# Contents

## **Complexity Problems Handled by Advanced Computer Simulation Technology in Smart Cities 2021**

Zhihan Lv , Kaoru Ota, Jaime Lloret , Wei Xiang, and Paolo Bellavista 

Editorial (3 pages), Article ID 9847249, Volume 2022 (2022)

## **Analysis of Feature Extraction and Anti-Interference of Face Image under Deep Reconstruction**

### **Network Algorithm**

Jin Yang , Yuxuan Zhao , Shihao Yang , Xinxin Kang , Xinyan Cao, and Xixin Cao

Research Article (15 pages), Article ID 8391973, Volume 2021 (2021)

## **E-Commerce Enterprise Supply Chain Cost Control under the Background of Big Data**

Haijun Mao and Long Chen 

Research Article (11 pages), Article ID 6653213, Volume 2021 (2021)

## **Complex System of Vertical Baduanjin Lifting Motion Sensing Recognition under the Background of Big Data**

Yan Zhang, M. M. Kamruzzaman , and Lu Feng 

Research Article (10 pages), Article ID 6690606, Volume 2021 (2021)

## **Earthquake Disaster Rescue Model Based on Complex Adaptive System Theory**

Fujiang Chen , Jingang Liu, and Junying Chen

Research Article (12 pages), Article ID 6655574, Volume 2021 (2021)

## **Construction of a Complex System Based on Big Data for the Intelligent Service System of Youth Physical Health**

Xinwen Li, Chao Song, Christine A. Rochester, and Chaobing Yan 

Research Article (12 pages), Article ID 6635346, Volume 2021 (2021)

## **Flood Simulation Analysis of the Biliu River Basin Based on the MIKE Model**

Qi Liu , Dianwu Wang , Yulong Zhang, and Li Wang

Research Article (10 pages), Article ID 8827046, Volume 2021 (2021)

## **Cluster Coordination between High-speed Rail Transportation Hub Construction and Regional Economy Based on Big Data**

Liang Zhao  and Yuanhua Jia

Research Article (18 pages), Article ID 6610882, Volume 2021 (2021)

## **Museum Display Showcase Furniture System Research Based on Internet of Things Technology in Intelligent Environment**

Jiaojiao Hu, Zhihui Wu , and Lei Jin

Research Article (14 pages), Article ID 6689744, Volume 2021 (2021)

## **Application of Remote Sensing Image Data Scene Generation Method in Smart City**

Yuanjin Xu 

Research Article (13 pages), Article ID 6653841, Volume 2021 (2021)

**Modeling and Research on Human Capital Accumulation Complex System of High-Tech Enterprises Based on Big Data**

Yanan Shen 

Research Article (14 pages), Article ID 6635228, Volume 2021 (2021)

**Development and Supervision of Robo-Advisors under Digital Financial Inclusion in Complex Systems**

Wensheng Dai 

Research Article (12 pages), Article ID 6666089, Volume 2021 (2021)

**Detection and Adaptive Video Processing of Hyperopia Scene in Sports Video**

Qingjie Chen and Minkai Dong 

Research Article (13 pages), Article ID 6610760, Volume 2021 (2021)

**Study on Mechanical Characteristics of Energy-Absorbing and Anti-Scour Bolts**

Zhi Tang , Hao Wu, Jinguo Lv, Zhuangzhuang Xin, and Wenbo Zuo

Research Article (9 pages), Article ID 8876517, Volume 2021 (2021)

**Electroencephalogram of Happy Emotional Cognition Based on Complex System of Music and Image Visual and Auditory**

Lin Gan, Mu Zhang , Jijia Jiang, and Fajie Duan

Research Article (14 pages), Article ID 6631400, Volume 2020 (2020)

**Collaborative Intelligent Environment Perception and Mission Control of Scientific Researchers in Semantic Knowledge Framework Based on Complex Theory**

Jingfeng Zhao and Yan Li 

Research Article (11 pages), Article ID 6637375, Volume 2020 (2020)

**Impact of Financial R&D Resource Allocation Efficiency Based on VR Technology and Machine Learning in Complex Systems on Total Factor Productivity**

Hui Sun  and Xiong Zhong 

Research Article (15 pages), Article ID 6679846, Volume 2020 (2020)

**Simulation Study on Fire Visibility of Typical Floor Planes of Modern Super High-Rise Office Buildings in China**

Tongtong Zhang 

Research Article (14 pages), Article ID 8868522, Volume 2020 (2020)

**Simulation Study on the Spatiotemporal Difference of Complex Neurodynamics between P3a and P3b**

Xin Wei, Xiaoli Ni , Junye Liu, Haiyang Lang, Rui Zhao, Tian Dai, Wei Qin, Wei Jia, and Peng Fang

Research Article (11 pages), Article ID 2796809, Volume 2020 (2020)

**Intelligent Digital Currency and Dynamic Coding Service System Based on Internet of Things Technology**

Shanshen Li  and Xin Jing 

Research Article (16 pages), Article ID 6647039, Volume 2020 (2020)

# Contents

## **Research on Lung Nodule Detection Based on Improved Target Detection Network**

Ye Li , Qian Wu , Hongwei Sun , and Xuewei Wang 

Research Article (7 pages), Article ID 6633242, Volume 2020 (2020)

## **Robust Adaptive Control for a Class of T-S Fuzzy Nonlinear Systems with Discontinuous Multiple Uncertainties and Abruptly Changing Actuator Faults**

Xin Ning, Yao Zhang, and Zheng Wang 

Research Article (16 pages), Article ID 8863073, Volume 2020 (2020)

## **M&A Short-Term Performance Based on Elman Neural Network Model: Evidence from 2006 to 2019 in China**

Ming Xiao , Xionghui Yang , and Ge Li 

Research Article (15 pages), Article ID 8811273, Volume 2020 (2020)

## **The Organizational Structure and Operational Logic of an Urban Smart Governance Information Platform: Discussion on the Background of Urban Governance Transformation in China**

Junfang Kang and Xianjun Wang 

Research Article (16 pages), Article ID 6638958, Volume 2020 (2020)

## **Research on the Impact of Green Finance and Fintech in Smart City**

Zheng He, Zhengkai Liu, Hui Wu , Xiaomin Gu , Yuanjun Zhao, and Xiaoguang Yue

Research Article (10 pages), Article ID 6673386, Volume 2020 (2020)

## **Application Research of Intelligent Classification Technology in Enterprise Data Classification and Gradation System**

Lina Yu , Chunwei Wang , Huixian Chang , Sheng Shen , Fang Hou , and Yingwei Li 

Research Article (9 pages), Article ID 6695484, Volume 2020 (2020)

## **Mechanism of Drag Reduction in Floating Plate of Paddy Field Based on CFD**

Xiaoze Yu, Baofeng Zhang, and Jiahao You 

Research Article (12 pages), Article ID 8852941, Volume 2020 (2020)

## **A New Method for Optimizing the Cabin Layout of Manned Submersibles**

Wenzhong Wang , Shusheng Zhang, Cong Ye, Dengkai Chen , and Hao Fan 

Research Article (11 pages), Article ID 6626602, Volume 2020 (2020)

## **Green Energy Strategic Management for Service of Quality Composition in the Internet of Things Environment**

Jianhao Gao 

Research Article (10 pages), Article ID 6678612, Volume 2020 (2020)

## **Visualization of Information Retrieval in Smart Library Based on Virtual Reality Technology**

Shulin Fang 

Research Article (18 pages), Article ID 6646673, Volume 2020 (2020)

**Landscape Image Layout Optimization Extraction Simulation of 3D Pastoral Complex under Big Data Analysis**

Juan Du  and Yuelin Long

Research Article (11 pages), Article ID 6620216, Volume 2020 (2020)

**Improved Newton Iterative Algorithm for Fractal Art Graphic Design**

Huijuan Chen and Xintao Zheng 

Research Article (11 pages), Article ID 6623049, Volume 2020 (2020)

**Resource Scheduling and Strategic Management of Smart Cities under the Background of Digital Economy**

Qing Yin  and Gang Liu

Research Article (12 pages), Article ID 6624307, Volume 2020 (2020)

**Corrigendum to “Explosion Resistance of Three-Dimensional Mesoscopic Model of Complex Closed-Cell Aluminum Foam Sandwich Structure Based on Random Generation Algorithm”**

Zhen Wang, Wen Bin Gu , Xing Bo Xie, Qi Yuan, Yu Tian Chen, and Tao Jiang

Corrigendum (2 pages), Article ID 9519832, Volume 2020 (2020)

**The Measurement of Chinese Sentence Semantic Complexity**

Shuqin Zhu , Jihua Song , Weiming Peng , Dongdong Guo, and Jingbo Sun

Research Article (10 pages), Article ID 8871263, Volume 2020 (2020)

**Three-Dimensional Finite Element Numerical Simulation and Analysis of Solid-State Processing of Metal Material**

Guang Su and Aimin Zhang 

Research Article (12 pages), Article ID 8819745, Volume 2020 (2020)

**Accurate Recognition and Simulation of 3D Visual Image of Aerobics Movement**

Wenhua Fan and Hyun Joo Min 

Research Article (11 pages), Article ID 8889008, Volume 2020 (2020)

**Moving Vehicle Tracking Optimization Method Based on SPF**

Caixia Lv  and Xuejing Zhang

Research Article (14 pages), Article ID 8829167, Volume 2020 (2020)

**Power Control for Full-Duplex Device-to-Device Underlaid Cellular Networks: A Stackelberg Game Approach**

Zhen Yang, Titi Liu , and Guobin Chen

Research Article (12 pages), Article ID 1786349, Volume 2020 (2020)

**Performance Investigation of Stochastic Resonance in Three Types of Asymmetric Bistable System Driven by Trichotomous Noise**

Si-Hai Zhao , Jiang-Ye Xu, Yu-Xiao Liu, Ze-Xing Zhao, and Zhong-Shun Qin

Research Article (12 pages), Article ID 8842122, Volume 2020 (2020)

# Contents

## **Prediction Mathematic Model and Influencing Factors of Contact Stress of Cylindrical Gear with Arc Tooth**

Qi Zhang , Guang Wen, Shuang Liang, Qin Tong, Li Hou, and Guangchun Yang  
Research Article (15 pages), Article ID 8888407, Volume 2020 (2020)

## **Analysis of Asymmetric Piecewise Linear Stochastic Resonance Signal Processing Model Based on Genetic Algorithm**

Lina He  and Chuan Jiang   
Research Article (11 pages), Article ID 8817814, Volume 2020 (2020)

## **Decision Tree Algorithm-Based Model and Computer Simulation for Evaluating the Effectiveness of Physical Education in Universities**

Zhifei Zhang, Zijian Zhao , and Doo-Seoung Yeom  
Research Article (11 pages), Article ID 8868793, Volume 2020 (2020)

## **Real-Time Visualization Optimization Management Simulation of Big Data Stream on Industrial Heritage Cloud Platform**

Mengya Gao   
Research Article (10 pages), Article ID 8885191, Volume 2020 (2020)

## **Application of Empirical Orthogonal Function Interpolation to Reconstruct Hourly Fine Particulate Matter Concentration Data in Tianjin, China**

Hongwu Zhou, Haidong Pan, Shuang Li , and Xianqing Lv   
Research Article (15 pages), Article ID 9724367, Volume 2020 (2020)

## **Research on the Measurement, Evolution, and Driving Factors of Green Innovation Efficiency in Yangtze River Economic Belt: A Super-SBM and Spatial Durbin Model**

Renyang Long , Hangyuan Guo, Danting Zheng, Ronghua Chang, and Sanggyun Na   
Research Article (14 pages), Article ID 8094247, Volume 2020 (2020)

## **Optimization and Simulation of Controller Area Network Communication Model Based on Industrial Internet of Things Platform**

Haifeng Lin  and Lin Du   
Research Article (11 pages), Article ID 8864722, Volume 2020 (2020)

## **Heuristic Sensing: An Uncertainty Exploration Method in Imperfect Information Games**

Zhenyang Guo , Xuan Wang , Shuhan Qi , Tao Qian , and Jiajia Zhang   
Research Article (9 pages), Article ID 8815770, Volume 2020 (2020)

## **A Dynamic Hierarchical Clustering Data Gathering Algorithm Based on Multiple Criteria Decision Making for 3D Underwater Sensor Networks**

Xiaoying Song , Wei Sun, and Qilong Zhang   
Research Article (14 pages), Article ID 8835103, Volume 2020 (2020)

**Hemodynamic-Based Evaluation on Thrombosis Risk of Fusiform Coronary Artery Aneurysms Using Computational Fluid Dynamic Simulation Method**

Haoran Wang, Hitomi Anzai, Youjun Liu, Aike Qiao , Jinsheng Xie, and Makoto Ohta 

Research Article (11 pages), Article ID 8507273, Volume 2020 (2020)

**Optimization and Simulation for E-Commerce Supply Chain in the Internet of Things Environment**

Liwei Zhu 

Research Article (11 pages), Article ID 8821128, Volume 2020 (2020)

**A Three-Dimensional Complex Measurement Model-Based Avionic Radio-Frequency Power Source Health Assessment Method**

Lin Huo , Shiqi Li, Simiao Fei, and Chuan Lyu

Research Article (14 pages), Article ID 6369729, Volume 2020 (2020)

**Multiple-Devices-Process Integrated Scheduling Algorithm with Time-Selective Strategy for Process Sequence**

Xiaohuan Zhang , Dan Zhang, Zhen Wang, and Yu Xin

Research Article (12 pages), Article ID 8898536, Volume 2020 (2020)

**Panoramic Display and Planning Simulation of Civil Engineering Project Based on Virtual Reality Technology**

Zheng Wang , Chang Liu, and Bin Song

Research Article (11 pages), Article ID 1424757, Volume 2020 (2020)

**Research of the Context Recommendation Algorithm Based on the Tripartite Graph Model in Complex Systems**

Fei Long 

Research Article (11 pages), Article ID 7945417, Volume 2020 (2020)

**Numerical Investigation on the Dynamic Characteristics of an Adjustable Power Turbine Used in Environmental Control System**

Qihang Lu , Qi Zhang, and Dalin Zhang 

Research Article (12 pages), Article ID 7916936, Volume 2020 (2020)

**Diagnosis and Exercise Rehabilitation of Knee Joint Anterior Cruciate Ligament Injury Based on 3D-CT Reconstruction**

Shunchao Zhang 

Research Article (13 pages), Article ID 3690124, Volume 2020 (2020)

**Big Data Analytics for Complex Credit Risk Assessment of Network Lending Based on SMOTE Algorithm**

Aiwen Niu, Bingqing Cai, and Shousong Cai 

Research Article (9 pages), Article ID 8563030, Volume 2020 (2020)

# Contents

## **Articulatory-to-Acoustic Conversion Using BiLSTM-CNN Word-Attention-Based Method**

Guofeng Ren , Guicheng Shao, and Jianmei Fu

Research Article (10 pages), Article ID 4356981, Volume 2020 (2020)

## **Optimization and Simulation of a Reasonable Scheduling Model under Multiple Tasks in Company Management**

Zhuo Wang 

Research Article (10 pages), Article ID 1204815, Volume 2020 (2020)

## **A 3D Reconstruction Method Using Multisensor Fusion in Large-Scale Indoor Scenes**

Panlong Gu , Fengyu Zhou , Dianguo Yu , Fang Wan , Wei Wang , and Bangguo Yu 

Research Article (14 pages), Article ID 6973790, Volume 2020 (2020)

## **Meso-Complexity Computer Simulation Investigation on Antiexplosion Performance of Double-Layer Foam Aluminum under Pore Grading**

Zhen Wang, Wen Bin Gu , Xing Bo Xie, Yu Tian Chen, and Lei Fu

Research Article (13 pages), Article ID 4121926, Volume 2020 (2020)

## **Dynamic Response of a Semiactive Suspension System with Hysteretic Nonlinear Energy Sink Based on Random Excitation by means of Computer Simulation**

Hui Chen  and Wuyin Jin 

Research Article (13 pages), Article ID 3181423, Volume 2020 (2020)

## **A Deep Learning Approach for a Source Code Detection Model Using Self-Attention**

Yao Meng  and Long Liu

Research Article (15 pages), Article ID 5027198, Volume 2020 (2020)

## **Photovoltaic Generation Prediction of CCIPCA Combined with LSTM**

E. Zhu  and D. Pi

Research Article (11 pages), Article ID 1929372, Volume 2020 (2020)

## **Analysis and Simulation of Multimedia English Auxiliary Handle Based on Decision Tree Algorithm**

Kaiwei Yan 

Research Article (12 pages), Article ID 9028303, Volume 2020 (2020)

## **Emotion Recognition of Students Based on Facial Expressions in Online Education Based on the Perspective of Computer Simulation**

Weiqing Wang, Kunliang Xu, Hongli Niu, and Xiangrong Miao 

Research Article (9 pages), Article ID 4065207, Volume 2020 (2020)

## **An Innovative Aerial Manipulator with Tandem Ducted Fans: Modeling, Control, and Simulation**

Yibo Zhang, Wei Fan , Changle Xiang, Bin Xu, Tianfu Ai, Lei Yuan, and Yang Liu

Research Article (24 pages), Article ID 7923539, Volume 2020 (2020)

**Research on the Niche Evolution Game of Ecological Community Innovation of Corporate Venture Capital Based on Logistic Extended Complexity Model**

Fanglin Meng , Zengrui Tian , Beiquan Chang , Hongxin Yu , and Shuai Zhang  
Research Article (13 pages), Article ID 6327218, Volume 2020 (2020)

**Multiobject Detection Algorithm Based on Adaptive Default Box Mechanism**

Jinling Li , Qingshan Hou , and Jinsheng Xing   
Review Article (11 pages), Article ID 5763476, Volume 2020 (2020)

**Hybrid Depth-Separable Residual Networks for Hyperspectral Image Classification**

Cuijie Zhao, Hongdong Zhao , Guozhen Wang, and Hong Chen  
Research Article (17 pages), Article ID 4608647, Volume 2020 (2020)

**Modeling and Simulation of English Speech Rationality Optimization Recognition Based on Improved Particle Filter Algorithm**

Hui Dong   
Research Article (10 pages), Article ID 6053129, Volume 2020 (2020)

**Numerical Simulation of Ambiguity Resolution in Multiple Information Streams Based on Network Machine Translation**

Lei Wang and Qun Ai   
Research Article (10 pages), Article ID 7278085, Volume 2020 (2020)

**Emotional Interactive Simulation System of English Speech Recognition in Virtual Context**

Dan Li   
Research Article (11 pages), Article ID 9409630, Volume 2020 (2020)

**Explosion Resistance of Three-Dimensional Mesoscopic Model of Complex Closed-Cell Aluminum Foam Sandwich Structure Based on Random Generation Algorithm**

Zhen Wang, Wen Bin Gu , Xing Bo Xie, Qi Yuan, Yu Tian Chen, and Tao Jiang  
Research Article (16 pages), Article ID 8390798, Volume 2020 (2020)

**Study on Global Parameters Optimization of Dual-Drive Powertrain System of Pure Electric Vehicle Based on Multiple Condition Computer Simulation**

Yong Wang, Hongguo Cai , Yinghua Liao, and Jun Gao  
Research Article (10 pages), Article ID 6057870, Volume 2020 (2020)

**Optimal Pricing Decision of Fashion Apparel considering Experiential Service and Design Enhancement**

Qi Xu , Lili Zhou , and Qi Chen   
Research Article (11 pages), Article ID 9505120, Volume 2020 (2020)

**Application Study of Sigmoid Regularization Method in Coke Quality Prediction**

Shaohong Yan, Hailong Zhao, Liangxu Liu, Qiaozhi Sang, Peng Chen, and Jie Li   
Research Article (10 pages), Article ID 8785047, Volume 2020 (2020)

# Contents

## **A Research on the Control System of High-Speed Homopolar Motor with Solid Rotor Based on Flywheel Energy Storage**

Lili Jing, Yandong Yu , and Xiaochuan Xue

Research Article (12 pages), Article ID 6537563, Volume 2020 (2020)

## **DTFNet: Dynamic and Texture Features Fusion Attention Network for Face Antispoofing**

Xin Cheng , Hongfei Wang , Jingmei Zhou , Hui Chang , Xiangmo Zhao , and Yilin Jia

Research Article (11 pages), Article ID 5836596, Volume 2020 (2020)

## **Semiparametric Deep Learning Manipulator Inverse Dynamics Modeling Method for Smart City and Industrial Applications**

Nan Liu, Liangyu Li, Bing Hao, Liusong Yang, Tonghai Hu, Tao Xue, Shoujun Wang , and Xingmao Shao

Research Article (11 pages), Article ID 9053715, Volume 2020 (2020)

## **An Anonymous Authentication Scheme in VANETs of Smart City Based on Certificateless Group Signature**

Yuanpan Zheng , Guangyu Chen, and Liguan Guo

Research Article (7 pages), Article ID 1378202, Volume 2020 (2020)

## **Adaptive Language Processing Based on Deep Learning in Cloud Computing Platform**

Wenbin Xu  and Chengbo Yin

Research Article (11 pages), Article ID 5828130, Volume 2020 (2020)

## **A Multiscale and High-Precision LSTM-GASVR Short-Term Traffic Flow Prediction Model**

Jingmei Zhou , Hui Chang , Xin Cheng , and Xiangmo Zhao 

Research Article (17 pages), Article ID 1434080, Volume 2020 (2020)

## **Research on Complex Classification Algorithm of Breast Cancer Chip Based on SVM-RFE Gene Feature Screening**

Guobin Chen, Xianzhong Xie, and Shijin Li 

Research Article (12 pages), Article ID 1342874, Volume 2020 (2020)

## **Automatic Grading for Complex Multifile Programs**

Tiantian Wang , Djoko Budi Santoso, Kechao Wang, and Xiaohong Su

Research Article (15 pages), Article ID 3279053, Volume 2020 (2020)

## **A Hemodynamic-Based Evaluation of Applying Different Types of Coronary Artery Bypass Grafts to Coronary Artery Aneurysms**

Haoran Wang, Hitomi Anzai, Youjun Liu, Aike Qiao , Jinsheng Xie, and Makoto Ohta 

Research Article (10 pages), Article ID 9359340, Volume 2020 (2020)

## **Study on the 2D Optimization Simulation of Complex Five-Hole Cutting Blasting under Different Lateral Pressure Coefficients**

Jing Gao, Shizhen Xie, Xiantang Zhang , Hongli Wang, Wenle Gao, and Hongmin Zhou

Research Article (12 pages), Article ID 4639518, Volume 2020 (2020)

**A Bayesian Network under Strict Chain Model for Computing Flow Risks in Smart City**

Zengfanxiang Wei , Lei Zhang , Qi Yue , and Muchen Zhong 

Research Article (8 pages), Article ID 5920827, Volume 2020 (2020)

**Research on Sentiment Tendency and Evolution of Public Opinions in Social Networks of Smart City**

Yanni Liu, Dongsheng Liu , and Yuwei Chen

Research Article (13 pages), Article ID 9789431, Volume 2020 (2020)

**A Complexity Analysis of User Interaction with Hotel Robots**

Lina Zhong , Liyu Yang, Jia Rong, and Xiaonan Li

Complexity science technology will bring opportunities for the continuous expansion of new simulation research fields, especially for human simulation, social simulation, and human brain simulation, and provide unprecedented opportunities for simulation for social governance, prediction, and urbanization. The development of complexity science technology provides an important opportunity to use modeling and simulation methods to study new virtual information spaces. As we all know, the advantage of modeling and simulation technology is to provide a bridge from the real world to the virtual space, which provides a substitute for studying the unknown fields of human society and the physical world.

However, virtual information spaces are a completely new virtual space that are completely different from the physical world and human society. This virtual space is not only “human, machine, and object” but also a space where the three notions are combined, and there are also the characteristics of multilayer mesh and cross-domain association. The study of this new virtual space is a complex and current scientific research area. On the basis of making full use of the results of complexity science research, using parallel systems, embedded simulation, and other methods to build a bridge to this new type of space, they provide a virtual alternative for the interaction or behavioral characteristics between the research. Using the results of complexity science to constantly modify and test the models built is an issue that needs to be addressed for the further development of modeling and simulation science.

This special issue collates 189 original research papers and comments with a focus on up-to-date technology related to computer simulation for complexity issues in smart cities and serves as a forum for researchers all over the world to discuss their work and recent advances in this field. In particular, this special issue aims to showcase the most recent achievements and developments in complexity problem discovery and exploration.

With the development of science and technology, the demand of human-computer interaction has increased, and the research on human-computer interaction in real and virtual scenarios has become more and more extensive. The use of virtual reality technology and the combination of human-computer interaction technology have been increasingly used in the fields of simulated sports, medical rehabilitation, and game creation. Action is the basis of human behaviours, among which human behaviours and movement analysis are an important research direction. Among human behaviours and actions, the recognition research based on behaviours and actions has the characteristics of convenience, intuition, strong interaction, and rich expression information. It has become the first choice for many researchers to analyse human behaviours. At the same time, the study of some complex objects such as human movement has many fuzzy factors, which are difficult to express and deal with. A total of 26 research papers in this special issue propose processing methods and optimization algorithms for human-computer interaction applications in multiple scenarios, providing solutions to complex human-

computer interaction problems from many aspects, and all have good application performance.

Urban digital twins are virtual representations of urban physical assets and are an important development direction of digital twin technology. Smart cities built under the support of digital twin technology can bring better cost efficiencies, operational efficiencies, better crisis management, more openness and better-informed decision-making, more participatory governance, or better urban planning. The special issue contains 5 representative research papers on smart city construction. I. Meta et al. proposed a modular framework for urban digital twins, combined with the concept of urban physiology, to better solve the theoretical problems of smart city construction. Y. He et al. proposed a knowledge graph fusion framework for building smart cities. S. Wang et al. provided a feature extraction method for the spatial distribution of urban landforms. Starting from the energy efficiency management of smart cities, L. Chen and P. Han constructed an efficient system platform based on the mobile data of the Internet of Things. H. Wang et al. improved the KNN algorithm and optimized the preprocessing process of the city center. In addition, the special issue also includes a total of 129 papers on the optimization methods of urban life in other fields, which include research methods from different perspectives of urban development and urban life, which optimize and enrich urban construction and daily need to a great extent. These areas include education, healthcare, construction, tourism development, financial transactions, entertainment consumption, urban security services, low-carbon and green development, urban resource allocation and control optimization, environmental and geological monitoring, urban production, sports, and urban transportation. In these areas, this special issue brings together a wealth of optimization methods.

In the field of education, the complexity of the education system at all levels has gradually deepened. Whether it is a junior high school, high school, or university, excellent student management systems, online education systems, teaching quality evaluation, and more intelligent teaching models are the main development directions. The special issue contains 32 education-related papers. Starting from the practical development of subject education in many aspects, a series of optimization algorithms and platform construction methods are proposed. In addition, this is not only limited to conventional teaching types but also includes painting, sports, and student psychological supervision, which promote the intelligent development of education in a more comprehensive manner.

In terms of healthcare, Y. Chen proposed an optimized plan for the clinical nursing management system to make the overall clinical nursing process more perfect. Y. Jiang et al. also proposed an optimized method for analyzing clinical information. Aiming at the fusion of supporting medical image data on the ground, R. Chen et al. proposed a system framework that breaks through some of the limitations of traditional image fusion. X. Che compared the difference between exercise intervention and other nondrug therapies. B. Yang and S. Wang investigated the cognitive function.

For the field of urban building structure, here are some further improvements based on typical treatment methods. J. Yu et al. put forward a method on how to achieve healthy development of contaminated areas and facility construction. M. Wei combined augmented reality to realize more intuitive visualization of building data and intelligent detection. Other papers include such as the treatment method of building fire protection, the distribution method of housing construction in some newly developed areas, the virtual reality construction technology of landscape architecture, the intelligent combination of architecture and environment, and landscape space layout or landscape planning and design method. The special issue contains 4 papers on tourism. With the development of the national economy and society, the scale of the tourism market has expanded rapidly. The informatization and intelligent construction of scenic spots cannot keep up with the pace of economic development, and there is a lack of effective management methods to predict or even improve the overloading of scenic spots, which objectively leads to problems of congestion and overload. More and more tourists flock to the scenic area, which brings greater pressure and safety hazards to the scenic area. The relevant research in this part effectively responded to this problem, formulated a suitable flow control plan, and promoted the intelligent development of scenic spot management.

In the field of urban economy, it includes financial transactions, entertainment consumption, and urban security services. The problem of economic structure equilibrium and its development trend have far-reaching theoretical significance and important practical value. In theory, the study of economic structure equilibrium is an intuitive reflection and detailed elaboration of the status quo of economic development and is an extension and expansion of economic research theories. The changes in the economic structure are more complicated, and the problem of building intelligent economic industry forecasting models needs to be solved urgently. It is very important to study the balance of economic structure and economic development trends and to carry out macrocontrol on the status and trends of economic development. This part contains 39 research papers and 1 comment. In terms of entertainment consumption, the special issue includes movie recommendation, movie big data analysis, and other movie-related applications. At the same time, there are many papers about music feature optimization, music signal segmentation retrieval, and other applications. In urban security, social security services, logistics services, and effective optimization of news reports promote the lives of residents and social security from multiple perspectives. By combining advanced technologies such as big data, Internet of Things, and artificial intelligence, it has promoted the intelligent development of urban economy and entertainment guarantee.

A total of 20 papers were included to discuss the low-carbon and green development of the city, the allocation of urban resources, and the optimization of control. Against the background of the development of innovative countries, climate change and environmental issues have become increasingly prominent. Low-carbon economy has become an important choice for the future economic development of all

countries, and the green development of cities is an inevitable trend. Representatives such as the twin cities proposed by Y. Liu et al. provide a new perspective for the development of urban intelligence. H. Liu integrated low-carbon concepts into urban development. Xu et al. proposed digital technology to help food supply and provided corresponding optimization solutions. L. Zhang built a marketing management system based on cloud computing and big data. S. Mao and R. Huang also proposed intelligent construction methods for marketing strategies. The development of emerging technologies improves the basic appearance of cities by regulating the rational allocation of urban resources. Urban services also include research on sports, urban production, basic transportation, and environmental monitoring. Among them, there are 9 sports-related papers, and most of the papers contain related concepts of human-computer interaction, which can realize the monitoring and modeling of complex movements in some sports, and make a certain contribution to the intelligent development of urban sports. In terms of environmental monitoring, J. Jin et al. provided supporting technologies for geological monitoring in important strategic areas in some countries.

Some new data processing methods in the background of big data are also proposed here. X. Wang et al. proposed a digital image processing method based on the geographic information system. X. Xu et al. combined virtual reality technology to realize the restoration of similar images. S. Wu et al. used virtual reconstruction technology to acquire 3D images. X. Liu created a 3D modeling method that is more in line with image sequences. In addition, the special issue includes 21 algorithm optimization methods, covering most fields such as deep learning, blockchain distributed computing, edge computing, animation synthesis, and semantic similarity algorithms, providing many algorithm optimizations for different field methods.

This special issue has made important contributions to all the fields mentioned above and has promoted the development of the complexity science of smart cities from multiple perspectives. Combining the new generation of information technology and big data technology in the Innovation 2.0 environment, it strengthens open data and social participation in smart cities, solves the problems of open data and privacy protection in the context of big data, and lays the foundation for the construction of new smart cities.

In face recognition systems, highly robust facial feature representation and good classification algorithm performance can affect the effect of face recognition under unrestricted conditions. To explore the anti-interference performance of convolutional neural network (CNN) reconstructed by deep learning (DL) framework in face image feature extraction (FE) and recognition, in the paper, first, the inception structure in the GoogleNet network and the residual error in the ResNet network structure are combined to construct a new deep reconstruction network algorithm, with the random gradient descent (SGD) and triplet loss functions as the model optimizer and classifier, respectively, and it is applied to the face recognition in Labeled Faces in the Wild (LFW) face database. Then, the portrait pyramid segmentation and local feature point segmentation are applied to extract the features of face images, and the matching of face feature points is achieved using Euclidean distance and joint Bayesian method. Finally, Matlab software is used to simulate the algorithm proposed in this paper and compare it with other algorithms. The results show that the proposed algorithm has the best face recognition effect when the learning rate is 0.0004, the attenuation coefficient is 0.0001, the training method is SGD, and dropout is 0.1 (accuracy: 99.03%, loss: 0.0047, training time: 352 s, and overfitting rate: 1.006), and the algorithm proposed in this paper has the largest mean average precision compared to other CNN algorithms. The correct rate of face feature matching of the algorithm proposed in this paper is 84.72%, which is higher than LetNet-5, VGG-16, and VGG-19 algorithms, the correct rates of which are 6.94%, 2.5%, and 1.11%, respectively, but lower than GoogleNet, AlexNet, and ResNet algorithms. At the same time, the algorithm proposed in this paper has a faster matching time (206.44 s) and a higher correct matching rate (88.75%) than the joint Bayesian method, indicating that the deep reconstruction network algorithm proposed in this paper can be used in face image recognition, FE, and matching, and it has strong anti-interference.

## 1. Introduction

FR technology has been extensively adopted in identity recognition, but it is mainly used to detect biological features in the face for recognition, with strong uniqueness and security [1]. However, the dataset made up of face images is one that presents a highly nonlinear distribution, and if simple classification method is applied, higher classification errors will occur due to individual differences [2]. Moreover, the face image will be disturbed by lighting, decorations, scenes, and other factors during the shooting, which makes FR extremely difficult. At present, the methods commonly used for face detection include principal component analysis, support vector machine, CNN, and active deformation model [3].

Depth model has been applied in many fields, and its application in image recognition is the first to be concerned. Moreover, the depth model is used for FE in the image, which is far better than manual FE, and can be effectively applied in the field where manual FE is not perfect [4]. The common feature of DL and most machine learning is the ability to extract features. In DL, multilayer network structure is mostly applied, which can fuse the bottom features in the image to form the top features [5]. ImageNet's annual ImageNet Large-Scale Visual Recognition Challenge is the largest and most advanced image recognition competition in the world. Since 2012, AlexNET used DCNN to reduce the recognition error rate of the top 5 to 16.4%, and DCNN algorithm has been adopted in the subsequent champion recognition models [6, 7].

The rest of the paper is organized as follows. Section 2 discusses the related work of the DCNN network and image FE technology. Then, in Section 3, a deep reconstruction network is proposed, and the face recognition and facial FE algorithm is constructed based on the optimized deep reconstruction network. Section 4 carries out the verification of face recognition and FE and matching algorithms proposed in this paper and compares them with other DCNN algorithms. Section 5 discusses and analyzes the results obtained in this paper, and the results of the paper were compared with other people's relevant research results. Section 6 concludes the paper with summary and points out the future research directions.

## 2. Related Work

NN is a common computer model, which is mainly based on the traditional statistical modeling of complex relationships to explore the relationship between different datasets. The NN structure in different application fields is different, but the NN structure with the largest application in image-related fields is CNN. Seeliger et al. applied DCNN to the detection of magnetoencephalogram signal map and reconstructed the cerebral cortex activity model based on the extracted resolution source [8]. Hoang and Kang proposed a method for fault diagnosis of rolling axis based on CNN and vibration images based on the depth structure and found that this method does not need FE technology and has high diagnostic accuracy and robustness under noisy environment [9]. At present, deep learning has been widely used in the field of image analysis, especially in facial image recognition, which has obtained excellent results. Zhang et al. proposed a convolutional neural network model based on three-stage filtering and HOG, which was applied to the recognition of color face images and obtained excellent effect [10]. Goswami et al. proposed a framework for face recognition based on deep neural networks and used a characteristic anomaly filter to detect singularities. Finally, after verification with public data, it was found that the model built by it had strong face recognition robustness [11]. Isogawa et al. indicated that there was no denoising method capable of parameter adjustment in the DCNN model.

They used the proportional coefficient of soft shrinkage threshold to optimize DCNN, which was found to be applicable to noise removal in the image [12]. Nakazawa and Kulkarni proposed a method to detect and segment abnormal defect patterns using the NN architecture of deep convolutional encoder-decoder and finally found that these models could detect invisible defect patterns from real images [13].

The basic principle of image FE is to use a computer to extract the information in the image and then judge whether the differences in the image are one of the features in the image. An and Zhou proposed an image FE algorithm based on two-dimensional empirical mode decomposition and scale-invariant feature change. After verification, they found that it could effectively improve the speed and accuracy of FE [14]. Xu et al. proposed a model for automatically extracting noise level perception features based on the CNN model and

feature vectors and found that the proposed algorithm had high extraction speed and accuracy at different noise levels [15]. Fieldin et al. used enhanced adaptive particle swarm optimization to conduct deep CNN evolution, and after training and verification, they found that the extraction error rate was 4.78% [16].

To sum up, it is evident that DCNN is widely used in image recognition. The improved DCNN can effectively extract the features in the image. However, there are few research studies on the anti-interference of DCNN in face image recognition. Therefore, a DCNN based on Caffe depth framework is proposed. Matlab simulation software is used to explore the influence of different parameter settings on the performance of FR by constructing the DCNN model. Then, the LFW database and the self-constructed face database in this paper are combined to explore the anti-interference performance of the DCNN model constructed in this paper for face image recognition in different scenarios. The results of this paper are intended to lay a foundation for improving the efficiency of FR.

## 3. Methodology

*3.1. Design of Deep Reconstruction Network Structure.* Existing studies have shown that, with the gradual deepening of the CNN structure, the CNN training results become better, but while improving the results, it will also increase the amount of network computation [17]. Therefore, an inception network structure is proposed in the GoogleNet network, which can make full use of the features extracted by each layer of the network, and the structure can increase the depth and complexity of the network while ensuring the network computing complexity. In the paper, some network parameter adjustments are proposed for the basic structure of the GoogleNet network: (1) the size of the feature map of the input network should be slowly reduced in the network to avoid the bottleneck of the feature representation in the image; (2) high-dimensional features are easier to obtain than low-dimensional features and can accelerate the training speed of the model; (3) the adjacent neurons in the network have close correlations and can be integrated into spatial relations in low-dimensional spaces.

In the convolutional neural network, the  $5 * 5$  size convolution kernel is  $25/9$  times the size of  $3 * 3$  convolution. If the larger convolution kernel can be replaced with the superposition of multiple  $3 * 3$  size convolution kernels, then it can make the network have fewer parameters in the same field of view. Therefore, a hypothesis is proposed in the study. First, a  $3 * 3$  size convolution filter is adopted to process a  $5 * 5$  size block to obtain a  $3 * 3$  size output feature map. After the convolution with a  $3 * 3$  size convolution kernel,  $1 * 1$  size output is obtained. At this time, the final calculation amount is about  $18/25$  of the direct use of the  $5 * 5$  size convolution kernel, which saves 28% of the calculation amount, but the network also needs to use the ReLu activation function to correct the output. After that, the  $2 * 2$  size convolution kernel is adopted to replace the  $3 * 3$  size convolution kernel, which can save 11% of the calculation, but the use of an asymmetric convolution kernel

is better. Therefore, in the study,  $1 * 3$  and  $3 * 1$  size cascaded convolution kernels are used to replace  $3 * 3$  size convolution kernels to save 33% of the calculation, so the larger size convolution kernel can be decomposed in the same way. Based on this, an improved Inception structure is obtained, as shown in Figure 1.

The structure of ResNet can have up to 152 layers [18]. This model adds an identical high-speed channel to a simple stacked shallow network, as shown in Figure 2. On the left is the ordinary network, and its output value is  $H(x)$ , which represents any ideal feature transformation. The residual network output value on the right is  $H(x) = F(x) + x$ , and what needs to be fitted in the network is the residual  $F(x)$ . Adding an identical shortcut connection in the network Europe can make the input mapping and input of the network overlap. The output formula of the residual unit is  $y = F(x, \{Wi\}) + x$ , where  $x$  represents the input and  $y$  represents the output, and the function  $F(x, \{Wi\})$  is the residual mapping obtained by learning. Theoretically, the following two networks can approximate any function. But if the optimal solution of the network is close to the identity mapping, it is easier to optimize using the residual network; if the convolution branch appears as gradient dispersion, the features and gradients in the network can also flow in the branches of the identity mapping, which ensures the reliability of information transmission.

The convolution layer in the convolution branch  $F(x, \{Wi\})$  of the residual unit can be composed of multiple layers, and the residual unit can also be modified by scaling of the mapping branch, convolution kernel size, dropout, and the activation function location. Therefore, a new DCNN network structure is constructed based on the inception structure in the GoogleNet network and the residual structure in the ResNet network, to improve the network's computational efficiency and information circulation effect. The combined new network structure is shown in Figure 3.

The basic parameters of the deep reconstruction network constructed in this paper are shown in Table 1, where the dropout parameter is  $x$ , and the subsequent continuous adjustment of the parameters is required to select the optimal dropout value for the final test.

Deep neural networks often use Softmax as a classifier, and the triplet loss function is a classifier function proposed by Google for face recognition CNNs. Studies have also shown that its recognition rate on the LFW dataset has reached 99.63%, and the recognition rate on the YouTube dataset has also reached 95.12% [19]. Therefore, the impact of different classifiers on the model's face recognition rate is analyzed. In this paper, triplets are composed of a reference (anchor) of random samples in the training set, a reference sample (positive), and a sample of different categories (negative). Assuming that the sample features obtained by extracting each sample in triplets are  $f(x_1)$ ,  $f(x_2)$ , and  $f(x_3)$ , respectively, then the goal of optimization is as follows:

$$\|f(x_1) - f(x_2)\|_2^2 + \alpha < \|f(x_1) - f(x_3)\|_2^2, \quad \forall (x_1^i, x_2^i, x_3^i) \in \tau, \quad (1)$$

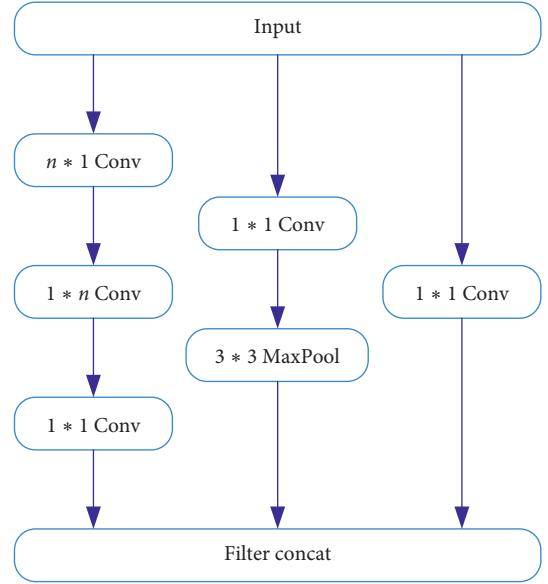

FIGURE 1: Improved inception structure.

FIGURE 2: Differences in the structure of different networks. The left is an ordinary network, and the right is a residual network in ResNet.

in which  $\alpha$  is the Euclidean distance between sample features of the same category or the minimum interval of Euclidean distance between sample features of different categories.

At this time, the mathematical expression of triplet loss is as follows:

$$L = \sum_i^N \left[ \|f(x_1^i) - f(x_2^i)\|_2^2 - \|f(x_1^i) - f(x_3^i)\|_2^2 + \alpha \right]. \quad (2)$$

In the training process of the neural network, the gradient equation corresponding to each parameter is as follows:

$$\frac{\partial L}{\partial f(x_1^i)} = 2(f(x_3^i) - f(x_2^i)), \quad (3)$$

$$\frac{\partial L}{\partial f(x_2^i)} = 2(f(x_2^i) - f(x_1^i)), \quad (4)$$

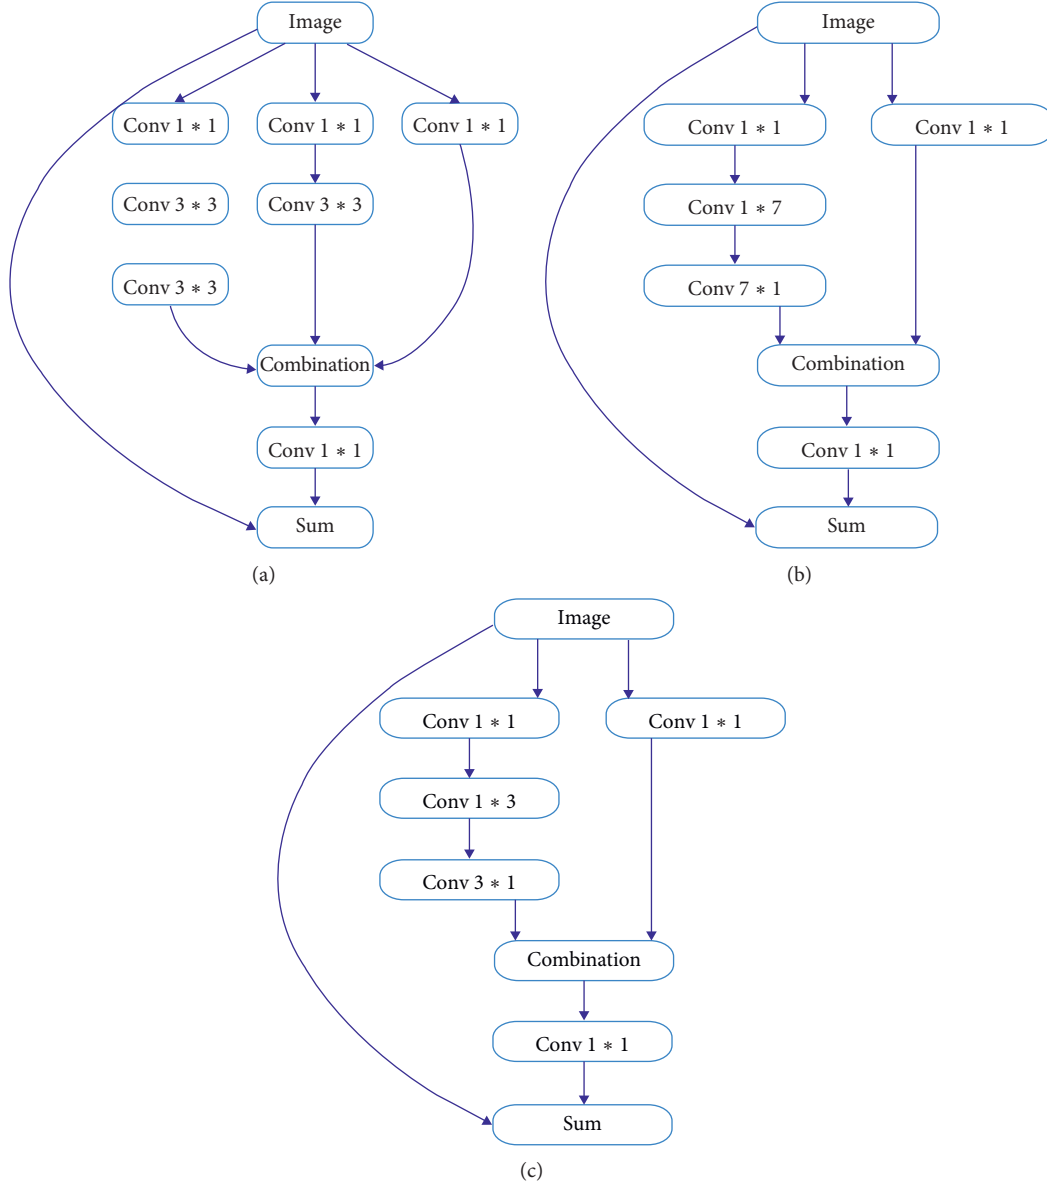

FIGURE 3: (a) ResNet-Inception-1 structure; (b) ResNet-Inception-2 structure; (c) ResNet-Inception-3 structure.

$$\frac{\partial L}{\partial f(x_3^i)} = 2(f(x_1^i) - f(x_3^i)). \quad (5)$$

In order to improve the optimization efficiency of the model, the online method is used to select the combination of triplets. At the same time, in order to prevent the model from falling into the local optimal solution state,  $\alpha$  is removed when selecting the negative sample, so  $x_n^i$  only needs to satisfy

$$\|f(x_1^i) - f(x_3^i)\|_2^2 < \|f(x_1^i) - f(x_n^i)\|_2^2. \quad (6)$$

Center loss can ensure the separation of samples of different categories during the training process and also ensure the aggregation characteristics between samples of

the same category [20]. Center loss can be defined as follows: in which  $c_{yi}$  is the feature center of the  $i$ -th category.

$$L_C = \frac{1}{2} \sum_{i=1}^m \|x_i - c_{yi}\|_2^2, \quad (7)$$

where  $L_C$  is the center loss.  $C_{yi}$  is the feature center of  $i$ -th category.  $x_i$  is the feature before full connection layer, and  $m$  is the size of the mini-batch.

Therefore, the equation expects the smaller the sum of the distances between the characteristics and the feature center of each sample in the batch, that is, the smaller the distance within the class, the better the performance is.

TABLE 1: Basic parameters of ResNet-Inception network structure.

| Structure          | Parameter | Output image size |
|--------------------|-----------|-------------------|
| Conv-1             | 3 * 3     | 147 * 147 * 32    |
| Conv-2             | 3 * 3     | 145 * 145 * 32    |
| Conv-3             | 3 * 3     | 145 * 145 * 64    |
| Pool-1             | —         | 73 * 73 * 64      |
| Conv-4             | 1 * 1     | 73 * 73 * 80      |
| Conv-5             | 3 * 3     | 70 * 70 * 190     |
| Conv-6             | 3 * 3     | 33 * 33 * 256     |
| ResNet-Inception-1 | 5         | 33 * 33 * 256     |
| Reduction-1        | —         | 16 * 16 * 512     |
| ResNet-Inception-2 | 10        | 16 * 16 * 512     |
| Reduction-2        | —         | 8 * 8 * 1024      |
| ResNet-Inception-3 | 5         | 8 * 8 * 1024      |
| Pool-2             | —         | 1792              |
| Dropout            | $x$       | 1792              |

The  $c_{y_i}$  is updated to update the sample set in the input network, and the update rule is as follows:

$$c_u^{v+1} = c_u^v - \frac{\sum_{i=1}^n \delta(y_i = u) \cdot (c_{y_i} - x_i)}{1 + \sum_{i=1}^n \delta(y_i = u)}, \quad (8)$$

in which  $\delta$  belongs to 0 or 1.

Then, the error function in the network can be defined as follows:

$$\text{LOSS} = \text{LOSS}_s + \lambda \text{LOSS}_c, \quad (9)$$

in which  $\lambda$  is the weight in the loss function. When  $\lambda$  is 0, the classifier in the network is Softmax.

**3.2. Face Fe and Matching Based on Deep Reconstruction Network.** In the process of taking photos, people may not fully expose their faces due to the camera angle, light, mood, and equipment. In order to detect faces in different positions or different angles in the image, it needs to first change the scale of the sliding window or the input image. The sliding window also needs to scan the input image according to a certain step size ( $w$ ); as  $w$  increases, the quantity of judgment windows and the amount of computation in the model network will decrease geometrically. When the image is input into the DCNN, there is no need to preprocess the image. However, in order to better detect faces of different sizes, the subacquisition rate of the original input image is scaled at different scales, and then, the image pyramid is obtained, as shown in Figure 4.

In this paper, DCNN is used to process each face image located in the image pyramid according to the input order, and the potential regions in the detected face image are marked at the same time. The coordinate points and size of the specific area of the face in the image are recorded. After all images are processed, all regions of response points in the detected images are reversely mapped to the original face image input in the input layer. Then, the overlapping areas of the image are fused to obtain the final result. Subsequently, face straightening is performed at the stage of no face

alignment, and the face features in different poses are extracted, mainly partial images around the eyes, corners of the mouth, and the tip of the nose in the face image, as shown in Figure 5.

Subsequently, the Euclidean distance [21] and the learning feature matching algorithm are applied to feature matching in the face image, and the matching process is shown in Figure 6.

In the first step, it is necessary to quickly judge the sample that is easy to judge in matching face image samples. The Euclidean distance is used for the similarity between samples, and then, the absolute distance between two points in space is calculated as follows:

$$d(u, v) = \sqrt{\sum_{i=1}^n (u_i - v_i)^2}. \quad (10)$$

In the second step, on the premise of ensuring the feature recognition rate in the face image, a learning algorithm with a higher recognition rate is used to model the features in the face image, and the similarity of the complete face features is matched to realize the refined judgment of the sample. It is evident from Figure 5 that it is needed to extract five local value features in the face image and obtain a total of six 160-dimensional feature vectors, which are spliced into 960-dimensional facial feature vectors. Then, the feature image is reduced to 160 dimensions again by PCA dimension reduction.

Besides, in the second step, joint Bayesian is used to calculate the similarity between samples. Assuming that the two faces are the joint distribution of  $x_1$  and  $x_2$ , respectively, and both obey the Gaussian distribution feature of 0 mean, then the mathematical expression of the covariance between these two face images is as follows:

$$\text{cov}(u_i, v_j) = \text{cov}(\mu_i, \mu_j) + \text{cov}(\varepsilon_i, \varepsilon_j), \quad (11)$$

in which  $\mu$  is the identity of the character and  $\varepsilon$  is the difference between the face itself (light, expression, and posture).

**3.3. Evaluation Indexes for the Testing and Identification of Deep Reconstruction Network Algorithm.** In this paper, Matlab software is used to simulate the deep reconstruction network, and LFW dataset is used for training and testing. In this paper, the following experiments are carried out on TensorFlow platform with Linux as the operating system and 2 \* TITAN X as the GPU. The LFW dataset has a total of 13233 face images, each of which gives the corresponding name, there are a total of 5749 people, and most people have only one picture. The size of each image is  $250 \times 250$ , most of which are color images, but there are also a few black and white face pictures. In this paper, the face images in the dataset are randomly divided into a training set and a verification set. The training set contains 10,000 face images, and the verification set contains 3233 face images. When training the model, first the effects of different parameter settings (learning rate  $\eta$ , attenuation coefficient  $\lambda$ , training

FIGURE 4: Flow chart of face detection in face image.

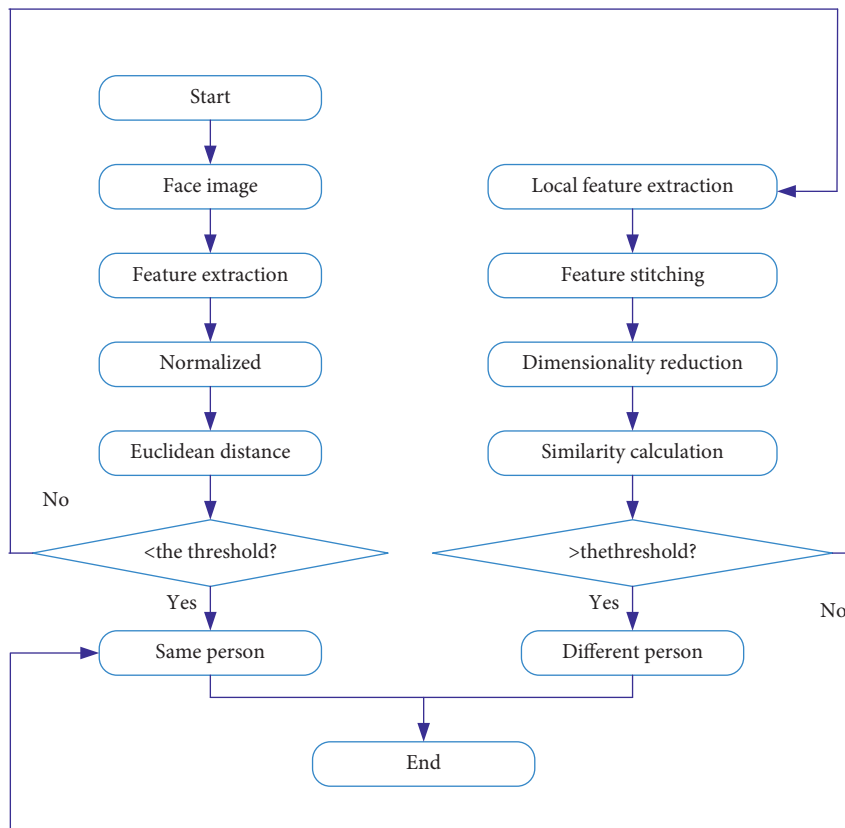

FIGURE 6: Matching process of face feature points.

optimization algorithm, and dropout) on the training effect of the model are analyzed, and the loss value, accuracy value, overfitting rate, and training time are adopted for evaluation of the training effect. Based on the model with the optimal parameter settings, it is applied to the verification set, and the mean average precision (mAP) value is used to evaluate the model recognition effect.

In order to evaluate the effect of the proposed algorithm on face FE, 10140 images of 1150 people from the LFW dataset are selected, and 180 pairs of positive face samples and 180 pairs of negative face samples are randomly selected as test sample pairs. Then, the construction network is used to perform face FE, and the simplest Euclidean distance is used to match feature similarity. Finally, classification accuracy and matching accuracy are used to evaluate the effectiveness of face FE. Subsequently, these 10140 images are used to continue segmentation. Images of 1050 people are selected for facial feature matching algorithm training. For the remaining 100 images of individuals, 200 pairs of positive samples and 200 pairs of negative samples are randomly selected to verify. The recognition accuracy rate, positive sample error rate, negative sample error rate, pairing correct rate, and pairing average time are used to evaluate the matching effect of face features.

In the field of target recognition and detection and recognition, mAP is often used to evaluate the effect of algorithm detection and recognition [22]. In the paper, basic concepts such as error rate, accuracy, precision, recall, and average precision are first introduced. The error rate and accuracy rate are the most commonly used measurement terms in classification evaluation, where the error rate is the ratio of error samples to the total sample, and the accuracy rate is the ratio of correct sample to the total sample. Assuming that the sample dataset is  $S$ , the sample is defined as  $u_i$ , the type of the sample is  $v_i$ , the algorithm's prediction result is  $f(u_i)$ , and then the calculation equations of error rate and accuracy rate are as follows:

$$\text{Error}(f; S) = \frac{1}{m} \sum_{i=1}^m I(f(u_i) \neq v_i), \quad (12)$$

$$\text{Acc}(f; S) = \frac{1}{m} \sum_{i=1}^m I(f(u_i) = v_i) = 1 - \text{Error}(f; S). \quad (13)$$

The calculation equations for the precision rate (Pre) and the recall rate (Recall) are as follows:

$$\text{Pre} = \frac{\text{TP}}{\text{TP} + \text{FP}}, \quad (14)$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}, \quad (15)$$

where TP is the true positive, FP is the false positive, and FN is the false negative.

Using the precision rate as the vertical axis and the recall rate as the horizontal axis, a P-R curve is obtained. The area under the P-R curve is average precision (AP), and mAP is the average of AP indicators in each type of classification

task. In addition, the overfitting ratio (OR) is used to evaluate the algorithm. The calculation equation of OR is as follows:

$$\text{OR} = \frac{\text{TrainAcc}}{\text{ValAcc}}, \quad (16)$$

in which TrainAcc is the training accuracy rate and ValAcc is the verification accuracy rate.

## 4. Results

*4.1. Comparison of Recognition Rate Based on Deep Reconstruction Network Algorithm.* By adjusting the learning rate  $\eta$ , attenuation coefficient  $\lambda$ , training method, and dropout, the impact of different parameters on the accuracy of DCNN model recognition is explored, the database is used to train the DCNN model, and the maximum number of iterations is set to 1000. In the experiment, the activation function in the network is always kept as ReLU. First, the effects of different learning rates  $\eta$  on the model recognition rate are compared. The results are shown in Figures 7 and 8. It is evident from Figure 7 that when  $\eta = 0.0004$ , the recognition accuracy of the algorithm is the highest; when  $\eta = 0.001$ , the recognition accuracy of the algorithm is the lowest. It is evident from Figure 8 that when  $\eta = 0.0004$ , the loss value of the algorithm is the smallest, and when  $\eta = 0.001$ , the loss value of the algorithm is the largest. With the gradual increase in  $\eta$ , the accuracy value gradually decreases and the loss value gradually increases.

Then, the effects of different learning rates on the face recognition performance of the algorithm are quantitatively compared. It is evident from Table 2 that when  $\eta = 0.0004$ , the algorithm has the largest accuracy value (99.03%), the smallest loss value (0.047), and the shortest training time (352 s). When  $\eta = 0.0007$ , the algorithm has the lowest overfitting rate (1.005). In summary, when  $\eta = 0.0004$ , the performance of the algorithm is the best, so follow-up tests are conducted based on this.

The effect of different attenuation coefficients  $\lambda$  on the model recognition rate is compared. The results are shown in Figures 9 and 10. It is evident from Figure 9 that when  $\lambda = 0.0001$ , the recognition accuracy of the algorithm is the highest; when  $\lambda = 0.09$ , the recognition accuracy of the algorithm is the lowest. It is evident from Figure 10 that when  $\lambda = 0.0001$ , the loss value of the algorithm is the smallest; when  $\lambda = 0.09$ , the loss value of the algorithm is the largest. With the gradual increase in  $\lambda$ , the accuracy value gradually decreases and the loss value gradually increases.

Then, the effects of different attenuation coefficients on the face recognition performance of the algorithm are quantitatively compared. It is evident from Table 3 that when  $\lambda = 0.0001$ , the accuracy value of the algorithm is the largest (99.03%), and the loss value is the smallest (0.047). When  $\lambda = 0.0007$ , the training time of the algorithm is the shortest (342 s). When  $\lambda = 0.0001$  and 0.0009, the overfitting rate of the algorithm is the smallest (1.006). In summary, when  $\lambda = 0.0001$ , the performance of the algorithm is the best, so follow-up tests are conducted based on this, and the classifier

| $\eta$ | Acc (%) | Loss  | Training time (s) | Overfitting rate |
|--------|---------|-------|-------------------|------------------|
| 0.0004 | 99.03   | 0.047 | 352               | 1.006            |
| 0.0005 | 96.74   | 0.059 | 354               | 1.006            |
| 0.0006 | 93.15   | 0.062 | 368               | 1.082            |
| 0.0007 | 90.31   | 0.120 | 370               | 1.005            |
| 0.0008 | 88.07   | 0.115 | 400               | 1.011            |
| 0.0009 | 86.41   | 0.170 | 398               | 1.026            |
| 0.001  | 85.05   | 0.206 | 405               | 1.058            |

used in this model is determined to be the triplet loss function.

After comparing the effects of different training methods on the model recognition rate, the results are shown in Figures 11 and 12. It is evident from Figure 11 that when the training method is SGD, the recognition accuracy of the algorithm is the highest; when the training method is Adagrad, the recognition accuracy of the algorithm is the lowest. It is evident from Figure 12 that when the training method is SGD, the loss value of the algorithm is the smallest; when the training method is Adagrad, the loss value of the algorithm is the largest.

Then, the effects of different training methods on the face recognition performance of the algorithm are quantitatively compared. It is evident from Table 4 that when the training method is SGD, the algorithm has the largest Acc value (99.03%), the smallest loss value (0.047), and the lowest overfitting rate (1.006). When the training method is RMSprop, the training time of the algorithm is the shortest (351 s). In summary, when the training method is SGD, the performance of the algorithm is the best, so follow-up tests are performed based on this.

Finally, the impact of different dropout values on the model recognition rate is compared. The results are shown in Figures 13 and 14. It is evident from Figure 13 that when dropout = 0.1, the algorithm has the highest recognition accuracy; when dropout = 0.6, the algorithm has the lowest recognition accuracy. It is evident from Figure 14 that when dropout = 0.1, the loss value of the algorithm is the smallest, and when dropout = 0.6, the loss value of the algorithm is the largest. With the gradual increase in the dropout value, the accuracy value of the algorithm gradually decreases, and the loss value gradually increases.

Then, the effects of different dropout values on the face recognition performance of the algorithm are quantitatively compared. It is evident from Table 5 that when dropout = 0.1, the algorithm has the largest Acc value (99.03%), the smallest loss value (0.047), and the lowest overfitting rate with dropout = 0.2 (1.006). When dropout = 0.6, the training time of the algorithm is the shortest (337 s). In summary, when dropout = 0.1, the performance of the algorithm is the best, so follow-up tests are conducted based on this.

It is set that  $\eta = 0.0004$  and  $\lambda = 0.0001$  in the construction of the deep reconstruction network, SGD is selected as the training method, and dropout = 0.1. Then, the effects of different activation functions on the model recognition rate are compared, as shown in Figures 15 and 16. It is evident from Figure 15 that the recognition accuracy rate is the highest when the activation function is ReLu, and the recognition accuracy rate is the lowest when the activation function is sigmoid. From Figure 16, it is evident that the loss value is the lowest when the activation function is ReLu, and the loss value is the highest when the activation function is sigmoid.

Then, the effects of different activation functions on the face recognition performance of the algorithm are quantitatively compared. It is evident from Table 6 that when the

TABLE 3: Influence of different attenuation coefficients on the training effect of deep reconstruction network algorithm.

| $\lambda$ | Acc (%) | Loss  | Training time (s) | Overfitting rate |
|-----------|---------|-------|-------------------|------------------|
| 0.0001    | 99.03   | 0.047 | 352               | 1.006            |
| 0.0009    | 97.63   | 0.048 | 342               | 1.006            |
| 0.001     | 95.17   | 0.102 | 358               | 1.037            |

activation function is ReLu, the Acc value of this algorithm is the largest (99.03%), the loss value is the smallest (0.047), and the overfitting rate is the lowest (1.006). When the activation function is Tanh, the training time of this algorithm is the shortest (341 s). In summary, when the

activation function is ReLu, the performance of the algorithm is the best, so follow-up tests are carried out on the basis.

Based on the results obtained above, in the deep reconstruction network constructed in this paper,  $\eta = 0.0004$ ,  $\lambda = 0.0001$ , the training method is set to SGD, and dropout = 0.1 for face recognition verification, and the recognition effect is compared with LetNet-5, GoogleNet, AlexNet, VGG-16, VGG-19, and ResNet network. It is evident from Figure 17 that the area under the P-R curve of the algorithm constructed in this paper is the largest; that is, the mAP value is the largest. The mAP values of different models are ranked, and the result is the algorithm proposed in the paper > ResNet > AlexNet > VGG-19 > GoogleNet > VGG-16 > LetNet-5.

4.2. Face Fe and Matching Verification Based on Deep Reconstruction Network Algorithm. The face recognition and FE algorithm proposed in this paper is applied to the LFW dataset to extract and match face features. The results are shown in Figure 18. It is evident that the algorithm proposed in this paper can effectively extract the features in the face image and can complete the matching of the same features and then realize the recognition and detection of the same face.

Then, the deep reconstruction network algorithm constructed in this paper is applied to FE and feature matching in face images, and the performance is compared with other models. It is evident from Table 7 that when the construction method of this paper is trained, the classification accuracy rate on the training set is 97.94%, and it is higher than the LetNet-5, VGG-16, and VGG-19 algorithms, the accuracy rates of which are 2.1%, 0.94%, and 1.16%, respectively, but lower than GoogleNet, AlexNet, ResNet algorithm, the accuracy rates of which are 0.14%, 0.58%, and 0.46%, respectively. In the verification set, the correct matching rate of the algorithm constructed in this paper is 84.72%, and it is higher than the LetNet-5, VGG-16, and VGG-19 algorithms, the correct matching rates of which are 6.94%, 2.5%, and 1.11%, but lower than the GoogleNet, AlexNet, and ResNet algorithms, the correct matching rates of which are 0.56%, 1.39%, and 1.95%, respectively.

The matching effect of the features extracted from the face image is compared. The comparison results of the total recognition rate are shown in Table 8. It is evident that, after the joint Bayesian method is used in the algorithm proposed in this paper, the correct recognition log rate in the verification set is the highest (88.75%), and it is higher than LetNet-5, GoogleNet, AlexNet, VGG-16, VGG-19, and ResNet algorithms, the correct recognition rates of which are 4%, 1.25%, 0.75%, 3.75%, 3.25%, and 0.25%, respectively.

The effects of using only the joint Bayesian method and the algorithm in this paper on the matching effect of face features are compared, and the results are shown in

DCNN model. In this paper, the effects of different learning rates, training methods, attenuation coefficients, and dropout on the recognition performance of the algorithm are compared. Studies have shown that too large learning rate will cause the algorithm to appear unstable during the learning process, which in turn affects the performance of the algorithm [23], which is consistent with the results of this paper that the learning rate is negatively correlated with the performance of the algorithm proposed in this paper. Then, the effects of different training methods on the recognition rate of the DCNN model are compared. The RMSprop-based network training method will increase the probability of overfitting, and the madam-based network training method will increase the momentum parameter of Nesterov, so the training will take more time. Previous studies have shown that adjusting dropout discarding rate in many network parameters can solve the problem of overfitting in the model, but excessively increasing dropout discarding rate will reduce the RA of image classification, and the overfitting probability will increase [24], which is basically consistent with the results in this paper that the dropout is negatively correlated with the recognition performance of the constructed face recognition algorithm. At the same time, the effect of different attenuation coefficient settings on the recognition performance of the proposed algorithm is compared. It is found that the attenuation coefficient is negatively correlated with the recognition rate of the proposed algorithm. This is because excessive weight attenuation coefficient will destroy the stability of the algorithm in the learning process, so choosing the smallest possible attenuation coefficient can ensure the stability of the face recognition algorithm [25].

Facial features are mainly divided into color (skin color), contour (ellipse), illumination (hair, eyes, and jaw), template

TABLE 9: Comparison of total recognition rates of facial features of different models.

| Algorithm    | Matching time (s) | Match log correctly | Correct match rate (%) |
|--------------|-------------------|---------------------|------------------------|
| United Bayes | 240.15            | 350                 | 87.5                   |
| Our method   | 206.44            | 355                 | 88.75                  |

(mean and variance), transformation domain (feature representation), structure (facial symmetry), inlay (mosaic rule), and histogram features (grey distribution) [26]. In the process of face feature detection, because of factors such as highly nonlinear distribution (such as facial expression and color difference), ornaments (beard, glasses, and hats), the expression (facial muscle movement), light (brightness and angles), image quality (resolution), and a complex scenario (face number and gap), classification errors are caused [27]. Xu et al. proposed a semisupervised method for FR in LFW and YTF databases and found that the recognition rate of the algorithm was 98.63% and 91.76%, respectively [28]. In this paper, the constructed deep reconstruction network is applied to the FE of face images in LFW data; after the proposed algorithm is compared to LetNet-5 [29], VGG-16 [30], and VGG-19 [31] algorithms, it is found that it has a higher matching accuracy rate but slightly lower than GoogleNet [32], AlexNet [33], and ResNet [34] algorithms. However, the algorithm proposed in this paper can reduce the complexity of model generation, while preventing the occurrence of overfitting. Finally, the Bayesian method [35] is used to match face features. It is found that the accuracy rate of the proposed algorithm for face features matching is higher than LetNet-5, VGG-16, VGG-19, GoogleNet, AlexNet, and ResNet. At the same time, compared with the joint Bayes method alone, it can reduce the time consumption of feature

matching [36] and improve the matching accuracy [37], indicating that the algorithm proposed in this paper can quickly perform large-scale face image feature matching and has certain advantages compared with other DCNN models.

## 6. Conclusion

In this paper, a new deep reconstruction network is constructed using the Inception structure in the GoogleNet network and the residual structure in the ResNet network, and it is applied to face recognition for optimal parameter selection of the algorithm. Based on this algorithm, face pyramid and local feature segmentation are applied to construct a face FE algorithm. It is found that it has a better FE effect than the general DCNN model. Finally, based on the algorithm, the face feature matching is achieved using the joint Bayesian method, and the results are verified. The results show that the model constructed in this paper can effectively identify face images with different interference factors. However, the model is trained and verified only through the images in the database. A specific FR system needs to be developed to explore its application effect in video portrait recognition. In conclusion, the results help for the subsequent development of FR system based on DCNN and the improvement of the efficiency of FR.

## Data Availability

The raw/processed data required to reproduce these findings cannot be shared at this time as the data also form part of an ongoing study.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Since the twentieth century, it has been an era of rapid development of information technology; the scale of data is almost the growth rate of the blowout type; no matter what it is, a large number of enterprises or departments are increasing a large number of cost data. However, the current cost management model still remains in the traditional management method and lacks a smarter big data analysis method. In addition, there is a lot of research on big data applications, and there are few e-commerce supply chains. Therefore, the research purpose of this study is to use big data technology to explore a series of practical operation methods for supply chain Cultural Communication Enterprises and summarize the operation mode of building SCC control by using big data technology. In terms of research methods, this study combined bibliographic review and empirical analysis, explored cost-based mobile e-commerce (EU) cost control related to big data information, used smart and digital analysis methods to thoroughly analyze CCE business issues from internal and external supply chains, established an e-commerce business supply chain cost control model based on big data technology and elaborated cost control procedures and measures. Finally, it summarized the research results and drew conclusions to provide a theoretical basis for promoting enterprises products products to reduce supply chain costs. The research in this study has achieved a breakthrough in the cost management and control of EE; it provides empirical guidance and theoretical reference for EE to adopt big data technology for cost command of supply chain (CCSC), could help EE to reduce cost of supply chain management to gain higher profit margins, and promote e-commerce industry as a whole to the next level eventually. This study concluded that the use of big data technology for cost command can solve a series of problems effectively, such as the lack of systematic analysis of cost, the lack of contractual partners, the serious waste of sales links, and the policy errors of logistics links, and continuously improve the enterprise management level and the decline of comprehensive cost. The application mode of supply chain CCE enterprises using big data technology constructed in this study has universal applicability.

## 1. Introduction

With the popularity of the computer and the rapid development of Internet, the worldwide data online, platform, and cloud technology, such as vocabulary, more and more frequent in people's daily life, the need for a smartphone has been preliminarily realized. Chinese Internet users have also been broke through 800 million; this is really beyond the forecast process of some experts, can say, today's world has entered the Internet era of big data in advance. The development of big data technology in daily life is not only a subversive change to the traditional way of life but also a

profound change to the production and operation mode of traditional enterprises. Under the background of big data technology era, most enterprises relying on traditional sales means have been seriously impacted, and some enterprises are difficult to adapt to the changes of big data era and survive [1].

More and more people realize that the development of enterprises must take advantage of the trend and only rely on the advancement of current Internet technology to innovate and change the business model and get out of a development model that not only has the traditional offline model but turns to the integration of the traditional offline model and

modern online model [2]. More and more business operators are understood; the economy and the great development of science and technology have brought the big changes in the business mode and not only will have a profound impact on supply and demand; in the context of the overall supply, companies increasingly need to spend more cost to satisfy the consumers with a variety of consumer demand; in order to fundamentally profit space, enterprises urgently need to be done in each link cost control, and the informationization of modern society relying on the traditional cost accounting method efficiency is extremely low and obviously cannot meet the needs of the era of the current business development at high velocity. If enterprises want to change this situation, they must innovate the cost control mode. The arrival of the era of big data makes all this possible. The development of big data technology makes every data full of effective value space, and every piece of information contains a large number of value clues, which undoubtedly provides some enlightenment for many enterprises in transition [3]. How to make full use of Internet big data technology to analyze and control the cost of production and sales and realize enterprise profit has become a major issue that all enterprises need to face and solve.

The current technology for large data in the electronic commerce research mainly concentrated in the following three points: first, in terms of the application of the big data technology, with the influence of the technology, the government pays more and more attention to the technology as it plays a role in economic development; the domestic experts and scholars have put forward their own mentality, and the representative professor Wang Shan from big data technology professional characteristics discusses the data about the role of e-commerce platform to create. He discussed different aspects that infect big data technology and analyzed the technology of data in the foreseeable future opportunities and challenges facing; he thinks that big data technology in the application of e-commerce is a double-edged sword and can better serve the economic construction; it is very difficult, if there is no scientific system to regulate guarantee has been playing a positive role [4]. Second, in terms of the cost command, the scholar Han Lan believes that the cost command of the enterprise should be extended to all related enterprises in the whole supply chain rather than confined to the enterprise itself. He shall, in accordance with the scientific supply chain management thinking, in order to control cost as the core goal to set up the control model of SCC and its cost to enterprises, use the model analyzed with the laws of the cost management thinking and understanding and successfully applying cooperation and game thinking into SCC control thinking [5]. Third, in the cost control and combining uses of big data technology, a relevant expert Cheng Ping with large depth of the data mining technology construct the ERP management model; the model mainly integrates the cloud computing platform, the Internet of things technology, large inventory management, and data analysis center four core modules; e-commerce products were introduced in detail from the inbound to the outbound way of concrete application and pointed out the enterprise plays a leading role in this process [6]. By consulting a large amount of literature, we found that

domestic and foreign scholars have basically the same pace of research on this issue, and both of them focus their research on the application field, cost control, and the combination of the two. First, in terms of the application of large data, Martin Christopher's study, this study discusses the big data technology development potential and future development direction and is trying to expand its application field to healthcare, retail, education, and other industries; he also probes into the technology of big data in the department of public safety space, and the big data technology popularization after how to ensure the security of personal information anxiety is proposed. Second, in terms of SCC command, Charles Bolier proposed SCC management strategies based on the challenges and opportunities of big data [7]. He also focused on analyzing how enterprises should improve the level of cost command by applying the principles of supply chain in the process of cost command [8]. Finally, in the electronic commerce enterprise cost control and combining use of big data technology, Michel Roberto thinks that the future competition between electric business platforms will focus on the logistics speed contest; he thinks target cost law should get electricity business management platform and thinks rising competitiveness comes from the reasonable positioning of the enterprise; the enterprise's distribution network can improve the distribution of costs and benefits, in terms of specific measures, and he also gives some suggestions and opinions to the construction [9, 10].

It is not difficult to find that although the current research on the control of traditional SCCs has become mature, the research focus of many experts, and scholars have not focused on the background of big data technology, and the combination of supply chain ideas and the target cost method has basically achieved an organic combination. However, at present, experts and scholars have not been able to really shift their attention to the background of big data technology. Their current research is still in the traditional medical care, education, and search industries, and there is still a lack of study on the integration in e-commerce, a sunrise industry. Therefore, after fully consulting and analyzing the shortcomings of domestic and foreign research results, this study decides to carry out the following innovations on the existing research: first, the research purpose of this study is clear, which directly targets the innovation of the cost control mode under the background of big data technology. Second, this study boldly broke through the current research is only limited to the theoretical dilemma, the first to carry out specific application research. Finally, this study is neutral and does not have the color of commercial dependence, which is different from previous studies that are often subject to the manipulation of a specific company or organization and affect the objective neutrality of research results.

## 2. Related Research Review and Theoretical Basis

*2.1. Research Practice.* This study is split into five parts, and the command of each part is arranged.

The first part is the referral. In this part, the significance of this research is stated [11]. On the basis of analyzing numerous research results, we summarized the current research status and objectively pointed out the limitations of

existing research. Finally, according to the goal of this research and the idea of improving the existing research, the new innovation point and goal of this research are summarized [12]. The second part of this study is a review of relevant research and a summary of the theoretical basis; mainly in this study, core concepts and basic theories were described, and the SCC command method of this study is described [13, 14]. The third part analyzes the trouble existing in the CCE enterprises. This study analyzes the trouble existing in the cost command process of e-commerce industry. The fourth part is the construction of the cost command model of big data technology in the supply chain of EE. This study adopts the method of case analysis and constructs a scientific cost control application model [15]. The fifth part is the summary of the research conclusion.

## 2.2. Core Concept Elaboration

**2.2.1. Big Data Technology.** Big data is a collection of data processing technologies with a large scale and the ability to store, analyze, and process data for surpassing the scope of conventional database processing capabilities. Big data has fast data flow cycle, massive data scale, low value density space, and diversified data types [16]. Different from traditional database processing technology, big data need to go through the deep processing of big data processing technology to truly play its value. Massive parallel processing, distributed file, data mining, and distributed database technology is the big data technology to adapt to the form, and the concrete form of big data is often characterized by big data pretreatment technology, data acquisition technology, and data statistical analysis technology [17, 18]. Large data pretreatment technology is the combination of large data acquisition technology of large amounts of data input to a centralized distribution of a large database, and on the basis of the data preprocessing and data cleaning, make vast amounts of information data and valuable data, and the characteristic of the process need a lot of import data; its transport amount could reach MB per second or even in the near future to gigabit per second. Data collection technology is to use multiple database tags to collect and store data information from the Internet, mobile phone client, and other end users [19]. The depth of the data mining technology is according to the relevant provisions of the state and the request; using the algorithm classifies the concept of the data and extracting; the technology is mainly suitable for column type storage calculation and may use GreenPlum algorithm; the process of data mining is the most critical step because the link is often needed to use tools and Kmeans clustering Naive Bayes classification and SVM statistical tools to assist in the completion; the challenge to give priority to with single thread control algorithm is complex and both computation and large amount of data [20].

**2.2.2. SCC and Control Theory.** SCC refers to the sum of all costs incurred by enterprises in production, sales, procurement, and other links to support the operation of the supply chain. The cost of supply chain management is the extension of the cost of the whole supply chain. Cost of SCC

control is the enterprise according to the previous data as well as the recent strategic arrangements and make cost management control plan in advance before the creation of the cost or being in the process of producing cost of the various factors that affect the cost to ensure the expected cost goals to achieve management behavior.

The theory of SCC command mainly includes transaction cost theory, interorganization cost management theory, and value chain theory. Transaction cost is the cost generated in the transaction process, including negotiation, contrast, contract signing, supervision performance, incentive, and other expenses. In addition, interest sharing is the basis for long-term cooperation between supply chain companies. It is based on the contribution of each company to the entire supply chain, but it is actually difficult to divide and evaluate the tribute of each enterprise. In this case, the profit distribution may be unfair, resulting in a large number of agency arbitration events, which leads to the increase of transaction costs, and the increase of these costs has no economic benefits. Therefore, only by mutual trust and full information sharing can enterprises reduce the total cost of the supply chain. Interorganizational cost management is to regard the upstream and downstream enterprises or related enterprises as the same organization. The common goal of the organization is to reduce the total cost of the supply chain through joint efforts. All the relevant enterprises in the supply chain share risks and share profits and strive to improve their profits and efficiency on the same ship. The greater the contribution of the chain, the more profit is allocated. However, the interorganizational cost management mode is largely dependent on the coordination among the interorganizational enterprises, so the model is more suitable for information sharing and fine-grained supply chain with larger interaction. The greater the contribution of the chain, the more profit is allocated.

### 2.2.3. Methods of SCC Control

- (1) Target cost control method. The target cost control method is based on customer demand and market-oriented. It uses value engineering to analyze the cost function in the planning and design stages of products and thus creates a method to manage the cost.
- (2) Activity cost control method. Activity-based costing is usually based on the guiding ideology of "products consume activities, activities consume resources." Under the guidance of this idea, resource cost is allocated to the process of operation, and then, the cost of product consumption is tracked based on the driver of activity, so as to calculate the unit cost of various products and the cost of bulk total products to achieve the optimal cost management scheme.
- (3) Responsibility cost control method. Responsibility cost refers to the cost generated in the process of assigning the enterprise to each responsibility management center. The establishment of responsibility cost needs the support of the responsibility

cost system, which establishes the responsibility cost center according to the production and operation structure of the enterprise, divides responsibility into the control cost control effect, and carries out performance assessment, and carries out cost control responsibility for each department and specific executive to control cost.

- (4) Standard cost control methods. The standard cost control method is a comprehensive management method which combines the accounting function, feedback function, and forecast function organically.

The management mode constructed in this study is to distinguish the process steps, including the comprehensive cost management method of pregeneration prediction and adjustment in the process of production and postproduction analysis. In the forecasting stage before cost generation, it is necessary to use target cost law and standard cost law to reasonably forecast the cost of each department. In the process of cost generation, it is often necessary to conduct repeated accounting combined with activity-based cost rule. After the cost is generated, the utility of the cost control process is judged, and the consequence is held accountable according to the liability cost law.

**2.3. Supply Chain Cost Control Methods.** According to the "Organizational Industry Theory," first assume that consumers have the following preferences:

$$U = \int_0^{Q_s} Q_s - P. \quad (1)$$

The positive real number  $Q_s$  is the quality preference parameter of consumers. At a given price, all consumers like high quality, but consumers with high quality preferences are more willing to spend money for high quality. The model assumes that product preferences are uniformly distributed in a positive interval  $(Q_L, Q_H)$ :

$$f(Q) = \frac{1}{\Delta Q} (Q_L < Q < Q_H). \quad (2)$$

Assuming that there is only one product in the market with quality  $s$  and price  $p$ , the demand for this product is equal to the number of consumers who have product preference parameter  $Q$  and satisfy  $Q_s \geq p$ . In other words, assuming that the total number of consumers is 1, the demand for the product is

$$D(p, s) = \begin{cases} 0, & \left(\frac{p}{s} > Q_H\right), \\ \frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s}, & \left(Q_L \leq \frac{p}{s} \leq Q_H\right), \\ 1, & \left(\frac{p}{s} < Q_L\right). \end{cases} \quad (3)$$

The demand for products cannot reach the total number of consumers, so it can be seen that the actual demand for products is

$$D(p, s) = \frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s}. \quad (4)$$

**2.4. Financial Benefits under Supply Chain Management.** Assume that the supply chain is a simple supply chain consisting of a manufacturer and a seller. Assuming that the quality of the product is constant, the manufacturer and seller only determine the output  $QM$ , the sales  $QR$ , and the final market price  $P$  of the product. The median price  $PM$  of the product is set as the product price that the manufacturer asks for when the product is delivered to the seller's location, which actually includes the production cost and transportation cost of the product. Assume that the manufacturer's marginal production cost and transportation cost of the product are uniformly recorded as  $CM$ , and the seller's marginal cost of sales of the product is  $CR$ . It is assumed that the information between the manufacturer and the seller is symmetrical and complete, that is, the demand function faced by the product and  $CM$  and  $CR$  are the common knowledge of the manufacturer and the seller.

When manufacturers and sellers cooperate to determine output and final prices, the supply chain can be regarded as a "super organization." The purpose of manufacturers and sellers is to maximize the profits of the entire supply chain. Distribute effectively and reasonably among enterprises. Then, the financial benefits of the organization can be seen as

$$\max \pi = (p - CM - CR) * QM = (p - CM - CR) * \left(\frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s}\right). \quad (5)$$

$P_0$  is the consumer's maximum payment capacity for the product. Assuming that the payment capacity is large enough to not affect the company's decision-making conditions, the solution can be obtained:

$$\begin{aligned} p^* &= \frac{1}{2} (sQ_H + CM + CR), \\ QM^* &= \frac{1}{2\Delta Q} \left(Q - \frac{CM + CR}{s}\right), \\ \pi^* &= \frac{1}{2s\Delta Q} (sQ_H - CM - CR)^2. \end{aligned} \quad (6)$$

It can be seen that  $\pi^*$  is the largest profit achieved under the collaborative management of the supply chain.

**2.5. Financial Benefits under Nonsupply Chain Coordination.** Assuming that the manufacturer has absolute authority and can unilaterally determine the most favorable intermediate price  $PM$ , since the assumption is that the information is symmetric, the manufacturer can accurately predict the seller's optimal price and optimal sales volume. A rational manufacturer should make own output and sales volume consistent, that is,  $QM = QR$ ; then, the manufacturer's profit function is

$$\begin{aligned} \max \pi &= (CM - CR) * \left( \frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s} \right), \\ \text{s.t. } \max_p \pi &= (P - PM - PR) * \left( \frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s} \right). \end{aligned} \quad (7)$$

Solving this function can be obtained, and the optimal solution for the seller is

$$\begin{aligned} p^* &= \frac{1}{2} (sQ_H + PM + CR), \\ QM^* &= \frac{1}{2\Delta Q} \left( Q_H - \frac{PM + CR}{s} \right), \\ \pi^* &= \frac{1}{16s\Delta Q} (sQ_H - CM - CR)^2. \end{aligned} \quad (8)$$

For the manufacturer, the optimal solution is

$$\begin{aligned} p^* &= \frac{1}{4} (3sQ_H + CM + CR), \\ QM^* &= \frac{1}{4\Delta Q} \left( Q_H - \frac{CM + CR}{s} \right), \\ \pi^* &= \frac{1}{8s\Delta Q} (sQ_H - CM - CR)^2. \end{aligned} \quad (9)$$

The total profit of the supply chain is

$$\pi_{SC1} = \frac{1}{16s\Delta Q} (sQ_H - CM - CR)^2. \quad (10)$$

Assuming that the seller has absolute power and can unilaterally determine the most favorable middle price PM because the hypothetical information is symmetric, the seller can accurately predict the seller's optimal price and optimal sales volume, and a rational seller should make your sales volume consistent with the expected output, that is,  $QM = QR$ ; then, the seller's profit function is

$$\begin{aligned} \max_p \pi &= (P - PM - CR) * \left( \frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s} \right), \\ \text{s.t. } \max_p \pi &= (PM - CM) * \left( \frac{Q_H}{\Delta Q} - \frac{p}{\Delta Q \cdot s} \right). \end{aligned} \quad (11)$$

Solving this function can be obtained, and the optimal solution for the seller is

$$\begin{aligned} p^* &= \frac{1}{2} (sQ_H + CM + CR), \\ QM^* &= \frac{1}{2\Delta Q} \left( Q_H - \frac{CM + CR}{s} \right), \\ \pi^* &= \frac{1}{4s\Delta Q} (sQ_H - CM - CR)^2. \end{aligned} \quad (12)$$

As for the manufacturer, his profit depends entirely on the intermediate price and the order quantity. In this case,

the manufacturer is completely passive, and the manufacturer's profit is 0. The profit of the entire supply chain is

$$\pi_{SC2} = \frac{1}{4s\Delta Q} (sQ_H - CM - CR)^2. \quad (13)$$

Compared with the formula profit under collaborative management, there is no loss, but because the producer has no profit, this structure is very unstable.

