filtering model based on tourists. Then, the formula is as follows:

$$Y_{qd} = \frac{\left(\sum X_{qd} \times y_{k,j}\right)}{\sum X_{q,d}}. \quad (6)$$

Assuming that a tourist has been to m cities, the expression of the number of interest points that can be mined is obtained according to the sign-in times and stay time of his activity track:

$$Z_{qd} = \left(\frac{\sum l_c}{m}\right) \times X_{qd} \times Y_{qd}. \quad (7)$$

In formula (7), l_c represents the vector set represented by the points of interest. To ensure that the mining of interest points is comprehensive enough, it is necessary to use the characteristics of tourist similarity, social relations, and geographical location information to realize the mining [33,34]. Because the probability values of interest points are different, the standardized weighting method should be used for processing during integration, and the processing results should be substituted into the model of mining interest points. The construction of intelligent tourism information service model can be realized [35,36], and its expression is as follows:

$$S_{ab} = P_{ab} \times Z_{qd} \times \lambda. \quad (8)$$

In formula (8), P_{ab} represents the collection of users check-in interest points, and λ represents the training parameters. Intelligent tourism is a highly complex and dynamic field. Intelligent tourism information service providers often need to rely on models to predict the marketing objectives of

FIGURE 4: Environment diagram of simulation experimental platform.

the tourism market and explore the potential market. Users also need tourism information to assist decision-making. These need to be realized through the organization and integration of intelligent tourism information service models. There is an urgent need for an Internet of things processing technology to organize them in depth. In the Internet of things environment, various network information technologies are used as a structured data application specification, to realize the construction of intelligent tourism information service model considering tourist experience in the Internet of things environment.

4. Experimental Analysis

In the experimental platform of this study, the CPU is Intel (R) Q4800, the frequency is 2.66 GHz, the computer memory is 512 GB, the simulation programming environment is MATLAB 2016 under windows 10 system, the classifier uses LIBSVM and grid search method for parameter optimization, and the kernel function used is Gaussian kernel. The experimental equipment includes two servers and one client, which stores the communication transmission information in the cloud. The experimental environment is shown in Figure 4.

According to Figure 4, to ensure the time synchronization between sampling and updating, the time can be calibrated by smoothing and extrapolation. To ensure the reliability of the experiment, the experiment is carried out according to the method in Figure 5.

In the simulation platform, the initial parameters of the sensor are set: the position coordinate is $(X, Y) = (120km, 120km)$, the observation radius r_1 is 100 km, the ranging error σ_{l_1} is 150m, and the angle measurement error σ_{θ_1} is 1° . In the simulation experiment, five data sets of wine, forest, glass, iris, and segmentation used for identification in the UCI standard database are used. The basic information of the data set is shown in Table 5.

Under the five authoritative data sets in Table 5 above, the model in this study, the model in reference [8], and the

FIGURE 5: Simulation principle of intelligent tourism information service model.

TABLE 5: Basic information of data set.

Data set	Sample input dimension	Number of training samples	Number of test samples	Number of identifications
Wine	24	133	133	4
Forest	47	247	317	7
Glass	18	159	114	2
Iris	11	121	84	3
Segmentation	37	331	3310	5

TABLE 6: Experimental environmental parameters.

Experimental configuration	Experimental parameters
CPU	Dual-core 2 GHz
Effective memory, memory	3.4 GB, 4 GB
The server	ASUA RS100-X5

model in reference [9] are used for experimental verification, respectively. The experimental environmental parameters are shown in Table 6.

The dynamic virtual variable of the intelligent tourism information service model is set to 0, and the three models are used to predict the passenger flow of a scenic spot on a working day and compared with the actual value. The overall scatter diagram of the predicted passenger flow and the real passenger flow is shown in Figure 6.

According to the analysis of Figure 6, the scattered points of the passenger flow prediction results of the model in this study are roughly distributed at the 45° boundary, while the scattered points of the passenger flow prediction results of the model in reference [8] and the model in reference [9] are relatively scattered. This shows that the passenger flow prediction error of this model is small and has good effect.

FIGURE 6: Scatter diagram of model prediction period.

TABLE 7: Forecast results of tourists' demand for scenic spot selection.

Scenic spot category	Actual person times	Predicted person times	Absolute quantity difference	Relative difference (%)
Resort	10222	11433	1221	5.6
Ecological farm	25340	24200	1140	2.3
Water hole	34586	35442	-856	-1.2
Drift	38351	37607	744	0.9
Picking point	21004	19412	1592	3.9

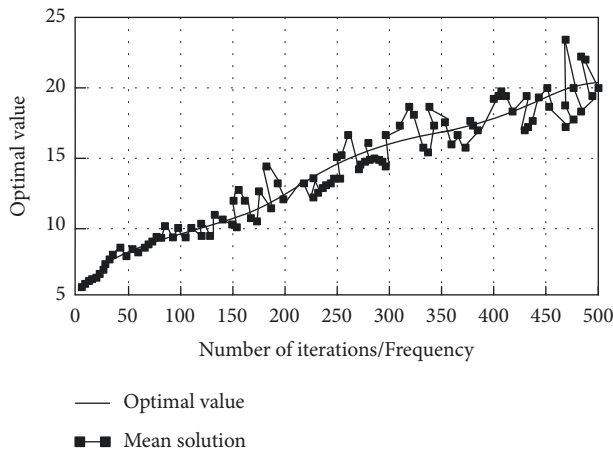

FIGURE 7: Optimal travel route search results.

To test the intelligent tourism information service performance of the model in this study, 2021 is taken as an example to predict the demand for tourists for scenic spot selection. The prediction results are shown in Table 7.

As shown in Table 2, the relative error between the number of tourists choosing scenic spots and the actual number of tourists in 2021 predicted by the model in this study is less than 6%. The experimental results show that the model in this study has a good prediction effect on the demand for selecting scenic spots. The method in this study is used to search the optimal tourism route, and the results are shown in Figure 7.

According to Figure 7, with the increase in iteration algebra, the optimal solution of the search results of the optimal tourism route shows an upward trend, the average value fluctuates up and down in the optimal solution, and the fluctuation range of iteration oscillation is small. When the number of iterations reaches 470 generations, the peak value of iteration fluctuation appears, indicating that the optimal path has been found and has good convergence.

To sum up, the prediction error of the model in this study is small and has a good prediction effect. The intelligent tourism information service model considering tourist experience in the Internet of things environment can effectively find the optimal path.

5. Conclusions and Prospects

5.1. Conclusions.

- (1) Under the environment of Internet of things, the prediction error of passenger flow of intelligent tourism information service model considering tourist experience is small
- (2) The intelligent tourism information service model has a good effect on the demand prediction of tourist attraction selection
- (3) When the number of iterations reaches 470 generations, the peak value of iteration fluctuation appears, indicating that the intelligent tourism information service model considering tourist experience in the designed Internet of things environment has found the optimal path

5.2. Prospects

- (1) As the infrastructure construction of intelligent tourism information service is still relatively backward, which is the biggest obstacle to the intelligent development of tourism industry, in the future, we can design intelligent tourism information service system under the background of intelligent tourism and use all kinds of network information technology under the environment of Internet of things to provide intelligent tourism services for tourists. Therefore, whether the establishment of the model can be truly implemented remains to be verified by the development of the times.
- (2) The next step is to establish an intelligent tourism information service model based on the tourism consumption model, user needs, and functional needs, through the current situation and investigation and analysis, and establish an intelligent tourism

information service model considering the experience of tourists using the service design methods such as tourist experience map, tourist role model, and interview. At the same time, it also needs to be verified by testing.

- (3) To facilitate the travel needs of tourists, the operation mode of intelligent tourism information service model is set as tourism app, the main functional modules of tourism app are determined according to the priority of tourist behavior path and service contact point, the corresponding service blueprint and app information architecture diagram are drawn, and the interactive interface prototype of tourism app is designed in combination with the design principles of interactive interface, and the visual design is improved.

Data Availability

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Conflicts of Interest

The authors declare that they have no conflicts of interest regarding this work.

The traditional online teaching platform has poor compatibility due to the high data delay in practical applications. Therefore, a Multimedia English online teaching platform under wireless network communication technology is designed. Aiming at the actual functional requirements of online teaching, the overall architecture of the Multimedia English online teaching platform is designed. In this architecture, the hardware of the data collector, memory, and main controller is deployed to build the platform. Based on the wireless network communication technology, the software modules are divided into two parts. It is made of a number of functional modules. The design of the platform functional modules is mainly based on the main functions of the administrator submodule, the teacher submodule, and the student submodule. At the same time, the weight of the indicators is determined by combining the analytic hierarchy process and the evaluation domain for the quality evaluation of Multimedia English online teaching is established. The level model completes the platform design. The experimental results show that the test results of the designed platform meet the expected goals and can effectively improve the quality and efficiency of Multimedia English online teaching. The teaching quality is always higher than 95%, and the average teaching efficiency is 96.27%.