### 3. Analysis of the Problems and Causes in the Cost Control Process of the Supply Chain of EE

#### 3.1. Problems and Reasons of External Supply Chain

*3.1.1. Lack of System.* Instead, it makes a preliminary calculation of the costs of product sales, management, operation, and production and processing, which are difficult to truly reflect the logistics cost. Therefore, EE have not yet made accurate cost accounting in terms of logistics costs, and it is difficult to control the costs of each link in detail. In addition, it is difficult to evaluate the marketing impact and understand the true intentions of customers to accurately control them. The imperfect information security of the e-commerce platform is also an important reason for adapting to the difficulties of SCC e-commerce. Information security in the information society is also very important for e-commerce operators. A series of operations of consumers purchasing consumer goods often involve personal data security in various aspects. However, the information security situation of EE is not optimistic at present, and consumers' information such as registration, browsing, payment, purchase, and address are still at risk of being leaked. The EE exposed to the existence of leakage of user information scandal will bring incalculable losses to enterprises.

*3.1.2. Lack of Stable Business Partners.* Purchasing departments are often cheaper than prices as a means of supplier selection at this stage; but even with long-term cooperation, they are not formed for long-term cooperation in supply chain channels. In fact, relationships tend to be due to price discounts and improved quality of service for suppliers, but a truly valuable spirit of cooperation must be based on contracts. EE is always looking for a partner because there is no stable partner. Such frequent partner changes actually increase the cost of inventory management.

Problems existing in the external supply chain have an adverse impact on cost control, which is reflected in the lack of systems and stable business partners. Specific research data are shown in Table 1 and Figure 1.

*3.2. Problems and Reasons of Internal Supply Chain.* The cost analysis results of internal supply chain issues affecting the supply chain are shown in Table 2 and Figure 2.

*3.2.1. Trouble and Cause in the Procurement Process.* Now, many EE do not have a clear definition of the rights and responsibilities of the procurement system, and there

TABLE 1: Cost analysis table of external supply chain problems affecting supply chain.

| External supply chain problems affect SCC analysis table |  |  |                                      |                    |

| Negative composition reduces institutional defects       | High cost operation project name             | Current cost value (ten thousand yuan) | Ideal cost range (ten thousand yuan) | Results the rating |
| System lack  | Imperfect audit system                       | 37                                     | 20-30                                | Not ideal          |
|  | Evaluation system standards are inconsistent | 32                                     | 18-25                                | Not ideal          |
|  | Consumer information security                | 46                                     | 35-50                                | Fair               |
| Lack of stable business partners                         | Procurement costs                            | 18                                     | 10-15                                | Not ideal          |
|  | Cost of finding business partners            | 10                                     | 5-8                                  | Not ideal          |

FIGURE 1: Cost analysis table of external supply chain problems affecting supply chain.

are many problems not only in the postsetting, even some nominal, but also in the name of saving costs. For individual purchasers, the lack of audit link or slack audit makes the procurement link prone to fraud. This responsibility setting mode that fails to regulate the procurement standard will inevitably lead to the procurement link cost higher than the actual required cost, resulting in inflated cost.

**3.2.2. Trouble and Cause in the Sales Link.** Now, most large e-commerce platforms lack quantitative segmentation of the sales market, with large span of sales objects and levels, complex business scope, and failure to form core competitiveness, which inevitably leads to excessive marketing costs.

**3.2.3. Existing Problems and Reasons in Logistics.** Along with our country logistics network, the upgrade of the actual logistics cost is gradually narrowing, but the implementation of the phase to the terminal consumers rarely see the substantial fee reduction effect, still appeared in some remote areas, and the present situation of the cost is higher and higher; this seems to increase the income of electricity, but in terms of volume compromised, and network construction is, in fact, is not conducive to reduce logistics cost of recovery.

The side effect of the lack of the internal supply chain system on cost reduction is also increased. The survey and analysis table is given in Table 2.

#### 4. Construction of the Supply Chain Cost Control Instruction Mode under Big Data

Based on the analysis of a huge number of cases, this study constructs a model of using big data technology to control the cost of supply chain. This model is based on the analysis and research of a large number of e-commerce cases through big data technology, which is the core part of this study with most energy.

**4.1. Construction Principles of the SCC Command Model.** Building big data technology under the cost command model is a complex and systematic project, wants to get ideal result, inevitable need in the process of constructing the model following the general principles of control, and in particular also requires a combination of electricity enterprise organization structure, the advantages and disadvantages, the enterprise strategic target, and the industry of the enterprise environmental factors. These factors can be summarized in the following principles: first, to cut the cost as the basic guide; second, pay more attention to the control

TABLE 2: Cost analysis table of internal supply chain problems affecting supply chain.

| External supply chain problems affect SCC analysis table |  |  |                                      |                       |
|--|--|--|--------------------------------------|-----------------------|
| Negative composition reduces institutional defects       | High cost operation project name                                 | Current cost value (ten thousand yuan) | Ideal cost range (ten thousand yuan) | Results the rating    |
| Procurement  | Define the rights and responsibilities of the procurement system | 45                                     | 25–35                                | Not ideal             |
|  | Individual purchaser qualification review                        | 7                                      | 10–12                                | Is not up to standard |
| Sales section  | Quantitative segmentation of sales markets                       | 32                                     | 25–30                                | Not ideal             |
|  | Sales level span   | 21                                     | 15–20                                | Not ideal             |
|  | Business scope span  | 2                                      | 0.5–1                                | Not ideal             |
| Logistics links  | Construction of the logistics network                            | 136                                    | 80–110                               | Excessive             |
|  | Terminal earnings  | 56                                     | 60–100                               | Is not up to standard |

FIGURE 2: Cost analysis table of internal supply chain problems affecting supply chain.

of core costs; third, the implementation of the employee responsibility incentive and punishment system, to ensure the cost of the problem to the people responsible; and fourth, strengthen overall planning for the cost of each link to avoid the domino effect. The priority of these principles is shown in Figure 3.

4.2. *SCC Analysis under Big Data Technology.* SCC under big data technology mainly includes commodity cost, ordering cost, transaction cost, information cost, labor cost, and transaction cost. Among them, the cost incurred in a series of negotiation, contract signing, and negotiation activities with the supplier is the transaction cost. Information cost refers to the cost of unable to effectively select high-quality suppliers caused by information asymmetry. The order cost is divided into fixed cost and variable cost. The order number and variable cost are related, and the fixed cost does not change. The total cost is the sum of information cost, ordering cost, and commodity cost. The cost composition of the procurement link is shown in Table 3 and Figure 4.

### 4.3. Analysis of the Role of the SCC Command Mode

4.3.1. *Continuously Improve Performance Appraisal Results.* The control effect in turn improves performance and helps to continuously improve performance evaluation results. The schematic diagram of the 2016–2020 KPI performance evaluation is shown in Figure 5.

4.3.2. *Continuous Improvement of Enterprise Supply Chain Management.* Prior to cost command, the organization can make a reasonable budget and inform and correct the deviation in time in cost control. After cost control, the course can be summarized, and the next management plan can be improved. Enterprising the cost of data in the business process is improved, through scientific analysis of defects in the process of management, to improve and promote the improvement of the enterprise management level, not only it can produce positive impact to the enterprise, and the progress of the domain also has a strong reference meaning, This field also has strong reference significance. The distribution diagram of the standardized enterprise supply chain management model is shown in Figure 6.

4.3.3. *Steadily Improve the Comprehensive Competitiveness of Enterprises.* EE to strengthen the training and the training of staff, improve staff’s professional skills and culture quality, fundamentally protect the company’s operating efficiency, effectively command the company cost, implement relevant indicators, and make the enterprise overall goals agreed, can promote to achieve the enterprise strategic goals; the standardization of the competitive enterprise image shows the diagram as shown in Figure 7. After the establishment of the cost command system, the cost command can be effectively implemented. With the improvement of the enterprise management level, enterprise competitiveness will be more and more strong. The enterprise will have strong and huge space.

Through the establishment of the assessment system, the innovation of the management level and the improvement of comprehensive competitive power, the cost of EE under the background of big data technology is significantly reduced

| Algorithm                   | 1   | 2   | 3    | 4    |
|-----------------------------|-----|-----|------|------|
| Collaborative optimization  | 850 | 800 | 4950 | 3760 |
| Genetic algorithm           | 650 | 580 | 3600 | 2660 |
| Particle swarm optimization | 320 | 200 | 2150 | 1770 |

FIGURE 9: Comparison of Co, GA, and PSO when applied to the Plants dataset.

compared with the traditional model. The specific comparison figure is shown in Figure 8.

#### 4.4. Analysis of Data Mining Algorithms under Big Data.

The coevolutionary algorithm is implemented by Matlab7.6 programming under the Windows XP operating system, and the genetic algorithm, particle swarm algorithm, and coevolutionary algorithm are, respectively, applied to association rule mining by tracking the average fitness value and running time of the population during the evolution process. Performance pros and cons at the time.

Using genetic algorithm, particle swarm algorithm, and co-evolution algorithm for data mining and calculation, the Chess dataset, Solar Flare dataset, and the Plants dataset are obtained respectively, which is shown in Table 4. The dimensions of these two datasets are 6-dimensional and 10-dimensional, respectively, which belong to low-dimensional datasets. It can be seen from Figure 9 that Using the genetic algorithm, particle swarm algorithm, and co-evolution algorithm for data mining and calculation, the Chess dataset, Solar Flare dataset and the Plants dataset are obtained respectively. It can be seen from Figure 9 that in the early stage of evolution, the convergence speed and individual quality of the coevolutionary algorithm are slightly better than the other two algorithms. As the number of iterations continues to increase, the three algorithms all converge. From the experimental results, when mining association rules on low-dimensional datasets, the mining quality of the three is not very different, and the coevolutionary algorithm is slightly better than genetic algorithm and particle swarm algorithm.

## 5. Conclusion

This study mainly studies the trouble existing in the SCC command process of EE in the era of big data, proposes the management and command mode of SCC command based on big data technology, and analyzes the role that each supply chain link can play in this mode. In this study, the research for big data era background, promoting EE, adopts the strategy of big data view for cost control experience

theory instruction and guidance, gives full play to the author's knowledge and energy to help e-commerce businesses to get more profit by reducing cost, and vigorously promotes the further development of the electricity industry.

This study reflects the strong characteristics of new arguments in both the topic selection stage and the creation stage. First of all, this study discusses how to apply big data to EE to save the cost of supply chain under the background of booming big data technology. Second, in the creative process, this study changes the previous scholars' emphasis on theory and ignores the practical defects and focuses on the possibility of practice on the basis of summarizing the theory.

Through research, this study finds that there are still many improvements to be made in the practice of SCC command in the e-commerce industry. For example, most EE lack systematic analysis of costs, do not have contractual partners, serious waste of costs in sales, and wrong policies in logistics. Through the study of this research work, the conclusion is drawn that using big data technology for cost control can effectively solve many of the above problems, so as to continuously promote the progress of enterprise management and the reduction cost. The practical feature of this study lies in that it not only puts forward corresponding measures but also has a general significance for the CCE industry.

## Data Availability

No data were used to support this study.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Nowadays, the development of big data is getting faster and faster, and the related research on motion sensing recognition and complex systems under the background of big data is gradually being valued. At present, there are relatively few related researches on vertical Baduanjin in the academic circles; research in this direction can make further breakthroughs in motion sensor recognition. In order to carry out related action recognition research on the lifting action of vertical Baduanjin, this paper uses sensor technology to collect the motion video image of vertical Baduanjin based on the background of big data and uses action recognition technology and related algorithms to obtain the action. Recognize the video image to obtain the data, get the acceleration, angular velocity, and EMG data, and count the end time and duration according to the change of the action. According to the data table and graph change trend compiled at the end of the experiment, we can see the following: after the data is preprocessed, the acceleration signal change range is limited to  $[-1, 1]$ , and the acceleration change has a clear directionality; and, after 15 lifts of the detected object, its angular velocity in  $X$ -axis direction is basically negative. However, when the ninth lift is performed, the angular velocity of the movement in  $X$ -axis direction is 36.09, the largest of all angular velocities. When performing the 15th lifting action, the angular velocity of this action in  $Z$ -axis direction is  $-26.05$ , which is the smallest of all angular velocities. The longest duration of the left muscle discharge during the lifting action of the subject is 15.24 for the tibial anterior muscle and 8.91 for the external oblique muscle with the shortest duration. The longest discharge duration of the right muscle is also the tibial anterior muscle with 12.15, and the shortest duration is the erector spinae with 8.79.

## 1. Introduction

**1.1. Background Meaning.** With the development of big data-related technologies, the applications of its scholars are increasingly being applied to big data human-computer interaction, motion recognition, and sensor technology. Nowadays, people are paying more and more attention to health-related sports, and the research on health and sports-related exercise recognition is also following closely. As an important part of healthy traditional culture, vertical Baduanjin has been bred in the soil of traditional Chinese culture for thousands of years. Its unique cultural tone and characteristics have aroused people's attention.

**1.2. Related Work.** Many scholars have done some researches on motion recognition. Wang proposed a new method, namely, weighted hierarchical depth motion map (whdmm) + three channel deep convolution neural networks (3convnets), which is used to recognize human actions from depth maps on small training data sets. Three strategies were developed to mine distinguishing features by using the ability of ConvNets [1]. Yan proposed an improvement to the soft attention model by combining convolutional long short-term memory (LSTM) with a layered system architecture to identify the action categories in the video, and Yan called this model a convolutional hierarchical attention model (CHAM), the model unit inside LSTM

convolution operation, and, using the focus map generation process to identify the action, layered architecture model is based on the particle size that can be more clearly the operation type [2].

*1.3. Innovation in This Article.* This paper studies the lifting motion of the vertical Baduanjin. The experimental research background is big data technology, using motion recognition related methods and sensor technology and using complex system theory to analyze the experiment. The innovations of this article are mainly reflected in the following aspects: (1) research on experiment in the context of big data, it is very convenient to collect data in experiments, which saves the time of data collection; (2) research on vertical Baduanjin lifting movements subject new and innovative matter; (3) the analysis of experiments using complex systems theory can draw more scientific and reasonable experimental results.

## 2. Relevant Technology of Vertical Baduanjin Lifting Motion Sensing Recognition

*2.1. Big Data.* As an important factor in production, data has penetrated into every industry today, and the efficiency of data mining and implementation will directly affect the development of the new productivity cycle. Big data is a huge, diverse, and rapidly changing information asset. It needs to adopt new processing methods to improve people's ability in vision expansion, process optimization, and decision formation [3, 4]. The volume of big data greatly exceeds the capabilities of commonly used software tools, and it is difficult to obtain, manage, grasp, and process within a tolerable time. There are many specific processing methods for data, but the current general process of big data processing can be summarized into four steps: big data collection, big data input and preprocessing, big data analysis and statistics, and big data mining [5]. Its specific processing flow is shown in Figure 1.

Big data analysis process is collected and introduced into the first structured, semistructured, and unstructured data and then converts the data quality and loading operation by the data integration. If the data needs to be processed in real time, data will then flow into the computing module; if the data does not need to be processed in real time, the data can first enter the data integration module data quality screening; filtration pretreatment may not be direct via the data integration module and offline processing incoming data analysis module. It is necessary to conduct modeling and predictive analysis by mining data analysis tools. Finally, when data reaches the presentation layer, management can make decisions, discovery, modeling and forecasting analysis, reporting, planning prophecy, and content analysis applications show. The operation of large data sharing and data sharing module refers to a repeating operation in different applications or data information may be precipitated into the module, the data for later analysis of other common applications. The analysis and processing process of big data can be represented by a big data analysis architecture diagram, which is shown in Figure 2.

Large and complex data only exist as data material before being identified and discovered. When people have discovered its value but have not yet begun to classify its value they can only be regarded as a data resource [6]. Only after collection and merging, valuable information can be extracted from data analysis tools to form data assets and utilize resources [7]. Although the data materials, data resources, and data assets in big data have the same material connotation, they belong to different management categories and have significant differences. The relationship between the three is shown in Figure 3.

The characteristics of big data can be summarized as four V: volume, velocity, variety, and value. The amount of data aggregated by big data is very huge, and the unit of measurement has usually reached PB (1 million G), EB (1 billion G), and ZB (1 trillion G). The speed of big data is reflected in two aspects: first, the speed of data generation is fast. The other is the need for very fast data processing speed. Being fast is the biggest difference between big data technology and traditional data technology. In the era of big data, not only the amount of data has surged, but also the sources and types of data have become more and more complex. The huge amount of traditional data is usually predefined structured data. With the emergence and development of detection technology and the Internet, semistructured and unstructured data have emerged in large numbers, enriching data. Diversity also increases the difficulty of processing and storing data. However, current data usually has the problem of low value density. As the data grows, the amount of useful information that can be extracted from the massive data may be very small and cannot increase according to the amount of data. It is more obvious in unstructured and semistructured data. Therefore, how to use powerful data calculation methods to quickly obtain data value and improve the quality of data information is one of the urgent problems to be solved in the context of the current rapid development of big data.

*2.2. Sensor Technology.* A sensor is a device that can sense the measured object and convert it into a signal that can be used to transmit a signal according to a specific rule. It is also an energy conversion device that can convert one energy into another energy [8, 9]. The sensor is mainly composed of two parts: the sensitive element and the conversion element. Some sensors also include signal amplification circuits, mainly because the electrical signal output from the sensor is relatively weak and difficult to measure [10]. The block diagram of the sensor is shown in Figure 4.

The relationship between the sensor and the detection technology is very close. The detection technology is the window through which the sensor obtains the measurement. The sensor is at the interface of the object to be measured and the detection system. You need to understand the detection technology before you can better use the sensor [11]. The most important thing in detection technology is the measurement of the detected object. The measurement can be expressed by the following formula:

$$x = nu, \quad (1)$$

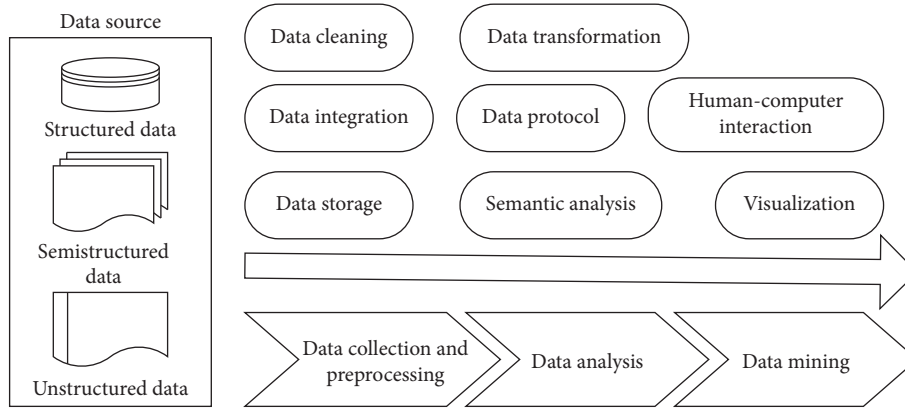

FIGURE 1: Big data processing flow.

FIGURE 2: Big data analysis architecture diagram.

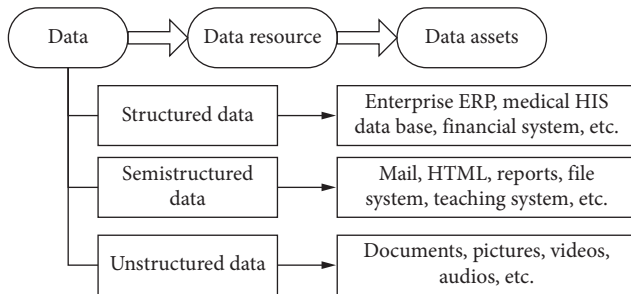

FIGURE 3: Relationship diagram of data materials, data resources, and data assets.

FIGURE 4: Sensor composition block diagram.

where  $x$  is the measured value,  $u$  is the standard quantity, the unit of measurement, and  $n$  is the multiple of the measurement object. The direct detection method of detection technology can be expressed by the first following formula and the indirect detection method can be expressed by the second following formula:

$$y = x, \tag{2}$$

$$y = f(x). \tag{3}$$

In the detection system, the sensor is connected to the measured object and the signal conditioning circuit. The signal conditioning circuit acquires the measured object through the sensor and then processes the signal. The basic framework of the detection system is shown in Figure 5.

In the open-loop measurement of the detection system, the direction of information transition is in one direction. There are two channels for the information direction in the closed-loop measurement, one is the positive channel, and the other is the feedback channel. Their input and output relationship formulas are shown in the following formulas respectively:

$$y = k_1 k_2 k_3 x, \tag{4}$$

$$y = \frac{k k_1}{1 + k \beta} x \approx \frac{k_1}{\beta} x, \tag{5}$$

where  $k_1, k_2, k_3$  is the transfer coefficient between each link,  $\beta$  is the feedback coefficient of closed-loop measurement, and  $k = k_2 k_3$ . In the actual measurement process, due to the influence of environmental factors and human factors, it is difficult to achieve accurate measurement, which will cause measurement errors. The expression methods of measurement error mainly include absolute error, actual relative error, quoted error, basic error, and additional error. The formula for absolute error is as follows:

$$\Delta = x - L. \tag{6}$$

The actual relative error formula is as follows:

FIGURE 5: The basic framework of the detection system.

$$\delta = \frac{\Delta}{L} \times 100\%. \quad (7)$$

The formula for citation error is as follows:

$$\gamma = \frac{\Delta}{\max - \min} \times 100\%, \quad (8)$$

where  $\Delta$  represents absolute error,  $x$  is the measured value,  $L$  is the true value, and  $\max$ ,  $\min$  are the true value.

The relationship between sensor input and output is a key feature of the sensor. Different sensors produce different forms of electrical energy, which mainly depends on the basic characteristics of the sensor. The sensor has static characteristics and dynamic characteristics. If the input signal is static, then the relationship between the output  $y$  of the sensor and the input  $x$  does not change with time; that is, the output can be expressed by an equation without time:

$$y = a_0 + a_1x + a_2x^2 + \dots + a_nx^n, \quad (9)$$

where  $a_0$  represents the output when the input is equal to 0 and  $a_1, a_2, \dots, a_n$  is the nonlinear coefficient. The indicators of the static characteristics of the sensor include the sensitivity, linearity, repeat-ability, hysteresis, and drift of the sensor. Their formula expression is as follows:

$$\text{sensitivity: } S = \frac{\Delta y}{\Delta x},$$

$$\text{linearity: } \gamma_L = \pm \frac{\Delta L_{\max}}{Y_{FS}} \times 100\%, \quad (10)$$

$$\text{hysteresis: } \gamma_H = \frac{\Delta H_{\max}}{Y_{FS}} \times 100\%,$$

$$\text{temperature drift: } W = \frac{y_t - y_{20}}{Y_{FS} * \Delta t} \times 100\%.$$

$S$  in the formula represents the sensitivity of the sensor,  $\Delta L_{\max}$  is the absolute error of the maximum nonlinearity,  $Y_{FS}$  is the output value of the full scale of the sensor,  $\Delta H_{\max}$  is the hysteresis difference of the output,  $y_t$  is the output output temperature, and  $y_{20}$  is the output at temperature 20 degrees Celsius when the output, and  $\Delta t$  is the difference between the temperature  $t$  and 20 degrees Celsius.

The dynamic characteristics of the sensor mean that the output of the sensor changes with time; that is, the output of the sensor is a time function of the input. For ideal dynamic characteristics, the output time function and the input time function are not the same, and the difference between them

lies in the dynamic error. The dynamic equation of the sensor is as follows:

$$\begin{aligned} a_n \frac{d^n y}{dt^n} + a_{n-1} \frac{d^{n-1} y}{dt^{n-1}} + \dots + a_1 \frac{dy}{dt} \\ + a_0 y = b_m \frac{d^m y}{dt^m} + b_{m-1} \frac{d^{m-1} y}{dt^{m-1}} \\ + \dots + b_1 \frac{dy}{dt} + b_0 x. \end{aligned} \quad (11)$$

**2.3. Action Recognition.** The process by which the computer can analyze and judge various behaviors and movements through automatic detection is called action recognition [12]. The main task is to analyze the motion recognition image or video collection to determine the sequential images or motion video, using a video editing operation of the computer image, using a computer to locate the last track, the video image to identify a target. The traditional action recognition method is to manually extract the graphic features from the video or image, then reduce the dimensionality of the generated feature vector, and finally use different classifiers for classification and recognition [13]. According to the description method used in the video recognition process, action recognition technology can be roughly divided into the following four categories: Patios-temporal feature recognition method, probability recognition and reasoning method, action rule recognition method, and action pattern recognition method. According to the number of levels of action features, action recognition technology can be divided into single-level recognition methods and multilevel recognition methods. It is widely used in video surveillance, human-computer intelligent interaction, medical care, virtual reality, sports, and other fields. It is an interesting and challenging problem. The application areas of action recognition in young and old people are shown in Figure 6.

Action recognition can obtain raw data by using video equipment and wearable equipment according to the difference of sensor electronic equipment [14]. The motion recognition method using video equipment is a computer vision-based system method, and the motion recognition method using a wearable device is a sensor-based system method. With the increasing maturity of the manufacturing process of microelectronic mechanical systems, various electronic components and products, especially sensors, have been greatly improved and developed rapidly in terms

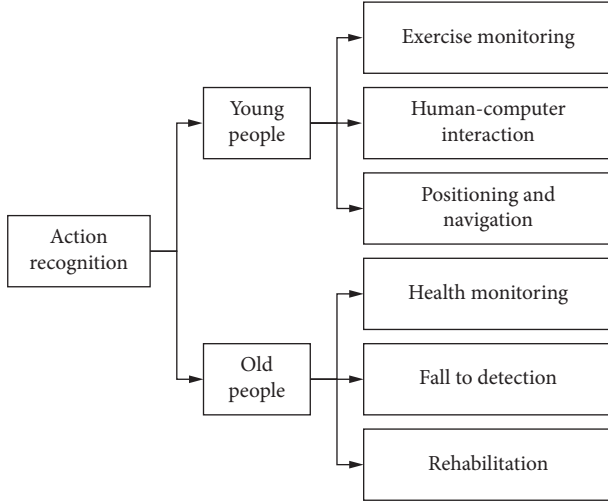

FIGURE 6: Action recognition application area diagram.

of volume, accuracy, power consumption, and performance. Sensors play an increasingly important role in action recognition [15, 16]. There are many ways to recognize actions; the basic idea is to match the template to be classified with the template of the known category. By measuring the similarity between the patterns, the unknown category can be classified. The second is a generative model-based method that uses a common probability function to determine the relationship between the observed attribute value and the action category information. Another method is based on the recognition model, which can directly model the conditional probability of a given category of operators. The classification model of this method is relatively simple and the calculation efficiency is high.

**2.4. Complex System.** Complex systems are the main research objects of complexity science and can be found in every corner of daily life. Life system and social system are complex systems [17]. Complex systems are usually composed of multiple interactive units, which have characteristics or features that not every component unit has. For a complex system, its total performance is not a simple superposition of partial performance, and the relationship between total performance and partial performance is a complex nonlinear relationship [18]. The complex system emphasizes the hierarchical relationship and appearance characteristics between the individual and the whole and pays attention to dynamic issues in the overall evolution of the system. The interaction of various factors in the system, various subsystems, and the environment in which the system is located makes the system continuously upgrade and develop. It does not depend on one or a specific pair of influencing factors, and the system is very sensitive to this interaction. Small changes between projects can lead to completely different results [19, 20]. Complex systems have the characteristics of openness, hierarchical structure, complexity, dynamics, and nonlinearity.

The complex system is still in its infancy and may include a new system or even a revolution in traditional scientific

methods. The complex system is constantly developing and evolving under the action of force. The dynamic process of the entire complex system can be described by the dynamic behavior of the individual. The complexity and interdisciplinary nature of the complex system field determines that there is no proprietary model in the complex system field [21, 22]. The basic model of a complex system is a cellular automaton, which is a dynamic system. Research on the complex evolution of cellular automation system behavior and its occurrence mechanism is helpful to explore the complexity of complex systems and the study of their internal laws [23, 24]. Cellular automata have different times, different states, different spaces, homogeneity, normal positions, and parallelism.

Cellular automata can be represented by a four-tuple,  $S$  is the state of the cell,  $L_d$  is the discrete cell space,  $N$  is the cell neighborhood of finite radius, and  $f$  is the local rule:

$$A = (S, L_d, N, f). \quad (12)$$

The expression of elementary cellular automata: assuming that the number of cell states is  $k$ , its state set is  $\{s_1, s_2, \dots, s_k\}$ , the neighbor radius is  $r$ , and the cell state at time  $t$  is  $s_i^t$ ; the neighbor cell of this cell and itself is called neighborhood cells, and its state is

$$s = \{s_{i-r}^t, \dots, s_{i-2}^t, s_{i-1}^t, s_i^t, s_{i+1}^t, s_{i+2}^t, \dots, s_{i+r}^t\}. \quad (13)$$

An arrangement of state values of neighboring cells will correspond to a regular function  $f$ . Suppose that the state of the cell at the next moment is  $s_i^{t+1}$  and  $f$  is defined as follows:

$$s_i^{t+1} = f(s). \quad (14)$$

The state set of elementary cellular automata is usually defined as  $\{0, 1\}$ , and its state transition function can be expressed as

$$s_j^{t+1} = f(s_{j-1}^t, s_j^t, s_{j+1}^t). \quad (15)$$

The cell state at time  $t$  is  $s_j^t$ .  $D$ ,  $s_{j-1}^t, s_{j+1}^t$ , are the states of the left neighbor and right neighbor of the cell, respectively.

Reversible cellular automata can be used in information security fields such as information encoding, image encryption, and decryption, and its formula is described as

$$s_i^{t+1} = f(s_{i-r}^t, \dots, s_{i-2}^t, s_{i-1}^t, s_i^t, s_i^{t-1}, s_{i+1}^t, s_{i+2}^t, \dots, s_{i+r}^t). \quad (16)$$

All the cells of a two-dimensional cellular automaton are distributed in a plane grid composed of regular cells, and its cell state at the next moment can be expressed as

$$s_{i,j}^{t+1} = f(s_{i-1,j}^t, s_{i+1,j}^t, s_{i,j-1}^t, s_{i,j+1}^t). \quad (17)$$

### 3. Vertical Baduanjin Lifting Motion Sensor Recognition Experiment Design

**3.1. Data Collection.** The recognition of lifting motion is divided into two parts: data collection end and data processing end. Sensor-based action recognition is a process of

data collection and feature extraction and classification. The data collection terminal can be regarded as a whole, which includes the main control module, sensor module, and communication module. The block diagram of the data acquisition terminal is shown in Figure 7.

The data collection of actions can be divided into three types according to the data transmission method: the use of wired connection, the wireless transmission, and the direct reading of the data through the local data storage method. The wireless transmission of data collected can only increase the comfort performance data collection system that is worn and can observe real-time data acquisition storage; thus, it is superior choice. This experiment uses sensors as the transmission channel for wireless data transmission, uses sensor technology to identify motion data, and transmits the motion data to the receiving end. The processing flow of data collection is shown in Figure 8.

**3.2. Action Data Preprocessing.** In the process of collecting experimental data, even the best data acquisition equipment will inevitably introduce noise into the experimental data stream. The appearance of noise will affect the follow-up research work and interfere with the judgment of the final experimental results. This experiment uses smoothing denoising and normalized data preprocessing methods to denoise the acquisition process of the acceleration signal and angular velocity signal of the upper limb lifting motion of the measured object. Many studies of denoising embodiment implemented using wavelet denoising noisy signals to the original signal select a wavelet basis function and decomposition level  $n$  (generally  $n$  takes 3–5) for wavelet decomposition, select a threshold to quantize the high-frequency coefficients of each level wavelet decomposition, and then reconstruct the low-frequency coefficients and high-frequency coefficients after threshold quantization. The flowchart of wavelet threshold denoising is shown in Figure 9.

There are mainly two commonly used threshold functions: hard threshold function and soft threshold function. Suppose that  $\omega$  is the original wavelet coefficient and  $T$  is the set threshold; then, their expressions are

$$\eta(\omega) = \begin{cases} \omega, & |\omega| \geq T, \\ 0, & |\omega| < T, \end{cases} \quad (18)$$

$$\eta(\omega) = \begin{cases} \text{sgn}(\omega)(|\omega| - T), & |\omega| \geq T, \\ 0, & |\omega| < T. \end{cases}$$

Due to the differences between individuals, different people perform the same upper limb movement; their acceleration performance, including movement amplitude and execution speed, is always different. Through the normalization technology, the user's action acceleration data of different intensities (the amplitude of the acceleration signal) can be adjusted. This experiment uses normalization to standardize the amplitude range of the original acceleration data to the same amplitude range of  $[-1, 1]$ . Assuming that the original data is  $P = \{p_1, p_2, \dots, p_n\}$ , normalize it to  $[m, n]$  above the interval, and the normalized data is

FIGURE 7: Block diagram of the data acquisition terminal.

FIGURE 8: Data acquisition processing flowchart.

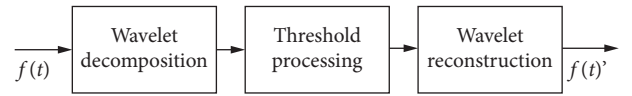

FIGURE 9: Wavelet threshold denoising flowchart.

represented by  $T = [t_1, t_2, \dots, t_n]$ ; then, the normalized formula is as follows:

$$t_i = m + \frac{(n - m) * (p_i - \min(p))}{(\max(p) - \min(p))}. \quad (19)$$

**3.3. Feature Parameter Extraction.** The time-frequency analysis method is used to extract the characteristic parameters of the action, which is based on the wavelet theory. Denote the wavelet scaling function  $\Phi(t)$  and the wavelet function  $\Psi(t)$  by  $\Phi(t) = u_0(t)$  and  $\Psi(t) = u_1(t)$ , respectively, and use  $u_n(t)$  to satisfy the following two-scale equation:

$$\begin{cases} u_{2n}(t) = \sqrt{2} \sum_{k \in \mathbb{Z}} h_k u_n(2t - k), \\ u_{2n+1}(t) = \sqrt{2} \sum_{k \in \mathbb{Z}} g_k u_n(2t - k). \end{cases} \quad (20)$$

The conjugate filter coefficient  $g_k = (-1)^k h_{(1-k)}$  in the formula has an orthogonal relationship. The  $\{u_n(t)\} (n \in Z^+)$  constructed by formula (20) is called the wavelet packet determined by the basis function  $\Phi(t) = u_0(t)$ . The wavelet packet of the signal is expressed as

$$g_j^n(t) = \sum_{k \in Z} d_l^{j,n} u_n(2^j t - k). \quad (21)$$

The collected three-dimensional acceleration information of the upper limbs of the human body has signals in X, Y, and Z directions that are mutually perpendicular. For each dimensional acceleration signal, the same wavelet packet decomposition is performed to obtain the energy of each frequency band in three directions.

#### 4. Data Analysis of Motion Sensing Recognition of Vertical Baduanjin Lifting

**4.1. Acceleration Signal Comparison before and after Motion Data Preprocessing.** The normalized motion acceleration signals have the same maximum value, so the motion acceleration signals of different test objects are integrated according to the same standard, thereby creating conditions for feature parameter extraction and motion classification and recognition. In this experiment, after preprocessing the relevant data of the vertical Baduanjin lifting movement, the acceleration signal changes of this movement are shown in Table 1.

According to the data in Table 1, we can see the change of acceleration signal before and after the data preprocessing of the action. In order to observe the change trend of the acceleration signal more intuitively, we compare the change of the acceleration signal of the action. We convert the data in Table 1 into a graphic way, and the final conversion result is shown in Figure 10.

According to the graph change in Figure 10, we can see that the acceleration variation range without pretreatment is between  $[-1500, 1000]$  and the data change span is large. After preprocessing, the amplitude of acceleration signal change is limited between  $[-1, 1]$ , and the change of acceleration has clear direction.

**4.2. Angular Velocity Change of Lift.** After the feature extraction of the detected object, the angular velocity signal changes of the object in 15 lifts are counted, and the angular velocity changes in X, Y, and Z directions are analyzed. According to the data acquisition terminal, the angular velocity data of 15 times of lifting actions are shown in Table 2.

According to the data in Table 2, we can understand the angular velocity change of the action after 15 lifts. In order to change the angular velocity of the operation for visual analysis, we converted the data in Table 2 and the final result is shown in Figure 11.

According to the data in Figure 11, we can see that, after 15 lifts, the angular velocity of the action is basically negative in x-axis direction; however, in the ninth lift, the angular velocity of the action in x-axis direction is 36.09, which is the

TABLE 1: Action acceleration signal change table.

| Sampling times | before |      |      | after |       |       |
|----------------|--------|------|------|-------|-------|-------|
|                | X      | Y    | Z    | X     | Y     | Z     |
| 0              | -100   | 900  | 0    | 0.95  | 0.92  | 1     |
| 30             | -120   | 950  | 20   | 1     | 1     | 1     |
| 60             | -1200  | 0    | -400 | -1    | -0.6  | -0.8  |
| 90             | -600   | -400 | -625 | -0.6  | -0.9  | -1    |
| 120            | -800   | -450 | -500 | -0.45 | -1    | -0.7  |
| 150            | -850   | -455 | -520 | -0.55 | -0.95 | -0.85 |

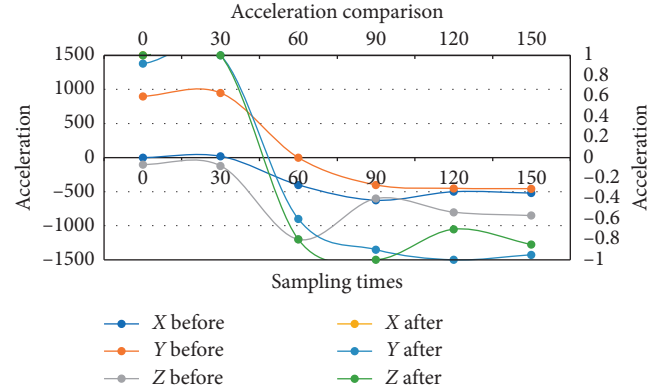

FIGURE 10: Comparison of acceleration signal before and after data preprocessing.

largest among all the angular velocities; in the 15th lifting action, the angular velocity of the action in z-axis direction is  $-26.05$ , which is the smallest among all the angular velocities.

**4.3. Muscle EMG Test Results of Lifting Motion.** The electrocardiography signals of tibial anterior muscles (TAM), erector spinae (ES), rectus abdominis (RA), external oblique muscles (EOM), and gluteus maximus (GM) were collected, and the trigger time, end time, and duration were analyzed. The statistical data of muscle electricity are shown in Table 3.

According to the data in Table 3, we can know the trigger time, end time, and duration of the EMG signal of some muscles when the body is performing the vertical Baduanjin lifting action. Convert the data in Table 3 to the left side of the body. The EMG signal time data graph of the side muscles and the EMG signal time data graph of the right muscles of the body: the converted results are shown in Figures 12 and 13.

According to the data in Figures 12 and 13, we can see the discharge sequence and sustained discharge time of part of the muscles of the test object during the lifting action. From Figure 12, we can see that the longest duration of the left muscle discharge is the tibial anterior muscle at 15.24 and the shortest duration is the external oblique muscle at 8.91. From Figure 13, we can see that the longest duration of the right muscle discharge is also the tibial anterior muscle with 12.15 and the shortest duration is the erector spinae with 8.79.

TABLE 2: Action angular velocity change table.

| Sampling point | X      | Y      | Z      |

## 5. Conclusions

Big data is an emerging technology closely related to data collection, data transmission, and data analysis in recent years. It can also be the sum of a type of complex and huge data. Experimental research in the context of big data can solve the problem of experimental data collection. Combining big data, sensor technology, and complex system theory effectively and conducting related research in the direction of motion recognition will help scholars find technological breakthroughs and innovations in the field of motion recognition.

This research uses big data as the background to design experiments for the motion recognition of the vertical Baduanjin lifting motion, using sensor technology to collect the video image of the vertical Baduanjin lifting motion of the detected object, and use motion recognition related methods and formulas to compare motion video data for calculation and finishing; the final tally triggers time action acceleration, angular velocity, and part of the muscle EMG signal detection object, end time, and duration of the use of complex systems theory to experimental data analysis.

Although this experiment was performed well, there are still some shortcomings: first, although big data solves the problem of data collection well, the data in it is too large and difficult to store. Secondly, after the action video image was collected, the video image was not optimized, which caused some errors in the experimental data. Finally, the complex system theory is not very suitable for the research of vertical Baduanjin lifting motion sensing recognition, and it should be improved.

## Data Availability

No data were used to support this study.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

China is located in the intersection area of two seismic zones. Due to this special geographical location, earthquake disasters occur frequently in China. Earthquake emergency rescue work is one of the key construction works of disaster prevention and mitigation in China. This paper mainly studies the earthquake disaster rescue model based on the complex adaptive system theory and establishes the earthquake disaster rescue model by analyzing the complex adaptive system theory and combining the earthquake rescue process. In this paper, through the task allocation mechanism task, the disaster rescue task is divided into simple task and complex task, and the executive task subject is divided into single task subject and multitask subject. On the basis of considering the shortest emergency rescue time goal and the goal of maximizing the deployment utility of rescue team, the reasonable deployment of a rescue team is realized through a complex adaptive system, that is, the deployment utility of the rescue team is maximized. In this paper, the simulation experiment and comparison of the earthquake disaster rescue model based on the complex adaptive system theory are carried out. The experimental results show that the model used in this paper is better than the other two models in terms of algorithm convergence, rescue number, and overall score; in different scenarios, the relative survival probability of the model in this paper is 58.92%, 67.85%, and 77.46%, and the proportion of the wounded rescued is 66.31%, 76.45%, and 83.06%, which were higher than those of the other two models. The earthquake disaster rescue model based on the complex adaptive system theory proposed in this paper provides an effective theoretical basis and method system for postdisaster emergency rescue decision making and enhances and improves the emergency response ability to deal with large-scale geological disaster events.

## 1. Introduction

Large-scale earthquake disaster has become the focus and difficulty of research because of its wide influence range, huge population, serious economic loss, high uncertainty, derivation, and evolution. In recent years, large-scale earthquake disasters occur frequently in the world, which is a serious threat to the safety of human life and property. For example, the Wenchuan earthquake caused more than 80000 deaths and missing people and 370000 injured people. A total of 45 million people were affected, and more than 800 billion economic losses were caused. It can be seen that major geological disasters have a large influence range, a large number of affected population, and serious economic losses (including buildings, roads, cash crops, etc.), which

can have a serious impact on people's lives and even cause devastating consequences. In recent years, the occurrence of major earthquake disasters is more frequent, resulting in serious losses and difficult rescue, which is the focus and difficulty of emergency management research. Once a major earthquake disaster occurs, its loss and impact are immeasurable. It is necessary to strengthen the work of emergency rescue and response to major earthquake disasters. In the process of emergency rescue of major earthquake disasters, the core is the rescue of disaster victims, and the main participants are rescue teams. The effective deployment of rescue teams and the cooperation between rescue teams are important to guarantee to control the further deterioration of disaster situation and reduce casualties in disaster areas [1, 2].

Foreign experts and scholars have conducted a lot of research on emergency disaster rescue, and many research results are worth learning. Based on literature research and expert research, Baroni first selected the relevant important indicators to evaluate the priority and obtained the weight of these indicators through an analytic hierarchy process (AHP). Then, the spatial multicriteria decision analysis method was used for modeling in GIS to analyze the priority of disaster areas. Finally, the urban search and rescue operations were allocated based on this. But, his research is not applicable to earthquake disaster relief. Nakanishi et al. discussed the influence of the environment on each individual in pedestrian evacuation and proposed a social force evacuation model. In order to better describe the force of individual pedestrian evacuation, the model established three indicators including self-driving force, surrounding pedestrian influence, and surrounding obstacle influence. However, their conclusion is not supported by specific experimental data [3]. Gordon uses a mathematical model to establish an emergency plan and establishes an emergency decision support system of automatic response, which realizes the automatic decision making of the system through the interdependence and restriction relationship among the response tasks in the emergency plan. However, his contingency plan is not comprehensive enough.

Based on the theory of complex adaptive system, this paper establishes the earthquake disaster rescue model. By analyzing the task allocation mechanism and team deployment model, this paper studies the optimization method of emergency deployment decision making of a rescue team, which can effectively save the wounded and minimize the loss caused by the disaster, so as to realize the improvement of the emergency rescue effect in a real sense and provide a reliable basis for disaster relief and disaster reduction work.

## 2. Theoretical Basis of the Complex Adaptive System and Establishment of the Disaster Rescue Model

### 2.1. Complex Adaptive System Theory

*2.1.1. Theoretical Basis of the Complex Adaptive System.* The complex adaptive system is composed of adaptive agents, who constantly learn and accumulate experience in the process of interaction and accordingly change their own structure and behavior mode [4]. It is this kind of adaptive behavior that makes the subject and the environment constantly change, so that the system constantly evolves and becomes more complex. The theory of complex adaptive system includes two levels: a macrolevel and microlevel. The microlevel refers to that the adaptive subject constantly adjusts the behavior criterion according to the effect of behavior in the process of interaction with the environment to realize adaptive survival; the macrolevel refers to the system composed of adaptive subjects, which realizes adaptation, emergence, and differentiation in the process of interaction between the main body and the external environment iteration.

Professor Holland proposed that the complex adaptive system includes four characteristics, aggregation, flow, nonlinearity, and diversity, and three mechanisms, identification, internal model, and building blocks [5]. Generally speaking, all the systems that meet the abovementioned seven basic points are complex adaptive systems and can be applied to solve related problems.

*2.1.2. Complex Adaptive Subject.* The complex adaptive system is composed of multiple individuals who actively and intelligently interact to realize the evolution and iteration of the system. Adaptation refers to the active and repeated interaction between the subject and the environment. The so-called subject refers to the active individuals in the system. The subjects aggregate into larger subjects and then form the system. Therefore, the subjects at different levels are also systems in different levels. When the adaptive agent plays an adaptive role, it follows the common model system rules [6, 7]:

#### (1) Executive system model

The executive system model is the “detector input + IF/THEN rule set + effector output” model. The detector filters the information in the surrounding environment, receives the useful stimulus, and transmits it to the subject, which reflects the agent’s ability to collect information. The IF/THEN rule set is a set of rules that define the subject. After receiving the information from the detector, the agent uses the rule set to process, continuously activate other rules, or directly activate the effector, reflecting the agent’s ability to analyze and process information. After the effector is activated, the subject takes corresponding actions to reflect the subject’s ability to cope with environmental changes.

#### (2) Credit assignment

When dealing with and applying rules, adaptive agents will comprehensively consider the environment and other agents and rank the roles of various rules. The assignment of this role is the trust degree. The competitiveness of a rule, that is, the trust degree, mainly depends on the past usefulness of the rule. In the process of adapting to the environment, the usefulness of various rules is changing and the trust degree is also changing. Therefore, the process of modifying rule trust strength based on experience and learning is credit assignment.

#### (3) Rule generation

The environment of the complex adaptive system is complex and changeable, and the adaptability of the main body is also changing. Any IF/THEN rule set is accumulated and evolved in adaptive activities. The existing rules with high success rate generate new rules by copying and reorganizing, thus enriching the rule set and increasing the fitness of the subject. The continuous emergence of new rules is an important source for the subject to adapt to the

environment and is also the main driving force of system evolution iteration.

**2.1.3. Complex Adaptive System Model.** The evolution process of the complex adaptive system is realized by the stimulation response model in the microlevel and the echo model in the macrolevel. The stimulus-response model is for adaptive agents, while the echo model is for complex adaptive systems. The model application of CAS has the characteristics of initiative, dynamic operability, and hierarchy. It studies the evolution process of CAS in a way that is more in line with the facts and combines qualitative and quantitative changes [8].

(1) *Stimulus-Response Model.* The stimulus-response model describes how the subject adapts, learns, and accumulates experience. The adaptive agent can respond to the stimulation of the surrounding environment and other agents by establishing the executive system model, credit allocation, and rule generation, thus evolving towards the highest point of adaptability in many directions.

(2) *Echo Model.* The echo model is based on the stimulus-response model, which simulates, describes, and studies the behavior of the whole complex adaptive system from a macroscopic perspective. In the echo model, in addition to defining topics, sites and resources are defined. The complex adaptive system is composed of several sites, which are connected with each other; each site has resource and environmental conditions to accommodate several main activities; the subject site carries out resource and information exchange. The basic model of the echo model can describe the resource exchange activities of adaptive agents at the same level and basically reflect the functional relationship and behavior mechanism between adaptive agents.

In the basic model, the agent is composed of a resource database, attack identifier, and defense identifier. The resource library processes and stores the acquired resources; it is the attack mark that actively establishes contact with other subjects to explore whether there are needed resources; the defense identification is used to accept the contact of other subjects, which is used to respond when receiving the contact of other subjects [9]. The basic model of the complex adaptive system is shown in Figure 1.

## 2.2. Overview of Earthquake Disaster Rescue Process

**2.2.1. Disaster Emergency Rescue Process.** Disaster emergency rescue refers to a series of means and countermeasures adopted by the government and other public organizations in the process of prevention, response, response, and recovery in the process of sudden and destructive emergency disasters. The purpose is to ensure the life safety of the people in the disaster area as much as possible, so as to minimize the loss caused by the disaster [10, 11]. The three core links of disaster emergency rescue process are “preparation before disaster,” “emergency in disaster,” and “recovery after disaster.”

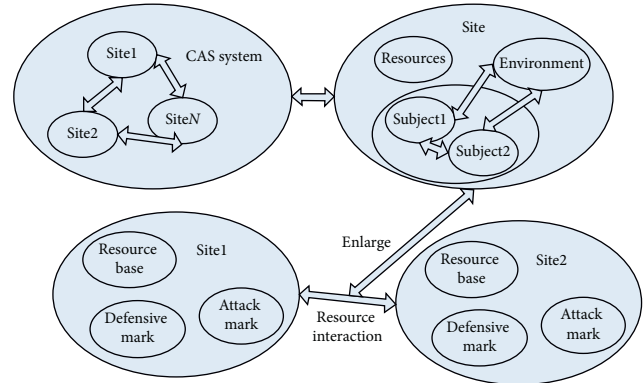

FIGURE 1: Basic model of the complex adaptive system.

### (1) Predisaster preparation stage

The purpose of predisaster preparation is to ensure the necessary conditions and capabilities for post-disaster emergency rescue work. The main task is to take some organizational preparations and emergency support in advance for possible disaster events, so as to ensure the response and disposal in the first time after the occurrence of disasters and prevent the deterioration of disaster emergencies. The main work includes the distribution of emergency resources and the distribution of emergency materials emergency plan design, etc.

### (2) Emergency stage in disaster

The emergency stage in disaster refers to the rescue measures taken after the occurrence of major geological disasters in order to prevent further expansion or deterioration of disaster events and minimize the loss or damage caused by disasters. The main research contents of the emergency stage include the demand forecast of emergency resources, the allocation of emergency resources, personnel search, and rescue and evacuation.

### (3) Postdisaster recovery stage

Postdisaster recovery refers to the measures or actions taken to restore production, work, life, and ecological environment to the normal state as soon as possible after the impact of disaster events is controlled. At present, the research on the recovery stage mainly focuses on the assessment of emergency response capacity.

### 2.2.2. Task Allocation of Disaster Search and Rescue.

Most of the research studies on task allocation are related to work allocation and cooperation in a multirobot system [12]. In fact, the research of task allocation can also be applied to solve some similar problems in many other fields, such as UAV cooperation, RoboCup, assignment problem, and emergency rescue cooperation. The main factors of disaster search and rescue task allocation and classification are the complexity of the task and the function of the main body. The tasks to be completed are divided into simple tasks and

complex tasks according to their complexity. Simple tasks represent tasks that only need one agent to complete, and complex tasks represent tasks that need to be completed by multiple agents. According to the function, the subject of task execution is divided into single task subject and multitask subject. Single task subject means that the subject can execute at most one task at the same time, and multitask subject means that the subject can perform multiple tasks at the same time [13, 14].

(1) Single task subject- simple task

Task allocation in the context of single task subject and simple task is actually a classic assignment problem. Assuming that there are  $m$  single task agents  $a_i$  and  $n$  single agent tasks  $t_j$ , each agent can complete any task with corresponding cost  $c_{ij}$  and completion quality  $q_{ij}$ . The goal of the assignment model can be to minimize the total cost after allocation or to achieve the highest total completion quality or to maximize the allocation benefit (a comprehensive consideration of the total cost and completion quality). Suppose  $m = n$ ; then, this is a balanced assignment problem.

$$\begin{aligned} \text{Maximize } Z &= \sum_{i=1}^m \sum_{j=1}^n x_{ij} u_{ij}, \\ \text{s.t. } \sum_{i=1}^m x_{ij} &= 1, \quad 1 \leq j \leq n, \\ \sum_{j=1}^n x_{ij} &= 1, \quad 1 \leq i \leq m. \end{aligned} \quad (1)$$

(2) Single task subject- complex task

Some of these problems can be transformed into set partitioning problems. Consider a nonempty set  $Y$ ; the set  $Y$  is divided into several nonempty subsets, these nonempty subsets have no intersection, and the union of the elements of these nonempty subsets is exactly equal to  $Y$ . If  $x$  is used to represent the set of nonempty subsets, there exists a utility function:

$$u: X \longrightarrow R^+. \quad (2)$$

Then, we need to find the set partition method  $X$  to maximize the utility. SPP is a NP hard problem, but on the other hand, many heuristic algorithms have been proposed to solve the problem.

(3) Multitask subject- simple task

This kind of problem is not very common in reality because it requires a single agent to perform multiple tasks at the same time, which only appears in a very few cases. However, the method to solve this kind of problem is similar to the single task subject complex task problem mentioned above. Some algorithms such as spp can be applied to these two models.

(4) Multitask subject- complex task

The task assignment problem can be transformed into the collection coverage problem. Set  $Y$  as a nonempty set. The elements in set  $Y$  can form several nonempty subsets, and these nonempty subsets can intersect. If  $X$  is used to represent the set of these nonempty subsets, then there is a cost function:

$$c: X \longrightarrow R^+. \quad (3)$$

Then, we need to find a subset of  $X$  that minimizes the cost, and the union of the elements in these subsets is exactly equal to  $Y$ . The SCP problem is also NP hard, but many scholars have proposed the algorithm to obtain the approximate solution.

*2.3. Earthquake Disaster Rescue Deployment Model.* After the occurrence of large-scale earthquake disaster, there are  $j$  disaster areas with scattered geographical locations and different disaster situations and  $i$  rescue points participate in the rescue. There are rescue teams with different numbers and abilities in each rescue point. For any disaster site, according to the disaster information we collected, we can know the type of rescue team that the disaster site needs the most. Therefore, the optimal deployment of rescue teams can be transformed into the problem of finding the most similar rescue teams. By calculating the similarity between rescue teams and selecting the rescue teams with high similarity for deployment, the emergency rescue effect is the best [15].

According to the actual situation of emergency rescue after a large-scale earthquake disaster, the following assumptions are given: each rescue team may include four types of personnel, namely, armed police officers and soldiers, doctors, nurses, and volunteers; the number of rescue teams required by the disaster site is highly related to the population size and the number of survivors; the road condition and corresponding geographic location information are obtained through GIS.

Once a large-scale earthquake disaster occurs, it often causes damage to the road network in the disaster area. Combined with the internationally accepted definition of the 72 hour golden rescue period after the disaster, in order to shorten the rescue time, the helicopter is also used as an emergency transport tool [16]. The parameter  $t_{ikj}$  represents the transportation time from the  $k$ -type transport vehicle in the rescue point  $i$  to the disaster site  $j$  under the condition of road network damage. Considering the characteristics of the transport vehicle, it is discussed in the following situations:

- (1) The transport tool  $k \in H.$ , in the rescue point, is transported by a helicopter. At this time, the transportation time is not affected by the road conditions; therefore,  $t_{ikj} = t_{ikj}^n$ .
- (2) The means of transport  $k \in E.$ , in the rescue point, that is, road transportation, is adopted. At this time, the transportation time will be affected by the road conditions. According to the road damage degree  $\lambda_{ij}$ , it can be divided into the following situations:

- (1) When  $\lambda_{ij}=0$ , the road is not damaged and the transportation time is not affected,  $t_{ikj} = t_{ikj}^n$ .
- (2) When  $0 < \lambda_{ij} < \alpha$ , it means that the road has been damaged but can pass and the transportation time is affected. At this time,  $t_{ikj} = t_{ikj}^n (1 + \lambda_{ij})$ .
- (3) When  $\alpha \leq \lambda_{ij} \leq 1$ , it means that the road is damaged and cannot be passable, but can be repaired. At this time, the transportation time is  $t_{ikj} = t_{ikj}^n (1 + \lambda_{ij}) + t_{ij}^r$ .
- (4) When  $\lambda_{ij} = 1$ , it means that the road is damaged and cannot be repaired in a short time, so the route is not feasible and the transportation time is  $t_{ikj} = +\infty$ .

To sum up, the parameter  $t_{ikj}$  can be expressed as follows:

$$t_{ikj} = \begin{cases} t_{ikj}^n, & k \in H. \text{ or } k \in E. \text{ and } \lambda_{ij} = 0, \\ t_{ikj}^n (1 + \lambda_{ij}), & k \in E. \text{ and } 0 < \lambda_{ij} < \alpha, \\ t_{ikj}^n (1 + \lambda_{ij}) + t_{ij}^r, & k \in E. \text{ and } \alpha \leq \lambda_{ij} < 1, \\ +\infty, & k \in E. \text{ and } \lambda_{ij} = 1. \end{cases} \quad (4)$$

Based on the abovementioned analysis, this paper establishes a rescue team deployment model to solve the contradiction between the disaster severity and the complexity of the rescue team in the process of large-scale earthquake disaster rescue team deployment, effectively depict the difference between the rescue team and disaster site, and realize the personalized deployment of the rescue team.

After the occurrence of a large-scale earthquake disaster, the earlier the rescue team arrives in the disaster area, the more we will be able to reduce casualties and property losses. In addition, the rescue team is different from the emergency

materials, and the same rescue team deployed to different disaster areas has different effects [17, 18]. Therefore, the reasonable deployment of a large-scale earthquake disaster rescue team must consider both timely and efficient objectives, that is, to deploy the most suitable rescue team to the disaster site in the shortest time.

- (1) Shortest time target of emergency rescue

The time the rescue team arrives in the disaster area will directly affect the rescue effect. Therefore, the shortest emergency rescue time target is an important objective function in the deployment model of a large-scale geological disaster rescue team. This paper uses the time when all rescue teams arrive at the disaster area to measure [19]. Since the rescue vehicles in each rescue point can be parallel, the maximum rescue transportation time is taken as the minimum.

- (2) Goal of maximizing the effectiveness of rescue team deployment

The difference between the rescue team and the disaster site leads to the different effects of the same rescue team deployed to different disaster areas. Therefore, in the process of emergency deployment, we should strive to make the best use of the talents of the people and make the best use of the personnel. In this paper, the complex adaptive system is used to realize the reasonable deployment of rescue teams, that is, to maximize the effectiveness of the deployment of rescue teams.

On this basis, the deployment model of the rescue team based on the complex adaptive system is constructed as follows:

$$\text{Min } Z_1 = \max_{j \in J} \left\{ \max_{i \in I} \left\{ \max_{k \in K_i} t_{ikj} \left( 2 \left\lceil \frac{(\sum_{p \in P_i} y_{ikpj} * n_{ip})}{q_k} \right\rceil - 1 \right) \right\} \right\}, \quad (5)$$

$$\text{Max } Z_2 = \sum_{j \in J} \sum_{i \in I} \sum_{k \in K_i} \sum_{p \in P_i} e_{ipj} y_{ikpj}, \quad (6)$$

$$\text{s.t. } \sum_{j \in J} \sum_{k \in K_i} \sum_{p \in P_i} y_{ikpj} \leq s_i, \quad i \in I, \quad (7)$$

$$\sum_{i \in I} \sum_{k \in K_i} \sum_{p \in P_i} y_{ikpj} \leq d_j, \quad j \in J, \quad (8)$$

$$\sum_{k \in K_i} \sum_{j \in J} y_{ikpj} = 1, \quad i \in I, p \in P_i, \quad (9)$$

$$\sum_{i \in I} \sum_{k \in K_i} \sum_{p \in P_i} \sum_{j \in J} c_p y_{ikpj} + \sum_{i \in I} \sum_{k \in K_i} \sum_{j \in J} 2c_{ikj} \left\lceil \frac{(\sum_{p \in P_i} y_{ikpj}) * n_{ip}}{q_k} \right\rceil \leq C_0, \quad (10)$$

$$\sum_{i \in I} \sum_{k \in K_i} \sum_{p \in P_i} \sum_{j \in J} y_{ikpj} > \varphi, \quad (11)$$

$$y_{ikpj} \in \{0, 1\}, \quad i \in I, j \in J, p \in P_i, \quad (12)$$

$$t_{ikj} = \begin{cases} t_{ikj}^n, & k \in H. \text{ or } k \in E. \text{ and } \lambda_{ij} = 0, \\ t_{ikj}^n(1 + l\lambda_{ij}), & k \in E. \text{ and } 0 < \lambda_{ij} < \alpha, \\ t_{ikj}^n(1 + l\lambda_{ij}) + t_{ij}^r, & k \in E. \text{ and } \alpha \leq \lambda_{ij} < 1, \\ +\infty, & k \in E. \text{ and } \lambda_{ij} = 1. \end{cases} \quad (13)$$

Formulas (7) to (13) are the constraints of the model, where formula (7) indicates that the deployment quantity of rescue teams does not exceed the available quantity; formula (8) indicates that the deployment quantity of rescue teams does not exceed the demand of the disaster stricken area; formula (9) indicates that each rescue team can only be deployed to one disaster site no matter what transportation mode is used; and formula (10) represents the constraint of available rescue cost at the initial stage after the disaster, which reflects the possible financial constraints in the early postdisaster period, and the emergency manager can adjust the parameter  $C_0$  according to the actual situation; formula (11) indicates that at least 0 rescue teams should be deployed to participate in the rescue work, and  $\varphi$  is a constant greater than 1; equation (12) is a decision variable, indicating whether to deploy rescue teams; and equation (13) represents the transportation time from the rescue point to the disaster site when the road network is damaged.

### 3. Rescue Model Simulation Experiment Based on the Complex Adaptive System Theory

**3.1. Comparison Objects.** This paper establishes an earthquake disaster rescue model based on the theory of complex adaptive systems. In order to verify the performance and effectiveness of this model, it is first compared with other rescue models and then compared with the rescue model based on the *F*-Max-Sum algorithm. *F*-Max-Sum is also a distributed algorithm, which is improved on the basis of Max-Sum algorithm. It is suitable for solving similar dynamic task allocation problems and has excellent performance [20, 21]. At present, the Max-Sum algorithm and the *F*-Max-Sum algorithm are used for task allocation in disaster environments, as well as for the allocation of spectrum resources and cloud resources. The *F*-Max-Sum algorithm first converts the problem to be solved into the expression form of a factor graph and iterates the value of information transfer between variable nodes and function nodes in the factor graph until it converges or iterates a certain number of times.

**3.2. Experimental Parameter Setting.** This paper uses *R* and Netlogo software to calculate and simulate. It is assumed that the disaster area is a circular area with a radius of 150 m, and

a certain number of wounded are scattered in several burial sites. The simulation step size ticks are in minutes. When there are no survivors on the scene, the simulation ends. The longest simulation cycle is 72 hours.

Combined with the statistical results of earthquake casualties in recent years, assuming the specific distribution of the injury degree of landslide disaster under different scenarios, as shown in Table 1, in the “extremely serious” scenario, the proportion of wounded death is 35%, the proportion of serious injury is 30%, the proportion of minor injury is 20%, and the proportion of no injury is 15%.

The input variables include the number of wounded in each mask point  $n_s-U(1,3)$ ; the injury degree  $v_{si}$  of each wounded person is given the initial number according to Table 1; and the burying condition of each buried point is  $v_{\text{rubble}}-N(120,30)$ ; the results show that the search speed is 3 m/min; the radius shown is  $s_r = 3$  m; and the rescue speed is  $S_{\text{rubble}} = 0.5$ ; when there is a buried point in the search radius, the simulation rescue team can find it with a certain probability, assuming the probability of prob = 20%; the cooperation range  $s_c$  is 40 m.

### 4. Simulation Results and Performance Comparison of Different Rescue Models

**4.1. Performance Comparison of Different Rescue Models.** As shown in Table 2 and Figure 2, the algorithm in the model used in this paper converges after 40 hours of running the simulation program, while the *f*-max-sum model converges after 50 hours. The simulation results show that the convergence speed of the model algorithm in this paper is faster than that of the other two model algorithms. The reason is that, firstly, the model algorithm in this paper does not blindly process all the perceived information, but only selects the information that has an impact on the assistance task. Secondly, it uses the screened information to predict the relevant state and formulate the cooperation strategy, which can quickly find the convergence path after interference, so as to improve the rescue efficiency.

As shown in Table 3 and Figure 3, it can be seen that, after 72 hours, the rescue number of the model in this paper reached 138, higher than that of the other two models. The number of rescuers in this model is higher than that of the other two models because the cooperation information obtained is more comprehensive, which improves the accuracy of the prediction results, and uses action evaluation

TABLE 1: Distribution of the injury degree under different disaster scenarios.

| Degree of injury- disaster scenario | Extremely serious (%) | Serious (%) | Ordinary (%) |
|-------------------------------------|-----------------------|-------------|--------------|
| Death                               | 35                    | 25          | 15           |
| Serious injury                      | 30                    | 20          | 20           |
| Minor wound                         | 20                    | 35          | 25           |
| No injuries                         | 15                    | 20          | 40           |

TABLE 2: Comparison of convergence of different model algorithms.

| Path length        | 10 H | 20 H | 30 H | 40 H | 50 H | 72 H |
|--------------------|------|------|------|------|------|------|
| This paper         | 34   | 23   | 14   | 9    | 9    | 9    |
| Other model        | 38   | 30   | 23   | 16   | 12   | 9    |
| $F$ -max-sum model | 37   | 25   | 19   | 14   | 9    | 9    |

FIGURE 2: Comparison of convergence of different model algorithms.

and trigger class to realize the dynamic adjustment of the cooperation strategy to help the task to be completed smoothly.  $F$ -max-sum model algorithm reduces the efficiency of cooperation due to the high complexity of information processing algorithm, and it is difficult to get the optimal cooperation strategy, which leads to low rescue efficiency.

As shown in Table 4 and Figure 4, the overall scores of the three models in the simulation experiment within 72 hours are shown. Among them, the score of the model proposed in this paper is the highest among the three models after 72 hours, reaching 98. The scores of the other two models are 80 and 84, respectively. When the simulation program runs for about 40 hours, the scores of the three models are the closest. The results in Table 4 and Figure 4 further show that the performance of the proposed model is better than that of other models.

*4.2. Comparison of Simulation Results of Different Rescue Models.* As shown in Table 5 and Figure 5, the simulation results of the rescue model in this paper are compared with those of the other two models, and some indexes of the former are better than those of the latter two. The results

show that compared with other models, the performance of this model is not inferior, and some indicators are better than the other two models. One of the biggest advantages of this model is the low complexity of the calculation process. In the iterative process of  $f$ -max-sum algorithm, function nodes need to traverse the various combinations of surrounding variable nodes, which will consume a lot of time, especially when the cooperation set is large, that is, there are more rescue teams to be deployed around the rescue task. In addition,  $f$ -max-sum was originally designed for the cooperation between devices with computing functions, such as robots and sensors. It has adaptability problems when it is directly applied to the cooperation between rescue teams on the disaster scene (Tables 6 and 7).

As shown in Figures 6 and 7, the average situation of the relative production probability and the proportion of the wounded rescued in the earthquake disaster rescue based on the complex adaptive system within about 2000 simulation steps in three different scenarios after 100 simulation times are shown. It can be seen that, in the initial stage of rescue, the relative survival probability decreases rapidly. With the development of rescue work, the decline speed of relative survival probability slows down after about 300 minutes. In the early stage of rescue, the average survival probability

TABLE 7: Proportion of wounded rescued in different situations.

|                   | 1    | 501  | 1001 | 1501 | 2001 |
|-------------------|------|------|------|------|------|
| Extremely serious | 0.42 | 0.67 | 0.83 | 0.98 | 1    |
| Serious           | 0.42 | 0.66 | 0.82 | 0.9  | 0.93 |
| Ordinary          | 0.42 | 0.65 | 0.81 | 0.83 | 0.85 |

decreases faster, mainly because of the existence of seriously injured trapped people. However, the survival probability of such wounded people drops very fast, about 300 minutes. After that, the seriously injured died or were rescued and only slightly injured or not injured persons were left on the whole scene, and the average survival probability of the wounded decreased slowly.

*4.3. Frequency of Earthquakes in Recent Years.* We have made statistics on the frequency of earthquakes with magnitude 5 and above in recent years and also the property and life damage caused by them, as shown in Table 8.

It can be seen from Figure 8 that, in recent years, the global threat of earthquakes has been more serious. On average, there are about 5 earthquakes of magnitude 7 or

FIGURE 8: Number of earthquakes and losses.

above each year. The remaining small earthquakes are even harder to count. The property losses caused by earthquakes are as high as tens of millions each year. This also shows that the earthquake relief system proposed in this article is particularly necessary.

## 5. Conclusions

The frequent occurrence of major earthquake disasters is an urgent problem faced by all countries in the world. The traditional emergency management and emergency response decision making focus on the dispatching and distribution of relief materials, ignoring the role of human beings. In fact, in the process of disaster relief, the rescue team is the main body of participation. Under the background of frequent occurrence and increasingly serious impact of major earthquake disasters, it is not only of important theoretical value to carry out the research on search and rescue model to deal with such disasters but also has a strong practical significance for guiding the emergency rescue work after disasters and improving the effectiveness of the rescue decision-making scheme.

The main research content of this paper is an earthquake disaster rescue model based on the theory of complex adaptive systems. Aiming at the contradiction between the severity of large-scale earthquake disasters and the complexity of rescue teams, an earthquake disaster rescue model based on complex adaptive systems is established. The model considers the two goals of timeliness and efficiency, deploys the most suitable rescue team to the disaster site in the shortest time, and better describes the needs of large-scale geological disaster emergency rescue decision making. In the context of large-scale earthquake disasters, the research content of this paper solves many difficulties faced in the deployment of rescue teams and improves the efficiency of emergency rescue work. It provides an effective solution tool for postdisaster emergency rescue decision making and improves the emergency response capability for large-scale geological disasters.

Although this paper has carried on the beneficial exploratory research on the optimization deployment and decision making of a large-scale earthquake disaster rescue team and has achieved certain innovative results, there are still many work that need further study, mainly including the following: in the future, we will study the demand quantity of the rescue team in a disaster area by the tensor decomposition and filling method; pay attention to the data collection of rescue cases, according to the model proposed by relevant scholars, and use limited data to correct the model parameters, so as to improve the applicability of the model to the actual situation.

The progress of social economy has created a better environment for the healthy development of young people, but the heavy schoolwork and life pressure have caused many students to ignore the scientific management of physical health. At this stage, people need a scientific physical health service system to help students understand their own health data, propose targeted exercise methods and health knowledge, and actively encourage and guide students to participate in physical exercise. The purpose of this article is to cultivate students' good self-exercise awareness and improve their physical fitness and health. To this end, this article has designed a smart health service system for young people. This article introduces the various service functions in the health management service system and explains in detail the entry, induction, and analysis of student physical health data in the system. The essence of the health intelligent service system is to provide students with targeted healthy exercise strategies through data analysis. This paper studies the health intervention plan of the health intelligent service system. From the experimental data, the improved particle swarm algorithm in this paper increases the effectiveness of the system in adolescent health data mining from 80.5% to 92.19%, which undoubtedly optimizes the system. It helps a lot.

## 1. Introduction

In recent years, the number of obese children in my country has increased, and the rate of adolescents' myopia has continued to increase. Physical fitness indicators such as vital capacity, speed, endurance, and explosive power have continued to decline. The physical health of adolescents has increasingly become a concern of the whole society. To ensure that young people have a healthy body, they must establish the concept of scientific fitness and have a certain degree of understanding of the basic physiology of the human body and exercise methods. Scientific fitness guidance can help young people improve the effects of exercise and effectively improve their physical fitness. In this era of the rapid development of computer technology, it is a very good choice to spread fitness information and fitness

guidance services through the Internet because the network can infinitely enlarge the capacity of stored information and provide more targeted fitness guidance for teenagers through big data intelligent calculation.

In foreign countries, many scholars have conducted research on the management system to improve the health of young people. Laurson cross-validated fitness standards related to Hungarian youth health. He collected data from 400 teenagers using treadmills to conduct aerobic capacity tests to determine peak oxygen consumption and bioelectrical impedance assessment data. Combined with the FitnessGram standard, young people are divided into healthy groups and groups in need of improvement, and logistic regression is used to estimate the probability of metabolic syndrome. Judging from the experimental data, he believes that 62.3% of the 400 research subjects are in a healthy state

of fitness. Of course, considering that there are only 400 people in the survey, this affects the persuasiveness of the data to a certain extent [1]. Welk hopes to establish an effective physical education program through the Internet to support and enhance the school's physical education program. He combined with FitnessGram, an American youth physical fitness assessment system, to provide unique insights on how to effectively provide large-scale school-based physical exercise. But on the whole, when he formulated the physical test data management, the design of the evaluation system was not perfect, and there is still a lot of room for improvement [2].

In recent years, the country has also begun to work on the organic integration of Internet technology and adolescent health management system. Wang believes that the overall health status of the youth in our country is on a downward trend at this stage, and a scientific health management system needs to be built for this. In his research, he elaborated on the information management plan of the leading thought of the system development and argued that testing is not the purpose, and collecting data should be to better judge the physical health of students and give further exercise suggestions. From the actual experimental results, the function of the system in terms of information feedback and supervision is not perfect [3].

The research of this article mainly starts with the following parts. First, this article introduces various technologies and methods in the health intelligent service system, including big data visualization technology, genetic algorithm and particle swarm algorithm in data mining algorithm, optimal sequence diagram method, and multiple methods of juvenile health literacy evaluation. Next, this article describes in detail the experimental development and database development of the health intelligent service system based on big data. Finally, this article conducts an in-depth analysis of the construction of the complex system of the adolescent physical health intelligent service system. The research focuses on the service functions in the health management service system, the entry, analysis, and calculation of health data, and the health intervention based on the health intelligent service system.

## 2. Technology and Methods in the Health Intelligent Service System

**2.1. Big Data Visualization.** The physical fitness test of young people is passed because these tests can reflect the physical health of the test subjects to a large extent. The big data visualization technology helps the test results to be displayed in a clearer way, allowing the young people to intuitively realize the health problems in their bodies and find the direction of fitness exercise [4]. The development of technologies such as big data storage, the Internet, and the Internet of Things has created better conditions for the processing of youth physical health data. Because physical health data has the characteristics of large data scale, multiple data types, low value of individual data, and fast data update, if you want to make an accurate comparison of the

physical health of adolescents, the accuracy and reliability of data processing are very high requirements [5].

**2.1.1. Distance-Based Visual Clustering Technology.** The visual layout technology proposed in this paper takes the parallel coordinate visual layout as the prototype, and the visual layout technology based on indicator health data enhances the visualization effect, making the visual analysis more clear and convenient for users [6]. The original parallel coordinate visualization layout does not enable users to quickly understand the distribution of data records as a whole. The distance-based visualization clustering method introduced in this section can make the data categories of different distribution characteristics in the data records clear [7]. Figure 1 is a schematic diagram of distance-based visual clustering.

In Figure 1,  $n$  represents the number of attribute axes, and  $d$  represents the distance between the two lines on the attribute axis, and they satisfy the following formula:

$$d_i = \|P_{ix} - P_{iy}\|. \quad (1)$$

Among them,  $p_{ix}, p_{iy}$  represents the coordinate position of the two polyline segments on the  $i$ -th attribute axis. Then the average distance  $\bar{d}$  formula and vertical coordinate calculation formula of two polyline segments satisfy the following:

$$\bar{d} = \frac{d_1 + d_2 + d_3 + \dots + d_n}{n}, \quad (2)$$

$$y'_p = F_a \cdot y_p + (1 - F_a) \cdot y_m.$$

In parallel coordinate visualization, each data record is connected to each other to form a polyline segment according to its position on each attribute. As the amount of data increases, the staggering phenomenon of parallel coordinate line segments becomes more and more obvious [8]. Set  $p_0, p_2$  to be the vertical coordinates of the two ends of the curve, and  $p_1$  to be the vertical coordinates of the quadratic interpolation point, then the intensity factor of the attraction within the class and the quadratic spline curve formula satisfy the following:

$$F_a = e^{-dh/\|y_m - y_p\|} \cdot \cos \alpha \cdot \Delta, \quad (3)$$

$$B(t) = (1 - t)^2 p_0 + 2t(1 - t)p_1 + t^2, \quad t \in [0, 1].$$

**2.1.2. Visual Aggregation Technology Based on Membership Degree.** The biggest advantage of scatter plots over other visualization layouts is that they can quickly get the distribution information of the data, such as the main distribution range of the data, the type of data, the characteristics of various data, and other information [9]. However, users can only get rough data distribution information through the points scattered in the graph, and the observation of the scattered point distribution in the three-dimensional scatter plot is not clear. The visual aggregation technology based on membership degree can better enable users to more quickly

FIGURE 1: Schematic diagram of distance-based visual clustering.

obtain the distribution characteristics of the data records, thereby effectively enhancing the visualization effect of the scatter plot [10].

This method uses the objective function as the benchmark for clustering, and the objective function is as follows:

$$J = \sum_{i=1}^c \sum_{j=1}^n u_{ij}^m \|x_j - c_i\|^2. \quad (4)$$

At the same time, there are constraints on the objective function:

$$\sum_{i=1}^c u_{ij} = 1, \quad j = 1, 2, 3, \dots, n, \quad (5)$$

where  $n$  is the number of scattered points,  $c$  is the number of classifications,  $u_{ij}^m$  is the membership degree of the  $j$ th scattered points relative to the  $i$ th category,  $m$  is the fuzzy weighting coefficient,  $c_i$  is the center coordinate of the  $i$ th category, and  $x_j$  is the  $j$ th scattered point coordinates. Then the distance between two points and  $c_i$  satisfy the following formula:

$$L = \|x_j - c_i\|, \quad (6)$$

$$c_i = \frac{\sum_{j=1}^n (x_j u_{ij}^m)}{\sum_{j=1}^n u_{ij}^m}.$$

It can be seen that in order to obtain  $c_i$ , the value of the membership matrix must be calculated first, then  $u_{ij}$  and the radius of the sphere satisfy the calculation formula:

$$u_{ij} = \frac{1}{\sum_{k=1}^c \left( \|x_j - c_i\| / \|x_j - c_k\| \right)^{(2/(m-1))}}, \quad (7)$$

$$d_i = \frac{\sum_{k=1}^n \|x_{ik} - c_i\|}{n}.$$

**2.2. Data Mining Algorithm.** The main job of the health intelligent service system is to collect various physical information data of the youth group, judge the physical health of the students based on intelligent analysis, and give targeted exercise opinions [11]. However, the human body's health data is not only diverse in types but also very fast to update. In addition, there are still many data with low

reference value, which brings great adjustments to data analysis. Faced with this situation, it is necessary to find valuable information contained in a large amount of data through data mining technology to improve the efficiency and accuracy of data analysis [12]. Genetic algorithm (GA) and particle swarm optimization (PSO) are two very commonly used data mining algorithms.

**2.2.1. Genetic Algorithm.** The essence of a genetic algorithm is to simulate the genetic mechanism in nature and the theory of biological evolution. It has a very good performance when searching for the optimal solution randomly [13]. The genetic algorithm can be calculated as long as it has the information data of the objective function and will not be disturbed by spatial continuity. In addition, the genetic algorithm can also solve complex nonlinear problems and multidimensional space optimization problems, so it has a very wide range of applications in various fields [14, 15]. For a health management system based on big data, it is an excellent choice to analyze adolescent body data through genetic algorithms. Generally speaking, the genetic algorithm and the initial population can be formally described as follows:

$$\text{GA} = (P(0), N, I, S, g, p, f, t), \quad (8)$$

$$P(0) = (a_1(0), a_2(0), \dots, a_N(0)) \in I^N.$$

The basic operation steps of genetic algorithm are as follows: After clarifying the basic information of the objective function and variables of the problem, the variables can be coded, and the initial group  $\text{pop}_i(t)$  can be randomly generated according to the established coding method.

$$\text{pop}_i(t), \quad t = 1, 2, 3, \dots, N. \quad (9)$$

Individual fitness value is a concept used to evaluate and select individuals for various genetic operations. Generally speaking, fitness can reflect the excellence of each individual. The individual fitness value satisfies the following formula:

$$f_i = \text{fitness}(\text{pop}_i(t)). \quad (10)$$

When performing genetic algorithms, the value of individual fitness will directly affect operator selection in subsequent operations. Combining the value of the individual fitness function, it can be calculated that the selection probability of each individual satisfies the following formula:

$$P_i = \frac{f_i}{\sum_{i=1}^N f_i}, \quad i = 1, 2, 3, \dots, N. \quad (11)$$

Some excellent individuals are randomly selected from the original target group to complete genetic operations to form a new group of the next generation. The basic expression is as follows:

$$\text{newpop}(t+1) = \{\text{pop}_j(t), q = 1, 2, 3, \dots, N\}. \quad (12)$$

**2.2.2. Particle Swarm Algorithm.** Particle swarm algorithm is a kind of swarm intelligence algorithm. The inspiration of the swarm intelligence method comes from the research on the behavior of various biological groups in nature [16]. Compared with individual biological individuals, a large number of biological groups gathered together can more clearly reflect the behavioral characteristics of species. The steps of the particle swarm algorithm mainly include initializing particles, evaluating the fitness value of the particle by the fitness function, updating the particle swarm, checking whether it is terminated, and finally outputting the optimal solution.

Particle swarm optimization is also a population-based optimization algorithm like a genetic algorithm. It was originally used to solve continuous optimization problems and was specifically applied to function optimization and training neural network weights. The basic particle swarm algorithm satisfies the following formula:

$$\begin{aligned} v_i &= \omega \times v_i + c_1 \times \text{rand} \times (\text{pbest}_i - x_i) \\ &\quad + c_2 \times \text{rand} \times (\text{gbest}_i - x_i), \\ x_i &= x_i + v_i. \end{aligned} \quad (13)$$

Among them,  $\omega$  is the nonnegative inertia factor,  $c$  is the acceleration coefficient,  $x_i$  is the point in the D-dimensional space,  $v_i$  is the particle velocity, pbest is the individual extreme value, and gbest is the global extreme value. Since the parameter settings of the particle swarm algorithm have a great influence on the performance of the algorithm, it is mainly suitable for the optimization of continuous space functions. When applied to the optimization of health data in this paper, certain improvements and adjustments to the particle swarm algorithm are required [17].

**2.2.3. Particle Swarm Optimization.** At this stage, methods to improve the search accuracy of particle swarm optimization include dissipation theory, quantum update, chaotic update, etc. [18, 19]. Among them, quantum update and chaotic update have a good effect on the diversity of the population, and the dissipation theory can mainly improve the convergence speed and search ability of complex models, so these methods are beneficial to algorithm improvement. The following uses several standard mathematical model functions to test an improved real-number particle swarm algorithm and perform simple analysis of its performance.

$$f_1 = \sum_{i=1}^n \left( \sum_{j=1}^i x_j \right)^2. \quad (14)$$

Search space  $1 \leq x_j \leq 10, d = 20$ , global minimum  $f_1(x^*) = 0, x^* = 0, 0, \dots, 0$ .

$$f_2 = \sum_{i=1}^{n-1} \left( 100(x_{i+1} - x_i^2)^2 + (x_{i-1})^2 \right). \quad (15)$$

Search space  $1 \leq x_j \leq 10, d = 20$ , global minimum  $f_2(x^*) = 0, x^* = 1, 1, \dots, 1$ .

$$f_3 = \frac{1}{4000} \sum_{i=1}^n x_i^2 - \prod_{i=1}^n \cos\left(\frac{x_i}{\sqrt{i}}\right) + 1. \quad (16)$$

Search space  $1 \leq x_j \leq 10, d = 20$ , global minimum  $f_3(x^*) = 0, x^* = 0, 0, \dots, 0$ .

$$f_4 = \sum_{i=1}^n \left( x_i^2 - 10 \cos(2\pi x_i) + 10 \right). \quad (17)$$

Search space  $1 \leq x_j \leq 10, d = 20$ , global minimum  $f_4(x^*) = 0, x^* = 0, 0, \dots, 0$ .

In order to improve the correlation between the test and the application effect of the physique test, each function model was randomly run 10 times, and the mean and variance of the running results were calculated. On the whole, quantum theory can effectively improve the search ability and search accuracy of the algorithm. For the effect of data mining in the health and intelligent service system, it is very necessary to improve the particle swarm algorithm [20].

**2.3. Sequence Diagram.** The principle of the optimal sequence diagram method is to compare and analyze the importance of each factor to the goal through the means of matrix illustration, and the purpose is to provide a basis for managers to make decisions [21, 22]. The optimal sequence diagram method is based on the number  $n$  of factors to be compared, and numbering the  $n$  factors. Let  $n$  be the number of comparison objects, and form a checkerboard pattern with  $n * n$  spaces for  $n$  comparison factors. When comparing factors in pairs, users need to compare the importance or pros and cons of the two and use numbers. To simply express the comparison result.

When judging the superiority or inferiority of each factor or the order of importance by using the superior sequence diagram method, it is necessary to check the validity of the results to ensure that the subjects are objective when comparing the various factors and will not appear because of the order in which the problems appear to be judgment deviation [23]. Assuming that the scores of each influencing factor are, respectively,  $A_1, A_2, \dots, A_i$ , then the weight of the  $i$ th influencing factor satisfies the following formula:

$$a_i = \frac{A_i}{\sum_{k=1}^{10} A_k}. \quad (18)$$

**2.4. Adolescent Health Literacy Evaluation Method.** The research of this paper is centered on the guidance service system of adolescent physical health based on big data. Since the construction of this system is based on the health needs of adolescents, it is necessary to comprehensively understand the health standards and scientific fitness needs of adolescents before proceeding with system development. To this end, this article has consulted a large amount of literature, combined with questionnaire surveys and interviews to collect basic personal information of some young people, their understanding of fitness knowledge, their acceptance of fitness guidance, and fitness needs. Since the satisfaction survey questionnaire used in this article is a qualitative factor questionnaire, it needs to pass the  $\alpha$  reliability coefficient method to accurately reflect the consistency between the scores in the scale [24]. The calculation formula meets the following:

$$\alpha = \frac{k}{k-1} \left( 1 - \frac{\sum s^2}{S_T^2} \right). \quad (19)$$

In addition, this article also uses SPSS statistical software and EXCEL to enter and analyze the surveyed data. Perform statistical processing on the data results to obtain the basis for quantitative analysis. At the same time, on the basis of the paper's interviews, questionnaire surveys and health management training camps, the collected data are analyzed and studied using logical thinking methods such as induction and deduction, analysis and synthesis, analogy, classification, and comparison [25].

### 3. Big Data-Based Health Intelligent Service System Experiment

**3.1. Experimental Background.** The successful development and promotion of adolescent health management system in some European and American countries can not only effectively improve the physical health of students but also have a very good effect in disease prevention. From a macroperspective, ensuring the physical and mental health of young people can also have a positive impact on promoting social harmony and economic stability. On the whole, this article can learn from the advantages of foreign health management systems and draw lessons from them to further promote the development of my country's physical health intelligent management system.

**3.2. Experimental System Design.** Adolescent fitness test and subsequent data processing and analysis are a series of tedious but meticulous work. The statistics of the data after the physical fitness test of all students, the results of data analysis, and the management of user data are not allowed to make mistakes. Therefore, this article needs to develop a system that can simplify the tedious work according to requirements. System administrators can use the system to conveniently manage information and data. Users can query their own information and physical test results through the system and obtain corresponding fitness program

recommendations. Figure 2 is a diagram of the functional modules of the juvenile physical health intelligent service system.

According to the system module functions in Figure 2, this article uses a lot of technologies in the development of the juvenile physical health intelligent service system, including Win8, Tomcat9, MySQL, Redis, and MAVEN; development tools include Eclipse Oxygen.Ia.Release, Navicat for Mysql and visual operation tools.

This article divides the use of the system into four parts: data administrators, general administrators, teachers, leaders, and ordinary students. After logging into the system, people with different identities have different permissions and available functions in the system. The module authority of the data administrator is to enter the data of the student's physical test into the system database and to manage and maintain the data on a regular basis. The general administrator can comprehensively manage the system. In addition to adding, deleting, and modifying data, it can also manage all user accounts, such as adding user IDs and modifying user passwords. The module permissions of teachers and leaders can query the physical test scores and various health scores of all students in their school as needed. Students can log in to the system with their own ID and password and inquire about their physical test scores and various health scores.

**3.3. Experimental Database Design.** The database is composed of many data tables. In the process of completing the database, it is necessary to write code to add configuration files required for reverse engineering of each data table. Among the more important data table diagrams in the database table include workbook, student mark, student info, body mass index, and record file info.

This study collects and analyzes the physical data of adolescents in various ways, and finally obtains the complete data requirements of the system. Based on a series of surveys, collections, and analyses, this article confirms the various information data required by the system, including student information data sheet, a list of student physical test scores, physical test index weighting tables for different grades, single index score sheets, bonus index score sheet, and application form for exemption from execution.