1. Introduction

In order to improve the stability of the Multimedia English online teaching platform and meet the needs of Multimedia English online teaching in larger colleges, it is really necessary to improve the management mode of resources in the platform [1]. At the same time, how to carry out Multimedia English online teaching in a more vivid form is also the key to improving teaching quality [2, 3]. Wireless network communication technology refers to the long-distance transmission of signals between multiple nodes without transmission through conductors or cables. Wireless network communication can be carried out by using various fixed, mobile, and portable applications, such as two-way radio, mobile phones, personal digital assistants, wireless networks, and radio, which can make students pay more attention to learning situations and minimize the interference of the surrounding environment [4]. The Multimedia English online teaching platform breaks the restrictions of time and space, but it is more dependent on the network

environment [5]. Therefore, improving the operation ability of the platform is also the focus of future research [6].

Relevant scholars have carried out research on this; the study in [7] provides a platform for online teaching to adapt to large concurrent visits. The Multimedia online teaching platform is one of the important contents of the Internet plus education platform. Constructing an online teaching platform suitable for large concurrent access is an urgent requirement for the transmission of university information. Compared with the construction of the Multimedia English online teaching platform in colleges and universities under the new situation, there are some new problems. Large concurrent access puts forward new requirements for platform performance, network bandwidth, and teachers' and students' literacy. Based on the new objectives and main problems of educational informatization 2.0, this paper puts forward countermeasures and suggestions from the aspects of new objectives of platform construction, network bandwidth, quality of teachers and students, new platform selection concept, new platform deployment mode, new

network unblocked mode, new teaching evaluation method, new quality improvement requirements, etc. The study in [8] puts forward the practice and research of hybrid teaching of sports anatomy courses based on the Multimedia English online teaching platform and demonstrates the superiority and feasibility of the hybrid teaching mode through experimental comparison, mathematical statistics, and literature review. The results show that the students in the experimental group with a mixed teaching mode had better knowledge and understanding of the relevant contents of the experiment than the students in the control group with traditional teaching methods. The mixed teaching mode is especially suitable for the characteristics of students majoring in physical education, and it is worth popularizing and applying in the teaching of sports anatomy.

Although the above research has made some progress, the application under wireless network communication technology is not enough. Therefore, the design of a Multimedia English online teaching platform under wireless network communication technology is proposed. Wireless network communication technology is a communication method for information exchange by using the characteristics that electromagnetic wave signals can propagate in free space. It can be point-to-point communication, point-to-multipoint communication, broadcasting, cellular network, other wireless networks, and WiFi technology. Its application in the Multimedia English online teaching platform had a good effect. Setting the actual functional requirements of online teaching as the goal, the author designs the overall architecture of the Multimedia English online teaching platform, deploys hardware and software modules in this architecture, determines the index weight combined with the analytic hierarchy process, establishes the evaluation-domain level model of Multimedia English online teaching quality evaluation, and completes the design of the Multimedia English Online teaching platform. The results show that the designed platform can meet the expected objectives and improve the quality and efficiency of Multimedia English online teaching.

2. Multimedia English Online Teaching Platform Based on Wireless Network Communication Technology

2.1. Architecture Design of the Multimedia English Online Teaching Platform. The Multimedia English online teaching platform is based on the open-source platform for architecture and secondary development. In order to standardize the development process and improve the development efficiency, the overall architecture of the Multimedia English online teaching platform is designed with wireless network communication technology to achieve the design goal of the platform [9, 10]. The upper layer does not need to completely rely on the specific implementation details of the lower layer. Changing the structure of the upper layer will not affect the lower layer, making the code more concise, so as to meet the coupling requirements of various modules of the Multimedia English online teaching platform [11].

When the server receives the user's request to access the page, it first loads the global configuration file, initializes the loading core framework, such as data operation, routing, and security, schedules the controller according to the configured route, requests the business logic layer and data layer to load data, and renders the data to the page, thus completing the whole process of request operation and rendering and outputting the data to the page [12, 13]. The overall architecture of the Multimedia English online teaching platform is shown in Figure 1.

As shown in Figure 1, the Multimedia English online teaching platform adopts a hierarchical tree structure design, which can be divided into five modules: user layer, application layer, middle layer, data layer, and basic environment layer for the user [14]. According to the actual functions of these five modules, a Multimedia English online teaching platform is designed.

2.2. Platform Hardware Design. Platform hardware refers to the physical equipment that constitutes the computer and is the realistic carrier for the operation of various logic programs. In the Multimedia English online teaching platform [15, 16] designed with wireless network communication technology, the key hardware used includes a data collector, memory, and master controller, which will be analyzed in detail as follows.