### 4. Construction of a Complex System Based on Big Data for the Intelligent Service System of Youth Physical Health

#### 4.1. System Analysis Module of Health Intelligent Service System

**4.1.1. Current Status of Adolescents' Health and the Construction of Management Service System.** When analyzing the status quo of adolescents' physical health, it can be considered from many aspects such as body shape, physical function, and physical fitness. Based on the survey data in recent years, the overall physical health of adolescents in my country has shown a downward trend. Figure 3 shows the

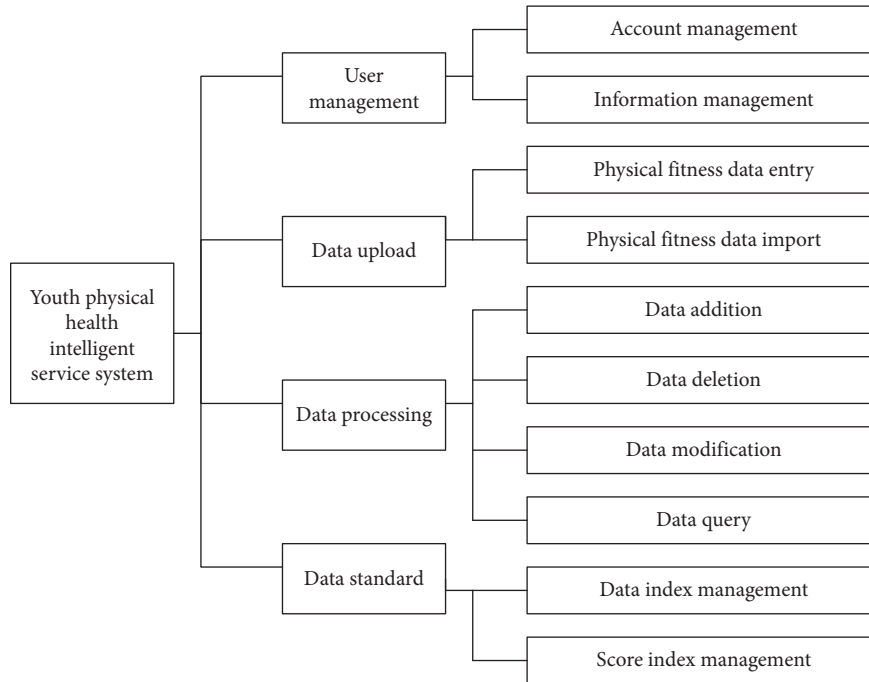

FIGURE 2: Functional module diagram of adolescent physical health intelligent service system.

FIGURE 3: Statistics on the change in adolescent obesity rate from 1985 to 2019.

statistics on the changes in student obesity rates during the eight national student physical health surveys from 1985 to 2019.

It can be seen from Figure 3 that the proportion of malnutrition and low weight among Chinese adolescents has continued to decrease over the past 30 years, which corresponds to the continuous increase in the number of overweight and obese students. In the past ten years, the obesity rate of Chinese adolescents has nearly doubled. Even taking into account the factors of average height growth, these data are still worthy of attention.

There is no doubt about the positive effect of physical exercise on the physical health of young people. Maintaining three to four times a week of exercise is very helpful for students to improve their physical fitness and promote their

physical health. Figure 4 is a survey of the number of weekly exercises for students in a college.

It can be seen from Figure 4 that only 17.63% of students do physical exercises 3-4 times a week, and most students only do simple physical exercises during physical education classes. Therefore, the proportion of students who exercise 1-2 times a week is as high as 48.5%. In addition, there are even close to 30% of students who said they basically do not participate in physical exercise.

As an important part of student health management, the physical education department is responsible for helping students prevent health risks. At the current stage, physical education in schools often ignores the pertinence and intensity requirements for the classroom. In this context, the top priority is to continue to innovate ways to promote the

FIGURE 4: Investigation and statistics of students' weekly exercise times.

health of young people and to better provide systematic and scientific help and services for the health of young people.

At this stage, the school's physical examination simply records various indicators of the student's body and cannot effectively help students to correctly understand their own health status and arouses students' attention to strengthening their physical fitness. In the smart service system for youth physical health based on big data, based on the detection of student health information, the information data will be further summarized, analyzed, and evaluated, and targeted health guidance and intervention will be provided to help students improve their health. Comprehensive quality.

**4.1.2. Service Function in Health Management Service System.** In the development of a youth physical health intelligent service system, this article unites the school physical education department, physical test center, school hospital, mental health center, and food and nutrition science health resource sharing platform to unify these advantageous resource platforms to realize the sharing of data resources. By establishing individual health management files for young people, we can better manage and serve the health of students. Table 1 and Figure 5 show the percentage of data of the types of adolescent psychological counseling problems.

It can be seen from Figure 5 that the most common types of problems in adolescents' psychological distress are depression and anxiety, problems in personal growth (lack of self-confidence and trust, etc.), and stress in learning. It is worth noting that although learning pressure accounts for 68.1% of the troubled problems, only 23.7% of students are willing to go for psychological counseling.

To ensure the physical health of young people, it is very important to ensure that they have a healthy mind. While the pressure of social competition is increasing, the learning pressure that young people endure from an early age has also continued to increase. Excessive learning pressure is very detrimental to the physical and mental health of students.

Therefore, the health intelligence service system developed in this article cooperated with the Mental Health Center and added a psychological counseling section to the platform. In the online environment, young people can conduct psychological consultation anonymously and seek help from professional psychologists to reduce the probability of mental illness.

In the health intelligence service system, the school hospital undertakes various service responsibilities such as student body examination, physical fitness assessment, disease treatment, medical supervision, and health knowledge publicity. The prevention, diagnosis, and treatment of students' physical diseases in school hospitals can not only alleviate the pain caused by diseases to students but also reduce students' financial expenditure on medical treatment. School hospitals can help students strengthen their self-care awareness and improve their quality of life by carrying out regular health consultations, disease surveys, and promoting healthy living behaviors.

The Academy of Nutritional Sciences provides scientific diet guidance and scientific diet promotion services for students' health. In the platform, the system will provide corresponding scientific recipes based on student body data. For example, students who are underweight can add more protein and carbohydrates, and students who are overweight need to control their diet and reduce calorie intake. All in all, it is to help students develop healthy eating habits through a scientific diet.

#### 4.2. Data Analysis Module of Health Intelligent Service System

**4.2.1. Entry and Processing of Physical Health Data.** When entering adolescent physical health data in the health intelligence service system, the data administrator can choose the appropriate entry method according to the actual situation. The most traditional method is to collect paper reports of student test data, sort all the data, and enter them into the system database by class. In addition, there are now

TABLE 1: Proportion of types of adolescent psychological counseling problems.

|   | Depression and anxiety (%) | Suicide and other serious psychological problems (%) | Insomnia and eating disorders (%) | Personal growth problems (%) | Learning pressure (%) | Emotional problems (%) |
|---|----------------------------|--|-----------------------------------|------------------------------|-----------------------|------------------------|
| Proportion of troubled problems         | 76.2                       | 14.8   | 32.5                              | 72.6                         | 68.1                  | 35.2                   |
| Proportion of people willing to consult | 58.2                       | 51.6   | 40.3                              | 34.8                         | 23.7                  | 25.2                   |

FIGURE 5: Types of adolescent psychological counseling problems.

many advanced testing instruments and systems that can automatically record data and generate excel forms. Administrators only need to add Excel forms into the health service system.

Using the health and wisdom service system, students can view various indicators in their physical fitness tests, and teachers can further understand the physical health of the student group by class. Table 2 is a single item score table for girls' body mass index (BMI). Figure 6 is a statistical chart of the body mass index of female students in a high school.

Compared with tables, statistical graphs can help teachers and leaders understand the overall health data of students more intuitively. It can be seen from Figure 6 that the overall body mass index of female students in the 21 classes of the high school from Grade One to Grade Three is in a normal state, but they are bound to be lighter and heavier students. Big data does not mean a general reference to data information. Choosing the correct data comparison indicators can help people further clarify the physical changes of students. Table 3 and Figure 7 show the body mass index of girls in the 7 classes in the second year of school. Figure 7 clearly shows the number of students who are lighter, heavier, and obese in each class. After the data is systematically summarized and sorted out, the effective calculation and analysis of the data health data can be ensured.

*4.2.2. Intelligent Calculation and Analysis of Physical Fitness Data.* In order to eliminate the interference items in a large amount of physical health data and correctly evaluate the health status of students, this paper uses intelligent data mining algorithms in the system. Figure 8 shows the change in accuracy of health data trait analysis before and after the improvement of the particle swarm algorithm.

It can be seen from Figure 8 that the improved particle swarm algorithm has increased its accuracy from 80.56% to 92.19% during the calculation, which is a good improvement. With the support of the improved particle swarm algorithm, the health intelligent service system based on big data can more accurately determine the health status of students from the physical fitness data of students and provide health intervention programs.

*4.3. Health Intervention Based on Health Intelligent Service System.* In the health intelligent service system, data collection, induction, and analysis are all for feature summary, and finally implement scientific health education intervention. In the smart health platform, people can not only understand the physical health of students through visual graphics but also harvest corresponding health education knowledge teaching and scientific exercise programs in the

health advice column. Table 4 shows the changes in various indicators after students receive scientific exercises.

It can be seen from Table 4 that the  $p$  values of all dimensions in the health survey summary table are less than 0.05, which indicates that the differences in the indicators of each dimension are significant after students listen to the health interventions given by the health smart service

system. Comparing the various dimensions of the health scale before and after the experiment, it is not difficult to see that the students' health in all aspects of the body has been significantly improved after scientific physical exercise. In the seven dimensions of the health survey summary table, the average value of each dimension has improved after the experiment than before the experiment. Especially in the dimensions of social function, emotional function, and physical pain. In terms of the overall health dimension, the average after the experiment also reached 86.31, which is a very high score, indicating that health management is of great help to the overall health of students. Figure 9 shows the changes in the average scores of female students after scientific exercise.

From Figure 9, after a period of exercise through the scientific intervention program recommended by the system, the students' performance in the physical test has been significantly improved. According to the comprehensive assessment standards, all students can exceed the passing line, and most students can get good grades and above. Figure 10 shows the survey data of students' satisfaction with the health intelligent service system.

It can be seen from Figure 10 that although traditional online fitness guidance also includes texts, pictures, videos, and other ways of guidance, it lacks understanding of students' physical conditions and cannot give targeted guidance. Therefore, students are satisfied with it. The degree is also relatively general. In contrast, the juvenile physical health intelligent service system built with big data has a significantly higher rate of praise among students.

Most youth associations lack a correct understanding of their changing physical conditions. At this time, scientific

FIGURE 8: Optimization accuracy changes after particle swarm optimization improved.

TABLE 4: Statistical table of changes in various indicators after students' scientific exercise.

| Project                | Before exercise | After exercise | <i>t</i> | <i>p</i> |
|------------------------|-----------------|----------------|----------|----------|
| Physiological function | 68.22 ± 19.63   | 76.23 ± 19.98  | -15.63   | <0.001   |
| Body pain              | 72.53 ± 15.48   | 81.42 ± 13.51  | -17.88   | <0.001   |
| Social function        | 62.31 ± 25.88   | 81.84 ± 24.02  | -30.45   | <0.001   |
| Energy                 | 77.69 ± 14.21   | 84.21 ± 13.05  | -23.27   | <0.001   |
| Emotional function     | 62.76 ± 31.25   | 84.21 ± 24.83  | -21.20   | <0.001   |
| Mental health          | 83.21 ± 16.02   | 89.38 ± 11.37  | -15.32   | <0.001   |
| General health         | 74.23 ± 16.82   | 82.53 ± 16.01  | -33.21   | <0.001   |

physical health indicators are needed to provide students with reference to keep students more concerned about physical exercise. In the growth process of young people, both the body and the mind are in a state of constant maturity. The health service system based on big data is dedicated to accurately understanding the health status of

FIGURE 10: Survey data of students' satisfaction with the system.

each student and provides targeted health guidelines through intelligent analysis.

### 5. Conclusions

This article analyzes the system analysis module of the health intelligent service system. When analyzing the physical health of adolescents, it can be found that the overall physical health of adolescents in my country is on the decline. Therefore, helping students to form a correct understanding of physical exercise and choose appropriate exercise programs has become an important task of the physical health intelligent service system. When constructing the system, this article worked closely with the school's physical education department, physical test center, school hospital, mental health center, and the Academy of Food and Nutrition Sciences, and consolidated the data resources of each platform to establish the personal health of young people, managing files to provide scientific management and services for students' physical and mental health.

This article analyzes the data analysis module of the health intelligent service system. Based on the smart platform of big data, the most basic workflow is to provide powerful data support for people to make correct decisions through data collection, entry, induction, calculation, and analysis. In the growth stage, various physical data of young people are in the process of constant change. In order to accurately obtain the valuable part of a large amount of physical health data, this paper uses an improved particle swarm algorithm for data mining. From the experimental results, the improved algorithm increases the accuracy of data analysis from 80.5 to 92.19. Based on the data analysis results of the health intelligent service system, this article has conducted health education intervention and health exercise intervention for young people. After scientific exercise, the students' various physical indicators and physical test scores have been improved to a certain extent. On the whole, the physical intelligence service system can play a very good effect in promoting the physical and mental health of students.

Based on big data, this article has launched research on the construction of a youth physical health intelligent service

system. This article uses database analysis and processing technology to collect a large number of young people's physical health data, combined with intelligent algorithms to comprehensively analyze the data and provide scientific guidance and suggestions for students to perform physical exercises. Judging from the survey results, the system has achieved high levels of satisfaction among students, but on the whole, the platform still has many shortcomings. In future research, from the perspective of big data, we can realize the comprehensive management of youth physical health data, optimize the operation process of the system during work, and further improve the effect of data mining algorithms.

The Biliu River is the largest river in Dalian. The occurrence of floods and droughts in this basin has extremely important impacts on local industry, agriculture, and urban development. For a long time, the annual distribution of precipitation in the Biliu River Basin is extremely uneven, the river runoff varies greatly from year to year and season to year, floods and droughts occur frequently, and serious soil erosion results in fragile ecological environment and severe shortage of water resources. In this paper, the spatial and temporal changes of rainfall and runoff in the Biliu River Basin are studied through the coupling of the MIKE 11 model and the MIKE SHE model. The hydrological changes in the Biliu River Basin are simulated. The coupled model is verified by monthly runoff data from 1996 to 2015, and the simulation values are found to be true. The values match well. Based on the cyclical pattern of precipitation and runoff in the Biliu River Basin, the rainfall and runoff data in the Biliu River Basin from 2016 to 2030 are derived. The MIKE SHE/MIKE 11 coupling model is used to predict the Biliu River from 2016 to 2030. The results show that flood disasters are expected to occur in August 2020, July 2025, and July 2030, which can provide a basis for hydrological management in the Biliu River Basin.

## 1. Introduction

The Biliu River is the largest river in the south of Liaoning Province. The basin runs through Yingkou and Dalian. The flood and drought conditions in the basin directly affect the industrial and agricultural development and economic growth of the people in the two places. The Cocoon Hydrological Station is located in Taudaoling Village, Guiyunhua Township, Zhuanghe City, Liaoning Province. It has a longitude of 122° 33'E and a latitude of 40° 02'N. It was established in 1958. It is the longest station in the river basin and has the longest statistical period. The comprehensive hydrological monitoring station with the longest and most complete hydrological and meteorological data is the only provincial hydrological monitoring point in the Biliu River Basin. The Biliu Hydrological Station is located in Shuangta Town, Pulandian City, Liaoning Province, with 122° 28' east

longitude and 39° 49' north latitude. The station was established in 1986. The total length of 42 km from Cocoa Field Station to Biliu Reservoir is a relatively concentrated area for catchment of water in the upper and upper reaches of the Biliu River Basin. The rainfall during the flood season at each station exceeds 70% of the annual rainfall [1, 2]. The hydrological conditions of Hehe Reservoir can well reflect the flood and waterlogging rules of the Biliu River, which is of great significance to the flood forecasting of the Biliu River Basin [3].

With the deepening of research on natural phenomena, accurate description and scientific disclosure of rainfall-runoff patterns in the natural world through mathematical methods can help people better understand and predict the water cycle in nature and rationally and scientifically allocate and use water resources. This has become a hotspot in hydrology research [4–6]. The distributed hydrological

model is to digitize rainfall, evaporation, and runoff data through elevation to show the hydrological change process of runoff and sink, which has higher requirements for the accuracy of the data [7]. In terms of professional software, the Danish Institute of Water Resources and Water Environment has been a world leader [8]. The company's software has been verified in actual engineering and has been widely recognized in water resources research. The functions of the software cover production, sink, and flow, including land, rivers, lakes, and oceans. The spatial scope ranges from one dimension to three dimensions. The research area ranges from water environment to hydrodynamics, and the research business ranges from water resource assessment and management to surface water and groundwater [9, 10]. In combination, one-dimensional river networks, two-dimensional estuaries, and three-dimensional deep seas are involved. The Danish Institute of Water Resources and Water Environment is a professional research department dedicated to water resources and the water environment [11]. Their technology has always been a leader in the world [12]. Hydrology in France, the United Kingdom, and Denmark has developed the first hydrological model for small watersheds, SHE [13]. In order to solve the calculation relationship between different hydrological processes and the values of different processes at the same time, the ASHE Association splits and combines the components that make up the SHE model and initially realizes the coupling [14]. The Danish Institute of Water Resources (DHI) uses the same code to port all the important coupled components. Relevant scholars improved the MIKE SHE model through the techniques of MODFLOW and OPENMI [15, 16]. MIKE 11 is a widely used one-dimensional river canal hydrodynamic model. Related scholars used the MIKE 11 modeling system to manage water resources in Strymonas River and Kerkini Lake and achieved good results [17, 18]. MIKE SHE is widely used in various runoff simulations. The researchers took the Saliberta Basin in the middle of the Mahanadi River Basin as the research object and focused on the application of the physical-based distributed modeling system MIKE SHE with good results [19]. Relevant scholars use the spatial distribution model MIKE SHE SWET to analyze the impact of afforestation and tree species on hydrology in different watersheds and use MIKE 11/MIKE SHE to study regional water resources management [20, 21].

This paper uses the hydrometeorological data from southern Liaoning from 1978 to 2016, based on an in-depth analysis of the occurrence of rainfall, evaporation, and runoff and its impact on floods and droughts. The dynamic process of runoff drainage is numerically simulated, the characteristics of floods and droughts in the Biliu River Basin are systematically studied, and related mechanisms are discussed. Local suggestions for controlling natural disasters such as floods and droughts and strengthening ecological construction are proposed.

The rest of this article is organized as follows. Section 2 analyzes the collection and processing of data. The model is established in Section 3, and the model is verified and predicted in Section 4. Finally, Section 5 summarizes the full text.

## 2. Data Collection and Processing

According to the actual conditions of the Biliu River Basin, the channel conditions in the simulated section, and the ultimate goal of the study, several modules such as river runoff (OC), slope flow (OL), and unsaturated flow (UZ) were selected in the MIKE 11 model.

For all hydrological processes and selected modules of the MIKE 11 model, we collate the collected data, summarize the model range, terrain, rainfall, vegetation, and other data, establish SHE parameters, and fully prepare for the modeling. The range of the Biliu River Basin is shown in Figure 1.

*2.1. Terrain.* The topographic data come from the topographic map with elevation data downloaded from Ovi Map, including the water system map of the simulated watershed. The elevation data come from the geographic and national conditions monitoring cloud platform; through the adjustment of the coordinate system and the rasterization of ArcGIS, the corresponding topographic water system map is generated.

*2.2. Land Cover/Use.* The land cover/use data is from the historical statistics of the Ministry of Agriculture. The land cover type, soil type, and vegetation classification are all extracted from the observation data with a resolution of 500 m. The data projection is converted and merged with the MODIS Reprojection Tool (MRT). Based on this, a commonly used Gauss Kruger format is formed, which can facilitate data synchronization processing.

There are multiple classification systems for land cover. This study uses a common vegetation classification scheme for agriculture. Most of the Biliu River Basin is a rural area, and the land use has not changed much between 1978 and 2016, and it is relatively stable. Therefore, the land use type in 1999 was used for treatment and it was divided into forest land (coniferous forest, broad-leaved forest, and shrubs) accounted for 45.41%, arable land (all agricultural land) accounted for 42.45%, residential and industrial land accounted for 7.07%, garden land accounted for 1.66%, unused land accounted for 0.02%, and water area accounted for 3.39%. The land-use types in the Biliu River Basin are shown in Table 1.

*2.3. Soil Types.* Based on the local soil data query, the soil types and their parameters in the Biliu River Basin are shown in Table 2. It can be found from Table 2 that the saturated hydraulic conductivity of brown earth soil is the highest; the saturated moisture content of meadow soil is the highest; the field water holding capacity of paddy soil is the largest; in addition, the withered moisture content of paddy soil is also the biggest.

*2.4. Plant Foliar Index.* The leaf surface index (LAI) of each coverage type in this research process can be determined based on actual measurement results, and the relevant results are shown in Table 3.

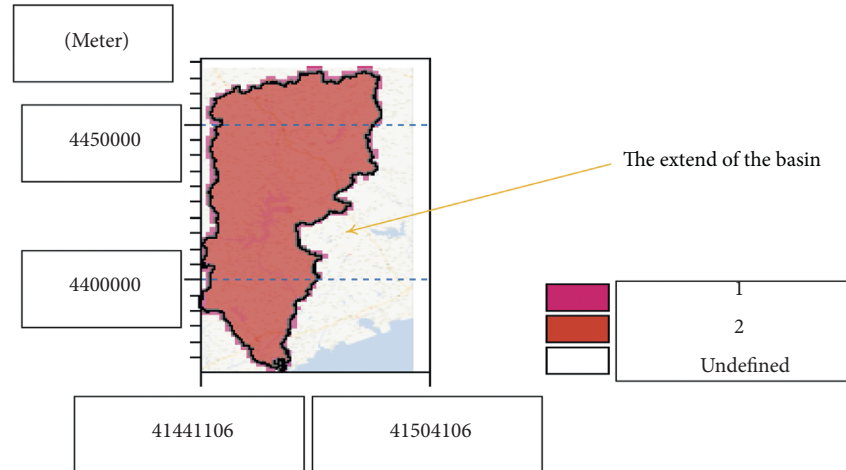

FIGURE 1: The extent of the Biliu River Basin.

TABLE 1: Land-use types in the Biliu River Basin.

| Soil use type             | Proportion (%) |
|---------------------------|----------------|
| Woodland                  | 45.41          |
| Arable land               | 42.45          |
| Garden                    | 1.66           |
| Waters                    | 3.39           |
| Urban and industrial land | 7.07           |
| Unused land               | 0.02           |
| Total                     | 100            |

2.5. *Others.* The four hydrological stations of the Biliu River are cocoon field, Xiaosongjiatun, Biliu Reservoir, and a tributary Yushi Reservoir. The annual average runoff is 612 million  $m^3$ .

Parameters related to rainfall, evaporation, and runoff were determined according to the statistics of the Hydrological Bureau. The meteorological data used in the calculation and analysis came from the Liaoning Meteorological Bureau. The location of the Biliu River Basin is shown in Figure 2.

There are obvious similarities between the average rainfall and annual rainfall distribution in the river basin during the flood season. The entire river basin gradually decreases from Dajiangtun in the north to Kuangdonggou in the southwest and Chengzitan in the south. All areas are gradually decreasing from the northeast to the southwest. The areas with increased rainfall are located in Dongsandaogou and Taipingzhuang in the northeast. The rainfall is greater than 560 mm, while the areas with lower rainfall are located in Bangladesh, in which the rainfall is less than 500 mm.

### 3. Model Establishment

3.1. *The Basis of the Model.* The runoff depth of each station does not change with time. The runoff depth of the Yushi Reservoir site has become smaller due to the commissioning of the Yushi Reservoir in 2003. At the same time, the Yushi Reservoir also affects the runoff depth of the mainstream cocoon field of the Biliu River and Xiaosongjiatun. Xiaosongjiatun Station is located in the lower

reaches of the Biliu River, and its runoff is greatly affected by the Biliu River Reservoir. In addition, the gradual decrease in rainfall over time is also the main reason for the depth of runoff. The blockage of river channels and the interception of vegetation will cause a decrease in runoff depth.

In the process of hydrological research, it is generally believed that a high-water year is a year when the flow is greater than the normal flow, while the opposite is true for a low-water year. The results of this paper show that the Biliu Reservoir has had more wet years than dry years in the past 40 years, while the results of other sites are opposite. The overall analysis shows that the ratio of the wet year to the dry year of the Biliu Reservoir is about 3 : 2, and the flood season is basically in line with the annual average, which shows that the regulation effect of the Biliu Reservoir is obvious.

The modeling process adopts the section from the mainstream cocoon field in the Biliu River Basin to the Biliu Reservoir. This section of the river has a large runoff and frequent floods. It plays a very important role in preventing floods in the Biliu River Basin. During the simulation, MIKE SHE was used to simulate the runoff, rainfall, and evapotranspiration fitting conditions at the cocoon field station, and MIKE 11 was used to simulate the water level change of the Biliu Reservoir.

Combined with the design data of the reservoir, the flood prevention alert water level is set. In this study, the Biliu Reservoir warning line 69.8 m designed by Liaoning Province Water Conservancy Survey and Design Institute in 1982 was used as an indicator of flood occurrence, and the maximum safe water level was 68.1 m. If the Biliu Reservoir water level reaches or exceeds the warning level, floods will occur and the reservoirs need to be flooded.

There are many factors that affect runoff changes, but rainfall is the most important factor. Analyzing the relationship between rainfall and runoff at various stations in the Biliu River Basin, it is found that the overall trend of annual runoff and rainfall is consistent. Secondly, the completion and commissioning of the Yushi Reservoir in 2003 greatly improved the hidden flood hazards and runoff conditions in

TABLE 2: Calculation of soil parameters.

| Numbering           | Withering water content (% vol) | Tianwen water holding capacity (% vol) | Saturated water content (% vol) | Saturated hydraulic conductivity (10 <sup>-6</sup> m/s) | Note                   |

the Biliu River Basin, and the design standards of the Biliu Reservoir have been continuously improved. Third, the improvement of the river course reduces the leakage loss of the river course, so that the impact of runoff is not obvious when the annual rainfall continues to decrease.

There is a total of 42 km from the cocoon field to the Biliu Reservoir. During the modeling process, sections were established at Cocoon Station, 40.5 km from Cocoon Station, 41.99 km from Cocoon Station, and 42 km from Cocoon Station to ease the water flow. A weir was established at 41.999 km from the cocoon field station to control the water level. When the water level exceeds 89.2 m, the weir will automatically prevent flooding until it reaches a safe water level of 68.1 m.

Runoff concentration is to synthesize the monthly runoff by the vector method, and the ratio of the resulting composite amount to the annual runoff can be used to describe the concentration level of the runoff during the year. The concentration period refers to the orientation of this composite vector, which describes the month corresponding to the center of gravity of the annual runoff concentration. In the process of mathematical analysis, it is generally described by the tangent angle of the ratio of the component sum.

For the convenience of research, the Biliu Reservoir was generalized into a part of the river during the research. The river below the reservoir was set at a constant water level of 30 m and the natural slope drop ratio of the river was 2‰.

In this study, the 5-year moving average method was used to select typical stations on the Biliu River, namely, the cocoon site, Biliu Reservoir, Xiaosongjiatun, and Yushi Reservoir, to analyze the change trend of its runoff. Then, the MK method was used to analyze the cocoon site and Biliu River. The MK method is used to test the sudden change of the rainfall trend. The MK method is a nonparametric test method. It does not need to analyze the distribution of the sample. The impact of abnormal values is very small. It does not need to be considered. It has high applicability to various types of variables. The accuracy of the result obtained is high, and the calculation is simple. The M-K method is widely used in hydrological research and meteorological research trend checking.

For the climate sequence  $x_i$ , at time  $i$ ,  $i = 1, 2, \dots, n-1$ , there are

$$m_j = \begin{cases} 1, & x_j > x_i, \\ 0, & \text{others,} \end{cases} \quad (1)$$

$$r_i = \sum_{j=i+1}^n m_j, \quad (2)$$

$$Z = \frac{4 \sum_{i=1}^{n-1} r_i}{n(n-1)} - 1. \quad (3)$$

We set the significance level to  $\alpha = 0.05$ , and then the criterion is

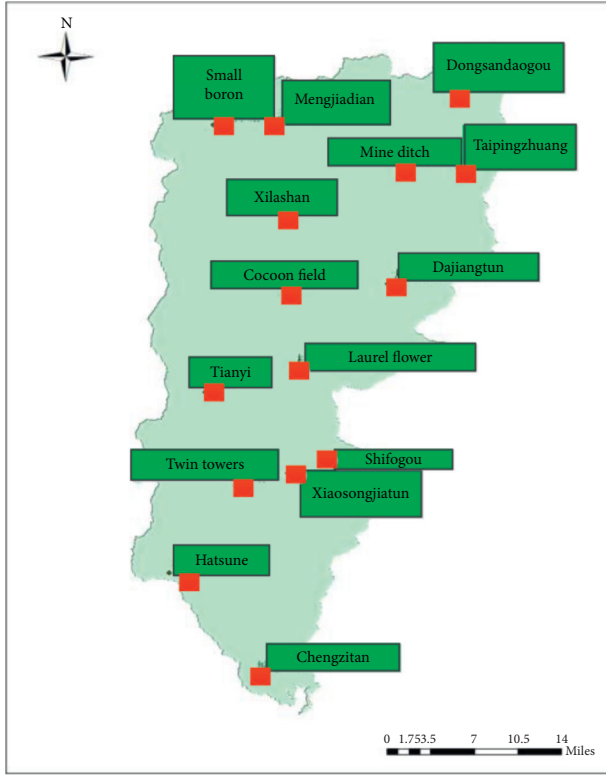

FIGURE 2: Survey station map of the Biliu River Basin.

$$Z_{\alpha} = 1.96 \times \left[ \frac{4n + 10}{9n(n-1)} \right]^{(1/2)}. \quad (4)$$

Suppose that the sequence is  $x_1, x_2, \dots, x_n$ ,  $S_k$  represents the cumulative number of the  $i$ -th sample  $x_i > x_j$  ( $1 \leq j \leq i$ ), and the defined statistics are

$$S_k = \sum_{i=1}^k r_i, r_j = \begin{cases} 1, & x_i > x_j, \\ 0, & x_i \leq x_j. \end{cases} \quad (5)$$

**3.2. Model Establishment.** The MIKE SHE model runoff simulation is performed by the Saint-Venant equations, where the momentum equation is simulated by the following equations:

$$\frac{\partial h}{\partial t} + \frac{\partial(uh)}{\partial x_i} + \frac{\partial(vh)}{\partial x_j} = q, \quad (6)$$

$$\frac{\partial(h)}{\partial x_i} = S_{oxi} - S_{fxi}, \quad (7)$$

$$\frac{\partial(h)}{\partial x_j} = S_{oxj} - S_{fxj}. \quad (8)$$

In the formula,  $h(x_i, y_j)$  represents the surface water depth (m),  $(x_i, y_j)$  represents the space coordinates,  $t$  is time (s),  $u$  and  $v$  represent the surface runoff velocity (m/s), and  $q$  represents the horizontal direction of the source-sink term

of inflow per unit area ( $\text{m}^3/\text{s m}^2$ ),  $S_{oi}$  and  $S_{oj}(x_i, y_j)$  represent the ground slope in the directions of  $x_i$  and  $y_j$ , and  $S_{fi}$  and  $S_{fj}(x_i, y_j)$  represent downhill in the directions of  $x_i$  and  $y_j$ .

The rainfall and runoff of the Biliu River Basin were simulated, and MIKE 11 and MIKE SHE were coupled for flood forecast research.

**3.2.1. MIKE 11 Model.** We establish a river network file based on the DEM data in the Biliu River Basin as required. The cross-section data are converted into a .shp file and entered into the MIKE 11 model to adjust the hydrodynamic parameter data.

The cross-section data simulated by the MIKE 11 model are derived from the generalization of the reservoir channel design and actual topographical data. The amount of water comes from the runoff generated by rainfall at the confluence of the cocoon field station. The cocoon field station is located 59 km from the river source; the lower boundary is 101 km from the river source. The river basin in this section is located in the middle of the Biliu River Basin. The concentrations of river runoff and large drop are of great significance for studying the drought and flood laws and forecasting in the Biliu River Basin. The height difference between the upper and lower boundaries will be calculated from the average ratio of the river channel and the actual relative height difference. Hydrodynamic parameters are set by default.

**3.2.2. MIKE SHE Model.** In the model calculation area, the mainstream of the Biliu River Basin was selected. When the grid was set, the grid size was determined to be 1 km. The target area was divided to determine  $50 \times 100$  units. In the course of this research, for the convenience of preprocessing and supplementation, all of them were uniformly transformed into the Xi'an 80 coordinate system. The rainfall data can be processed and determined based on the measured values of various stations in this area. The obtained results are processed appropriately to form the corresponding time series file (\* .dfs0); the evaporation data is determined according to local meteorological statistics. The Penman formula is calculated on the obtained raw data, and the resulting ET0 value is used to generate a \* .dfs0 file. In the model, the rainfall data and evaporation data are set separately by Tyson polygons. Thiessen polygon is a set of continuous polygons composed of vertical bisectors connecting two adjacent points. The distance from any point in a Thiessen polygon to the control points constituting the polygon is less than the distance to the control points of other polygons.

**3.2.3. Coupling of MIKE SHE/MIKE 11.** The water movement module of MIKE SHE covers the main processes of the hydrological cycle. It can study the hydrological cycle processes at different scales. It describes the hydrological cycle process of the runoff through evapotranspiration, slope flow, rivers and lakes, unsaturated flow, and saturated flow: evapotranspiration (ET) related factors mainly include

interception, soil, and water surface evaporation; surface runoff is described according to slope flow (OL), etc.; rivers and lakes (OC) are obtained by MIKE simulation analysis; and the correlation of reservoirs and dams is also calculated. However, the simulation of the hydrodynamic part of the MIKE SHE channel is insufficient and needs to be coupled with MIKE 11. Building a comprehensive MIKE SHE/MIKE 11 model includes the following basic steps.

First, we set the corresponding MIKE 11 hydrodynamic independent model and then test and analyze, under the possible conditions through the specified flow-related parameters to make a preliminary determination. Then, we establish the NIKE SHE model, the modules of which mainly include surface flow and saturated band, unsaturated band, and so on. Hydrodynamic simulation (1) and hydrodynamic simulation (2) are shown in Figures 3 and 4, respectively.

The branch river is defined as the connection between the two models, and the two are coupled. The lake submodule OC is used to import the simulation files related to the previous model. In this simulation system, the two models are simultaneously simulated and analyzed, and the data of the two is processed by the switch based on the shared storage space. MIKE 11 calculated the corresponding runoff water level, transferred the results to the latter model, and then compared the analysis results with the surface terrain information stored in the model to determine the remaining water volume. It can be inferred that the influential factors of water exchange between the two are mainly the corresponding evaporation and infiltration of surface water and the corresponding river exchange. Finally, the calculated water flow is exchanged with the first model through the sink source term of the Saint-Venant equation.

During the MIKE SHE model input process, the corresponding input data content is determined based on the corresponding modules and problem-solving requirements of the simulated hydrological process. The basic parameters include the model range, terrain, and rainfall. These data are indispensable in various MIKE SHE models. Based on the research area, a grid size of 1 km was set during the research in this paper. The target area was partitioned to determine  $50 \times 100$  cells. In the course of this research, for the convenience of preprocessing and supplementation, all data were converted and uniformly converted to the Xi'an 80 coordinate system.

We use MIKE 11 to simulate the river from the cocoon field in the Biliu River Basin to the Biliu Reservoir. According to the needs, the DEM data in the Biliu River Basin is used to create a river network file, and the cross-section data are converted into a .shp file to enter the MIKE 11 model to adjust the hydrodynamic parameter data.

The cross-section data simulated by the MIKE 11 model are derived from the generalization of the reservoir

FIGURE 3: Hydrodynamic simulation (1).

FIGURE 4: Hydrodynamic simulation (2).

channel design and actual topographical data. The amount of water comes from the runoff generated by rainfall at the confluence of the cocoon field station. The cocoon field station is located 59 km from the river source; the lower boundary is located 101 km from the river source; the river basin in this section is located in the middle of the Biliu River Basin. The concentrations of river runoff and large drop are of great significance for studying the drought and flood laws and forecasting in the Biliu River Basin. The height difference between the upper and lower boundaries will be calculated from the average ratio of the river channel and the actual relative height difference. Hydrodynamic parameters are set by default. The coupling between MIKE SHE and MIKE 11 is shown in Figure 5.

#### 4. Model Verification and Prediction

In order to verify the model effect, the adjustment of MIKE SHE model parameters should be as small as possible. In the MIKE SHE/MIKE 11 coupling model, the setting of parameters affects both the MIKE SHE and MIKE 11 models, and they are uniform in the river network. The correlation level between the measured value and the simulated value is

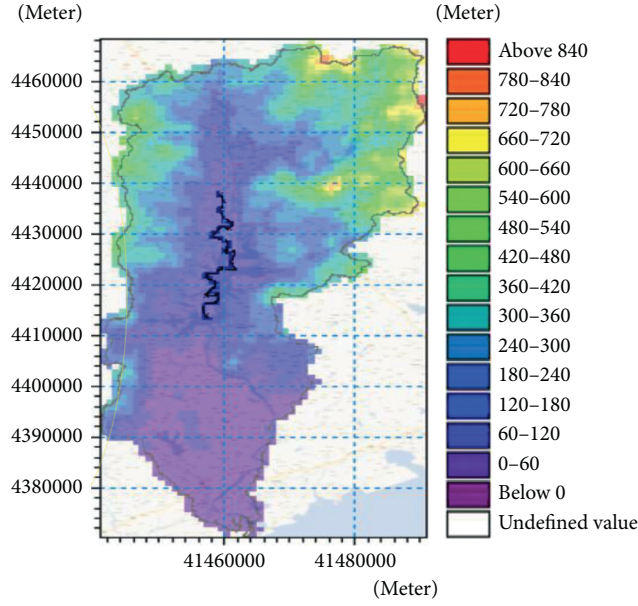

FIGURE 5: Coupled river pattern of MIKE 11/MIKE SHE.

described by the correlation coefficient, and the fitting degree of the two is evaluated by the Nash coefficient (Nse).

$$R = \frac{\sum_t (\text{Calc}_{i,t} - \overline{\text{Calc}_i}) \cdot (\text{Obs}_{i,t} - \overline{\text{Obs}_i})}{\sqrt{\sum_t (\text{Calc}_{i,t} - \overline{\text{Calc}_i})^2 \cdot \sum_t (\text{Obs}_{i,t} - \overline{\text{Obs}_i})^2}} \quad (9)$$

$$\text{Nse} = 1 - \frac{\sum_t (\text{Obs}_{i,t} - \text{Calc}_{i,t})^2}{\sum_t (\text{Obs}_{i,t} - \overline{\text{Obs}_i})^2} \quad (10)$$

Among them,  $\text{Obs}_i$ ,  $\text{Calc}_i$ ,  $\overline{\text{Obs}_i}$ , and  $\overline{\text{Calc}_i}$  are the measured and calculated values and their average values at  $i$ , respectively. The value range of Nse is negative infinity to 1. The larger the parameter is, the better the simulation effect can be judged to be, and the credibility requirements are met. If Nse is close to 0, it can reflect that the obtained result is close to the observation mean; that is, credibility is in the acceptance interval. If it is small, the model is untrustworthy. Relevant experience shows that if Nse is greater than 0.75, the simulation effect can be judged to be good; within the range of 0.36 to 0.75, it can be considered basically satisfactory; if it is less than 0.36, the requirements are not satisfied. Generally, when  $R > 0.8$ , it is considered that the level of linear correlation is high.

**4.1. Calibration of Parameters.** The MIKE SHE/MIKE 11 coupling model uses the data of the cocoon field from 1986 to 1995 for the parameter calibration. The calibration results are shown in Table 4. The simulation results of the runoff process before and after calibration are shown in Figures 6 and 7.

The correlation coefficient before calibration is  $R = 0.751294$ , and the Nash index is  $\text{Nse} = 0.531545$ ; the correlation coefficient after calibration is  $R = 0.94583$ , and the Nash index is  $\text{Nse} = 0.71379$ . The simulated and observed values achieve a good fitting effect.

**4.2. Model Verification.** The MIKE SHE/MIKE 11 coupling model was verified using two consecutive 10-year rainfall and runoff data from the cocoon field from 1996 to 2005 and 2006 to 2015. The results are shown in Figures 8 and 9, respectively. Time series verification results are from 1996 to 2005, correlation coefficient is  $R = 0.98818$ , and Nash index is  $\text{Nse} = 0.918427$ ; time series verification results are from 2006 to 2015, correlation coefficient is  $R = 0.964802$ , and Nash index is  $\text{Nse} = 0.895926$ . It shows that the simulated values and observed values of the two periods are in good agreement whether from the peak flow or the observation time.

Figures 10 and 11 show the changes in the water level at the Biliu Reservoir Station for two consecutive years (1996–2005 and 2006–2015). It can be found that, in the 20 consecutive years from 1996 to 2015, the water level of the Biliu Reservoir exceeded the warning level by 69.8 m: July 1995, July 1996, August 1997, August 1998, and August 2001, July 2005, August 2006, August 2010, August 2011, July 2012, and July 2013, these time nodes coincide with the historical changes in the water level of the Biliu Reservoir, indicating that the water level simulation results of the river reservoir can well reflect the real water level change of the reservoir. At this time, the reservoir needs to be discharged to prevent floods.

**4.3. Application of the Model and Flood Disaster Prediction.** The MIKE SHE/MIKE 11 coupling model was calibrated and verified by the rainfall, evaporation, and runoff data from the cocoon field from 1985 to 2015. It is found that the verification model is in good agreement with the real effect, and the water level changes of the Biliu Reservoir obtained from the simulation are basically consistent with the historical data of the Biliu Reservoir. This shows that the application of this model to predict flood disasters in the Biliu River Basin has a good effect.

TABLE 4: Parameter rate determination result.

| Parameter name                          | Calibration results   | Parameter unit  |
|---|-----------------------|-----------------|
| Evapotranspiration (ET)                 | 1.665                 | mm/d            |
| Slope roughness ( $M$ )                 | 5.0                   | $m^{1/3}s^{-1}$ |
| Initial water depth                     | -0.5                  | m               |
| Channel roughness (RM)                  | 5.0                   | $m^{1/3}s^{-1}$ |
| <i>Saturated hydraulic conductivity</i> |                       |                 |
| Brown soils                             | $4.13 \times 10^{-6}$ | $ms^{-1}$       |
| Brown earth                             | $3.72 \times 10^{-6}$ | $ms^{-1}$       |
| Coastal solonchaks                      | $3.68 \times 10^{-6}$ | $ms^{-1}$       |
| Meadow soils                            | $4.68 \times 10^{-6}$ | $ms^{-1}$       |
| Paddy soils                             | $2.80 \times 10^{-6}$ | $ms^{-1}$       |

FIGURE 6: Simulation results of monthly runoff in Jianchang field (1986~1995).

FIGURE 7: Simulated results of monthly runoff in the cocoon field after calibration (1986~1995).

Based on the cyclical pattern of precipitation and runoff in the Biliu River Basin from time to time, the precipitation and runoff data of the Biliu River Basin from 2016 to 2030 are derived. The MIKE SHE/MIKE 11 coupling model was used to predict flood disasters in the Biliu River Basin from 2016 to 2030.

Figure 12 shows the results of the monthly runoff simulation through the cocoon field. It can be seen that the correlation coefficient of the correlation coefficient between the derived value and the simulated value is  $R = 0.965588$ , the Nash index is  $Nse = 0.920947$ , and the fitting effect is very good. Figure 13 shows the water level change of the Biliu Reservoir. It can be seen that flood disasters are expected to occur in August 2020, July 2025, and July 2030.

## 5. Conclusion

For the section of the Biliu River Basin from the cocoon field to the Biliu Reservoir, this paper uses the MIKE 11 model to create a one-dimensional hydrodynamic model. Through various terrain indicators, the MIKE SHE model is established. The coupling of MIKE 11 model and MIKE SHE model is used to study the temporal and spatial changes of rainfall and runoff in this basin and to simulate the hydrological changes in Biliu River Basin. Based on the monthly runoff data of Biliu River Basin from 1986 to 1995, the parameters were calibrated, and the model was given a reasonable parameter scheme. The model was verified through monthly runoff data from 1996 to 2015, and the simulation values were found to be in good agreement with the real values, which ensured the applicability of the model in the study area. Based on the cyclical pattern of precipitation and runoff in the Biliu River Basin from time to time, the precipitation and runoff data of the Biliu River Basin from 2016 to 2030 are derived. The MIKE SHE/MIKE 11 coupling model was used to predict flood disasters in the Biliu River Basin from 2016 to 2030. The results show that flood disasters are expected in August 2020, July 2025, and July 2030.

As people's lives get better and better, more and more people choose to travel and with that comes the demand for more transportation. For now, traditional transportation hubs can temporarily meet people's travel needs. If driven by big data concepts and methods, the various capabilities of high-speed rail transportation hubs will be sublimated, and the regional economy will be in line with the prosperity of this place. Proportionally, railway hubs are extremely attractive to the rapid growth of the regional economy. This paper takes the high-speed railway hub construction model under big data as the research object and verifies the reliability of the research model and the development of economic regions based on the high-speed railway data in recent years as reference parameters. This article selects the panel data of railway transportation and regional economy in China's provinces for 10 consecutive years from 2011 to 2020. Among them, seven indicators were selected for railway transportation: passenger volume, freight volume, passenger turnover, cargo turnover, number of railway employees, railway transportation industry fixed asset investment and construction scale, and per capita railway network density. In terms of regional economy, six indicators were selected: regional GDP, per capita GDP, per capita investment in fixed assets, per capita total retail sales of consumer goods, per capita investment in imports and exports, and the proportion of the added value of the tertiary industry in GDP. The experimental results prove that each sample is tested in pairs, the standard error level of the mean is 0.002, which is less than 0.05, and high-speed railway construction can finally achieve economic integration. By improving the development of high-speed railways, continuously shortening the distance between time and space, breaking regional trade barriers, and reducing the cost of commodity circulation, industrial interaction and coordinated development between different regions can be effectively promoted.

## 1. Introduction

Rapid economic growth has led to a large amount of transportation demand, and differences in travel and service requirements have gradually diversified transportation and established a complete transportation hub. This is consistent with the ideas and methods of big data. How to use big data ideas and technologies to effectively use this information to serve the construction, management, and operation of nodes has become an important issue for improving the service level of integrated transmission nodes.

The development of railway transportation abroad has existed for a long time, and the research on the relationship between railway transportation and regional economic

development is relatively mature. China's railway construction is relatively late, but, with the construction and operation of railway transportation in various parts of our country, the relationship between railway transportation and the coordinated development of regional social and economic development has attracted more and more attention. There is a strong interdependence between a region and its neighbors. Therefore, the economic development of a region depends not only on its own foundation and investment but also on the development history of other regions. Li et al. pointed out that participation in high-level education and R&D has a higher impact on economic welfare. Furthermore, R&D indicators can be used as an important driving factor for evaluating economic welfare

[1]. When Wang and Loo studied the travel time of passengers, they studied the impact of high-speed railway on the time and space distance in the city network and derived the relationship between travel time and regional accessibility [2]. Pascal and Souza obtained the construction and operation of the high-speed railway through the research of the French high-speed railway TGV, which can improve regional accessibility [3].

Domestic researchers later studied the impact of high-speed railway construction on the local economy, but there are few studies. However, with the rapid development of China's high-speed railway construction and operation, research in this field has gradually been enriched and certain results have been achieved. With the improvement of technology and the wide application of measurement methods, scholars began to use quantitative analysis tools to quantitatively study the coordination relationship between railway transportation and regional economy. Based on the status quo of China's railway transportation and economic development, foreign theories and methods are used to conduct relevant research and analysis in different regions. Ikeda et al. used the industrial agglomeration theory of new economic geography to analyze the differences in China's regional economic development. It has been found that, since joining the World Trade Organization, the Gini coefficient where the industry is located has been declining, and the changes in regional economic differences have slowed down [4]. Han et al. used the linear weighting model and the dispersion coefficient method to quantitatively study the dynamic coordinated development level of the regional system and evaluated the effective degree of coordination and development within the regional system and between subsystems [5]. Li et al. established a dynamic model through dynamics and analyzed the relationship between transportation and economy [6].

Based on the research results at home and abroad, this paper finds that the algorithm of each method is based on different research data. This paper constructs a high-speed railway regional economic development model and studies route planning and high-speed railway integration models for big data. This paper conducts cluster analysis on three types of data and analyzes that the overall dimensionality reduction based on four weighting algorithms can effectively remove the attributes of less important research objects.

## 2. Cluster Coordination between High-Speed Railway Transportation Hub Construction and Regional Economy Based on Big Data

### 2.1. High-Speed Railway Transportation Hub, Hub Informatization, and Big Data

*2.1.1. Informatization of High-Speed Railway Transportation Hub.* Renewing the high-speed railway hub is very important to the management of the hub. Information management can further highlight the benefits of various transportation, high-speed railway, effective and targeted solutions for node management problems, and improving the service level of the transmission system. In terms of

coordinating transportation methods, handling emergency situations, and managing transportation needs, the management of high-speed railway hubs faces many management problems [7, 8]. To create a high-speed railway hub, we must propose targeted solutions to these management problems. Currently, a large number of nodes have created node information management platforms; these platforms have made significant contributions to coordinate link management, emergency, and rapid response and guide the flow of passengers. After determining the two basic conditions, use the reachability calculation model for calculation.

*2.1.2. High-Speed Railway Transportation Hub and Big Data.* From the current general point of view, big data has the characteristics of large quantity, variety, and speed, which represents a huge data scale, complex and diverse data forms, and the possibility of accurate and fast processing [9, 10]. Due to specific traffic functions and design locations, high-speed railway hubs have the characteristic of generating a large amount of different and complex data at high speed. For the city's large passenger transport hub, hundreds of thousands of passengers enter the hub every day. Faced with a large number of passenger transportations and logistics, high-speed railway operators have to deal with a large amount of complex information from video surveillance systems [11]. Big data indicates higher requirements for information: more information, more complete types of information, and more effective processing methods.

*2.2. Regional Economic Coordination.* First, construct the database according to the national economic census report specifications and prepare the network data report; then each census unit fills in the network report according to the nature of the unit and reports it directly, and each basic statistics bureau or department reviews the reported data and then reports it level by level. Analyze and process the final reported data, dig out the laws of economic development, discover economic development problems, and use modern information technology to make scientific predictions to form an analysis report [12, 13]. The economic census data processing process mainly includes four steps: report preparation, data collection, summary analysis, and data release.

*2.2.1. Improve Regional Accessibility.* Regional accessibility is reflected in the diversity of ways to reach a city. The improvement of traffic conditions has shortened the space-time distance between cities, and the frequency and spatial distance of people's travel have increased a lot compared to before. The convenient transportation environment improves the accessibility of the region and increases the attractiveness of the region. More enterprises and productivity are attracted to inject new vitality into the development of the region [14, 15]. The station has improved the city's traffic conditions and increased the radius of the city's activities and exchanges. The increase in speed and the reduction in

travel distance have resulted in cross-regional work and schooling.

**2.2.2. The Impact of High-Speed Railway on Regional Integration.** The integrated big data center collects a large amount of data from multiple sources in the transportation industry, such as urban roads, railway transportation, land public transportation, leasing, railway passenger and freight transportation, and freight Hadoop to create large data processing groups. Large amounts of traffic data are stored and processed [16, 17]. The integrated big data center is mainly divided into four databases: basic database, business database, exchange database, and theme database, used to store structured and unstructured data and, on this basis, carry out statistical analysis, web analysis, and data mining. The big data of the completed transmission node is waiting to be processed.

**2.3. Method Based on Clustering Feature Summary.** For the original data set that is too large to be read into memory at one time, you can first identify and summarize some of the data objects, reduce their memory usage, and complete large-scale data cluster analysis. Classical methods can be used, such as hierarchical method of balanced iterative induction clustering algorithm [18, 19]. The BIRCH clustering algorithm uses the CF tree to summarize information. CF is the main component of the node of the tree and the core of BIRCH. All the information of the cluster in the CF includes all the information needed for clustering. If you want to merge two clusters, you only need the sum of their corresponding CFs.

$$\begin{aligned}\bar{X}_0 &= \frac{\sum_{i=1}^N \bar{x}_i}{N}, \\ R &= \left( \frac{\sum_{i=1}^N (\bar{x}_i - \bar{x}_0)^2}{N} \right)^{1/2}, \\ D &= \left( \frac{\sum_{i=1}^N \sum_{j=1}^N (\bar{x}_i - \bar{x}_j)^2}{N(N-1)} \right)^{1/2}.\end{aligned}\quad (1)$$

The above information can be used to represent the information of the internal members of a cluster. The distance between clusters is used to express the degree of separation between clusters [20]. BIRCH defines the following 5 types of distance formulas between clusters. These distance formulas describe the degree of separation between clusters from different angles.

$$\begin{aligned}D_0 &= \left[ (\bar{x}_i - \bar{x}_j)^2 \right]^{1/2}, \\ D_1 &= |\bar{X}_{0_1} - \bar{X}_{0_2}| = \sum_{i=1}^N |\bar{X}_{0_1}^{(i)} - \bar{X}_{0_2}^{(i)}|, \\ D_2 &= \left( \frac{\sum_{i=1}^{N_1} \sum_{j=N_1+1}^{N_1+N_2} (\bar{x}_i - \bar{x}_j)^2}{N_1 N_2} \right)^{1/2}, \\ D_3 &= \left( \frac{\sum_{i=1}^{N_1+N_2} \sum_{j=1}^{N_1+N_2} (\bar{x}_i - \bar{x}_j)^2}{(N_1 + N_2)(N_1 + N_2 - 1)} \right)^{1/2}, \\ D_4 &= \sum_{j=N_1+1}^{N_1+N_2} \left( \bar{x}_j - \sum_{i=N_1+1}^{N_1+N_2} \frac{\bar{x}_i}{N_2} \right)^2.\end{aligned}\quad (2)$$

Because CF completely retains some of the key information required for the above calculations, BIRCH can use CF to complete large-scale data clustering. For example, CF can calculate the cluster radius  $R$ , where  $R = (((SS - \overline{LSLS}^T)/N)/N)^{1/2}$ . Similarly, the diameter  $D$  and the distance between clusters  $D_0 - D_4$  can be calculated using CF. It can be calculated by the six following formulas:

$$\begin{aligned}D &= \left( \frac{2N(SS) - 2\overline{LSLS}^T}{N(N-1)} \right)^{1/2}, \\ D_0 &= \left[ \left( \frac{\overline{LS}_1}{N_1} - \frac{\overline{LS}_2}{N_2} \right)^2 \right]^{1/2}, \\ D_1 &= \left| \sum_{i=1}^d \left( \frac{1}{N} \overline{LS}_1^{(i)} - \frac{1}{N_2} \overline{LS}_2^{(i)} \right) \right|, \\ D_2 &= \left( \frac{N_2 SS_1 - 2\overline{LS}_1 \overline{LS}_2^T + N_1 SS_2}{N_1 N_2} \right)^{1/2}, \\ D_3 &= \left( \frac{2(N_1 + N_2)(SS_1 + SS_2) - 2(\overline{LS}_1 \overline{LS}_1^T + \overline{LS}_2 \overline{LS}_2^T)}{(N_1 + N_2)(N_1 + N_2 - 1)} \right)^{1/2}, \\ D_4 &= \frac{\overline{LS}_1 \overline{LS}_1^T}{N_1} + \frac{\overline{LS}_2 \overline{LS}_2^T}{N_2} - \frac{\overline{LS}_1 \overline{LS}_1^T + \overline{LS}_2 \overline{LS}_2^T}{N_1 + N_2}.\end{aligned}\quad (3)$$

Dice similarity coefficient calculation formula is as follows:

$$\text{DICE} = \frac{2|\text{SEG} \cap \text{GT}|}{|\text{SEG}| + |\text{GT}|},$$

$$y = \alpha W y + \beta_1 X - W \beta_2 X + \varepsilon, \quad (4)$$

$$\ln g_{it} = \alpha_0 + \alpha_1 du * dt + \sum_{i=1}^N b_j Xu + \varepsilon_u.$$

SEN coefficient calculation formula is as follows:

$$\text{SEN} = \frac{|\text{SEG} \cap \text{GT}|}{\text{GT}}, \quad (5)$$

$$\theta(p, q) = \arctan\left(\frac{L(p, q+1) - L(p, q-1)}{L(p+1, q) - L(p-1, q)}\right), \quad (6)$$

$$\psi = \sum_{x=1}^{\theta} Vx = \sum_{x=1}^{\theta} \left( \frac{Wx}{\sum_{x=1}^x Wx} Sx \right). \quad (7)$$

In the process of clustering, if you want to cluster efficiently, you need to determine what is important data and what is secondary data; important data is very important to the role of the cluster, and secondary data can be processed secondarily [21]. Keep the primary data, summarize the secondary data, and save their clustering information with appropriate statistics.

## 2.4. Conception of Hub Informatization Based on Big Data

**2.4.1. Discover More Needs and Patterns from the Data.** The high-tech data analysis technology of this node will enable managers to proactively investigate traffic demand without waiting for passengers to make requests or even solve the supply-demand relationship when problems arise. Due to its content, the integrated transportation node has different operation modes and characteristics from general transportation methods and transportation stations. Their completeness and complexity make it difficult to penetrate many node information processing methods. With the help of big data ideas and technologies, it can not only process and publish diverse, comprehensive, and complex data but also provide valuable resources. For administrators and service providers, it is undoubtedly beneficial to discover the tacit traffic demand from these information-rich resources and discover the changing mode of the mobile center [22, 23]. Mined needs and patterns can also provide targeted and personalized traffic services for functional groups and scenarios. With the help of big data, it will be possible to meet the needs of traffic service users and improve the experience of using traffic services.

**2.4.2. More Accurate Warning and Faster Response.** Emergency management is the most difficult part of managing an integrated transportation hub. In emergency situations, the quick response level can usually tell you the advantages and disadvantages of node management. The node information management method can help managers to be calmer and effectively deal with emergencies and can

help managers to develop better evacuation plans and more effective passenger flow guidance. With the help of big data, the emergency response level of the center will be significantly improved. This is reflected not only in the effectiveness after emergence but also in effective early warning. Standard mode analysis of multiple data conditions will help establish an effective and accurate event warning mechanism. By analyzing a large amount of emergency data at historical nodes [24, 25], the emergency mode can be obtained, and then the phenomenon warning can be compared with the operation management, or the display mechanism can be further analyzed by the following method: mode to achieve event warning and quick response effect. With the help of big data processing methods, real-time monitoring can also quickly make faster and more accurate judgements about the state of the center.

**2.4.3. Basis of Complex Coordinated Linkage Technology.** Efficient data processing mechanism will lay the foundation for complex adjustment and link technology. Large-scale data analysis and processing methods will enable integrated transmission nodes to quickly process this data while receiving large amounts of data. The complexity of a node determines the complexity of its data structure. The data used by the management and transmission service provider must also be processed before it can be released and exchanged with the connection provider. Under normal circumstances, only simple data such as train arrivals and messages can be transmitted in real time. Slightly more complex data interactions require at least one day, even a week, or a month to be transmitted to the other party [26, 27]. At present, due to lack of timeliness, it is difficult to provide help for the current services of the node, and most of them are used to summarize experience. The mechanism for quickly processing large amounts of data can quickly improve and transmit effective information and even interact to achieve the goal of high-quality services. Within the scope of application of big data technology, better coordination and link management will be carried out.

## 2.5. Influence of Railway on Regional Economy

**2.5.1. The Influence of Railway on the Formation and Development of China's Regional Economic Belt.** China's railway development process reflects the course of China's economic development from the side. Judging from its early military and political importance or its successor economic importance, railway transportation has always played an important role and has made indelible achievements in China's economic development. It is obvious to promote the development of railway in the development of regional economy. The development of regional economy has always been closely connected with transportation, which requires strong transportation guarantee. As the main force of transportation, railway transportation has an irreplaceable status. Since the reform and opening up, railway transportation has undergone many major developments and accelerations to realize the effective circulation of human

resources, logistics, and other market elements. The construction and continuous improvement of the railway network have promoted the development of China's southeast coastal areas and linked the supply of raw materials with the central and western regions. It can be understood that railway transportation is a necessary and sufficient condition for the formation of a regional economy, the first construction of railway transportation, and the subsequent formation of the regional economy. Looking at the main railway lines in China, it is not difficult to see that they connect China's central cities to develop urban economic and commercial circles and guide urban development. For example, as transportation hubs, central cities such as Shanghai and Beijing have played a role in economic radiation and have become continuous trade corridors.

*2.5.2. Links between Railways and Major Economic Regions.* Railway transportation has played an important role in China's economic development. Significant changes have taken place in the industrial layout of areas along the railway, and railways have become an important part of the industrial layout. After the reform and opening up, we have observed the process of China's economic development, and it is not difficult to see that important industries are concentrated in areas along the main railway lines. The development of large railways has paved the way for the establishment of economic zones, and the layout of the railway network has also contributed to the economy and has had a significant impact on development. So far, the strategic planning for the distribution of productivity along the main railways in Northeast, North China, Southeast, Northwest, and Southwest has been completed, and the development of railways has become the political guide for economic development strategies. Facts fully show that the gradual maturity of urban settlements will stimulate interregional traffic demand, and the increasing traffic demand will in turn promote the connections and exchanges between urban settlements and will also develop regional economies.

*2.5.3. Influence of the Railway on the Economic Structure Adjustment of the Areas along the Route.* Passenger and cargo exchange in railway transportation is an important factor in economic growth. The construction and sustainable development of the railway will inevitably have an impact on the economic structure of the regions along the route, and the subsequent economic growth along the route will also expand the total regional economy. The direction of the railway also reflects the layout of the resource flow. The resource line can promote the formation of the regional economy by promoting the development and upgrading of industry and providing appropriate materials and labor.

*2.5.4. Influence of Railway on the Economic Development of Underdeveloped Areas.* Railway traffic has a unique role in promoting the economy of underdeveloped areas along the line. Take a typical case in the economic development of the United States to illustrate that the development of natural

resources and economic development in the western region of the United States benefited from the large-scale railroad construction in the United States in modern times, especially the rapid development of heavy industrial industries such as steel and machinery related to the railway industry. Our country's economic development has always been uneven. Since the reform and opening up, the economic gap between regions has gradually widened. Economically active areas have more human resources, modernization and economic development levels are higher, but the geographical space is smaller, and more regional space is needed; meanwhile those economically backward areas have abundant natural resources and vast geographical space but scarce economic growth point. Transportation is the main channel and important link for communication between these two types of regions, which organically connects the economically developed and economically backward regions, carries out the flow and transfer of economic factors between them, and effectively transfers capital, technology, and talents.

### **3. Coordination between the Construction of High-Speed Railway Transportation Hub and Regional Economy**

*3.1. Demand Analysis.* Intelligent data analysis is based on data collection, statistics, and aggregation and uses intelligent analysis models to mine and discover census data relationships, economic development issues, economic level regional division, economic index level status, and national economy based on economic indicators development layout countermeasures and suggestions. Intelligent data analysis needs to meet the needs of effective statistics and clustering of data reports that cannot be counted by existing database technology, the need to assist database technology in order to find problems more comprehensively, so as to have a more comprehensive grasp of the overall situation, and the need to plan for the next step of economic development basic analysis work and forecast suggestions.

*3.2. Database Storage System.* The database storage system is the foundation of the entire system and a prerequisite for intelligent analysis of census data. This database storage system mainly includes functions such as user management, data entry and import and export, data query and summary, system navigation assistance, and system security management.

*3.3. Test Subject.* The intelligent data analysis system mainly completes the intelligent analysis of economic census data, and its goal is to use intelligent analysis methods and data mining related technologies to discover unknown laws in economic census data. The system tried four methods of intelligent analysis of the economic census data, fuzzy clustering, MMD algorithm, K-means algorithm, and FCM algorithm, and analyzed three types of data: economic growth, financial status, employment by industry and wages. A cluster analysis was carried out and a good conclusion was obtained. At the same time, data from railway traffic and

regional economic data tables are selected for 10 consecutive years from 2011 to 2020. Among them, the railway traffic data comes from the “National Railway Statistics Abstract 2011–2020,” the Ministry of Transport, and regional economic data from China’s 2011–2020 statistical year, provincial and municipal statistical yearbooks, and the National Bureau of Statistics. It provides practical value that can be reported at the decision-making level and can refer to information that cannot be obtained by traditional database analysis methods and statistical methods.

**3.4. Experimental Method.** This paper selects the panel data of China’s provincial railway traffic and regional economy for 10 consecutive years from 2011 to 2020. Among them, railway transportation selects seven indicators: passenger volume, freight volume, passenger turnover, cargo turnover, number of railway employees, railway transportation industry fixed asset investment construction scale, and per capita railway network density. In terms of regional economy, six indicators are selected: regional GDP, per capita GDP, per capita fixed asset investment, per capita retail sales of consumer goods, per capita import and export investment, and the proportion of tertiary industry added value in GDP.

**3.5. Data Processing.** The index selected in this article is the annual statistical data of books, which is the index data of practical value. Therefore, the trapezoidal fuzzy table distribution function is usually used to calculate the participation of each indicator. The specific formula is as follows: partially large trapezoidal distribution is as follows:

$$r(x) = \frac{x-c}{d-c}, \quad c < x < d. \quad (8)$$

Partially small trapezoidal distribution is as follows:

$$r(x) = \frac{b-x}{x-a}, \quad a < x < b. \quad (9)$$

For the ideal score value, it can usually be set as the middle value of each interval. This paper divides the evaluation grades into five grades, and the index data after normalization processing all fall into the [0-1] interval.

There are many ways of data standard processing, but different data standardization methods will have a certain impact on the evaluation results of the system. For the positive index standardization method,

$$y_{ij} = \frac{x_{ij} - \min(x_{ij})}{\max(x_{ij}) - \min(x_{ij})}. \quad (10)$$

For negative index standardization methods,

$$y_{ij} = \frac{\min(x_{ij}) - x_{ij}}{\max(x_{ij}) - \min(x_{ij})}. \quad (11)$$

After standardizing the data, using the principal component analysis of nonlinear logarithmic centering, the

processing steps of logarithmic transformation and row vector centering are

$$z_{ij} = \ln y_{ij} - \sum_{i=1}^m \frac{\ln y_{ij}}{m}. \quad (12)$$

**3.6. Statistical Methods.** SPSS 23.0 software was used for data processing, and the count data was expressed as a percentage (%),  $k$  is the amount of data in this experiment,  $\sigma^2$  is the variance of all survey results, and  $P < 0.05$  indicates that the difference is statistically significant. The formula for calculating reliability is shown in equation (7).

$$a = \frac{k}{k-1} \left( 1 - \frac{\sum \sigma_i^2}{\sigma^2} \right). \quad (13)$$

## 4. Coordination between the Construction of High-Speed Railway Transportation Hub and Regional Economy

**4.1. Evaluation Index System Based on Index Reliability Testing.** Reliability refers to the stability and reliability of the questionnaire. This article adopts the  $\alpha$  coefficient method created by L. J. Cronbach. The  $\alpha$  coefficient can be obtained by Reliability Analysis in SPSS software. It is generally believed that the  $\alpha$  coefficient above 0.8 indicates that the effect of index setting is very good, and that above 0.7 is also acceptable.

This experiment can be used to perform cluster analysis on three types of data: economic growth, financial status, employment status by region and wages ( $\alpha > 0.7$ ). As shown in Table 1, the economic growth under the fuzzy clustering model is 0.8427. There are no absolute pros and cons between analyses, not to say that the more complex the model, the better the prediction performance. Within an acceptable range, the preconditions of the experiment are met, which provides a basis for subsequent experimental analysis.

**4.2. Three Indicators by Different Intelligent Analysis Methods.** As shown in Figure 1 and Table 2, economic attributes are mainly divided into three subitems: economic growth, financial status, and employment of personnel by industry and wages by region. There are 79 dimensions in total. This time, 4 algorithms are used for overall dimension reduction, which overcome the shortcomings of inaccurate clustering results of different densities by general algorithms.

It can be seen from Figure 2 and Table 3 that the overall dimensionality reduction based on the four weighted algorithms can effectively remove the attributes of the research object with less significance. It is similar to the principal component analysis and the multiattribute projection pursuit method, but the effect is better after clustering.

As shown in Table 4, the result is more accurate. Here, choose the intelligent analysis of four methods: fuzzy clustering, MMD algorithm, K-means algorithm, and FCM algorithm, and perform cluster analysis on the three types of

TABLE 1: Summary table of reliability test results.

| Intelligent analysis | Type of data  | Alpha coefficient ( $\alpha$ ) |
|----------------------|---|--------------------------------|
| Fuzzy clustering     | Economic growth   | 0.8427                         |
| MMD algorithm        | Financial situation   | 0.7652                         |
| K-means algorithm    | Personnel employment and personnel salary by industry by region | 0.7372                         |
| FCM algorithm        |   | 0.7592                         |

data of economic growth, financial status, and regional employment and wages. It proves that the growth level of the regional economy and the development of the railway hub have a mutually promoting effect.

As shown in Figure 3 and Table 5, the scope of the overall planning of innovation resources at the city level has been expanded to form a hub innovation circle within 10 minutes of a comprehensive transportation hub site. The change in the spatial form of the innovation block at the block level has formed a TOD innovation block within an 800 m walk-in radius of a high-intensity development area. The vertical concentration of innovative functions at the architectural level is a comprehensive innovation core that uses the complex as a carrier to gather innovative elements.

#### 4.3. Evaluation Model of System Coupling Coordination and Analysis of Results

**4.3.1. Judgement Analysis of the Correlation of Evaluation Indicators.** As shown in Table 6 and Figure 4, before further analysis of the data, first analyze the correlation of evaluation indicators and the partial correlation between variables. The correlation coefficient matrix and the corresponding statistical value are obtained through 4 algorithms. Judging whether the evaluation index is suitable for principal component analysis according to the value, KMO greater than 0.9 indicates very suitable; KMO less than or equal to 0.9 and greater than 0.8 indicates appropriate; KMO less than or equal to 0.8 and greater than 0.7 indicates appropriate; KMO less than or equal to 0.7 and greater than 0.6 indicates barely appropriate; KMO less than or equal to 0.6 and greater than 0.5 means inappropriate; KMO less than 0.5 means inappropriate.

As shown in Figure 5, the existence of high-speed railway and air service time windows will have a certain impact on the decision-making of multimodal transportation routes for fresh products. When the total cost is the goal, the “high-speed railway + highway” transportation combination

method can be selected in consideration of the node time window; in addition, compared with the optimal route without the node time window, the existence of the time window of the transportation mode at the node is to a certain extent. It increases the cost of time value, but it is more realistic and reasonable than the idealized scenario without time window in previous studies. Multimodal transport operators can choose appropriate routes and transportation methods according to the situation.

The result is shown in Figure 6 and Table 7; at the same time, each sample is tested on the selected samples, and the mean, standard deviation, standard error of the mean, and other data are obtained, as shown in Table 2.

It can be seen from Table 8 that, at the same time each sample is tested in pairs, the standard error level of the mean is 0.04, which is greater than 0.05, indicating that the correlation matrix of the evaluation indicators of the railway transportation system and the regional economic system is suitable for principal component analysis.

It can be seen from Figure 7 and Table 9 that the construction of high-speed railways is an important means to accelerate regional economic development. High-speed railways can not only adjust the industrial structure and improve the market structure but also deepen interregional connections, increase the employment rate, and inject the regional economy vitality.

#### 4.3.2. Railway Traffic Index Data Based on MMD Algorithm.

As shown in Figure 8 and Table 10, in terms of railway transportation, we select passenger volume, freight volume, passenger turnover, cargo turnover, railway employment, railway transportation industry fixed asset investment and construction scale, and per capita railway network density. These seven indicators mainly adjust the maximum number of iterations of the model, the learning rate, and the maximum depth of the tree. Each iteration will produce a weak learner. If the number of weak learners is too small, it is easy to underfit, and if there are too many, it is easy to overfit.

| 2019 | 4.16                        | 4.8       | 2.88 | 3.3         | 5.41   |
| 2020 | 2.28                        | 4.35      | 3.48 | 4.32        | 4.02   |

FIGURE 10: High-speed railway has promoted interpersonal communication.

The result is shown in Figure 9; at the same time, each sample is tested on the selected samples, and the mean, standard deviation, standard error of the mean, and other data are obtained, as shown in Table 11.

It can be seen from Table 12 that, at the same time each sample is tested in pairs, the standard error level of the mean is 0.002, which is less than 0.05, and high-speed railway construction can finally achieve economic integration. By improving the development of high-speed railways, continuously shortening time and space distances, breaking regional trade barriers, and reducing commodity circulation costs, industrial interaction and coordinated development among different regions can be effectively promoted.

As shown in Figure 10, relying on the high-efficiency and rapid advantages of high-speed railways drives the efficiency of personnel exchanges between different regions; through the release of existing line transportation capacity, the efficiency of cargo transportation is improved.

**4.3.3. Regional Economic Index Data Based on MMD Algorithm.** In terms of regional economy, we select six indicators of regional GDP, per capita GDP, per capita fixed asset investment, per capita retail sales of consumer goods, per capita import and export investment, and the proportion of tertiary industry added value in GDP and adjust the maximum number of iterations, learning rate, and maximum depth of the tree. Each iteration will produce a weak learner. As shown in Figure 11 and Table 13, if the number of weak learners is too small, it is easy to underfit, and if there

are too many, it is easy to overfit. Each sample is tested on the selected samples, and data such as the mean, standard deviation, and standard error of the mean are obtained, as shown in Table 14.

It can be seen from Figure 12 that, at the same time each sample is tested in pairs, the standard error level of the mean is 0.015, which is less than 0.05, indicating that, in the future development of high-speed railways, it is necessary to clarify and solve the problems since the opening of high-speed railways.

It can be seen from Figure 13 and Table 15 that, along the railway line, the effect of high-speed railways on the regional economy will be reflected to the greatest extent. The specific manifestation is the use of transfer stations and the radiation effects of large- and medium-sized cities to gradually expand the formation of regional economic belts and continue to improve the road network planning. Based on the economic development of the central and western regions, pay attention to the construction of high-speed railway infrastructure in the central and western regions. For busy areas, consider increasing the auxiliary railway network.

As shown in Figure 14, in order to better present the simulation results, the calculation example parameters are set on the basis of real data. Refer to the national highway odometer, 12306 official website of high-speed railway operating mileage, and China Southern Airlines flight mileage for the node distance under different transportation modes. Since the transit time of the node gradually increases according to the transportation process, the setting of the

FIGURE 11: Contribution of high-speed railway economy in the economic field.

| Personnel employment and personnel salary by industry by region | -1.33 | 9.643              | 1.275                      |

node service time window follows a certain order of increase. The transportation unit price, transit time, transit cost, and time window data are shown in Table 16. Among them, the high-speed railway and aviation time window widths at the nodes are set to 0.5 and 1 h, respectively.

As shown in Figure 15 and Table 17, most of the previous researches on multimodal transportation routes tend to be in the ideal state of no node time window. If the alternative transportation mode has no service time window constraint at the node, there is no need to wait for the goods in the

transit process, and the transit efficiency will be improved, a substantial increase. Under the condition of keeping the assumptions and other parameter settings unchanged, the path model without node time window is solved, and the optimal path is obtained as follows: AEHNO, the transportation mode combination is [3, 1, 1, 1], and the total transportation distance is 3654 km, the total path time is 28.29 h, and the total cost is 31057.38 yuan. Analyze and output the five path schemes with the smallest total cost, as shown in Table 5.

## 5. Conclusions

The data storage system ensures the timeliness and sharing of inventory data. In the past, data inventories used inventory personnel to access and manually import electronic devices. The existing system can meet the direct input of the electronic inventory unit, and the inventory staff can view and modify it in real time, thereby saving time; at the same time, the inventory data network can allow all levels from the top to the bottom to control and process the data to avoid a situation that the superior had to submit long data to subordinates to understand the data status and the system to perform data exchange. The intelligent data analysis system uses the current popular data mining technology. National financial inventory data meets a number of characteristics. Although it has some possible laws, there are inevitably many inherent problems, which are difficult to find. Generally speaking, big data has broad prospects for the development of information services in integrated transportation hubs, which need to be explored.

Because the traditional economy cannot conduct comprehensive research on various factors that affect the economy, this article analyzes data mining technology in a targeted manner to find a data mining algorithm suitable for regional economic analysis. Enhancing the accessibility of the railway transportation system will bring about huge economic benefits to the region, and improving the economic benefits will enable the country to increase the construction of railway transportation facilities to better serve economic development and improve the relationship between the two. Development is also an important way to promote the sustainable and healthy development of cities. Strengthening the importance of coordination between the two and studying the interaction between railway accessibility and regional economic development are important research topics for China's railway development.

There is a two-way feedback mechanism between the railway transportation system and the regional economic system. Railway transportation mainly affects the regional economy from two aspects: the overall economy and the spatial industrial structure. The investment in railway construction will affect the expansion of the regional structure and provide new impetus for economic development. On the contrary, the development of the regional economy will have a positive impact on railway transportation from three aspects: the supply of construction funds, the demand for railway transportation, and the supply of labor and technology. The survey results show that, in order to maintain the coordination between railway transportation and regional economic development, the state

must control the investment in railway construction to achieve a virtuous circle, narrow the gap between regions, and improve the level of coordination.

The protection of cultural relics has always been an important issue in the field of museums and archaeology. With the development of Internet of Things technology, the security system of the museum is more intelligent and integrated. In order for the museum display system to keep up with the intelligent age, this article mainly studies the research and realization of the museum showcase system based on the Internet of Things technology in a smart environment. Before the start of the experiment, we developed the overall design of the system, including three functional modules: temperature module, illumination module, and monitoring module. The experiment is done mainly for system testing. The performance test of the sensor module needs to sample the temperature and humidity sensor to verify the accuracy of the temperature and humidity signal collected in the instrument circuit. The light information collection test uses the ADC sampling inside the CC2530 to obtain the required data and judges whether these temperature, humidity, and light intensity values exceed the preset values. The serial port needs to be initialized to carry out data communication and transmission normally. After the receiving end finishes receiving, the sending end will clear the data buffer to prepare for the next data transmission. The experimental data show that the error between the predicted value and measured value of the temperature system is about 3°C, which is within the allowable error range of the experiment. The results show that the system has perfect functions, is safe and reliable, meets the expected requirements, and has good practicability.

## 1. Introduction

The Internet of things is a new network communication technology in recent years. It is a new network based on the Internet, through various information sensing devices, using cloud computing and big data technology, to connect “human machine things” together by means of communication, so as to realize informatization and intelligence. With the development of social economy, people pay more and more attention to the construction of spiritual civilization. Museums play an important role in providing social education, recording historical changes, and displaying cultural details. It has become an indispensable part of the construction of human spiritual civilization. As an important part of the museum, the display cabinet has a close relationship with the exhibits, so the design of the

display cabinet has a strong influence on the overall exhibition effect.

Cultural relics are the product of history. In the course of five thousand years of development, the Chinese nation has created brilliant material and spiritual civilizations for us but also left us countless treasures of cultural relics. Only by better preserving these cultural heritages in the form of material and promoting them to better serve the development of mankind can it promote the better development of mankind. As the highly integrated and comprehensive application of a new generation of information technology, the rapid development of the Internet of Things plays an important role and significance in promoting the design of museum showcases and the green, intelligent, and sustainable development of the

society. According to the specific environment, the corresponding sensor is selected to obtain the parameters, which improves the accuracy of obtaining the environmental parameters and eliminates the drawbacks of manual detection.

The Internet of Things technology has brought tremendous changes to human life. Wu believes that, in recent years, museums have invested a lot of manpower and material resources to promote the construction of digital museums. However, in the construction of digital museums, it is very difficult to manage so many collections and find a collection in them. Therefore, he used information technology to identify collections. He described the digital construction of the museum and proposed the idea of using the Internet of Things technology in the construction of the digital museum. He proposed a system design for museum collection management, which provides a new way for the construction of smart museums. Although his research is theoretically correct, it lacks specific experimental content [1]. Palattella believes that, in recent years, a variety of communication technologies have gradually emerged, reflecting the diversity of application fields and communication requirements. He analyzed in detail the potential of 5G technology in the Internet of Things by considering technology and standardization. He reviewed the current IoT connectivity landscape and the main 5G support factors for IoT. He explained that the close connection between the Internet of Things and 5G may cause huge business changes in the operator and supplier ecosystem. His research is not comprehensive enough [2]. Bello believes that similar to the way humans use the Internet, devices will become the main users of the Internet of Things (IoT) ecosystem. Therefore, device-to-device (D2D) communication is expected to become an inherent part of the Internet of Things. Devices will automatically communicate with each other without any centralized control and cooperate in a multihop manner to collect, share, and forward information. He believes that the ability to collect relevant information in real time is the key to harnessing the value of the Internet of Things because such information will be transformed into intelligence, which will help create a smart environment. Ultimately, the quality of the information collected depends on the intelligence of the device. He outlined how to implement smart D2D communication in the IoT ecosystem. His research is not accurate enough [3]. Akpakwu believes that the Internet of Things (IOT) is a promising technology, which tends to change and connect the global world through seamless connection and heterogeneous intelligent devices. The current demand for machine-type communication (MTC) has led to a variety of communication technologies and services to achieve the vision of modern IOT. He surveyed the latest Internet of things application requirements and related communication technologies. In addition, he discussed in detail the 3G partner program's cellular-based low-power wide area solution to support and enable new service requirements for "large to critical IOT" use cases. He presented a comprehensive overview of emerging technologies and enabling technologies, with a focus on 5G mobile networks, to support the exponential traffic growth of IOT. Although his research is comprehensive, it lacks necessary data [4].

The innovation of this article is to connect this emerging wireless communication technology with the current cultural relics protection hotspot and design a museum showcase system based on the Internet of Things technology. The system can monitor environmental information parameters in real time and realize the monitoring of multiple environmental parameters in the same network. It can not only monitor the environmental parameters that affect the preservation of cultural relics in the showcase in real time but also adjust the temperature and humidity in the showcase in real time. Compared with the traditional environmental monitoring system, this scheme has good scalability, convenient use, and strong portability. It can be used for environmental monitoring in other fields through simple parameter modification. At the same time, this paper compares and analyzes the key technologies in the system and focuses on the detailed introduction and analysis of single-chip technology, WiFi technology, cloud computing mode, and other technologies. Finally, the overall architecture of the system is built, the design plan is determined, and the appropriate chip is selected for design.

## 2. Internet of Things and Showcase System

*2.1. Internet of Things Technology.* Information and communication technology currently has the ability to transmit any place and any information to designated people or objects in a short time, and this information line is connected into an intricate network, which is the Internet of Things. The main function of the Internet of Things technology is to finally realize a technology of information transmission between objects through the perception and transmission of information. The roles and functions of the various structures of the Internet of Things technology are also different. The perception layer is mainly used for the perception of information, such as information collection and recognition; the network layer is mainly used for the transmission of various information, and the application layer is mainly presents the result of the final identification information to humans. The result of the final identification information is presented in front of human beings, which further promotes human's intelligent management of something [5]. Sensor nodes generally belong to embedded systems (micro) in the aforementioned Internet of Things, and their basic functions are mainly manifested in routing, wireless communication, and collecting, storing, and processing data. In addition to collecting and processing local information, it is also necessary to forward and save data transmitted from other nodes. The electrical energy of the sensor node mainly comes from the battery, so its energy consumption is positively related to its function. The more nodes in the Internet of Things, the more data will need to be forwarded by sensor nodes, which will increase its energy consumption. The monitoring area of the heterogeneous Internet of Things is divided into multiple clusters. Each cluster is usually composed of several nodes (sensor nodes) in the cluster and one cluster head node (sink node). All sensor nodes in the cluster need to transmit data to the cluster aggregation node, and then, each cluster aggregation

node in the network will send the collected data to the task management node through satellite channels, the Internet, and other channels [6, 7].

The network layer is an indispensable part of the ZigBee protocol stack. It is connected with the media access control layer and the user layer confidentiality. The joining and leaving of nodes in the network, routing lookup, and other functions must be implemented through this layer. The network layer reference model is shown in Figure 1. The network layer provides a function interface to the media access control layer to ensure the normal operation of this layer.

The source node forwards the data packet to its corresponding neighbor node, and then, it uses this routing algorithm to check that the destination node is its parent node. The parent address of the neighbor node is given as follows:

$$P_{LA} = L_A + \left[ \frac{D_A - (L_A + 1)}{C_{\text{skip}}(d)} \right] \times C_{\text{skip}}(d) + 1. \quad (1)$$

The Euclidean distance between two points is given as follows:

$$d(x_i, x_j) = \sqrt{\left( |x_{i1} - x_{j1}|^2 + |x_{i2} - x_{j2}|^2 + \cdots + |x_{in} - x_{jn}|^2 \right)}. \quad (2)$$

Among them,  $x_i = (x_{i1}, x_{i2}, \dots, x_{in})$  and  $x_j = (x_{j1}, x_{j2}, \dots, x_{jn})$  are the data objects of the monitoring points.

The formula for the average distance between monitoring data points is given as follows:

$$\text{avgDist} = \frac{1}{c_N^2} \times \sum d(i, j). \quad (3)$$

In the formula,  $c_N^2$  is the number of combinations of two points taken from  $n$  points.

The square error criterion function is as follows:

$$\text{SSE} = \sum_{i=1}^k \sum_{m \in c_i} |m - m_i|^2. \quad (4)$$

The difference within the cluster measures the compactness within the cluster, that is, the density distribution of the data points in the museum. It can be judged here that the sum of the squares of the distance from each data point in the cluster to the cluster center is calculated. The formula is as follows:

$$w(c) = \sum_{i=1}^k w(C_i) = \sum_{i=1}^k \sum_{x \in c_i} d(x, C_i)^2. \quad (5)$$

The balanced environmental evaluation function is as follows:

$$W(c, k) = \sqrt{w^2(c) + b^2(c)}. \quad (6)$$

From  $t=1$  to  $t=T$ , in the 16 channels of the ZigBee wireless sensor network, the probability of the hidden state observation sequence is given as follows:

$$\Pr(x^T) = \prod_{t=1}^T a_{x_{t-1}x_t}, \quad (7)$$

where  $x_t$  is the hidden channel state of the channel at time  $t$ . Under the given hidden state sequence  $x^T$ , from  $t=1$  to  $t=T$ , the conditional probability of the observation state sequence  $y^T$  is given as follows:

$$\Pr(y^T | x^T) = \prod_{t=1}^T b_{x_t}(y_t). \quad (8)$$

In the KSS-HMM model, the historical hidden state and detected channel state are determined. Therefore, if the ZigBee network device performs channel switching at time  $t_0$ , the probability of the observation sequence of the channel time slot time  $T_1$  is given as follows:

$$\Pr(y^{T_1}) = \prod_{t=t_0-T_1+1}^{t_0} a_{x_{t-1}x_t} b_{x_t}(y_t), \quad (9)$$

where  $y_1^{T_1}$  is the observation state sequence of the time slot time  $T_1$ .

Based on the known observation sequence  $y_1^{T_1}$ , the expected channel idle time in the future is given as follows:

$$E(T) = \sum_{T_2=1}^{\infty} T_2 \cdot \Pr(y_1^{T_1}, y_2^{T_2}). \quad (10)$$

**2.2. Museum Showcase.** Museum display cabinet refers to the cabinet specially designed and manufactured by the museum for the storage and display of collections to meet the needs of collection display and realize the purpose of research, education, and appreciation. From the definition of museum display cabinet, a museum display cabinet must serve as the display of the museum and realize the purpose of museum design and production. The lighting mode of the independent cabinet generally adopts top-line fluorescent lamp lighting or spotlight lighting. In order to prevent the damage of lighting lamps to cultural relics, the lighting part and display part are generally separated by aluminum grille and glass [8]. The function of the aluminum grille is to provide uniform illuminance so that visitors cannot see the structure of the lamp. The upper part of the grille is generally made of glass with an antiultraviolet film to effectively isolate harmful light and heat. The display cabinets of precious cultural relics generally adopt optical fiber lighting. This lighting method generates less heat and can protect cultural relics to the utmost extent. The full-body wall cabinet is generally placed against the wall, usually used to display large or grouped cultural relics, and the display part usually has side panels or back panels, which can only be viewed from the front or from both sides. The display cabinets of precious cultural relics generally adopt optical fiber lighting. This lighting method generates less heat and can protect cultural relics to the utmost extent. The lighting of table-style showcases generally uses external lighting, and some precious paper or organic cultural relics use optical fiber

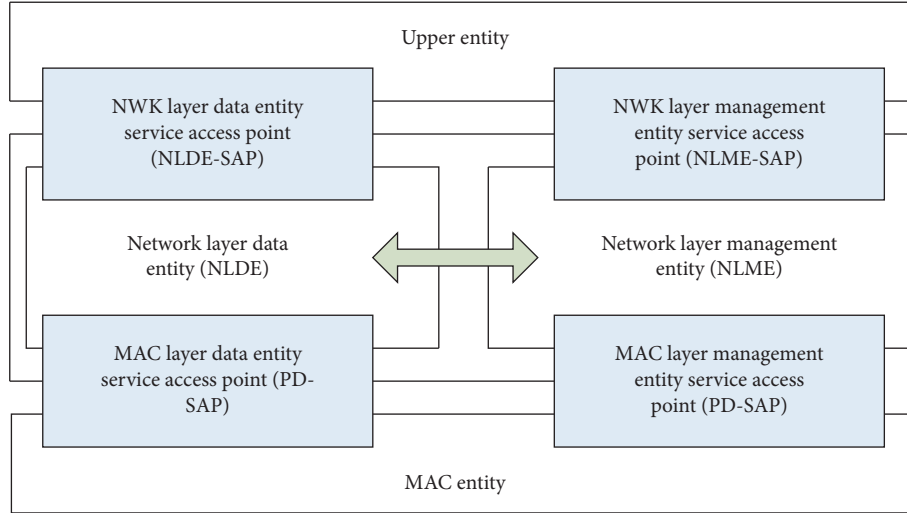

FIGURE 1: Network layer reference model.

lighting in the cabinet. This lighting method generates less heat and can protect cultural relics to the utmost extent [9, 10].

PID controller can be expressed as follows:

$$u(t) = k_p \left( \text{err}(t) + \frac{1}{T_i} \cdot \int \text{err}(t) dt + \frac{T_D d_{\text{err}(t)}}{dt} \right). \quad (11)$$

Among them,  $k_p \text{err}(t)$  is a proportional control item.

The PI mathematical model is given as follows:

$$\mu(t) = K_p \left[ e(t) + \frac{1}{T_I} \int_0^t e(t) dt \right] + \mu_0. \quad (12)$$

The transfer function form is given as follows:

$$G(s) = \frac{U(s)}{E(s)} = K_p \left( 1 + \frac{1}{T_I s} + T_D s \right). \quad (13)$$

When increasing the gain, the system will become more sensitive. But when the gain is too large, the number of system vibrations will increase and the adjustment time will

be prolonged. Therefore, it is very important to determine the appropriate gain value in the control process.

**2.3. System Design.** To realize the monitoring of showcase parameters, corresponding sensors are needed. In addition to sensors, instruments are also needed to collect and process sensor data and can control humidity in a certain way and send the data to the host computer after networking [11].

**2.3.1. Temperature Module.** The momentum conservation equation follows Newton's second law of motion, and the differential form of conservation is expressed as follows:

$$\frac{\partial}{\partial t} (\rho u_i) + \frac{\partial}{\partial x_j} (\rho u_i u_j) = -\frac{\partial p}{\partial x_i} + \frac{\partial \tau_{ij}}{\partial x_j} + \rho g_i + F_i. \quad (14)$$

In the formula,  $p$  is static pressure, and  $F_i$  is unit mass force in different directions.

The energy conservation equation follows the first law of thermodynamics, and the differential form of conservation is expressed as follows:

$$\frac{\partial}{\partial t} (\rho E) + \frac{\partial}{\partial x_i} (u_i (\rho E + p)) = \frac{\partial}{\partial x_i} \left( k_{\text{eff}} \frac{\partial T}{\partial x_i} - \sum_j h_j J_j + u_j (\tau_{ij})_{\text{eff}} \right) + S_h. \quad (15)$$

In the formula,  $E$  is the total energy of fluid clusters, and  $k_{\text{eff}}$  is the effective thermal conductivity.

The system is mainly composed of the wireless sensor network and monitor platform. The zig node is composed of the zigs node and bee node. The ZigBee terminal node is connected with various sensors, which are used to collect environmental data in the museum. The TCP socket receiver program on the server side writes the data from GPRS DTU to the database on the server side and then uses the php script program based on Web technology to display the data to the

user. The user can analyze and process the data through the PC client [12]. The intelligent greenhouse communication mode needs to collect as much data as possible and also uses video surveillance. Therefore, the data rate of network transmission is relatively high to accommodate video communication. Transmission of information should be secure, and information security has been paid more and more attention now, and there will be no application market if there is no security application; since the equipment is the uninterrupted automatic work, the communication stability needs to be guaranteed [13, 14].

In order to measure the temperature and humidity value, a sensor is needed to measure it. This design uses the integrated temperature and humidity sensor DHT11. DHT11 has undergone precise humidity adjustment and stores the school team coefficients in the memory and calls these calibration coefficients during detection signal processing. Generally, a 4-pin package is used, in which the 3 pins are floating, and the second pin is transmitted by a single bus. The photoresistor module is generally used to detect the brightness of the light in the surrounding environment, trigger the single-chip microcomputer or relay module, etc [15].

The methods and steps to determine the humidity index of cultural relics preservation are summarized as follows: when there is no moisture absorption model corresponding to various materials, the moisture regain of materials under different humidities is measured by the experiment, and then, the moisture absorption isotherm is drawn according to the data obtained; the parameter values of the moisture absorption model are obtained by nonlinear regression of several existing moisture absorption models with 1<sup>st</sup>Opt statistical software. Analyze the fitting procedures of each moisture absorption model and material moisture absorption isotherm, and find the model with the highest fitting accuracy; the model with the highest fitting accuracy is the best moisture absorption model of the material. Through this model, the relative humidity index of the material can be deduced by giving the moisture regain value under the condition of known temperature [16].

**2.3.2. Illumination Module.** In terms of hardware, the CC2530 chip is selected to deploy the wireless sensor network, and the PWM module is used as an LED-dimming module; in terms of software, an IAR-integrated development environment is used as the development tool, MySQL is used as the database software, and easyUI framework is used to realize the function of data viewing on Web. The illuminance sensor adopts nhzd10au series. The special-purpose optical chip has the advantages of low illumination and strong illumination. Sensor measurement signal transmission distance is long, and signal stability and transmission anti-interference ability are strong [17]. The system consists of server, gateway, and intelligent lighting terminal. The server serves as a node for collecting and storing terminal information and provides users with an interface for registering, inquiring, and controlling terminal lighting equipment. WEB/APP server, database server, and terminal access server are set up on the server. The system consists of server, system gateway, and intelligent lighting terminal. The server is the node for collecting and storing terminal information and provides users with an interface for registering, querying, and controlling terminal lighting equipment. The server is equipped with Web/app server, database server, and terminal access server. The system gateway is responsible for maintaining and coordinating networking and exchanging communication between many terminals and servers, and the gateway is connected up to the

terminal access server. The smart lighting terminal is used to collect the status information of LED lights and control the LED status, which is the final execution system of user actions [18, 19].

**2.3.3. Monitoring Module.** The hardware block diagram of the security instrument in the museum's smart showcase security system is shown in Figure 2. The security instrument uses the ARM CORTEX-M3-based STM32F103ZET6 microcontroller as the core controller to design the hardware circuit, which mainly includes a power-supply module, a real-time clock module, four groups of sensor monitoring modules, a WIFI module, a GSM communication module, and a booth lifting device. The display cabinet security instrument has less need for buttons, so it adopts the independent button design. The hardware circuit of the independent button is simple and easy to operate. It can be directly connected to the IO port of the single-chip microcomputer to obtain button information, which is widely used in the industrial embedded field [20]. Aiming at the cultural relics on display in the independent cabinet, this paper designs a booth lifting device. When the security system is triggered, if the booth is at the upper limit of the stroke, it will automatically descend to the dark warehouse of the showcase, reducing the risk of cultural relic damage. At the same time, the administrator can also control the lifting of the showcase booth through the remote control. The booth lifting device is composed of four DC motors and auxiliary mechanical devices to further improve work efficiency and ensure the safety of cultural relics. The security instrument controls the forward rotation, reverse rotation, and stop rotation of the electric push rod through the corresponding circuit to realize the function of lifting the booth. The remote control sends up, down, and stop commands to the security instrument through the wireless sending and receiving module PT2262/2272 [21].

### 3. Function Test of Museum Showcase System

**3.1. Experimental Environment.** Before testing the system, a test outline should be made in accordance with the system requirement documents, and a feasibility analysis of the test outline should be performed, to design reasonable test cases and to perform the test. The experimental equipment are as follows: a computer, a network coordinator (FFD) and a terminal node (RFD), a temperature and humidity sensor, ground temperature and humidity sensor, simulator, GPRS DTU, error detection wizard, and an integrated IAR development environment. Both test units are equipped with two independent data transmission and network control buttons and are connected to an LCD screen to observe the experimental results. Among these, the termination node is also used as a control center for the smart home system, which is connected to the higher computer via the RS232 channel, and the ZigBee network and operation can be further observed via the above computer [22, 23].

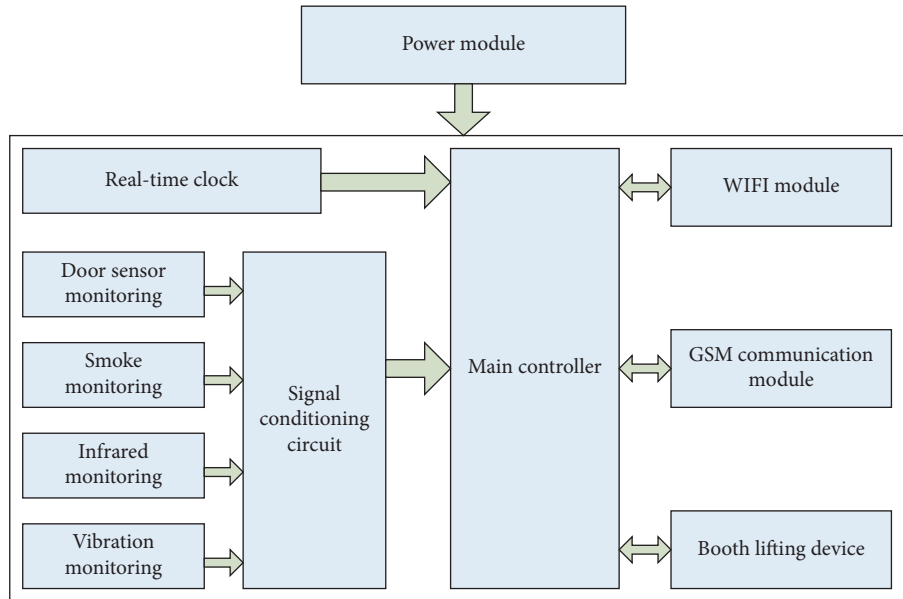

FIGURE 2: Hardware block diagram.

**3.2. System Function Test.** Functional testing is a verification test for each function of the system. According to the analysis of functional requirements and design requirements of the system, functional test cases are designed and tested item by item to check whether the prototype system has reached the functional goal of the design. Before performing functional testing, we must first build a testing environment. The steps to set up a test environment are as follows.

- (1) Open Eclipse, debug, and run the program, and start the system server.
- (2) Connect the Ethernet interface of the coordinator node to the router and the miniUSB interface to the 5 V power interface. The coordinator node starts to create the ZigBee network and waits for other nodes to join.
- (3) Deploy sensor nodes. After testing, the communication range of the node is 5–10 meters. Since the sensor is networked with a star structure and the coordinator node is placed in the museum, the nodes deployed in the museum can guarantee communication [24].

**3.3. Sensor Module Performance Test.** When collecting data on greenhouse environmental factors, in order to ensure the accuracy of its numerical reference, it is necessary to accurately test each sensor module. Various types of sensors are installed in different corners of the laboratory to ensure the integrity of data collection at any location in the laboratory. When detecting the received data, in order to be able to observe the change trend of the data more intuitively, select one of the sensors to collect data interface, compare the detection value obtained by the interface with the data collected by the actual engineering instrument, and verify the effectiveness of data collection [25]. By running the IAR

software tool, to various sensor modules of different types, the control instructions that conform to their own data acquisition process are programmed, which are the same principles as the operating instructions programmed in the coordinator module. When the coordinator module is called for communication, the LED1 diode can always keep on after each node applies to join the wireless network communication. A portable heating and humidifying device is used to gradually increase the temperature and humidity of the air around the room [26].

First, sample the temperature and humidity sensor to verify the accuracy of the temperature and humidity signal collected in the instrument circuit. Place the sensor and instrument in a built-up constant temperature and humidity room, set the temperature at 25°C and 40% RH, and use the serial debugging assistant to observe the collected data values. Then, the sensor whose signal type is analog signal is collected to verify that the Butterworth filter in the circuit will not make the data deviate, while ensuring the stability of the data. The debugging process is as follows: use a voltmeter to measure the voltage value connected to the AD pin of the microcontroller, use the serial debugging assistant to view the converted digital quantity, and judge the corresponding relationship between the two [27].

**3.4. Light Information Collection Test.** The collection of light intensity information is obtained by sampling the ADC inside the CC2530. It collects the amplified voltage signal of the BPW34S sensor and connects it to the port of the CC2530 chip. Finally, the sampled data is packaged and sent to the network coordinator in a wireless manner. The coordinator processes these data and judges whether these temperature, humidity, and light intensity values exceed the preset value. If it is greater than the previously set value, the

buzzer will send out an alarm signal so that the manager can turn on the corresponding button. The company's control equipment can adjust temperature, humidity, and light intensity [28].

*3.5. Serial Communication Function Test.* The serial port must be initialized before data communication, and transmission can be carried out normally. This is a prerequisite to ensure the smooth operation of the serial port. If the serial port wants to send data, first, save the data in the buffer of the sender and then start writing data through the serial port, and the data starts to transmit. After the receiver finishes receiving, the sender will clear the data buffer to prepare for the next data transmission [29].

## 4. System Test Results

*4.1. Temperature Module Test Results.* The exhibits in the museum must use a certain form of the museum showcase to achieve the purpose of the external display. At the same time, museum showcases must be based on exhibits and designed and manufactured in accordance with the different characteristics of different exhibits. Therefore, when discussing the design and selection of museum showcases, we must fully understand the relationship between exhibits and showcases, and on this premise, fully consider and study the impact of exhibits on showcases. The relationship between museum showcases and exhibits can be said to be interdependent and indispensable. On the one hand, in order to realize its display, education, and research functions, the museum needs to concentrate a large number of collections for the external display. In this way, it provides a broad stage and good prospect for the survival and development of the showcase. On the other hand, the showcase creates excellent conditions for the display of exhibits. It not only creates an extremely comfortable storage space for the exhibits inside but also effectively prevents external threats from harming the exhibits. In the museum's security system, it is the various security technologies and security equipment that ensure its survival and long-term maintenance. Various security technologies and security equipment play a huge role in the museum's daily security work.

The temperature test results are shown in Table 1 and Figure 3. In the control command test process, no matter it is single lamp control, area control, or global control, precise control is achieved. Whether it is time control, illuminance control, or instant control, real-time response is achieved, and there is no packet loss during communication. It is phenomenal that the control success rate is as high as 100%. From a macro point of view, the temperature and humidity environment in the cabinet will be affected by the changes in the environment outside the cabinet and show a relative change in time lag. The changes in the indoor environment outside the cabinet (exhibition room) will also be affected by the outdoor environment. The change of climate presents the effect of delay, and its delayed time-lag characteristics are generally affected by the construction

materials, airtight characteristics of the building, and display cabinet envelope structure, which presents different delay effects, and is vulnerable to the external environment. Under the influence of the external environment, the temperature change of the cabinet will show obvious fluctuations. The temperature change in the atmospheric environment has the regular characteristics of annual and daily changes. Similarly, the temperature environment in the exhibition room environment is not adjusted by the environmental adjustment equipment during the closing process. It will also show corresponding fluctuations, only because the time of the impact is lagging and the degree is weakened.

Simulation is carried out by NS2 software. In the simulation environment, the network range is  $200\text{ m} \times 200\text{ m}$ , and the number of network nodes is up to 220 and randomly distributed. The neighbor table of each node allows storage of 9 neighbor node information, and the network coordinator is located in the center of the network area. Considering the increasing number of nodes in the network, the end-to-end average delay is shown in Figure 4. The packet transmission rate is shown in Figure 5. The routing efficiency is shown in Figure 6. It can be seen from the simulation results that the improved ImcTR algorithm reduces the node and average energy consumption, while at the same time it also reduces the number of hops from the source node to the destination node and improves the network performance.

*4.2. Function Analysis of Showcase System.* The fuzzy control method requires that the equipment must be continuously adjustable or it can be divided into multiple levels with different control capabilities in order to design fuzzy control rules. In order to make fuzzy control have a certain adaptive ability, usually use the neural network or genetic algorithm for optimization. The regeneration of the dehumidifier mainly uses heating to evaporate the water in the solution. The temperature and humidity monitoring experiment data are shown in Table 2. The experimental data shows that the system test data is basically the same as the instrument test data, the temperature measurement error is  $\pm 0.3\%$ , and the humidity measurement error is  $\pm 3\%$ . During the experiment, the temperature of the simulated exhibition hall (constant temperature and humidity room) fluctuates around  $20^\circ\text{C}$ , and the humidity fluctuates around 45%. The initial temperature in the simulated showcase (standard test box) is  $20.0^\circ\text{C}$ , and the initial humidity is 40.6% RH. The initial temperature and humidity of the test box is different from that in the constant temperature and humidity room because of the tightness of the test box. Different positions, forms, specifications, and outlet wind speeds of air supply and exhaust ports will cause different indoor air flow conditions, and different air flow conditions will achieve different air conditioning effects. Reasonable airflow organization can make the personnel working area and specific area reach the required four degrees, namely, temperature, humidity, speed, and cleanliness, and its distribution is uniform and stable so that it can meet the requirements of human comfort and special production technology.

TABLE 1: Temperature test results.

|                      |        |        |        |        |        |        |        |        |        |        |        |        |
|----------------------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|

FIGURE 3: Temperature test results.

FIGURE 4: End-to-end average delay.

4.3. *Sensor Error Analysis.* System data collection: its collection method is the fusion of cluster collection and distributed collection. Distributed collection is to use the connection points of multiple sensing devices to lay out the

agent items of distributed collection in it to achieve the goal of data collection. Among them, the sensor device connection point transmits the collected information to the information-processing module through the wireless

| 6             | 17.9                 | 17.8                     | 40.3              | 40.5                  |
| 7             | 18.3                 | 18.1                     | 40.0              | 40.1                  |
| 8             | 18.9                 | 19.0                     | 39.7              | 39.7                  |
| 9             | 19.5                 | 19.4                     | 39.6              | 39.7                  |
| 10            | 19.5                 | 19.5                     | 39.6              | 39.6                  |

network, which processes the data and at the same time feeds the processing results back to the upper computer client and loads the records in the database. Convergent collection is to realize the networking of multiple sensor equipment connection points, set up observation ports on the upper computer terminal, realize centralized observation of multiple sensor equipment connection points, and collect data information corresponding to the observation items. Data transmission is a process of transferring data from the information source to the database through one or several data links based on certain regulations. Its function is to exchange information among multiple nodes, and the information transmission methods are usually wired and wireless. Comparing the two, the wireless method has excellent adaptability, and the regional dimension has little influence. Before information enters the data fusion process, the step of data cleaning is essential. It is to delete invalid information and error information and duplicate information collected by the sensor to ensure the authenticity and validity of the data in the later fusion. Supplemented with the adaptive weighting algorithm, it can solve the time-varying and limited nature of independent sensing devices. The temperature data comparison is shown in Figure 7. It can be seen that there is a time interval between the measured values, indicating that the trend of the predicted value and measured value are close. The error between the predicted value and measured value is about 3°C, which is within the allowable error range of the experiment.

*4.4. System Accuracy Analysis.* In the design of relational database, the most important part of the work is to allocate metadata to various relational data tables and complete the classification of these metadata, and the operation of data will depend on the relationship between these data tables; through the relationship between these data tables, these data can be linked together in a meaningful way. In a relational database, creating a relationship between tables means that columns in one table are linked to columns in another table. This relationship can prevent redundant data and ensure that the information in one table matches that in the other. Relationships are generated by matching data in key columns, which are columns with the same name in two

tables. Usually, primary keys in one table are matched with external keys in another table. There are many kinds of harmful gases in the microenvironment of museum's cultural relics. When the cultural relics are exposed to a certain concentration of pollution gas for a long time, the harm of cultural relics will be very obvious. Therefore, the air quality monitoring system of cultural relics should meet the characteristics of high sensitivity, high reliability, small size, good anti-interference ability, and real-time online detection of multiple gases. The system accuracy test results are shown in Table 3 and Figure 8. It can be seen from the experimental results that the accuracy of the system on the first day is not high enough due to the lack of sufficient sample data in the early stage. However, with the increase of the number of training samples, the accuracy of the system output has also been improved. In addition, the output of the control group has no obvious relationship with the input of the sample number; that is, the increase of the sample number cannot improve the performance of the system without the genetic fuzzy neural network, and the performance is obviously slightly better than that of the complete system. It shows that the intelligent computing module has a good practical effect in predicting user behavior and realizing intelligent control.

There are many exhibition halls in the museum, and the objects that need environmental protection are also different. Therefore, the data of monitoring points are also increasing, and the data tends to show a massive trend. Using traditional data analysis and processing methods to process massive amounts of monitoring data has low efficiency and cannot effectively give information on the pollution level and quantitative evaluation of monitoring points. Using *K*-means cluster analysis and prediction methods, environmental monitoring data can be effectively processed. The traditional method of predicting trends is nothing more than carrying out a large amount of manual data analysis to predict conclusions, and data mining, as a new data-processing technology, can automatically search for information that is valuable for prediction in large databases and can quickly pass the massive data itself. And, draw a conclusion. The most representative one is the Decision Support System (DSS). Data mining can analyze historical sales data to find the market law that can bring the most profit to the enterprise in the future. It can be seen that predicting trends and behavior is discovering predictive knowledge. The showcase security instrument and host computer software constitute a complete system based on the C/S architecture. The showcase security instrument acts as a server to collect monitoring data and process and send them to the upper computer for storage; the host computer acts as a client to send a connection request to the showcase security instrument and deliver working parameters. The display cabinet setting includes the display cabinet quantity setting and display cabinet parameter setting. The former determines the number of display cabinets displayed on the host computer interface, which is convenient for the adjustment of the number of display cabinets in the exhibition hall; the latter determines the display cabinets connected to the host computer, which facilitates the replacement of the security equipment in the display cabinet and enhances the

FIGURE 7: Comparison of temperature data.

TABLE 3: System accuracy test results.

| Serial number | 1     | 2     | 3     | 4     | 5     | 6     | 7     |
|---------------|-------|-------|-------|-------|-------|-------|-------|
| Using GFNN    | 0.440 | 0.716 | 0.689 | 0.696 | 0.749 | 0.666 | 0.600 |
| No GFNN       | 0.452 | 0.338 | 0.394 | 0.394 | 0.344 | 0.284 | 0.334 |

FIGURE 8: System accuracy test results.

intelligence of the museum. The expansibility of the showcase security system makes later maintenance more convenient. The accuracy of the alarm system is shown in

Figure 9. It can be seen from the figure that the application of the Internet of Things technology in the alarm system can significantly improve the accuracy of the system. At the same

FIGURE 9: The accuracy of the alarm system.

TABLE 4: Comparison results of performance indicators of three control algorithms.

| Controller name            | Overshoot (%) | Steady-state error | Adjustment time (min) |
|----------------------------|---------------|--------------------|-----------------------|
| Conventional PID control   | 36.18         | 0                  | 11.2                  |
| Pure fuzzy control         | 14.34         | 0.003              | 7.4                   |
| Fuzzy adaptive PID control | 8.12          | 0                  | 5.6                   |

time, the sensitivity of the sensor is better, which greatly avoids the destruction of cultural relics.

Compared with the PID control algorithm and pure fuzzy control algorithm, the fuzzy adaptive PID control algorithm has no better control effect in terms of overshoot or other performance indicators. The performance index comparison results of the three control algorithms are shown in Table 4. By comparing the performance indexes of the three control methods, the effectiveness of temperature control in the fuzzy adaptive PID control mode is higher than that of PID control and pure fuzzy control.

## 5. Conclusions

This article mainly studies the research and implementation of the museum's window system based on Internet of Things technology in a smart environment. By introducing the concept, architecture, and basic technologies of the Internet of Things, the article explains the theoretical and practical importance of creating a smart home scene for the Internet of Things. And, with the microcontroller core of the STM32F103xx series as the core, the display casing is monitored through various monitoring channels, such as infrared and smoke. When an alarm occurs, the on-site sound and light alarm shall be sent to the central computer and to the specified mobile terminal at the same time. The radio-controlled method is used to operate the remote control of LED lamps, which can improve the level of

lighting management, save energy, reduce emissions, and reduce maintenance costs.

The system designed in this paper mainly detects the environmental parameters such as temperature, humidity, and illumination in the museum system. The system can effectively detect these data information, so as to achieve the purpose of protecting museum collections. After training the lighting environment data, the dimming classification model is generated, which realizes six levels of intelligent dimming in complex environment and can automatically adjust the dimming level in real time in case of emergency. Through the algorithm, the system realizes the effective energy saving and intelligent control of illumination. At the same time, the hardware circuit of the system is small in size and low in power consumption, which meets the requirements of energy conservation and emission reduction; the software design structure is clear, which is convenient for the later maintenance and upgrading of the system; the test results show that the basic lighting function, Internet of things communication function, and server control function of the system are reliable and meet the design requirements.

With the rapid development of electronic technology, the application scope of the Internet of Things has gradually expanded. From the initial smart home to the intelligent museum showcase system, it is getting closer and closer to our lives. Through the design and construction of the Internet of Things temperature and humidity monitoring system, continuous observation and data collection of the air

temperature, air humidity, and light intensity in the greenhouse are carried out. Through ZigBee communication technology, each node is networked. The control system is equipped with a coordinator, a wireless control node, and multiple wireless detection nodes. The coordinator collects all detection node information and transmits the data to the upper computer through the serial port for display and storage. The monitoring interface is designed through LabVIEW to realize the acquisition, setting, and control of the parameters of each node.

Remote sensing image simulation is a very effective method to verify the feasibility of sensor devices for ground observation. The key to remote sensing image application is that simultaneous interpreting of remote sensing images can make use of the different characteristics of different data, eliminate the redundancy and contradiction between different sensors, and improve the timeliness and reliability of remote sensing information extraction. The hotspots and difficulties in this direction are based on remote sensing image simulation of 3D scenes on the ground. Therefore, constructing the 3D scene model on the ground rapidly and accurately is the focus of current research. Because different scenes have different radiation characteristics, therefore, when using MATLAB to write a program generated by 3D scenes, 3D scenes must be saved as different text files according to different scene types, and then extension program of the scene is written to solve the defect that the calculation efficiency is not ideal due to the huge amount of data. This paper uses POV ray photon reverse tracking software to simulate the imaging process of remote sensing sensors, coordinate transformation is used to convert a triangle text file to POV ray readable information and input the RGB value of the base color based on the colorimetry principle, and the final 3D scene is visualized. This paper analyzes the thermal radiation characteristics of the scene and proves the rationality of the scene simulation. The experimental results show that introducing the chroma in the visualization of the scene model makes the whole scene have not only fidelity, but also radiation characteristics in shape and color. This is indispensable in existing 3D modeling and visualization studies. Compared with the complex radiation transmission method, using the multiple angle two-dimensional image generated by POV rays to analyze the radiation characteristics of the scene, the result is intuitive and easy to understand.

## 1. Introduction

With the development of science and technology, digital cities have received more and more attention [1]. The concept of digital city originates from the strategic concept of digital earth, also known as network city or smart city, or more precisely information city. It refers to the comprehensive use of computer tools (GIS, remote sensing, telemetry, network, multimedia, and virtual simulation technology). The use of digital technology to collect and process the city's infrastructure and functional mechanisms to enable it to have digital functions, which is conducive to optimizing and improving the city's ecological environment and resources, economy, population, and other complex fields, effectively predicts the future of the city. [2, 3]. The

essence or core of a digital city is the fusion of massive urban spatial data with three-dimensional urban geographic information systems and time series urban geographic information systems [4]. The outstanding feature of digital cities is the ability of applying digital information to grasp the changing process of urban regional structure in time and space. The application research of 3D urban geographic information system and time series urban geographic information system will be an important part of recent digital city theory research. Digital city construction will provide an information security system for the city's sustainable development strategy, meet the government's decision-making, macrocontrol, scientific and technological innovation, natural resources and environmental monitoring, intelligent transportation and urban

management, and various social welfare undertakings, and further provide solutions for the sustainable development of cities. [5, 6]. To build a digital city, we must first apply high-tech means such as computer technology to model the urban environment [7].

Remote sensing image fusion is a process of comprehensive processing the image data obtained by multiple remote sensing sensors or the same kind of sensor for the same target at different times. The image is processed by using certain rules or algorithms, and the useful information contained in the image is fused into a new image. The image contains more accurate and abundant information than any single image, in order to achieve a comprehensive description of the target and ground objects.

The problem of three-dimensional reconstruction of urban buildings has been studied by experts and scholars from various countries for many years and has achieved a series of results. The most representative ones are Google Earth and Microsoft Virtual Earth, which use satellite remote sensing images to generate virtual ground scenes, which have been successfully commercialized on the Internet [8, 9]. Image-based three-dimensional reconstruction of urban buildings is mainly divided into three categories according to the different data sources used: (1) based on remote sensing images, this method uses three-dimensional reconstruction of urban buildings using approximately vertical satellite remote sensing images or aerial images [10]. According to the characteristics of remote sensing imaging, based on the reconstruction of remote sensing images, the reconstruction space is large, and the roof information of the building can also be obtained and the accumulation of errors can be effectively reduced, but the reconstructed buildings have poor fidelity [11]. (2) Based on ground image, ground image-based reconstruction is a three-dimensional reconstruction of urban buildings using images acquired by various ground shooting techniques. According to the characteristics of ground imaging, the reconstruction of this method is better, and the wall texture of the building can be obtained, but the roof information of the building is not obtained, the reconstruction scale is small, and the error accumulation is large [12]. (3) Regarding combination of remote sensing image and ground image, there are advantages and disadvantages in remote sensing and ground-based imaging reconstruction. In fact, remote sensing image and ground image are two important complementary source data. Combining the two for reconstruction is expected to be obtained. This resulted in a reconstruction method combining remote sensing images with ground images. Generally, there are insufficient data acquisition costs, large data volume, complicated calculation, and low automation [13, 14].

Based on the second generation bending wave transform and Dempster-Shafer (DS) evidence theory, Huang C proposed a new remote sensing image fusion method. Huang C uses the bending wave transform to decompose the remote sensing image to obtain the coefficients and uses DS evidence theory to optimize the high coefficients [15, 16]. First, the high-resolution and multiple spectral remote sensing images are decomposed by bending wave transform

to obtain bending wave transform coefficients (coarse, detailed, and fine scale layers) of all layers. Second, the coarse scale layer uses the maximum fusion rule. The detailed scale layer is used by the weighted average fusion rule. The fine scale layer is optimized by DS evidence theory. Three features of the fine scale layer coefficients are obtained. These three characteristics are variance, information entropy, and energy. The use of these features is some parametric belief function and rationality function. The mass function is then combined and a new fusion factor is obtained. Finally, the scene image is obtained by inverse bending wave transform. Rhee et al. attempt to apply two types of image matching, object space based matching techniques and image space based matching techniques, and compare the performance of the two techniques [17, 18]. The object space based match used sets a list of candidate height values for a fixed horizontal position in the object space. For each height, its corresponding image points are calculated and similarity is measured by gray level correlation. The image space based matching used is a modified slack match. Rhee and Kim designed a global optimization scheme for finding the best pair (or group) to apply image matching, defining local matching regions in the image or object space, and merging local point clouds into global point clouds. For optimal pairing selection, the connection points between the images are extracted and a stereoscopic overlay network is defined by using the connection points to form a maximum spanning tree. Qin built the core technology and method related to 3D model reconstruction, focusing on matching of point cloud data registration to simplify denoising, 2D contour extraction, and finally achieving the high complexity of 3D geometric model of farmland site, using advanced 3D printing. Technology produces small 3D printed point cloud data [19, 20].

The innovations of this paper are as follows: (1) introducing the principle of colorimetry method into the visualization of the image simulation scene model and replacing the complex texture with color can reflect the spectral radiation characteristics of the object to a certain extent. Through investigation and research, it is found that the only one that can correspond to the spectral characteristics is its chroma characteristic. Therefore, the chroma is introduced into the scene model visualization so that the whole scene not only is in shape and color, but also has radiation characteristics. This is not available in existing 3D modeling and visualization studies. (2) The remote sensing imaging process can be simulated using the POV ray visual ray tracing software package. It has a convenient and fast programming language, high computational efficiency, and intuitive output. Compared with the complex radiation transfer equation, the multiple angle two-dimensional image generated by POV ray is used to analyze the radiation characteristics of the scene, and the result is intuitive and easy to understand. POV ray can simulate the remote sensing imaging process, mainly because it first defines the position of the light source (sun) and camera (sensor), zenith angle and azimuth, and also sets the camera's field of view, which is another 3D visualization software. And the higher computational efficiency is also relatively advanced in the

field of visualization. (3) Considering the differences of different scenes, the design of remote sensing images for different scenes is different, so that the experimental structure can reflect the diversity and rationality.

## 2. The Proposed Method

### 2.1. Preparation of Remote Sensing Images

*2.1.1. Image Preprocessing.* When the obtained source image is blurred, the contrast is not strong, and the noise interference is large; the corresponding method needs to be used for some processing, so that the subsequent work can be carried out more effectively. Common methods include image enhancement, filtering, histogram correction, and gradation transformation. However, when the quality of the source image is good, it is not necessary to perform these processes. Therefore, the preprocessing of the source image is an optional link, and the processing method is different for different images. The omnidirectional image is used in the experiment in this paper; because the camera has been calibrated before shooting, the lighting conditions are better at the time of shooting, so the obtained image quality is better and generally does not have to be preprocessed.

*2.1.2. Registration.* Registration is to find the mutual correspondence between the omnidirectional map and the remote sensing map and achieve the purpose of reconstruction service through information fusion. Information fusion is the foundation of all subsequent work, so registration is a core component of the entire reconstruction. Conventional methods generally solve the problem of registration between images from homologous images or from the same type of sensor. The omnidirectional and remote sensing images are images formed by heterogeneous sensors. The general reconstruction method of the source image requires registration of the source image, and more registration methods are available at present. However, the existing conventional methods cannot solve the registration problem of remote sensing maps well. The registration of remote sensing maps belongs to the specific key technical problems of 3D reconstruction of remote sensing images.

*2.1.3. High Extraction.* Height extraction is to obtain the height value of the target building in real space, which is an important information of the space structure of the building. The height of the building can be combined with the top view of the building available in the remote sensing map to obtain the approximate spatial structure of the building. Therefore, the height of the building plays a crucial role in the reconstruction of the shape and contour. There are two conventional solutions; one is direct measurement using instruments and equipment, such as laser range finder. The second is to use computer vision principles for estimation. Direct measurement with related instruments is costly. With computer vision estimation, accurate absolute heights are generally not obtained without accurate scale reference objects.

*2.1.4. Shape Modeling.* The goal of shape modeling is to get the outer shape of the entire building. It is also an important part of reconstruction. It is generally modeled based on certain assumptions or prior knowledge (such as a box in the shape of a box and a flat roof) using the obtained height and roof shape information obtained from the remote sensing map. The outer shape of the building is more complex and precise than the approximate spatial structure. The key to shape modeling is to extract the outline of the building. At present, the contour detection algorithms generally have shortcomings such as low detection rate and inability of fully automating. The method of semiautomatic human-computer interaction can be adopted; that is, the existing detection algorithm is combined with the manual correction method for detection. Due to limited time and energy, image-based 3D reconstruction mostly requires shape modeling, and shape modeling methods are almost universal.

*2.2. Building Outline Segmentation and 3D Model Extraction.* How to obtain the singular model of the building from the three-dimensional model of the scene generated by oblique photography is the goal of this paper. DOM can be seen from the high-resolution scene, which has obvious image difference between the building and other features. The image analysis method can be used to extract the outline of the building from the scene DOM and obtain the position information of the building outline, thereby realizing the positioning and segmentation of the building model in the three-dimensional scene model.

*2.2.1. High-Resolution Image E Building Feature Analysis Method.* In an image, the edge information is the most important and basic feature, and the edge feature is the most direct expression and embodiment of the image geometric information. The low-altitude drone oblique photography obtains a higher resolution of the image, and the texture of the scene DOM obtained after the correction is clear. The difference in shape, size, and texture patterns is the basic basis for distinguishing between different features. Through vision, the color of the scene DOM is very realistic, the texture information is very rich, the geometrical structure of the object is more refined, and the recognition of different target objects in the image is more accurate; from a local perspective, a single feature, especially the boundary between the edge of the building and its surrounding environment, is obvious, and the details inside the target object are richly expressed. These features are very advantageous for identifying and extracting the target individual of the building. However, because of the rich information contained in high-resolution images, the phenomenon of "homologous" and "homogeneous foreign matter" appears, resulting in increased noise interference.

In order to extract buildings (houses) in high-resolution images, the characteristics of the buildings are analyzed to establish a good basis for building identification. From spectral and texture characteristics, usually the gray distribution of buildings is relatively uniform. The gray value of the

top is higher than the gray value of other surrounding objects and the texture mode is relatively regular. Generally, the texture performance of buildings has the outline direction of the building that is approximately uniform or orthogonal. For the shape feature, usually the building has geometrically regular edges and corners, and the whole is presented as a regular polygon. From the spatial distribution characteristics, usually the roads in the urban area will be divided into several blocks like chessboards. The buildings are regularly distributed in the block, and the surrounding objects mainly include roads and tree vegetation, so the roads and buildings have strong spatial associations, and usually densely populated buildings will also be arranged regularly and have similar configurations. When considering the geometric features, spectral features, and spatial distribution characteristics of features in high-resolution images, the algorithm is not mature enough and complicated, having low efficiency, which needs further study. According to the research objectives and needs of this paper, the rough positioning of the target of the suspected building does not require accurate and complete extraction of the building. Therefore, this paper only analyzes the geometric features of the building from the geometric shape. In the scene DOM, the geometry of buildings and other features is significantly different. From a straight-down perspective, no matter which building is an individual wrapped by its outer contour, in the high-resolution scene DOM, the outer contour of the building is a connected area with a certain length and area. As a basis for identifying buildings, the internal structure of vegetation such as trees is disorderly, and the boundaries of the whole forest are not clear enough and there are no rules: there are often no clear and regular boundaries on both sides of the road, and the roads are lacking in certain areas. From the perspective of individual buildings, there are also separate topological relationships between different buildings. In the scene DOM, the target features that can be approximated as connected areas tend not to have only buildings, but the buildings also contain other distinguishable geometric features, and the more prominent common features are the length of the outer contour of the building. The outer contour of the building must contain at least a certain number of linear features, according to which the connected areas surrounded by the outline of the building can be further identified and screened.

Therefore, by analyzing the features of the building on the image, the difference and segmentation between the building and other features and buildings can be realized, and the outline of a single suspected building can be extracted and used as a basis for the three-dimensional scene model. A rough monomer model was extracted.

**2.2.2. Building Edge Feature Detection Method Based on Canny Operator.** Edge detection is to obtain information about shape and reflection or transmittance in an image. It is a basic step in image processing, analysis, understanding, pattern recognition, and computer and human vision, being

a very important technology. There are many edge detection methods, such as Roberts operator, Pruitt operator, Sobel operator, and Laplace operator. These are the operators that detect features through local window and are sensitive to noise. Canny proposed the best edge detection operator Canny operator. The operator determines the edge pixels by the maximum value of the image signal function, and the detection performance is good, which has been widely used. Therefore, this paper uses Canny operator to perform edge detection on scene digital image. The scene DOM is a true color image, which needs to be grayed out. The color image can be converted into a grayscale image by using the following formula:

$$P(x, y) = 0.3 * R + 0.59 * G + 0.11 * B, \quad (1)$$

where  $P(x, y)$  is the gray value of the pixel at the  $(x, y)$  coordinate and  $R$ ,  $G$ , and  $B$  are the values in the red, green, and blue primary color channels in the pixel at the  $(x, y)$  coordinate, respectively. There are four main steps in detecting the edge features of grayscale images using the Canny operator:

(1) *Eliminate Noise.* The differential algorithm is highly sensitive to noise, and the Gaussian smoothing filter is used to convolve the image before edge detection to reduce noise interference. The first following formula is a two-dimensional Gaussian function. The principle of Gaussian smoothing is the discrete Gaussian function. The Gaussian function value on the discrete point is used as the weight. For each pixel in the gray image, it is within the window neighborhood of a certain size. Considering pixel weighting to eliminate Gaussian noise, the second following formula is a discrete Gaussian function weight window template with a window size of  $5 \times 5$  pixels, the third following formula is a convolution formula for Gaussian filtering of image  $J$ , and  $g$  is the result of convolution:

$$f(x, y) = \frac{1}{2\pi\sigma^2} e^{-((x^2+y^2)/2\sigma^2)}, \quad (2)$$

$$K = \frac{1}{159} \begin{bmatrix} 2 & 4 & 5 & 4 & 2 \\ 4 & 9 & 12 & 9 & 4 \\ 5 & 12 & 15 & 12 & 5 \\ 4 & 9 & 12 & 9 & 4 \\ 2 & 4 & 5 & 4 & 2 \end{bmatrix}, \quad (3)$$

$$g = I * K. \quad (4)$$

(2) *Calculate the Image Gradient Amplitude Value and the Gradient Direction.* The first-order finite difference is used to approximate the gray gradient of the image. In the Canny operator, the first following formula is used to convolve in  $x$  and  $y$  directions of the image. As shown in the second and third following formulas, the Sobel template is shown,

wherein  $S_x$  is a convolution template in the horizontal direction, and  $S_y$  is a convolution template in the vertical direction:

$$\begin{aligned} G_x &= g^* S_x, \\ G_y &= g^* S_y, \end{aligned} \quad (5)$$

$$S_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}, \quad (6)$$

$$S_y = \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix}. \quad (7)$$

According to the following formulas, the gradient magnitude value  $G$  and the direction  $\theta$  of the image can be, respectively, calculated and the gradient direction is approximated to be generally  $0^\circ$ ,  $45^\circ$ ,  $90^\circ$ , and  $135^\circ$ :

$$G = \sqrt{G_x^2 + G_y^2}, \quad (8)$$

$$\theta = \arctan\left(\frac{G_y}{G_x}\right). \quad (9)$$

(3) *Nonmaximum Suppression.* The pixel corresponding to the local maximum point is found and retained or marked as an edge pixel, and the gray value of the pixel of the non-maximum point is suppressed and set as the background. This step is mainly to discriminate and remove nonedge pixels, leaving only the candidate image edges.

$$A = \sum \left[ Si^* \log\left(\frac{Si}{Qi}\right) \right]. \quad (10)$$

The image edge is solved using a hysteresis threshold algorithm. The method of lag threshold is to use two thresholds (high and low). The following discriminant basis is used when determining the true edge and removing the false edge: if the gradient amplitude value of a pixel is greater than the high threshold, it is determined that the pixel is a true edge pixel and is retained; if the gradient amplitude value of a pixel is less than the low threshold, it is determined that the pixel is not a true edge pixel and is excluded; if the gradient amplitude value of a pixel is between the high and low thresholds, the pixel has only one gradient amplitude value. When pixels larger than the high threshold are connected, it is determined that the pixel is reserved for the real edge pixel. The scene digital orthophoto is rich in texture, and the geometric features of the features are complex. The edge obtained by the Canny operator for edge detection usually contains a lot of noise. Therefore, the DOM edge detection result needs to be Gaussian. In order to facilitate the identification of the building outline, it is necessary to highlight the contour edge features of the target such as a building from the numerous edge feature pieces of

information in the scene and further suppress the edge pixels whose edge features are not obvious into the background. Therefore, it is necessary to perform Gaussian smoothing on the scene edge detection result and then perform binary processing. Treated by formula (10), we get

$$g_{\text{new}}(x, y) = \begin{cases} 255 & (g_{\text{old}}(x, y) > T), \\ 0 & (g_{\text{old}}(x, y) \leq T), \end{cases} \quad (11)$$

In the formula,  $g_{\text{new}}(x, y)$  is the new gray value of the pixel at the  $(x, y)$  coordinate;  $g_{\text{old}}(x, y)$  is the previous gray value of the pixel;  $T$  is the gray threshold set according to experimental experience and belongs to 0–255. If the gray value of a pixel is greater than the threshold, the gray value of the pixel is set to 255. If it is not greater than the threshold, the gray value is set to 0, and the background is suppressed, thereby obtaining a scene edge with a distinct target edge feature.

### 2.3. Construction of the Original Features of the Front Image.

According to the previous preset, the output of the CNN convolutional layer is more than fully connected:

$$a_k = \sum_{y=1}^H \sum_{x=1}^W w_{x,y} b_{x,y} \cdot f_{x,y,k}. \quad (12)$$

Among them,  $w_{x,y}$  is the response weight at the point  $(x, y)$  in the feature map, and  $b_{x,y}$  is the depth weight of the point. For the response weight matrix  $W \in R^{W \times H}$ , we use the feature map  $f_k$  to construct

$$W = \sum_{k=1}^N f_k. \quad (13)$$

For the depth weight, we use the depth information of the image to assign the weight. We first scale the depth map of the input image to  $W \times H$ ; then,

$$d_{x,y} = \left( \frac{d_{\text{max}} - d(x, y)}{d_{\text{max}} - d_{\text{min}}} \right) + \gamma. \quad (14)$$

Among them,  $d_{\text{max}}$  is the maximum depth,  $d_{\text{min}}$  is the minimum depth, and  $d(x, y)$  is the depth information at  $(x, y)$ .  $\gamma$  is a very small amount to ensure that the depth estimation process of the monocular image is very far away (the misjudgment). The weight value tilts the image feature to the close range.

For the obtained weight matrix, we use the  $L2$  norm to normalize; namely,

$$V = \frac{V}{\|V\|_2}. \quad (15)$$

We perform the above sum pooling calculation on all  $N$  feature maps output by the convolutional layer  $L$  to obtain an  $N$ -dimensional feature vector  $\varphi$  of the convolutional layer, and use the same-dimensional PCA whitening, and then perform the whitening features obtained. The  $L2$  norm is normalized, and finally  $N$ -dimensional image features are obtained.

For comparison, we extract the SPOC algorithm as follows:

$$a_k = \sum_{y=1}^H \sum_{x=1}^W c_{x,y} f_{x,y,k}. \quad (16)$$

Among them,  $c_{x,y}$  is the Gaussian center prior, and its weights are set as follows:

$$c_{x,y} = \exp\left(-\frac{(y - H/2)^2 + (x - W/2)^2}{2\partial^2}\right). \quad (17)$$

Among them,  $\partial$  is the distribution covariance, which is set to one-third of the length of the feature map center from the nearest boundary. It can be seen that the SPOC algorithm adds a Gaussian center prior on the basis of sum pooling and does not effectively reflect the icon in the image. Objects cannot reflect the characteristics of close-up shots.

### 3. Experiments

**3.1. Data Acquisition.** Remote sensing is a means of collecting electromagnetic fields, force fields. Remote sensing maps record this information as an image. The classification of remote sensing maps is more complicated due to differences in sensors, imaging conditions, and types of information collected. They are also treated differently. The proposed method is suitable for visible light imaging and satisfies the remote sensing map of the vertical parallel projection imaging model. Considering the cost and simplicity of acquisition, this paper uses a satellite remote sensing map downloaded from the "satellite" mode of Google Maps. Its resolution accuracy is acceptable, it can be downloaded as long as it can be connected to the Internet, and it is completely free, so it is not only simple and practical but also low in cost. Its data components are more complex, mainly from Digital Globe and MDA Federal. Its imaging feature is a high-altitude bird's-eye view, which provides information on the roof of the building and covers a large area. In addition, it is visible light imaging and approximate vertical shooting; it can be assumed that the downloaded remote sensing image conforms to the vertical parallel projection imaging model; that is, it can meet the requirements of the algorithm.

#### 3.2. Scene Visualization

**3.2.1. Basic Steps of Reverse Tracking.** According to the set image size, the number of rays is determined to be slightly higher than the total number of pixels in the image. If the image size is 160\*120, the total number of pixels is 19200, and the light is 22630; if the image size is 640\*480, the number of pixels is 307200, and the light is 363388; when the image size is 1024\*1280, the number of pixels is 1310720, the light is 1550877, and the number of rays is more than 18% of the number of pixels, so that each cell has a light, and the extra light can be used to verify the correctness of each cell

calculation. When the number of rays is determined, tracking begins. The specific tracking process is as follows:

Step 1: Determine the position of the sensor and the viewing plane, and the light is directed to the scene through the viewing plane;

Step 2: When the light reaches the set opaque surface, the light source is tracked according to the surface reflection principle of the object. At this time, no other object is blocked between the light sources, and the reflection portion is a bright portion;

Step 3: When the light is reflected by the opaque surface, the scene entity that is set when tracking the light source is occluded (the sphere in the figure), and the reflective surface is dark;

Step 4: When the light hits the solid in the scene (the sphere in the figure), it is reflected to the opaque surface, and then the reflection can be traced to the light source. The reflection of the object is bright and there are some optics of the opaque surface characteristic; the light reverse tracking step is shown in Figure 1.

**3.2.2. Acceleration Algorithm.** In the process of ray tracing by POV ray, there are a large number of rays intersecting the object. In order to improve the judgment efficiency of the intersection of light and object, POV ray uses a variety of acceleration algorithms, including multiple layers nested bounding box algorithm. The most important multiple levels nested bounding box algorithm is introduced here, depending on the buffer algorithm and the ray buffer algorithm. The bounding box algorithm is widely used in ray tracing. The traditional bounding box algorithm divides the scene into virtual cubes (such as bounding boxes). First, it is determined which intersecting box the light intersects. If it intersects, it is judged whether the light and the entity in the bounding box are intersecting; compared with the original algorithm that uses image space as an order, this can greatly reduce the number of judgments and improve efficiency. The traditional bounding box algorithm steps are shown in Figure 2.

Since not every bounding box contains entities, POV ray uses a multiple layers nested bounding box algorithm. The multiple levels nested bounding box is similar to the structure of a tree, and the whole scene is first divided into larger bounding boxes. It is judged whether the light intersects with the bounding box. If they intersect, the intersecting bounding box is decomposed into smaller bounding boxes, and the judgment is performed again, and the layers are subdivided into multiple layers in order. In this way, when the entities are discretely distributed in the scene, the computational efficiency can be greatly improved; however, when the entities are continuously distributed, the efficiency is not as good as the traditional bounding box algorithm. Therefore, when using the multiple layers nested bounding box algorithm, the key is to start the bounding box. In POV ray, Bounding = on/off controls whether to use the bounding box, and Bounding Threshold =  $n$  controls the

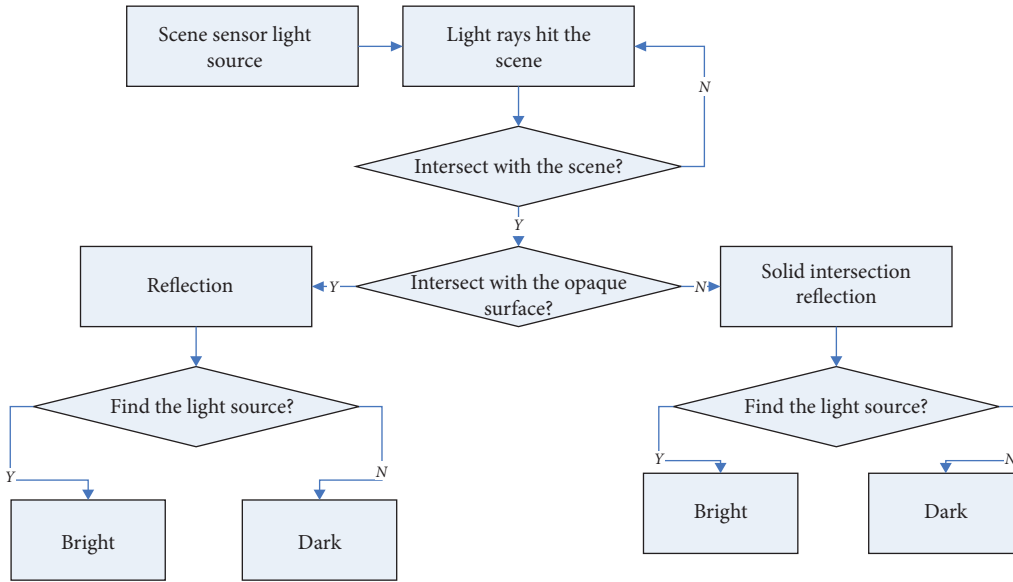

FIGURE 1: Light reverse tracking step.

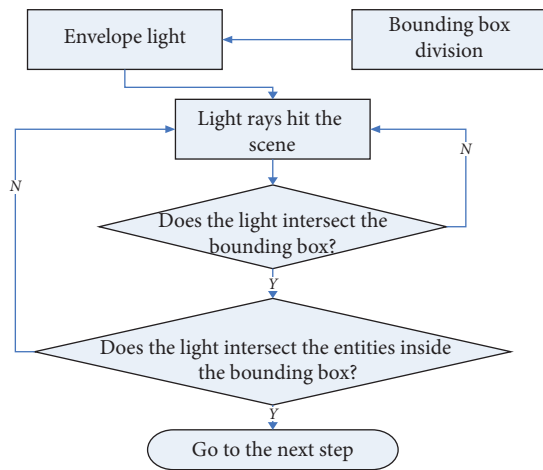

FIGURE 2: Traditional bounding box algorithm steps.

starting layer number  $n$  of the bounding box. POV ray defaults to 3 layers.

**3.3. Generation of House Scenes.** The three-dimensional model of the house can be divided into two parts: the main body of the house and the roof. Therefore, the generation of the house scene can be divided into two parts: the main body of the house and the roof. Considering the complexity of the actual building, this article has been simplified accordingly: the complex building is broken down into a simple four-corner house model. For four-corner houses, there are roughly two categories, one is the most common flat-top houses, and the other is non-flat-top houses. To build a three-dimensional model of a house, you must first obtain some information about the house from some way. Undoubtedly, the information related to the house is mainly the corner coordinates of the house, the elevation of the bottom,

and the height of the house; for nonflat houses, the information about the height of the roof of the house is also known.

**3.3.1. Acquisition of Corner Information of Houses.** The house generally appears as a relatively regular shape in the two-dimensional image, so this paper decomposes it into a rectangle or a square, so that, for the house in the south of the south, it is only necessary to extract the coordinates of the two corners of the diagonal of the house, but for nonpositive south and north houses, the coordinates of the four corners of the house do not have a mutual relationship and must be extracted. In order to be able to generate the above two types of house models at the same time, this paper extracts all the corner coordinates of the house. So, how to extract corner coordinates has become a focus of this article. There are two ways to extract the corner information. One is to extract the boundary information of the house as a straight line segment and then find the intersection point of the straight line segment as the coordinates of the corner of the house; the other is to extract directly according to the gray information of the image (corner coordinates). By comparison, the latter method is found to be simpler and more accurate than the first method. When directly using the image gray scale to extract the angular coordinates of the house, a corner feature extraction algorithm such as a Harris operator and a Moravec operator is often used, which are all difficult to meet the needs of this study to extract the corner coordinates of the house. But with MATLAB's powerful matrix processing capabilities, you can easily solve the problem.

**3.3.2. Acquisition of the Elevation of the Bottom of the House.** Using the classification map, we obtained the coordinate information of the four corner points on the bottom of the house. The acquisition of the elevation of the bottom of the

house is simpler. Since the bottom of the house in the study area is generally flat, the elevation of the bottom surface is uniform. The DEM elevation value of the selected area has been assumed to be 0 before, so the bottom elevation value is 0 from the DEM.

## 4. Discussion

### 4.1. Remote Sensing Image Registration Analysis

*4.1.1. Registration Error.* The registration error is shown in Table 1 and Figure 3. It can be seen from the table that the camera optical axis position error is below 1.3 meters. The result of this accuracy is acceptable. The result has reached the practical standard and is large. In some cases, the resolution of the satellite remote sensing map is also meter level or lower.

The error of the registration algorithm mainly comes from two aspects, one is the error of the experiment itself, and the other is the algorithm error. For the omnidirectional diagram, errors in the relative positional mounting of the components of the camera, errors in the attitude of the device at the time of shooting (such as the level of the device), errors in the imaging device itself, etc. can cause errors in the imaging of the omnidirectional image. Remote sensing maps also have corresponding errors. The error of the experiment itself can be reduced by precisely adjusting the installation of the imaging device and correcting the obtained image. This part will not be discussed in this paper. The registration algorithm error mainly comes from feature extraction, because, from the principle of the algorithm, as long as the extracted features are absolutely accurate, the calculated registration result error is very small. Therefore, the accuracy of feature extraction is the bottleneck of the accuracy of the registration algorithm, especially the principal point registration method, because the features used are basically no information redundancy.

*4.1.2. Registration Time Consuming.* The registration time consumption is shown in Table 2 and Figure 4. It can be seen from the table that both methods are relatively fast and can be controlled within 6 seconds. In comparison, the primary point registration method is faster. Moreover, the time-consuming search registration method will increase with the increase of scene buildings, and the main point registration method will be more time-consuming. This is consistent with theoretical analysis because the equal angle search registration method requires searching for a set of points. And the calculation amount used to judge the feasibility of any point in the point set increases with the increase of the number of linear features used and the principal point registration method only. One or several points need to be calculated, and the amount of calculation for calculating any point is fixed.

### 4.2. Scene Generation Results

*4.2.1. Acquisition of Corners of Houses.* Therefore, based on the classification map obtained from the remote sensing image, the image is read into MATLAB using the `imread` function to generate a matrix, and then the matrix gray information of the house area is given to another matrix of the same size as the original image, so that these two matrices coincide. There are only two values: the gray value of the house and the background gray value. Each house is then marked or given a different color using the `bwlabel` function. Finally, the `regionprops` function can be used to extract the coordinates of the corner points of the region boundary. According to a certain rule, the coordinates of the four corner points of each house can be obtained. The corner points of the house extracted from the classification map are shown in Figure 5.

*4.2.2. Generation of House Scenes.* When obtaining the building model construction information, the various types of information should be stored in the form of a matrix or an array, and then the `patch` function is used to draw the planes. The color of the roof and the color of the surrounding walls are separated, and the storage of the coordinate files is also required. The results of using MATLAB 3D building modeling are shown in Figure 6.

The modeling method of the three-dimensional house is relatively simple, and the required three-dimensional data is small, but the distortion is large, and there is a defect in the aesthetic angle when used for three-dimensional visualization. However, the modeling required in this paper can reflect the radiation characteristics of the ground object. Because the radiation characteristics are only related to the material of the ground under the conditions determined by the lighting conditions and the external environmental conditions, the radiation characteristics of the house are mainly the study of the radiation characteristics of both the exterior wall and the roof of the house. For this purpose, this modeling approach is feasible.

*4.3. Clustering Algorithm on Remote Sensing Images.* Through experiments, it can be concluded that the clustering collective scale of ECUNGA algorithm is set to 5, 10, 20, 30, 40, and 50, the initial random parameter is 20, the maximum allowable algebra of GA is 500, and the maximum allowable stagnant algebra is 50. Perform clustering on the three data sets of Iris, Wine, and Glass, respectively, and compare the best correct rate, average correct rate of 20 times, and worst correct rate of the clustering results under the collective scale of each cluster. The experimental results are shown in Table 3 and shown in Figure 7.

From the experimental results, it can be found that the algorithm is not sensitive to the size of the clustering collective on the data sets Iris and Wine, while the clustering collective scale on the Glass data set is not very stable at 5 and

TABLE 1: Registration error.

|        | Isometric search registration method (m) | Main point registration method (m) |
|--------|--|------------------------------------|

10, the best and worst results. The difference is relatively large.

4.4. *Remote Sensing Image Registration.* Analyze the experimental part and get Tables 4 and 5 and Figure 8.

Figure 9 shows the relationship between the number of sampling times of the RANSAC algorithm and the number of last correct matching point pairs and the execution time of the RANSAC algorithm. Red, green, and blue curves represent the experimental results on the test image pairs PA, PB, and PC, and the time unit is seconds. It can be

FIGURE 5: House corner extraction effect map.

FIGURE 6: Housing scenario generation results.

TABLE 3: The influence of remote sensing image clustering algorithms.

| Data set | Scale | Best | Average | Worst |
|----------|-------|------|---------|-------|
| Iris     | All   | 0.89 | 0.89    | 0.89  |
| Wine     | All   | 0.7  | 0.7     | 0.7   |
|          | 5     | 0.56 | 0.529   | 0.46  |
|          | 10    | 0.54 | 0.48    | 0.46  |
| Glass    | 20    | 0.54 | 0.52    | 0.52  |
|          | 30    | 0.54 | 0.53    | 0.52  |
|          | 40    | 0.54 | 0.51    | 0.52  |
|          | 50    | 0.54 | 0.53    | 0.52  |

clearly seen from the figure that the number of correctly matched feature points remains unchanged after the number of iterative samples is greater than 80, so the threshold value is set to 100 in the RANSAC algorithm based on the similarity transformation model. RANSAC algorithm execution time and sampling times meet a

linear relationship, so the RANSAC algorithm has a higher execution efficiency. It is worth noting that the RANSAC algorithm based on affine transformation usually requires more iterations. Since SIFT is a classic image registration algorithm based on scale space and point features, the SIFT algorithm is still compared here.

FIGURE 9: The relationship between the number of samples of the algorithm RANSAC and the running time.

It shows the image after registration and fusion using the algorithm proposed in this chapter. It can be seen that the edges and regions overlap well. Therefore, it can be judged intuitively that the registration result is accurate, which again proves the effectiveness of the algorithm proposed in this chapter.

## 5. Conclusions

This paper analyzes and elaborates the concept of hyperspectral remote sensing system and the absorption and reflection of electromagnetic waves. The structure of the hyperspectral scene system is analyzed, and the influencing factors of solar radiation and atmospheric effects and ground reflectivity model are introduced. The imaging mode and imaging principle of the imaging spectrometer were studied and discussed, and the parameters of the remote sensing system of the two scenes were determined.

For the simple scene, the simulation principle and implementation method of spatial correlation and spectral correlation in the ground reflectivity model are studied. The research shows that the spectral and spatial correlation of the features makes the spectral reflection of the pixels belong to different locations of the same type of features. The rate curve fluctuates around its mean reflectance. At the same time, the influence of the atmosphere on solar irradiation intensity and atmospheric transmission coefficient is analyzed. The analysis shows that the worse the visibility of the atmosphere, the smaller the solar irradiation intensity and the atmospheric transmission coefficient.

Based on the remote sensing image, a three-dimensional scene model is constructed. Based on the three-dimensional

scene model and the scene digital orthostatic image, a series of processing is extracted from the geometric and texture features of the scene orthostatic image and the contour features of the building. The minimum rule of the outline of the building is used to outsource the rectangle, and then these outsourcing rectangles are used as the constraint domain to segment the three-dimensional scene model to obtain the coarse single model. On this basis, the triangular and vertical classes of the triangular patches in the three-dimensional space are performed (classification). Calculate the roughness of the regional triangular patches. Based on this, combined with the height of the patch, the triangular patches that are not part of the building features in the coarse single model are purified, and then the adjacent patch growth method is used. The number of feature patches generates a more accurate building unit model and stores a single model from a single file, thus enabling automatic singular modeling of buildings in 3D scenes.

At present, high-tech enterprises are mainly organizations engaged in the production, research, and development and service of high-tech products. The current development of high-tech industries in various countries in the world is of great significance to improving social productivity and overall national strength. This article mainly introduces the modeling and analysis of the complex system of human capital accumulation in high-tech enterprises based on big data. This paper proposes a theoretical analysis of corporate human capital data and proposes regression analysis and analytic hierarchy process to calculate and analyze the process of corporate human capital accumulation and collect and analyze the data using questionnaire surveys and other methods. In addition, complex systems were modeled based on big data, and a cloud computing-based human capital big data analysis platform was established. The experimental results show that complex system modeling based on big data has a positive impact on the human capital accumulation of high-tech enterprises. For high-tech companies at different stages of development, the relationship between various types of human capital and corporate performance is inconsistent with the market economy. In contrast, the current salary system of some high-tech companies still has many drawbacks. The cost of using human resources controlled by the wage system accounts for more than 24%.

## 1. Introduction

With the development and dissemination of information technology and computers, the flow of personnel, capital, goods, and information in the production and living activities of human society gradually tends to be digital. Digital products are not uncommon in life, which in turn activates industry data. Explosive development has promoted the rapid development of big data. However, traditional human resource management often lags behind, even simple manual and subjective personnel management. Even the performance appraisal standards are subjective, which run counter to the development of society.

With the emergence of network and information, especially the widespread popularization of computer and Internet technology, we should make full use of the convenience provided by information technology to make human resource management more scientific, reduce

human capital, and give full play to the role of human resource management [1]. Through the production of a large amount of internal and external data, the processing and analysis of a large amount of human capital accumulation data of high-tech enterprises can bring huge added value to enterprises and adapt to the changing economic environment [2]. Through the analysis of the current situation of human resource information system, we found its shortcomings and further put forward the theory and method of creating a new platform, which provides support for the establishment of analysis platform based on high-tech enterprise data of computing cloud [3].

H. Chen, B. Xuan, P. Yang, and others stated that safety requirements are becoming more and more important for various industrial production processes. Although many facilities have been designed and used to ensure safety, some safety accidents still occur [4]. But he did not come up with a plan on how to prevent brain drain. D. Sledgianowski et al.

responded to the initiative to apply big data technology to accounting courses and used the lens of the accounting education ability integration framework to provide examples of integrating big data and information systems into teaching resources [5]. From the accounting of R&D expenses of enterprises, the expenses in the process of R&D are calculated, and reasonable cost sharing standards are formulated. The main purpose of this paper is to improve the cost control of R&D projects of high-tech enterprises, so as to ensure the economic benefits of high-tech enterprises. However, his research on high-tech enterprises is more invested in enterprise benefits and does not consider how to introduce high-tech talents [6]. Z. Wang, J. Yang and others took high-tech companies listed on the small board from 2007 to 2010 as a sample and used the structural equation model to explore the political connection mechanism of technological innovation in small and medium-sized high-tech companies. They said that politically connected managers can play an active role in the technological innovation of small- and medium-sized high-tech companies. External financing and entry barriers play an indirect role in the transmission of political connections to technological innovation, that is, political connections indirectly affect the technological innovation of enterprises through external financing and entry barriers [7]. This strategy is based on fully realizing that the international competition at present and in the future is mainly scientific and technological competition and also a correct decision based on China's national conditions and the rise and challenge of knowledge economy in the world. The enlightenment of human capital investment theory to us: Talent is capital [8]. This view sees the importance of talent but it does not have a good explanation for big data. To attract talents, we should first know where the talents are and rely on big data technology for precise positioning [9]. Although the theory of human capital has been attached importance to by various disciplines, scholars have been studying it more and more. In recent years, most of the researches at home and abroad have focused on the relationship between human capital and economic growth or enterprise performance, or the impact of the combination of human capital and technological innovation on economic growth [10]. The research on the relationship between human capital and technological innovation is scattered, and most of them only use qualitative analysis to analyze the relationship between human capital and technological innovation ability. The mechanism of human capital on technological innovation capability is ignored [11].

This article mainly introduces the modeling and analysis of the complex system of human capital accumulation in high-tech enterprises based on big data. This article puts forward the theoretical analysis of enterprise human capital data, questionnaire survey, and other methods and proposes regression analysis and analytic hierarchy process to calculate and analyze the process of enterprise human capital accumulation. In addition, complex systems were modeled based on big data, and a cloud computing-based human capital big data analysis platform was established.

## 2. Human Capital Acquisition Method of High-Tech Enterprises Based on Big Data Technology

### 2.1. Method of Analyzing the Data of Human Capital of High and New Enterprises

*2.1.1. Methods of Theoretical Analysis.* This paper expounds the background and content of the theory of enterprise capability in detail and expounds the mechanism of the relationship among human capital investment, enterprise capability, and enterprise performance, so as to provide a reasonable theoretical basis and suitable and meaningful hypothesis to be tested for the empirical research in the following paper. Analyze the connotation and characteristics of core human capital and general human capital and the different characteristics between high-tech enterprises and traditional enterprises and understand the commonness and individuality between them [12]. So we have a deeper understanding of the core human capital and its internal relationship with the competitiveness of high-tech enterprises. In the competition of the enterprise, only know the enemy and the friend can win the victory [13]. The theoretical analysis method can help the enterprise to understand the strengths and weaknesses and can analyze the strengths and weaknesses of the competitors [14].

*2.1.2. Questionnaire Analysis.* In this paper, a questionnaire about the relationship between the optimal allocation of human resources and the performance of high-tech enterprises is developed, and some enterprises of high-tech enterprises are surveyed by questionnaire [15]. It is a kind of survey method to collect research materials indirectly in written form, a method of obtaining materials and information indirectly by sending a concise inquiry form to the investigator and filling in the opinions and suggestions on the relevant issues [16]. In this way, we can clearly know the human resources structure of high-tech enterprises, and the following investigation and analysis can be carried out more smoothly [17].

### 2.2. Base on Human Capital Law of High-Tech Enterprises Based on Big Data

*2.2.1. Visual Research Method.* Visual analysis refers to the mutual analysis of a large amount of data, which is affected by the information dispersion and nonuniform data structure [18]. In addition, manual analysis occupies the core means, and the analysis process lacks structure and stability. This leads to the analysis process and mode cannot be clear, which makes it more difficult for the application system to obtain data, which hinders the subsequent mining and processing analysis [19]. The construction of visual data analysis platform effectively solves this problem and realizes association analysis manually. The essence of data visualization is a research system based on service-oriented guidance, which is comprehensive and unique [20]. This theoretical concept first appeared in the 15th century and has not been well developed before the 20th century. With the emergence and update of electronic computers, this

guiding ideology has been reborn [21]. With the continuous promotion and application of “big data,” the efficient graphic carrier of visual analysis makes the analysis and understanding of nonsimple data more concise and can effectively assist the application, prediction, and decision-making of data information [22].

**2.2.2. Predictive Analysis.** Analysis and prediction are the ultimate goal of big data application, which must be based on effective and reliable data sources [23]. The basic data needed by HR management is mainly divided into two parts, internal and external, including market environment factors [24]. Generally, the internal data has good accuracy, but it lacks conciseness in collection and application. In addition to the support of data sources, professional analysis software and big data professional analysts are more efficient predictive analysis methods [25].

**2.3. Principal Agent Theory Based on Utility Function.** The principal-agent theory is completely based on the hypothesis of “economic man.” For a rational economic man, the choice of his working style and effort is based on the maximum utility. The general utility function is as follows:

$$U = U(w, e). \quad (1)$$

Among them,  $w$  refers to employee’s income or remuneration and  $e$  refers to employee’s effort. Generally speaking, income is directly proportional to utility, and effort is inversely proportional to utility. Thus, the following formula is established:

$$\frac{\partial U}{\partial w} > 0. \quad (2)$$

Obviously, employees choose as much as possible in exchange for more remuneration with less effort so as to have

$$\frac{\partial U}{\partial e} < 0. \quad (3)$$

The output of an enterprise is a function of effort and environmental factors:

$$q = q(e, s). \quad (4)$$

In the formula, the environmental factor  $s$  is a random variable, which has an important impact on the output of enterprises.

**2.4. Regression Analysis of Human Capital Calculation.** In the regression analysis, firstly, the two factors extracted are taken as the explanatory variables and the explanatory variables to establish a linear regression equation to analyze in detail the impact of large technology on the human capital of high-tech enterprises. The formula of the regression model

$$Y = C_1X_1 + C_2X_2 + \text{Control} + e_1. \quad (5)$$

The regression model is as follows:

$$\begin{aligned} M_1 &= C_1X_1 + C_2X_2 + \text{Control} + e_2, \\ M_1 &= A_{11}X_1 + A_{22}X_2 + \text{Control} + e_2. \end{aligned} \quad (6)$$

The human capital investment of high-tech enterprises can mainly positively affect the production efficiency and operation ability of the enterprise, but the influence on the management efficiency of the enterprise is not significant and not positive. It focuses on the mediating role of the two dimensions of the ability of the enterprise’s production efficiency and operation ability in the impact of human capital investment on enterprise performance. The formula of specific regression models is

$$Y = C_1X_1 + C_2X_2 + B_1M_1 + B_2M_2 + \text{Control} + e_3. \quad (7)$$

**2.5. Analytic Hierarchy Process of Human Capital.** The AHP is to solve a decision-making problem, which will be solved as a subsystem, and then solve the decision-making problem by analyzing the influencing factors and divide a complex problem into simple problems related to it. In this subsystem, the decision problem to be solved is taken as the goal, and the factors affecting the target level are taken as the standard and then further decomposed at different levels as the standard.

According to the scale value and the method of pairwise comparison, the formula is as follows:

$$\begin{aligned} a_{ij} &> 0, \\ a_{ij} &= \frac{1}{a_{ji}}, \\ a_{ij} &= 1. \end{aligned} \quad (8)$$

## 2.6. Mode of High-Tech Enterprise Entrepreneurs’ Human Capital Participating in Income Distribution

**2.6.1. Determination of Withdrawal Amount of Virtual Stock Option Award Fund.** Before the implementation of the option incentive plan, the general meeting of shareholders shall discuss and determine a basic withdrawal proportion and withdraw a certain amount from the current year’s EVA value as the company’s first period incentive start-up fund, including  $F_0$ , the initial incentive plan start-up fund,  $z_0$ , the enterprise’s EVA value when implementing the option plan for the first time, and  $F_0$ , the withdrawal proportion of the first incentive fund:

$$F_0 = z_0 * f_0. \quad (9)$$

After that, the incentive fund FN of that year will be extracted from the EVA value created in that year according to a certain proportion, so as to reward the virtual stock option. The reward level is linked with the company’s operating performance level and is calculated according to the company’s operating performance according to the specific calculation formula, where FN is the reward fund of the

company in the  $n$ th year;  $Z_n$  is EVA value of the company in the  $n$ th year;  $F_n$  is the proportion of the bonus fund withdrawn in the  $N-1$  year of the company;  $G_n$  is determined by the excess EVA growth rate of the company in the  $n$ th year:

$$\begin{aligned} F_n &= Z_n F_n - 1(1 + G_n) \quad (Z_n > 0 \text{ and } 1 + G_n > 0), \\ F_n &= 0 \quad (Z_n < 0 \text{ and } 1 + G_n < 0). \end{aligned} \quad (10)$$

The calculation method of the excess EVA growth rate is as follows, where the expected value is recorded as E1:

$$G_n = \frac{(\Delta \text{EVA} - \text{EI})}{\text{EVA}_{N-1}}. \quad (11)$$

Since the values of the source data are both negative numbers, all source data need to be taken as absolute values:

$$\begin{aligned} U &= \{P_1|D, L, f_2, Q, d, l \quad P_2|f_1, \mu \quad P_3|N, M, I\}, \\ \text{IR} &= \sum_{s=1}^U \sum_{d=1}^K f_s, DV_s, d. \end{aligned} \quad (12)$$

Take the first 4 values of the RSRP value of the service station received at time  $t$ , and form the short sequence of the GM (1,1) model with the predicted value obtained at the previous time, denoted as

$$\sigma_{ikjl} = \begin{cases} \frac{n}{\Delta_{ikjl}} \sqrt{\sum_{s=1}^n (x_{ik}(\varepsilon) - x_{jl}(\varepsilon))^2 \Delta_{ikjl}(\varepsilon)}, & \Delta_{ikjl} > 0; \\ 0, & \Delta_{ikjl} < 0, \end{cases}$$

$$X_1 = \{X_1(t - 4\Delta t), X_1(t - 3\Delta t), X_1(t - 2\Delta t), X_1(t - \Delta t)\}. \quad (13)$$

In the same way, remember the short sequence formed by the RSRP value of the target site as

$$X_2 = \{X_2(t - 4\Delta t), X_2(t - 3\Delta t), X_2(t - 2\Delta t), X_2(t - \Delta t)\}$$

$$\text{BMI}(b) = 2n \ln(\sigma) + n \ln(2\pi) + n \left\{ \frac{n + tr(S)}{n - 2 - tr(S)} \right\},$$

$$W(T) = K(y(T-1), u(T-d-1)). \quad (14)$$

Establish a GM(1,1) model based on the short sequence  $X$ , and get a new set of prediction sequences after performing operations:

$$\begin{aligned} Y_1 &= \{Y_{1,1}, Y_{1,2}, Y_{1,3}, Y_{1,4}, Y_{1,5}\}, \\ y_i &= \beta(u_i, v_i) + \sum_{j=1}^p \beta_j(u_i, v_i) x_{ij} + \varepsilon_j \beta_j. \end{aligned} \quad (15)$$

In the same way, a GM(1,1) model is established based on the short sequence  $2X$ , and a new set of prediction sequences are obtained after calculation:

$$\begin{aligned} Y_2 &= \{Y_{2,1}, Y_{2,2}, Y_{2,3}, Y_{2,4}, Y_{2,5}\}, \\ w_G^{A_i A_j} &= \max\left\{0, W_G \cdot \varepsilon \left( f_G^{A_i}, f_G^{A_j} \right)\right\}. \end{aligned} \quad (16)$$

Take the average of the predicted sequence of the service site and the target site obtained after the prediction to obtain the average sequence:

$$\begin{aligned} Y'_1 &= \text{avg}(Y_1), \\ Y'_2 &= \text{avg}(Y_2). \end{aligned} \quad (17)$$

### 3. Human Capital Accumulation System Experiment under Big Data Technology

**3.1. Basic Characteristics of Big Data Machine Learning.** The large system of machine data learning includes many complex technical problems in mechanical learning and big data processing, such as model structure, teaching algorithm, accuracy of mechanical learning model, distributed storage, and parallelism of big data processing. These are closely related to calculations, network communications, local calculations, work plans, system fault tolerance, and other factors. However, data development method is a nonparametric estimation method, which uses mathematical programming to evaluate the relative effectiveness of multiple input and output decision-making units, that is, to judge whether DMU is within the "limit" of total production potential. Since production boundary is the extension of production function in the case of multiple costs in finance, DEA method and model can determine its structure. For production boundary, DEA method can be regarded as a nonparametric statistical method. When you use data envelopment analysis to evaluate the effectiveness of decision-making units, you can not only get the information decision-making of relative performance and scale economy of each receiving unit but also obtain a lot of management information with profound economic significance and background.

**3.2. Analytic Hierarchy Process Test.** Analytic hierarchy process (AHP) is a kind of multiple criteria decision-making process that combines qualitative and quantitative analyses. Its characteristic is to establish a hierarchical structure model by analyzing the essence, influencing factors, and internal relations of complex problems and then determine the decision-making process mathematically with less quantitative information, thus providing a simple decision-making method for the resolution of composite materials and providing quantitative basis for analysis, decision-making, prediction, or mathematical control. The following is how to use it:

- (1) According to different objectives and functions, the system is divided into different levels, such as target level, standard level, and system level.

- (2) In pairwise comparison, the detailed level procedure of decision table (AHP) is mainly for people to evaluate the relative importance of each factor at each level. These decisions are expressed in the form of numbers by introducing appropriate scales, reflecting people's understanding of the relative importance of various factors. Generally, the 1–9 scale method and the reciprocal scale method are used. By pairing and comparing the factors, the values are assigned according to the importance level, thus completing the transformation from qualitative analysis to quantitative analysis.
- (3) Hierarchical single sort. It is to calculate the weight of the elements related to the upper level according to the decision table. Theoretically, the calculation of the single level classification of the problem may be limited to the calculation of eigenvalues and the maximum value of the sector of the crisis matrix.
- (4) In order to determine the relative importance or relative advantages and disadvantages of the lower level elements of the overall goal, the comprehensive weight of each element in each layer is calculated and the general classification is carried out.

#### 4. Human Capital Analysis of High-Tech Enterprises Based on Big Data

**4.1. Item Data Analysis Based on Scale.** As shown in Figure 1, the test of item analysis is to explore the difference of subjects with high and low scores in each item or to test the homogeneity among items. The difference between the first 27% and the last 27% of the total score of the scale is called the comparison of the two extreme groups, and the difference value of the comparison results of the extreme group is called the decision value or critical ratio. Data analysis is shown in Table 1 and Figure 2.

As shown in Table 2, *t*-test of independent samples is to test whether the average of each item in the high score group and the low score group is significant, so as to know whether the average of each item in the scale is different due to the different groups (high group and low group). In terms of the variable C1, the average of the high group was 2.5, the standard deviation was 1.4, the average of the low group was 3.7, and the standard deviation was 1.2. The greater the difference between the two groups was, the more likely the difference would be.

**4.2. Factor Analysis of Human Capital.** KMO and Bartlett's test is the fitting test before factor analysis. KMO is an index for comparing the observed correlation coefficient and partial correlation coefficient. The value of KMO reflects the correlation degree of this factor analysis. In general,  $KMO > 1$  is very suitable for factor analysis;  $1 < KMO < 1.1$  is suitable; above 0.9 is acceptable; 0.7 is poor; below 0.4 is not suitable for factor analysis. The results of KMO and Bartlett's test on 12 variables in human capital measurement table are as follows:  $KMO = 0.8 > 0.7569$ , and the significance probability sig of  $\chi^2$  statistical value of Bartlett's sphericity test is

FIGURE 1: Statistical quantity of groups statistical graph.

less than 0.11, indicating that the factors in the questionnaire have certain relevance, as shown in Table 3.

Factor analysis is to study the internal dependence among many variables. The principal component method is used to extract common factors, and the orthogonal rotation method of varimax is used to obtain the load value of each factor. The main purpose is to condense many observation variables into a few factors to achieve the effect of reduction to make the scale more scientific and simplify the later calculation.

**4.3. Data Analysis of Regression Method.** When establishing the regression model of economic problems, it is necessary to consider whether there are conditions inconsistent with the assumptions of the model, such as heteroscedasticity. If the problem of heteroscedasticity exists in the model, the least-square method is still used to estimate the unknown parameters, which will lead to the results that the estimated values are not optimal. The residual graph analysis method of SPSS software is used to test the heteroscedasticity. The test results show that the model does not have heteroscedasticity problem.

As shown in Figure 3, high-tech enterprises' nonexecutive human capital investment and executive human capital investment can positively and significantly affect their performance, and this impact has a certain lag effect. In the control variables, the human capital stock of enterprises can promote the performance of enterprises and is significant, which also confirms that the reasonable human capital structure in high-tech enterprises is the premise to improve the efficiency of human capital investment, and the higher the quality of human capital, the better the performance of enterprises.

As shown in Table 4, when the flow of human capital is more frequent, it will reduce the performance of the enterprise. This may be because when the flow of human capital is more frequent, the recruitment cost that the enterprise needs to invest in the next year will increase, and the newly introduced human capital often has a certain running in period with the enterprise, which will have an adverse impact on the performance of the enterprise.

TABLE 1: Statistical quantity of groups.

| Participation_category | N | Mean value | Standard deviation | Standard error of mean |
|------------------------|---|------------|--------------------|------------------------|
| A1                     | 2 | 35         | 87                 | 328                    |
| A1                     | 3 | 30         | 60                 | 502                    |

4.4. HR Staff's Views on Big Data. The most important part of human resource planning is to investigate the current human resource situation of the company in the preparatory stage. The quantity and quality of all human resources of the company are the foundation of enterprise development. In general, the number of existing employees, the number of people of all ages, the distribution of employees at all levels of education, and the skills of employees are the contents of the company's thinking.

FIGURE 3: Regression analysis of human capital investment and enterprise performance.

TABLE 4: The more frequent flow of human capital.

| N  | Volatile factor | Pheromone concentration | Information quality | Valid data | Density |
|----|-----------------|-------------------------|---------------------|------------|---------|
| 10 | 3.82            | 1.47                    | 2.28                | 5.74       | 2.69    |
| 20 | 3.28            | 1.42                    | 2.47                | 1.19       | 4.07    |
| 30 | 5.17            | 3.75                    | 5.3                 | 3.31       | 5.07    |
| 40 | 6.2             | 1.72                    | 3.13                | 5.52       | 4.62    |
| 50 | 1.55            | 3.87                    | 2.74                | 2.79       | 1.84    |

TABLE 5: Employees' views on big data.

|            | Big data has a great impact on our lives (%) | Big data has a general impact on our lives (%) | Big data has a little impact on our lives (%) | Big data has a no impact on our lives (%) |
|------------|--|--|---|---|
| Proportion | 25   | 35   | 19  | 21  |

As shown in Table 5, these data and information are multidimensional. Companies need to process and analyze the information of these data to determine the current total number of company advantages in terms of employee composition, so as to distinguish between the company and competitors, especially the company's deficiencies in personnel structure. Prepare human resource planning; second, predict the company's human resource potential in the forecast phase.

The data in Figure 4 show that most people involved in human resource planning, including human resource managers and employees, do not generate much data awareness. Everyone says that they know they are in the era of big data, but they feel that big data is very far away from their life and work. 19% of the respondents think that big data has a general impact on their work and life, and 21% of them think that big data will not affect their work and life.

As shown in Table 6, the reality is that big data has penetrated into life and work, and human resource planning is no exception in all aspects. For the personnel involved in human resource planning, it is very important to cultivate a high degree of data awareness. Only when the relevant staff have a high degree of data awareness can they point out the value and influence of data in human design and make reasonable human resource planning according to the value reflected by big data. In this process, most people are managers and growers of enterprise employees.

As shown in Table 7, only when they take the lead in forming data awareness can they have a direct impact on other employees and promote the development of employee awareness in the whole enterprise. The formation of enterprise's overall consciousness can promote the digitalization process of enterprises and provide digital support for relevant personnel to predict the distribution of labor supply and demand.

**4.5. Market Use of Human Resource e-HR System.** With the development of human resource information software market, a certain scale has been formed. Domestic enterprises have a better understanding of the culture of domestic enterprises, and the user interface is more suitable for domestic enterprises. Especially after China's accession to the WTO, the software industry has sprung up like mushrooms. As shown in Figure 5, UFIDA, Kingdee, Qizheng, Neusoft, Jinyikang, and so forth have been recognized by domestic

enterprises, and they are ahead of foreign manufacturers in terms of cost performance.

As shown in Figure 6 and Table 8, although Microsoft, Oracle as the representative of the company, has been in the software industry for decades, its products are more mature and security is also higher; especially with Oracle database as the representative, open-source, security-incomparable, China's large enterprises generally choose Oracle as their own enterprise database. However, the price of foreign software industry is relatively high, and the maintenance cost is very high, and the interface does not necessarily conform to the norms and habits of Chinese enterprises. Therefore, the choice of information system should be combined with the enterprise itself rather than blindly choosing foreign software enterprises. According to the relevant statistical industry survey, most of China's enterprises have not yet introduced the information system for management. The figure below reflects the general trend of Chinese enterprises in choosing information system.

We can see clearly from Figure 7 and Table 9, where enterprises choose e-HR system, that the first consideration is the development stage of enterprise informatization. If the enterprise is just in the initial stage of informatization, it should choose a simple and easy-to-understand e-HR system for basic information operation. If enterprises do not require high degree of informatization, they only need simple employment data and choose e-HR system, which is easy to operate. If the enterprise develops into a medium-sized enterprise, is cross-regional, and has a large number of basic employees, it should choose e-HR system, which can process important data of the company and has additional functions.

As shown in Figure 8 and Table 10, if the enterprise is a large enterprise or requires a high degree of informatization due to the nature of the industry, it is necessary to select the e-HR system with the highest security level, which can process large data and provide data mining and data analysis. In a word, enterprises should choose e-HR system according to the development stage and scale of the enterprise and choose the e-HR system suitable for themselves.

**4.6. Human Capital Allocation in X Software Company.** As shown in Figure 9 and Table 11, X software company is a high-tech R&D company in the period of rapid

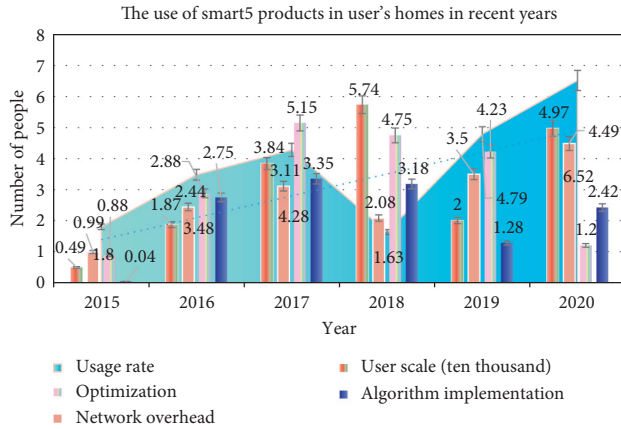

FIGURE 10: The stock of human capital of X software company.

enrich the company's structure. According to the human resource system disclosure, X software company has 2500 employees, of which more than 70% are R&D personnel. While the stock of human capital of X software is increasing rapidly, it should pay attention to maintaining a good structure of human capital. As a high-tech enterprise, the proportion of R&D personnel in the enterprise is about 70%, and the high proportion of R&D personnel ensures the development needs of Jinshan software products.

As shown in Figure 11, X software company attaches great importance to the training of its employees, and it takes one week every year for corporate culture training. The

FIGURE 11: Human capital structure of X software company in 2016–2019.

senior management of the company introduces the development history and corporate culture of X software company to the employees.

4.7. Education Framework of Human Capital in High-Tech Enterprises. As shown in Figure 12, we can see that, among the high-tech enterprises, the proportion of high-tech enterprises with high-level education accounts for a large proportion, accounting for 45%, followed by master's degree accounting for 35% and undergraduate education accounting for 20%, which

FIGURE 12: High-level education accounts for a large proportion.