2.2.1. Data Collector. The data collector is a programmable logic chip equipped with a crawler program, which can be used to complete the search and collection of user history learning data, including web browsing information, user retrieval keywords, resource download records, exchange and interaction information, and other data that can understand user preferences [17]. The programmable logic chip in this platform is EPM240T100I5N TQFP-100 CPLD. The basic parameters of the chip are shown in Table 1.

According to the basic parameters of the chip in Table 1, it can be seen that the programmable logic chip in the Multimedia English online teaching platform plays an important role and, at the same time, it needs to meet the requirements of low noise and high precision during use.

2.2.2. Storage. Massive English teaching resources and a large amount of user historical behavior data are not enough to be stored only by the storage space carried by the platform itself. Therefore, after the data collector completes a collection task, it is necessary to transfer the collected data to the external memory [18, 19]. The memory in this platform is a disk array with 12 disks, which is equipped with a 4-bit Annapurna Labs Alpine AL-324 ARM@Cortex@-A57 Quad-Core 1.7 GHz processor and 46BDDR4 memory (up to 16 GB) support SATA6Gb/s hard-disk transmission interface to provide faster read and write speed. In addition, two GbE SFP+ and two 2.5Gbe network ports are built in the disk array. Using the disk array can realize the reasonable deployment of the network environment, so as to realize the

Supply voltage-internal	2.5 V, 3.3 V
Number of logical elements/blocks	240
Number of macrocells	192
I/O count	80
Working temperature	$-40^{\circ}\text{C}\sim 100^{\circ}\text{C}$

tasks of copying, saving, repairing, and restoring massive data.

2.2.3. Master Controller. The main controller is the core hardware of the Multimedia English online teaching platform, which is mainly used for the overall operation control of the platform and the execution of various business logic operations [20]. The main controller of this platform is dtb-1022 J1900-embedded industrial computer, and its basic parameters are shown in Table 2.

According to the basic parameters of the embedded industrial computer in Table 2, it can be seen that the power supply, CPU, I/O interface, and other components are

centrally installed in a chassis, which has the characteristics of compact structure, small size, and low price and generally adopts an integral structure.

2.3. Platform Software Design. In order to further improve the overall function of the Multimedia English online teaching platform [12, 21], the software part of the platform can be divided into three modules: administrator management submodule, teacher management submodule, and student management submodule. The specific module function flow chart is shown in Figure 2.

The specific contents of the platform software design are given as follows.

2.3.1. Administrator Submodule. This module is the manager of the Multimedia English online teaching platform. Its main responsibility is platform maintenance and website management [22, 23], to ensure the stable operation of the platform and the effective development of teachers' teaching interaction. This module is the core part of the whole Multimedia English online teaching platform. The specific functions are described as follows:

- (1) *Role Division.* When logging into the Multimedia English online teaching platform with the browser for the first time, it is necessary to provide the e-mail and other contact information of new users and

Working temperature	-10°C to 70°C

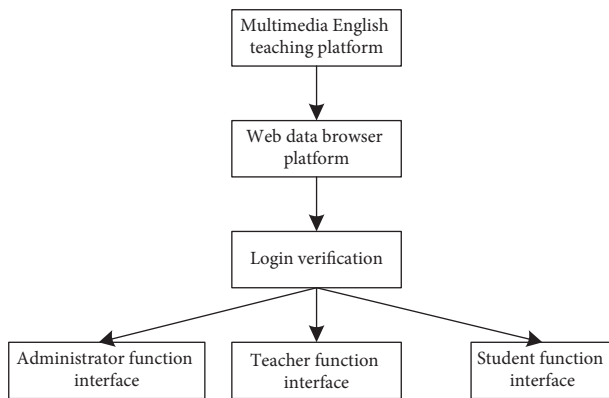

FIGURE 2: Specific design flow chart of the Multimedia English online teaching module.

realize role matching and authority division for new users according to the information provided by users [24, 25]. For example, if the new user is a teacher, the permissions that the new user can use include applying for adding or deleting courses and uploading teaching resources to the network platform; if the new user is a student, the permissions of the user include online course selection, online testing, and viewing results. At the same time, the administrator has the functions of increasing or decreasing users and managing user-level permissions.

- (2) *Course Management.* By this function, the administrator can add or delete the function categories in the platform through the actual situation of English teaching. At the same time, the administrator also has the right to move, modify, or import new courses for each function, as well as the right to restore and backup courses [26, 27].
- (3) *Web Page Setup.* The website administrator can choose to install different skin plug-ins to make the platform layout and appearance design more beautiful.
- (4) *Other Settings and Information Query.* The website administrator can view the online time, offline time, course selection, and listening and other activities of

users on this platform; notices and announcements can be issued on the platform, and multiple information can be accurately managed by using this module. The operation flow chart of the specific administrator submodule is shown in Figure 3.