TABLE 12: Education structure of human capital in high-tech enterprises.

| Education structure | Doctor's degree (%) | Master's degree (%) | Bachelor degree (%) | Other (%) |
|---------------------|---------------------|---------------------|---------------------|-----------|
| Tradition           | 15                  | 25                  | 30                  | 40        |
| Proportion          | 45                  | 35                  | 19                  | 1         |

FIGURE 13: Education structure.

shows that the demand of high-tech enterprises for various talents is also increasing. In traditional enterprises, the proportion of high-tech enterprises with high degree is small, accounting for 15%, followed by master's degree accounting for 25% and undergraduate degree accounting for 30%.

As shown in Table 12 and Figure 13, a department takes over the technical training in the company and forms corresponding training programs, such as developing a small toy or small unit. Several people form a team. Many groups will develop at the same time. Finally, each group will produce products to show the comparison. For the training of senior officials, X software company will regularly select employees who have worked for more than two years to study for graduate students. The company will pay them more than half of their study expenses or send them to foreign countries to learn and exchange advanced technologies, so as to better contribute to the company's R&D.

4.8. Problems in Cost Control of Human Resource Use. As shown in Figure 14 and Table 13, from the overall level of the

FIGURE 14: The proportion of human resource cost is increasing.

cost expenditure of high-tech enterprises in China, the proportion of human resource cost is increasing. The high-tech enterprises with strong economic strength can still afford it, but, for the small- and medium-sized high-tech

TABLE 13: Salary structure of human capital in high-tech enterprises.

| Occupation         | Annual cash income (%) | Total annual subsidy (%) | Total annual variable income (%) | Total annual benefits (%) | Total (%) |
|--------------------|------------------------|--------------------------|----------------------------------|---------------------------|-----------|
| The basic level    | 64                     | 7                        | 6                                | 23                        | 100       |
| Executive director | 62                     | 9                        | 9                                | 20                        | 100       |
| Management         | 65                     | 10                       | 13                               | 18                        | 100       |
| High level         | 68                     | 12                       | 5                                | 15                        | 100       |

FIGURE 15: Salary structure of human capital in high-tech enterprises.

enterprises that have just started, this expenditure undoubtedly adds a huge economic burden to them.

From Figure 15, we can see that, in high-tech enterprises, whether at the grass roots, middle level, or senior level, the proportion of annual cash income, that is, employees' cash salary, is the highest. Such a large amount of capital investment will inevitably require the enterprise's distribution system to be transparent, open, and fair. However, the reality is that, compared with the market economy, there are still many drawbacks in the current salary system of some high-tech enterprises, and the salary distribution system is directly related to the expenditure of the use cost of human resources, so the salary system also directly affects the control of the use cost of human resources.

## 5. Conclusions

In the economic level, science and technology tell development today, network and intelligent are no longer a strange topic, and this era is a modern era. In the field of human resources, it is no longer an era of tarnishing exploration. Relying on big data technology, the research on human resources of high-tech enterprises has entered a climax. With the in-depth application of cloud computing and other technologies, the construction of high-tech enterprise informatization is accelerated. It is a long-term process to build and implement the big data analysis platform for human resources of high-tech enterprises based on cloud computing. With the development of human resource system to cloud information, more and more enterprises will apply the human resource big data analysis platform based

on cloud computing. Therefore, the human resource big data analysis platform can contain information of many enterprises. Different enterprises can compare their own information with the information publicly disclosed by competitive enterprises in real time and make favorable decisions when they know themselves and their competitors. At the same time, the government can also use the platform to remote audit different enterprises to facilitate government supervision.

Of course, the support based on big data technology is far from enough. Every company should pay attention to the training of employees and spend a lot of time and energy on the allocation of employees among different departments, including job needs, employee abilities, employee wishes, and salary distribution. There are too many factors involved, so allocating employees in human resources will encounter various problems. Moreover, due to the lack of timely and in-place communication, there is a phenomenon of "re-work" in the work. That is, after working for a period of time, the employees reflect that they are not suitable and need to be readjusted. Therefore, this has brought about great trouble to the human resources department and delayed the work progress of the company. The use of big data can greatly avoid such a thing, because, before the allocation of manpower, big data will have human resource assessment, which can adjust the special situation in advance until it is suitable. Therefore, big data can help human resource units to make good use of human resources.

Human resource information management is the trend of future development; it can promote the value-added of human resources, and human resources management has

been raised to a strategic position; the implementation of human resources information management can enhance the core competitiveness of enterprises, which has important strategic significance for the development of enterprises. For high-tech enterprises, the success of informatization depends on staff training to a large extent. In the process of training, training should be carried out at different levels. Senior leaders focus on decision-making ability and strategic management ability, middle-level functional managers focus on communication ability, and grass-roots employees focus on technical ability. To do a good job in training evaluation, information management based on big data technology is a long-term implementation process. Enterprises should continuously improve the system, and information management is also a process of full participation.

With the rapid development of the market economy, there are more and more projects in the financial industry, and their complexity and technical requirements are getting higher and higher. The development of computer technology has promoted the birth of robot consultants, and it is of great significance to use robot consultants to manage and supervise financial industry projects. In order to further analyze the development and supervision of robo-advisors under the digital inclusive financial system, this paper uses complex systems and clustering algorithms as technical support to carry out research. First, the traditional K-means algorithm is used to select the initial clustering center, to improve the noise and outlier processing capabilities, and to build a data mining system based on the improved algorithm. Then, a product design model for robo-advisors is built and the risks of robo-advisors are analyzed from three aspects: technology, market, and law. Analyzing the performance of the improved K-means algorithm, in the operation of the experimental dataset B, the accuracy of the clustering result after 6 iterations reached 97.08%, which shows that the algorithm has good performance. During the trial operation of the data mining system, the four types of customers of financial institutions were accurately clustered, and it was concluded that the main type of customers who brought benefits to financial institutions was high-income customers accounting for 10.75%. Robo-advisory product models are used to build five risk-level investment portfolios and conduct risk backtests. Except for the growth and income portfolio, other portfolios have consistently outperformed the performance benchmark during the analyzed time period. Running the research system of this paper in a financial institution, comparing the capital budget before and after the operation, found that the system can improve the accuracy of the budget and reduce the risk of the robo-advisor for the financial institution.

## 1. Introduction

**1.1. Background Significance.** In the operation of financial activities, there are many projects and tasks in parallel, which brings great impact to the traditional financial management concept. As an important application of financial technology in the field of wealth management, the mode of intelligent investment adviser is more complex. In the era of big data, there are many problems in the development and supervision of intelligent investment advisers [1]. Complex systems can be said to be all over every corner of daily life. Complexity science is an emerging research form that reveals the operation laws of complex systems [2]. The development and supervision of robo-advisors in the digital age is also an extremely complex research object. Therefore,

it is a unique and meaningful new idea to study the development and supervision of digital inclusive finance and robo-advisors from the perspective of complex systems.

**1.2. Related Work.** Complex systems have become the focus of research in various fields due to their complexity and extensiveness. Lehuta et al. focused on handling uncertainties by optimizing model complexity for management goals and technical issues to increase confidence in complex system models. They reviewed how the complex system model fits into the existing institutional and legal environment of the current European fishery decision-making framework [3]. Although their research is of reference significance, their research methods lack innovation.

Inclusive finance plays an important role in improving the income gap and improving the living standards of the poor and disadvantaged groups, so it is the object of key research. Yan et al. studied the impact of digital financial inclusion (DFI) on the stabilization of household consumption in China. They used the data from the two “Chinese Family Forum” studies from 2010 to 2016. They divided household income shocks into permanent and temporary parts and assessed whether digital financial inclusion can help families resist income shocks [4]. Their research data are very representative but lack certain accuracy in processing the data. The risk analysis of robo-advisors has always been the focus of attention in the financial field. Jung et al. determined the needs of robo-advisors, derived design principles, and evaluated it through algorithm iterations in a controlled laboratory study [5]. Their research has given us a deeper understanding of robo-advisors, but they have not made constructive suggestions for the improvement of its supervisory system.

*1.3. Innovative Points in This Paper.* In order to build a more complete robo-advisory supervision system, reduce risks, and improve the digital level of inclusive finance, this paper studies the development and supervision of robo-advisors based on complex systems and clustering algorithms. The innovations of this research are as follows. (1) Improve the traditional K-means algorithm, optimize the selection of its initial clustering center, reduce the influence of noise, and improve the processing ability of isolated points. (2) A data mining system is constructed based on the improved algorithm. The functions of the system include opening files, importing data, data preprocessing, data clustering, and result query. (3) This paper constructs the product design model of intelligent investment consultant and uses the model to construct five risk-level portfolios for risk back-testing. This paper analyzes the risks of intelligent investment advisers from three aspects of technology, market, and law and puts forward suggestions to improve the supervision of intelligent investment advisers.

## 2. Complex Systems and Technologies Related to Digital Inclusive Finance

### 2.1. Complex System

*2.1.1. Characteristics of Complex Systems.* Complex systems exist in every corner of human life. Ecosystem, population system, and global economic system belong to the category of the complex system. They all have the same characteristics as the complex system. Complex systems are systematic first, which is not the superposition of simple systems and organizations. Therefore, it is not possible to study complex systems with traditional system analysis methods [6, 7]. The elements of a complex system are in a nonlinear relationship. Simple partial stacking cannot represent the whole. The local laws are not the same as the overall laws. Therefore, a new system theory is needed to consider the logical relationship between complex systems.

Complex systems are also hierarchical and interactive. The hierarchical nature of the complex system is mainly embodied in the nested relationship of different levels of interconnectedness [8]. Therefore, in the research of complex systems, it is necessary to update the traditional concept of hierarchy and analyze the research objects from the level of complex system theory. Complex systems and the external environment always interact. Different complex systems together form a larger and more complex system. When studying a complex system, we must fully consider the internal environment and external environment, study the information exchange between them, and consider the self-adjustment of the complex system in the complex external environment.

Complex systems have emergence and development. Complex systems are composed of various subsystems and local subsystems which are composed of various combinations and correlations. If the format and functional structure of the subsystem and the local subsystem are different, the complex system will no longer be the sum of the subsystem functions [9]. Complex systems may have a variety of new features, so when studying complex systems, we must consider the original features and the various new features that may appear. The self-renewability of complex systems is mainly reflected in the continuous development of the system, which is also the fundamental reason for biological evolution and the development of human society. Complicated systems become intelligent due to internal hierarchical, systematic and external interactivity, and emergence, so they can adapt to the needs and changes of the environment.

*2.1.2. Agent Complex System.* The complex adaptive system is based on the characteristics of the complex system and further develops the Agent theory. Agent is an independent individual or subsystem in a complex system, with a life cycle, which can perceive and adapt to the environment, run autonomously in the environment, and even change the environment. The structure of Agent generally includes environment perception, reasoning, control decision-making, knowledge base, and communication [10].

Agent has the characteristics of autonomy, social ability, initiative, learning, and adaptability [11]. Agents can use their own state and knowledge to make decisions independently, without relying on outside help. Agents can achieve a certain degree of communication, negotiate and cooperate to resolve conflicts, and complete complex tasks. Agents can judge their own situation according to the external environment and actively make choices that are beneficial to themselves at the right time. Agents can also continue to learn, adjust their own state and behavior, and adapt to the constantly changing external environment.

A single Agent has autonomous capabilities to a certain extent, but a single Agent cannot complete work in a complex and changeable environment. A multiagent system emerged at the historic moment, in which each Agent can communicate with each other. There are two or more Agents in a multiagent system, each with autonomy but limited

capabilities [12]. The multiagent system does not have complete global control. A single Agent has its own judgment and status. The calculation of the entire system is asynchronous, concurrent, or parallel. The coordination methods between Agents in the multiagent system are classified as follows.

As shown in Figure 1, the coordination methods of multiagent systems can be divided into two categories: explicit coordination and implicit coordination. The explicit coordination includes complete centralized coordination, complete distributed coordination, and centralized and distributed combined coordination, and implicit coordination includes social rules and filtering strategies.

*2.1.3. Evolutionary Dynamics of Complex Systems.* There are some common dynamic behaviors in the evolution of complex systems. Under the action of dynamics, complex systems can evolve and develop continuously. It is also feasible to use the dynamic behavior of individuals to illustrate the evolution of the entire complex system. Individual-based dynamic processes are usually defined by strategy update rules. The strategy update rule is based on factors such as environment and information to update and select the benchmark of the game strategy adopted by the individual in the system.

The evolutionary power strategy update rules of complex systems can be divided into two categories: imitation-learning strategy update rules. In this process, only the original strategy is imitated without innovation; the strategy update rules of the optimal response process include the optimal response process generated by the new strategy. In the process of evolution, individuals can use different types of strategies to update rules or use the same strategy to update rules [13]. There are two types of update methods: synchronous update and asynchronous update. Synchronous update refers to the synchronous update of the entire overall population in each individual time step. Asynchronous updates are updated in batches in a specific order.

In a complex system, individuals use a series of different dynamic behaviors in the development process according to different strategic update rules so that the evolution of the complex system shows the common characteristics of a series of complex systems. The dynamic behavior and dynamic factors of specific complex system evolution are also involved. Most of them start from the perspective of game theory and analyze the evolution of complex systems represented by individual competition, cooperation, and learning interactions in complex systems.

## 2.2. Digital Inclusive Finance

*2.2.1. Content Framework of the Inclusive Financial System.* The connotation of inclusive finance reflects fairness, comprehensiveness, and profitability, so inclusive finance has the characteristics of inclusive and sustainable development [14]. The complete framework of the inclusive financial system considers that large-scale groups excluded by traditional financial institutions want to obtain financial

services and benefit from them. Financial services must be integrated into the customer, micro, meso, and macro levels of the financial system. The framework of the inclusive financial system is as follows.

As shown in Figure 2, the customer level refers to the key service targets of inclusive finance, including vulnerable groups excluded by formal finance. The micro level refers to providers of financial services, including formal and informal financial institutions, as well as other types of financial institutions in the middle. The meso level refers to financial infrastructure and related services, including basic financial facilities, a series of auxiliary services that expand the scope of services, reduce costs, and promote transparency [15]. The macro level refers to the appropriate development environment, including the macroeconomic environment, institutional environment, and supervision and management environment.

The supply of the inclusive financial system is composed of commercial, policy, and cooperative financial institutions at the mature stage, and its structure is as follows.

As shown in Figure 3, commercial, policy, and cooperative financial institutions together form the ternary supply structure of the inclusive financial system at the mature stage [16]. They complement each other. Policy financial institutions provide policy guidance, and commercial financial institutions provide capital flows. Cooperative financial institutions provide necessary subsidies.

### 2.2.2. Development Stage of Digital Inclusive Finance.

Digital inclusive finance extends and expands the meaning of financial services by using digital technologies such as the Internet and big data, expands the coverage of its services, and reduces the threshold and cost of financial services [17]. Moreover, digital financial inclusion can promote information sharing and reduce the degree of information asymmetry. The development stages of digital financial inclusion are as follows.

As shown in Figure 4, the development of digital financial inclusion has gone through four stages. The initial form of microfinance was very simple, and then new business models such as the individual farmer household loan system and the installment payment system appeared. Although it overcomes the moral crisis brought about by information asymmetry to a certain extent, the scope is limited. And, its funding sources are mainly foreign aid funds provided by the government, international aid, and nonprofit organizations. Once the foreign aid funds are reduced, it will not be possible to continue lending, and sustainable development will face challenges [18]. The development of microfinance is more sustainable and diverse. Sustainability is reflected in the expansion of its business into deposits, wealth management, and other fields, without relying on the financial support of the government, other organizations, and individuals and financial sustainability. Diversity is reflected in the diversification of institutions, businesses, and service targets. Inclusive finance not only provides financial products and services to the poor and

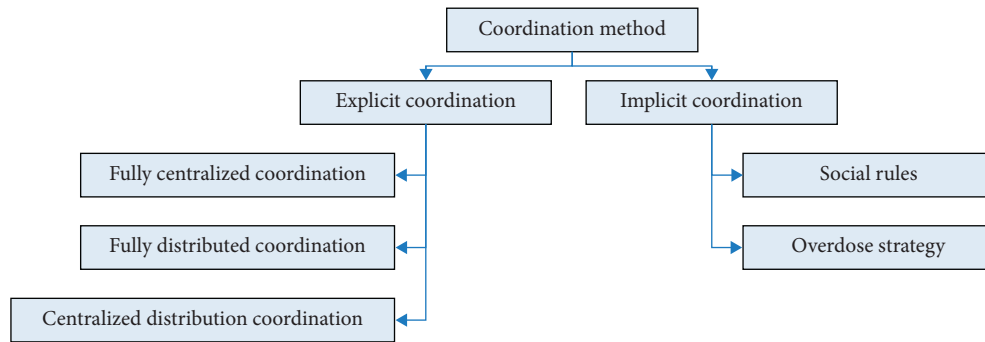

FIGURE 1: Coordination method of the multiagent system.

FIGURE 2: Framework structure of the inclusive financial system.

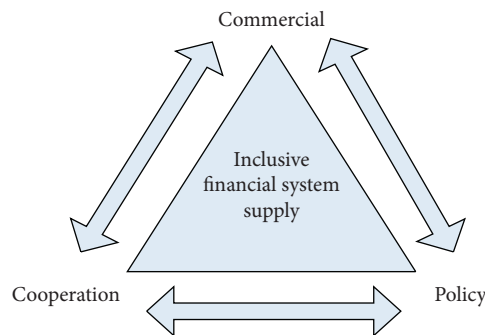

FIGURE 3: Supply structure of the inclusive financial system.

vulnerable groups but also promises to meet the diverse financial needs of all classes and groups in the society and encourages the wide participation of various financial institutions in the society. Digital finance is a new financial model that not only reduces transaction costs and information asymmetry but also expands the possibility of a series of transactions.

*2.2.3. Threshold Mechanism for the Development of Inclusive Finance.* The development of inclusive finance needs to face its threshold mechanism. In order to ensure profitability, financial institutions will set thresholds for mortgages and other services. Only when customers pay for financial services can they enjoy the services. In the mature stage of

financial development, low-income groups who were originally excluded from the financial service system can gradually accumulate wealth to enjoy financial services, which will narrow the investment income gap between different groups [19]. It is possible to establish a theoretical analysis framework for the impact of financial development on the income gap from the perspective of the production cycle of the two families.

Assuming that there are rich and poor families, the production cycle of the two families is the same, and the financial service lending thresholds are the same; we can deduce the wealth accumulation process of the two families in the context of the borrowing threshold constraints. A poor family can only save value first to maintain simple reproduction. The initial wealth of the family is as follows:

FIGURE 4: Development stage of digital financial inclusion.

$$C = K - D + (\alpha + e)Y_0. \quad (1)$$

Among them,  $K$  refers to the family's external endowment in the  $t$  period,  $\alpha$  refers to the proportion of the family's current wealth left to the next generation in each period of wealth distribution, and the remaining part of the current wealth for consumption is  $D$ .  $Y_0$  is the initial wealth from the family inheritance of the previous generation. After the preservation and saving with an interest rate of  $e$ , the wealth of the family in period  $t$  is as follows:

$$C_t = K + W_{t-1} + eC_{t-1} - D. \quad (2)$$

Among them,  $W_{t-1}$  refers to the inheritance of the previous generation family, so the inheritance left to the next generation by the family is as follows:

$$W_t = \alpha(K + W_{t-1} + eC_{t-1} - D). \quad (3)$$

From formulae (1)–(3), the convergence value of the wealth of the poor family can be derived:

$$C_\infty = \frac{(G - D)}{(1 - \alpha - e)}. \quad (4)$$

It can be seen from formula (4) that because it is difficult for poor families to cross the borrowing threshold, they are easy to fall into the “poverty trap” without the intervention of external forces. For wealthy families, their initial wealth is relatively abundant, and they can cross the borrowing threshold and obtain credit support. Therefore, the wealth of the family in period  $t$  is as follows:

$$C_t = K + W_{t-1} + S - M \times (1 + i) - H - D. \quad (5)$$

Among them,  $M$  is the amount of credit support,  $S$  is the income of each period after the credit support is invested in the project, and  $H$  is the cost of borrowers entering the financial market. In addition, the return on investment projects must be greater than the cost of the loan.

$$B = K + S - M \times (1 + i) - H - D. \quad (6)$$

According to formula (6), we can calculate the legacy of wealthy families to the next generation:

$$W_t = \alpha C_t = \alpha(W_{t-1} + B). \quad (7)$$

The convergence value of the wealth of the rich family can be deduced according to formulae (5)–(7):

$$C_\infty = \frac{B\alpha}{(1 - \alpha)}. \quad (8)$$

From formula (8), it can be seen that increasing the proportion of legacy left to the next generation and reducing the cost of entering the financial market can increase the wealth of wealthy families.

### 2.3. Related Technologies of Financial Data Mining

**2.3.1. Data Mining Technology and Data Storage Technology.** Data are the basis of data mining, and various algorithms are the means of data mining. The ultimate goal of data mining is to obtain the knowledge contained in the data to assist analysis and decision-making [20]. The mining of financial data is to promote the development of financial economy. The content of data mining includes things and dimensions, distribution and relationships, description and prediction, and phenomena and knowledge [21]. The main techniques of data mining include forecasting, clustering, association rules, and time series analysis.

MySQL is a relational database management system. The relational database uses the structured query language SQL as the most commonly used standard language to store data in various tables and access [22]. It can be used as individual application in the network environment of client and server. It can also be incorporated into other software as a library to provide multi-language support. MySQL database has good versatility and can improve storage efficiency.

Memcached is a high-performance distributed memory object caching system, which can reduce the load of the database, reduce the frequency of database access, and increase the high load of dynamic and data-driven websites [23]. Memcached has a simple protocol and built-in memory storage method. The data management access between the data layer and the service layer can cope with the emergence of high concurrent access and high concurrent query scenarios.

2.3.2. *Bayes Classifier.* The Bayes principle describes the probability of event  $Y$  when event  $X$  occurs. The Bayes formula is as follows:

$$P(X|Y) = \frac{P(Y|X)P(X)}{P(Y)}. \quad (9)$$

In order to adapt formula (9) to the entire sample space, it is necessary to derive the total probability formula on the basis of conditional probability. Assuming that the sample space is  $S$  and the remaining part of the sample space except event  $X$  is  $X'$ , the total probability formula is the conditional probability formula summarized in this sample space.

$$P(Y) = P(Y \cap X) + P(Y \cap X'), \quad (10)$$

$$P(X \cap Y) = P(Y|X)P(X), \quad (11)$$

$$P(Y) = P(Y|X)P(X) + P(Y|X')P(X'). \quad (12)$$

We can derive formula (12) from formulae (10) and (11). This is the total probability formula.  $P(X)$  is the prior probability,  $P(X|Y)$  is the posterior probability, and  $P(X|Y)/P(Y)$  is the likelihood function.

2.3.3. *K-Means Clustering Algorithm.* The K-means clustering algorithm is very common in the field of data mining. In this algorithm, K clustering centers are used to describe the clustering results. When the clustering objective function is known, the clustering analysis can be carried out by iterative updating to get the clustering results [24]. The schematic diagram of the K-means clustering algorithm process is shown in Figure 5:

The K-means clustering algorithm expresses the similarity measure between different clustered objects and data through distance. The performance evaluation method of the clustering result of this algorithm is usually the square of the mean square error [25]. After the iterative calculation, the objective function value of the algorithm will decrease, and the operation of the algorithm is a continuous iterative process.

The K-means clustering algorithm can process image and text features and has high stability and scalability. The clustering effect is good, and the result is more intuitive and easy to understand. When using an approximate algorithm to process datasets, as long as the target datasets are independent of each other, there is no need to restrict the scope of the dataset. However, the K-means clustering algorithm has limitations in practical applications, and the K value will directly affect the clustering effect. It is easy to be disturbed by local noise in the iterative process, which makes the result bias.

### 3. Experiments on Algorithm Optimization and Robo-Advisor Development and Supervision

#### 3.1. Improvement of K-Means Clustering Algorithm and Construction of the Data Mining System

3.1.1. *Improve the Selection of Initial Cluster Centers.* The key technologies to improve the K-means clustering algorithm include clustering information resource sharing technology based on the interoperability meta-model framework and cluster automatic detection technology based on multiengine fusion. The square error and the benchmark function can be used to achieve cluster analysis of datasets with large differences in shape. The most convenient method is to randomly select multiple different initial values to execute the algorithm to reduce the dependence of the K-means clustering algorithm. According to the processing method of the representative points, the ideal clustering result is obtained by selecting the global best solution in the clustering result. When choosing the initial clustering center of the clustering algorithm, it is necessary to improve the selection of the initial clustering center.

In order to improve the stability of K-means clustering algorithm results, it is necessary to select data samples according to the characteristics of data distribution. In the process of determining the initial cluster center, it can reflect the characteristics of the initial data, and the data will not be distorted after sampling.

3.1.2. *Improve Noise and Outlier Processing Capabilities.* Perform clustering according to the steps of the traditional K-means clustering algorithm, delete outliers, and obtain a new dataset. Select the data object corresponding to the smallest density value from the set  $S$  as the initial cluster center. When the distance between each point and the data and the remaining points is greater than the sum of the distances between the data object and all points, this point is treated as an isolated point.

In order to reduce the interference influence of the clustering effect of the K-means clustering algorithm, it is necessary to calculate the sum of the distance between each point and the data and the remaining points and the distance between the data object and all points.

$$Q_i = \sum_{j=1}^e \sqrt{\sum_{d=1}^e (x_{id} - x_{jd})^2}, \quad (13)$$

$$H = \sum_{i=1}^e \frac{Q_i}{e}. \quad (14)$$

Among them,  $e$  and  $d$  are the sample data and data dimensions, respectively;  $i$  is all points in the set; and  $j$  is a constant.

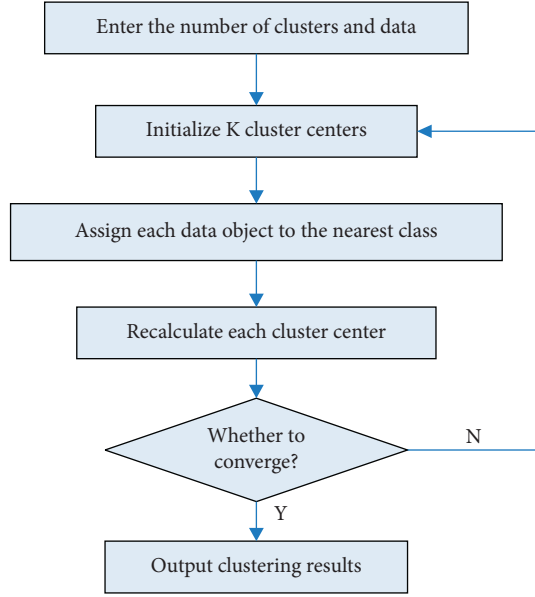

FIGURE 5: Schematic diagram of K-means clustering algorithm process.

**3.1.3. Data Mining System Construction.** There are five functions of the data mining system, which are file opening, data importing, data preprocessing, data clustering, and result query. The overall program flow of the system is as follows.

As shown in Figure 6, the user can specify the stored data file according to the flow instructions and then preprocess the data. After the data are stored in the database, users can choose whether to generate data or not and can query the data.

**3.2. Robo-Advisor Product Design Model.** Assuming that the asset portfolio  $R$  selected by the investor contains  $M$  different asset targets, the capital weight for investing in the  $n$ -th asset is  $X_n$ , and the expected return calculation method of portfolio  $R$  is shown in the following formula:

$$Q_R = \sum_{n=1}^M X_n Q_n. \quad (15)$$

The variance calculation of portfolio  $R$  returns is shown in the following formula:

$$\sigma_R^2 = \sum_{n=1}^M X_n^2 \sigma_n^2 + \sum_{n=1}^M \sum_{\substack{j=1 \\ j \neq n}}^M X_n X_j \sigma_{nj}. \quad (16)$$

For each asset target,  $\sigma_n^2$  is a diversifiable risk, but  $\sigma_{nj}$  is a nondiversifiable overall market risk. Then, when the target expected rate of return of the investment portfolio is determined, the investment portfolio with the least risk has the largest rate of return. The expression is shown in the following formula:

$$\begin{aligned} & \min \alpha^T \sum \alpha \\ \text{u.c.} & \begin{cases} \alpha E(Q_R) = \eta \\ 0 \leq \alpha_n \leq 1 \\ 1^T \alpha = 1 \end{cases} \end{aligned} \quad (17)$$

Among them,  $\eta$  is the expected rate of return of the investment portfolio target and  $\alpha$  is the combination weight of the asset and the covariance matrix between the asset targets.

**3.3. Risk Analysis of Robo-Advisor.** The risk analysis of robo-advisors can be conducted from three aspects: technology, market, and law. Technical risks can be divided into internal and external. The external is cyber risk, and the internal is algorithmic defects and operational risks. The investment effect of market risk on robo-advisors needs to be tested by the market. The homogeneity of robo-advisory algorithms may have an intensifying effect on market resonance, thereby exacerbating the procyclicality of investment behavior. The complexity of robo-advisor business is directly proportional to the correlation between institutions. Legal risks include the contradiction between operational intelligence and fiduciary obligations and the contradiction between the professionalism of algorithms and regulatory methods.

## 4. Discussion on Robo-Advisor Development and Regulatory Issues

### 4.1. Algorithm Performance and System Operation Effect

**4.1.1. Algorithm Performance.** In order to verify the effectiveness of the improved K-means clustering algorithm, three datasets (A, B, and C) in the UCI database are randomly used as experimental datasets. The traditional K-means clustering algorithm, Clara algorithm, and the improved algorithm of this research are used for comparative analysis. The details of the experimental dataset are as follows.

As shown in Table 1, the total number of samples in the three datasets varies, and the number of attributes is also different. There are three cluster centers in dataset B and dataset C and four in dataset A. The traditional K-means clustering algorithm, Clara algorithm, and the improved algorithm of this research are run 10 times to compare the accuracy of clustering. The results are as follows.

As shown in Figure 7, in the three datasets, the accuracy of the clustering results of the traditional K-means clustering algorithm is lower than the Clara algorithm and the improved algorithm in this paper. The accuracy of the improved algorithm in this paper is higher than the traditional K-means clustering algorithm and Clara algorithm. Among them, in dataset B, the improved algorithm has the highest accuracy, up to 97.08%. In dataset C, the traditional K-means clustering algorithm has the lowest accuracy, as low as 62.17%. This shows that the improved algorithm in this

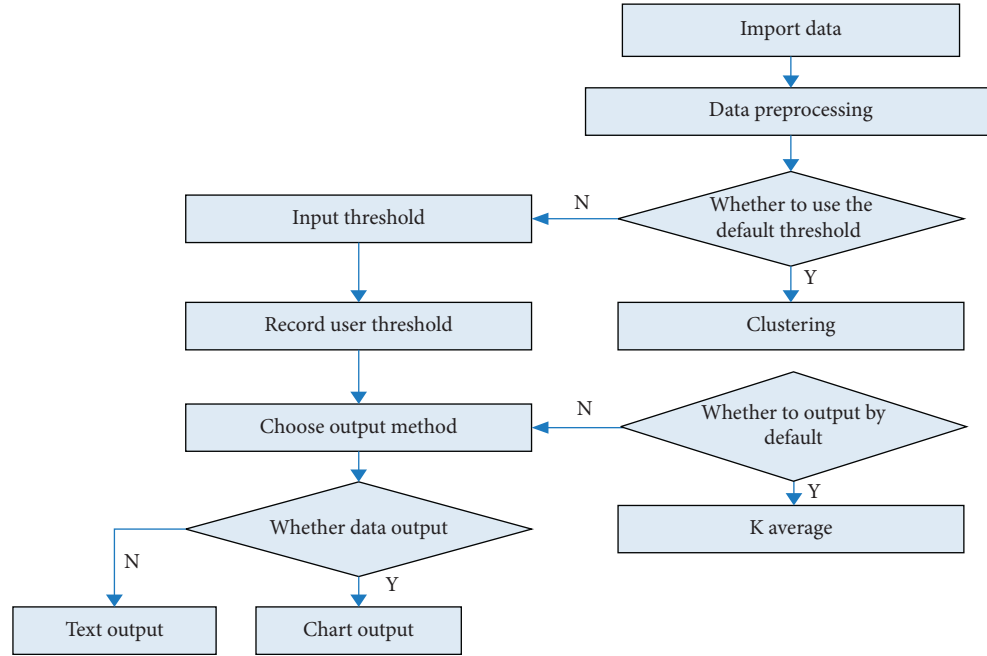

FIGURE 6: System operation flow chart.

TABLE 1: Experimental dataset.

| Dataset | Number of samples | Number of attributes | Number of clusters |
|---------|-------------------|----------------------|--------------------|
| A       | 155               | 5                    | 4                  |
| B       | 180               | 12                   | 3                  |
| C       | 540               | 9                    | 3                  |

paper has a better performance in the accuracy of the clustering results.

Then, compare the number of iterations of the three algorithms in the clustering process to analyze the stability of the algorithms. The results of the number of iterations are compared as follows.

As shown in Figure 8, the improved clustering algorithm in this paper and the traditional K-means clustering algorithm have 4 and 7 iteration times in A dataset, 6 and 11 iterations in B dataset, and 11 and 18 iterations in C dataset, respectively. This shows that the improved algorithm in this paper has strong stability in the selection of initial clustering centers.

**4.1.2. System Operation Effect.** Run a data mining system based on the improved K-means clustering algorithm of this paper to analyze 1804 customers of digital financial institutions. Use the system to divide customers into four categories: high-income customers, low-income customers, customers to be developed, and consumer customers. The criteria for dividing customers are as follows.

As shown in Table 2, there is not much difference in age between the four types of customers, mainly middle-aged people. The salient feature of high-income customers is that their annual income exceeds 100,000 and their deposits exceed one million. The salient feature of low-income

customers is that the annual income is less than 40,000 and the deposit is less than 500,000. The notable feature of the customers to be developed is that they have deposits of more than 500,000, but they have not been used for financial management or loans. The salient feature of consumer customers is that their annual income and deposits are relatively high, the amount used for financial management is higher than the annual income, and the loan amount exceeds 200,000.

After the customer classification standard is established, the type distribution of 1804 customers is analyzed, and the results are as follows.

As shown in Figure 9, among the 1804 customers of digital inclusive financial institutions, the number of customers to be developed is the largest, accounting for 46.12% of the total, and the number of high-income customers is the least, accounting for 10.75% of the total. The main types of customers who bring benefits to financial institutions are high-income customers with the smallest proportion. They often purchase wealth management products and are good at making reasonable use of the inclusive financial system to generate income for themselves.

**4.2. Evaluation and Risk Backtesting of Robo-Advisor Product Models.** Use backtesting analysis to compare the performance of robo-advisor product portfolios with performance benchmarks and evaluate the quality of product design based on the calculation of various indicators. The five risk-level investment portfolios are the capital preservation group, income group, growth and income group, growth group, and capital appreciation group. Compare the performance of the five portfolios from February 1 to 10 and the corresponding performance benchmarks. The results are as follows.

FIGURE 7: Accuracy of clustering results of different algorithms in different datasets.

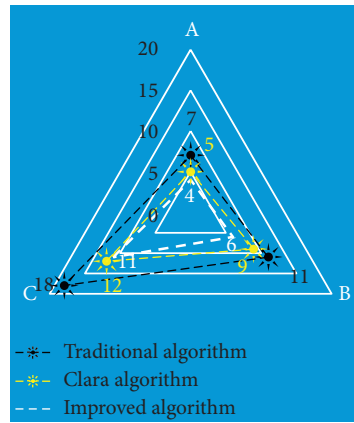

FIGURE 8: Comparison of the number of clustering iterations.

FIGURE 9: Distribution of the number of customers.

TABLE 2: Customer classification standard.

| Standard category    | High income | Low income | To be developed | Consumer |
|----------------------|-------------|------------|-----------------|----------|
| Age                  | 30–50       | <30        | 20–40           | 20–45    |
| Annual income        | >100000     | <40000     | >100000         | >100000  |
| Deposit              | >1000000    | <500000    | >50000          | >500000  |
| Financial management | >100000     | <100000    | 0               | >120000  |
| Loan amount          | >100000     | <30000     | 0               | >200000  |

As shown in Figure 10, select the RMB seven-day notice deposit interest rate, the five-year bank fixed deposit interest rate, half of the sum of the CSI All-in-One Index and the All-

in-China Securities Bond, 70% of the All-in-China Securities Index, and 30% of the All-in-China Securities Bond. The Hehe and China Securities Growth Index are used as the

| Sharpe ratio      | 1.58                 | 1.21     | -0.08             | 0.59     | 0.79                 |

TABLE 4: Comparison of capital budget before system use.

| Item number | Budget item     | Budget amount | Actual amount | Difference |
|-------------|-----------------|---------------|---------------|------------|
| H1          | Income          | 6320000       | 6200000       | 120000     |
| H2          | Tax refund      | 100000        | 120000        | -20000     |
| H3          | Cost of sales   | 4130000       | 3900000       | 230000     |
| H4          | Wage            | 1220000       | 1080000       | 140000     |
| H5          | Travel expenses | 100000        | 90000         | 10000      |
| H6          | Financial costs | 40000         | 30000         | 10000      |

FIGURE 11: Comparison of fund budget after system use.

performance benchmarks for the five risk levels. As can be seen from the figure, the performance of the growth and income portfolio was slightly lower than the performance benchmark on February 9 and February 10 and was better than the performance benchmark in the rest of the time. Other combinations have consistently outperformed performance benchmarks during the analyzed time period.

A backtest analysis of the five major risk-level investment portfolios and the backtest results are as follows.

As shown in Table 3, the combination of growth and income is in a state of diminishing returns in the interval, and other combinations are in an increasing state in both the range of returns and fluctuations. This shows that the construction of the five risk-level investment portfolios is reasonable.

#### 4.3. Effects and Suggestions of Robo-Advisor Supervision

**4.3.1. Effect of Robo-Advisor Supervision.** Analyze the fund budget of an inclusive financial institution before and after using the data mining system of this research. The 6 items of income, tax rebates, sales costs, wages, travel expenses, and financial costs (the item numbers are H1, H2, H3, H4, H5, and H6) are budgeted and compared with the actual amount, and the results are as follows.

As shown in Table 4, before the system was used, there was a big difference between the financial institution's capital budget and actual amount. Among them, the difference in cost of sales is the largest, with a difference of 230,000, followed by wages and income, with a difference of 140,000 and 120,000, respectively. After the system is put into use, compare the fund budget and actual amount of these six projects again, and the results are as follows.

As shown in Figure 11, after the system was put into use, the difference between the financial institution's capital budget and the actual amount has narrowed a lot. The budgets for tax rebates, travel expenses, and financial costs were consistent with the actual amounts. The sales cost, which had the biggest difference before, was controlled at 40,000 yuan after the system was used. This shows that the use of the system has greatly helped financial institutions' capital budgets and can improve the accuracy of budgets.

**4.3.2. Suggestions on the Supervision of Robo-Advisors.** Based on the above analysis results, the improvement of the robo-advisory regulatory system must innovate regulatory methods, promote financial pilots, use regulatory technology, and effectively prevent risks brought by opportunities and must rely on the existing financial supervision system and laws and regulations for supervision. The synergy of self-regulatory organizations between industries must be brought into play. Financial institutions must establish and improve dispute resolution and loss compensation mechanisms and information disclosure systems.

## 5. Conclusions

Complexity science is an emerging form of research that reveals the operating rules of complex systems. Complex systems can be found in every corner of life. The development of digital inclusive finance has gone through the four stages of microfinance, microfinance, inclusive finance, and digital finance. A data mining system based on complex systems and clustering algorithms can effectively cluster, help financial institutions analyze customer information, improve the accuracy of capital budgets, and reduce risks for financial institutions.

It is high-income customers who bring benefits to inclusive financial institutions because they often buy financial products and are good at making rational use of the inclusive financial system to generate income for themselves. In this paper, the construction of the five risk-level portfolio is very reasonable. After the risk backtest, we find that except the growth and income portfolio, the performance of other portfolios is better than the performance benchmark, and the interval return and interval volatility are increasing.

We must innovate regulatory methods, promote financial pilots, use regulatory technology, and effectively prevent risks brought by opportunities and must rely on the existing financial supervision system and laws and regulations for supervision. The synergy of self-regulatory organizations between industries must be brought into play. Financial institutions should establish and improve dispute resolution and loss compensation mechanisms and information disclosure systems. Only in this way can the problems that arise in the supervision of robo-advisors be improved, and the robo-advisor system can be improved.

In the research of motion video, the existing target detection methods are susceptible to changes in the motion video scene and cannot accurately detect the motion state of the target. Moving target detection technology is an important branch of computer vision technology. Its function is to implement real-time monitoring, real-time video capture, and detection of objects in the target area and store information that users are interested in as an important basis for exercise. This article focuses on how to efficiently perform motion detection on real-time video. By introducing the mathematical model of image processing, the traditional motion detection algorithm is improved and the improved motion detection algorithm is implemented in the system. This article combines the advantages of the widely used frame difference method, target detection algorithm, and background difference method and introduces the moving object detection method combining these two algorithms. When using Gaussian mixture model for modeling, improve the parts with differences, and keep the unmatched Gaussian distribution so that the modeling effect is similar to the actual background; the binary image is obtained through the difference between frames and the threshold, and the motion change domain is extracted through mathematical morphological filtering, and finally, the moving target is detected. The experiment proved the following: when there are more motion states, the recall rate is slightly better than that of the VIBE algorithm. It decreased about 0.05 or so, but the relative accuracy rate increased by about 0.12, and the increase ratio is significantly higher than the decrease ratio. Departments need to adopt effective target extraction methods. In order to improve the accuracy of moving target detection, this paper studies the method of background model establishment and target extraction and proposes its own improvement.

## 1. Introduction

With the maturity of computer technology, especially multimedia technology, and the processing and analysis theory of digital images, video images, as more direct and richer information carriers, are becoming more and more important research objects. In recent years, with the introduction of highway and digital earth concepts and the widespread application of the Internet, video image information has become an important source and means for humans to obtain and use information. The detection and tracking of target images is based on dynamic image analysis combined with image recognition and image tracking methods to detect targets in image sequences. The process of recognition and follow-up tracking is very important in the

field of image processing. After inspection, it was found that there was a sentence segmentation phenomenon, so the incomplete sentence was deleted directly. Inspection technology is the intersection of image processing technology, machine vision technology, and artificial intelligence technology. Therefore, detection technology has broad prospects in scientific theoretical research and also has broad prospects in practical engineering applications.

The research on video processing technology in foreign countries started early, almost accompanied by the birth of black-and-white TV sets, but limited by the technical level, the development is slow. The combination of embedded system and computer vision and image processing technology forms an object-oriented embedded video processing technology. Shukla and Sharma proposed that moving target

detection and moving target tracking algorithms are the most basic components, especially target detection algorithms, which have a direct impact on the overall performance of video surveillance systems and have been a hot spot in the field of image processing and machine vision. After inspection, it was found that there was a sentence segmentation phenomenon, so the incomplete sentence was deleted directly [1]. Yang et al. proposed an RFID security monitoring system that combines motion sensors and RFID modules. The system application relies on motion detection sensors to detect moving targets [2]. Chebi et al. used frame difference sharpness pattern matching to detect vehicles in motion and incorporated the background removal function into a small portable camera, which can better segment the foreground in the background area [3].

The domestic video surveillance industry initially developed from closed-circuit television surveillance. From simple analog video surveillance to the current purely digital network video surveillance, surveillance systems have been widely used in China recently, and their performance is comparable to that of large foreign companies. Quite a gap. Wang et al. uses the interframe difference method in the detection of moving objects in the video. Compared with the optical flow method, the advantage of the frame difference method is that the calculation speed is very fast, but there is still a big disadvantage, that is, in the detection process, the target object is easily detected [4]. Huang et al. proposed to use Wiener filtering to model and used it to predict the pixel value of the model and regarded the pixels that deviate from the estimated value as the former scenic spot [5]. Huang et al. assumed that the pixel value will change linearly with Gaussian changes over time, so a single Gaussian distribution is adopted to simulate the background model. This method mainly uses a Gaussian distribution to represent the characteristic value of a pixel and detects the pixel of the image. The eigenvalue size of will match the Gaussian distribution to classify the pixels [6].

Moving target detection and tracking are at the bottom of the vision system and are the basis for various subsequent advanced processing such as target classification and behavior understanding. This paper uses an adaptive background subtraction algorithm on a fixed single node to better complete the extraction of the moving area under a complex dynamic background and uses the static and dynamic characteristics of the moving target for multitarget tracking. The model of the tracking system under the condition that a single node can be moved is discussed, and a system model is proposed. In this paper, the contour of the target is detected, and the smallest bounding rectangle of the largest contour is used as the tracking frame of MeanShift, combined with the detection results to track the selected target, and the algorithm is applied to the UAV video to detect and track the target.

## 2. Detection and Adaptive Video Processing of Hyperopia Scene in Sports Video

*2.1. Background Modeling Based on Gaussian Mixture Model.* The  $K$ -Gaussian model is used to model every pixel in RGB color space to represent every pixel in the image. According

to the priority  $\omega_I, t (\omega_I, t = 1, I = 2k)$ , the  $K$ -Gaussian distribution used to describe the color distribution of each point has different weights from high to high  $\omega_I/\sigma_I$ . Let us say you have a low order [7, 8]. Given an appropriate background weight and threshold  $T$ , only the previous distribution within this threshold is considered as background distribution, and the other distribution is foreground distribution. At time  $t$ ,  $X_t$  is the pixel value, and the probability density function can be written as a linear combination of  $K$ -Gaussian distribution.

$$P(x_t) = \sum_{i=1}^k \frac{\omega_{i,t}}{(2\pi)^{d/2} |\text{Cov}_{t,i}|^{1/2}}, \quad (1)$$

where  $\omega_I, t, \mu_I, t, \text{Cov}_i$ , and  $t$  are the weight, mean, and covariance matrices of the  $i$  Gaussian distribution at time  $t$ , respectively. The  $K$ -Gaussian distribution is sorted in descending order of priority ( $\omega_I/\sigma_I$ ), while the previous  $b$  Gaussian distribution is used to represent the background distribution, for example,

$$B = \arg \min \left( \sum_{i=1}^b \omega_{i,t} > T \right), \quad (2)$$

where  $t$  is the set background threshold. For the convenience of calculation, it is assumed that the red, green, and blue components of pixels are independent of each other.

$$\begin{aligned} x_t &= (x_{r,t}^t, x_{g,t}^t, x_{b,t}^t), \\ \mu_{j,t} &= (\mu_{j,t}^r, \mu_{j,t}^g, \mu_{j,t}^b), \\ \text{Cov}_{i,t} &= (\text{Cov}_{i,t}^r, \text{Cov}_{i,t}^g, \text{Cov}_{i,t}^b). \end{aligned} \quad (3)$$

*2.2. Automatic Extraction of Stadium Main Area Based on Histogram Statistics.* The document used statistical information on the differences of color elements to distinguish legal areas. For the main characteristics of the green soccer field and the lawn tennis court, the extraction algorithm is used based on the difference in component color information. In the lawn area, the green element of the pixel is larger than the red and blue elements. The differences between the green component and the other two components were calculated and then the color characteristics of the lawn were obtained by threshold treatment. The grass area is extracted from the image, and the binary image is achieved by threshold processing [9, 10].

$$I(x, y) = \begin{cases} 1, & G(x, y) - R(x, y) > T \text{ and } (G(x, y) - B(x, y)) > T_b, \\ 0, & \text{other.} \end{cases} \quad (4)$$

Among them,  $R(x, y)$ ,  $G(x, y)$ , and  $B(x, y)$  are pixel values of color image and  $T_R$  and  $T_B$  are two thresholds which can be adjusted according to the position. Choosing reasonable parameters in the green football field, the extraction accuracy of the main areas of the stadium is relatively accurate [11, 12]. However, this algorithm can only be

used in lawns and other places with prior knowledge and cannot be extracted adaptively.

After inspection, it was found that there was a sentence segmentation phenomenon, so the incomplete sentence was deleted directly. Due to the influence of noise and other factors in the imaging process, there are many small noises or small areas in the main area of the segmented stadium, so it is impossible to remove them directly by removing small areas. According to the nature of noise, the method of eliminating block motion noise can solve this problem well [13, 14]. The blocking operation used in this paper is noise algorithm which is as follows: the image is divided into  $n \times n$  blocks, and the statistical value of stadium color in each block is greater than a certain percentage; the block is regarded as stadium; otherwise, the stadium block is considered. The formula is

$$B(i, j) \begin{cases} 1, & \text{if } \sum_{y=N*j}^{y=N*(j+1)} \sum_{x=N*i}^{x=N*(i+1)} G(x, y) > T \times (N^2), \\ 0, & \text{other.} \end{cases} \quad (5)$$

Among them,  $B(I, J)$  is a binary result graph composed of  $n \times n$  blocks,  $G(x, y)$  is the primary extracted main area of the course, and  $t$  is the proportion of the area. In most cases,  $t$  is 0.6 and  $n$  is 36.

It is assumed that the gray value of the pixel at the same point does not change significantly in two consecutive frames, so it can be considered to be approximately equal as shown in the following formula:

$$f(x + dx, y + dy, t + dt) = f(x, y, t). \quad (6)$$

Among them,  $f(x, y, t)$  is the gray scale of pixel  $(x, y)$  at time  $t$  and  $f(x + dx, y + dy, t + dt)$  is the gray scale of  $(x, y)$  moving to pixel  $(x + dx, y + dy)$ . Since the foundation of the algorithm is based on gray level consistency, it is also necessary to assume that formula (7) holds, namely:

$$\frac{\partial f(x + dx, y + dy, t + dt)}{\partial t} = 0. \quad (7)$$

After the second-order Taylor formula expansion and simplification of formula (7), we can obtain the optical flow field calculation formula:

$$\frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt} + \frac{\partial f}{\partial t} = 0. \quad (8)$$

Among them,  $(\partial f / \partial x)$  can be understood as the gradient of the brightness of the image in the horizontal direction,  $(dx / dt)$  can be understood as the gradient in the vertical direction,  $(\partial f / \partial t)$  can be understood as the gradient in time, and  $(dx / dt)$  and  $(dy / dt)$  are the optical flow in the horizontal direction and optical flow in the vertical direction, respectively.

**2.3. Eigen Image Filtering.** Among various image processing methods, adjusting pixels is the most basic image processing method. It can adjust the changes of the image under different illuminations through the logarithmic conversion of the pixel value. In addition, rendering is also a kind of image processing, and reasonable rendering can make the image

clearer [15, 16]. Recently, Finlayson proposed a new intrinsic image algorithm, and by calibrating the camera's sensitive equipment, the color image is converted into one-dimensional gray-scale image, thus eliminating the influence of shadow. We use this method in this article because there are few restrictions on this method, and it is not very strict. At the same time, this paper provides a method to improve the calibration technology and expand the scope of the algorithm.

Assuming that the Lambert model can be used in the imaging process of the camera photoreceptor, an integral formula can be used to describe the response of each color channel of the photoreceptor [17, 18].

$$\rho_k(x, y) = \sigma(x, y) \int E(\lambda, x, y) S(\lambda, x, y) Q_k(\lambda) d\lambda, \quad (9)$$

where  $k = B_{GR}$  represents the index of the color channel,  $Q_k$  is the spectral response function of the  $k$ th color sensing device,  $\sigma(x, y)$  is the Lambert light dark coefficient, which is the dot product of the normal vector of the reflection plane and the direction vector of the incident light,  $E(\lambda, x, y)$  is the spectral energy distribution function of the incident light, and  $S(\lambda, x, y)$  is the reflection function of the object surface. If the following two conditions are met at each point of the photosensitive device: the spectral response function of each color channel is a Dirac function and the illuminance function of the incident light can use Planck model, then  $Q_k(\lambda)$  and  $E(\lambda, x, y)$  can be expressed as follows:

$$Q_k(\lambda) = q_k \delta(\lambda - \lambda_k), \quad (10)$$

$$E(\lambda, T) \approx I_c \lambda^{-5} e^{-(c_2/T\lambda)}, \quad (11)$$

where  $Q_k$  is the response strength of the inductor. Because every pixel needs to be considered, the pixel position parameter in the function is removed.  $I$  refers to the absolute parameter of light control  $c_1$  and  $c_2$  refer to the intensity of light, and,  $t$  refers to the absolute temperature. Substituting formulas (7) and (8) into formula (6) yields

$$P_k = \sigma I_{c_1} \lambda_k^{-5} e^{-(c_2/T\lambda)} S(\lambda_k) q_k. \quad (12)$$

Now establish the ratio of the two channels:

$$r_k = \frac{P_k}{P_p}. \quad (13)$$

If  $p = G$ , then  $k = R, B$ ; take the natural logarithm for formula (10) and use two values to form a two-dimensional vector ( $R/G$ ):

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \log\left(\frac{S_R}{S_G}\right) \\ \log\left(\frac{S_B}{S_G}\right) \end{bmatrix} + \frac{1}{T} \begin{bmatrix} e_R - e_G \\ e_B - e_G \end{bmatrix}, \quad (14)$$

where  $\lambda_1 = R/G$  and  $\lambda_2 = B/k$ ; from (11), it can be seen that the first term on the right side of the formula is a constant, whose value is determined jointly by the reflecting surface

and the camera, and the second term is determined by the incident light temperature and the camera. With the change of the temperature of the incident light, the image points of the same medium are distributed along a straight line in the two-dimensional plane, and this straight line is only related to the camera, not to the incident light and the reflection plane [19, 20].

The basic idea of the interframe difference method is to obtain the shape of the moving target by performing the difference operation on two consecutive frames of the video image sequence.

The change between the images  $f_k(x, y)$  and  $f_{k+1}(x, y)$  of frame  $k$  and frame  $k + 1$  is represented by a two-finger differential image  $D(x, y)$ , as shown in the following formula:

$$D(x, y) = \begin{cases} 1, & \text{if } |f_{k+1}(x, y) - f_k(x, y)| > T, \\ 0, & \text{others.} \end{cases} \quad (15)$$

In formula (15), 0 corresponds to the area where the two frames of images have not changed and 1 corresponds to the area that has changed. The flowchart of the interframe difference method is shown in Figure 1.

**2.4. Background Recognition Modeling.** The common methods of background model building and updating are the statistical average method, coefficient updating method, Gauss model method, etc [21, 22]. The complexity of various methods of background model building and updating is different, and the effect of background model obtained is also different.

The statistical average method is to average the continuous video sequence and take the average value as the pixel value in the current background model. Assuming that the current video sequence is the  $n$ th frame, then the current time background model is common, and the formula is as follows [23, 24]:

$$B_{n-1}(i, j) = \frac{\sum_{k=1}^{n-1} f_k(i, j)}{n-1},$$

$$B_{n-1}(i, j) = (1 - \alpha)B_{n-2}(i, j) + \alpha f_n(i, j),$$

$$\mu_{n-1}(i, j) = \frac{1}{n-1} \sum_{k=1}^{n-1} f_k(i, j), \quad (16)$$

$$\sigma_{n-1}^2(i, j) = \frac{1}{n-1} \sum_{k=1}^{n-1} [f_k(i, j) - \mu(i, j)]^2,$$

where  $f_k(i, j)$  the pixel gray value at the  $k$  image coordinate  $(i, j)$ . When the  $H$ -th image is acquired [25, 26], the system will get the gray value. According to the above formula transformation process, the improved Gaussian function formula is as follows:

$$\mu_{n-1}(i, j) = (1 - \alpha)\mu_{n-1}(i, j) + \alpha f_n(i, j),$$

$$\sigma_n^2(i, j) = (1 - \alpha)\sigma_{n-1}^2(i, j) + \alpha [f_n(i, j) - \mu_n(i, j)]^2. \quad (17)$$

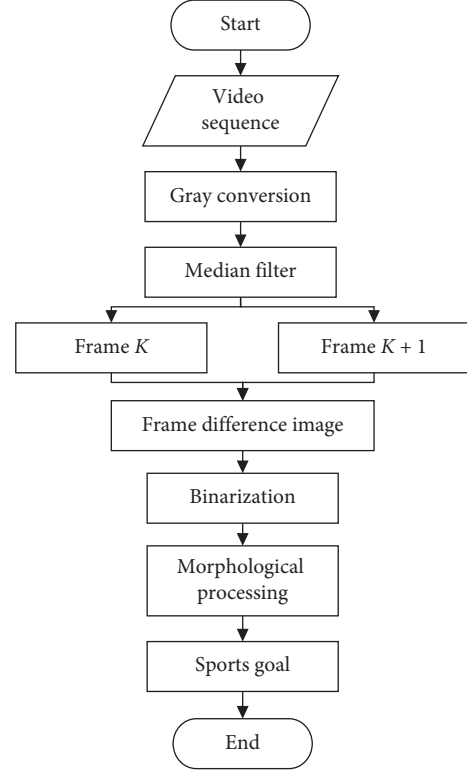

FIGURE 1: Interframe difference method flowchart.

Firstly, the first image of video sequence is used as the initial background, and the current tilt image  $f_n$  at  $n$  time in the post  $w$  sequence matrix is used with the previous moment background image  $F_0$  [27, 28]. A background model updating template is obtained by differential operation, and the common  $CB_{n-1}$  is obtained by binarization of the updated template with decision threshold  $BT_n$ :

$$BT_n(i, j) = \begin{cases} 0 \\ 1 |F_n(i, j) - CB_{n-1}(i, j)| > D. \end{cases} \quad (18)$$

Background image  $CB_n$  is updated as follows:

$$CB_n(i, j) = \begin{cases} CB_{n-1}(i, j), \\ \omega_1 CB_{n-1}(i, j) + \omega_2 F_n(i, j). \end{cases} \quad (19)$$

### 3. Hyperopia Scene Detection and Adaptive Video Processing Experiment Design

**3.1. System Design.** The image acquisition subsystem divides the video information collected by the USB camera into two parts. The first part is transmitted to the real-time monitoring client through the network; the other part enters the moving target detection subsystem. When a moving target passes in the surveillance area, the system will quickly detect the target. The subsystem calls the alarm subsystem to perform alarm work and at the same time compresses and saves the video pictures and several continuous screenshots when moving objects appear in the monitoring area through the image compression subsystem and the storage subsystem

and saves them locally. When a user wants to find a moving target, he can view the video or picture through the WEB subsystem of the network to quickly find the target object. The process is shown in Figure 2.

**3.2. Test Subject.** In order to compare the effect and processing speed of the remote scene detection system in this article, the system in this article is compared with several common systems that use other algorithms. The main comparison algorithms are GMG algorithm, GMM detection algorithm, IMBS detection algorithm, KDE detection algorithm, and VIBE detection algorithm; the algorithm in this article is an improved VIBE detection algorithm. The video images of the experimental database are used for qualitative comparison, and these experimental data are collected for data analysis to draw conclusions. In this paper, the precision rate and recall rate are used as indicators to evaluate the detection algorithm, and the processing speed is also used as the evaluation indicator. After inspection, it was found that there was a sentence segmentation phenomenon, so the incomplete sentence was deleted directly. The larger the value, the better the detection of the algorithm; the smaller the value of processing speed, the better the detection of the algorithm.

**3.3. Experimental Method.** First, it is necessary to fill the image with holes to remove small target impurities, that is, when there are disturbances in the background, such as the shaking of leaves, or the misdetection caused by changes in illumination, this will cause some false small targets in the foreground image. And there will be some defects and holes in the detected moving target, which will have an impact on the subsequent contour detection and tracking. In intelligent monitoring, some false targets will cause false alarms and incomplete targets will cause missed detection. Secondly, the circumscribed rectangle of the detected target after improvement needs to be used as the initial target of the MeanShift tracking algorithm. The contour of the final target image will be detected. After the moving target is obtained, the moving target to be tracked is selected, that is, select tracking target area, tracking the target.

**3.4. Statistical Data Processing Method.** SPSS23.0 software was used for data processing, and the count data were expressed in percentage (%);  $k$  is the number of data in this experiment,  $\sigma^2$  is the variance of all survey results, and  $P < 0.05$  indicates that the difference is statistically significant. The formula for calculating reliability is as follows:

$$a = \frac{k}{k-1} \left( 1 - \frac{\sum \sigma_i^2}{\sigma^2} \right). \quad (20)$$

## 4. Experimental Hyperopia Scene Detection and Adaptive Video Processing

**4.1. Evaluation Index System Based on Index Reliability Testing.** Reliability refers to the stability and reliability of the questionnaire. This article adopts the  $\alpha$  coefficient method created by L.J. Cronbach. The  $\alpha$  coefficient can be obtained

by reliability analysis in SPSS software. It is generally believed that the  $\alpha$  coefficient above 0.8 indicates that the effect of the index setting is very good, and above 0.7 is also acceptable. Here we analyze the reliability of each type of object, and the reliability index we choose for each type of object is slightly different. The results are shown in Table 1.

It can be seen from Table 1 that there are certain differences in the processing results of different scenes, but these processing results can be optimized technically, so the difference between the processing effects of different scenes has an acceptable impact on this experiment ( $\alpha > 0.7$ ). In order to better illustrate the detection effect, corresponding indicators are used to evaluate the detection effect. According to the segmented real foreground image, many indicators are used to evaluate the background modeling algorithm.

### 4.2. Comparison and Analysis of Detection Algorithms

**4.2.1. Effect Analysis of Baseline Video Library Scene.** First, we analyze the scenes of the baseline video library and compare the effect analysis of the algorithm used in the system with that of other algorithms. Here, five scenes are selected for comparative analysis: highway scene, indirect motion scene, scene with similar color, small target scene, and hyperopia scene. The results of the target scene and the hyperopia scene are shown in Table 2. We make a bar graph based on this result, as shown in Figure 3.

It can be seen from Figure 3 that although the GMG detection algorithm can detect a relatively complete target, the algorithm is more sensitive to illumination changes and background disturbance; the GMM detection algorithm is more obvious in the detection of the target wheel, but it is not easy to find it inside the target and when the target is hidden. When the background is more complex, the detection effect is not very good; the IMBS detection algorithm has a good detection effect, but it is very sensitive to light changes and background disturbance; the KDE detection algorithm has a bad detection effect, and the algorithm is more sensitive to the contour of the object. The detection rate is very high; the VIBE detection algorithm is more robust to illumination and background disturbance; the detection algorithm in this paper maintains the advantages of the VIBE algorithm and further improves the detection accuracy.

**4.2.2. Effect Analysis of Dynamic Background Video Library Scene.** We analyze the scenes of the dynamic background video library and compare the effect analysis of the algorithm used in the system with that of other algorithms. Here, five scenes are selected for comparative analysis: the oar shaking scene, water wave shaking scene, leaf shaking scene, fountain scene, and hyperopia scene. The results of the fountain scene and the hyperopia scene are shown in Table 3. We make a histogram based on this result, as shown in Figure 4.

It can be seen from Figure 4 that the GMG detection algorithm is very sensitive to background disturbances, and background disturbances have a great influence on the detection effect; the detection effect of GMM detection algorithm is not ideal for background disturbances; the IMBS

TABLE 1: Summary of reliability test results.

| Category                   | Index combination   | Alpha coefficient ( $\alpha$ ) |
|----------------------------|---------------------|--------------------------------|
| Highway scene              | Heuristic rule      | 0.8632                         |
|                            | Spatial correlation |                                |
| Indirect motion scene      | Heuristic rule      | 0.8447                         |
|                            | Spatial correlation |                                |
| Scenes with similar colors | Heuristic rule      | 0.7365                         |
|                            | Spatial correlation |                                |
| Small target scene         | Heuristic rule      | 0.7746                         |
|                            | Spatial correlation |                                |
| Hyperopia scene            | Heuristic rule      | 0.8124                         |
|                            | Spatial correlation |                                |

detection algorithm is very sensitive to the interference of leaf shaking, and there is a lot of false detection rate; VIBE detection algorithm still has a little false detection; the detection algorithm in this paper reduces the target of false detection for the rippling of water waves and the shaking of leaves, and it can also detect moving targets.

#### 4.2.3. Effect Analysis of Camera Shake Video Library Scene.

We analyze the scenes of the camera shake video library and compare the effect analysis of the algorithm used in the system with that of other algorithms. Here, five scenes are selected for comparative analysis, namely: badminton court scene, highway scene, zebra crossing scene, road scene, and hyperopia scene. The results are shown in Table 4, and we make a line chart based on this result, as shown in Figure 5.

It can be seen from Figure 5 that the GMG detection algorithm has a relatively high false detection rate for camera shake. Although the complexity of the GMM detection algorithm is reduced, its detection accuracy is not very high; although the KDE detection algorithm has a high detection rate, there are still errors, while the IMBS detection algorithm has large errors, and its detection effect needs to be further improved; the false detection rate of the VIBE

detection algorithm is relatively reduced, but there will still be some false warnings. The detection algorithm in this article guarantees the detection accuracy and reduces the false detection rate.

### 4.3. Evaluation Index Analysis

**4.3.1. Analysis of the Accuracy Index of Dynamic Background Video Library Scene Detection.** We analyze the detection accuracy index of dynamic background video library scenes and compare the algorithm used in this paper with other algorithms to analyze the motion state of people in the video and determine its accuracy. Here, five scenes are selected for comparative analysis. They are badminton court scene, basketball court scene, street scene, park scene, and hyperopia scene. The results are shown in Table 5. We make a combined picture based on this result, as shown in Figure 6.

It can be seen from Figure 6 that for the five scenes with dynamic background, there are fast-moving people or indirect-moving people, there are changes in illumination, and the leaves are slightly shaking. The improved algorithm in this paper is relatively stable in the detection accuracy index value. Compared with the original VIBE algorithm, it has increased to a certain percentage, so it verifies the effectiveness of the improved method in this paper.

**4.3.2. Analysis of the Recall Rate Index of Dynamic Background Video Library Scene Detection.** We analyze the detection recall rate index for the scene of the dynamic background video library and compare the algorithm used in this paper with other algorithms to analyze the motion state of people in the video and determine the recall rate. The results are shown in Table 6. This result makes a bar graph, as shown in Figure 7.

The improved algorithm in this paper has different recall rates for different scenarios. As can be seen from Figure 7, the recall rate is higher than that of the VIBE algorithm when

TABLE 2: Baseline video library scene effect analysis data.

| Algorithm                           | Highway scene | Indirect motion scene | Scenes with similar colors | Small target scene | Hyperopia scene |
|-------------------------------------|---------------|-----------------------|----------------------------|--------------------|-----------------|
| GMG detection algorithm             | 1.42          | 1.6                   | 1.83                       | 2.39               | 2.56            |
| GMM detection algorithm             | 1.62          | 1.85                  | 2.33                       | 2.45               | 3.11            |

| IMBS detection algorithm            | 2.21              | 2.04                     | 2.13               | 2.81           | 3.31            |
| KDE detection algorithm             | 2.39              | 2.17                     | 3.11               | 3.01           | 3.52            |
| VIBE detection algorithm            | 3.18              | 2.42                     | 3.04               | 3.77           | 3.79            |
| Detection algorithm of this article | 3.23              | 3.12                     | 3.63               | 3.93           | 4.16            |

the motion state is relatively uniform, and when there are more motion states, the recall rate is slightly better than that of the VIBE algorithm. It decreased about 0.05 or so, but the relative accuracy rate increased by about 0.12, and the increase ratio is significantly higher than the decrease ratio.

**4.3.3. Analysis of the Speed Index of the Dynamic Background Video Library Scene Detection.** We analyze the detection speed index of the scene of the dynamic background video library and compare the algorithm used in this paper with other algorithms to analyze the motion state of people in the video and determine the detection speed. The results are shown in Table 7. The result is a histogram, as shown in Figure 8.

The improved algorithm in this paper has different detection speed changes for different scenarios. From Figure 8, it can be seen that when the motion state is relatively uniform, the increase in detection speed is not too large. When there are more motion states, the detection speed increases. It can be clearly observed.

**4.3.4. Analysis of the Accuracy Index of Camera Shake Video Library Scene Detection.** We analyze the detection accuracy index of the camera shake video library scene and compare the algorithm used in this paper with other algorithms to analyze the motion state of people in the video and determine its accuracy. Here, five scenes are selected for

FIGURE 4: Effect analysis diagram of dynamic background video library scene.

| GMG detection algorithm             | 5.01                  | 4.12          | 3.84                 | 3.45       | 4.87            |
| GMM detection algorithm             | 1.95                  | 2.19          | 3.02                 | 5.52       | 4.32            |
| IMBS detection algorithm            | 2.50                  | 1.32          | 1.88                 | 2.59       | 3.70            |
| KDE detection algorithm             | 2.81                  | 4.15          | 6.20                 | 5.65       | 6.53            |
| VIBE detection algorithm            | 3.41                  | 3.12          | 4.83                 | 5.19       | 7.03            |
| Detection algorithm of this article | 5.12                  | 4.91          | 4.80                 | 4.82       | 7.79            |

FIGURE 5: Effect analysis diagram of camera shake video library scene.

comparison and analysis. These are subway station scene, highway scene, zebra crossing scene, road scene, and far vision scene. The results are shown in Table 8. We make a histogram based on this result, as shown in Figure 9.

It can be seen from Figure 9 and from the experimental data that for the five complex scenes of camera shake, the effect of the improved algorithm in this paper is relatively stable in the detection accuracy index value, and the false detection rate is lower than that of other algorithms. The VIBE algorithm has been improved, so for camera shake, the detection effect is better than that of other algorithms.

*4.3.5. Analysis of the Recall Rate Index of Camera Shake Video Library Scene Detection.* We analyze the detection recall rate index of the camera shake video library scene and compare the algorithm used in this paper with other algorithms to analyze the motion state of people in the video and judge the recall rate. The results are shown in Table 9. This result makes a histogram, as shown in Figure 10.

The improved algorithm in this article has different recall rates for different scenarios. As shown in Figure 10, when the motion state is relatively uniform, the recall rate is higher than that of the VIBE algorithm, and when the motion state increases, it is higher than that of the VIBE algorithm. There is only an increase of about 0.02, but the relative accuracy rate has increased by about 0.08, and the improvement ratio is significantly higher.

4.3.6. *Analysis of the Speed Index of Camera Shake Video Library Scene Detection.* We analyze the detection speed index of the camera shake video library scene and compare the algorithm used in this paper with other algorithms to analyze the motion state of people in the video and determine the detection speed. The results are shown in Table 10. The result is a histogram, as shown in Figure 11.

The improved algorithm in this paper has different detection speeds for different scenarios. From Figure 11, it can be seen that when the motion state is relatively uniform, the detection speed will increase slightly due to the increase in the number of people to be detected. When the motion state increases, it will not increase because of the increase in the number of people tested.

FIGURE 11: Speed detection indicators for camera shake video library scene.

## 5. Conclusions

This topic is derived from a target image search project of a certain research. It detects intrusive moving targets in the monitored warning area. The background of the video is more complicated. Since the characteristics of the moving target are unknown, the background subtraction method is used. The key step of this method is the establishment of the background

model, the target extraction, and the update of the background model method; only the generated background model has good adaptability to the changes of the complex background and can reflect the real background image, and the target needs to be extracted after the background model is established. Departments need to adopt effective target extraction methods. In order to improve the accuracy of moving target detection, this paper studies the method of background model establishment and target extraction and proposes its own improvement.

Afterwards, an improved detection algorithm is used to clean and delete the shadow area of the moving target in order to better track the target. Combining the improved VIBE algorithm and the shadow removal of multifeature fusion, it has been verified by experiments to effectively remove the shadow of the detected target, making the detected moving target more accurate. Finally, we detect the maximum contour of the target from which the shadow is removed, use the minimum bounding rectangle of the target as the initial window of MeanShift tracking, and combine the detection results to track the target. Through comparison and verification, the MeanShift tracking algorithm combined with the improved detection algorithm in this paper has better tracking effect than the MeanShift algorithm without combined improvement. In this paper, the improved detection and tracking methods are applied to the video images captured by the drone, and the moving targets in the video are detected and the targets are tracked. It can be seen from the experimental results that the moving targets in the video taken by the drone are clearer. The target detection and tracking effect is relatively ideal, which further proves the effectiveness of the improved method in this paper.

By applying the detection and tracking system of moving objects to sports video, the system will process the collected motion information data and obtain the motion parameters of human body. It is very important to send some data to improve the quality of athletes and coaches and expand the development direction of athletes. This paper is based on the background of the research and development of sports video object detection and tracking system, through the Gauss model to separate the scene, through the eigen extraction to extract the characteristics of the players in the stadium, and finally through the difference method to identify the video content, which opens a new idea for the detection and adaptive processing of the athletes in sports video.

In order to improve the impact resistance and mechanical performance of anchor rods and satisfy the requirements for supporting rockburst roadways, the energy balance equation of the energy-absorbing support and roadway surrounding rock system is established. Moreover, to effectively prevent rockburst disasters, the energy criterion for roadway instability is derived. From the perspective of an energy-absorbing support, a yield-absorbing anti-shock anchor composed of a rod body, tray, constant resistance energy-absorbing device, and special-shaped nut is designed and developed; compared with ordinary anchor rods, this rod has stronger mechanical properties for resisting impact. Theoretical and numerical simulation studies show that the energy-absorbing device has a repeatable deformation failure mode and a constant yield force. The paper also presents the principle involved in the design of anti-shock bolt supports. The energy-absorbing support not only effectively guides and controls the release and conversion of impact energy but also consumes the impact energy in the buffering process of the anchor to ensure the stability of surrounding rock and support protection system. This study aims to provide reference for roadway support design and to improve rock bolts used in rockburst roadways.

## 1. Introduction

The current energy system requires coal to further perform its function as “ballast stone.” Coal is therefore anticipated to continue as China’s leading energy source in the future. The continuous large-scale exploitation of resources in previous decades, however, has exhausted the country’s shallow coal resources. Future exploitations of coal resources are expected to reach depths of 1000–2000 m. At depths beyond 1000 m, the geological conditions of coal resources become more complex, the original rock stress increases, the surrounding rock deformation of roadways becomes severe, and ground pressure impact becomes the primary threat leading to disaster in many mining areas [1–5]. In Poland, from 1949 to 1982, a total of 3097 large-scale destructive shocks occurred, causing 401 deaths and damaging 1, 20, 000 m of wells and roads. From 1910 to 1978, the Ruhr Coal Mine in Germany experienced 283 large-scale destructive shocks [6], and from 1933 to 2019, China experienced 9020

destructive coal mine rockbursts [7]. It is predicted that as mining depths increase, rockburst and its resulting series of accidents will increasingly become severe, extremely retarding the exploitation of deep coal resources. The control of surrounding rock of deep roadways is one of the key problems in deep mining theory. In coal mining, the inadequacy of roadway support is the main problem encountered in roadway surrounding rock control as well as rockburst prevention and control.

For rockburst roadway support, a new type of suction bolt with a constant working resistance and good elongation capacity has been developed [8–11]. In reality, suction bolts have been studied by scholars from various countries for over 20 years. In the early 1990s, Ortlepp [12] proposed the concept of an energy-absorbing support system, and Jager [13] developed the first true suction bolt—the cone bolt. It was not until the late 1990s that resin-anchored tapered bolts were introduced [14]. In recent years, having gained in-depth knowledge on energy-

absorbing bolt and supports, experts have developed a variety of supports such as Garford anchor, Durabar anchor, yielding Secura anchor, Roofex anchor, and anchor conceived by Varden et al. [15–17]. With the focus set on the actual surrounding rock deformation of coal mine roadway sustaining ground pressure impact, the negative Poisson's ratio material of the anchor rod (cable) is investigated, and a high constant resistance large deformation anchor cable is designed. Most existing anchor rods are not designed based on attaining strong impact resistance; consequently, they are weak against impact. From the perspective of impact resistant design, most investigations focus on the research and development of new materials and new types of support members. Although the application of these research results has resulted in certain headways, it has also considerably increased the cost of roadway support. In view of the limitations of existing bolts and the dearth of special requirements for tunnel support in sustaining ground pressure impact, a new type of energy-absorbing anti-scour bolt is designed and developed. In order to provide reference for the design and improvement of rock bolt support in rockburst roadway, the structure composition and working principle of this new bolt are investigated.

The specific contributions of this paper include the following:

- (1) The energy balance equation of the energy-absorbing support and roadway surrounding rock system is established based on the principle of energy conservation.
- (2) The energy criterion for the instability of roadway supported by an energy-absorbing system is deduced. Accordingly, the foregoing provides a theoretical basis for energy-absorbing support and anti-scour design.
- (3) This paper presents the principle involved in energy absorption and anti-scour.
- (4) In view of the advantages afforded by energy-absorbing supports, a type of energy-absorbing anti-scour bolt, composed of rod body, tray, constant resistance energy-absorbing device, and special nut, is designed and developed. The test results indicate that the energy-absorbing anti-scour bolt has stronger impact mechanical properties than the ordinary bolt.

The rest of this paper is organized as follows. In Section 2, the energy balance equation of the energy-absorbing support and roadway surrounding rock system is established based on the principle of energy conservation. Moreover, the energy criterion for the instability of roadway supported by an energy-absorbing system is deduced. A type of energy-absorbing anti-scour bolt, composed of rod body, tray, constant resistance energy-absorbing device, and special nut, is designed in Section 3. Section 4 shows the simulation experimental results, and Section 5 concludes the paper with summary.

## 2. Energy Criterion for Instability of Roadway

Rockburst is defined as the sudden and instantaneous release of energy from the coal and rock mass around the roadway. This energy mainly emanates from a source and is transmitted to the roadway in addition to the energy accumulated through the elastic deformation of roadway surrounding rock.

The initial energy of an earthquake (as impact source) is reduced by the propagation of waves through the surrounding rock until the roadway surrounding rock is reached. Let it be assumed that the initial energy of the rockburst source is  $E_z$ , the radius of the circular roadway is  $r$ , the distance from the rockburst source to the center of the roadway is  $d$ , and the energy attenuation index of the rockburst shock wave propagating through the coal rock medium is  $\eta$ . With the foregoing, the energy ( $E_{zh}$ ) released from the impact ground pressure of the impact source is calculated as follows:

$$E_{zh} = E_z (d - r)^{-\eta}. \quad (1)$$

The elastic deformation energy of the roadway surrounding rock that has accumulated in the original rock stress field is expressed by the following equation:

$$E_3 = \iiint_V \left[ \frac{[\sigma_1^2 + \sigma_2^2 + \sigma_3^2 - 2\nu(\sigma_1\sigma_2 + \sigma_1\sigma_3 + \sigma_2\sigma_3)]}{2E} \right] dx dy dz. \quad (2)$$

Upon the initiation of roadway surrounding rock failure, the stress state of the coal rock mass rapidly changes from a three-way to a two-way force and then immediately transforms to a one-way force. According to the minimum energy principle for energy transfer, the energy required for coal rock mass failure is the failure energy under unidirectional stress, i.e., the minimum failure energy ( $E_{\min}$ ).

$$E_{\min} = \frac{\sigma_c^2}{2E}, \quad (3)$$

$$\text{or } E_{\min} = \frac{\tau_c^2}{2G}.$$

In the roadway excavation process, various forms of energy dissipation (e.g., plastic deformation of rock mass, relative joint plane slippage in surrounding rock mass, viscous flow deformation, secondary crack, and crack propagation at the crack tip of surrounding rock mass) occur. If it is presumed that the right side of the equation is  $E_q$ , then the rockburst energy ( $E_p$ ) derived from the elastic deformation energy of the surrounding rock is as follows:

$$E_p = E_3 - E_{\min} - E_q. \quad (4)$$

According to equations (1) and (4), the energy released from coal and roadway surrounding rock mass is obtained when rockburst occurs.

$$E_{cj} = E_{zh} + E_p = E_z (d - r)^{-\eta} + E_3 - E_{\min} - E_q. \quad (5)$$

When rockburst occurs, a part of the energy released by the coal rock mass around the roadway is absorbed by the roadway support structure, and the other part is released to the roadway in the form of coal rock kinetic energy.

If it is assumed that  $\delta$  denotes the maximum deformation of the roadway supporting structure, which can withstand an impact load,  $F_{zf}$ , under the surrounding rock pressure, then the energy absorbed by the elastic deformation of the roadway supporting structure can be calculated as follows:

$$E_{zf} = \frac{\delta F_{zf}}{2}. \quad (6)$$

If it is assumed that the energy released to the roadway in the form of coal rock kinetic energy is  $E_k$  when rockburst occurs, then according to the law of conservation of energy,

$$E_{cj} = E_{zf} + E_k. \quad (7)$$

That is,

$$E_z(d-r)^{-\eta} + E_3 - E_{\min} - E_q = \frac{\delta F_{zf}}{2} + E_k. \quad (8)$$

To prevent the roadway from impacting the ground pressure, the energy ( $E_k$ ) that should be released to the roadway in the form of coal rock kinetic energy must be equal to zero. If  $E_k$  is greater than zero, then

$$E_z(d-r)^{-\eta} + E_3 - E_{\min} - E_q > \frac{\delta F_{zf}}{2}. \quad (9)$$

The foregoing shows that the roadway support structure cannot fully absorb the energy released by rockburst, and the residual energy ( $E_k$ ) will be released to the roadway in the form of coal rock kinetic energy, resulting in the damage of the support structure and collapse of the surrounding rock. Equation (9) is therefore the energy criterion for roadway impact failure.

If it is assumed that the support has an energy absorption function and the energy absorbed by the energy-absorbing device is  $E_x$ , then according to equation (8), the energy conservation equation for energy absorption and roadway anti-scour support is expressed as follows:

$$E_z(d-r)^{-\eta} + E_3 - E_{\min} - E_q = \frac{\delta F_{zf}}{2} + E_x + E_r + E_k. \quad (10)$$

If the energy ( $E_{cj}$ ) released by rockburst is greater than the energy ( $E_x$ ) absorbed by the energy-absorbing device and the energy ( $F_{zf}$ ) absorbed by the elastic deformation of the support structure, then

$$E_{cj} = E_z(d-r)^{-\eta} + E_3 - E_{\min} - E_q > E_x + E_r + E_{zf}. \quad (11)$$

This shows that the support cannot completely absorb the impact pressure to release energy, and the remaining energy ( $E_k$ ) is either projected as kinetic energy or transformed into a large displacement of the surrounding rock to free space; this causes support damage and collapse of the roadway surrounding rock. Equation (11) is therefore the

energy criterion for the instability of roadway supported by an energy-absorbing system.

According to the foregoing criterion, the adoption of an energy-absorbing support in the roadway can considerably enhance the anti-impact performance of the support system as well as effectively preclude and control the occurrence of rockburst. Ultimately, the criterion provides a theoretical basis for the anti-impact design of an energy-absorbing bolt support.

### 3. Design of Energy-Absorbing Anti-Impact Anchor

**3.1. Structural Design of Energy-Absorbing Anti-Impact Anchor.** The incorporation of a constant resistance energy-absorbing device to the conventional anchor rod is adopted for the design of the energy-absorbing anti-scour anchor rod shown in Figure 1. This rod includes four parts: rod body (1), tray (2), constant resistance energy-absorbing device (3), and special-shaped nut (4). The right end of the rod body is fabricated with external threads that can be connected to the nut, and the center of the tray has a mounting hole for the rod body. The constant resistance energy-absorbing device, which has a 150–200 mm thin-walled circular tube structure, is placed between the tray and special-shaped nut. The special nut (Figure 2) is fabricated by integrating a round table block, a ring block, and a square block.

**3.2. Theoretical Analysis of Mechanical Properties of Energy-Absorbing Devices.** During impact, existing energy-absorbing devices have large load fluctuations, which do not satisfy the mechanical performance requirements for anti-scour bolt; hence, it is necessary to design a new device [18–20]. The constant resistance energy-absorbing device is designed as a thin-walled circular tube that slides along the round table block of the special nut to achieve a constant resistance yield. Let the outer diameter, inner diameter, and wall thickness of the thin-walled circular tube be  $2R_0$ ,  $2r_0$ , and  $t$ , respectively (note that the inner diameter ( $2r_0$ ) is larger and smaller than the diameters of the left and right circles of the special-shaped nut round block, respectively). Through expansion, these outer and inner diameters are made to transition to the larger outer and inner diameters, denoted as  $2R_1$  and  $2r_1$ , of the rear thin-walled tube, respectively. The round nut angle of the special-shaped nut is  $\alpha$ , the axial compressive stress is  $\sigma_z$ , the radial compressive stress is  $\sigma_n$ , the hoop tensile stress is  $\sigma_\theta$ , and the friction coefficient between the inner wall of the thin-walled tube and special-shaped nut is  $\mu$ . To analyze the expansion force on the thin-walled circular tube, a circular ring-shaped element is obtained from the expansion area bounded by two planes normal to the axis of the tube, as shown in Figure 3 [21].

$$\begin{aligned} & (\sigma_z + d\sigma_z)\pi[(R+dR)^2 - (r+dR)^2] - \sigma_z\pi(R^2 - r^2) \\ & + 2\sigma_n\pi r dR + 2\frac{\mu\sigma_n\pi r}{\tan\alpha} dR = 0. \end{aligned} \quad (12)$$

FIGURE 1: Energy-absorbing anti-impact anchor.

FIGURE 2: Diagram of special-shaped nut.

FIGURE 3: Diameter and base body. (a) Radius expansion diagram. (b) Primitive body force diagram.

Set the basic element in the  $Z$ -axis direction of the equilibrium equation.

Omitting the high-order trace yields the following:

$$(R^2 - r^2)d\sigma_z + 2[(R - r)\sigma_z + \sigma_n r (1 + \mu \cot \alpha)]dR = 0. \quad (13)$$

Assuming that  $\sigma_r$  is the combined stress of the radial compressive and frictional stresses of the toroidal base body, the following relationship can be introduced:

$$\sigma_n = \frac{\sigma_r}{1 - \mu \tan \alpha}. \quad (14)$$

If it is assumed that the wall thickness of the thin-walled tube remains constant during radius expansion, then the corresponding yield condition is

$$\sigma_z + \sigma_\theta = K, \quad (15)$$

where  $K$  is the plane deformation resistance, given as  $K = 1.155\sigma_s$ , and  $\sigma_s$  is the yield stress of the material.

For the stress analysis, half of the circular ring element is considered as shown in Figure 4.

The vertical balance equation is as follows:

$$2\sigma_\theta t = \int_0^\pi \sigma_r r d\theta \cdot \sin \theta. \quad (16)$$

Equation (15) is rewritten as equation (16).

$$\sigma_r = \frac{R - r}{r} (1.15\sigma_s - \sigma_z). \quad (17)$$

Combining equations (17) and (14) and substituting the results into equation (12) yield

$$\frac{d\sigma_z}{\sigma_z a - 1.15\sigma_s(a + 1)} = \frac{2dR}{R + r}, \quad (18)$$

where  $a = (1 + \mu \cot \alpha / 1 - \mu \tan \alpha) - 1$ .

FIGURE 4: Half ring body force diagram.

When the integral of equation (18) is substituted into the boundary condition ( $R = R_0$ ,  $r = r_0$ , and  $\sigma_z = 0$ ), the yield stress of the constant energy-resistive device is given by the following:

$$\sigma_z = \beta \sigma_s \frac{a+1}{a} \left[ 1 - \left( \frac{R_1 + r_1}{R_0 + r_0} \right)^{2a} \right]. \quad (19)$$

In the foregoing,  $\beta = (K/\sigma_s)$ .

The yield force of the constant resistance energy-absorbing device can be obtained from equation (19), as follows:

$$F = \pi(R_0^2 - r_0^2)\sigma_z. \quad (20)$$

That is,

$$F_{\max} = 1.15\pi(R_0^2 - r_0^2)\sigma_s \frac{a+1}{a} \left[ 1 - \left( \frac{R_1 + r_1}{R_0 + r_0} \right)^{2a} \right]. \quad (21)$$

Based on equation (20), it can be concluded that the bearing capacity of the constant resistance energy-absorbing device is influenced by inner diameter, wall thickness, material yield strength, friction coefficient, and other parameters.

The energy absorbed can be calculated as

$$E = F\delta = 1.15\pi(R_0^2 - r_0^2)\sigma_s \frac{a+1}{a} \left[ 1 - \left( \frac{R_1 + r_1}{R_0 + r_0} \right)^{2a} \right] \left( L - \frac{r_1 - r_0}{\sin \theta} \right), \quad (22)$$

where  $L$  and  $\delta$  are the length and compression distance of the thin-walled tube, respectively.

**3.3. Numerical Simulation of Mechanical Properties of Constant Resistance Energy-Absorbing Device.** The model is established using ABAQUS finite element analysis software [22–28]. The special-shaped nut is assumed to be a 160 mm high rigid body with a 110 mm lower end diameter, a 100 mm upper end diameter, and a 10 mm high round table block. Considering the influence of the mechanical properties of thin-walled circular tube materials on energy absorption, three materials, specifically, T700L, Q550, and Q235, are simulated. The material parameters are shown in Tables 1 and 2. The thin-walled circular tube is 3 mm thick

and 150 mm long with a 105 mm inner diameter. The circular tube network is mainly a quadrilateral element with a 2 mm characteristic length. With all degrees of freedom of the special-shaped nut constrained, the thin-walled tube is placed above the nut, and a rigid plate is pressed axially from above the thin-walled tube at a constant speed of 1 m/s. An automatic point-to-surface contact mechanism is used between the rigid plate and circular tube. During the deformation process, the internal and external surfaces of the component are set to self-contact with a 0.3 friction coefficient.

The compression deformation process of the constant resistance energy-absorbing device is shown in Figure 5, and the force and energy absorption displacement curves are shown in Figures 6 and 7, respectively.