2.3.2. Teacher Management Submodule. One of the main users of the Multimedia English online teaching platform is teachers. The main responsibility of the design is to provide teachers with various permissions and functions through the platform, which can better complete teaching activities. Using the characteristics of the network platform, we can vividly design the English teaching process and carry out effective interactive activities, so as to achieve the purpose of teaching in a fun manner [28, 29]. The specific functions are described as follows:

- (1) *Applying for Courses.* After receiving the notice of teaching, teachers can apply for adding new courses through the platform and simply design the new courses. At the same time, they can realize the functions of adding, deleting, modifying, moving, and so on. After the administrator imports the students into the platform in batches, group teaching can be realized according to the situation of the students.
- (2) *Teaching Design and Organizing Activities.* According to the course content and the characteristics of each course, teachers can upload teaching plans, teaching materials, teaching dynamic videos, teaching courseware, and other resources to the Multimedia English online teaching platform to facilitate the teaching process [30]. Based on the above teaching resources, they can achieve the predesigned teaching purpose, so as to improve the teaching quality and promote students to effectively acquire knowledge.
- (3) *Online Test Management.* In this function module, teachers can use the topic selection function of the question bank in the module to select the test questions in the question bank by random selection or manual selection to form the test paper. At the same time, teachers can also set the test time, the option of whether to answer again, and the number of answers and have the authority to delete, add, and change the order of the test questions. After the end of the semester teaching course, you can also use the network platform to prepare the final examination paper, in which the objective test questions can be judged by yourself through the platform.
- (4) *Personal Data Management.* Teachers can view and change personal information and also have the functions of setting up personal microblogs and transmitting personal messages. The specific operation flow of the teacher management submodule is shown in Figure 4.

2.3.3. Student Management Submodule. In the Multimedia English online teaching platform, another main user is students. In order to facilitate students to browse the network

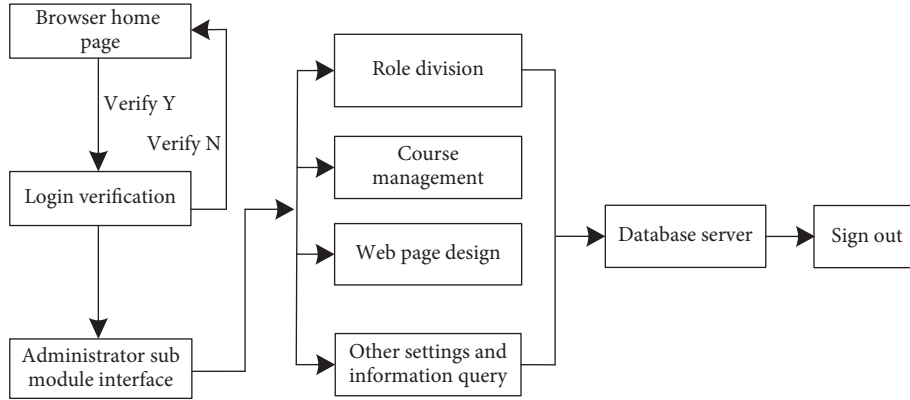

FIGURE 3: Operation flow chart of the administrator submodule.

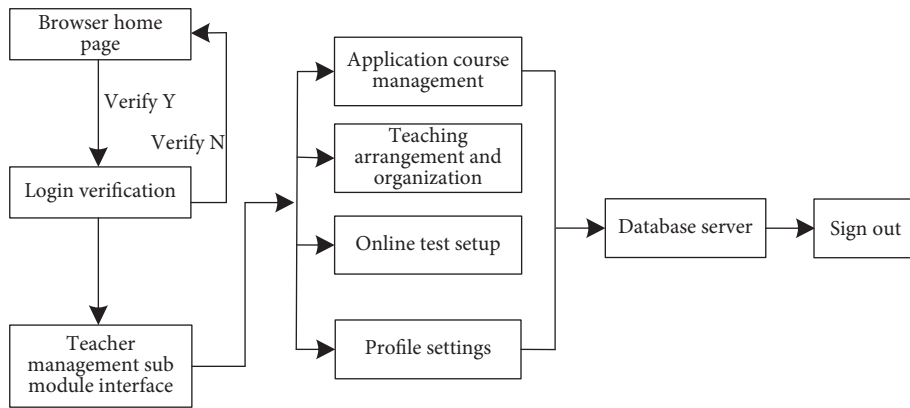

FIGURE 4: Operation flow chart of the teacher management submodule.

platform, functions such as selecting course learning, course's interactive activities, online test answers, and setting up personal data are added to the student management submodule [31, 32]. The specific functions are described as follows:

- (1) *Course Learning*. After successfully registering new users through the browser, students can view the teaching introduction and courses, as well as all learning courses in the semester.
- (2) *Teaching Interaction*. In the Multimedia English online teaching platform, according to the scene of teachers' curriculum, students can discuss relevant problems with teachers and other students to realize a series of interactive activities, so as to improve students' learning ability [33].
- (3) *Online Answers*. In order to understand students' mastery of knowledge, students can conduct online self-evaluation according to the unit test provided by teachers after the unit course. After completing the test, they can also enter the Multimedia English teaching platform to realize the score query function, which can consolidate and review knowledge [34, 35].
- (4) *Personal Data Management*. Students can change their basic personal information in the Multimedia English online teaching platform and establish a

personal learning space according to their interests and hobbies. The specific operation flow of the student management submodule is shown in Figure 5.

To sum up, the overall framework of the Multimedia English online teaching platform is preliminarily designed using wireless network communication technology. On the basis of this framework, each functional module is analyzed and designed in detail. A planning decision-making goal is set as M_b , and the expression is as follows:

$$M_b = Y_x \times Q_s. \quad (1)$$

Here, Y_x represents the influencing factors and Q_s represents the importance data of Y_x corresponding to the planning objectives. Due to the difference in influence degree of influencing factors on the target M_b , it is necessary to compare the influence degree, and all the comparison results can be expressed by D matrix:

$$D = \begin{bmatrix} d_{11}, d_{12}, \dots, d_{1m} \\ d_{21}, d_{22}, \dots, d_{2m} \\ \vdots \\ d_{m1}, d_{m2}, \dots, d_{mm} \end{bmatrix}. \quad (2)$$

Here, d_{mm} represents the influence degree coefficient in row m and column m . Assuming that the matrix D satisfies

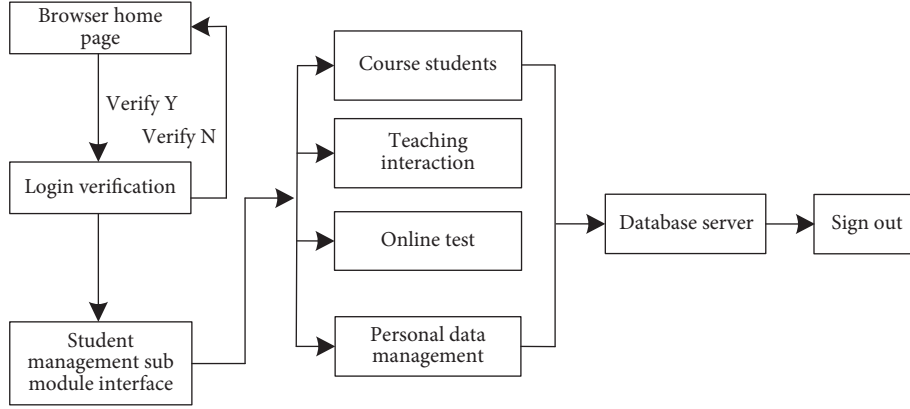

FIGURE 5: Operation flow chart of the student management submodule.

the consistency condition, the corresponding solution to the eigenvalue problem is as follows:

$$D' = d_{mm} \times R_u. \quad (3)$$

Here, R_u represents the fuzzy comprehensive evaluation coefficient. The fuzzy comprehensive evaluation method is a mathematical evaluation method. It mainly deals with the fuzzy things in the real world quantitatively through the basic theories and methods of fuzzy mathematics and makes an objective, accurate, and practical Multimedia English online teaching evaluation, so as to effectively solve the problems in the actual teaching process. The basic principle of a fuzzy comprehensive evaluation is as follows: give priority to collecting materials for accurate evaluation of Multimedia English online teaching and determine the main factors and grades of evaluation; then, the weight distribution of the online teaching evaluation index is determined by the above analytic hierarchy process, and the fuzzy mathematical model is established. Assuming that the analytic hierarchy process is used to determine the weight, the evaluation-domain level model is set as follows:

$$A = (a_1, a_2, \dots, a_n). \quad (4)$$

Here, a_1 , a_2 , and a_n all represent the evaluation grade coefficient. The teaching quality evaluation results of different teachers are obtained through the evaluation-domain level model, and the corresponding improvement measures are given in time combined with the evaluation results to ensure the effective improvement of the quality of the Multimedia English online teaching platform, so as to complete the design of the Multimedia English online teaching platform under the wireless network communication technology.