- (1) The various materials of the constant resistance energy absorbing-device have stable and repeatable deformation and failure modes during compression.
- (2) The constant resistance energy-absorbing device composed of different materials has a constant force during the yielding process, and the absorbed energy increases approximately linearly with the increase in compression distance. The yielding force and energy absorption results of the device during compression deformation are summarized in Table 1. (a) The yielding force and absorbed energy of T700L are 344 kN and 46.90 kJ, respectively, and the theoretical yielding force and absorbed energy are 347 kN and 45.47 kJ, respectively; the relative errors are 1% and 3%, respectively. (b) The simulated yielding force and absorbed energy of Q550 are 276 kN and 35.33 kJ, respectively, and the theoretical yielding force and absorbed energy are 262 kN and 35.87 kJ, respectively; the relative errors are 5% and 1%, respectively. (c) The simulated yielding force and absorbed energy of Q235 are 156 kN and 20.33 kJ, respectively, and the theoretical yielding force and absorbed energy are 112 kN and 15.10 kJ, respectively; the relative errors are 28% and 26%, respectively.

**3.4. Principles of Energy Absorption, Anti-Scour, and Anti-Scour Bolt Support.** For the energy-absorbing device to effectively function, its displacement force should be greater than the yielding force of the bar body; moreover, the breaking force of the bar body should be low. When the bearing capacity of the bolt is less than its yielding force, the energy-absorbing device will not yield to deformation. The principle of the support afforded by energy-absorbing anti-shock bolts is mainly reflected in two aspects: resistance and yield. The energy-absorbing device is not deformed and destroyed by the resisting bodies under the static pressure of the surrounding rock. The device is allowed to absorb energy to reduce impact when the ground exerts pressure. These processes are reflected in three aspects: first, the energy-absorbing device directly dissipates the impact energy of the surrounding rock

through plastic deformation; second, the resulting conditions effectively improve the impact resistance of the anchor; third, the deformation space of the device provides a certain amount of energy release space for coal rocks. As a result, the surrounding rock impact energy is indirectly dissipated, the release and conversion of impact energy are effectively guided and controlled, and the impact energy is diminished in the buffering process of anchor bolts, thus

ensuring the stability of the surrounding rock and support system of the roadway [29–31].

#### 4. Yielding Test Analysis of Energy-Absorbing Anti-Shock Anchor

The energy-absorbing device theoretically analyzed is made of Q235 material with an inner diameter, wall thickness, and length of 44, 3.5, and 150 mm, respectively. The size of the special-shaped nut is shown in Figure 2. The rod body is made of a 22 mm diameter rebar. Ordinary and energy-absorbing anchor bolts are subjected to static load and impact tests. These tests are performed on a 600 kN anchor bolt static load test bench (Figure 8) and a 300 kN anchor bolt impact test bench (Figure 9). The comparison of the energy-absorbing anchor before and after deformation is shown in Figure 10. The force-displacement curves of the common and energy-absorbing bolts tested are shown in Figure 11; Figure 12 depicts the energy absorption characteristic curves.

The tensile strength, yield distance, and absorbed energies of ordinary and energy-absorbing bolt are summarized in Tables 3 and 4.

- (1) Under static load, the tensile strength, yield distance, and absorption energy of ordinary anchor bolts are 505.46 MPa, 197 mm, and 31.99 kJ respectively, and those of the energy-absorbing anti-scour anchor bolts are 506.46 MPa, 329 mm, and 51.62 kJ, respectively. The tensile strength, yield distance, and absorption energy of the latter are 1, 1.67, and 1.61 times those of the former.

FIGURE 9: 300 kN test bench.

FIGURE 11: Force-displacement curves.

FIGURE 10: Before and after experiment contrast.

FIGURE 12: Energy absorption characteristics.

(2) Under impact load, the tensile strength, yield distance, absorbed energy, and impact time of ordinary bolt are 535.31 MPa, 195 mm, 35.08 kJ, and 0.15 s, and those of the energy-absorbing anti-shock bolt

are 534.84 MPa, 332 mm, 57.63 kJ, and 0.22 s, respectively. The tensile strength, yield distance, absorbed energy, and impact time of the latter are 1, 1.70, 1.64, and 1.47 times those of the former.

TABLE 3: Static loading of ordinary and energy-absorbing anti-shock bolt.

| Bolt form            | Tensile strength (MPa) | Abdicated distance (mm) | Absorbed energy (kJ) |
|----------------------|------------------------|-------------------------|----------------------|
| 335/22 ordinary bolt | 505.46                 | 197                     | 31.99                |
| MSGHS-335/22(1800)   | 506.55                 | 329                     | 51.62                |

TABLE 4: Impact loading of ordinary and energy-absorbing anti-shock bolt.

| Bolt form            | Tensile strength (MPa) | Abdicated distance (mm) | Absorbed energy (kJ) | Impact time (s) |
|----------------------|------------------------|-------------------------|----------------------|-----------------|
| 335/22 ordinary bolt | 535.31                 | 195                     | 35.08                | 0.15            |
| MSGHS-335/22 (1800)  | 534.84                 | 332                     | 57.63                | 0.22            |

- (3) Under the action of impact load, the tensile strength of both ordinary and energy-absorbing anti-impact bolts increase by 5%. The absorbed energy also increases, but the effect of loading mode on bolt displacement is reduced. This demonstrates that the latter has a stronger capacity to absorb energy and longer impact resistance time than the former.

## 5. Conclusion

The energy balance equation of the energy-absorbing support and roadway surrounding rock system is established based on the principle of energy conservation. Moreover, the energy criterion for the instability of roadway supported by an energy-absorbing system is deduced. It can be concluded that this type of support can significantly enhance the anti-scour performance of the support system and effectively prevent the occurrence of rockburst. Accordingly, the foregoing provides a theoretical basis for energy-absorbing support and anti-scour design.

In view of the advantages afforded by energy-absorbing supports, a type of energy-absorbing anti-scour bolt, composed of rod body, tray, constant resistance energy-absorbing device, and special nut, is designed and developed. Based on the theoretical and numerical analyses of mechanical properties, it is concluded that the energy-absorbing device has a repeatable deformation failure mode and a constant yielding force. The test results indicate that the energy-absorbing anti-scour bolt has a stronger impact mechanical properties than the ordinary bolt.

This paper presents the principle involved in energy absorption and anti-scour. The energy-absorbing support effectively guides and controls the release and transformation of impact energy. It also consumes the impact energy in the process of bolt displacement and buffer to ensure the stability of the surrounding rock and support system.

People are ingesting various information from different sense organs all the time to complete different cognitive tasks. The brain integrates and regulates this information. The two significant sensory channels for receiving external information are sight and hearing that have received extensive attention. This paper mainly studies the effect of music and visual-auditory stimulation on electroencephalogram (EEG) of happy emotion recognition based on a complex system. In the experiment, the presentation was used to prepare the experimental stimulation program, and the cognitive neuroscience experimental paradigm of EEG evoked by happy emotion pictures was established. Using 93 videos as natural stimuli, fMRI data were collected. Finally, the collected EEG signals were removed with the eye artifact and baseline drift, and the *t*-test was used to analyze the significant differences of different lead EEG data. Experimental data shows that, by adjusting the parameters of the convolutional neural network, the highest accuracy of the two-classification algorithm can reach 98.8%, and the average accuracy can reach 83.45%. The results show that the brain source under the combined visual and auditory stimulus is not a simple superposition of the brain source of the single visual and auditory stimulation, but a new interactive source is generated.

## 1. Introduction

The study of audiovisual synchrony induced electroencephalogram (EEG) is an important part of the brain-computer interface (BCI) system. The BCI system provides a new way for humans to communicate without relying on peripheral nerves and muscles, that is, to communicate and control the outside world by measuring brain waves or other electrophysiological signals in the human brain. By studying the cognitive mechanism of the brain, exploring its efficient way of information processing, and popularizing the research results in the fields of intelligent systems such as computers, the intelligent processing ability of computers can be improved, so as to promote the rapid development of information science.

By converting the original brainwave signal into characteristic space in the form of string to a certain extent, the signal noise can be reduced, the change mode of brainwave signal can be abstracted, and the local information of

brainwave signal can be kept to the maximum extent. In order to overcome the shortcomings of traditional methods, we extract the modal functions related to specific EEG signal tasks, which greatly improves the performance of emotion classification tasks based on EEG signals.

In the practical application of EEG signal analysis and processing, signal analysis methods such as time domain and frequency domain are successively introduced. Lawhern believes that the BCI uses neural activity as a control signal to communicate directly with the computer. For a given BCI example, the feature extractor and classifier are customized for the different features of the EEG control signal expected to limit its application to this specific signal. Here, he proposed whether it is possible to design a CNN architecture to accurately classify EEG signals from different BCI paradigms while making it as compact as possible. In this work, he introduced EEGNet, a compact convolutional network based on EEG's BCI. He introduced the use of deep convolution and separable convolution to construct an EEG-

specific model, which encapsulates the famous EEG feature extraction concept of BCI. He compared EEGNet with the current state-of-the-art methods of the four BCI paradigms: P300 visual evoked potential, error-related negative response (ERN), motor-related cortical potential (MRCP), and sensorimotor rhythm (SMR). Although the conclusions of his research are correct, the research objects are rather vague [1]. Zhang believes that regularization has become a way to prevent overfitting of the brain-computer interface EEG classification. The effectiveness of regularization is usually highly dependent on the choice of regularization parameters usually determined by cross-validation (CV). However, CV imposes two main restrictions on BCI: (1) the user needs a large amount of training data; (2) it takes a relatively long time to calibrate the classifier. These restrictions will greatly reduce the practicality of the system and may cause users to be reluctant to use BCI. They introduced the sparse Bayesian method to classify EEG by using the Laplacian prior, SLaplace. Under the framework of Bayesian evidence, they use Laplacian priors to learn sparse discriminant vectors in a hierarchical manner. All required model parameters can be automatically estimated from the training data without the need for CV. Although their research is more targeted, it is not comprehensive enough [2]. Van believes that many variables in social sciences, physical sciences, and biological sciences (including neuroscience) are nonnormally distributed. In order to improve the statistical properties of such data or to allow parameter testing, logarithmic or logarithmic transformations are usually used. Box-Cox transformation or ad hoc method is sometimes used for parameters, and for these parameters, there is no known transformation that approximates normality. However, these methods are not always consistent with Gaussian. They discussed a transformation that maps the probability distribution to the normal distribution as much as possible and has precise consistency for the continuous distribution. To illustrate this point, the transformation was applied to the theoretical distribution and applied to quantitative electroencephalogram (qEEG) measurements from repeated recordings of 32 highly abnormal subjects. Consistency with Gauss is better than using logarithm, logarithm, or Box-Cox transformation. Their research lacks experimental data [3].

The main contributions of this paper are as follows: (1) an effective experimental paradigm of cognitive neuroscience is established, and the cognitive law of visual emotion is obtained, which improves the classification recognition rate; (2) the analysis and processing process of EEG signal is improved to promote the better integration of computer science and medicine; (3) the feature extraction and classification algorithm improvement of EEG data are carried out by using ERP technology.

## 2. Emotional Cognition and EEG Signals

*2.1. Emotional Cognition Based on Complex System.* Emotion is a kind of psychological evaluation made by the body for the things in the surrounding environment relative to its own needs. It can be seen that the cognitive process has a very important meaning for the generation and adjustment

of emotions. The body constantly uses cognitive mechanisms to evaluate and judge whether things in the surrounding environment can meet the body's adaptation needs, and on this basis, there are positive or negative emotional reactions. When the body adopts a more concise and clear cognitive structure and strategies, the way the body evaluates things will be relatively simple, and the emotional experience generated at this time is more likely to be in a strong state; and when the human body adopts more complex and changeable cognitive structures and cognitive strategies, the body will evaluate the surrounding things from multiple aspects and multiple levels, and the emotional experience generated at this time is more likely to tend to a mild state; that is, the complexity of the cognitive structure and the difference in cognitive strategies can greatly affect the generation and experience of emotions [4].

Complex system theory is a frontier direction in system science, and its main purpose is to reveal some dynamic behaviors that are difficult to explain with existing scientific methods. Different from the traditional reductionist method, the complex system theory emphasizes the combination of holism and reductionism to analyze the system. Complex systems are very sensitive to changes in individual parameters and partial structures in the system, while the human brain and nervous system are nonlinear and extremely complex systems. Therefore, when conducting research on emotional cognition, people will use the theory of complex systems to better feel the changes in the human body and achieve a high degree of correlation in many fields such as psychology, physiology, and neuroscience.

*2.2. EEG Signal.* When the external stimulation acts on the neurons, the potential difference between the inner and outer sides of the cell membrane decreases, and the excitability is enhanced. As the active potential is generated, a peak pulse will be generated on both sides of the cell membrane, which changes the positive and negative values from the inside to the outside. Synapses are the processes needed to transmit excitability between different neurons, and synapses play a very important role in transmitting excitability. In the process of transmission is excited, excited feeling of cells before contact position after pulse synapses, capsule into the hot spring active, after the release of the neurotransmitter substance synaptic relaxation, like a receiver cell membrane, it can be felt on the surface of the neurotransmitter substance and catch the body cause a series of changes of cell membrane ion channels, to cause the membrane potential of, namely the trigger synapses potential [5].

Brain waves can be roughly regarded as the dominant waveform of sine waves, so the waveform of brain waves can be represented by parameters such as frequency, amplitude, and phase. (1) Alpha waves appear when you are awake and close your eyes quietly. The frequency is 8~13 Hz, and the amplitude is 20~100  $\mu v$ . This is the most rhythmic waveform in brain waves. During visual stimulation or related cognition, the alpha wave will be immediately replaced by the beta wave. (2) Beta waves appear when the brain is excited,

which is related to mental tension and emotional excitement. The frequency is 14~30 Hz and the amplitude is 5~20  $\mu\text{V}$ , which is a fast wave. (3) When Cida waves indicate sleepiness or mental anxiety, the frequency is 4~7 Hz and the amplitude is 10~50  $\mu\text{V}$  when satisfied. (4) Delta waves are under deep anesthesia, hypoxia, or organic brain diseases, with a frequency of 0.5 to 3 Hz and an amplitude of 20 to 200  $\mu\text{V}$ . The actual measured brain wave is a signal composed of the above-mentioned multiple frequency components, which usually contains a lot of background noise [6].

The characteristics of EEG are as follows: (1) EEG is weak and interference noise is strong. Generally, the amplitude of EEG is only about 50  $\mu\text{V}$ . In the observation, the signal of the nonstudy object is very strong; for example, some unavoidable interference factors will cause strong interference noise. Due to these interference factors, the requirements for EEG extraction and processing devices need to be increased. For example, EEG detection systems and analysis systems require high input impedance, high common mode removal ratio, and low noise amplification technology. (2) EEG is unstable and random. The instability of the signal means that the statistical characteristics of the signal have nothing to do with the time of statistical analysis. In fact, the rhythm of brain waves is related to changes in mental state. The nonstationarity of brain waves is caused by certain changes in the physiological factors that constitute brain waves, and it has a relatively strong ability to automatically adapt to the outside world. (3) The frequency domain characteristics of EEG are clear, and power spectrum analysis and various frequency processing technologies decide to occupy a more important position than other physiological telecommunications. (4) There is very important mutual information between each read signal. This is because EEG generally uses multichannel signals obtained by a multielectrode measuring device [7].

**2.3. Emotional Classification of EEG Signals.** Emotional brainwave signals are generated by test subjects under specific emotional stimuli. Compared with sleep-related brain wave analysis tasks, the brain wave signal generated by emotional stimulation is longer. All points of the entire brain wave signal have nothing to do with a specific emotion, and most of the emotions are generated in local parts [8].

The Gaussian process is a collection of probability variables, which are distributed according to the combined Gaussian. In the Gaussian process regression, these probability variables represent the values of independent variable functions. Gaussian process regression assumes that the average value of the independent variable function distribution is 0, and the correlation between them is represented by the covariance function. The commonly used covariance function is as follows [9]:

$$K_{i,j} = K(X_i, X_j) = \theta_0 \exp \left\{ -\frac{1}{2} \sum_{d=1}^{D_1} \eta_d (x_{i,d} - x_{j,d}) \right\}. \quad (1)$$

The fully connected layer usually uses the Softmax model to solve multiclassification problems. The loss function of Softmax is as follows:

$$J(\theta) = -\frac{1}{m} \left[ \sum_{i=1}^m \sum_{j=1}^k l\{y^{(i)} = j\} \log \frac{e^{\theta_j^i}}{\sum_k e^{\theta_k^i}} \right]. \quad (2)$$

In the formula,  $\theta_j^i$  represents the input of the  $j$ th neuron node of the  $l$ th layer (usually the last layer), and  $\sum_k e^{\theta_k^i}$  represents the sum of the inputs of all the neuron nodes of the entire  $l$  layer. In order to prevent the local optimization of  $J(\theta)$ , the weight attenuation term is introduced. The specific expression is as follows:

$$J(\theta) = -\frac{1}{m} \left[ \sum_{i=1}^m \sum_{j=1}^k l\{y^{(i)} = j\} \log \frac{e^{\theta_j^i}}{\sum_k e^{\theta_k^i}} \right] + \frac{\lambda}{2} \sum_{i=1}^m \sum_{j=0}^n \theta_{i,j}^2. \quad (3)$$

Human beings do not recognize things by pixel by pixel but get local information from a part of the area, collect all the local information, and finally integrate it into the global information. In general, in any image, the closer the distance between two pixels is, the greater the correlation between them will be, while the correlation between two pixels that are far away is relatively small [10]. In fact, human neurons can only capture the local information of a picture and do not respond to global information. But in the end, the currently selected attribute is classified according to the impurity function. If selecting this attribute can reduce the impurity, then this attribute can separate the data. If the impurity function is denoted as  $i(t)$ , the purity gain is denoted as

$$\Delta i(t) = i(t_p) - E[i(t_c)] = i(t_p) - P_l[i(t_l)] + P_r[i(t_r)]. \quad (4)$$

Dice similarity coefficient calculation formula is as follows:

$$\text{DICE} = \frac{2|\text{SEG} \cap \text{GT}|}{|\text{SEG}| + |\text{GT}|}, \quad (5)$$

$$y = \alpha W y + \beta_1 X - W \beta_2 X + \varepsilon, \quad (6)$$

$$\ln g d p_{it} = a_0 + a_1 du^* dt + \sum_{i=1}^N b_j X u + \varepsilon_u. \quad (7)$$

Video coefficient calculation formula is as follows:

$$\text{SEN} = \frac{|\text{SEG} \cap \text{GT}|}{\text{GT}}, \quad (8)$$

$$l_{\text{ssim}} = 1 - \frac{(2\mu_x \mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)}, \quad (9)$$

$$\psi = \sum_{x=1}^{\theta} V x = \sum_{x=1}^{\theta} \left( \frac{W x}{\sum_1^n W \mathfrak{S}} S x \right). \quad (10)$$

VOE coefficient calculation formula is as follows:

$$\text{VOE} = 1 - \frac{|\text{SEG} \cap \text{GT}|}{|\text{SEG} \cup \text{GT}|}, \quad (11)$$

$$U_2 = \begin{cases} s - p_1 - kx_2, \\ x - p_2 - k(1 - x_2). \end{cases} \quad (12)$$

RVD coefficient calculation formula is as follows:

$$\text{RVD} = 100\% \times \left( 1 - \frac{|\text{SEG}| - |\text{GT}|}{|\text{GT}|} \right). \quad (13)$$

Jaccard coefficient calculation formula is as follows:

$$\text{Jaccard} = \frac{|\text{SEG} \cap \text{GT}|}{|\text{SEG} \cup \text{GT}|}, \quad (14)$$

$$x_H = \frac{p_2 - p_1 + 1}{2}. \quad (15)$$

**2.4. Physiological Basis of Music- and Image-Induced EEG.** There is a close relationship between emotion and emotion, which is both difference and connection. The process of cognition is accompanied by human emotions and emotions. It comes from the process of cognition and affects the conduct of cognition and activities.

When we have different emotions such as joy, anger, and sadness, we usually have emotions first and then emotions. The generation of emotion does not need conditioned reflex, while emotion is gradually acquired and evolved in the society. Emotions are extremely unstable and emotions are relatively stable. Generally, the emotion is not stable, which is situational and temporary. Compared with emotion, emotion is more stable, which is an embodiment of essence and will not change at any time. Inducing different emotions is the most important premise of emotion research. Emotion can be induced by external stimulation and internal response. At present, the common methods of emotion induction can be divided into two types: subjective induction and event induction. The subject elicitation is to make the subjects recall the memory fragments with emotional color or imagine the scene with a specific emotional state to induce the specific emotions of the subjects. The disadvantage of this method is that it cannot ensure that the participants can recall the corresponding memory fragments or imagine the scene of a specific emotional state, so it is difficult to ensure that the subjects can successfully induce specific emotions; even if the induction is successful, it is difficult to measure the duration of the corresponding emotions. Event elicitation is based on the mirror neuron theory, using external means to induce subjects to produce corresponding emotions. It is the most common event inducing method to induce the subjects' different emotions through external stimuli such as pictures, music, and video, and it is also the most commonly used emotion-inducing method by researchers. Emotion induction is the precondition of emotion recognition research. If the subjects' emotion cannot be

induced successfully, the follow-up research will not be conducted or the wrong results will be obtained [11, 12].

### 3. EEG Experiment on Emotional Cognition under Visual and Auditory Synergy Stimulation

**3.1. Experimental Data Set.** The DEAP data set includes a preprocessed version of the original EEG signal, and its main content is shown in Table 1. This version downsamples the original signal, and the sampling frequency is after 128 Hz. The signal is filtered at 4 to 45 Hz through a bandpass filter, and then the traces of the electrical signal are removed by blind source separation. In this experiment, 32 induced EEG signals in the data set were set to 5.0, and joy, arousal, and excitement were classified as low (score <5.0) and high (score ≥5.0), respectively; in 3 emotional dimensions, two classifications were made separately [13].

**3.2. Experimental Platform.** The experiment uses presentation to write the experimental stimulation program. Presentation can interact well with ERP, MEG, fMRI, and so on and is often used for stimulus presentation and experimental process control in cognitive experiments. It runs under the Windows environment and can reach millisecond time accuracy [14].

#### 3.3. Experimental Process

- (1) fMRI data collection was performed using 93 videos as natural stimuli. These videos were divided into eight large segments and played to three subjects using an MRI-compatible VR eyewear device, while they were scanned by fMRI. Parameters were 30-axis slice, matrix size 64 × 64, layer thickness 4 mm, 220 mmFOV, TR = 1.5 s, TE = 25 ms, and ASSET = 2 [15].
- (2) In order to prevent subjects from being stimulated by strong picture colors during the experiment, the experiment adopted a black background with a resolution of 640\*480 and a size equal to half of the screen. Moreover, the experimental pictures had the same brightness and contrast. The pictures were randomly divided into 5 sections and presented in a random manner to effectively avoid the practice effect and fatigue effect. Each image presented 3 s, and images were continuously presented between stimuli in each bar. After the end of each section of the experiment, the subjects could choose whether to take a rest. The experiment lasted for 5 minutes [16].
- (3) EEG data acquisition: firstly, set the storage path of EEG data; then the EEG signals recorded on the screen of the subjects were observed. When the EEG signals stabilized, the audiovisual stimulation experimental paradigm was presented on the screen of the subjects. Finally, in accordance with the designed experimental paradigm flow, the subjects were induced by emotional pictures and sounds to collect EEG signals [17].

TABLE 1: Experimental data set.

|                        |                            |
|------------------------|----------------------------|
| Number of participants | 32                         |

| Recorded signal        | Number of channels: 40     |
| Number of participants | Sampling frequency: 128 Hz |

### 3.4. Data Processing

- (1) Data format conversion (convert .cnt to .mat format): since the original data is a .cnt format file collected by the Scan software, this article uses the EEGlab toolbox to import it into Matlab and then process it. The data saved after processing is in the .mat format, and the data in the .mat format can be used. The data generated by subsequent feature extraction and other works can also use the .mat format.
- (2) Complete the independent component analysis processing of the data. Use the ICA algorithm in the EEGlab toolbox to decompose the data, and remove the artifact signals such as ocular electricity and myoelectricity to achieve denoising [18].

## 4. EEG Analysis of Emotional Cognition under Visual and Auditory Costimulation Based on Complex System

**4.1. Analysis of Global Feature Difference Results.** First, select the initial value of the weight vector in the convolutional layer, the learning rate is  $1e-5$ , and the momentum factor is 0.9. Under the eight probability distribution conditions of uniform distribution, zero-point distribution, and normal distribution, the effects of different initialization weight vectors on the accuracy of emotion recognition are shown in Figure 1. It can be found from the table that the classification accuracy is the highest when the initialization weight vector is uniformly distributed. The power spectrum entropy of  $P$  area,  $PT$  area, and  $O$  area does not change significantly with the level, which also shows that these areas have a small relationship with emotions.

As shown in Figure 2 and Table 2, the power spectrum entropy of  $F$  zone,  $AT$  zone, and  $C$  zone fluctuates greatly with the level change, especially in  $F$  zone. And the power spectrum entropy of the  $F$  zone has an upward trend with the level change. This may be due to the fact that the brain is in a highly stressed state when viewing lower-level pictures, which makes the regularity of the brain waves stronger, so that the power spectrum entropy is higher.

As shown in Table 3, as the level of the picture increases, the state of the subjects is more relaxed when watching the

picture, which makes the law of brain waves weaker, and thus the power spectrum entropy becomes larger. The importance of emotion to human life is self-evident, and it affects the individual's evaluation of external things and affects the individual's behavior mode in dealing with external things. The relationship between emotion and executive function has also become a research hotspot in recent years. Through research on patients with anxiety and depression, people have found that emotions affect individual working memory, renewal, transformation, and other abilities [19, 20].

Figure 3 shows the accuracy comparison of the two-category emotion recognition of the five algorithms. The horizontal axis in the figure represents the tester number, and the vertical axis represents the accuracy rate. It can be seen from the figure that when using statistical features as input, two algorithms, RBF-SVM and Linear-SVM, are used for emotion recognition, and their accuracy is generally lower than that of the algorithm in this paper.

As shown in Table 4, through the comparison of the accuracy of the algorithm in this paper and the algorithm in the literature, it can be found that this paper uses the preprocessed brain wave signal as input. By adjusting the parameters of the convolutional neural network, the highest accuracy rate of the two-class algorithm can reach 98.8%, and the average accuracy rate is 83.45%; compared to the emotion recognition algorithm of the convolutional neural network that uses statistical features as input, it is significantly improved [21].

As shown in Figure 4, with the increase in sparsity, the clustering coefficient  $C$  under different sparsity levels increases monotonically, and the clustering coefficient can measure the clustering characteristics and tightness of the brain function network. Under high arousal conditions, the clustering coefficient of the brain network with low pleasure is smaller than the brain network of high pleasure; under the condition of low pleasure, the clustering coefficient of low arousal is greater than the clustering coefficient of high arousal.

As shown in Figure 5 and Table 5, this may indicate that, under higher pleasure conditions, the brain nerves are more excited, local connections between brain regions increase, and brain function connections are enhanced, and under the same conditions of low pleasure, the brain function of the brain with low arousal is higher than the high arousal. The brain function of the brain network has more connections between brain regions, and the local connection function is stronger. The research results on local efficiency are consistent with the research results of clustering coefficients. Both of these two attributes can reflect the differentiation ability of local brain functions. Together, the two indicate that high-pleasure emotions promote the local information processing and processing of the brain [22].

**4.2. Analysis of EEG Feature Extraction Results.** The average accuracy of discrete dimensions is shown in Table 6. As can be seen from the figure, the average accuracy has improved. When using the convolutional neural network to solve the

problem of image classification, the input is unstructured image data; that is, we do not need to extract all the features of an image. At the same time, the operation of each layer in the convolutional neural network is equivalent to extracting the image features with a feature operator, and the parameters of the feature operator can be adjusted and updated

TABLE 3: The influence of different initialization weight vectors on the accuracy of emotion recognition.

of the network model. The larger the scale of the network model is, the more features can be extracted and the more types can be effectively distinguished [23]. In addition, since the convolution kernel parameters are constantly updated and adjusted throughout the training process, there is no need to pay special attention to the processing results of each layer, but to adjust the parameters of each layer within a reasonable range based on the output error of the network, and finally complete. From autonomous learning to abstract feature expression, image classification is realized. Instead, we use the average intensity of all voxels in the selected brain area as a benchmark. Such a choice has an advantage over the same conversion factor in the expansion result.

As shown in Figure 7 and Table 7, compared to the gray matter intensity calculated separately, it affects the change in signal percentage. A brain with 35% white matter is 15% brighter than gray matter, and the average

signal percentage using the whole brain is reduced by 5% of the baseline using only gray matter. Generally, the magnitude of this difference is small compared to other errors. Similarly, the threshold used to cover the whole brain only has a small effect on the reasonable range of the threshold [24].

**4.3. Synchronous Analysis of EEG Induced by Visual and Auditory Perception.** The results of the EEG phase synchronization index  $t$ -test are shown in Figure 8 and Table 8. The results show that there are significant differences between the EEG synchronicity index of happy emotion cognition (positive emotion) and anger, sadness, surprise, disgust, and fear emotion cognition (negative emotion). When receiving pleasant facial expression pictures and sound synchronization stimulation, the parietooccipital lobe and the left frontal lobe have a high EEG phase synchronization; that is, the visual area and the left emotional area have a synchronized oscillation phenomenon, and the synchronization of the glume lobe and the left frontal lobe is not high; that is, the phenomenon of synchronous oscillation is not obvious.

As shown in Figure 9 and Table 9, it can be inferred that the visual channel plays a dominant role in the perception of pleasure. When receiving the stimulus of the sad expression picture and the sound synchronization, the occipital lobe and glume lobe have a high EEG phase synchronization with the right frontal lobe; that is, the visual area and auditory area have synchronized oscillations with the right emotional area, but the leaves are displayed. Compared with the

FIGURE 6: Average accuracy of discrete dimensions.

FIGURE 7: The number of features that can be extracted and the size of the network model.

TABLE 7: Comparison of the effects of gray matter intensity and white matter on the brain.

| $N$ | Angle | Edge | Information gain | Area | Ridge | NLP  |
|-----|-------|------|------------------|------|-------|------|
| 1   | 0.6   | 0.86 | 0.29             | 0.95 | 0.69  | 0.14 |
| 2   | 1.62  | 3.95 | 3.08             | 3.27 | 1.46  | 3.44 |
| 3   | 5.81  | 5.38 | 2.6              | 5.73 | 5.52  | 3.81 |
| 4   | 2.5   | 3.57 | 1.03             | 4.4  | 4.52  | 3.61 |
| 5   | 4.21  | 3.19 | 3.81             | 4.7  | 3.25  | 3.28 |
| 6   | 6.79  | 5.39 | 2.97             | 4.04 | 2.16  | 6.99 |

synchronization of the right frontal lobe, the synchronization between the occipital lobe and the right frontal lobe is higher. From this, it can be inferred that, in the cognition of sad emotions, the auditory channel plays a leading role and the visual channel plays a supporting role. When neurons are in a resting state, positive and negative charges are evenly

distributed inside and outside the cell membrane, but due to the overlap of the positive and negative centers, all neurons neither will exhibit electrical properties on the outside nor will form galvanic couples [25,26].

As shown in Figure 10 and Table 10, when a neuron is stimulated, the cell membrane is in a state of polarization cancellation, the internal and external charge distribution are uneven, and the centers of positive and negative charges do not overlap, thus forming a pair of galvanic couples. Under sound conditions, a similar situation occurs. The three brain regions pF, LO, and PPA form a network, but they have nothing to do with STS. STS can perceive three modal stimuli: single vision, single hearing, and audiovisual integration, so it is possible that this mode of sound is only processed in STS and has nothing to do with the network formed by those three brain regions. According to the results of multivoxel mode analysis, we see that the STS brain area is also involved in representing

FIGURE 8: EEG synchronicity index of happy emotion cognition.

the semantic similarity between the scene and the sound, so we further explored the whole brain that is functionally connected to the STS under the sound and scene tasks.

As shown in Figure 11, the results found that there are common parts of the brain areas that are jointly responsible for processing scenes and sound tasks with STS: perception related (insular lobes), spatial imagery and memory (middle occipital region), semantic related (back of middle temporal gyrus) and object perception related brain area (LOC), and audiovisual integration. As the number of decomposition layers increases, the smoother the waveform is, the more the information is lost; on the contrary, the less the number of decomposition layers, the more the interference in the waveform. It can be obtained by plotting the approximation coefficients and detail coefficients of the above layers, and the preprocessed EEG signal is subjected to 5-layer wavelet decomposition, and the obtained waveform has good smoothness while retaining the details more completely.

Therefore, the wavelet coefficients of the fifth layer are algorithmically reconstructed to extract the P300 characteristics of evoked EEG in the visual, auditory, and visual and auditory target stimulation modes. Whether it is visual, auditory, or visual-auditory joint stimulation mode, the wavelet transform method can effectively extract the P300 characteristics of the evoked EEG signal, so that the target stimulus in the three modes can be effectively distinguished from the nontarget stimulus [27, 28].

As shown in Figure 12 and Table 11, in the ERP induced by different valence emotion pictures as a stimulus, the middle component and late component also showed significant differences in amplitude. In the right brain, the negative wave amplitude induced by high-pleasure pictures is significantly higher than the negative wave amplitude induced by low pleasure pictures. This phenomenon can indicate that positive stimulation can get more cognitive resources in the right brain, and emotions are in the right

| Fron-lobe   | 4.28                 | 3.9             | 3.46     | 2.72        | 5.03              |
| Cent-area   | 1.7                  | 3.75            | 3.58     | 2.43        | 3.79              |

brain. Subject to more refined evaluation processing, this cognitive process involves attention and memory cognitive processes. Different processing of visual information with different valence exists in every stage of mental processing.

As shown in Figure 13, whether under high arousal conditions or low arousal conditions, after 300 ms, the left

and right brains have different processing methods for different valence of visual information, but they are all involved in the emotional processing process, both in the frontal and central regions. Reflect this difference in processing. The research on the ERP effect of emotional valence mainly focuses on negative bias, but there is no obvious

FIGURE 13: Processing under different wakeup conditions.

negative bias in this experiment. This is because negative bias mainly occurs when attention resources are relatively lacking, and negative stimuli are allocated to more psychological resources. When psychological resources are sufficient, there is no difference in advantage between positive and negative emotional information processing.

## 5. Conclusions

This paper mainly studies the changes of EEG under the synergy of music and image visual and auditory stimuli based on complex systems. The event-related potential technology is used to analyze and study the rules of visual emotion cognition. The brain activity analysis method based on emotional valence and the brain activity analysis method based on emotional arousal are used to compare the tester's emotions on the two indicators of valence and arousal. Marking as a label, by selecting music videos as the tester's emotional inducing material, it effectively induces the tester to produce obvious emotional changes. Let the tester watch the video intermittently, collect the physiological signals generated by the body during the viewing process, preprocess the collected human physiological signals to construct a new data set, and finally use the data set for the algorithm test.

Feature extraction is performed on the preprocessed visual, auditory, and visual-auditory joint evoked EEG signals. When a single channel (visual or auditory) stimulation is given to complete positive emotional cognition, the right frontal lobe has a higher synchronization with the visual or auditory areas of the brain, which is related to the brain receiving visual or auditory stimuli; while completing the negative during emotional cognition, the left frontal lobe and other functional areas did not show synchronized activities. The results of this study show that when receiving a single channel (visual or auditory) stimulation to complete emotional cognition, positive emotions can cause

synchronized electrical activity in related areas of the brain more than negative emotions.

The body's emotional state affects the pattern of attention distribution. If the body is in a positive emotional state, it is more likely to adopt a top-down approach to information processing, which relies on the body's already formed knowledge and experience structure. On the contrary, the organism in a negative emotional state is more likely to adopt a more systematic information processing strategy, which is a bottom-up information processing method, which does not depend on the knowledge and experience of the body. Meanwhile, the organism adopting this method will pay more attention to the details of the current stimulus.

In the traditional scientific research and production activities, due to the lack of sufficient communication and communication between researchers, the phenomenon of waste of scientific research resources occurs from time to time, which hinders the efficiency of scientific research output. Based on the design principle of the semantic knowledge framework, this paper puts forward the definition of ontology and semantic relationship of the collaborative system of scientific researchers. In this paper, a framework of collaborative semantic knowledge among researchers is established through decentralized semantic information exchange architecture. In this article, the simulation is verified by experiments and compared with other exchange architectures. The results of the experiment confirmed the semantic information exchange architecture based on semantic knowledge proposed in this paper is 10.39% faster than the traditional centralized method in terms of data volume; the construction speed under the data node perspective is 12.84% higher than that of the traditional centralized construction method; the subject query speed is 36.84% higher than that of the traditional centralization method; the predicate query speed is 31.58% higher than that of the traditional centralization method. The experimental results confirm that the semantic information exchange architecture based on the semantic knowledge framework is feasible, and it has excellent performance in terms of construction speed and query speed. Under the background that researchers rely more and more on collaborative technology to interact with other members, this paper has a certain reference value and exploration value and proposes a new idea of group collaboration system under the framework of semantic knowledge.

## 1. Introduction

With the advent of the information age, especially the development of web technology and computer-supported collaborative technology, the academic environment of modern science and technology has changed. The interdisciplinary and interpenetration between disciplines is a remarkable feature of modern science and also the main direction of scientific research. Due to the complexity and specialization of scientific research tasks, it is more difficult for researchers to complete scientific research tasks relying on personal knowledge reserves [1]. The tasks in the field of scientific research should be based on team cooperation. As a

high-efficiency organization form of scientific research, collaborative research will become an effective way to improve scientific research efficiency, reduce research costs, strengthen academic exchanges, and stimulate academic innovation. At the same time, it hinders the rapid development of information for users. As a special kind of users, researchers' information behavior is different from other information users. The essence of scientific research personnel is not to obtain a large amount of information but to obtain information that can solve problems. In traditional scientific research and production activities, due to the lack of sufficient communication and communication between researchers, the phenomenon of waste of scientific research

resources occurs from time to time, which hinders the efficiency of scientific research output. In terms of an isolated scientific research environment, collaborative scientific research cooperation has become necessary [2].

Allen et al.'s research shows that collaborative research has become the pillar of knowledge production in many scientific fields and has been promoted as a method to improve the quality of scientific research, resource utilization, and influence. But he did not do more in-depth research, leading to the conclusion is not comprehensive [3]. In terms of the motivation of collaborative research, Botsford et al. analyzed the difference between the experimental research and the theoretical research and concluded that the difference of professional division was the main factor that promoted the collaborative research. In the process of research projects, it is easier to obtain knowledge and experience of new partners than to master new knowledge by themselves. Knowledge resources obtained from collaborative partners can improve scientific research efficiency and output. Due to the lack of comparison objects selected in the research project, the conclusion cannot be used as a reference basis [4]. At the same time, scholars have also noticed the impact of scenario factors on collaborative research and development. Berbegal's impact on collaborative research and cooperation shows that regional, cultural, economic, and political factors are the main factors affecting collaborative research, while the degree of collaboration decreases with the increase of space and geography among research partners. However, he did not list the detailed data, resulting in his research conclusion is not rigorous [5]. In addition, transportation and communication technology is also one of the factors affecting collaborative research. The convenient traffic conditions and convenient communication technology eliminate the collaborative obstacles brought by the region and also greatly reduce the cost of scientific research, which provides favorable conditions for the collaborative cooperation and academic exchange between scientific research studies.

This research breaks through the pure theory behavior discussion, based on the theoretical analysis, supplemented by the investigation and analysis of practical application, combines the theory and practice, focuses on the collaborative information behavior of users in the collaborative research environment, and takes the collaborative research environment as the background, based on the semantic knowledge framework, the language of the environment perception system, the collaborative architecture, and the knowledge framework of the researchers. Finally, the feasibility of the semantic knowledge framework is verified by simulation experiments.

## 2. Theoretical Basis of Group Collaboration Architecture, Intelligent Environment Awareness, and Semantic Knowledge Framework

### 2.1. Intelligent Environment Awareness

**2.1.1. Convolution Neural Network.** CNN is an important model in-depth algorithm. It is a nonlinear and adaptive mathematical model for processing information, and it

consists of a large number of independent computing nodes. It is suitable for processing data with grid structure (such as image composed of two-dimensional pixel grid). CNN structure is similar to ANN, which is mainly divided into three parts: the input layer receives the signals and data outside the model and receives the original image information as input in CNN; the hidden layer performs nonlinear mapping on the input data to form the characteristics of different levels of data; and the output layer outputs discrete or continuous data processing results [6, 7]. Based on ANN, CNN introduces sparse connection, weight sharing, and downsampling technology to realize hierarchical processing of visual information.

As shown in Figure 1, CNN model has a variety of structures, including convolution layer, downsampling layer, and activation layer. Convolution layer, pooling layer, and activation layer are three basic structures to form function modules to realize feature coding and nonlinear mapping. Multiple functional modules form the deep model to realize the abstract expression of features. Finally, class labels and probability are output through full connection layer and loss layer [8, 9].

(1) *Convolution and Activation.* Convolution operation can be regarded as a linear operation process of weighted sum of two-dimensional images. At this time, the weight matrix used is called convolution kernel. Unlike the dense connection of neurons in ANN, the convolution kernel of CNN is associated with a certain region in the two-dimensional image, and the value after weighted sum is activated as the corresponding pixel value of the new feature map [10]. The convolution operation in CNN is as follows:

$$x_j^l = f \left( \sum_{i \in M_i} x_i^{l-1} * k_{ij}^l + b_j^l \right), \quad (1)$$

where  $f$  is the layer index;  $x$  is the feature graph, which is a two-dimensional matrix;  $i$  and  $j$  represent the input and output feature map indexes, respectively. Specifically,  $x_j^l$  is the  $j$ -th output characteristic graph of this layer;  $x_i^{l-1} * k_{ij}^l$  is the convolution operation of the output characteristic graph of the upper layer through kernel  $k_{ij}^l$ ;  $i \in M_i$  is the traversal operation of all input characteristic graph;  $*$  is the convolution operation;  $b_j^l$  is the offset direction; and  $f$  is the activation function.

The main function of the activation layer is to realize the nonlinear transformation of CNN. Activation functions have many variations, such as sigmoid function, tanh function, and relu function. Currently, relu activation function is commonly used, which has the advantages of stable error propagation for different input sizes and avoiding gradient explosion or dispersion. Moreover, the activation function has zero response to negative input and can realize the sparse connection of the network [11].

(2) *Pooling.* Pooling layer is also known as the lower sampling layer, and the common ones are Max pooling, average pooling, and min pooling. The pooling layer can reduce the spatial resolution of the feature map, so as to reduce the

network scale, accelerate the network training, reduce the overfitting, and make the features have strong translation and scaling invariance for different inputs [12]. The general expression of pooling operation is as follows:

$$x_j^l = f(\beta_j^l \text{down}(x_j^{l-1}) + b_j^l). \quad (2)$$

Down( $\cdot$ ) is the partition calculation operation of the feature graph, such as dividing the feature graph into  $n \times n$  grids and calculating the sum, maximum value, and minimum value of each part.  $\beta_j^l$  is the weight parameter of grid elements; 1 is taken for maximum pooling;  $1/S$  is taken for average pooling ( $s = w \times h$ , where  $w$  and  $h$  are pool kernel sizes, respectively); and  $f$  is the activation function.

**2.1.2. MobileNet.** MobileNet is a lightweight CNN model designed for embedded hardware platform. By introducing a depth separable convolution layer, the standard convolution is decomposed into a combination of depth convolution which only extracts features from a single channel and point convolution that fuses all channel information, thus greatly reducing the amount of parameters and realizing model acceleration [13]. The number of input channels is  $n_i$ , and the size of the input characteristic graph is  $w_i$  and  $h_i$ . The corresponding output channel number and characteristic layer sizes are  $n_{i+1}$ , and  $w_{i+1}$  and  $h_{i+1}$ , respectively. If the size of the convolution kernel is  $k_i \times k_i \times n_i$ , the number of standard convolution multiplication operations is given by

$$k_i \times k_i \times n_i \times n_{i+1} \times h_i \times w_i. \quad (3)$$

Deep convolution is a special case in which the number of blocks is equal to the number of channels in block convolution:

$$k_i \times k_i \times n_i \times h_i \times w_i. \quad (4)$$

Deep convolution is independent in different channels, so there is a problem that information does not flow between channels. In MobileNet, different channel information is combined in the form of point convolution between channels:

$$1 \times 1 \times n_i \times n_{i+1} \times h_i \times w_i. \quad (5)$$

When the standard convolution is replaced by separable convolution, the compression ratio of the model is given by

$$\frac{k_i \times k_i \times n_i \times h_i \times w_i + n_i \times n_{i+1} \times h_i \times w_i}{k_i \times k_i \times n_i \times n_{i+1} \times h_i \times w_i} = \frac{1}{n_{i+1}} + \frac{1}{k_i^2}. \quad (6)$$

Generally, the convolution kernel size of CNN structure is  $3 \times 3$ , and the number of output characteristic layers  $n_{i+1}$  is often large. According to formula (6), when the standard convolution operation is replaced by separable convolution, the compression ratio of model parameters and multiplication operation is  $1/8 \sim 1/9$ .

The design of the MobileNet grid structure is very similar to VGGNet. The spatial resolution of the feature map decreases monotonously, and the number of channels increases monotonously. When the resolution is reduced by

FIGURE 1: CNN mode structure.

half, the number of feature layers is doubled. The differences are as follows:

- (1) MobileNet replaces the standard convolution with deep separable convolution in VGGNet
- (2) MobileNet does not set the pooling layer but reduces the spatial resolution of the feature map by the convolution step size of 2
- (3) MobileNet replaces the two full link layers of VGGNet  $4096 \times 4096$  and  $4096 \times 1000$  with  $7 \times 7$  average pooling layer, realizing further compression of the model [14]

## 2.2. Principle Design of Semantic Knowledge Framework

**2.2.1. Semantic Knowledge Framework.** Semantic knowledge framework can be considered as an analysis method in philosophy. The analysis method has one basic element and two cores. The basic element is concept. The first core is the relationship between concepts. The second core is to realize reasoning function through the relationship between concepts. Second, the semantic knowledge framework can be a form of computer knowledge storage and representation and concept. Finally, the semantic knowledge framework can also be used for knowledge processing, such as identification, reasoning, query, knowledge consistency maintenance, scenario calculus, and planning so as to achieve knowledge fusion, knowledge extraction, knowledge discovery, natural language generation, and other functions [15, 16].

Semantic knowledge framework can be used to describe any complex relationship between anything, but this description is based on a series of basic semantic relations. Basic semantic relations are the basic elements of complex semantic knowledge framework. The basic semantic relations are various and flexible. As shown in Figure 2, here are some commonly used relations.

(1) *Semantic Relation.* Semantic relation generally describes the generic relationship between things, including IS-A, A-Kind-Of, and Instance-Of.

IS-A means that one thing is an instance of another. It can be expressed as “. . . It’s an example of.” For example, if a geological researcher is regarded as a class and a geological

FIGURE 2: Framework diagram of the semantic knowledge framework.

exploration technician is a member of the class, then the geological exploration technician is an example of a geological researcher.

A-Kind-Of means that one thing is a type of another “It’s a kind of . . .” AKO represents a larger range than IS-A. It usually does not represent the relationship between specific individuals but represents the relationship between classes. AKO is generally used to establish the relationship between subclasses and superclasses. For example, geological researchers are a subclass, scientific researchers are a parent class, and the semantic relationship between geological researchers and researchers can be represented by AKO.

The Instance-Of relation is the opposite of IS-A relation, which means that one instance of something is another.

(2) *Attribute Relation.* Attribute relationship usually refers to the relationship between things and their attributes. Any object in any class has one or more properties, and each property corresponds to a value. Therefore, there will be a corresponding combination of properties and values. The commonly used attribute relation is the predicate or verb of a sentence. For example, Have, Can, and Is.

Have means that things have a certain attribute relationship, which is expressed as “have.”

Can means the relationship between certain attributes of things, which can be expressed as “can” or “will.”

Is has no specific representation and can be understood as a variety of relationships. If something has multiple relationships with other things or attributes, they can be connected through is.

(3) *Other Relationships.* The relationship in the real world is very complex. In addition to the above semantic relations and attribute relations, there are many kinds of relationships between things and between things and attributes. The other main relationships are inclusion relationship, time relationship, location relationship, and similarity relationship [17].

The inclusion relation represents the relationship between the whole and the part. The difference between inclusion relation and attribute relation is that inclusion relation can be inherited and part of it belongs to whole, but it has all attributes of whole. Inclusion relationships can be described as Part-of or Composed-of.

The time relation represents the sequence of events in time. For example, Before means that an event must occur before a specific event occurs; At means that an event occurs at the same time as another event; and After means that an event can only occur after a specific event occurs.

Positional relations represent the relationship between things in space. If the position of one thing is in front of another, it can be represented by Location-front; if something is behind another, it can be expressed by Location-behind.

2.2.2. *Knowledge Graph.* Knowledge map is actually a semantic network, which can form reasoning semantic knowledge network from the connection of different semantic entities according to the change (relationship). The representation form is a graphical structure. In fact, the construction process of knowledge map includes the following: integrating the form of semantic knowledge and data cleaning form into heterogeneous data sources, establishing the relationship model through relation extraction, and finally establishing a directed graph structure database, which can reflect the semantic relationship between entities [18]. The query of the knowledge map is based on visual query. The knowledge obtained through input information is not a large number of web pages obtained by string matching, but the structured knowledge that users really need.

### 2.3. Swarm Intelligence Algorithm

#### 2.3.1. Cuckoo Search Algorithm

(1) *Lévy Flight.* Lévy distribution is a kind of continuous probability distribution. The letters  $\delta$ ,  $\alpha$ ,  $\mu$ , and  $\beta$  represent the scale, characteristic index, displacement, and skewness parameters, respectively:

$$\begin{aligned}
 P_{\alpha,\beta}(\kappa; \mu, \sigma) &= F\{P_{\alpha,\beta}(x; \mu, \sigma)\} = \int_{-\infty}^{\infty} dx e^{ikx} P_{\alpha,\beta}(x; \mu, \sigma) \\
 &= \exp\left[iuk - \sigma^\alpha |k|^\alpha \left(1 - i\beta \frac{k}{|k|} \bar{\omega}(k, \alpha)\right)\right], \\
 \bar{\omega}(k, \alpha) &= \begin{cases} \tan \frac{\pi\alpha}{2}, & \text{if } \alpha \neq 1, 0 < \alpha < 2, \\ -\frac{2}{\pi} \ln|k|, & \text{if } \alpha = 1. \end{cases}
 \end{aligned} \tag{7}$$

The probability density function of the Lévy distribution is related to  $\alpha$  characteristic index and  $\beta$  skewness parameter. When  $\alpha$  and  $\beta$  take different values, they can be expressed by different distribution functions (such as Gaussian distribution, Cauchy distribution, and Lévy distribution).

When  $\alpha = 2$ , the following Gaussian distribution function is used:

$$p_2(x) = \frac{1}{\sqrt{4\pi}} \exp\left(-\frac{x^2}{4}\right). \quad (8)$$

When  $\alpha = 1$  and  $\beta = 0$ , it is expressed by the Cauchy distribution function:

$$p_{1,0}(x) = \frac{1}{\pi(1+x^2)}. \quad (9)$$

When  $\alpha = 1/2$  and  $\beta = 1$ , it is expressed by the Lévy distribution function:

$$p_{1/2,1}(x) = \begin{cases} \frac{1}{\sqrt{2\pi}} x^{-(3/2)} \exp\left(-\frac{1}{2x}\right), & x \geq 0, \\ 0, & x < 0. \end{cases} \quad (10)$$

The waiting time of Lévy flight jump length obeys the power law distribution function:

$$\text{Lévy}(\beta) \sim \mu = t^{-1-\beta}, \quad 0 < \beta \leq 2. \quad (11)$$

There are two main elements in Lévy flight, which are moving direction and jumping step size  $s$ . In Mantegana's law, the definition of step length  $s$  is as follows:

$$s = \frac{\mu \times \varepsilon}{|\nu|^{1/\beta}}, \quad (12)$$

where  $\mu$  and  $\nu$  obey the standard normal distribution,  $\beta = 1.5$ .

$$\varepsilon = \left( \frac{\Gamma(1+\beta) \times \sin(\pi \times \beta/2)}{\Gamma((1+\beta)/2) \times \beta \times 2^{(\beta-1)/2}} \right)^{1/\beta}. \quad (13)$$

**2.3.2. Clustering Algorithm.** In K-means algorithm, the sum of squares of errors is used as the partition criterion:

$$E(C) = \sum_{i=1}^K \sum_{x_j \in C_i} \|x_j - \mu_i\|^2. \quad (14)$$

K-medoids clustering algorithm uses the actual data points as the clustering center and takes the absolute error as the division:

$$E = \sum_{j=1}^k \sum_{x \in N_j} |x - C_j|. \quad (15)$$

**2.3.3. Fast Search Algorithm of Density Peak.** For each data point  $I$ , the DPC algorithm needs to calculate its local density  $\rho_i$  and its distance  $\delta_i$ . When the set of data points is large, the local density  $\rho_i$  of data point  $i$  is calculated by the following formula:

$$\rho_i = \sum \chi(d_{ij} - d_c), \quad (16)$$

where  $X(x)$  is given by

$$\chi(x) = \begin{cases} 1, & x < 0, \\ 0, & x > 0. \end{cases} \quad (17)$$

When the set of data points is small, the local density of data points is calculated by the exponential kernel:

$$\rho_i = \sum_j e^{-(d_{ij}/d_c)^2}. \quad (18)$$

The formula for calculating the distance of data point  $I$  is as follows:

$$\delta_i = \min_{j: \rho_j > \rho_i} (d_{ij}). \quad (19)$$

For local density maximum data point  $i$ , the distance formula is as follows:

$$\delta_i = \max_j (d_{ij}). \quad (20)$$

### 3. Design of Simulation Experiment

#### 3.1. Group Collaboration Architecture

(1) Introduction: the design of group architecture is related to the level and function division of each unit in the system and is the basis of each unit structure design [19]. The structure of the unit determines the assignment of tasks, the content of information flow, and the specific stage of task execution. The design of group architecture should follow the following principles:

- (a) Clear hierarchy: hierarchical relationship includes two parts: group level and internal operation level. A clear hierarchical relationship helps to plan and integrate each unit into the system independently; the hierarchical structure of internal functional units is conducive to the standardization and design of the system and is convenient to adjust and expand the system [20, 21].
- (b) Reasonable function distribution: it is necessary to make logical planning for the functions of different levels in the system, so as to avoid some functions being too complex and others relatively single. Otherwise, it will not only affect the overall performance of the system but also reduce the execution efficiency due to the large amount of data processing, leading to the paralysis of some system units.
- (c) Efficient information transmission: the content and form of information transmission between units and operation modules should be fully considered in the design of system structure. In the unit, the standardization of information and the design of the summary process are of great significance to improve the execution efficiency and reduce the cost of the system.

- (2) As shown in Figure 3, the organizational forms of group collaboration can be divided into centralized, decentralized, and distributed.

**3.1.1. Centralized Control Structure System.** The system is controlled by a main control unit, which is a top-down hierarchical control structure for planning and decision-making. The number and complexity of the main control units determine the time required to respond to the system and the quality of decision-making behavior [22]. The main control unit is responsible for the dynamic allocation of tasks and the potential planning of resources and coordinates the competition and cooperation among various posts. The system is easy to manage, control, and program.

**3.1.2. Decentralized Control Structure System.** Each individual in the system has an equal relationship, has a high degree of intelligent autonomy, independently processes information, design, and decision-making, performs its own tasks, and communicates with other units to coordinate their behavior without a central control unit [23]. The structure has good flexibility, scalability, and reliability, but the communication requirements are high and the efficiency of multilateral negotiation is low. Therefore, it is difficult or unable to guarantee the realization of the global goal.

**3.1.3. Distributed Control Structure System.** This structure is the product of the combination of decentralized horizontal interaction and centralized vertical control. It is composed of a group of independent, completely equal, no logical master-slave relationship and self-discipline. According to the predefined protocol, according to the system goal, state, and its own state, ability, resources, and knowledge, each unit uses the communication network to consult and negotiate with each other to determine their respective tasks, coordinate their own activities, realize the sharing of resources, knowledge, information, and functions, and cooperate to complete common tasks to achieve the overall goal. In this kind of system, each unit is independent of each other in structure and function, and they all communicate with each other through the network in the same way, with good encapsulation, so the system has good fault tolerance, openness, and scalability [24, 25].

**3.2. Experimental Dataset.** In this paper, we build a decentralized system of 6 nodes in win10 environment. The protocol includes Hypertext Transfer Protocol and Peer-to-Peer. The ArchiveHub dataset is used in the experiment. The size of the dataset is 72 m, the quantity of the substance is 107219, the number of subjects is 51385, the number of unique predicates is 143, the quantity of unique objects is 104389, and the number of triples is 432142. In this article, the data collection is carved up into six parts, named X1~X6, construct a respective knowledge map for each data collection and save it in six nodes.

Table 1 shows the essential information of the six datasets. In the subsequent comparative experiments, the trend of construction time and query time is related to the trend of the number of unique entities. It can more directly reflect the series ring in the process of physical connection building the global knowledge map, and a copy of the selected node information is copied in XL-X6.

**3.3. Verification Test.** Building module verification experiment: Several entity modules are randomly selected for construction. In this process, we can explore and verify the construction effect of the semantic information exchange system by viewing the connection period between the entity modules. With physical resources self3810 as an example, self3810 points to dataset X2 (port number 8002) in the connection information table of the node where dataset X1 (port number is 8001) is located and in the connection information table of the node where dataset X2 (port number 8002) points to dataset X3 (port number 8003). Dataset X3 (connection information table with port number 80031) points to dataset X1 (port number 8001). From the above results, the entity resource self3810 forms a link cycle in the three nodes of the system, and the link cycle trend is as follows: the next largest node is the next node pointed to by the current node.

## 4. Comparison of Test Results of Different Methods

This article mainly conducts experiments from two aspects: the construction speed of the semantic knowledge framework and the query speed.

**4.1. Construction Rate Comparison (Data Volume Perspective).** The contrast experiment design of construction rate is compared with the centralized construction system from two dimensions of data size and node number size.

As shown in Figure 4 and Table 2, from the perspective of data volume, the construction rate of other methods and the semantic knowledge framework system proposed in this paper is compared. Taking three nodes as a group, the amount of data gradually increases to observe the respective performance of the centralized system and decentralized system. It can be concluded from the figure that

- (1) With the increase of data volume, the construction time of both centralized and decentralized knowledge maps will show a slow upward trend. A very important part of the construction process of the knowledge map is the data transmission and connection, and the construction time is mainly increased in the data transmission connection part. Therefore, because of the growth of data volume, the construction time of both the centralized system and the decentralized system will increase correspondingly.

FIGURE 3: Organization form chart of group collaboration.

TABLE 1: Basic information of experimental data collection.

| Data collection | File size | Quantity of unique substance | Quantity of triplet | Quantity of unique subjects | Unique predicate quantity |
|-----------------|-----------|------------------------------|---------------------|-----------------------------|---------------------------|
| X1              | 5.8       | 16875                        | 29746               | 6971                        | 14082                     |
| X2              | 6.9       | 21538                        | 39910               | 9285                        | 13369                     |
| X3              | 9.4       | 20364                        | 54189               | 2614                        | 20871                     |
| X4              | 15.7      | 29483                        | 79852               | 4536                        | 27259                     |
| X5              | 16.1      | 40576                        | 101987              | 12857                       | 30364                     |
| X6              | 18.9      | 43295                        | 123948              | 14921                       | 30428                     |

(2) According to Figure 1, when the size of the dataset is small, the construction speed of the proposed semantic knowledge framework system is lower than that of the traditional construction method. But, with the increase of datasets, the semantic knowledge framework system gradually shows its advantages. The reason is that the system constructed by the traditional method needs to transmit all datasets, but in order to protect the information of each node, the system only transmits the unique entity set. The reason why the rate of early construction of the system proposed in this paper is slower than that of the traditional method is that the empty node needs to send the generated information back to each node, which takes a lot of time.

#### 4.2. Construction Rate Comparison (Data Node Perspective).

As shown in Table 3 and Figure 5, this paper compares the construction rate of traditional methods with that of the semantic knowledge framework system proposed in this paper. With the increasing number of nodes, the performance of the centralized system and decentralized system is observed. It can be concluded from the figure that

- (1) From the overall trend, with the increase in the number of nodes, the construction time of both centralized and decentralized semantic knowledge framework will show an upward trend. Since the construction of the semantic knowledge framework requires the connection between nodes and data transmission, with the increase in the number of nodes, the construction time of both centralized and decentralized systems will increase correspondingly.
- (2) As shown in Figure 5, we can see that the construction rate of the semantic information exchange

architecture in this paper is lower than that of the traditional semantic information exchange architecture in the case of a small number of nodes. However, with the increasing number of nodes, the construction speed of the decentralized semantic information exchange architecture proposed in this paper is gradually higher than that of the traditional semantic information exchange architecture construction. The reason is that the traditional method of transmitting information only needs to protect part of the dataset. The reason for the slow construction speed of the system proposed in this paper is that the empty node needs to return the generated connection information to each node, which takes part of the time.

#### 4.3. Comparison of the Number of Subject-Predicate Word Number Queries.

As shown in Table 4 and Figure 6, the query time of the two types of systems under different subjects is shown.

As shown in Table 5 and Figure 7, the query time of the two systems under different predicates is shown. It can be concluded from Figure 4 that

- (1) With the increasing number of subject-predicate words, the query time will also increase. This is because the number of query levels in the query mode is determined by the number of subject-predicate words. If the number of subject-predicate words increases, the number of query connection levels will increase.
- (2) In terms of the same subject or predicate word number, the query speed of the decentralized query mode is faster than that of the centralized query mode. This is because in the decentralized query

FIGURE 4: Rate comparison (data volume).

TABLE 2: Rate comparison (data volume).

|               | AH1,2,3 | AH2,3,4 | AH3,4,5 | AH4,5,6 |
|---------------|---------|---------|---------|---------|
| Decentralized | 2784    | 3129    | 3926    | 4089    |
| Centralized 1 | 3632    | 3775    | 3851    | 3967    |
| Centralized 2 | 2564    | 2941    | 3472    | 3845    |

TABLE 3: Rate comparison (data node).

| Build time    | 1    | 2    | 3    | 4    | 5    |
|---------------|------|------|------|------|------|
| Decentralized | 516  | 524  | 1418 | 1895 | 2654 |
| Centralized 1 | 1136 | 957  | 1594 | 2015 | 1720 |
| Centralized 2 | 1306 | 1274 | 1453 | 1801 | 1651 |

TABLE 4: Query rate comparison (subject).

| Query time    | 1   | 2   | 3   | 4   |
|---------------|-----|-----|-----|-----|
| Decentralized | 58  | 102 | 167 | 194 |
| Centralized 1 | 103 | 181 | 253 | 328 |
| Centralized 2 | 109 | 196 | 261 | 341 |

mode, queries are parallel, and the connection between tables is based on the connection information part of each node dataset; in the centralized system, the table join during query is the self-join of the whole large dataset.

- (3) In terms of the overall trend, the increase of query time in the decentralized query mode is gradually decreasing, while that in the centralized query mode is unchanged. This shows that with the increase of subject-predicate words, the advantage of the decentralized query mode will become more and

more obvious. This is because each table join of a centralized query queries the semantic knowledge framework, so the increase is not changed, and each connection of the distributed query is based on the connection information part of each node dataset. In summary, the performance of decentralized semantic information exchange query mode based on the semantic knowledge framework of group collaborative intelligent environment and mission control is better than that of the traditional centralized query mode.

FIGURE 5: Rate comparison (data node).

| Query time    | 1   | 2   | 3   | 4   |
|---------------|-----|-----|-----|-----|
| Decentralized | 51  | 105 | 154 | 187 |
| Centralized 1 | 101 | 194 | 246 | 337 |
| Centralized 2 | 107 | 203 | 259 | 352 |

FIGURE 7: Query rate comparison (predicate).

## 5. Conclusions

The main research content of this paper is based on the semantic knowledge framework of collaborative intelligent environment perception and mission control. In this paper, the concept of environmental awareness system, group collaboration, and semantic knowledge framework is introduced and analyzed in detail. In this paper, through the establishment of temporary space-time nodes with the same level as other nodes in the network, the interconnection and interaction between nodes can be realized, and the self-determination mechanism can realize the knowledge connection between nodes on the basis of maintaining their own knowledge. On the basis of the interaction mechanism of Unicom, we design and implement the decentralized Iterative Incremental Construction Scheme of the semantic knowledge framework and the corresponding query mode. On the premise that knowledge is not acquired, the connection construction and query between nodes are realized.

Experiments show that the semantic information exchange system structure constructed in this paper is feasible and effective. The integrity of the global semantic knowledge framework and the centralized semantic knowledge framework is the same, and the global semantic knowledge framework constructed in this paper has better performance than the middle school system in the construction speed and query rate.

At present, there are few research studies on the semantic knowledge framework, and there are still many deficiencies in this paper due to the limitation of time, specialty, and technical level, for example, lack of rule layer, only realize the sharing of data rather than rules; need to further improve the

algorithm to improve the query efficiency; and do not discuss the specific factors and influence coefficient of collaborative information in the collaborative research environment. The above shortcomings will be the next step of this project.

## Data Availability

No data were used to support this study.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the development of the globalization of science and technology, innovation has become an important driving force for regional economic development. As a core element of regional innovation, financial R&D resources have also become a key element to enhance national innovation capabilities and national economic competitiveness. National and regional innovation capabilities have a direct impact. There are also many deep-seated problems behind the world-renowned achievements, such as irrational industrial structure, insufficient independent innovation capabilities, low resource utilization efficiency, and the service quality and efficiency of financial institutions for the transformation of total factor productivity. These problems extremely restrict the efficiency upgrade and further development of our country's total factor productivity. This study uses the DEA-Malmquist index model to measure the efficiency of fiscal R&D resource allocation in 28 provinces and regions in China in the past 10 years and uses Mapinfo12.0 software to analyze regional differences in the efficiency of fiscal R&D resource allocation in China from a spatial perspective. During the year, the overall R&D resource allocation efficiency of 28 provinces and autonomous regions in China has shown an upward trend. The efficiency of fiscal R&D resource allocation and the concentration of financial factors have had a positive impact on total factor productivity, transform and upgrade factors, increase total factor productivity, and provide empirical evidence for building a strong country.

## 1. Introduction

**1.1. Background and Significance.** In recent years, China has been steadily increasing R&D investment to improve its own level of innovation, but R&D varies greatly between different regions. Therefore, studying the efficiency of our country's R&D resource allocation and its regional differences is of great significance for reducing the differences in the efficiency of R&D resource allocation among regions, improving total factor productivity, enhancing regional innovation capabilities, and promoting the coordinated development of regional economies. As the main force of innovation resources, the effective allocation of R&D resources is playing an increasingly important role in the

process of economic development [1]. Total productivity and economic growth are the two main driving forces of modern economic growth and are important indicators of the quality of economic growth in a country or region. In order to cope with the long-term imbalance of our country's economic growth, the overall productivity level of each region has become an important basis for measuring economic efficiency and economic growth [2].

**1.2. Related Work Research.** Domestic research on the efficiency of fiscal R&D resource allocation is mainly carried out by different regions, different industries, and different R&D entities. The stochastic boundary analysis method is

used to measure the effectiveness of R&D resources in 28 provinces and regions. The factors affecting the effectiveness of regional R&D in our country from 2014 to 2019 are analyzed. DEA model and SFA model are mainly used to study the efficiency of R&D resource allocation in various regions of our country. The conclusions are basically the same. It can be considered that in the eastern, central, and western regions of our country, the allocation efficiency of R&D resources is significantly different. In regions with better economic growth, the allocation efficiency of R&D resources may not be high. The efficiency of allocating R&D resources to economically underdeveloped regions is not necessarily low, and DEA is effective or ineffective [3].

As early as the 1960s, scholars began to pay attention to the efficiency of R&D resource allocation, using the Cobb-Douglas production function to measure the efficiency of R&D resource allocation, using only R&D stock as an input indicator, select data from 40 countries and regions from 1960 to 2000 to study the effectiveness of R&D resource allocation in each country, and analyze its influencing factors. The survey results show that per capita GDP has the greatest impact on the efficiency of R&D resource allocation, and they also have a positive impact on the efficiency of R&D allocation [4, 5].

Liu G used nonparametric production frontier methods to study the components of our country's total factor productivity growth from two different perspectives: technological contribution and factor contribution. By combining two-year environmental technology and nonradiative directional distance functions, he developed a biennial. The nonradiation direction distance function measurement can overcome the well-known infeasibility problem, incorporate the total slack of the variable, and explore the driving factors of our country's TFP. Although this growth rate has slowed down recently, our country's TFP is still growing at an annual rate of 2.02%. Secondly, from the perspective of technological contribution, technological progress is the main driving force of total factor productivity [6]. Tugcu CT studied the causal relationship between energy consumption and TFP growth in the BRIC countries. Using panel bootstrapping Granger causality test, there is no significant causal relationship between renewable energy consumption and TFP growth in BRIC countries. Concerning nonrenewable energy, there is a two-way causal relationship between Brazil and South Africa's total factor productivity growth [7].

**1.3. Innovation.** Based on the New Economic Development Theory, Resource Allocation Theory, New Economic Geography Theory, etc., this article examines the effectiveness of our country's R&D resource allocation and its spatial differences from the perspective of time and space and combines them organically. Economy and geography make it more intuitive and clear to reflect the geographical and spatial arrangement of our country's R&D activities and their temporal and spatial evolution.

In this study, the DEA-Malmquist index model and factor analysis method are used to conduct an in-depth study

of the regional differences in the effectiveness of R&D resource allocation and environmental impact factors in our country. The effectiveness of R&D allocation is broken down into technical performance and pace of technological progress, as well as regions and regions. We conduct a more thorough and specific analysis of the differences in R&D efficiency within R&D distribution and try innovative research methods.

This article is based on endogenous development theory and mathematical statistics. When estimating total factor productivity, this article uses the Cobb-Douglas production function and Malmquist index methods to cover the weaknesses of a single model in the calculation process. The overall growth rate of factors calculated by these methods is basically the same.

This paper separates the fiscal market from the financial market. When analyzing the impact of the resource allocation efficiency of the tax market on total factor productivity, it combines theoretical research with practical research, enriching the current domestic and foreign scholars' research on the impact of fiscal R&D resource allocation efficiency on total factor productivity and theoretical research on the mechanism of factor productivity.

## 2. Impact of Total Factor Productivity under Complex Systems

**2.1. Complex System.** The definition of a complex system first appeared in the American journal "Science" magazine "Complexity Album." The two authors gave the following definition: by understanding the system's subsystems, it is impossible to fully explain the nature of the system. In other words, for a complex system, its total performance is not a simple superposition of partial performance, and there is a complex nonlinear relationship between total performance and partial performance [8].

Complex systems are the main research object of complexity science, and the synchronization phenomenon of complex systems is the current research focus. When studying complex systems, complex networks are considered to be important mathematical models, and their related theories are of great significance to the study of complex systems. Durability is a key attribute of dynamic systems and is usually used to describe the dynamic behavior of spaced systems. A retrospective graph is a visualization tool based on robustness. Quantitative robustness analysis is a measure of quantitative robustness analysis [9]. As a new method of studying complex systems, retrospective graphs and quantitative reduction analysis have been widely used in many complex system problems. The logical relationship between the theories used in this article is shown in Figures 1–3.

The concept of a complex system is realized based on the critical inheritance of reductionism. The theory of complex systems is not just a refusal to restore. Reductionism is valid and logical within a certain range, because in addition to complex systems, there are other types of systems in the world. Generally, there are three types of systems in the world: simple systems, random systems, and complex systems [10].

FIGURE 1: Complex system framework.

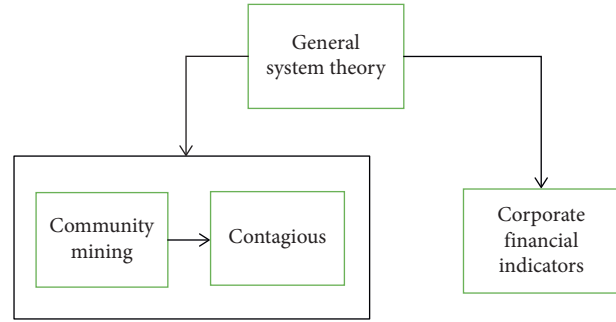

FIGURE 2: General system theory construction.

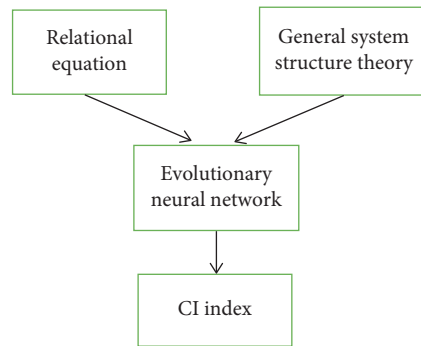

FIGURE 3: Logical relationship diagram of each theoretical tool.

A complex network is a mathematical model of a complex system. Its main purpose is to explain the existing phenomena and complexity of the network. The research object is the network [11]. The Internet is ubiquitous in nature and human society and has a profound impact on human development. Graph theory is an important tool for studying complex networks. Generally, a network is considered a graph, which contains a series of nodes and the ends that connect these nodes.

**2.2. VR Technology and Machine Learning.** VR technology is a virtual reality technology that uses computers to simulate real and unreal 3D scenes. Virtual reality technology is the highest level of current simulation and virtual reality, and it has integrated a variety of technologies, such as multimedia technology, digital image processing, sensor technology, and computer graphics [12]. VR technology can create 3D visual and sound effects. Since human-computer interaction is a friendly and harmonious state based on physical skills, 3D virtual reality technology can change the passive and boring state between man and machine. Virtual reality technology

combines computer technology, multimedia technology, image technology, simulation technology, and various electronic technologies to create new technology in the computer field, as shown in Figure 4.

Virtual reality technology is a computer simulation system that can build and experience the virtual world. Virtual reality technology is a very challenging interactive technology, which is gradually being widely used in the field of scientific research [13, 14]. At present, in the fields of military, medicine, film, and television, virtual reality technology has gradually become an important technology, and the development of virtual reality technology in the field of education is gradually deepening. Virtual reality technology is a cutting-edge technology in the computer field, which combines human-computer interaction technology, sensor technology, network technology, graphics technology, simulation technology, and stereo display technology. Virtual reality technology has three main characteristics, as shown in Figure 5.

Machine learning enables computers to learn and deal with human-like problems. Therefore, it is very important to focus on how to apply machine learning algorithms to solve

FIGURE 4: VR technology elements and characteristics.

FIGURE 5: Three characteristics of virtual reality.

practical problems. Machine learning has a wide range of research scenarios and applications. It is a multidisciplinary field, including artificial intelligence, information theory, statistical probability, government, and other academic achievements [15, 16]. The machine learning algorithms involved in this research are Bayesian statistical conclusions, EM algorithms, and ADMM algorithms, as shown in Figure 6.

According to historical data, with the help of the dynamic grouping method, the indirect correlation between parameters is determined through the EM algorithm, which aims to realize the dynamic vector grouping support algorithm, which is beneficial to reduce the risk of information decision-making [17]. The specific technology application path is shown in Figure 7.

Machine learning uses detailed methods in statistics, evidence theory, neural networks, fuzzy sets, primitive sets, evolutionary computing, and other fields to complete data summarization, concept description, classification rule extraction, grouping analysis, data analysis, analysis and sequence pattern discovery, and other types of work [18, 19]. Compared with data mining, machine learning tends to provide different algorithms, while data mining tends to use these algorithms to solve problems. Common machine learning algorithms include the following categories:

- (1) Classification algorithm: representative algorithms are decision tree algorithm and a naive Bayes algorithm
- (2) Clustering algorithm: representative algorithms are K-means algorithm and EM algorithm
- (3) Association rule extraction algorithm: the representative algorithm is the Apriori algorithm
- (4) Support vector machine, namely, SVM algorithm
- (5) Neural Networks
- (6) Genetic algorithm

Logistic regression (LR) is a machine learning algorithm with low model complexity and a classic statistical

classification algorithm. Its advantages are low computational complexity, easy to understand and apply, and can be used for large-scale machine learning and online learning tasks [17]. The conditional probability distribution formula of the binomial logistic regression model is

$$P(A = 1|x) = \frac{\exp(mx + n)}{1 + \exp(mx + n)}, \quad (1)$$

$$P(A = 0|x) = \frac{1}{1 + \exp(mx + n)}.$$

*2.3. Fiscal R&D Resource Allocation Efficiency.* R&D (Research and Development) refers to the human, material, and financial resources required to participate in scientific research and experimental development activities. R&D expenditure and its proportion in GDP reflect the important content of our country's independent innovation capability and the process of building an innovative country. It is an important indicator to measure the scale of a country's scientific and technological activities and the level of scientific and technological investment, and it is also an important indicator to improve our country's innovation potential and enhance the competitiveness of the national economy. UNESCO believes that R&D is a systematic creative activity that uses new knowledge to create new applications. OECD (Organization for Economic Cooperation and Development) believes that R&D is a more systematic and creative activity. This type of activity is based on increasing the total amount of knowledge and using that knowledge to create new applications [20].

Resource allocation was first proposed by the classical economy. It emphasized the role of the market in the allocation of resources and believed that the market was the most important way to allocate resources. However, in fact, due to the shortcomings of the market itself, especially the failed market, it seriously wasted resources. Adam Smith believes that due to a lack of resources, the market uses

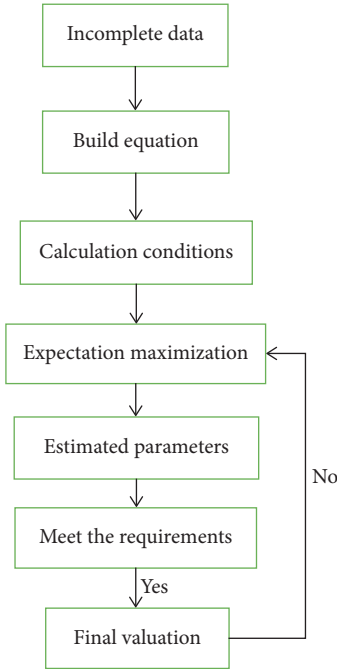

FIGURE 6: Flow chart of the EM algorithm.

FIGURE 7: Technical route of dynamic clustering decision.

profit-driven methods to achieve effective resource allocation. Tables 1 and 2 list the average fiscal R&D resource allocation efficiency of countries and regions.

**2.4. TFP.** Total factor productivity (TFP) refers to factors other than capital and labor income that contribute to economic growth. It is an important indicator to measure the quality of economic growth. Our country has a lot of research on total factor productivity. Total factor productivity is proposed relative to the concept of single-factor productivity. After excluding the increase in input rate, the remaining contribution of production improvement sources is attributed to the improvement of technology and efficiency. This part is total factor productivity, that is, the rest of the economic growth that cannot be explained by input factors. Fundamentally speaking, total factor productivity measures the influence of factors such as technological innovation, process improvement, management level, and efficiency. The role of industrial organization in economic development reflects the quality of economic development and represents the overall efficiency of the use of input factors [21].

Comparing the differences in total factor productivity between different countries, the scale of total factor productivity will directly affect the level of economic growth. There are several methods for calculating TFP in empirical research. Solow residual algorithm will be used, and its approximate algorithm is as follows:

$$\text{TFP growth} = \frac{\dot{L}}{L} = \frac{\dot{M}}{M} - \beta \frac{\dot{N}}{N} - (1 - \beta) \frac{\dot{O}}{O}, \quad (2)$$

where  $L$  is the technology input,  $M$  is the output,  $N$  is the capital input,  $O$  is the labor input, and  $\beta$  is the proportion of capital input to output. According to the above Solow formula, if we want to be able to accurately calculate the growth of TFP, we must adopt the function of neoclassical production. The factor market is fiercely competitive, and the growth rate of various inputs must be accurate. In addition, many papers have adopted the following methods, but the basic idea is the same as the above formula:

$$\text{TFP} = \frac{M}{N^\beta \times O^{1-\beta}}. \quad (3)$$

In order to calculate total factor productivity, some documents divide the calculation methods into two categories: trend estimation method and production function method. Trend estimation methods include parametric, semiparametric, and nonparametric methods. It uses total factor productivity as the default variable and uses long-term statistical information to estimate total factor productivity based on a set of assumptions. The production function method is mainly based on the basic form of the Cobb-Douglas production function in the neoclassical development theory. It uses mathematical transformations to discover the number of factors affecting economic growth, such as technological level and technical performance, in addition to capital and labor. Therefore, the productivity of all factors can also be called the residual value of the production function [22].

This article will choose the SFA method and use the prior logarithmic function to calculate our country's interprovincial total factor productivity. The production function has the following form:

$$\begin{aligned} \ln S_{a,b} = & \alpha_0 + \alpha_1 \ln M_{ab} + \alpha_2 \ln N_{ab} + \beta_1 b \\ & + \frac{1}{2} \beta_2 \ln^2 N_{ab} + \frac{1}{2} \beta_3 \ln^2 M_{ab} \\ & + \frac{1}{2} \beta_4 b^2 + \beta_5 \ln N_{ab} M_{ab} + \beta_6 b \ln M_{ab} \\ & + \beta_7 b \ln N_{ab} + x_{a,b} - y_{a,b}. \end{aligned} \quad (4)$$

When all  $\beta$  is 0, the model will become a technically neutral Cobb-Douglas production function. In addition, the model also considers static and dynamic technological

TABLE 1: Average allocation efficiency of our country's fiscal R&amp;D resources.

| Year          | Technical efficiency | Technological progress rate | Pure technical efficiency | Scale efficiency | Allocation efficiency |

TABLE 2: Average allocation efficiency of financial R&amp;D resources in each region.

| Year    | Technical efficiency | Technological progress rate | Pure technical efficiency | Scale efficiency | Allocation efficiency |
|---------|----------------------|-----------------------------|---------------------------|------------------|-----------------------|
| East    | 0.996                | 1.016                       | 0.996                     | 1.001            | 1.015                 |
| Central | 1.003                | 1.000                       | 0.998                     | 1.005            | 1.001                 |
| West    | 1.020                | 0.986                       | 1.018                     | 1.002            | 1.007                 |

progress and the dynamic interaction of labor and capital input into production. By organization, we get

$$IHK_{ab} = IJ_{ab} + IK_{ab} + (JF - 1)(\lambda_N(\lambda_N + \lambda_M)N + \lambda_M(\lambda_N + \lambda_M)M), \quad (5)$$

and decomposing it, the production efficiency change rate is

$$IJ_a = J[\exp(-y_a)|x_a - y_a]. \quad (6)$$

The technical progress rate is

$$IK_{ab} = \frac{\partial \ln S_{ab}}{\partial} = \beta_1 + \beta_4 b + \beta_6 \ln m_{ab} + \beta_7 \ln n_{ab}. \quad (7)$$

The rate of change of scale efficiency is

$$FJC = (JF - 1) \left( \frac{\mu_N}{\mu_N + \mu_M} \times N + (\mu_N + \mu_M)M \right). \quad (8)$$

Among them,  $\mu_N$  and  $\mu_M$ , respectively, represent the output elasticity of capital and labor relative to the overall return to scale:

$$\begin{aligned} \mu_N &= \alpha_N + \beta_7 b + \beta_5 \ln M_{ab} + \beta_2 \ln N_{ab}, \\ \mu_M &= \alpha_M + \beta_6 b + \beta_5 \ln N_{ab} + \beta_3 \ln M_{ab}. \end{aligned} \quad (9)$$

**2.5. Model Building.** In this study, the DEA-Malmquist index model was used to measure the effectiveness of R&D allocation in our country. In the DEA empirical research, in order to reflect the evolution of production unit efficiency in different periods, the most widely used production efficiency index is the Malmquist index [23]. Caves proposed that under multiple inputs and outputs, the total productivity based on the input data can be expressed by the Malmquist index. In order to obtain the Malmquist efficiency value, the distance function  $S^a(x_0^a, y_0^a)$  needs to be input, which is the inverse of the input efficiency, namely,

$$S^a(x_0^a, y_0^a) = \frac{1}{T^a(y_0^a, x_0^a)}. \quad (10)$$

This function is the smallest degree where  $x_0^a$  can be reduced under a given  $y_0^a$ . When

$$S^a(x_0^a, y_0^a) = 1, \quad (11)$$

$(x_0^a, y_0^a)$  on the frontier of production,

$$S^a(x_0^a, y_0^a) > 1 \quad (12)$$

indicates that the technology is invalid, and the performance value can be expressed by the Malmquist index:

$$T^a = \frac{S^a(x_0^a, y_0^a)}{S^a(x_0^{a+1}, y_0^{a+1})}, \quad (13)$$

$$T^{a+1} = \frac{S^{a+1}(x_0^a, y_0^a)}{S^{a+1}(x_0^{a+1}, y_0^{a+1})}.$$

These two indicators are the Malmquist index in the period  $a$  and period  $a + 1$ , respectively. We use the geometric mean of these two Malmquist indices to calculate the change in productivity, namely,

$$\begin{aligned} TI &= \frac{S^a(x_0^a, y_0^a)}{S^{a+1}(x_0^{a+1}, y_0^{a+1})} \left[ \frac{S^{a+1}(x_0^{a+1}, y_0^{a+1})}{S^a(x_0^{a+1}, y_0^{a+1})} \times \frac{S^{a+1}(x_0^a, y_0^a)}{S^a(x_0^a, y_0^a)} \right]^{1/2} \\ &= EF \times AC. \end{aligned} \quad (14)$$

$TI > 1$  shows that the productivity of the period  $t + 1$  is higher than the productivity of period  $a$ . Malmquist index can be decomposed into technical performance index and technological progress rate index. EF and AC are greater than, equal to, and less than 1, respectively, indicating that the technical performance and technological progress rate remain unchanged or decline, and the technical efficiency is

decomposed into pure technical efficiency index and index scale efficiency. The survey is used to measure the changes in the effectiveness of R&D allocation in 28 provinces and regions in our country from 2014 to 2019 [24].

A general method of estimating capital stock and current capital is the sum of current new capital investment and previous capital minus capital depreciation. The basic types of calculations are

$$R_x = \frac{A_x}{B_x} + (1 - \mu)R_{x-1}. \quad (15)$$

Among them,  $R$ ,  $A$ , and  $B$  are the capital stock, investment, and fixed asset investment price index,  $\mu$  is the annual depreciation rate of capital, and the subscript  $x$  represents the period [25].

### 3. Experiment on the Influence of Total Factor Productivity under Complex Systems

A large number of research results show that the efficiency of fiscal R&D resource allocation is a key factor in promoting overall productivity and economic growth. Comparing the results of different empirical methods, we can conclude that the massive influx of R&D funds based on international trade has greatly increased the overall factor productivity of our country's industry, while the low efficiency of domestic fiscal R&D resource allocation has restricted its growth. Therefore, it is recommended to improve the efficiency of fiscal R&D resource allocation and strengthen trade with developed countries.

**3.1. Test Subject.** The empirical part of this article first examines the direct impact of R&D resource allocation efficiency on improving the overall productivity of participants. In addition, in order to further determine the impact mechanism, this article decomposes the overall productivity of agents into changes in technical progress (TE) and technical efficiency (EF). Conversely, as explained by the variables, it empirically examines the impact of R&D resource allocation efficiency on technological progress and technical efficiency. Therefore, this paper constructs the following model with total factor productivity (TFP) as a variable explanation:

$$\begin{aligned} TFP_{ab} = & \omega + \lambda_1 TFP_{ab-1} + \lambda_2 FA_{ab-1} + \lambda_3 RND_{ab} + \lambda_4 HC_{ab} \\ & + \lambda_5 GI_{ab} + \lambda_6 FDI_{ab} + \lambda_7 OPEN_{ab} + \lambda_8 DAR_{ab} + z_{ab}. \end{aligned} \quad (16)$$

**3.2. Test Design.** Total factor productivity is the main indicator to measure the impact of resource allocation efficiency and technological innovation level on economic growth. In order to be able to estimate total factor productivity, we introduced the Cobb-Douglas (CD) production function into the analysis process based on the practice of other scholars. The production function is as follows:

$$S_{ab} = L_{ab} M_{ab}^\alpha N_{ab}^\beta, \quad (17)$$

where  $S_{ab}$  represents the GDP of province  $a$  in year  $b$ ,  $L_{ab}$  represents the total factor productivity of province  $a$  in year  $b$ , and  $M_{ab} N_{ab}$  represents the capital stock and labor force of province  $a$  in year  $b$ .  $\alpha$  and  $\beta$ , respectively, represent the output elasticity of the two production factors of capital and labor. Taking the logarithm of both sides of the formula equation at the same time, you can get

$$\ln S_{ab} = \ln L_{ab} + \ln M_{ab} + \ln N_{ab}. \quad (18)$$

Doing further transformation, you can get

$$\ln L_{ab} = \ln S_{ab} - \ln M_{ab} - \ln N_{ab}, \quad (19)$$

where  $\ln L_{ab}$  is the logarithm of the total factor productivity of each province over the years. Taking the physical indicators on the left and right sides of the equation at the same time, we can get the final expression of total factor productivity:

$$\ln L_{ab} = \exp(\ln S_{ab} - \ln M_{ab} - \ln N_{ab}). \quad (20)$$

We use the Solow residual method to decompose and measure total factor productivity and set the total production function as the C-D production function:

$$G_a = X e^{\lambda a} Y_a^\alpha Z_a^\beta. \quad (21)$$

Among them,  $G_a$  is the actual output,  $Z_a$  is the labor input,  $Y_a$  is the capital stock, and  $\alpha, \beta$  are the average labor output share and the average capital output share, respectively.