3. Experimental Analysis

In order to verify the feasibility of the designed Multimedia English online teaching platform under wireless network communication technology, the following experiments are designed. Taking the course teaching of a college English major as an example, the teaching content is set as the experimental object. On this basis, combined with the virtual

TABLE 3: Platform test environment.

Name	Parameter
Platform	Windows 10
CPU	Intel Zhiqiang E5-2600
Development tool	Sublime
Deep learning tools	Theano

simulation platform, the host used for the test is Microsoft Windows Professional Tomcat7.0 host, using Myeclipse software as the simulation environment, the database type is SQL SERVER2012 Database 5.3, and the expansion device is Web Server, equipped with FTPServer, Mail Server, and Database Server subplatforms. The platform is controlled using Adobe Dreamweaver CS, PhotoImpact12, and Acrobat9, the network program language is JSP, and the TCP/IP communication protocol is executed. Other test environments are shown in Table 3.

According to the platform test environment in Table 3, the experiment uses English books in a university library as English teaching resources to test the application performance of the platform. The test process is shown in Figure 6.

Based on the test process of the Multimedia English online teaching platform in Figure 6, the simulation test parameters are set, as shown in Table 4.

In order to verify the practicability of the designed platform, the function and performance of the platform are simulated and tested, respectively. Functional testing is to use test cases to verify the function of the platform. The platform teaching function and platform management function are tested, and the results are shown in Tables 5 and 6.

Through the function tests in Tables 5 and 6, it can be seen that during the operation of the platform data function, the client has relatively completed verification measures. Without going through the server, the client can complete reliable information category calibration, prevent the input of dirty data, ensure the quality of teaching resources of the platform, and quickly save the complete information to the database. All test results are passed, and the test results meet the expected objectives.

In order to further verify the effect of the Multimedia English online teaching platform under wireless network

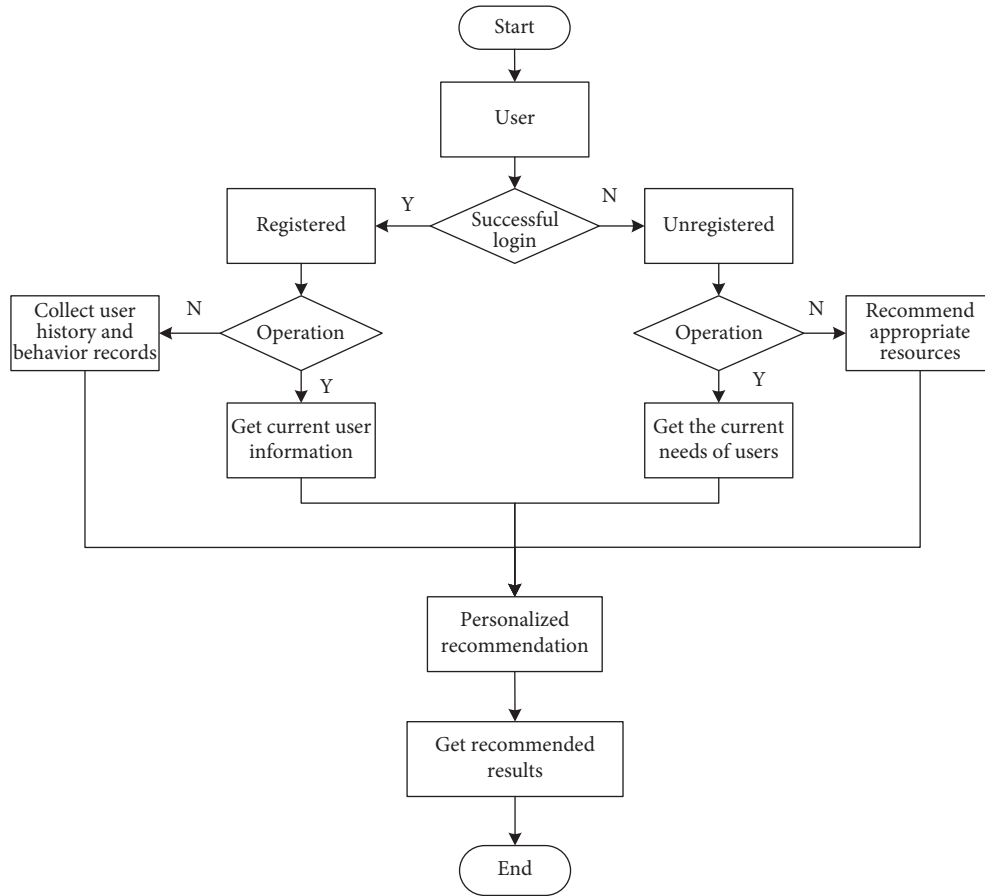

FIGURE 6: Test flow chart of the Multimedia English online teaching platform.

Note. L stands for the characteristic scale.

communication technology and compare the teaching quality of three different platforms for testing, 150 students with equivalent academic achievements are selected as the test objects, of which every 50 students are a group, and three different platforms are used to teach the same content, of which the full score of the test score is 100, where $100 \sim 85$ points mean excellent; $84 \sim 60$ points mean qualified; and if the score is below 60, it means unqualified. The comparison

TABLE 5: Platform teaching function test.

Number	Test items	Test method	Result
1	Admin/12345	Is the format correct	Adopt
2	Course view	Whether the course is displayed or not	Adopt
3	Search courses	Can I search	Adopt
4	Job submission	Can I submit normally	Adopt
5	Video playback	Can it play normally	Adopt

results of teaching quality of each teaching platform are given in Figure 7.

By analyzing the experimental data in Figure 7, we can see that the teaching quality of the designed platform is always higher than 95%, while the teaching quality of the platform in reference [7] and the platform in reference [8] is lower than 90%. Our platform uses analytic hierarchy process to evaluate the quality of Multimedia English online teaching, so as to obtain the evaluation results of Multimedia English online teaching in time. Through the evaluation results, the corresponding improvement measures are given in time to ensure the effective improvement of the teaching quality of the designed platform. The student test scores of the designed platform are significantly higher than those of the other two platforms, which shows that the designed platform can obtain more satisfactory teaching results. The

FIGURE 7: Comparison results of teaching quality on different platforms.

TABLE 7: Comparison results of teaching efficiency of different Multimedia English online teaching platforms.

Number of experiments/frequency	Teaching efficiency of the Multimedia English online teaching platform/%		
	Designed platform	Reference [7] platform	Reference [8] platform
2	99.69	98.63	93.52
4	99.37	96.09	92.03
6	98.44	95.25	90.09
8	97.85	94.59	89.21
10	96.33	93.85	87.63
12	96.12	92.43	85.14
14	95.99	91.52	84.22
16	95.47	89.20	82.30
18	94.58	88.30	80.25
20	94.44	86.72	79.12
22	93.29	83.45	77.41
24	93.65	81.43	77.22
Average value	96.27	90.96	84.85

following experimental tests compare the teaching efficiency of three different platforms. The specific experimental comparison results are shown in Table 7.

By analyzing the experimental data in Table 7, we can see that the teaching efficiency of each platform is constantly changing with the increase in the number of experiments. The average teaching efficiency of the designed platform is 96.27%, the average teaching efficiency of the platform in reference [7] and the platform in reference [8] are 90.96%

and 84.85%, respectively, and the decline trend of literature platform teaching efficiency is very obvious, mainly because the two teaching platforms failed to evaluate the teaching quality in the process of practical application, resulting in the cumbersome whole teaching process; it also proves that it is feasible and effective to add analytic hierarchy process to the designed platform for teaching quality evaluation.

To sum up, the designed Multimedia English online teaching platform under wireless network communication technology has a good effect in practical application and can produce positive results. As a practical technical scheme, it is not something in the abstract thinking stage but something that can be implemented in the industry and has the characteristics of enforceability, reproducibility, and usefulness. Compared with other literature platforms, the teaching quality and teaching effect of the designed platform are better and the performance is improved to a greater extent.

4. Conclusions and Prospects

4.1. Conclusions

- (1) During the operation of the data function of the Multimedia English online teaching platform under the designed wireless network communication technology, the client has relatively complete verification measures, which can complete reliable information category calibration and ensure the quality of platform teaching resources. A passing status is presented, and the test results meet the expected goals.
- (2) The designed platform uses the analytic hierarchy process to evaluate the quality of Multimedia English online teaching and obtains the evaluation results of Multimedia English online teaching in time to ensure that the teaching quality of the designed platform is effectively improved, and more satisfactory teaching results can be obtained.
- (3) The teaching efficiency of the designed platform is good, and it is effective to add the analytic hierarchy process to the platform to evaluate the teaching quality.

4.2. *Prospects.* Due to the limitation of time and other factors, there are still some deficiencies in the designed platform. The follow-up research will focus on the following aspects:

- (1) We will expand the scope of research, make teachers give more targeted teaching, and ensure the effective improvement of teaching quality and efficiency

- (2) In the follow-up, we will comprehensively analyze the learning situation of different students, so that the platform can comprehensively summarize and analyze them and give the corresponding teaching plan in time

Data Availability

The raw data supporting the conclusions of this article will be made available by the author, without undue reservation.

Conflicts of Interest

The author declares that there are no conflicts of interest regarding this work.