Now, we make the following assumptions: constant returns to scale; if the input quantity increases by the same percentage, the output also increases by the same percentage; the neutral technology assumes that labor productivity and capital productivity increase by the same percentage; the natural logarithm of the two sides is as follows:

$$\ln(G_a) = \ln(X) + \lambda a + \alpha \ln(Y_a) + \beta \ln(Z_a). \quad (22)$$

The growth rate of total factor productivity is derived as

$$\frac{\Delta X}{X} = \frac{\Delta G}{G - (1 - \alpha)} \times \frac{\Delta Z}{Z} - \alpha \times \frac{\Delta Y}{Y}. \quad (23)$$

Under the constraint condition  $\alpha + \beta = 1$  of constant return to scale, we have

$$\ln\left(\frac{G_a}{Z_a}\right) = \ln(X) + \lambda a + \alpha \ln\left(\frac{Y_a}{Z_a}\right). \quad (24)$$

After estimating the average share of capital production and labor productivity, the growth rate of total factor productivity can be obtained by introducing equations. We judge  $\alpha = 0.7, \beta = 0.3$  according to the empirical method and bring the total factor productivity table.

## 4. Impact on Total Factor Productivity

*4.1. Time Series Changes in the Efficiency of Fiscal R&D Resource Allocation.* As shown in Figure 8, the TFP growth rate of the entire industry from 2014 to 2019 was 8.4%, the average growth rate of technical performance was  $-1.4\%$ , and the average growth rate of technological progress was  $9.9\%$ . Technological progress plays a leading role in changes in total factor productivity. The contribution of technological progress to the overall productivity growth of the industry is far greater than changes in technical performance. Further analysis of the net changes in technical performance and scale performance changes of EF decomposition elements shows that my country as a whole has reduced the return to scale ( $-2.4\%$ ). The speed of technological progress is a key factor that affects the efficiency of R&D resource allocation. On this basis, the factor analysis method is used to analyze the environmental factors that affect the efficiency of R&D resource allocation. The research results show the government support, economic development level, and foreign investment level. It plays an important role in promoting my country's total factor productivity and is also an important reason for regional differences, as shown in Table 3.

As shown in Figure 9, the change in the efficiency of my country's fiscal R&D resource allocation is almost the same as the change in the pace of technological progress, while pure technical efficiency and scale performance have little effect on the efficiency of R&D allocation, indicating that technological progress at this pace directly affects the allocation of R&D resources. The overall efficiency of efficiency, the level of research, and development need to be improved. The efficiency of resource allocation must be based on the perspective of technological progress. As shown in Table 4, the rapid improvement of technological level, the renewal of technical equipment, technological innovation, and the introduction of advanced technology have a greater impact on improving the efficiency of my country's R&D resource allocation.

As shown in Figure 10, from 2014 to 2019, my country's overall resource allocation for fiscal research and development showed a slow growth trend, with an average rate of return of 1.01, but the growth rate was very slow. During these 7 years, the average growth rate of my country's R&D resource allocation efficiency was only  $0.5\%$ , which was mainly attributed to the slight increase in the rate of technological progress during the research period. In addition, the resource allocation efficiency of R&D reached the highest level in 2018, mainly due to the greatly improved technical level and the acceleration of technological progress. As shown in the figure, the slowing rate of technological progress has led to a decrease in the efficiency of R&D distribution, which is different in 2015 and 2018. The growth rate in 2016 has slightly decreased, as shown in Table 5.

*4.2. Regional Differences in the Efficiency of Fiscal R&D Resource Allocation.* As shown in Figure 11, in order to facilitate the analysis of regional differences in the efficiency of

my country's fiscal R&D resource allocation, this study divides my country's 30 provinces into eastern, central, and western regions. The R&D resource cost-sharing rate and national change coefficient of 30 provinces in eastern, central, and western regions of my country from 2000 to 2012 are given. The distribution efficiency of R&D resources in the eastern and central regions has shown a downward trend, while the western region has shown an upward trend.

As shown in Table 6, from the overall level, the efficiency of R&D resource allocation in each region is characterized by the highest in the east, the second in the west, and the lowest in the middle. The average efficiency is 1.014, 1.004, and 1.000 in order. The R&D distribution efficiency in the eastern region is 1.005 higher than the national average, and the central and western regions are lower than the national average. The coefficient of variation of the national average rate of return on R&D resources shows a downward trend, indicating that the regional differences in the efficiency of R&D resource allocation in my country are generally shrinking, as shown in Figure 12.

*4.3. Overall Situation of Total Factor Productivity.* As shown in Figure 13, total factor productivity decreased significantly from 2000 to 2016, and total factor productivity increased significantly from 2013 to 2014. This fully shows that my country's deepening reform and opening-up have led to economic growth and total factor productivity. Total factor productivity reached its peak in almost every city in 2014 and then declined every year. This shows that reform and opening-up can indeed bring technological progress and increase overall factor productivity, but with the past of reform and opening-up, this impact will continue to weaken, as shown in Table 7.

As shown in Figure 14, from a national level, the overall factor productivity generally declined. From 2010 to 2019, the growth rate of the total factor productivity in most cities was less than zero in most years. This shows that my country's economic growth is highly dependent on capital and labor, and my country's technological progress is not obvious. On average, my country's major cities have shrunk by  $5.78\%$ . During these years, the total factor productivity of 41% of the cities increased in 2010, which was the best year for total factor productivity. However, the overall factor productivity in 2015, 2018, and 2019 showed an overall downward trend. Almost 95% of cities showed negative growth in all factors.

*4.4. TFP and Decomposition Index.* As shown in Figure 15, using DEAP2.1 software, we select the input-oriented fixed income statement model and use table data from 30 provinces to obtain the results of the Malmquist index method. The Malmquist index decomposition model provides a comprehensive performance index for the total factor productivity of each province in my country. The index can be decomposed into the rate of scale efficiency change and the net change of technical performance according to the rate of change of technical performance, the rate of technological progress, and the rate of change of technical

FIGURE 8: Net changes in technical performance and changes in scale performance.

TABLE 3: 2014–2019 total factor productivity index.

| Year    | Technical efficiency changes | Technological progress changes | Scale efficiency changes | TFP   |
|---------|------------------------------|--------------------------------|--------------------------|-------|
| 2014    | 1.101                        | 0.987                          | 1.070                    | 1.086 |
| 2015    | 0.925                        | 1.236                          | 0.945                    | 1.142 |
| 2016    | 0.886                        | 1.135                          | 0.905                    | 1.006 |
| 2017    | 1.014                        | 1.041                          | 1.001                    | 1.055 |
| 2018    | 0.988                        | 1.038                          | 0.999                    | 1.025 |
| 2019    | 1.005                        | 1.028                          | 1.002                    | 1.032 |
| Average | 0.987                        | 1.078                          | 0.987                    | 1.058 |

performance rate. As shown in Table 8, from 2014 to 2019, my country's total factor productivity increased by 4.02% annually, net efficiency changed (-0.37%), net technological progress changed (3.91%), scale efficiency changed (-0.08%), and technology scale changed (-0.37%).

Technological progress is the main factor leading to the increase in green total factor productivity. The regional differences in my country's green factor productivity growth are very obvious. From east to west, there is a gradual downward trend. From 2014 to 2019, the average annual

FIGURE 15: Results of the Malmquist index method.

growth rate of total factor productivity in the eastern region was 5.56%, the central region was 3.60%, and the western region was 2.79%, as shown in Table 9.

4.5. Calculation and Analysis of TFP in the East, Middle, and West. As shown in Figure 16, in order to avoid duplication of the work of this article when analyzing the TFP differences in the three main regions of eastern, central, and western regions, this article studies the differences in these three regions based on the results of the Malmquist index calculation method. In order to visually see the

changes in total factor productivity in the three main regions, the average total factor productivity value of each region and province is used. In the case of subregional levels, the overall growth rate of agents in the eastern region is the fastest. Secondly, the overall growth rate of agents in the central region is usually higher than that in the western region.

As shown in Figure 17, the development of total factor productivity in these three regions from 2004 to 2009 was mainly attributed to technological progress. After 2009, this is the result of the comprehensive influence of technological

TABLE 8: The index is based on the rate of change of technical performance.

FIGURE 16: Average TFP of east, mid, and west.

progress and technical efficiency, making total factor productivity an annual trend. After 2000, the macroeconomy entered a stage of improvement. The technological progress in the eastern region has always been higher than that in the central and western regions, followed by the technological progress in the central region, and the lowest in the western region. This is the result of the spread of technological

progress. While taking advantage of the geographical advantages of the neighboring eastern region, the central region of my country must introduce advanced technologies, maintain technological progress, and at the same time pay attention to improving technical efficiency to more effectively promote the development of total factor productivity, as shown in Table 10.

FIGURE 17: The macroeconomy has entered an improvement stage.

TABLE 10: Differences in TFP between the three main regions in the central and western regions.

| Years | East  | Central | West  | South | North |
|-------|-------|---------|-------|-------|-------|
| 2000  | 0.968 | 2.31    | 0.958 | 3.5   | 1.87  |

| 2019  | 3.97  | 4.02    | 4.59  | 6.51  | 3.2   |

### 5. Conclusion

In the short term, the efficiency of fiscal R&D resource allocation promotes the development of total factor productivity, but as time goes by, its effect weakens. TFP limits the quality of economic growth in the short term, and the long-term effect of promoting the quality of economic growth tends to increase; during the inspection period, the economic growth rate is restricted. Among the three economic growth variables studied, the speed of economic growth has the greatest impact on the quality of economic growth. Therefore, at this stage, our country should control the rate of economic growth, improve the rationality of the allocation of R&D resources, promote the growth of total factor productivity, and achieve a slowdown in economic growth and high-quality growth.

Improving the quality of total factor productivity and economic growth will in turn help the rational allocation of fiscal R&D resources. The impact of economic growth on this has changed from positive to negative, which indicates that the excessive pursuit of economic growth will be ignored. This shows that excessive pursuit of economic growth will be ignored and to a certain extent will lead to waste of resources. The quality of economic growth has a deterrent effect on total factor productivity in the short term, but in the long run, it has an increasingly stronger role in promoting total factor productivity. Among these three variables, the

quality of economic growth has an effect on total factor productivity, which is the greatest contribution. Therefore, our country's pursuit of low-speed, high-quality economic growth can feedback the rational allocation of fiscal R&D resources and the development of total factor productivity, which forms a virtuous circle of economic activities.

If our country blindly pursues economic growth at the expense of the environment and resource waste, it will lead to a shortage of various social and natural resources, which will lead to a financial crisis, inflation, weak economic growth, and even serious problems. Excessive pursuit of the quality of economic growth requires increasing welfare benefits, increasing the cost of controlling environmental pollution, and shutting down a large number of seriously polluting enterprises. This poses a huge challenge to our country's fiscal expenditure capacity and leads to a slowdown in economic growth. Therefore, the relationship between the two must be properly handled to ensure healthy and stable economic growth.

With the development of office forms, the space form of super high-rise office buildings changed from the unitary efficient office space to a complex space that integrated office, communication, and experience, which also diversified the design of typical floors in the office zone. However, from the perspective of fire prevention, the placement of shared space changed the form of the plane in typical floors in the office zone, affecting the smoke spreading of fire and paths of personnel evacuation. Hence, the subject on the planar relationship among high-rise office buildings based on fire prevention analysis, which optimizes space design, is worthy of discussion. After collecting many cases of super high-rise office buildings in China, this study categorized them into six typical planes and adopted the software PyroSim for comparative simulation of the smoke spreading of fire. By comparing the visibility of different zones in fires, this study analyzed the effects of the area of the office zone, the location of the atrium, and the form of the plane on the fire visibility on the typical floor and put forth the key factors that influence fire visibility, thus optimizing the plane design of the typical floor of super high-rise buildings. The findings show that in the six fire scenes, the area of the office zone is between  $1136\text{m}^2$  and  $1736\text{m}^2$ . The peak of duration for visibility decline at 1.5 m appeared in Scene 3. Its office zone is  $1536\text{m}^2$ , and the duration of visibility decline is greater than 1000 s. In other fire scenes, the duration of visibility decline is less than 300 s. By comparing the plane arrangement features of the fire scenes, the paper concludes that in a given fire scene, establishing an atrium in the office zone, expanding the length of the adjacent edge between the atrium and the office zone, and building an evacuation corridor between the atrium and the core tube can greatly extend the effective evacuation time. This can serve as reference for the plane design of super high-rise office buildings.

## 1. Introduction

Super high-rise office buildings shoulder the important mission of multilayered optimization and development. Advancements in structural engineering have arisen to make possible the increase in height size and complexity, the reduction of cost and carbon footprint, and architectural imagination and economic versatility of these buildings [1]. As the modern office model becomes increasingly integrated, open, and smart, the plane design of typical floors, on the one hand, has increased the utilization value of the building space. But on the other hand, it has caused new fire safety problems to the buildings and resulted in greater difficulty in the fire safety design of the typical floor of buildings (Torero et al. [2]).

From both functional and structural perspectives, the typical floor plane of super high-rise office buildings, in general, can be roughly divided into two parts—the service part featuring core tubes and the service-receiving part characterized by frameworks. Judging from the development trend of existing structural techniques and the area of the typical floor, the upper limit of the ideal area of a typical floor can be lifted to  $4000\text{m}^2$  in a predictable future. After analyzing and investigating into the plane design drawings of super high-rise office buildings in recent years, this study has found that the floor space of an open and integrated office model needs to be as large as possible and continuous. Maximizing the plane area of the typical floor and exploring open office compartments are the two trends in the plane design of these buildings in modern times. For an office

space, a greater pillar spacing provides a broader view. As a design principle followed by the buildings of this kind in modern times, the pillar-free design indicates that in a designated office space, all bearing pillars are located near the curtain walls on all sides of the space to create a pillar-free space to provide a more flexible and efficient office zone. The correct definition of the design fire for open plan compartments is identified as the critical knowledge gap that must be addressed in order to achieve tall building performance objectives and to provide truly innovative, robust fire safety for these unique structures [1].

We have seen how classic prescriptive solutions failed to manage smoke (Cook Country Building (USA) [3] and Camberwell fire (UK) [4] and how modern buildings using state-of-the-art fire engineering failed to contain the full propagation of a fire (TVCC, China) [5]. Analyses of several failures and current design practices reveal that fire safety codes are no longer capable of providing implicit safety for the rapidly evolving needs of modern tall buildings and are being extensively substituted by nonvalidated performance-based design methods [1, 6]. Therefore, how to maximize the office zone on the typical floor and the space utilization efficiency while meeting the technical requirements on fire safety is a difficulty in typical floor design (Xing et al. [7]).

### 1.1. Fire Load of Super High-Rise Office Buildings.

Usually, massive office equipment, materials, papers, and archives are placed in an office. All these are highly combustible objects, thus imposing a heavy fire load on the office zone. Fire load ( $Q_f$ ) refers to both the heat of combustion of all combustible objects in the office zone and within the regional space. It is directly proportional to fire risks and the difficulty of firefighting (Yao et al. [8]). The total fire load of a unit area is fire load density ( $q$ ), which shows the severity of fire. Table 1 demonstrates the statistics on the average levels of fire load density in various functional space types of accredited buildings.

The computational analysis of the fire growth model effectively controlled smoke spread and emission.  $t^2$  model, MRFC model, and FFB model are the mathematical models of fire growth [10]. According to the results of numerous experiments and experience, the  $t^2$  model is used to describe the early stages of fire development in a specific space. Equation (1) is according to NFPA204M (2002):

$$Q_f = \alpha t^2, \quad (1)$$

where  $Q_f$  is the heat release rate(HRR), kW, and  $\alpha$  is the fire increasing modulus, kW/s<sup>2</sup>.

Table 2 shows the  $t^2$  model of different fire growth coefficients ( $\alpha$ ) adopted by various building designs and the maximum heat release rate and time of different materials.

### 1.2. Smoke Discharge of Office Zone in Super High-Rise Buildings.

According to the plane features and development trend of super high-rise office buildings, the demand for a pillar-free, open space has exceeded the maximum for a fire safety zone as required in the standards, which makes it

TABLE 1: Fire load density of different types of buildings [9].

|        | Space function | Density of combustible material |
|--------|----------------|---------------------------------|
| Office | General        | 30                              |
|        | Design         | 50                              |
|        | Administration | 60                              |
|        | Research       | 60                              |

impossible to achieve the fire safety zoning according to the traditional fire safety design. A higher office zone has a higher wind speed which will accelerate fire spreading on the typical floor in case of fire. Worse still, the absence of division in the interior lateral space would speed up the spreading of smoke [11].

According to the Code for Fire Protection Design of Building (GB50016-2014), "Mechanical smoke exhaust facilities should be installed and sites with interior net story height less than 6 m should include smoke control zones; the area of structure in each smoke control zone should not exceed 500 m<sup>2</sup>; and the smoke control zone should not cross beyond the fire protection zone. The smoke control zone should be separated by structural beams of partitions and ceilings with downward bulges no less than 500 m, or incombustible components of ceilings and canopies with downward bulges no less than 500 m." The smoke exhaust volume of mechanical smoke exhaust devices is demonstrated in Table 3.

Hence, it can be concluded that the area ( $S$ ) of each outlet is obtained with the following equation:

$$S = \frac{S1 \times 60 \text{ m}^3/\text{h}}{n \times 3600 \times 5 \text{ m/s}}, \quad (2)$$

where  $S$  is the area of the smoke discharge outlet,  $S1$  is the area of the smoke safety zone, and  $n$  is the number of smoke discharge outlets.

The area ( $s$ ) of each outlet was calculated according to the volume of the atrium through the following equation:

$$S = \frac{V \times 6}{n \times 3600 \times 10 \text{ m/s}}, \quad (3)$$

where  $S$  the area of the smoke discharge outlet,  $V$  is the volume of the atrium, and  $n$  is the number of smoke discharge outlets.

### 1.3. Crowd Evacuation of Super High-Rise Buildings.

Crowd evacuation in super high-rise buildings is a major safety concern [12]. According to the standards (GB50016-2014), the typical floor must provide two evacuation routes in case of fire, so that those trapped in fire can take the other if either of the routes is blocked (Wang and Liu [13]). For a more spacious typical floor, evacuation routes are longer present, and the choice of routes is blurrier, which would affect evacuation (Rodrigo and Marshall [14]). A subsafety zone can be established in the atrium to alleviate the pressure of evacuation (Liu [15]). But, the fire danger of the atrium is special, so if the subsafety zone is established in an inappropriate way, it will not reduce the pressure of evacuation and will even accelerate the vertical spreading of smoke.

TABLE 2: Fire growth coefficient (NFPA204M(2002)).

| Fire categories | $\alpha$ (kW/s <sup>2</sup> ) | $Q_f$ = the time of 1000 kW/s | Functions   |
|-----------------|-------------------------------|-------------------------------|---|
| Slow fire       | 0.0029                        | 600                           | Art gallery   |
| Medium fire     | 0.012                         | 300                           | Dwelling, apartment, construction room,<br>hotel reception, hotel bedroom |
| Fast fire       | 0.047                         | 145                           | Store   |
| Superfast fire  | 0.187                         | 75                            | —   |

TABLE 3: Minimum smoke exhaust volume of the mechanical system.

| Conditions and parts   | Unit smoke exhaust volume (m <sup>3</sup> (h))    | Ventilation (time/h) | Notes   |
|--|---|----------------------|---|
| One section of smoke control zone  | 60  | —                    | The smoke exhaust volume of each draught fan should not be less than 7200 m <sup>3</sup> /h                     |
| Areas with no smoke control zone and interior net story height greater than 6m |   |                      |   |
| Two or more smoke control zones  | 120   | —                    | Determined according to the maximum area of smoke control zone  |
| Atrium   | Volume less than or equal to 17000 m <sup>3</sup> | —                    | Volume greater than 17000 m <sup>3</sup> , smoke exhaust volume should be no less than 102000 m <sup>3</sup> /h |
|  | Volume greater than 17000 m <sup>3</sup>          | —                    |   |
|  |   | 6                    |   |
|  |   | 4                    |   |

Compared with CO mass fraction and temperature, visibility was a more influential factor in determining the critical time required for fire to become a hazard, and smoke affected the adjacent open area in approximately 60 s [12]. When a fire hazard is occurring, office zone visibility can directly affect the velocity of walking. In the irritating state and nonirritating state, the velocity of walking declines as the obscuration coefficient increases. In the irritating state, the velocity of walking showed sudden decline. Hence, the visibility of the horizontal section (1.5 m of interface) at the height of sight of crowd evacuation is one of the effective evaluation criteria about whether a certain area fits the condition of evacuation. In simulated calculations, the critical time of a dangerous situation is time  $T_4$  for visibility to decline to 10 m [16].

## 2. Materials and Methods

This research uses the software PyroSim to simulate the smoke spreading of fire [17]. The simulation process includes the following steps: (1) Building geometric models; (2) Establishing fire scenarios, including location and load of combustion source, simulation scope and boundary condition, different types of combustible materials, performance of firefighting equipment, duration and accuracy of simulation; and (3) conducting simulated calculation through FDS/smokeview for posttreatment of results [18]. In this process, by building the models, the simulation results could indicate the distribution graph of visibility of fire smoke in the model [19].

*2.1. Establishment of an Abstract Model.* After the investigation and the analysis of the existing super high-rise office buildings in China, this study confined the research subjects to those with a height of at least 150 m, a typical floor plane

of less than 3,000 m<sup>2</sup>, and a tube-in-tube structure. To carry out a comparative simulation experiment, the plane prototype of the typical floor of an office building was made. The plane was a 45 m × 45 m square plane, with an area of 2,475 m<sup>2</sup>. In the center of the plane was a 17 m × 17 m core tube. The space beyond the core tube was an integrated office area of 2,186 m<sup>2</sup>, whose story height was 4.2 meters and net height was 2.9 meters.

In most of the super high-rise office building designs, the atrium is the primary spatial element of plane design. The position and form of atrium is the main factor leading to different typical floor planes. Hence, by incorporating an atrium into the plane prototype, it can be deformed and derived. The approach and logic of incorporating the atrium have two aspects worth discussion: (1) In a fire hazard, the impact of the atrium area on visibility of the office zone; (2) in a fire hazard, the influence of position of atrium space in the office floor plane on visibility of office space. Responding to the above questions, (3) by gradually increasing the area of the atrium in the plane prototype, the derivative plane is obtained, which is shown in Figure 1. (4) By changing the position of the atrium in the plane prototype, the derivative plane is obtained, which is shown in Figure 2. Lastly, six typical floor planes (plane A–plane F) are concluded to serve as the typical floors and planes in this research.

In the above six typical planes, other than the core tube, all areas of plane A are the office zone, which is distributed in the way similar to the character shape “回.” It has the highest efficiency and stable structure for office utilization. However, due to the excessive spatial continuity, the horizontal smoke spreading rate is rather high. There is no atrium space to contain the excessive depth of the office zone, so the smoke exhaust efficiency is low, and crowd evacuation is difficult to be carried out. In plane B/C, plane D, and plane E/F, when the atrium space ratio increased, the office zone area decreased, and the smoke exhaust efficiency increased as well.

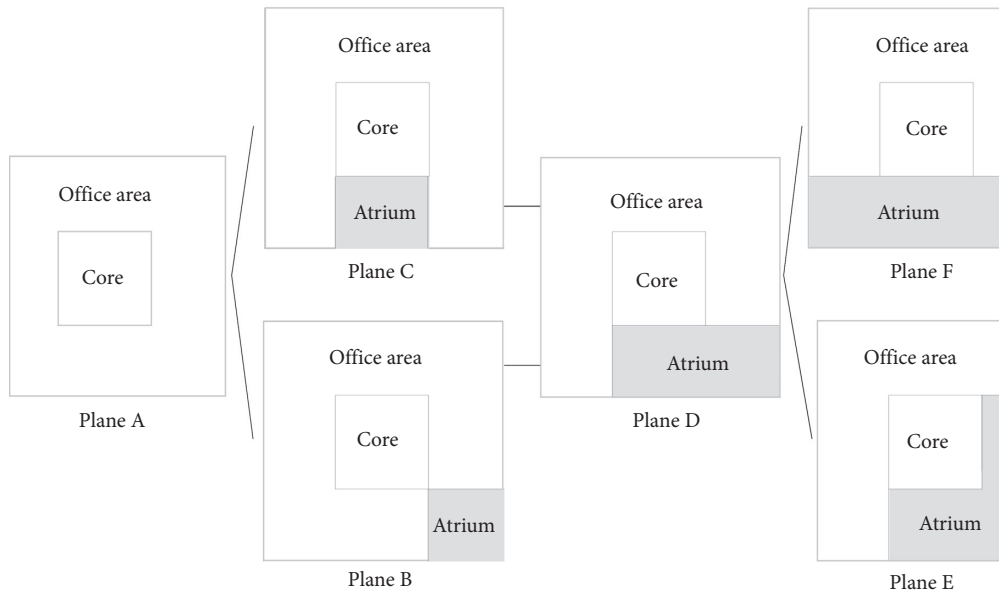

FIGURE 1: Different area proportions of the same atrium position in the plane prototype.

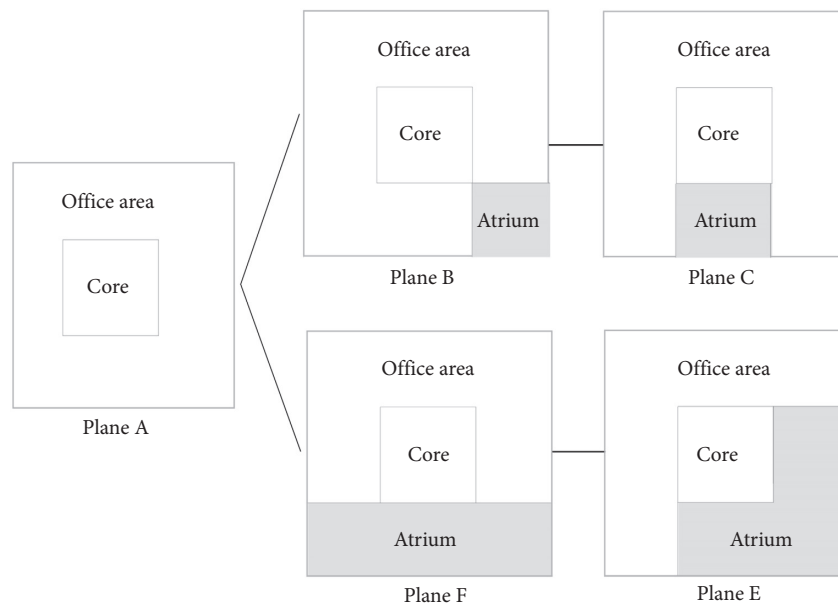

FIGURE 2: Different positions of the same atrium area in the plane prototype.

However, when the area of the office zone became smaller, the time for smoke to sink declines, which may negatively influence visibility. Moreover, smaller office zone reduced the service efficiency and structural stability of buildings. Plane B/C and plane E/F are the typical floor planes with the same atrium area. The atrium positions of the two planes are, respectively, in the single-sided area and corner area of the “回”-shaped office zone. It significantly improved the plane modality of the office area and affected the routes of smoke

spreading. The contrast and analysis of plane features of the six typical floors are shown in Table 4.

In the comparative simulation experience, a piece of virtual land was chosen for a single super high-rise building with a  $45\text{ m} \times 45\text{ m}$  base. The six typical planes were modeled according to the same rules, and their planes were initially designed according to the existing standards to ensure that all the six buildings were a super high-rise office building 294 m high. Besides, there was no atrium in Model A, while

TABLE 4: Contrast of spatial elements in the six typical floor planes.

| Typical planes                         | Plane A | Plane B     | Plane C           | Plane D  | Plane E     | Plane F           |

there was a 42 meter-high atrium for every ten floors in Models B to F. The comparative models are shown in Figure 3, where light pink indicates the scope of simulation and dark red represents the floor with fire. Geometric models of simulation scope are shown in Figure 4.

**2.2. Design of Fire Scenes.** According to the standards, geometric models were established based on the hypothesized comparative simulation schemes, and the fire scenes were designed. In all the six fire scenes, the  $t^2$  fire was regarded as the source of fire, and the heat release rate was medium.

To ensure that people on the typical floor of super high-rise office buildings could evacuate in two different directions, the planes were optimized in the geometric model designs: a 2-meter-wide corridor was created adjacent to the core tube for the two office areas separated by the atrium in the planes equipped with an atrium, so that the office areas always encircle the core tube. As the whole typical floor was an integrated office space, the office area was not furnished with a fire shield. However, the fire shield was utilized to separate the atrium from the office area, and the atrium was established as a separate fire safety zone. An adequate number of smoke safety zones were established in all the six scenes. The largest smoke safety zone was 434 m<sup>2</sup>, smaller than the maximum of 500 m<sup>2</sup> as specified in the standards. The height of all the antismoke boards was 0.6 m, higher than the maximum of 0.5 m as specified in the standards.

As for the layout of the firefighting facilities, the sensing temperature of all the automatic sprinklers was 68°C, and the wind speed of the smoke discharge outlets was 5 m/s, and the outlets would stop working if the temperature reached 280°C. At least two smoke discharge outlets were installed in each smoke safety zone in the office area, and the distance between outlets was shorter than 60 m. The specification of smoke discharge outlet was determined according to the area of the smoke safety zone. According to previously mentioned standard requirements and formulas, ten 0.6 m × 0.9 m outlets were installed. The lower parts around the office area were equipped with five air supplies, and the wind speed was 5 m/s. Besides, the air supply amount met the minimum value (no less than 50% of smoke discharge amount) as specified in the national standards. In the atrium area, the atrium worked as a separate fire safety zone. As the height of the atrium was over 12 meters, the mechanical smoke discharge was adopted. All the smoke discharge outlets were installed on the top of the atrium and on the sides of each structural floor. Smoke shields were installed between the atrium and the office area and would be shut 30 s after the smoke alarm went off. A hole sharing the same

size with mesh was used to simulate a crack. A controlling device was installed on the curtain wall closest to the burner. If the temperature reached 500°C (flash burning), the window would be broken (vanish). Horizontal slices were installed 1.5 m above the ground to collect data of visibility [20].

The floor plans of the geometric models and the firefighting facilities are shown in Figure 5. The parameters of each fire scene are shown in Table 5.

### 3. Results and Discussion

Multiple slices were installed for measurement. Holes sharing the same size with a mesh cell were distributed evenly around the model to simulate the cracks between a normal curtain wall and the floor slab and simulate a real scene. A comparative experiment on the six models was carried out. In a fire, the basic logic of smoke control was as follows. In Models A to F, the burner started to burn from second 0, and the first sprinkler was initiated at a different time, and the HRR curve was kept constant; at this moment, the fire continued to burn but stopped spreading (for specific data, see Figure 6). After the first smoke alarm was initiated, the exhaust system was initiated, and the smoke shield was shut 30 seconds later. In Models B to F, thermocouples were placed near the window closest to the burner and beside the glass in the atrium garden. The controlling device was installed, and when the temperature reached 500°C (flash burning), the window would be broken (vanished). None of the Models B to F reached 500°C.

**3.1. Results of Visibility Simulation.** Sections at different temporal points of the horizontal plane 1.5 m (average practical height) above the ground were taken to observe the changes of the visibility graph, in order to obtain the results of simulation in six fire scenes (Table 6).

The results of visibility simulation show the change to visibility of all the typical planes under the same fire condition. ① In Fire Scene 1, there was no atrium, and the office area encircled the core tube. In a fire, the visibility in the fire safety zone of the fire source was reduced to below 10 m 120 s after the fire started. Then, smoke spread to both sides at the same time, and the visibility of two adjacent fire safety zones began to decline and then went down to less than 10 m 174 s after the fire started. When the smoke spread for 230 s, the visibility of the whole office area was less than 10 m. ② In Fire Scene 2, there was an atrium on the typical floor. As the atrium was located at one corner of the plane, the core tube was still encircled by the office area. In a fire, the visibility in the fire safety zone of the fire source declined to less than

FIGURE 3: Architectural models of the typical planes.

FIGURE 4: Geometric models.

10 m 96 s after the fire started. Then, smoke spread to both sides at the same time. As the size of two openings between the fire area and the two adjacent areas was different, there was a noticeable asymmetric distribution of the reduction rates of visibility: the visibility of the area with the larger opening was reduced significantly, while that with the smaller opening dropped slower. When the smoke spread for 255 s, the visibility of the whole office area was less than 10 m. ③ In Fire Scene 3, there was an atrium on the typical floor. The atrium covered one-fourth of the circumference of the core tube, and the office area covered three-fourths of the circumference. In a fire, the visibility in the fire safety zone of the fire source was reduced to less than 10 m 78 s after the fire started. Then, smoke spread to both sides at the same time. As the size of two openings between the fire area and the two adjacent areas was different, there was a noticeable

asymmetric distribution of the reduction rates of visibility: the visibility of the area with the larger opening was reduced significantly, while that with the smaller opening dropped slower; besides, a visual corridor with high visibility was formed between the atrium and the core tube. The visibility of the whole office zone was below 10 m 1000 s after the fire started. ④ Fire Scene 4 had a similar process of visibility reduction with Fire Scene 3. The atrium still covered one-fourth of the circumference of the core tube. But, as the atrium area was larger and the office area was smaller in Fire Scene 4 than Fire Scene 3, it took a shorter time (260 s) for the visibility of Fire Scene 4 to drop to less than 10 m. ⑤ In Fire Scene 5, the atrium on the typical floor continued to become larger, and the office area continued to shrink to 1,136 m<sup>2</sup>, and both the atrium and the office area covered half of the circumference of the core tube, respectively. In a

fire, the visibility in the fire safety zone of the fire source was reduced to less than 10 m 85 s after the fire started. As the size of two openings between the fire area and the two adjacent areas was different, there was a noticeable asymmetric distribution of the reduction rates of visibility: the visibility of the area with the larger opening was reduced significantly, while that with the smaller opening dropped slower; besides, a visual corridor with high visibility was formed between the atrium and the core tube. When the smoke spread for 230 s, the visibility of the whole office area was less than 10 m. © Fire Scene 6 shared the same area of

the office zone (1,136 m<sup>2</sup>) with Fire Scene 5. The atrium took the shape of “—,” covering one-fourth of the circumference of the core tube. In a fire, the visibility in the fire safety zone of the fire source was reduced to less than 10 m 85 s after the fire started. As the size of two openings between the fire area and the two adjacent areas was different, there was a noticeable asymmetric distribution of the reduction rates of visibility: the visibility of the area with the larger opening was reduced significantly, while that with the smaller opening dropped slower; besides, a visual corridor with high visibility was formed between the atrium and the core tube. When the

smoke spread for 232 s, the visibility of the whole office area was less than 10 m.

### 3.2. Visibility Comparison Analysis

3.2.1. Overall Visibility Comparison Analysis. When the area of the typical floor and the height of the floor remained

unchanged, the area (volume) of the office zone gradually became smaller with the increasing single-floor area of the atrium from Fire Scene 1 to Fire Scene 6, but the time for the visibility to drop to 1.5 m due to the spreading of smoke did not show any sign of becoming shorter. The duration of visibility reduction reached a peak value in Fire Scene 3. In other words, when the office area was 1,536 m<sup>2</sup> and the atrium was established on one side of the core tube, the

TABLE 7: Comparison of visibility data among different fire scenes.

|  | Scene 1 | Scene 2 | Scene 3 | Scene 4 | Scene 5 | Scene 6 |
|--|---------|---------|---------|---------|---------|---------|
| Office area (m <sup>2</sup> )            | 1736    | 1536    | 1536    | 1336    | 1136    | 1136    |
| Smoke spreading path                     | 2L      | 4L      | 5L      | 4L      | 4L      | 3L      |
| Duration of overall visibility reduction | 230 s   | 226 s   | >1000 s | 260 s   | 230 s   | 232 s   |

Plane shape

duration of visibility reduction was the longest. Under other circumstances, the area (volume) of the office zone, the area of the atrium, and the location of the atrium all had influence on the duration of overall visibility reduction of the office area. Therefore, a comparative research on the six models under two circumstances “when the area (volume) of the office zone was different” and “when the area (volume) of the office zone was the same but the location of the atrium was different” was carried out.

- (1) When the area (volume) of the office zone was different but the location of the atrium was the same.

In the comparison among Fire Scenes 1, 2, and 4, the office area of Models A, B, and D decreased progressively with a tolerance of 200 m<sup>2</sup>, and the spreading rate of smoke showed a trend of increasing progressively ( $V_A > V_B > V_D$ ). But, as there was a great difference in the plane of the office area of the three models, there was some difference in the smoke spreading path. According to the abstract plane of the office area (Table 7), the smoke in Model A spread to both sides in a symmetric way, so its smoke spreading path was counted as “2L.” The smoke spreading path of Model B and Model D was a one-way path which was counted as “4L.” The relationship among the three smoke spreading paths of the three models was “ $LA < LB = LC$ .” According to the simulation results, the total duration of visibility reduction of the three fire scenes was almost the same. This demonstrates that the establishment of the atrium reduced the area of the office zone, but this improved the smoke spreading path, and a one-way smoke spreading path had greater impact on overall visibility than the area (volume) of the office zone.

- (2) When the area (volume) of the office zone was the same but the location of the atrium was different.

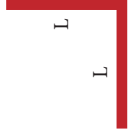

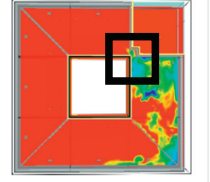

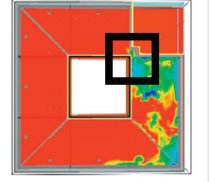

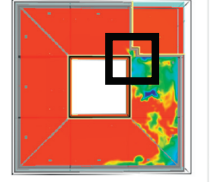

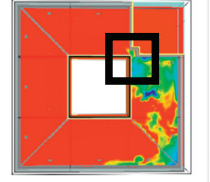

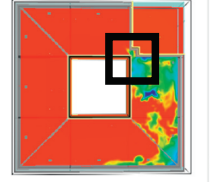

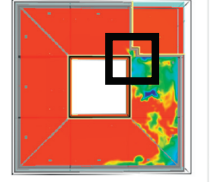

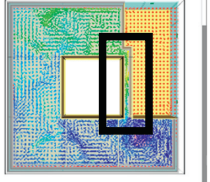

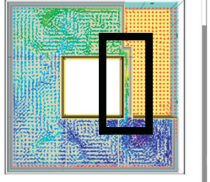

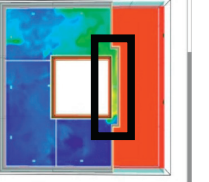

In the comparison between Fire Scene 2 and Fire Scene 3, the office area (volume) and smoke spreading rate of Models B and C were the same. According to the abstract plane of the office area (Table 7), the smoke spreading path of Model B was “4L” and that of Model C was “5L.” The simulation

results show that the duration of visibility reduction in Fire Scene 3 was remarkably longer than that in Fire Scene 2.

In the comparison between Fire Scene 5 and Fire Scene 6, the office area (volume) and smoke spreading rate of Models E and F were the same. According to the abstract plane of the office area (Table 7), the smoke spreading path of Model E was “4L” and that of Model F was “3L.” The simulation results show that the duration of visibility reduction in Fire Scene 5 was longer than that in Fire Scene 6. It is obvious that the smoke spreading path had greater influence on the overall visibility of the office than smoke spreading rate. In other words, the location of the atrium had greater influence on the duration of overall visibility reduction than the area (volume) of the office zone.

**3.2.2. Corridor Visibility Comparison.** According to the standards, an evacuation exit was set on one side of the office area adjacent to the atrium to ensure that each fire safety zone was equipped with two evacuation exits, and the exit must be as close to the core tube as possible. Therefore, evacuation corridors of different lengths between the atrium and the core tube were established according to different floor planes. As there was no atrium in Model A, there was no evacuation corridor. In Model B, the atrium was established at one corner of the plane, so an L-shaped corridor (represented as “L”) was formed between the atrium and the core tube. In Model C, a corridor with the length of “L” was formed between the atrium and the core tube. The two ends of the corridor were connected with two fire safety zones. In Model D, a corridor with the length of “L” was formed between the atrium and the core tube. One end of the corridor was connected with the fire safety zone, and the other end was linked with the L-shaped corner of the fire safety zone. In Model E, a corridor with the length of “2L” was formed between the atrium and the core tube. The two ends of the corridor were connected with two fire safety zones. In Model F, a corridor with the length of “L” was formed between the atrium and the core tube. One end of the corridor was connected with the fire safety zone, and the other end was linked with the L-shaped corner of the fire

shows the corridor zone between atrium and core tube. It is also the key area leading to differences between personnel evacuation and smoke spreading.

safety zone. Table 8 shows the length and end of different evacuation corridors as well as the duration of corridor visibility reduction.

In the comparison between Fire Scene 2 and Fire Scene 4, there was no evacuation corridor in Fire Scene 2, and the two fire safety zones were connected through the corner only. In Fire Scene 4, there was an evacuation corridor with a length of “L,” and a corner was set on one end. According to the results, the visibility on one end of the corridor began to decline nearly at the same time in both fire scenes, but the duration of visibility reduction in Fire Scene 4 was noticeably longer than that in Fire Scene 2. In the comparison among Fire Scenes 3, 4, and 6, no corner was set on either end of the corridor in fire scene with the corridor length in all the three fire scenes being “L.” But, there were smoke discharge outlets in Fire Scene 3, a corner was set on one end of the corridor in Fire Scene 4, and there were corners on both ends of the corridor in Fire Scene 5. According to the results, there was marked difference in the duration of visibility reduction among the three fire scenes, and the area with a corner effectively lengthened the duration of visibility reduction on the ends of the corridor and in the corridor. Compared with a corner, a smoke discharge outlet in the corridor was more effective in slowing down the visibility reduction rate and saving more effective evacuation time for the people in the corridor.

#### 4. Conclusion

- (1) The location of the atrium on the typical floor has a direct effect on the duration of visibility reduction.

The area (volume) of the office zone is an influencing factor to the smoke spreading rate in a fire. But, when the area of the office zone is the same or almost the same, the duration of visibility reduction in the area is, to a larger extent, influenced by the smoke spreading path. In the floor plan of a typical floor, changing the location or the plane of the atrium would effectively change the smoke spreading path in the office area. If the plane area of the typical floor is the same, more diverse and longer smoke spreading paths will lengthen the overall duration of visibility reduction on the typical floor and thus make it easier for people to evacuate.

Given the structure of super high-rise office buildings, a typical floor without atriums tends to take a symmetric form. In a fire, the smoke spreading path is the same as the evacuation path, and the fire would spread towards both ends of the fire safety zone where the fire started. This will impede evacuation. An atrium can change the smoke spreading path to ensure that the evacuation path is different from the smoke spreading path, which will facilitate the evacuation.

A longer edge shared by the atrium and the office area will lengthen the smoke spreading path and expand the duration of visibility reduction, which will lengthen the evacuation time.

In summary, establishing an atrium on the typical floor of super high-rise office buildings and lengthening the edge shared by the atrium and the office area will effectively lengthen the evacuation time in a fire.

- (2) Establishing evacuation corridors around core tubes can hinder the duration of visibility reduction.

Establishing an evacuation corridor can effectively stop smoke spreading, change the smoke spreading path in the whole office area, and effectively separate the evacuation path from the smoke spreading path. A longer evacuation corridor will lengthen the duration of visibility reduction in the evacuation corridor and will thus facilitate evacuation. Setting corners on both ends of the evacuation corridor can effectively slow down the visibility reduction on both ends and inside the evacuation corridor. But, a corner on the evacuation path would impede the evacuation and is against the design principles of an evacuation corridor. Therefore, corners are not recommended. It is suggested that smoke discharge outlets should be installed in the evacuation corridor.

The integration of event-related potential (ERP) and functional magnetic resonance imaging (fMRI) helps to obtain and study neural networks with high temporal and spatial resolution. EEG/fMRI data proves that in the visual tritestimulus oddball paradigm, two P300 potentials (P3a and P3b) induced by target stimulation and novel stimulation are detected at the frontal-middle (Fz), center (Cz), and mid-apical (Pz) electrodes. Previous studies have shown that P3a and P3b have different spatial distributions of brain activation, but it is unclear whether they have the same neural mechanism. The purpose of this study is to determine the neuropsychological mechanisms of P3a and P3b, as well as the spatiotemporal differences in neurodynamics between the two ERP subcomponents. In a group of 25 subjects, P300 ERP induced by target stimulation and novel stimulation can be detected at the Fz, Cz, and Pz electrodes. At Cz and Fz, compared with P3b related to the target stimulus, the P3a related to the novel stimulus has a higher amplitude and the waveform declines more slowly. But at Pz, P3b has a higher amplitude than P3a. P3a appeared earlier than P3b at Cz and Fz, but the opposite phenomenon was observed at the Pz electrode. The activated brain regions of P3a included the left frontal-parietal lobe region, left anterior wedge lobe region, and right insula, while the target-driven P3b was significantly associated with BOLD changes in the bilateral fusiform gyrus, the left frontal region, and the bilateral insula. The results showed that the integration of the spatial and temporal information of the two imaging modes, namely, ERP and fMRI, proves the existence of the different brain function processes of the two P300 subcomponents. Through the analysis of the composition of P300, the results further proved that the top-down and bottom-up processing processes have played a role in the occurrence of attention capture. It is just that the modulation effects of the two processing mechanisms are different in different tasks. Therefore, it should be noted that the captured neural mechanism is not a single top-down or bottom-up processing process but should be the result of the interaction between the two.

## 1. Introduction

For the human, rapidly distinguishing the relevant targets from distracting stimuli is one of the critical ability to execute an appropriate response according to the environmental requirement. One widely used task to assess this cognitive ability is oddball paradigms. In a three-stimulus oddball, it presents infrequent target stimuli in a background

of frequent standard stimuli and infrequent novel stimuli, and the subject is instructed to respond mentally or physically to the target stimuli as quickly and accurately as possible, but not to others [1].

The brain activity related to this ability has been widely studied with electrical recordings using ERP. Previous ERP research has shown that the P300 is the characteristic endogenous positive wave, arising between 260 and 500 ms

after the onset of each rare stimulus, which is more prominent over the centroparietal region of the scalp [2]. The oddball tasks can typically evoke two highly characteristic P300 ERPs, the target-related P3b and the novel-related P3a. The P3b is seen as a long positive slow wave occurring after a button press, which is affected by the expected versus actual action effects [3]. And the scalp distribution is defined as the amplitude change over the three midline electrodes (Fz, Cz, and Pz), which typically increases from the frontal to parietal sites and is the largest over parietal areas [4]. An infrequent novel stimulation, presented in a series of frequent standard stimuli without a target stimulation, can produce a positive-going waveform with a frontoparietal maximum amplitude distribution and relatively short peak latency and was dubbed the P3a to distinguish it from the target-related P3b potential [5, 6]. Many studies have found that P3a and P3b have different topographic amplitude distributions and peak latency. P3a and P3b data, using a difficult target/standard discrimination task in a three-stimulus paradigm from 120 healthy young adults, have shown that P3a has a central maximum, whereas P3b has a parietal maximum, and the peak latency for both was shorter over the frontal and longer over the parietal sites [7]. The topographic variation suggested that there may be overlapping neural activation patterns, which are functionally distinct [8, 9].

However, EEG traceability positioning is a relatively complicated problem, and there are infinitely many solutions that satisfy the EEG signal recorded by the scalp. Therefore, we need a priori assumption to constrain the solution space to obtain a unique solution. Functional magnetic imaging (fMRI) can be used to study the source localization of P300; many studies have identified brain activation evoked by detecting targets and novels in oddball tasks, which have shown different neuronal networks activated by targets (right temporoparietal junction and inferior frontal gyrus) and by novels (intraparietal sulcus and left inferior frontal sulcus) [10–13]. The relationship between abnormal ERP components and dysfunctional fMRI activation during oddball tasks in patients has also been extensively studied. Patients with frontal lobe lesions demonstrated diminution of P3a amplitude, whereas the same patients demonstrated a parietal maximum for the P3b, which suggested that frontal lobe integrity is necessary for P3a generation [14]. For the patients with comorbid depressive and anxiety disorders, findings showed an abnormal frontal-greater-than-parietal P3b topography in the right hemisphere and the highest P3a amplitude at frontal and central sites at the scalp midline [15]. It is proposed that P300 amplitude is affected by temporal-parietal junction integrity for its absence greatly reduces component size over the parietal area [16, 17]. This connection implies that the P3a and P3b indicate a circuit pathway between frontal and temporal/parietal brain areas [18, 19].

Event-related potential (ERP) and functional magnetic resonance (fMRI) are two advanced functional detection techniques for nondamaging brains today. EEG signal is a biological electrical activity spontaneously generated by the central nervous system, contains a wealth of information on

the state and changes of the nervous system, and can reflect the brain's skin reflection on stimulation. EEG signals are easier to obtain, and it is easier to establish interfaces with external devices (such as computers) to achieve direct interaction between the human brain and computers. This interaction is realized through brain-computer interface technology and then realizes a system to control the brain. EEG/ERP has a high temporal resolution and can track the processing of brain information, but the spatial resolution is low. fMRI can repeatedly observe and study the human brain function (language, cognition, exercise, etc.). It can not only observe the structure and shape of the brain but also get real-time information about blood flow functional images and metabolism. However, fMRI has a high spatial resolution, but a low temporal resolution. Combining EEG and fMRI signals and using information fusion theory to find the relationship between them may become a new and very effective method for scientific analysis and processing of brain function data.

Brain function modeling has always been a big problem that puzzled scholars from various countries. Due to the complexity of brain structure and function, it is difficult to model brain function alone. Internationally, the research on brain function modeling in recent years has mainly focused on the detection of EEG and fMRI signals. In order to improve the sensitivity and accuracy of detection, foreign researchers in recent years have vigorously improved measurement equipment and measurement methods; for example, improving the field strength of fMRI is very high. And some new methods in the extraction of useful signals and noise filtering, feature extraction, and data classification improve the signal quality of EEG and fMRI and the effectiveness of feature extraction, but this progress is slow. A new trend is that brain function detection is developing in conjunction with multiple technologies. For example, MRI and PET use image fusion or registration technology to obtain more information on brain functional activities; at the same time, EEG and MRI signals are obtained for information fusion can get more comprehensive features of brain function and improve resolution. Research in this area has been carried out in Germany, Canada, Japan, and other countries and a few domestic units. The representative of the Charlotte Hospital in Germany scans fMRI images while acquiring EEG signals for pathological research and pattern recognition and localization of brain function when the brain receives different stimuli from the body. But their research has just begun, and the correlation between EEG and fMRI signals is lacking.

Obtaining high imaging resolution and correct interpretation, analysis and processing of brain activity features have become the frontier of current research. The use of brain functional imaging technology to model, classify, and recognize the pattern of human brain nerve response can not only provide a more accurate and rich basis for the diagnosis of certain diseases but also more objectively study the human brain in psychology and intelligence. This aspect of the activity lays the foundation and is a crucial step in further understanding the function of the brain and the connections between the peripheral nerves and the brain. Due to the high

cost and difficulty of using a single method to improve resolution and improve the analysis of brain functional characteristics, and the fact that any single method has its own advantages and disadvantages, no modern medical imaging technology is perfect and can be suitable for all experiments or clinical applications. It is precisely because of the incompleteness of a single imaging method that more and more researchers begin to consider the fusion of multiple modalities of medical images, so it is an effective technical approach to use multiple technical means to obtain composite signals and perform information fusion.

In the present simultaneous ERP/fMRI experiment, 25 healthy participants were confronted with a visual three-stimulus oddball (standard, target, and novel stimuli). The present study aimed to explore the differences of the spatiotemporal neural dynamics between the P3a and P3b and the neuropsychological origins underlying these two ERPs.

The main purpose of this study is to accurately locate the brain activation status of the target recognition process. One of the methods is to use the EEG data collected by the scalp to calculate the activation status in the brain. However, due to the low spatial resolution of the EEG data, the EEG accurate calculation of dipole data also requires certain assumptions, so it is very difficult to accurately obtain the position of the brain source. With the development of modern brain imaging technology, especially the application of functional magnetic resonance technology, it has made an accurate determination of brain activity and location becomes possible. The spatial resolution of functional magnetic resonance technology is very high, but the temporal resolution is limited. In order to further study the brain activation of P300 operation, we combined high-resolution EEG with high-spatial-resolution functional magnetic resonance technology in this process.

To show the novelty of our research, in fMRI acquisition and analysis, we added combined ERP/fMRI analyses to test for significant BOLD changes of each deviant stimulus (target, novel) with covariates defined using the P300 amplitude or latency. Given that both P300 amplitude and latency are informative to analyze the fMRI data, which suggest that measures of ERPs' amplitude may reflect the intensity of responses whereas measures of latency may reflect time duration of responses [20, 21], therefore, we used these two parameters as covariates to constrain fMRI data in the General Linear Model. In this way, we have found other forms of specific brain activation associated with P3a and P3b, such as hippocampal gyrus, bilateral fusiform gyrus, and insula, which extends prior studies.

The mainstream view is that selective attention is controlled by the combined brain area of the parietal and frontal lobes (e.g., SPL of the parietal lobe, FEP of the frontal eye area, SEP of the auxiliary eye area, etc.), which is perceived through top-down neural connections analysis [22, 23]. However, recent studies on time orientation have shown that attention control and attention regulation involve several other different neural mechanisms. Some researchers believe that the neural mechanisms of temporal and spatial expectations are independent. Spatial expectations affect early perception components, such as P1 and starvation time

expectations, which affect the late selection or response-related components, such as P300 components [24, 25]. Other researchers believe that the neural mechanisms of temporal and spatial expectations are partially independent and partially overlapping. They also admit that spatial expectations affect early perception components, but they believe that, according to different mission requirements, temporal expectations affect different stages of stimulus processing, including the early perception stage and late response selection stage [26, 28]. Coull and Nobre [27] used functional nuclear magnetic resonance imaging (fMRI) technology to find that there is a partial overlap between the neural mechanisms of spatial and temporal attention toward the task. Spatial and temporal attention showed hemispherical asymmetric activation on the right and left parietal lobe, respectively. And when paying attention to both time and space information, both parietal lobes are activated.

## 2. Methods

*2.1. Subjects.* Twenty-five healthy volunteers (average age =  $22 \pm 3$  years, range = 20–31 years, 22 men and 3 women), with no history of neurological or psychiatric diseases, participated in this study. All participants were carefully screened to ensure that they met the inclusion and exclusion criteria. They were all right-handed with normal or corrected to normal visual acuity. Finally, all participants provided written informed consent after the experimental procedures were fully explained.

*2.2. Study Procedure.* All participants completed the visual oddball task inside the scanner under a typical fMRI scanning environment with an MR-shielded EEG cap on. During this experiment, a visual three-stimulus oddball task was presented via the E-Prime software (Psychology Software Tools, Pittsburgh, USA). The novels were large colorful checkerboard squares (never repeated), and the targets were blue discs which were slightly larger than the standard blue discs. Within each task, a total of 128 stimuli were shown: 103 standard stimuli (85%), 15 target stimuli (12%), and 10 novel stimuli (8%). All stimuli were presented for 30 ms with an interstimulus interval of 1800 ms. All stimuli were in a pseudorandom sequence both within and between 25 subjects. Each participant laid inside the fMRI scanner with a button press box placed in the right hand, and they were instructed to press with their thumb when a larger blue disc was presented.

The radiology laboratory of Xijing Hospital uses a direct rear projection visual stimulation device. The projection system is completely nonmagnetic radio frequency shielding, which can be placed in the magnetic resonance scanning room and has an air-cooled heat dissipation device to ensure the stability of the projection. Compared with the general placement of projectors in the scanning control room, the rear projection method can avoid brightness attenuation and visual signal attenuation, maintain uniform brightness, ensure high-resolution visual signals, ensure the consistency of the experimental environment, and can easily be compared with others.

Magnetic resonance imaging brain functional audio visual stimulation system is mainly used in fMRI experiments to carry out visual and auditory stimulation. The system has good magnetic compatibility, can work normally in 3T MRI environment, and provides clear visual and auditory information to the subjects in the experimental process. According to the need, the experimenter can send the specific text, image, sound, and other experimental stimulus information materials to the subjects. At the same time, the feedback information of the subjects can be recorded in real time through key operation. There is also a clear voice communication between the experimenter and the subjects. The experimental stimulation task is synchronized with MRI scan, which ensures the time synchronization of brain function data and visual visual stimulation task. The system consists of visual stimulus host, data acquisition system, projection system, auditory stimulation module, stimulus feedback component, etc. (Figure 1).

The radiofrequency buttonless response control box designed according to ergonomics transmits the response of the subject directly to the computer through the CREATOR optical fiber transmission system. Event-related design can be used to statistically compare different types of cognitive tasks. CREATOR fiber optic synchronization system can send pulses to trigger the start of E-Prime stimulation program when the magnetic resonance scanning system starts scanning, so that the scanning and stimulation are strictly synchronized, providing a guarantee for accurate data analysis.

MRI examinations used the GE 3.0 T MRI scanner produced by the American General Medical Company and a 32-channel phased-array surface coil on the head. Conventional structural MRI examinations include T1W1 (TSE, TR/TE/TI 2510/9.6/1038 ms; flip angle 130°; layer thickness 3 mm; layer interval 0.3 mm; FOV 180 mm × 180 mm; matrix 256 × 256), T2WI (TSE, TR/TE 5000/93 ms, other scanning parameters are the same as before), and T2WI-FLAIR (TR/TE/TI = 9000/93/2500 ms; layer thickness 3.0 mm; layer interval 0.3 mm). In addition, in order to obtain a good gray-white contrast image, the scanning scheme also includes transversal IR sequence (TR/TE/TI = 1500/13/499 ms, layer thickness 4 mm, layer spacing 0.6 mm, flip angle 150°).

EEG data acquisition adopts 32-lead MR-compatible EEG system of German Brain Products company. The electrode is an antimagnetic material electrode. The electrode placement: the elastic electrode cap international 10–20 system is used to place the electrode. At the same time, the ECG is placed to record the heart rate change of the subject and identify electrocardiography traces. This study specifies that the scalp resistance is less than 10 k $\Omega$  and the acquisition frequency is 5000 Hz.

**2.3. EEG Acquisition and Analysis.** This laboratory uses a direct rear projection visual stimulation device. The projection system is completely nonmagnetic radio frequency shielding, which can be placed in the magnetic resonance scanning room, and there is an air-cooled heat dissipation device to ensure the stability of the projection. Compared with the general placement of projectors in the scanning control room, the rear projection method can avoid

brightness attenuation, visual signal attenuation, maintain uniform brightness, ensure high-resolution visual signals, ensure the consistency of the experimental environment, and can easily be compared with other The stimulation device is matched.

The CREATOR optical fiber synchronization system can send pulses to trigger the start of the E-Prime stimulation program when the magnetic resonance scanning system starts scanning, so that the scanning and stimulation are strictly synchronized, providing a guarantee for accurate data analysis.

The radiofrequency buttonless response control box designed according to ergonomics transmits the response of the subject directly to the computer through the CREATOR optical fiber transmission system. Event-related design can be used to statistically compare different types of cognitive tasks,

because it will generate a strong magnetic field when used in MRI work. According to the characteristics of magnetic resonance imaging (MRI), if the traditional VGA transmission cable is used, it will be interfered with by a large and strong magnetic field and cannot transmit signals normally. At the same time, the traditional VGA transmission cable will generate electrical and electromagnetic signals that will interfere with the normal operation of MRI. Therefore, CREATOR fiber transmission has become a wise choice. The biggest advantage of optical fiber transmission is the following. (1) It solves the long-distance or ultralong distance (tens of kilometers) VGA signal transmission and is the lossless transmission. (2) In many specific occasions, such as the electromagnetic environment, optical fiber transmission is very bad. The antijamming feature of the system can be brought into full play, expanding the range of VGA signal transmission applications. (3) Compared with the traditional analog cable mode, the thinking mode of all-digital and all-fibers is self-evident, and it will certainly bring a lot of new opportunities and growth points, which has been confirmed. (4) On many occasions, the comprehensive cost of digital fiber mode can be compared with analog and cable modes and may even be lower, which provides the possibility for a large number of future applications.

VGA signal transmission system uses CREATORVGA-F500 T/RVGA optical fiber transceiver, computer output, uses its VGA port to lead analog signals to VGA-F500TVGA optical fiber transceiver, and converts VGA signal to optical signal transmission. VGA-F500 R is responsible for optical revert to VGA signal. The signal quality after digital transmission can be greatly improved, and problems such as smearing, blurring, and ghosting, which were common in analog transmission in the past, will not occur.

Electroencephalogram (EEG) data was recorded simultaneously with fMRI data using a BrainAmp MR-compatible EEG system (BrainProducts GmbH, Munich, Germany), which includes a 32-channel MR-compatible amplifier and an MR-compatible EEG cap. The EEG cap included 30 scalp electrodes, one electrooculogram (EOG), and one electrocardiogram (ECG). The EOG electrode was placed beneath the subject's left eye to monitor the eye blink, and the ECG electrode was placed over the subject's back. The common recording reference was referenced online to

FIGURE 1: Study procedure.

the frontocentral midline electrode. Impedance for the electrodes was kept below 5 k $\Omega$  by using the electrode paste. The EEG signals were digitally sampled at 5000 Hz.

Next, the EEG data were analyzed by BrainVision Analyzer software (Brain Products GmbH, Gilching, Germany). First, scanner gradient artifacts and pulse-related artifacts were removed using an adaptive average subtraction method [20] and an algorithm based on a constrained independent component analysis (ICA) method [21]; meanwhile, the EEG signals were down-sampled at 250 Hz. Second, EEG signals, rereferenced to right and left mastoids (M1 M2), were low-pass filtered (between 0.01 and 35 Hz). Finally, eye blinks were manually detected and then regressed from the EEG signal.

The ERPs were computed for the target, novel, and standard stimuli, respectively. The P3a (novel effect) and P3b (target effect) components were separately defined as the largest positive deflection during the time window between -200 and 800 msec. The grand average ERP waveforms for the target and novel stimuli at typical three midline electrodes were all used to acquire our results in the study.

**2.4. fMRI Acquisition and Analysis.** fMRI data were acquired by a GE 3T MR scanner (GE Health Care, Milwaukee, WI) at the Department of Radiology of Xijing Hospital, Xi'an, China. The functional images were collected using a gradient-echo planar imaging sequence with the following parameters: TR = 2000 ms, TE = 30 ms, FOV = 240 mm  $\times$  240 mm, data matrix = 64  $\times$  64, flip angle = 90', slices = 45, and 150 volumes. The anatomical images were also obtained (TR/TE: 8.2 ms/3.18 ms, field of view: 256  $\times$  256 mm<sup>2</sup>, matrix size: 512  $\times$  512, flip angle = 9°, in-plane resolution: 0.5  $\times$  0.5 mm<sup>2</sup>, slice thickness = 1 mm, 196 sagittal slices).

Preprocessing and data analysis were both performed with the SPM8 software (Wellcome Department of Cognitive Neurology, London) implemented in MATLAB. First, in order to ensure the stability of the radial magnetic field, we discard the first four volumes of whole-brain images. Second, images were corrected for the acquisition delay between the slices and were realigned to the first volume. After the adjustment for movement-related effects, functional and

anatomical data were coregistered, spatially normalized into the standard stereotactic MNI space, and spatially smoothed with a 6 mm full width half maximum (FWHM) Gaussian kernel.

The event-related design (e-fMRI) was reported to be highly sensitive to the oddball task-related. A conventional analysis was conducted to assess the related activation in BOLD response associated with the processing of three stimuli. Each stimulus type (target, standard, and novel) was used as a regressor in the GLM after convolution with the hemodynamic response function. And the six movement parameters were used as regressors of noninterest. Target and novel functional activation was discriminated from baseline activation through the regression analysis. Regions that are significantly more activated by the targets relative to the novels were also given using a fixed-effect analysis ( $p < 0.001$  uncorrected and the cluster size  $> 50$  voxels).

### 3. Results

**3.1. Behavioral Data.** Based on the statistical data, for the target stimuli in the task, all subjects responded correctly to 97.6% (SD: 5.7%) with a response time of 408 ms (SD: 48 ms), which indicated that they were able to concentrate on their tasks during the EEG recording and MRI scans.

**3.2. ERP Data.** Figure 2 shows the ERP results computed across 25 subjects for three electrodes (Fz, Cz, and Pz) and three stimuli (standard, target, and novel). The figure illustrates that P300 ERPs could be detected at the frontocentral (Fz), central (Cz), and centroparietal (Pz) electrodes for targets and novels. Using paired  $t$ -test, the novel-related P300 ERP (P3a) had a higher amplitude and decreased more slowly than the target-related P300 ERP (P3b), at Cz and Fz (all  $p < 0.01$ ), but for Pz, the P3b ERP had a significantly higher amplitude ( $p < 0.01$ ). P3a arose earlier than P3b at Cz and Fz (all  $p < 0.01$ ), but the opposite phenomenon was observed for Pz ( $p < 0.01$ ). Figure 2 demonstrates that P3a and P3b have distinct topographic amplitude distributions. The P3b activated frontal areas, while P3a activated frontoparietal areas. These topographic variations may be induced by different functional areas.

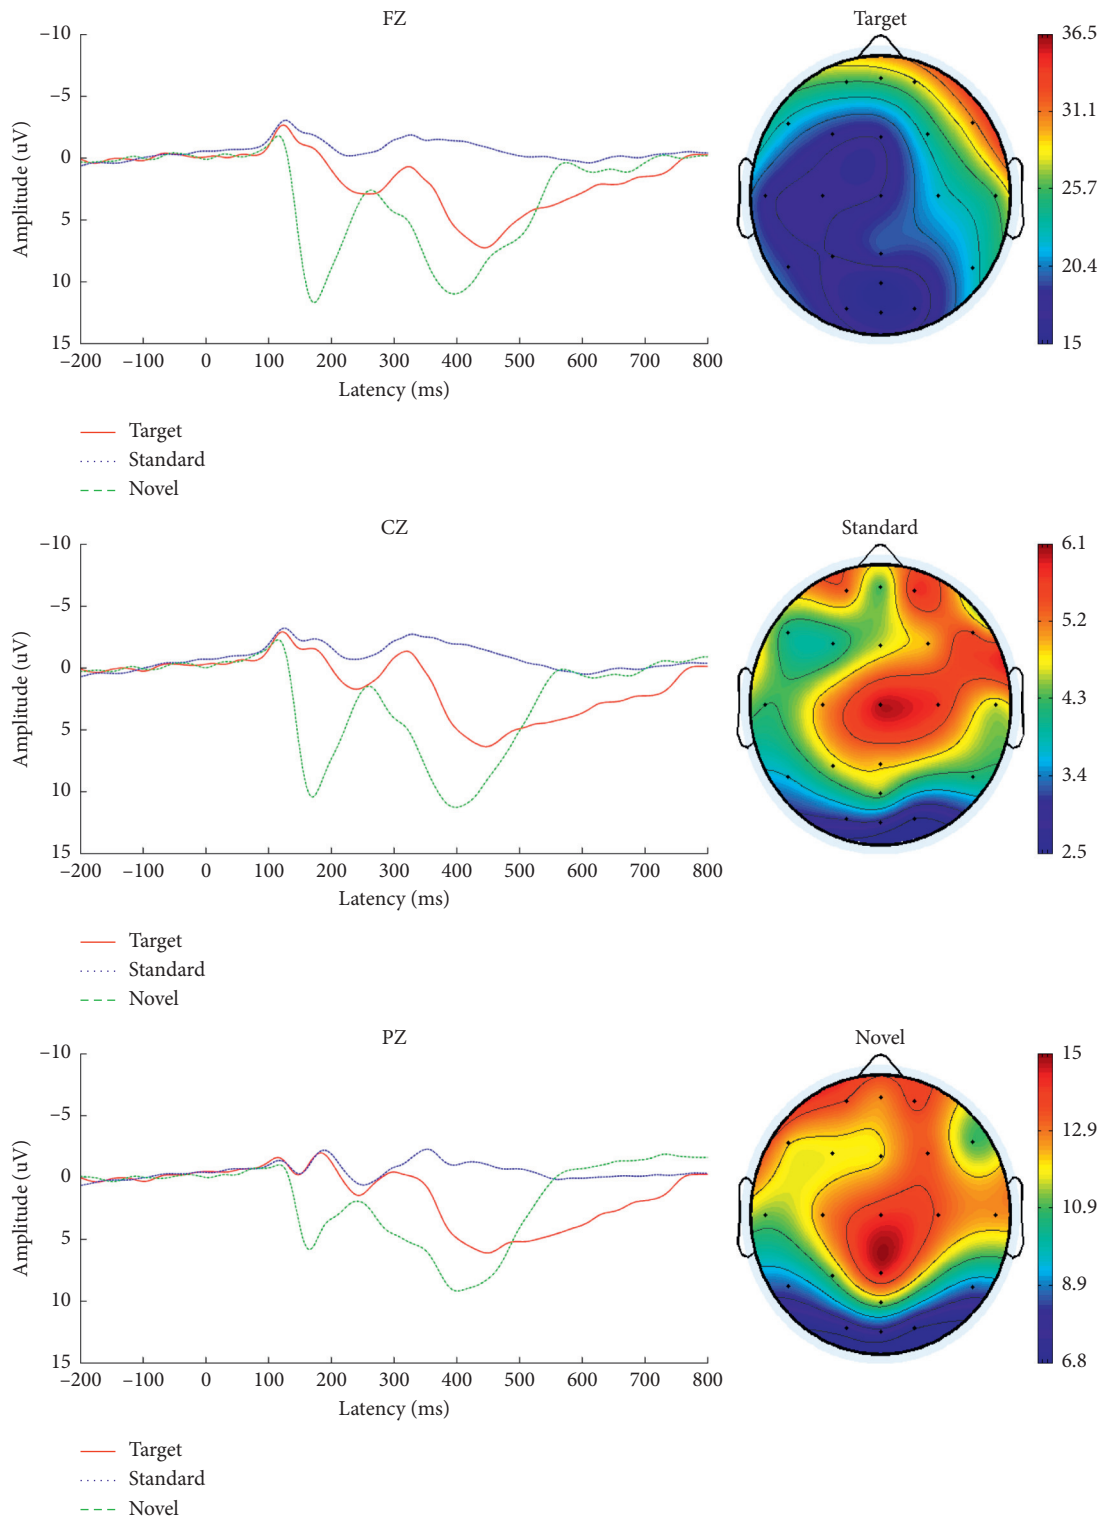

FIGURE 2: (a) Grand-averaged waveforms (mean across the 25 participants and 3 types of stimuli) on Pz, Cz, and Fz electrodes: target stimuli (red), standard (blue), and novels (green). (b) Topography distributions for the mean target (A), standard (B), and novel (C) amplitude.

3.3. *fMRI Data.* Figure 3(a) and Table 1 illustrate the activation for the novel stimuli. The novels activated the left frontoparietal areas, left precuneus areas, and the right insula. Figure 3(b) and Table 2 illustrate the activation for the target stimuli. The targets activated the bilateral fusiform gyrus, left frontal areas, and

bilateral insula. Figure 3(c) and Table 3 illustrate the activation for the novel-target contrast. These included the left frontoparietal areas, the left postcentral, and the left fusiform.

Gray reflects the background baseline state of the cerebral cortex; the darker the color, the closer to orange-red,

FIGURE 3: Functional activation 3D maps of left and right brain obtained for the novel (a), target (b), and target-novel contrast (c). (a) Brain regions showing activity to the novel stimuli. (b) Brain regions showing activity to the target stimuli. (c) Brain regions showing activity to the novel-target contrast. Reported activation became all thresholds at  $p < 0.001$  uncorrected. Gray reflects the background baseline state of the cerebral cortex; the darker the color, the closer to orange-red, indicating that the increased rate of blood oxygen concentration in the brain area is more significant, indicating that the area is being activated. The lighter the color, the closer to blue, which means that the rate of decrease in blood oxygen concentration in this brain area is more significant, indicating that this area is negatively activated. a1: in the new heterostimulus task state, the activation area of the left brain 3D model; a2: in the new heterostimulus task state, the activation area of the 2D model of the left cerebral cortex; a3: in the new heterostimulus task state, the activation area of the right brain 3D model; a4: in the new heterostimulus task state, the activation area of the 2D model of the right cerebral cortex; b1: in the target stimulation task state, the activation area of the left brain 3D model; b2: in the target stimulation task state, the activation area of the 2D model of the left cerebral cortex expanded; b3: in the target stimulation task state, the activation area of the right brain 3D model; b4: in the target stimulation task state, the activation area of the 2D model of the right cerebral cortex; c1: for fMRI image data, using target stimulation-new stimulation, the activation area of the left brain 3D model; c2: for fMRI image data, using target stimulation-differential stimulation, the activation area of the 2D model of the left cerebral cortex; c3: for fMRI image data, use target stimulation-new stimulation, the activation area of the right brain 3D model; c4: for fMRI image data, using target stimulation-differential stimulation, the activation area of the 2D model of the right cerebral cortex.

#### 4. Discussion

The current study used the simultaneous ERP/fMRI data collected in a visual three-stimulus oddball task to examine the differences of spatiotemporal neural dynamics between the P3a and P3b and the neuropsychological origins underlying these two ERPs.

The results obtained from the electrical recording, as shown in Figure 2, showed that P3a and P3b have different topographic amplitude distributions, which were in line with previous studies [29, 30]. As expected, two P300 ERPs were observed at middle sites (Fz, Cz, Pz, C3, and C4) for the novel and target conditions, and statistical differences in amplitudes between targets and novels were found [30, 31]. P3a and P3b data, using a difficult target/standard discrimination task in a three-stimulus paradigm from 120 healthy young adults, have shown that P3a has a central maximum, whereas P3b has a parietal maximum, and the

peak latency for both was shorter over the frontal and longer over the parietal sites [7, 19, 32].

Simultaneous fMRI and ERP findings demonstrated different brain regions related to different stimuli. P3a and P3b generation is assumed to stem from frontal and temporal/parietal activation. In the present study, P3a was related to the frontal lobe. It is proposed that P3a may be generated when rare or novel stimuli are processed if sufficient attentional focus is engaged (see Figure 3 and Tables 1–3) [33]. Many studies suggest that a frontal attention mechanism governs neural responsivity to novels [34] and then implies top-down control [35]. Attentional resources used to maintain memory items in parietal regions may result from response organization produced by bottom-up processing [7]. P3b was associated with parietal regions, prefrontal cortex, and medial temporal regions [36]. Evidence suggested that P3b appears when subsequent attentional resource activation promotes memory operations in temporal-parietal areas [37, 38]. Thus, the simultaneous ERP/fMRI findings extended the proposed model which suggested that P300 comprises an early attention process stemming from a frontal working memory representational change to produce the P3a, and the attention-driven stimulus signal is then transmitted to temporal and parietal structures, which were related to P3b [36, 39–41].

The limitations of this study should also be mentioned. First, 19 of the 25 subjects, from the Fourth Military Medical University, showed higher scores ( $128 \pm 5$ ) in the intelligence tests, which may have affected the result. The subsequent research can explore the potential impact of intelligence on ERP. Second, ERP analysis was restricted to only 3 electrodes without taking into account the full amount of the temporospatial information included in the ERP data. Third, gender has been shown to modulate the P300 component in emotional oddball tasks [42], but our sample included both female and male participants. Consequently, it is unknown whether our results were affected by the gender effect.

Furthermore, in order to better promote the fusion research of EEG-fMRI, there are still some deficiencies in the research of this article; the specific improvements are as follows.

Offline antialiasing processing is performed on the three artifact components of pulse artifact, gradient artifact, and electrocardiographic artifact. Due to the tedious experiment of synchronously collecting EEG signals in the magnetic resonance scanner, the limb movement or Mental state, etc. may introduce many unknown artifacts. Therefore, how to simplify the collection steps and minimize the generation of unknown artifacts is a problem to be improved in the future.

The amount of experimental calculation data of the synchronous EEG-fMRI brain-computer interface system in this article is large. In order to have a better real-time effect and reduce the amount of calculation, we only conducted the lead of the specific brain area where the P300 signal is active and analyze and ignore the information that other leads may reflect. Therefore, this topic should continue to improve the research. In addition, only 32-lead amplifiers were used in this experiment. In order to observe EEG signals more accurately, it may be considered to introduce 64-lead or 128-lead amplifiers for acquisition to obtain more detailed EEG information.

Because this experiment is designed for the P300 signal, but the research methods are universal, the next step should consider applying the synchronous EEG-fMRI brain-computer interface system to more experimental paradigms, such as emotion recognition and SSVEP.

Since this article only focuses on the EEG signals in the magnetic resonance scanning environment, most of the introduced artifacts are eliminated through real-time artifact removal processing. Therefore, in future research, the fMRI signal should be processed and the electroencephalogram signal and the fMRI signal should be fused to develop a brain signal that can observe multimodalities in real time, thus laying a foundation for humans to understand the brain from multiple angles and promote the development of brain science.

## 5. Conclusion

The integration of event-related potential (ERP) and functional magnetic resonance imaging (fMRI) can be used as a bridge between the well-established field of evoked cognitive potentials and the fast-growing field of fMRI. The simultaneous EEG/fMRI data provided further insight into

processes underlying the functional brain activation. In the oddball task, our results showed that P300 ERP induced by target stimulation and novel stimulation can be detected at the Fz, Cz, and Pz electrodes. At Cz and Fz, compared with P3b related to the target stimulus, the P3a related to the novel stimulus has a higher amplitude and the waveform declines more slowly. But at Pz, P3b has a higher amplitude than P3a. P3a appeared earlier than P3b at Cz and Fz, but the opposite phenomenon was observed at the Pz electrode. The activated brain regions of P3a included the left frontal-parietal lobe region, left anterior wedge lobe region, and right insula, while the target-driven P3b was significantly associated with BOLD changes in the bilateral fusiform gyrus, the left frontal region, and the bilateral insula. In summary, the current study replicates and extends prior studies.

## Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

## Conflicts of Interest

The authors declare no conflicts of interest.

## Acknowledgments

The authors are grateful to Professor Wei Qin for reading and correcting the manuscript and for fruitful criticisms. The authors thank Professor Junye Liu who designed and participated in the experiment in this study. Special thanks are due to Rui Zhao for her help in processing and interpreting the EEG data and Dian Dai and Xinxin Zhang for their help in the acquisition of fMRI data. This work was supported by the Department of Radiology of Xijing Hospital that provided the MRI device. This project was supported by the National Natural Science Foundation of China (Grant no. 61806210) and the National Social Science Foundation of China (Grant no. 15BSH023).

The amazing rise of digital currency is not only favored by investors but also attractive to lawbreakers for its anonymity and decentralization. This paper mainly discusses the intelligent digital currency and dynamic coding service system based on Internet of Things technology. In this paper, the RDCAR algorithm is used to realize the routing discovery process of the wireless network. When the intermediate node receives the RREQ message, first of all, to avoid the loop, it checks whether the same RREQ message has been introduced. If it has received it, it will discard it. Otherwise, it will cache the message and attach its own neighbor node list to the signal-to-noise ratio of the channel link, update the RREQ message, and broadcast it. The payment cipher is managed by the bank. When the user opens an account, the bank registers and sends it to the user. The key is generated by the algorithm chip, and the public key is kept in the bank background server. When the bill is delivered to the bank, the bank inputs all the elements on the bill on the counter terminal and transmits it to the verification machine for verification through the bank network. If the verification is correct, it indicates that the bill is indeed issued by the customer, and all bill elements are correct, and payment can be made. The node operation protocol of public chain and alliance chain maintains the operation of the Internet of Things system. The nodes of alliance chain generate new blocks according to the interval of 30 s. When the node fails to complete the block generation within 30 s, it will rotate to the next node. The mkfile command is used to generate 16b, 1 KB, 1 MB, and 1 GB files as input. The peak speed of the encoding service system is about 370 mb/s. The results show that the system designed in this study is robust and suitable for complex trading environment.

## 1. Introduction

With the rise of the wave of digital currency in recent years, some underlying technologies related to it, such as blockchain technology and distributed accounting methods, also show broad application prospects. Digital currency is moving from theory to reality, and its feasibility and security are being tested. As a typical application of the Internet of Things in the financial economy, the Bitcoin system has attracted much attention due to its decentralized, open, and transparent characteristics. Various cryptocurrencies such as Monero coins and dark coins emerge in endlessly. In addition, central banks and commercial banks in various countries have also used the underlying advanced technology of Bitcoin as a reference, planning to carry out

research on legal digital currency, so as to improve the national digital financial system. This shows that the future development of digital currency has broad prospects, but the accompanying digital currency security and privacy issues have become increasingly prominent.

The amazing growth of encrypted digital currency is not only favored by investors but its anonymity and decentralization are also quite attractive to criminals. Although some countries have considered introducing digital currency regulatory policies, the attitudes of different countries are different. Facing the diversified needs of people's life and work, research and deployment of legal digital currency are urgently needed. However, unlike Bitcoin's non-real-time, lightweight transaction information, small transaction volume, and low sensitivity, legal digital currency is circulated

throughout the country and the world, and its security and privacy issues are more prominent, and legal digital currency and its related applications should be suitable for more complex international environments. Therefore, how to strengthen the robustness of the legal digital currency system and build a harmonious credit society by learning from the security and privacy protection measures of the Bitcoin system and Bitcoin wallet is the research direction of our future work. Digital currency is backed by national credit, which can synchronize online and offline to the greatest extent, and maximizes the convenience and security of transactions.

Utilizing the advantages of distributed architecture and proximity to end users, fog/edge computing can provide faster response and higher quality of service for IoT applications. Lin et al. believed that the Internet of Things based on fog/edge computing will become the future infrastructure for the development of the Internet of Things. In order to develop the IoT infrastructure based on fog/edge computing, they first studied the architecture related to the IoT, supporting technologies and issues, and then explored the integration of fog/edge computing and the IoT. They gave a comprehensive overview of the Internet of Things in terms of system architecture, supporting technology, security, and privacy issues and studied the integration of fog/edge computing with the Internet of Things and applications. Their research lacks data [1]. In order to overcome the scalability problem of the traditional IoT architecture, Sun et al. proposed a novel method for mobile edge computing. At the same time, they proposed a layered fog computing architecture in each fog node to provide flexible IoT services while maintaining user privacy; each user's IoT device is associated with the proxy VM (located in the fog node), and proxy VM collects, classifies, and analyzes the raw data stream of the device, converts it into metadata, and then transmits the metadata to the corresponding application VM (owned by the IoT service provider). Each application VM receives corresponding metadata from a different proxy VM. Their research lacks practice [2]. Yang et al. believed that the Internet of Things (IoT) is ubiquitous in our daily lives. In order to protect the security of IoT devices, they have conducted a lot of research work to deal with these problems and find better ways to eliminate these risks, or at least minimize its impact on user privacy and security requirements. Their investigation consists of four parts. The most relevant limitations of IoT devices and their solutions will be discussed first. Then, the classification of IoT attacks will be introduced. Secondly, it will focus on the mechanism and architecture of authentication and access control. Finally, the security issues in different layers will be analyzed. Their research process is too complicated [3]. Yaqoob et al. discussed the architecture of the Internet of Things. In this case, first of all, they investigate, focus on, and report on the recent major research progress in the IoT architecture and then classify the IoT architecture and design a taxonomy based on important parameters (such as applications, supporting technologies, business goals, architecture requirements, network topology, and IoT platform architecture types).

They identified and outlined the key requirements of the future IoT architecture and discovered and introduced some outstanding case studies on the Internet of Things. Finally, they listed and outlined the future research challenges. Their research has no practical significance [4].

This research mainly discusses the intelligent digital currency and dynamic coding service system based on the Internet of Things technology. This research is mainly based on the RDCAR algorithm to realize the route discovery process of the wireless network. When the intermediate node receives the RREQ message, first, to avoid loops, check whether the same RREQ message has been introduced. If it is received, discard it. Otherwise, buffer the message and append its own neighbor node list, corresponding to the signal-to-noise ratio of the channel link, and update RREQ message and broadcast it. The payment cipher is managed by the bank. When the user opens an account, the bank registers and sends it to the user, and the key is generated by the algorithm chip, and the public key is stored in the bank's back-end server. When the bill is delivered to the bank, the bank enters the various elements of the bill on the counter terminal and transmits it to the verification machine through the bank network for verification. If the verification is correct, it indicates that the bill is indeed issued by the customer, and the bill elements are correct, so you can make payment. The public chain and alliance chain node operation agreement maintains the operation of the Internet of Things system. The alliance chain node generates new blocks at a time interval of 30 s. When the node cannot complete the block generation within 30 s, it will rotate to the next node.

## 2. Dynamic Coding Service System

*2.1. Internet of Things.* The IoT paradigm is expected to completely change the way we live and work through a large number of new services based on the seamless interaction between a large number of heterogeneous devices. After decades of creation of the concept of the Internet of Things, in recent years, various communication technologies have gradually emerged, reflecting the diversity of application fields and communication requirements. At present, this heterogeneity and fragmentation of the connectivity landscape hinder the full realization of the vision of the Internet of Things by posing some complex integration challenges. In this case, the emergence of 5G cellular systems with truly ubiquitous, reliable, scalable, and cost-effective connection technologies is considered to be a potential key driver of the yet-to-be-emerging global Internet of Things. Similar to how humans use the Internet, devices will become the main users of the Internet of Things (IoT) ecosystem. Therefore, device-to-device (D2D) communication is expected to become an inherent part of the Internet of Things. Devices will automatically communicate with each other without any centralized control and cooperate in a multihop manner to collect, share, and forward information. The ability to collect relevant information in real time is the key to leveraging the value of the Internet of Things because such information will be transformed into intelligence, which will help create a

smart environment. Ultimately, the quality of the information collected depends on the intelligence of the device. In addition, these communication devices will operate with different networking standards and may encounter intermittent connections with each other, and many of them will be limited by resources. These features bring some networking challenges that traditional routing protocols cannot solve. Therefore, devices will need intelligent routing protocols to be intelligent. Nowadays, the development of traditional business models has become more and more mature, and people use them to guide various e-commerce activities [5, 6]. The Internet of Things (IoT) is an innovative revolution on the Internet and has become a new platform for e-commerce [7]. The flow of static timing constraints is shown in Figure 1.

**2.2. Positive Impact of Digital Currency.** For many people, the concept of digital currency is abstract and confusing. Having confidence in intangible assets without government or precious metal support is a daunting task. However, the rapid spread of smartphones and tablets, the rapid transformation of cross-border banking, and the emergence of non-card real-time payments have made digital payments commonplace. First of all, it has a positive impact. Digital currency creates a relatively novel concept and model, which can improve transaction convenience and reduce transaction costs, promotes the progress and development of shared finance, and decentralizes the digital currency embedded payment system mainly from its own; the system allows users to directly carry out peer-to-peer transactions without resorting to financial units, which can improve transaction efficiency and reduce transaction costs. At the same time, its lower transaction costs will have an impact on traditional payment systems and promote banks and other financial institutions to continuously improve their service quality and reduce transaction costs. Secondly, digital currency can allow people who have not created an account in a financial unit to carry out noncash payments, and the speed is very fast, and the cost is low. Therefore, digital currency has a positive impact on the popularization of finance, especially for those who are relatively backward in finance. In regions and countries, the benefits it brings are also very large [8, 9]. Digital currency can realize network transfer with the help of mobile phones and so on, and the recipient only needs to obtain digital currency to exchange activities with it [10]. When there is no code perception, it is shown in Figure 2, and when there is code perception, it is shown in Figure 3.

**2.3. Verify Algorithm.** The Verify algorithm uses a layered verification mechanism to verify whether the hidden transaction amount is correct [11, 12]. Specifically, it will be stated in Verify-I that the payer has enough bitcoins; that is, the payee must be convinced that the input of the transaction

is greater than the output. Then, the recipient verifies that the transaction amount promised by the wallet is equal to the actual transaction amount in Verify-II. In the commitment phase, the wallet will make a commitment to both the bitcoin deposit amount  $b_1$  and the bitcoin transaction amount  $b_2$  ( $b < 2 \leq b_1$ ). In addition, the wallet will also promise the difference between  $b_1$  and  $b_2$ . In the verification phase, the correctness of the commitment value is checked in two steps: (1) the difference between the input amount  $b_1$  and the output amount  $b_2$  is always positive and (2) the promise made by the payee to the correct transaction amount is always the same as the promise value  $c$  of the wallet [13]. Online wallet calculates  $F_1$  and  $F_2$  and sends  $(F_2, F_3)$  to the payee:

$$F_1 = h_1^{m-a} h_2 \bmod n,$$

$$u(t) = u_i(t - \Delta t) R^L(\Delta t) + u_i(t) \sum_{i=1}^n (t + \Delta t)(t - \Delta t),$$

$$e_0(\lambda, T) = \frac{5\pi HC}{\lambda^6} \frac{1}{e^{(hc/\lambda KT)}} - \frac{hc}{e}. \quad (1)$$

Recipient calculation is as follows:

$$U = \frac{h_1}{F_3} = h_1^\beta h_2^{-r} a^{2-q_1} \alpha^{-q_2} \bmod n,$$

$$F_2 = \frac{1}{Q} \sum_{\omega \in Q} \exp\left\{-\frac{U(z)}{T}\right\} \delta(z - \omega), \quad (2)$$

$$M = T[x, y, p(x, y), f(x, y)].$$

If the check passes, the recipient can trust  $m \geq \alpha$ . At this stage, my country's main basis for this supervision is only this notice, and there is no other effective document [14, 15]. Moreover, the measures of my country's regulatory authorities are mainly aimed at preventing financial risks and money laundering crimes. The protection of financial consumers is mainly based on the principle of "risk yourself." The overall rules are relatively rough. The filing system for trading platforms is not a licensing system. This has led to the obligation of financial institutions and digital cryptocurrency trading platforms to be limited to popularizing industry knowledge and risk disclosure, accepting irregular administrative inspections, and so on [16] and make substantive requirements for deeper content such as the entry barriers of the trading platform, network security, information disclosure, and fund management. As a result, the chaos in the digital cryptocurrency market has not been curbed, and even with the emergence of ICOs, lawsuits for digital cryptocurrency continue to increase [17, 18]. Recipient calculation is as follows:

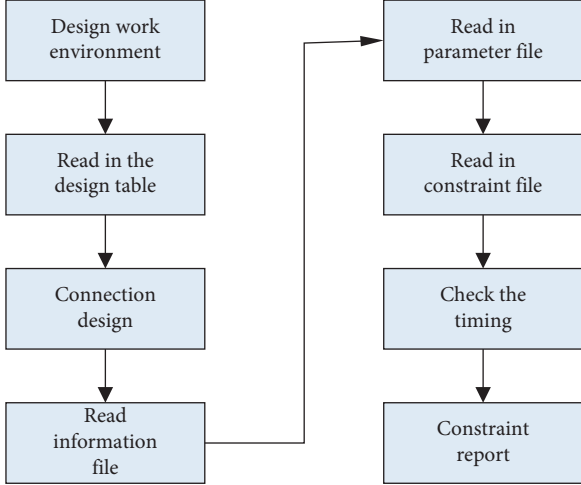

FIGURE 1: Flow of static timing constraints.

FIGURE 2: No coding perception.

$$\begin{aligned}
 c &= \frac{c_1}{c_2} = h_1^{b_1 - b_2'} h_2^{r_1 - r_2}, \\
 c_1 &= -2 \left( r_{ui} - \sum_{f=1}^F p_{uf} q_{if} \right) + 2p_{uf}, \\
 c_2 &= \frac{\sum_{i \in L} (h_1 - \bar{r}_u) \times (h_2 - r_u)}{\sqrt{\sum_{i \in L} (r_{ui} - \bar{r}_u)^2 \sum_{i \in L} (r_{vi} - \bar{r}_v)^2}}
 \end{aligned} \quad (3)$$

Verify that  $c$  is equal to  $c'$ . If there is any error in the verification process, the payee returns 0 and rejects the transaction [19]. If the verification is successful, the payee returns 1, and then the online wallet broadcasts the encrypted transaction and sends the digital currency amount to the payee account [20, 21].

**2.4. Code-Aware Routing Algorithm.** In wireless networks, the quality of the channel is the key to the successful transmission of data, which is generally measured by the signal-to-noise ratio [22]. The channel quality has great

FIGURE 3: Coding-aware.

differences in different links of the actual network [23, 24].

$$\begin{aligned}
 h &= \sum_{i=1}^n c o_i h_{\min} + \sum_{i=1}^n c o_i, \\
 D_1^K &= P(x_i \in x_k, y_i = 1) = \sum_i x \in x_k(i), \\
 D_{-1}^K &= P(x_i \in x_k, y_i = -1) = \sum_i x \in x_k D_{-1}.
 \end{aligned} \quad (4)$$

The final strong classifier is as follows:

$$H(x) = \sin g \left( \sum_{t=1}^T h_t(x) - \text{threshold} \right). \quad (5)$$

If you want to transmit under poor channel quality, you must choose a relatively low transmission rate. There are many broadcasting situations in network coding. When broadcasting to various downstream nodes, the signal-to-noise ratio of each single link in the broadcasting link is different [25]. Choosing a suitable broadcasting transmission rate can make the throughput efficiency reach during this broadcast maximum. The coding-aware routing algorithm based on rate selection is expressed as follows:

$$\begin{aligned}
 M &= \min_{l \in L} \left\{ M_l \mid M_l = \frac{H_l * H_l'}{R_l} \right\}, \\
 \text{MIQ}_s(c) &= \text{MQ}_s(c) + \sum_{t \in c} \text{MQ}_s(i), \\
 \text{MIQ}_d(c) &= \text{MQ}_d(c) + \sum_{t \in c} \text{MQ}(l),
 \end{aligned} \quad (6)$$

$$\text{CRM}_j = \frac{1 + \text{MIQ}_d(l)}{1 - P_t}.$$

Among them,  $M$  is a unicast or broadcast link on the entire link  $L$  for data packet transmission. When the data

link layer successfully transmits a data packet, the routing layer initiates a transmission [26].

$$\text{Angle}(a, r) = \arccos\left(\frac{a \bullet r}{|a| * |r|}\right),$$

$$\min(E^2) = \sum_{k=1}^N [y'(k) - y(k)]^2, \quad (7)$$

$$s = \{x_1, y_1\}, (x_2, y_2), \dots, (x_N, y_N).$$

The probability of successful data packet transmission on the data link layer is as follows:

$$p_i^j = \sum_{k=1}^5 (1 - p_{1i}^j)^{k-1} p_{1i}^j,$$

$$\text{CRM}_L = \sum_{l \in L} \text{CRM}_J,$$

$$F^2(s, v) = \frac{1}{s} \sum_{i=1}^s \{Y[N - (v - N_s) + i] - y_v(i)\}^2, \quad (8)$$

$$P_{n,j} = \frac{P_{n,t}}{P_{n,t-1}} - 1,$$

$$P_j = \frac{P_{n,t}}{P_{n,t-1}}.$$

That is, the probability of starting a routing layer transmission is  $p_i^j$ . The process of the Verify algorithm generating code is shown in Figure 4.

### 3. Dynamic Coding Service System Experiment

**3.1. System Framework Design.** The system is divided into four parts: the background server, the foreground management system, the foreground business system, and the cipher. The back-end server is equivalent to a certification authority CA, which stores the user's certificate information and completes the actual verification process. It is generally the server of the head office. The front-end management system is the management program on the front-end computer of the branch, which manages the user account information, the issuance and management of the user password, the management of the operator and the log query, and so on. The front desk business system is a business management program on the front-end computer of the branch. It uses the information on the check and the payment password to verify the authenticity of the check and generally provides services for the bank transfer system. The cipher is a handheld device used by the user, which is issued to the user by the bank to implement the user-side algorithm in hardware, including the generation of the key and the generation of the payment password. The system framework is shown in Figure 5.

**3.2. Cipher.** The encryption chip integrates RSA and SHA-1 algorithms and saves the user's key. There are two types of chips: A slice is mainly a public key algorithm, which is used

in the payment password verification subsystem, and B slice is mainly a private key algorithm, which is used in the payment cipher used by the account opening unit. The payment cipher adopts the B-chip arithmetic chip to make a handheld device to manage the user's account and key and generate payment password. The payment cipher is managed by the bank. When the user opens an account, the bank registers and sends it to the user, and the key is generated by the algorithm chip, and the public key is stored in the bank's back-end server.

**3.3. Password Management.** The payment cipher is issued by the bank to the customer who opens an account with the bank and downloads the account number of the customer with the bank and the corresponding account key in it. When the customer uses the account to issue a bill, enter the bill number, bill type, amount, and other information on the payment cipher and use the payment cipher to automatically calculate a string of numbers. This number is closely related to the payer account number, receiver account number, bill type, bill number, amount, and date of signing and is called the payment password. The customer fills in the number on the bill as the digital seal of the bill. When the bill is delivered to the bank, the bank enters the various elements of the bill on the counter terminal and transmits it to the verification machine through the bank network for verification. If the verification is correct, it indicates that the bill is indeed issued by the customer, and the bill elements are correct, so you can make payment.

**3.4. Calculate the Plaintext Format of Payment Password.** The format of the 48-byte plaintext data PLAIN\_TXT input to the B slice when the payment password is generated is shown in Table 1. After the chip output is converted, it is a 19-digit integer plus 1 identification bit to form a 20-digit payment password output. The plaintext format of the payment password is shown in Table 1.

**3.5. Design of the Alliance Chain.** System initialization completes the generation of system parameters and the initial state of the blockchain; transaction verification and forwarding are the process of sharing information among alliance chain members, ensuring that nodes reach consensus on the same basis; the consensus process includes the specific process of node interaction in CPBFT; transaction confusion is responsible for after the transaction is confirmed, and the transaction is processed before being sent to the public chain node to remove the transaction relationship information to protect transaction privacy; the final transaction traceability is the process of internal supervision of the system. The communication between nodes in the alliance chain uses encrypted channels to prevent information leakage when the communication transmits the plaintext and completes transactions.

**3.6. Choice of Algorithm.** The Verify algorithm aims to check that the difference  $b1 - b2$  between the input amount and the

FIGURE 4: The process of the Verify algorithm to generate code.

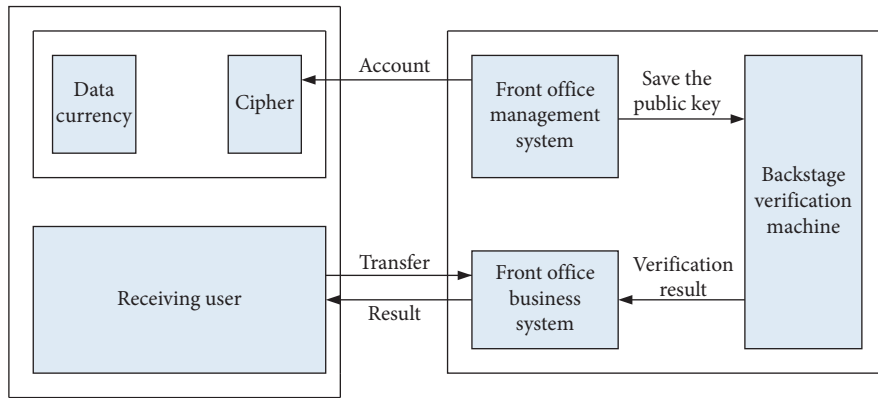

FIGURE 5: System framework.

TABLE 1: Plaintext format of the payment password.

|            |    |  |
|------------|----|--|
| ACCU       | 16 | Account, compressed BCD code               |
| Service    | 4  | Business type, $0 \times 31 - 0 \times 35$ |
| Date       | 4  | Date, compressed BCD code                  |
| Ticket_num | 8  | Voucher number, compressed BCD code        |
| Balance    | 9  | Amount, in minutes, compressed BCD code    |

output amount of the transaction is always positive, and the output amount  $b_2$  is the transaction amount specified by the payee. The algorithm first confirms that the promised secret value is always positive. To this end, the payer commits to the difference between the input amount and the output amount of the transaction. Then, use the range proof method to convince the payee to believe that the promised secret value is always positive. Secondly, because the recipient knows the correct transaction amount  $b_2$  in advance, he also needs to use the correct transaction amount and some auxiliary evidence  $c_1$  and  $r_2$  to verify that the final commitment value is equal to the commitment value  $c$  made by the wallet. We call this two-step verification method a layered verification mechanism. If the algorithm returns 1, the protocol goes to the next step.

**3.7. Operation Process Design.** The peer relationship between public chain nodes and alliance chain nodes in the system is just different in processing messages. Together, these two

parts can be regarded as servers. The user's wallet is the client and sends operation requests to the server. After each part of the system starts running, it performs related functions according to the protocol designed in chapter 4. When there is no user to send a transaction, the blockchain node automatically runs the consensus process in a loop to maintain the consistency of the system and waits to process the sent transaction information. After the user sends the transaction, it is collected and processed by the alliance chain nodes, including verification transactions, packaged transactions, and transaction confusion, and finally the confirmed transactions are confused and broadcasted to the public chain nodes to complete the complete transaction confirmation and recording process. When the system initiates the traceability, the entire process only occurs between the alliance chain nodes. The traceability initiating node initiates a request to other alliance chain nodes including the supervision node. The other alliance chain nodes in the figure include more than one node, and the request is judged separately, and the supervised node obtains the user identity after recovering the

key. The design values of running nodes are shown in Table 2. The running process is shown in Figure 6.

**3.8. Implementation of Routing Algorithm.** The route discovery process of RDCAR is as follows:

- (1) The source node initiates the route discovery process of the wireless network by broadcasting a route request (RREQ) message. In our algorithm, the routing request message needs to include the following messages: neighbor nodes within the range of the source node, high channel quality signal-to-noise ratio, and the path that has been transmitted.
- (2) The intermediate node receives the RREQ message; first to avoid loops, check whether the same RREQ message has been introduced and discard it if it is received; otherwise, it will buffer the message and attach its own neighbor node list, corresponding to the signal noise of the channel link, and then update the RREQ message and broadcast it.
- (3) When the RREQ arrives at the destination node, the destination node sends a route reply request (RREP) message to the source node. This is a unicast message that contains information on this unicast path.
- (4) When the intermediate node receives the RREP message, it selects a value from the set of rates supported in the 802.11 protocol, calculates the expected number of transmissions based on the stored signal-to-noise ratio information, selects the appropriate rate, updates the neighbor node list, and finally calculates the smallest metric value. Then, add this information to RREP. Take out the RREQ path in the cache and compare it with the upstream path set in the RREP. Use the conditions of the encoding node above to check whether there is an encoding opportunity for the new stream. If it exists, calculate the metric value of the broadcast link. Add the minimum metric value to RREP, and continue forwarding the cached path until it reaches each source node.
- (5) Maintain routing regularly, update routing messages, and reselect the most appropriate path for the current distributed flow. The realization of the routing algorithm is shown in Figure 7.

**3.9. IoT Node Operation.** The public chain and alliance chain node operation agreement maintains the operation of the Internet of Things system. The alliance chain node generates new blocks at a time interval of 30 s. When the node cannot complete the block generation within 30 s, it will rotate to the next node. Similar rules are also used in the public chain to generate block rights maintenance system operation.

**3.10. Realization of User Transfer Process.** The transfer behavior takes place in the user's wallet, and the user first verifies his identity using the wallet. The user's login name and corresponding password are stored locally, and the

password retains the value after MD5 calculation. During the login process, compare whether it is the same as the previously saved record. After the user logs in, the wallet will check whether the user has an identity certificate issued by the authentication server in the system. Only transactions sent by users registered in the system will be received by the alliance chain node. When the user does not store the identity certificate in the node, the wallet will prompt user complete the authentication. Users can use the wallet to initiate transfers, and they can also query the status of the account. Transfers between users need to use the public key as the address to receive the transfer. In fact, the public key is associated with the payment transaction so that the currency obtained in the payment transaction is used. When making a payment, you can prove your ownership of the currency through the private key corresponding to the public key and pass the cryptographic algorithm without the need to pass a centralized credit institution. The generated payment address will be displayed, and the corresponding private key will be stored in the file by the wallet and used in the transaction. The payment address can be sent to other users in the digital currency system by means of communication outside the system.

After sending the transaction, the user needs to wait for the alliance chain node and the public chain node to perform a series of operations and finally store the relevant transfer-in and transfer-out transactions in the public chain block. The wallet has stored the label and content of the complete transaction for a period of time. By comparing the data stored in the public chain, you can check whether the transaction you initiated has been written to the block and confirmed by multiple blocks. To initiate a transfer, users need to use their USOT as the payment method, provide the corresponding private key, send currency to the public key provided by the other party, and provide one or more public key addresses of their own as the change address. The total amount of currency in the USOT provided by the transaction initiator cannot be less than the payment amount. If the balance cannot be exactly equal, the excess amount will be sent to the change address and returned to the payer.

**3.11. Traceability and Transaction Disclosure.** Traceability is initiated and completed internally by the alliance chain, and the result of the transaction traceability can be seen in the end. The goal of retroactive transactions is generally a transfer-out transaction because the initiator of a complete transaction on the transfer-out exchange is the owner of the transfer-out transaction address, and the identity of the initiator can be queried. If no one spends it for a transfer-in transaction, it cannot get the owner of the transaction. When searching for a transaction, according to the query transaction serial number, it traverses the plaintext of transaction information saved in the block, finds the block containing the same serial number, decrypts the transaction, finally finds the transaction, and displays the complete record in the transaction.

**3.12. System Test and Implementation.** This system runs under Windows and uses Java language for programming.

TABLE 2: Design values of operating nodes.

| Constraint content    | Settings (ns) |
|-----------------------|---------------|
| Input delay           | 3.1           |
| Output delay          | 3.0           |
| Clock jitter and skew | 3.2           |
| Drive capability      | 3.2           |

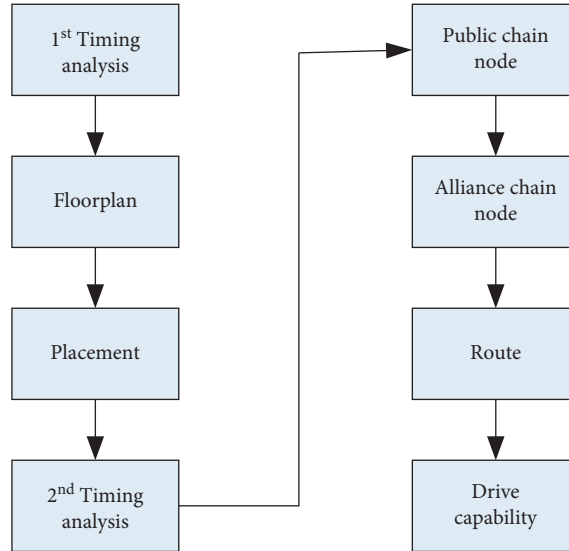

FIGURE 6: Running process.

FIGURE 7: Implementation of the routing algorithm.

The machine configuration for system testing is shown in Table 3. This system uses the JPBC (Java Pairing-Based Cryptography) library. JPBC is a Java package based on the paired cryptography library function (PBC). JPBC completely breaks away from the dependence of PBC, realizes the pair operation completely based on Java, and puts aside the limitations of the platform itself. This system uses it as the basic support library for cryptography. In addition to the basic upload and download function files, this system mainly includes the following types of files that generate user keys, generate keyword ciphertexts and secret doors, and implement keyword encryption and search. CLPEKS.java is used to implement various algorithms. CLPEKS Pub Params.java is used to store public parameters, Service and Client Key Interface java is an interface class for client and

server keys, CLPEKS Secret Key.java and CLPEKS Client Key java store server and client keys, respectively, and CLPEKS Cipher text.java and CLPEKS Trap door.java store ciphertext and secret door, respectively.

#### 4. Analysis of Dynamic Coding Service System

**4.1. Algorithm Performance Analysis.** The performance test mainly includes two aspects. On the one hand, the algorithm performance changes under different matrix sizes, that is, when  $N$  is different; on the other hand, the performance differs between the test algorithm and the SM2 algorithm. First, test the performance of the algorithm when different matrix sizes are different, that is, when  $N$  is different. When the test  $N$  is 4, 8, 16, 32, and 64, the number of signatures and

TABLE 3: Machine configuration during the system test.

| Project          | Value  |
|------------------|--|
| Operating system | Microsoft Windows 7 Ultimate                 |
| Version          | 6.1.7601 Service Pack1 internal version 7601 |
| System type      | x64-based PC                                 |
| Processor        | Intel8CoreTM i3-2310M                        |
| CPU              | 2.10 GHz                                     |
| RAM capacity     | 8 GB   |

verifications per second by the algorithm and the experimental results retain two significant digits. The performance of the algorithm at different matrix sizes is shown in Table 4. It can be seen from Table 4 that with the increase in the matrix size, the performance of algorithm signature and verification is gradually decreasing. The reason is that the larger the matrix size, the more cycles in the GeneratePrivateKey and Public Key Derivation GeneratePublicKey methods. At the same time, the performance of the verification algorithm drops faster because the loop of the GeneratePublicKey method in the verification process contains the accumulation of elliptic curve points which takes longer. However, although the performance of the algorithm decreases as the matrix size  $N$  increases, the security of the algorithm will increase as  $N$  increases. Next, test the performance difference between this algorithm and the standard SM2 signature algorithm. When the test matrix size  $N=64$ , the number of signatures and verifications per second of this algorithm and the SM2 algorithm are the same. The initialization of the private key matrix SKM and the public key matrix PKM will only be performed once, so this part of the time is not calculated. From an algorithm perspective, the performance difference between the two algorithm signatures (or signature verification) is the time it takes to derive the key from the matrix. The performance difference of the signature of the two algorithms is greater than the performance of the verification. This is because the calculation of the private key corresponding to the public key in the private key derivation algorithm (the private key class contains the public key) will involve the elliptic curve dot product operation. The dot multiplication operation takes a long time. It can be seen from Table 4 that when the matrix size is  $N=64$ , the signature and verification efficiency of this algorithm are both close to half of the efficiency of the SM2 algorithm, and the performance difference is due to the secret key of the proxy signature private key and the proxy verification public key derived from overhead. On the whole, performance has been lost, but according to the safety analysis of this algorithm, the overall safety limit of the system has been increased from 1 to 33. After that, the SM2 hash algorithm and this research algorithm are tested for performance comparison. Use the mkfile command to generate 16B, 1KB, 1MB, and 1GB files in sequence as input. After 10 tests, according to the test results, as the length of the input message increases, the computational efficiency of SM2 and this research show an upward trend first and then reach a peak. The peak algorithm speed of SM2 is around 100 MB/s, and the peak algorithm speed of RDCAR is around 370 MB/s. On the whole, the efficiency of the algorithm in this study is higher than that of SM2. This is

not because of the gap in the algorithm itself but because the bottom layer of the Go algorithm is implemented in assembly, which is more efficient. The performance analysis of the algorithm at different matrix sizes is shown in Figure 8. Before the simulation is carried out, it is necessary to specify specific voltage values for the power signal and ground as shown in Table 5.

*4.2. Dynamic Coding Analysis.* Use simulation tools to simulate the RDCAR routing algorithm. We take the network model of the grid graph and distribute 25 nodes in the range of  $100 \times 100 \text{ m}^2$ , and the communication range of each node is 20 m. 11 streams are randomly generated in the network. The purpose of our experiment is to compare RDCAR, DCAR protocol, and COPE coding protocol. Since there is no DCAR protocol and COPE coding protocol, there is no rate-aware algorithm, so the rate of DCAR and COPE cannot be automatically adjusted. Let's take a look at the coding opportunities and throughput. Under different speeds and signal-to-noise ratios, compare the coding opportunities and throughput of RDCAR. The rates of COPE and DCAR we used here are the same, so the difference in coding opportunities is enough to reflect the difference in throughput. At the same time, the increase in coding opportunities will lead to the increase in throughput, so the number of coding opportunities can reflect the size of throughput. The simulation shows the comparison of coding opportunities at different rates in a low channel capacity environment. We can see that in the actual situation of about 5 to 10 dB, the channel quality is very poor and the packet loss rate is quite high. DCAR and COPE use a minimum of 12 mbps, and DCAR and COPE use 24 mbps for coding opportunities. Our RDCAR uses a rate selection algorithm, so it will use a lower transmission rate to ensure the number of successes on a poor link and use a higher transmission rate on a better link to increase throughput. We found that DCAR adopts coding-aware routing scheme and can actively discover coding opportunities. Therefore, under the same circumstances, no matter what transmission rate is used, it is better than COPE. When the channel environment of 5 to 10 dB is poor, compared with the two cases of 12 mbps and 24 mbps, using 12 mbps to guarantee the transmission rate, the coding opportunity and throughput are better than those of 24 mbps. The medium quality channel ranges from 10 to 20 dB. Since under medium channel quality, a certain transmission success rate can be guaranteed even when 48 mbps is used again, and we can see that as the transmission rate increases, under the premise of ensuring a

TABLE 4: Algorithm performance at different matrix sizes.

| Algorithm | $N=4$  | $N=8$  | $N=16$ | $N=32$ | $N=64$ |
|-----------|--------|--------|--------|--------|--------|
| Signature | 221.72 | 262.47 | 251.89 | 239.81 | 219.78 |
| Check     | 245.10 | 227.27 | 224.72 | 189.39 | 155.28 |

FIGURE 8: Algorithm performance analysis at different matrix sizes.

TABLE 5: Before the simulation, you need to specify specific voltage values for the power signal and ground.

| Net name | Voltage value (V) |
|----------|-------------------|
| AWCC1V8  | 1.8               |
| DD RYTT  | 075               |
| GND      | 1.2               |
| YCC1V2   | 1.8               |
| YCC1V8   | 33                |

certain transmission probability, the coding of COPE and DCAR opportunities and throughput gradually approach RDCAR. Due to the high channel quality, the success rate of information transmission is very high, and the main factor that affects coding opportunities and throughput is the transmission rate. Therefore, we can see that in Figure 9, when DCAR and COPE only use low-speed channels, the low transmission rate guarantees success rate is no longer applicable but greatly affects the transmission efficiency, making the coding opportunity and throughput smaller. DCAR and COPE use medium-speed channels. It can be seen that the coding efficiency of RDCAR is still far behind when using 24 mbps. The transmission rate of RDCAR in our actual simulation is about 48 mbps. Therefore, we found in subsequent experiments that if 48 mbps high-speed transmission is used, the coding opportunities of DCAR and RDCAR are quite close, and there is a certain gap between COPE and DCAR. The coding situation monitored by different transmission rates is shown in Table 6. The learning step length of the RDCAR algorithm is shown in Table 7. The original high-frequency coded signal collected by using the oscilloscope is shown in Figure 10.

*4.3. Function Analysis.* The model proposed in this study not only includes the antitampering, traceability, and decentralization characteristics of transactions in the existing digital currency system but also adds supervisable attributes to the system to enhance the system's ability to protect user privacy. The performance test is divided into two aspects. On the one hand, it tests the performance changes of the algorithm under different matrix sizes, that is,  $N$ ; on the other hand, it tests the performance comparison between this algorithm and the standard SM2 signature algorithm. During the test, first create a plaintext byte array and assign values, then create a key byte array and assign values, create an encryption instance by calling `sm4.NewCipher(key)`, and then call `c.Encrypt` to calculate the encryption result. Then, call `c.Decrypt` to calculate the decryption result. The performance of the algorithm changes when the test matrix size  $N$  is different. When the test  $N$  is 8, 16, 32, and 64, calculate the number of signature tests and verification times of the algorithm per second. The result of functional analysis is shown in Figure 11. Since authorization generation and authorization verification will only occur once when the system is initialized, this part of the time is not calculated. In

FIGURE 9: Comparison of encoding opportunities at different rates.

|----------------------------|------------------------|------------------------|---------------|
| 100                        | 50                     | 8                      | 0.005, 0.005  |
| 100                        | 50                     | 8                      | 0.005, 0.005  |

terms of privacy protection, the complete transaction records are encrypted and stored. Only after initiating the traceability of the transaction and voting by the members of the alliance chain, can the transaction plaintext be viewed by the special members of the alliance chain. After completing a consensus, the alliance chain broadcasts a batch of transfer-in and transfer-out transactions, hiding multiple pieces of information belonging to the same complete transaction in a large amount of similar information and avoiding the leakage of user privacy in the process of information interaction. The public transaction records stored in the public chain for query, because of truncation and confusion, lose the traceable transaction relationship information and have the unlinkability of the transaction output required by the digital currency public chain data. The data stored in the alliance chain node have the most restrictive restrictions on access rights. During the normal operation, the alliance chain node only has the write permission, and the verification function in the system is completed by the data in the

public chain block. In terms of supervisable attributes, when there is a need for the system to trace the transaction, the alliance chain node initiates a transaction traceability application, and the nodes can understand the reason for initiating the traceability outside the system, and then the supervisory authority node is responsible for restoring the key and decrypting the traceability. Transaction records finally obtain the identities of relevant transaction participants through the identity verification server. But, only after a USOT is spent, the consortium chain can obtain its owner's identity signature through a transaction request from a public chain user. If a USOT has not been spent, its owner cannot be known. In order to increase the supervisable properties of the system, this research adds three parts of the supervision agency, identity authentication server, and encrypted storage to the Internet of Things system. When there is no need to initiate traceability, the supervisory agency only participates in the consensus process as a participant in the alliance chain, and only when it needs to

FIGURE 10: The original high-frequency coded signal collected by using an oscilloscope.

trace the transaction, can it act as a trusted secret shared share collector to decrypt data. The identity authentication server issues identity certificates to registered users, which can trace the transaction to a clear user and achieve thorough supervision. The addition of supervisory attributes reduces the degree of decentralization of the system, but it does not damage the Internet of Things from the user's perspective. The original intention of the design is that the members and data of the alliance chain and the public chain do not rely on centralized credit, and it can also achieve better protection for users. When a user loses an account or transaction certification document such as an identity certificate, he can protect his account through the identity authentication server and the system. Encrypted storage is to prevent consortium chain members from leaking transaction information after being attacked. The function of the regulatory agency has affected the decentralized structure, and it has also become a security weakness that the system may be attacked. The use of secret sharing to a certain extent prevents the possibility of stealing transaction data with the regulatory agency as the target, and only alliance chain members agree to restore only when the key is the supervisory authority which has the ability to decrypt data. The test results after changing the maximum number of learning times are shown in Table 8. The regulatory error is shown in Table 9.

**4.4. Security Analysis.** The issuance of legal digital currency requires the transformation of the payment system infrastructure. As a digital form of currency, legal digital currency needs to adopt extremely high technology in any link of circulation to reduce the degree of operational risk. Once the legal digital currency infrastructure is destroyed, it will cause the entire financial system to suffer losses. The system security results are shown in Figure 12. The analysis of legal digital currency has to deal with a large number of transactions, and the most mature distributed ledger technology cannot fully meet the requirements of the central bank's

payment system. In its fiat digital currency project, the Bank of Canada uses distributed ledger technology (DLT) to build a payment system, but the performance of distributed ledger technology is not optimistic. According to the report, it is difficult to use distributed ledger technology for transaction systems to process a large amount of instantaneous transaction data. After the official issuance of legal digital currency, it faces far more requirements than Bitcoin in terms of importance and transaction scale. The payment infrastructure established by the central bank must meet the transaction needs of the society. The issuance of legal digital currency will have a profound impact on the payment system of the entire country. Therefore, the construction of the payment system must consider the requirements of scalability, compatibility, and transaction throughput. This article divides the attacks faced by the supervisable digital currency model into three types according to their sources: attacks from outside the system, attacks from alliance chain nodes, and attacks from public chain nodes. In terms of the most basic security of digital currency transactions, the system uses identity certificates and signatures to ensure that attackers cannot forge identities to steal other people's assets; transactions in the system are based on USOT and use a unique public key as an address. The corresponding private key can be unlocked for payment. The purpose of the attack from outside the system is to destroy the function of the system and make the digital currency system unable to operate normally. The target of the attack may be a node in the system or a communication network. Due to the distributed nature of the blockchain, attacking a node in the system will not affect the operation of the system, but when an attacker has the ability to attack multiple nodes, the alliance chain as the core of the system must ensure that the node that stops working cannot exceed 1/3 of the system. Since the public chain uses DPoS as a consensus mechanism, during the election cycle, those nodes that are made public due to the operation of the system are likely to become targets for system attackers. Therefore, in order to ensure that the system does not stop running, it is necessary to

ensure that the system attackers are all before destroying the current witness node, complete a new round of witness node voting. Attacks from within the system are generally through the creation of system inconsistencies such as the fork of the Internet of Things to achieve double-spending by tampering or canceling transaction records. The CPBFT consensus mechanism adopted by the alliance chain does not have the possibility of forks of the Internet of Things. When the number of colluding attackers does not exceed the threshold, it can prevent double-spending attacks. Although there may be forks in the public chain, only attackers account for more than 50% of the total number of nodes to ensure the success of the attack. The real-name registration mechanism in the background also reduces the possibility of launching and succeeding from inside the system. Digital currency can record and check transaction information and information of both parties, can accurately reflect the implementation of monetary policy, and can strengthen financial management. The transaction record of digital currency cannot be tampered with, can completely record the transactions of each participant, and can form a unified distributed ledger in the entire digital currency system. Through the review of transaction information and the supervision of digital currency circulation, the national regulatory agency can accurately grasp the monetary policy and credit policy in real time, and then scientifically and comprehensively calculate the policy implementation status, and adjust relevant policies in time according to changes in the situation; It can promote the publicity, openness, and integrity of digital currency transactions as a whole by establishing an overlying public credit system.

*4.5. Efficiency Analysis.* Intermediaries such as digital currency trading platforms or traditional financial institutions and certain nonfinancial industries which are likely to participate in the flow of digital currency transactions should keep records and report suspicious transactions.

The specific methods include conducting due diligence on customer identity and storing customer identity information. The public key address, account, transaction nature, date, and amount involved in the transaction are helpful for monitoring transactions, recording suspicious transaction information, and combining the information on the blockchain ledger for more accurate recording. In order to prevent unqualified financial institutions from participating in the payment and settlement system, the access system sets specific conditions so that only payment and settlement participants who meet the corresponding conditions are allowed to be the counterparty of payment and settlement. The efficiency analysis result is shown in Figure 13. As the transparency and intensity of supervision have been greatly improved and the legal digital currency relies on advanced Internet technology, it can better identify the relevant conditions of financial institutions involved in payment and settlement and strengthen prudential supervision. The consensus mechanism used in the public chain part of the system is DPoS, and the consortium chain part uses CPBFT. Both consensus mechanisms are based on voting. The system state is determined according to the choice of the majority of nodes in the system, without the need for additional proof of work. The computational overhead of the system mainly occurs in the verification and encryption of transactions. In the process of verifying the block, each alliance chain node needs to encrypt and compare the transactions packaged into the block. This process uses a public key cryptographic algorithm, which has a high time complexity. Each node has basically the same demand for computing power, and there will be no system security problems and decentralized performance caused by the concentration of computing power. To achieve consistency within the alliance chain, nodes need to broadcast multiple times to achieve information interaction between the two. The communication complexity is  $O(n)$ , where  $n$  is the number of nodes. The system is

| $\Delta p$          | (c, 0, 0) | -3.898                  | -1.956            | Smooth        |

designed so that each participant can control multiple nodes proportionally. The more the number of nodes, the stronger the antiattack ability of the system, but the communication overhead will also increase. The system maintains two blockchains at the same time. Compared with a single chain system, the communication between some nodes of different systems is increased. If the nodes of the alliance chain and the public chain communicate with each other, the complexity of the communication is  $O(n, m)$ , where  $n$  is the number of nodes in the alliance chain,  $m$  is the number of nodes in the public chain, and  $m$  may be multiples of  $n$ , so the pair can be appropriately relaxed. The communication requirements between two blockchain nodes can reduce the communication complexity to  $O(m)$ . The supervisable digital currency system uses CPBFT and DPoS improved in this research. The characteristics of these two consensus mechanisms are that the block generation interval is short and the system transaction throughput is high, so there is no system bottleneck caused by increasing the system scale in the consensus mechanism. The correlation coefficient matrix of the independent variables is shown in Table 10. The unit root test results of the time series are shown in Table 11.

## 5. Conclusion

This research mainly discusses the intelligent digital currency and dynamic coding service system based on the Internet of Things technology. To a certain extent, digital currency can help save currency issuance and circulation costs, improve the effectiveness of monetary policy, accelerate the pace of development to a cashless society, and adopt effective methods for promotion and application. It is expected that digital currency will be widely used by all people, thereby contributing to building a robust and efficient new financial system. At the same time, the current

status of the use of digital currencies at home and abroad is also analyzed. The digital currency market is frequently traded. According to the traditional trading market, digital currency is an active market, but the currency value stability of digital currency is poor.

This research is mainly based on the RDCAR algorithm to realize the traceability of the route discovery process of the wireless network initiated and completed within the alliance chain, and finally the results of the transaction traceability can be seen. The goal of retroactive transactions is generally a transfer-out transaction because the initiator of a complete transaction on the transfer-out exchange is the owner of the transfer-out transaction address, and the identity of the initiator can be queried. If no one spends it for a transfer-in transaction, it cannot get the owner of the transaction. When searching for a transaction, according to the query transaction serial number, it traverses the plaintext of transaction information saved in the block, finds the block containing the same serial number, decrypts the transaction, finally finds the transaction, and displays the complete record in the transaction.

When the intermediate node receives the RREQ message, first, to avoid loops, check whether the same RREQ message has been introduced. If it is received, discard it. Otherwise, buffer the message and append its own neighbor node list, corresponding to the signal-to-noise ratio of the channel link, and update RREQ message and broadcast it. The payment cipher is managed by the bank. When the user opens an account, the bank registers and sends it to the user, and the key is generated by the algorithm chip, and the public key is stored in the bank's back-end server. When the bill is delivered to the bank, the bank enters the various elements of the bill on the counter terminal and transmits it to the verification machine through the bank network for verification. If the verification is correct, it indicates that the bill is indeed issued by the customer, and the bill elements are correct, so you can make payment. The public chain and alliance chain node operation agreement maintains the operation of the Internet of Things system. The alliance chain node generates new blocks at a time interval of 30 s. When the node cannot complete the block generation within 30 s, it will rotate to the next node.

Lung nodules are an early symptom of lung cancer. The earlier they are found, the more beneficial it is for treatment. However, in practice, Chinese doctors are likely to cause misdiagnosis. Therefore, deep learning is introduced, an improved target detection network is used, and public datasets are used to diagnose and identify lung nodules. This paper selects the Mask-RCNN network and uses the dense block structure of Densenet and the channel shuffle convolution method to improve the Mask-RCNN network. The experimental results prove that proposed algorithm is extremely effective.

## 1. Introduction

Pulmonary nodules [1, 2] are the result of the competition between unknown antigens and the body's cellular and humoral immune functions. It is very harmful to the human body. It is an early manifestation of lung cancer [3]. It usually appears as a circle in medical imaging. Shape or round shape, the lung tissue is complex, and it is difficult to distinguish lung nodules from blood vessels and bronchus in chest tissue very accurately based on the experience of clinicians and film readers. Vascular adhesion type and subpleural type are even more difficult in the screening of lung cancer.

In recent years, with the development of computer vision [4, 5] and artificial intelligence, the application of machine learning in medical image detection [6, 7] has also increased, among which machine learning is used in lung nodule detection the target detection network in deep learning [8, 9] can accurately locate the location of the region of interest and return its category. The common ones are R-CNN [10] series, SSD, and YOLO [11] series, among which R-CNN series mainly include R-CNN, fast R-CNN [12, 13], faster R-CNN, and Mask R-CNN [14, 15]. The advantage of the R-CNN series of target detection networks is that the

detection accuracy is high, but the disadvantage is that the detection time is long. The later SSD and YOLO series networks have fast detection speeds, but the accuracy is low; the accuracy of the YOLO-V3 network [16, 17] has been greatly improved. In terms of comprehensive detection speed and detection accuracy, YOLO-V3 network is often used.

In this paper, the YOLO-V3 target detection network in deep learning is selected and the network is improved. The reference network in the YOLO-V3 network is replaced with the SEnet network [18, 19], and the LIDC-IDRI public tuberculosis dataset [20] is used as the training dataset of the network. The trained network surpasses other target detection models and the unimproved YOLO-V3 network in many performances.

The rest of the paper is organized as follows. In Section 2, we introduce R-CNN network. In Section 3, an example is given to demonstrate the effectiveness of our method. In Section 4, the conclusions and future directions are given.

## 2. Network Improvement

This paper selects the mask R-CNN network, which has a higher accuracy rate in the field of medical imaging among

many models. The following introduces the Mask R-CNN network and its specific improvement methods.

*2.1. Introduction to the Dataset.* This paper selects the LIDC-IDRI public tuberculosis dataset as the training set of the network. The dataset is composed of chest medical image files (such as CT and X-ray film) and corresponding diagnosis result lesion labels. The data was collected by the National Cancer Institute (National Cancer Institute) in order to study early cancer detection in high-risk populations. This dataset contains a total of 1018 research examples. For the images in each example, four experienced thoracic radiologists performed a two-stage diagnosis and annotation. In the first stage, each physician independently diagnosed and marked the location of the patient. Three categories were marked: (1)  $\geq 3$  mm nodules, (2)  $< 3$  mm nodules, and (3)  $\geq 3$  mm nonnodules. In the subsequent second stage, each physician independently reviewed the labels of the other three physicians and gave their final diagnosis results. Such two-stage labeling can label all results as completely as possible while avoiding forced consensus. The image file is in Dicom format, which is a standard format for medical images. In addition to image pixels, there are some auxiliary metadata such as image type, image time, and other information. A CT image has  $512 \times 512$  pixels. Figure 1 is two randomly selected CT images.

*2.2. Mask R-CNN Network.* The detection of medical images pays more attention to the model performance. When the speed can meet the requirements, a network with higher detection accuracy should be selected as far as possible. The Mask R-CNN network is a highly accurate network, and its specific structure is shown in Figure 2.

Among them, CNN represents the benchmark network of the Mask R-CNN network, RPN represents the generation of the suggestion window network, ROIAlign represents the use of bilinear interpolation to obtain the region in the feature map corresponding to the ROI in the original image, the correspondence between the coordinates is preserved, and the mask branch represents FCN Internet.

It can be seen from the network structure that the mask R-CNN network finally outputs the results through two branches, the first branch outputs the background and object segmentation results, and the second branch outputs the classification and coordinate results. However, the benchmark network of the mask R-CNN network is the residual network, and it is not the best.

*2.3. Improve Mask R-CNN Network.* Densenet network is an improvement of residual network, which is a convolutional neural network with dense connections. In this network, there is a direct connection between any two layers, that is, the input of each layer of the network is the union of the outputs of all previous layers, and the feature map learned by this layer will also be directly passed to all subsequent layers are used as input. Figure 3 is a schematic diagram of Densenet's dense block. The structure of a block is as follows, which is the same as bottleneck in the residual.

The Densenet network is made up of dense blocks, and its specific structure is shown in Figure 4.

This paper selects the Densenet network as the reference network of the Mask R-CNN network, but the convolution method of the Densenet network will cause a lot of waste, and the experiment in this article is run on 3 GPUs, using the packet convolution method, in the packet volume. It is difficult to realize the information exchange between groups in the product. At the same time, the convolution method of the Densenet network will also cause a large amount of parameters. Therefore, this article uses the channel shuffle convolution method to reduce the amount of Densenet network parameters while also solving the grouping volume. There are many ways of product defects.

The convolution method in channel shuffle convolution is not the same as the convolution of the Densenet network. In the convolution of the Densenet network, a set of convolution kernels is responsible for a set of feature maps, while in the channel shuffle convolution, a convolution kernel is responsible for a feature map, which can greatly reduce the amount of parameters, but this will cause the loss of information between the same group of data. The shuffle operation can solve the problem of noncommunication of information in the group, and the shuffle operation can solve the problem of group and group convolution., the defect of not communicating information between groups. Figure 5 is a schematic diagram of channel shuffle, where input represents the input, GConv represents a grouped convolutional layer, Feature represents the feature map, and Output represents output.

Figure 5(a) represents a grouped convolution, and three colors represent three groups. It can be seen that there is no information exchange between each group of grouped convolution, and Figure 5(b) is the application of shuffle process, and it can be seen that there is an order to exchange information. Figure 5(c) is after shuffle is applied, and it can be seen that there are other groups of information between each group.

Change the convolution mode in the Densenet network to the channel shuffle convolution mode to get an improved network D-ShuffleNet network. In this paper, the D-ShuffleNet network is used as the reference network of the Mask R-CNN network to obtain the Per-T Mask R-CNN-II network.

To verify that the improvements made in this article are correct, four groups of networks are used to verify on the same small dataset. The four networks are Pre-T + Mask R-CNN-II improved by adding D-ShuffleNet network. The Pre + Mask R-CNN-II improved by the Densenet network, Mask R-CNN-II, and Mask R-CNN networks that only use the channel shuffle convolution method; the results are shown in Figure 6.

## 2.4. Network Training Strategy

*2.4.1. Activation Function.* Common activation functions include sigmoid, TANH, and Relu. The sigmoid function formula is as follows:

FIGURE 1: Picture of LIDC-IDRI data set.

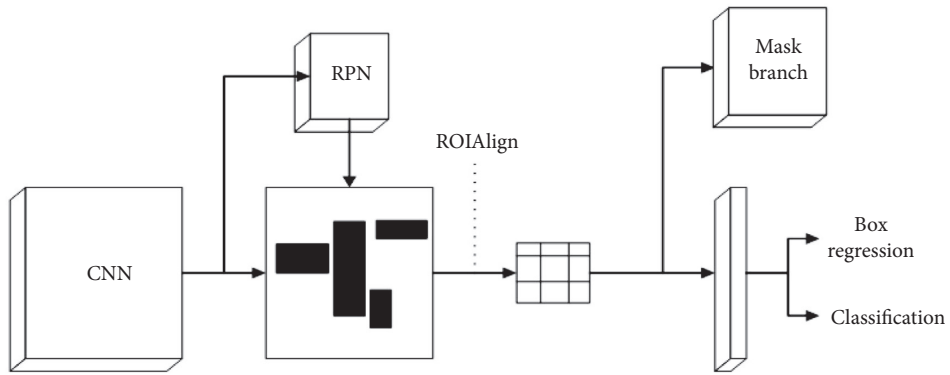

FIGURE 2: Mask R-CNN network structure.

FIGURE 3: Schematic diagram of dense block in Densenet.

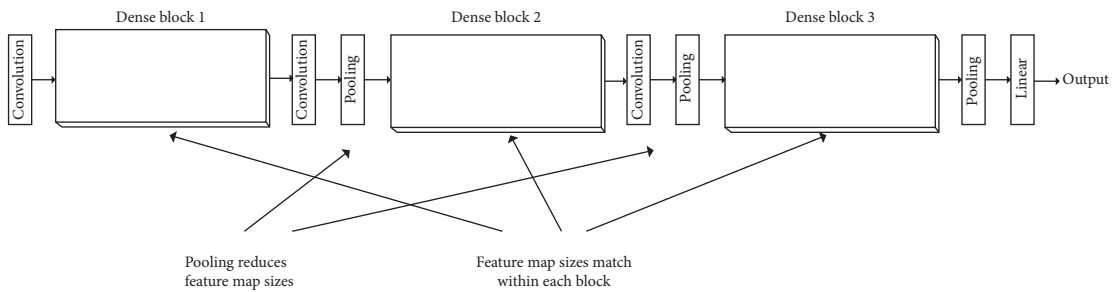

FIGURE 4: Schematic diagram of Densenet structure.

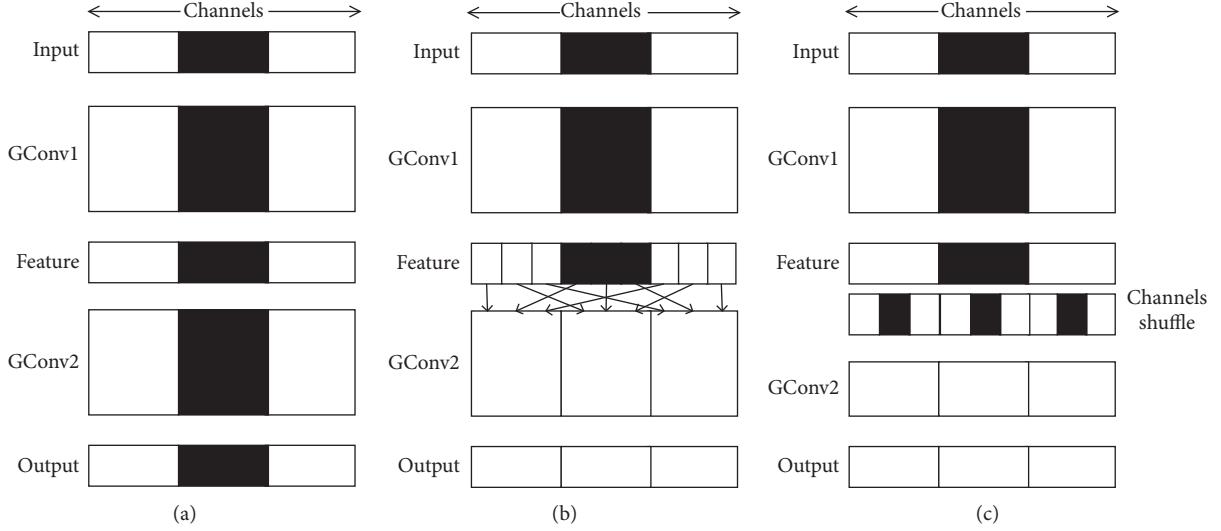

FIGURE 5: Schematic diagram of channel shuffle. (a) Grouped convolution. (b) Apply shuffle. (c) shuffle effect.

FIGURE 6: Schematic diagram of the four network results.

$$f(x) = \frac{1}{1 - e^{-x}}, \quad (1)$$

in which  $x$  represents the input and represents output. The output range from formula (1) is  $(0, 1)$ , which is not a 0-centralized distribution. During backpropagation, it is completely positive, so it will cause the weight parameter to update. The updated value is completely positive or completely negative. When the gradient is in the second or fourth quadrant, it will be difficult to find the optimal gradient. At the same time, since the gradient is close to 0, when the absolute value of the output value is large, the problem of gradient disappearance will be caused, and the sigmoid function will not be considered in general.

Equation (2) is the TANH function, which is better than the SIGMOID function:

$$f(x) = \frac{1 - e^{-2x}}{1 + e^{-2x}}. \quad (2)$$

It can be concluded from the formula that the output range of the tanh function is  $(-1, 1)$ , which solves the problem that the sigmoid function cannot be distributed with 0 centralization, but it still does not solve the problem of vanishing gradient.

Equation (3) is the Relu function, which solves the problem

$$f(x) = \begin{cases} x, & x > 0, \\ 0, & x \leq 0. \end{cases} \quad (3)$$

It can be concluded that when the input is greater than 0, the gradient is always 1, which solves the problem of gradient disappearance. However, some parameters with input less than 0 are all dead, and the output is 0.

To solve the shortcomings of the Relu function, improvements were subsequently made. LReLU, PReLU, RReLU, and ELU appeared successively. The core idea of these four functions is to make the output not 0 when the output is less than 0 and then solve the parameter less than 0. For the death problem, this article uses the ELU transfer function:

$$f(x) = \begin{cases} \alpha(e^x - 1), & x < 0, \\ x, & x > 0. \end{cases} \quad (4)$$

**2.4.2. Learning Rate.** The initial value of the learning rate is usually set to 0.01, and it should be determined according to the actual situation. The usual practice is to set it to 0.01, and then initially iterate for about 10 epochs, generally checking the loss function and the transformation trend of accuracy if the loss can be reduced as well as increasing the accuracy rate; it means that the initial learning rate is generally

appropriate. We can try several times to choose a good initial learning rate.

The most common learning method is the step learning method. The learning rate is attenuated to one-tenth of the original every certain step size, which generally meets the requirements of a large learning rate in the early stage of training and a small learning rate in the later stage of training. As the gradient reaches a plateau, the training loss will be more difficult to improve. A saddle point is a point where the derivative of the function is zero but is not a local extremum on the axis. The difficulty of reducing loss comes from the saddle point, not the local minimum. If the training does not improve the loss, we can change the learning rate of each iteration according to some periodic function.

This article chooses the Warm Restart (Warm Restart) proposed by Loshchilov and Hutter and improves it accordingly. This method uses a cosine function as a periodic function and restarts the learning rate at the maximum value of each period. The improvement of this paper is to change the learning rate every certain step size so that the learning rate changes in a decreasing cosine manner. This improvement has a better application in the later stage of training.

**2.4.3. Loss Function and Regularization.** Loss functions generally include mean square error, maximum likelihood error, maximum posterior probability, cross-entropy loss function, cross-entropy function, and mean square error is an earlier loss function definition method, which measures the corresponding dimensions of the two distributions the sum of differences, the maximum likelihood error is from the perspective of probability, the model parameter theta that can perfectly fit the training example is solved, so that the probability  $p(y|x, \theta)$  is maximized and the posterior probability is maximized, that is, The maximum probability  $p(\theta|x, y)$  is actually equivalent to the maximum likelihood probability with a regularization term. It considers prior information and prevents “overfitting” by constraining the size of parameter values and the cross-entropy loss function measuring the similarity of two distributions  $p$  and  $q$ .

This paper chooses a relatively good cross-entropy loss function; formula (5) is the cross-entropy loss function formula:

$$C = -\frac{1}{n} \sum_x [y \ln a + (1 - y) \ln (1 - a)], \quad (5)$$

in which,  $y$  is the expected output and  $a$  is the actual output of the neuron.

Regularization is added in this article to prevent overfitting. Common regularizations include L1 regularization terms and L2 regularization term. In this paper, L2 regularization term is selected. Equation (6) is the objective function formed by adding L2 regularization term, which is the weight attenuation, and set to 0.9:

$$L = C + \frac{\lambda}{2n} \sum_w w^2. \quad (6)$$

**2.4.4. Optimizer.** Common optimizers include SGD, Momentum, Nesterov, RMSprop, and Adam. Among them, SGD is the earliest optimization method, but SGD is easy to converge to the local optimum, and in some cases may be trapped at the saddle point. Momentum can determine the relevant direction, accelerates SGD, suppresses oscillation, and speeds up the convergence, but it cannot improve the sensitivity adaptively. Nesterov and RMSprop also have certain shortcomings. The best optimization method now is the Adam optimization method. This article selects the Adam optimization method.

Adam is essentially RMSprop with a momentum term, which uses the first-order moment estimation and second-order moment estimation of the gradient to dynamically adjust the learning rate of each parameter. The main advantage of Adam is that, after bias correction, each iteration of the learning rate has a certain range, making the parameters more stable.

This article chooses the Adam optimizer, which uses the first-order moment estimation and the second-order moment estimation of the gradient to dynamically adjust the learning rate of each parameter. The main advantage of Adam is that, after bias correction, each iteration of the learning rate has a certain range, which makes the parameters relatively stable. The update formula is as follows:

$$\begin{aligned} m_t &= \beta_1 * m_{t-1} + (1 - \beta_1) * g_t, \\ v_t &= \beta_2 * v_{t-1} + (1 - \beta_2) * g_t^2, \\ \hat{m}_t &= \frac{m_t}{1 - \beta_1^t}, \\ \hat{v}_t &= \frac{v_t}{1 - \beta_2^t}, \\ \theta_{t+1} &= \theta_t - \frac{\eta}{\sqrt{\hat{v}_t} + \epsilon} * \hat{m}_t. \end{aligned} \quad (7)$$

### 3. Experimental Results

Practice is carried out using the Pytorch framework; training is carried out using the Adam optimizer and selecting the ELU function for the activation function. The convolution method in the Densenet network is changed to the channel shuffle convolution method, and the network D-ShuffleNet is improved.

This article conducted 7 sets of comparative experiments, namely, Pre-T+Mask R-CNN-II improved by adding D-ShuffleNet network and Pre+Mask R-CNN-II improved only by Densenet network, using only channel shuffle convolution Mask R-CNN-II, Mask R-CNN network, YOLO-V3 network, Fast R-CNN network, and SSD network, it uses the same dataset for training. After training, the

TABLE 1: Confusion matrix of classification results.

| The true situation   | Forecast result      |                            |
|----------------------|----------------------|----------------------------|
|                      | Positive example (P) | Counterexample (N)         |
| Positive example (P) | TP (real case)       | FN (false counterexample)  |
| Counterexample (N)   | FP (false positive)  | TN (true negative example) |

experimental results of 7 sets of experiments are obtained. In this paper, mAP and ROC curves are used as evaluation criteria to analyze and evaluate the network results. AP in mAP refers to the area of the P-R curve of each class, mAP is the average of all APs, P in the P-R curve refers to precision, which is accuracy, and R refers to recall, which is the recall rate. The above concepts can be derived from the concept of confusion matrix. The confusion matrix table of classification results is shown in Table 1.

The formulas of recall rate and accuracy rate are shown in equations (8) and (9):

$$R = \frac{TP}{TP + FN}, \quad (8)$$

$$P = \frac{TP}{TP + FP}. \quad (9)$$

Table 2 shows the specific values of the seven groups of models after training, including the AP value and mAP value of each category.

The order of mAP size in Table 2 is Pre-T + Mask R-CNN-II, Pre + Mask R-CNN-II, Mask R-CNN-II, Mask R-CNN, YOLO-V3, Faster R-CNN, and SSD.

It can be seen from Table 2 that the training effect of the Pre-T + Mask R-CNN-II model is the best, indicating that the network proposed in this paper is suitable for lung nodule target detection.

Regarding model evaluation criteria, in addition to the most commonly used ones, it is often necessary to evaluate the model through the ROC curve. ROC space defines the false positive rate (False Positive Rate, FPR) as the X-axis, and the true positive rate (True Positive Rate) Rate, TPR for short) is defined as the Y-axis. These two values are calculated from the four values in Table 1.

For TPR, in all samples that are actually positive, the ratio of correctly judged positive is

$$TPR = \frac{TP}{TP + FN}. \quad (10)$$

For FPR, among all samples that are actually negative examples, the ratio of falsely judged positive examples is

$$FPR = \frac{FP}{FP + TN}. \quad (11)$$

The ROC curve can reflect the performance of the model well, and its area is AUC. The larger the AUC value, the better the performance of the model. Figure 7 is the ROC curve.

After calculation, the area of Pre-T + Mask R-CNN-II, Pre + Mask R-CNN-II, Mask R-CNN-II, Mask R-CNN, YOLO-V3, Faster R-CNN, and SSD is 0.942, 0.935, 0.916,

TABLE 2: Results of each model.

|                       | mAP   |
|-----------------------|-------|
| Pre-T + Mask R-CNN-II | 0.927 |
| Pre + Mask R-CNN-II   | 0.921 |
| Mask R-CNN-II         | 0.907 |
| Mask R-CNN            | 0.893 |
| YOLO-V3               | 0.881 |
| Faster R-CNN          | 0.871 |
| SSD                   | 0.865 |

FIGURE 7: ROC curve.

0.902, 0.893, 0.882, and 0.877, which are consistent with the results obtained by the mAP evaluation system.

## 4. Conclusions

This paper proposes a new network D-ShuffleNet network, by combining the Densenet network and channel shuffle convolution method, and then proposes a new target detection network. Through the last seven sets of comparative experiments, it is proved that the network proposed in this paper has better performance than other networks. All are good, but the network still has room for improvement. The next step is to improve the network performance and improve the recognition accuracy.

In the complex environment, the suddenly changing structural parameters and abrupt actuator failures are often encountered, and the negligence or improper handling method may induce undesired or unacceptable results. In this paper, taking the suddenly changing structural parameters and abrupt actuator failures into consideration, we focus on the robust adaptive control design for a class of heterogeneous Takagi–Sugeno (T-S) fuzzy nonlinear systems subjected to discontinuous multiple uncertainties. The key point is that the switch modes not only vary with the system time but also vary with the system states, and the intrinsic heterogeneous characteristics make it difficult to design stable controllers. Firstly, the concepts of differential inclusion are introduced to describe the heterogeneous fuzzy systems. Meanwhile, a fundamental lemma is provided to demonstrate the criteria of the boundness for a Filippov solution. Then, by using the set-valued Lie derivative of the Lyapunov function and introducing a vector of specific continuous functions, the closed-loop T-S fuzzy differential inclusion systems are proved to be ultimately bounded. The sufficient conditions for system stability are derived in term of linear matrix inequalities (LMIs), which can be solved directly. Finally, a numerical example is provided to illustrate the effectiveness of the proposed control algorithm.

## 1. Introduction

As it is well-known, the T-S fuzzy model is a powerful tool for the analysis and control design of nonlinear systems [1–4]. Therefore, a great wealthy of results has been achieved for T-S fuzzy systems in the past decades. In [5], the parameterized linear matrix inequality technique has been investigated for T-S fuzzy control systems. In [6], by using the LMIs and sum-of-squares-based approach, an output regulator has been constructed for the polynomial fuzzy control systems. In [7, 8], two fuzzy sliding mode control methods have been developed for the T-S fuzzy systems suffering from both matched and unmatched uncertainties. The fault-tolerant control approaches for T-S fuzzy nonlinear systems have been investigated in [9, 10]. As a further

development, a finite-time fault-tolerant control structure of T-S fuzzy nonlinear systems has been synthesized in [11]. The event-triggered control structures for T-S fuzzy nonlinear systems can be found in [12, 13]. In [14, 15], the robust filters have been constructed for continuous and discrete-time T-S fuzzy systems, respectively. For the delayed T-S fuzzy systems with and without stochastic perturbations, the stability analysis and stabilization methods have been provided in [16, 17]. Chang et al. [18] focused on the robust adaptive control design for a class of heterogeneous T-S fuzzy nonlinear systems subjected to discontinuous multiple uncertainties.

It is also well-known that the uncertainties and disturbances are often encountered in many practical systems. In [19, 20], the active disturbance rejection control methods

have been reported for the nonlinear systems with uncertainties. In [21–24], several antidisturbance controllers have been synthesized by constructing the disturbance observers. The composite antidisturbance controllers can be found in [25–29]. Aiming at the uncertainties existing in the quantized control systems, several robust and adaptive controllers have been proposed in [30–32]. For the unknown nonlinearities existing in the control systems, fruitful results have been reported. In [33], a fuzzy adaptive output feedback controller has been proposed for the multi-input and multioutput nonlinear systems with completely unknown nonlinear functions. For a class of switched stochastic nonlinear systems in a pure-feedback form, a fuzzy observer is constructed to approximate unmeasurable states in [34, 35]. In [36], an adaptive fuzzy tracking control problem has been investigated for a class of nonstrict-feedback systems with unmeasured states and unknown nonlinearities. For the state constrained control systems with unknown nonlinear functions, two adaptive control results have been reported in [37, 38]. In [39], the problem of adaptive neural finite-time tracking control for uncertain nonstrict-feedback nonlinear systems with input saturation has been studied.

In spite of the progress, in the aforementioned control results, a vital problem on heterogeneous uncertainties, in the sense that the parameters and the structures of the uncertainties keep switching with both the system time and the system states, was omitted. This kind of uncertainties and system nonlinearities are often encountered in many physical systems [40,41], and it is of significant importance to develop an effective controller for the heterogeneous uncertain nonlinear systems. When system-state-based switching uncertainties and system structures are taken into consideration, the traditional analysis and control methods become invalid. Furthermore, the control approaches of conventional switched systems cannot be applied neither because most of the switched systems are required to be

purely time-based [42–44]. Moreover, when the fuzzy modeling methods and fuzzy control strategies are introduced in the heterogeneous uncertain system, the control design problem becomes more challenging and interesting. As far as the authors know, no results have been reported for the T-S fuzzy systems subjected to heterogeneous uncertainties and system structures. For the purpose of improving the practicability of the proposed algorithm, the abruptly changing actuator faults are also considered. Motivated by the above considerations, this paper is committed to develop an effective control structure for the T-S fuzzy heterogeneous systems with discontinuous multiple uncertainties and abruptly changing actuator faults. Compared to the existing literature, the main contributions of this paper are as follows:

- (i) To the best of the authors' knowledge, it is the first control solution for the T-S fuzzy systems subjected to heterogeneous uncertainties and system structures, which keep switching with both the system time and the system states.
- (ii) A fundamental lemma is provided to demonstrate the criteria of the boundness for a Filippov solution, establishing the mathematical fundamentals for the adaptive control of differential inclusion systems.
- (iii) By proposing a specific vector of continuous functions, the closed-loop multivariable T-S fuzzy differential inclusion systems are proved to be ultimately bounded for the first time.

## 2. Problem Formulation and Preliminaries

**2.1. Problem Statement.** Consider the following T-S fuzzy nonlinear systems.

**Plant Rule:** IF  $\theta_{i,1}(t)$  is  $\mu_{i,1}$ ,  $\theta_{i,2}(t)$  is  $\mu_{i,2}$ ,  $\dots$  and  $\theta_{i,p}(t)$  is  $\mu_{i,p}$ , THEN

$$\dot{x}(t) = \begin{cases} f_i^1(t, x(t)) + A_i^1 x + B_i u, & \text{if } (t, x(t)) \in G_1, \\ f_i^2(t, x(t)) + A_i^2 x + \Delta A_i(t)x + B_i(u + d(t)), & \text{if } (t, x(t)) \in G_2, \\ f_i^3(t, x(t)) + A_i^3 x + \Delta A_i(t)x + B_i(\Lambda(t)u + \varepsilon_u(t) + d(t)), & \text{if } (t, x(t)) \in G_3, \end{cases} \quad (1)$$

where  $u(t) \in \mathbb{R}^m$  is the input signal of the system and  $x(t) \in \mathbb{R}^n$  are the system state vector.  $\theta(t) = [\theta_1(t), \theta_2(t), \dots, \theta_p(t)]$  are the premise variables.  $\mu_{i,1}, \mu_{i,2}, \dots, \mu_{i,p}$ ,  $i \in Y = \{1, 2, \dots, r\}$  are the fuzzy sets.  $r$  is the number of IF-THEN rules.  $G_k$ ,  $k = 1, 2, 3$  are the open connected sets satisfying that  $\cup_{k=1}^3 G_k = \mathbb{R}_+ \times \mathbb{R}^n$  and  $G_{k_1} \cap G_{k_2} = \emptyset$ ,  $\forall k_1, k_2 \in \{1, 2, 3\}, k_1 \neq k_2$ .  $S = \cup_{k=1}^3 \partial G_k$  is of Lebesgue measure zero, where  $\partial \Omega$  represents the boundary set of a set  $\Omega$ . For  $\forall i \in Y$ ,  $k = 1, 2, 3$ ,  $A_i^k \in \mathbb{R}^{n \times n}$ ,  $B_i \in \mathbb{R}^{n \times m}$ , and  $D \in \mathbb{R}^{n \times p_3}$  are all known matrices.  $f_i^k(t, x(t))$  is a vector of unknown nonlinear functions.  $\Delta A_i(t) \in \mathbb{R}^{n \times n}$  is an unknown matrix varying with the time.  $\Lambda(t)$  is a time-varying diagonal matrix of remanent actuator effectiveness and  $\varepsilon_u(t)$  is a vector of

actuator deviations when the actuator failure occurs.  $d(t)$  represents the external disturbance. The symbols used in the paper can be found in Table 1.

*Remark 1.* It should be highlighted that system model (1) can reflect the actual situation of many practical engineering systems and possesses important research significance. If  $(t, x(t))$  stays in  $G_1$ , the system is under a normal condition. When  $(t, x(t))$  enters  $G_2$  from  $G_1$ , the system uncertainties  $\Delta A_i(t)$  suddenly appear and external disturbances  $d(t)$  grow rapidly. Finally, if the system states travel into  $G_3$ , the actuator faults abruptly come out. Accompanied by  $(t, x(t))$  entering into different regions, the system matrix and the nonlinear function vector will change.

TABLE 1: The symbols used in the paper.

| Variable           | Implication                               |
|--------------------|---|
| $\theta(t)$        | Premise variables                         |
| $G_k$              | Open connected sets                       |
| $\partial G_k$     | Lebesgue measure zero                     |
| $\partial\Omega$   | Boundary set of a set $\Omega$            |
| $f_i^k(t, x(t))$   | Unknown nonlinear functions               |
| $A_i^k, B_i, D$    | Known matrices                            |
| $\Delta A_i(t)$    | Unknown matrix varying with time          |
| $\Lambda(t)$       | Matrix of remanent actuator effectiveness |
| $\varepsilon_u(t)$ | Vector of actuator deviations             |
| $d(t)$             | External disturbance                      |

It is supposed that  $\theta_i(t)$  never depends on  $u(t)$ ,  $\varepsilon(t)$ , and  $d(t)$ . Define

$$h_i(\theta(t)) = \frac{\prod_{j=1}^p \mu_{i,j}(\theta_j(t))}{\sum_{i=1}^r \prod_{j=1}^p \mu_{i,j}(\theta_j(t))}. \quad (2)$$

$\forall i \in \Upsilon, j = 1, 2, \dots, p, \mu_{i,j}(\theta_j(t))$  denote the degree of membership  $\theta_j(t)$  in  $\mu_{i,j}$ .  $h_i(\theta(t))$  is the fuzzy basis function. Clearly, for any  $i \in \Upsilon$ ,  $h_i(\theta(t)) \geq 0$  and  $\sum_{i=1}^r h_i(\theta(t)) = 1$ . Therefore, the dynamics of system (1) can be rewritten as follows:

$$\dot{x}(t) = g(t, x(t)),$$

$$g(t, x(t)) = \begin{cases} \sum_{i=1}^r h_i(\theta(t)) g_i^1(t, x(t)) & \text{if } (t, x(t)) \in G_1, \\ \sum_{i=1}^r h_i(\theta(t)) g_i^2(t, x(t)) & \text{if } (t, x(t)) \in G_2, \\ \sum_{i=1}^r h_i(\theta(t)) g_i^3(t, x(t)) & \text{if } (t, x(t)) \in G_3, \end{cases} \quad (3)$$

where

$$\begin{aligned} g_i^1(t, x(t)) &= f_i^1(t, x(t)) + A_i^1 x + B_i u, \\ g_i^2(t, x(t)) &= f_i^2(t, x(t)) + A_i^2 x + \Delta A_i(t) x + B_i(u + d(t)), \\ g_i^3(t, x(t)) &= f_i^3(t, x(t)) + A_i^3 x + \Delta A_i(t) x + B_i(\Lambda(t) u \\ &\quad + \varepsilon_u(t) + d(t)). \end{aligned} \quad (4)$$

Our control objective is to design an adaptive controller such that system states  $x(t)$  can converge into a desired compact set in the presence of the discontinuous multiple uncertainties and abruptly changing actuator faults.

To achieve the control objective, the following assumptions are necessary.

*Assumption 1.* For any  $i \in \Upsilon, k = 1, 2, 3, f_i^k(t, x(t))$  satisfy  $f_i^k(0, x(0)) = 0$  and

$$\|f_i^k(t, x_1(t)) - f_i^k(t, x_2(t))\| \leq \|U_i^k(x_1(t) - x_2(t))\|. \quad (5)$$

*Assumption 2.* For any  $i \in \Upsilon$ ,

$$\Delta A_i(t) = M_i \Xi_i(t) N_i, \quad (6)$$

where  $\Xi_i(t)$  are unknown time-varying matrices satisfying  $\Xi_i^T(t) \Xi_i(t) \leq I$  and  $M_i$  and  $N_i$  are known matrices.

*Assumption 3.* The discontinuous disturbances  $d_i(t)$  are Lebesgue measurable and locally bounded, i.e.,  $\|d_i(t)\| \leq D_i$ , where  $D_i$  is an unknown positive constant.

*Assumption 4.* It is supposed that  $\Lambda(t)$  and  $\varepsilon_u(t)$  are both Lebesgue measurable, and there exist lower and upper bounds for  $\Lambda(t)$  and  $\varepsilon_u(t)$ , respectively. In other words,  $\lambda_{\min}[\Lambda(t)] > \varepsilon_\Lambda > 0, \|\varepsilon_u(t)\| \leq D_u$ .  $\varepsilon_\Lambda$  and  $D_u$  are positive constants.

*2.2. Preliminaries.* Consider a nonlinear system:

$$\dot{x} = g(x(t)), \quad (7)$$

where  $x \in \mathbb{R}, g: \mathbb{R} \times [0, \infty) \rightarrow \mathbb{R}$  is Lebesgue measurable, essentially locally bounded and uniformly in  $t$ . Moreover, there exist discontinuities in  $g(x(t))$ .

*Definition 1.* A vector  $x(t)$  is called a Filippov solution of differential equation (7) over  $[0, \infty)$  if  $x(t)$  is absolutely continuous, and for almost everywhere  $t \in [0, \infty)$ ,

$$\dot{x} \in F[g](x(t)), \quad (8)$$

where  $\mathcal{F}[g](x(t))$  is a upper semicontinuous set-valued map defined by

$$F[g](x(t)) \stackrel{\Delta}{=} \bigcap_{\rho > 0} \bigcap_{\mu(N)=0} \bar{co} g\left(\frac{B(x(t), \rho)}{N}\right), \quad (9)$$

where  $\bigcap_{\mu(N)=0}$  denotes the intersection over sets of Lebesgue measure zero,  $\bar{co}$  represents the convex closure, and  $B(x(t), \rho) = \{z \in \mathbb{R}^n \mid \|x(t) - z\| < \rho\}$

*Definition 2* (see [45]). Given a locally Lipschitz function  $V(x(t))$ , the generalized gradient of  $V(x(t))$  is defined by

$$\partial V(x(t)) = \bar{co} \{\lim \nabla V(x^*(t)) \mid x^*(t) \rightarrow x(t), x^*(t) \notin \Omega_v\}, \quad (10)$$

where  $\Omega_v$  is the set of measure zero and  $\nabla V$  is not defined. Moreover, the set-valued Lie derivative of a  $V(x(t))$  is defined as

$$DV(x(t)) \stackrel{\Delta}{=} \bigcap_{\xi \in \partial V(x(t))} \xi^T F[g](x(t)). \quad (11)$$

*Definition 3.* In this paper, the generalized sections for variables, vectors, and matrices are defined. For  $a, b \in \mathbb{R}, a < b$ , define  $[b, a] = [a, b] = [\min\{a, b\}, \max\{a, b\}]$ . For  $a, b \in \mathbb{R}^n$ , define  $[a, b] = [b, a] = ([a_i, b_i])_n$ , where  $a_i$  is the  $i$ th component of  $a$ . For  $A, B \in \mathbb{R}^{m \times n}$ , define  $[A, B] = [B, A] = ([A_{ij}, B_{ij}])_{m \times n}$ .

**Lemma 1.** Consider nonlinear system (7). Suppose  $g(\cdot)$  is Lebesgue measurable and  $x \rightarrow g(x(t))$  is bounded. Let

$V: \mathbb{R} \times [0, \infty) \rightarrow \mathbb{R}$  be locally Lipschitz and regular such that

$$\begin{aligned} \alpha_1(x(t)) \leq V(x(t)) \leq \alpha_2(x(t)), \quad \forall t \geq 0, \\ DV(x(t)) \leq -\gamma_1 V(x(t)) + \gamma_2, \end{aligned} \quad (12)$$

where  $\alpha_1(\cdot)$  and  $\alpha_2(\cdot)$  are  $K_\infty$  functions,  $\gamma_1 > 0$  and  $\gamma_2 > 0$  are constants,  $x(t)$  is a Filippov solution of (7) with initial value  $x(t_0) \in \Omega_2 = \{x \in \mathbb{R}^n | \|x\| < r, \alpha_2(x) \leq \rho\}$ , and  $r > 0$  and  $\rho > 0$  are constants satisfying that  $\gamma_2/\gamma_1 < \rho < \min_{\|x(t)\|=r} \alpha_1(x(t))$ . Then,  $x(t)$  is bounded and converges to a compact set:

$$\Omega_f = \left\{ x \in \mathbb{R}^n | V(x) \leq \frac{\gamma_2}{\gamma_1} \right\}. \quad (13)$$

*Proof.* Define  $\Omega_V = \{x \in \mathbb{R}^n | \|x\| < r, V(x) \leq \rho\}$ . Since  $\alpha_2(x) \leq \rho \implies V(x) \leq \rho$ , it is obvious that  $\Omega_2 \subset \Omega_V$ . On the contrary, with the aid of  $V(x) \leq \rho \implies \alpha_1(x) \leq \rho$ , we can easily get that  $\Omega_V \subset \Omega_1$ . Moreover, considering  $\rho < \min_{\|x(t)\|=r} \alpha_1(x(t))$ , we know that  $\Omega_1 = \{x \in \mathbb{R}^n | \alpha_1(x) \leq \rho\}$  is an interior set of  $B_r = \{x \in \mathbb{R}^n | \|x\| < r\}$ . Hence,

$$\Omega_2 \subset \Omega_V \subset \Omega_1 \subset B_r. \quad (14)$$

If  $V(x(t)) \leq \gamma_2/\gamma_1$ , it is clear that  $x(t)$  stays in  $\Omega_f$ , which is  $x(t) \in \Omega_f \subset \Omega_V \subset B_r$ . On the contrary, for any  $x(t) \notin \Omega_f$ , we can obtain that  $V(x(t)) > \gamma_2/\gamma_1$  and  $\dot{V} < a.e. 0$ . Hence,  $V(x(t))$  is nonincreasing. Furthermore, for any  $x(t_0) \in \Omega_2$ , the solution of (7) stays in  $\Omega_V$ , which is  $x(t) \in \Omega_V \subset B_r$ . Therefore, it can be concluded that the solution of system (7) is bounded for all  $t \geq t_0$ . Furthermore, it follows from (12) that

$$\begin{aligned} \int_{t_0}^t [-\gamma_1 V(x(\tau)) + \gamma_2] d\tau \leq \int_{t_0}^t \dot{V}(x(\tau)) d\tau = V(x(t_0)) \\ - V(x(t)) \leq V(x(t_0)). \end{aligned} \quad (15)$$

Therefore,  $\int_{t_0}^t [-\gamma_1 V(x(\tau)) + \gamma_2] d\tau$  is bounded for all  $t \geq t_0$ . It should be noted that the existence of  $\int_{t_0}^t [-\gamma_1 V(x(\tau)) + \gamma_2] d\tau$  can be guaranteed because  $-\gamma_1 V(x(t)) + \gamma_2$  is locally Lipschitz and regular by definition. According to Barbalat's Lemma [46], it can be obtained that  $-\gamma_1 V(x(t)) + \gamma_2 \rightarrow 0$  as  $t \rightarrow \infty$ . Therefore, we know that  $x(t)$  will converge into  $\Omega_f$  finally. The proof is complete.  $\square$

**Lemma 2.** Given any constant  $\varepsilon > 0$  and any vector  $\xi \in \mathbb{R}^n$ , the following inequality holds:

$$\|\xi\| < \frac{\xi^T \xi}{\sqrt{\xi^T \xi + \varepsilon^2}} + \varepsilon. \quad (16)$$

*Proof.* Since  $\varepsilon > 0$  and  $\sqrt{\xi^T \xi + \varepsilon^2} > 0$ , it can be easily get that

$$\begin{aligned} \left[ \xi^T \xi + \varepsilon \sqrt{\xi^T \xi + \varepsilon^2} \right]^2 - \left[ \|\xi\| \sqrt{\xi^T \xi + \varepsilon^2} \right]^2 \\ = 2\varepsilon \xi^T \xi \sqrt{\xi^T \xi + \varepsilon^2} + \varepsilon^4 > 0. \end{aligned} \quad (17)$$

Hence, we know that

$$\|\xi\| \sqrt{\xi^T \xi + \varepsilon^2} < \xi^T \xi + \varepsilon \sqrt{\xi^T \xi + \varepsilon^2}. \quad (18)$$

By dividing  $\sqrt{\xi^T \xi + \varepsilon^2}$  in both sides of (18), inequality (16) can be obtained. The proof is completed.  $\square$

### 3. Main Results

**3.1. Control Design.** In the following text, the robust adaptive control problem for the concerned T-S fuzzy discontinuous nonlinear systems will be addressed.

In view of (3), according to Definition 1, we can get the following differential inclusion:

$$\begin{aligned} \dot{x} \in \sum_{i=1}^r h_i(\theta(t)) \{ F[f_i](t, x(t)) + F[A_i]x(t) \\ + F[\Delta \bar{A}_i(t)]x(t) + B_i F[\bar{\Lambda}(t)]u(t) + B_i F[\bar{d}(t)] \}, \end{aligned} \quad (19)$$

where

$$\begin{aligned} f_i &= f_i^k(t, x(t)) \quad \text{if } (t, x(t)) \in G_k, \quad k = 1, 2, 3, \\ A_i &= A_i^k \quad \text{if } (t, x(t)) \in G_k, \quad k = 1, 2, 3, \\ \Delta \bar{A}_i(t) &= \begin{cases} 0 & \text{if } (t, x(t)) \in G_1, \\ \Delta A_i(t) & \text{if } (t, x(t)) \in G_2 \cup G_3, \end{cases} \\ \bar{\Lambda}(t) &= \begin{cases} I & \text{if } (t, x(t)) \in G_1 \cup G_2, \\ \Lambda(t) & \text{if } (t, x(t)) \in G_3, \end{cases} \\ \bar{d}(t) &= \begin{cases} 0 & \text{if } (t, x(t)) \in G_1, \\ d(t) & \text{if } (t, x(t)) \in G_2, \\ \varepsilon_u(t) + d(t) & \text{if } (t, x(t)) \in G_3. \end{cases} \end{aligned} \quad (20)$$

Define

$D = \sup_{t \geq 0} \|\varepsilon_u(t) + d(t)\|$ ,  $\vartheta = 1/\inf_{t \geq 0} [\lambda_{\min}(\Lambda(t))]$ . Considering system (19), the control law is designed as follows.

**Controller Rule**  $R_{p,i}$ : IF  $\theta_1(t)$  is  $\mu_{i,1}$ ,  $\theta_2(t)$  is  $\mu_{i,2}$  and ... and  $\theta_p(t)$  is  $\mu_{i,p}$ , THEN

$$\begin{aligned} u(t) &= -\hat{\vartheta} \varphi_{\vartheta}(x(t), v(t)), \\ v(t) &= K_i x(t) - \hat{D} \varphi_D(x(t)), \end{aligned} \quad (21)$$

where  $K_i$  is the control gain matrix to be designed and  $\hat{\vartheta}$  and  $\hat{D}$  are the estimations of  $\vartheta$  and  $D$ , respectively. The continuous functions  $\varphi_{\vartheta}(x(t), v(t))$  and  $\varphi_D(x(t))$  are defined as

$$\begin{aligned}\varphi_{\vartheta}(x(t), v(t)) &= [\varphi_{\vartheta,1}(t), \varphi_{\vartheta,2}(t), \dots, \varphi_{\vartheta,m}(t)]^T, \\ \varphi_{\vartheta,l}(x(t), v(t)) &= \frac{v_l(t)[z_l(t)\widehat{\vartheta}v_l(t)]}{\sqrt{[z_l(t)\widehat{\vartheta}v_l(t)]^2 + \varepsilon_v^2}}, \quad l = 1, 2, \dots, m, \\ \varphi_D(x(t)) &= \frac{B^T P x(t)}{\sqrt{x^T(t) P B B^T P x(t) + \varepsilon_D^2}},\end{aligned}\tag{22}$$

where

$$B = \sum_{i=1}^r h_i(\theta(t)) B_i, \tag{23}$$

$P \in \mathbb{R}^{n \times n}$  is a symmetric positive matrix.  $\varepsilon_v, \varepsilon_D > 0$  are design constants.  $z_l(t)$  is the  $l$ th component of  $z(t) = [x^T(t) P \mathcal{B}]^T$ . The adaptive parameters are updated by

$$\begin{aligned}\dot{\widehat{D}} &= \eta_D x^T(t) P B \varphi_D(x(t)) - \eta_D \sigma_D \widehat{D}, \\ \dot{\widehat{\vartheta}} &= -\eta_{\vartheta} x^T(t) P B v(t) - \eta_{\vartheta} \sigma_{\vartheta} \widehat{\vartheta},\end{aligned}\tag{24}$$

where  $\eta_D, \eta_{\vartheta} > 0$  are the gains of adaptive laws and  $\sigma_D, \sigma_{\vartheta} > 0$  are design constants.

*Remark 2.* Note that it is improper to separately design the control laws for each  $G_k$ ,  $k = 1, 2, 3$ , and a universal controller has to be developed for all the three modes. In practical, the condition of multiple uncertainties suddenly changes or actuator failure abruptly occurs which cannot be determined easily. Moreover, the condition is concerned not only with the system time but also with the system states, which makes this problem more complex. Since the boundaries of  $G_k$  are unknown in practical, the separately design methods cannot be applied and a universal control law which is applicable for all the three modes is necessary. In this paper,  $G_k$ ,  $k = 1, 2, 3$ , are only used for analysis, but are not used in control design.

*Remark 3.* The considered system cannot be controlled by using the controllers of conventional switched systems possessing switching signals those only vary with time. The three modes of the concerned system are distinguished by using the conditions concerned with both the system time and the system states. In this paper, the switchings among the three modes are more intrinsic and are difficult to be dealt with. In fact, the proposed controller can degrade into an asynchronous control law if  $G_k$ ,  $k = 1, 2, 3$  is only concerned with time. For the considered  $G_k$ , the proposed controller can be thought of as a deep asynchronous controller.

**3.2. Stability Analysis.** Define  $\widetilde{\vartheta}(t) = \widehat{\vartheta}(t) - \vartheta(t)$ ,  $\widetilde{D}(t) = \widehat{D}(t) - D(t)$ . Combining (19)–(21) yields

$$\begin{aligned}\dot{x} \in & \sum_{i=1}^r h_i(\theta(t)) \sum_{j=1}^r h_j(\theta(t)) \{F[f_i](x(t)) + F[A_i + B_i K_j] \\ & \cdot (x(t)) + F[\Delta \bar{A}_i(t)](x(t)) + B_i F[\bar{d}(t)] - B_i \widehat{D} \varphi_D \\ & \cdot (x(t)) + B_i F[\bar{\Lambda}(t)](u(t)) - B_i v(t)\}.\end{aligned}\tag{25}$$

**Theorem 1.** Consider the closed-loop fuzzy differential inclusion (25) under Assumptions 1–4. The fuzzy controller is designed as (21) and the adaptive parameters are updated by (24). Given scalars  $\alpha, \lambda > 0$ . For any  $i, j \in Y$  and  $k \in \{1, 2, 3\}$ , if there exist matrices  $P, K$  such that

$$\begin{aligned}\Pi_{i,j}^k &< 0, \quad i = 1, 2, \dots, r, \\ \Pi_{i,j}^k + \Pi_{i,j}^k &< 0, \quad 1 \leq i < j \leq r,\end{aligned}\tag{26}$$

where

$$\Pi_{i,j}^k = \begin{bmatrix} \Pi_{i,j,11}^k & P \\ P & -\frac{1}{\lambda^2} I \end{bmatrix}, \tag{27}$$

$$\begin{aligned}\Pi_{i,j,11}^k &= P(A_i^k + B_i K_j) + (A_i^k + B_i K_j)^T P \\ &+ \frac{1}{\lambda^2} [U_i^k]^T U_i^k + P M_i M_i^T P + N_i^T N_i + \alpha P,\end{aligned}$$

then, for any initial conditions, the Filippov solution of closed-loop fuzzy differential inclusion (25) is bounded and converge to a compact set:

$$\Omega_f = \{x \in \mathbb{R}^n | V(x) \leq \varepsilon_f / \beta\}, \tag{28}$$

where

$$\varepsilon_f = \frac{\sigma_D D^2}{2} + \frac{\sigma_{\vartheta} \vartheta}{2} + D \varepsilon_D + \frac{m \varepsilon_v}{\vartheta}, \tag{29}$$

$$\beta = \min\{\alpha, \eta_D \sigma_D, \eta_{\vartheta}, \sigma_{\vartheta}\}.$$

*Proof.* Select a Lyapunov functional candidate as follows:

$$V(x(t)) = \frac{1}{2} x^T(t) P x(t) + \frac{1}{2 \eta_D} \widetilde{D}^2 + \frac{1}{2 \eta_{\vartheta}} \widetilde{\vartheta}^2, \tag{30}$$

where  $P$  is a positive definite matrix. According to Definition 2, the set-valued Lie derivative of a  $V(x(t))$  can be taken as

$$DV(x(t)) = \bigcap_{\xi \in \partial V(x(t))} \xi^T [\psi(x(t), \widehat{D}, v(t)), \dot{\widehat{D}}, \dot{\widehat{\vartheta}}]^T, \tag{31}$$

where

$$\begin{aligned}
\psi(x(t), \widehat{D}, v(t)) &= \sum_{i=1}^r h_i(\theta(t)) \sum_{j=1}^r h_j(\theta(t)) \{F[f_i](x(t)) \\
&\quad + F[A_i + B_i K_j]x(t) + F[\Delta \bar{A}_i(t)]x(t) \\
&\quad + F[\bar{d}(t)] - B_i \widehat{D} \varphi_D(x(t)) \\
&\quad + B_i F[\bar{\Lambda}(t)]u(t) - B_i v(t)\}.
\end{aligned} \tag{32}$$

By defining  $\pi_{f_i}, \pi_{A_{ij}}, \pi_{\Delta A_i}, \pi_{\Lambda}$ , and  $\pi_d$  such that

$$\begin{aligned}
\pi_{f_i} &\in \begin{cases} f_i^k & \text{if } (t, x(t)) \in G_k, \\ [f_i^{k_1} f_i^{k_2}] & \text{if } (t, x(t)) \in \partial G_{k_1} \cap \partial G_{k_2}, \end{cases} \\
\pi_{A_{ij}} &\in \begin{cases} A_i^k + B_i K_j & \text{if } (t, x(t)) \in G_k, \\ [A_i^{k_1} + B_i K_j, A_i^{k_2} + B_i K_j] & \text{if } (t, x(t)) \in \partial G_{k_1} \cap \partial G_{k_2}, \end{cases} \\
\pi_{\Delta A_i} &\in \begin{cases} 0 & \text{if } (t, x(t)) \in G_1, \\ \Delta A_i & \text{if } (t, x(t)) \in G_2 \cup G_3, \\ [0, \Delta A_i] & \text{if } (t, x(t)) \in \partial G_1 \cap \partial [G_2 \cup G_3], \end{cases} \\
\pi_{\Lambda} &\in \begin{cases} I & \text{if } (t, x(t)) \in G_1 \cup G_2, \\ \Lambda(t) & \text{if } (t, x(t)) \in G_3, \\ [\Lambda(t), I] & \text{if } (t, x(t)) \in \partial [G_1 \cup G_2] \cap \partial G_3, \end{cases} \\
\pi_d &\in \begin{cases} 0 & \text{if } (t, x(t)) \in G_1, \\ d & \text{if } (t, x(t)) \in G_2, \\ \varepsilon_u + d & \text{if } (t, x(t)) \in G_3, \\ [0, d] & \text{if } (t, x(t)) \in \partial G_1 \cap \partial G_2, \\ [d, \varepsilon_u + d] & \text{if } (t, x(t)) \in \partial G_2 \cap \partial G_3, \\ [0, \varepsilon_u + d] & \text{if } (t, x(t)) \in \partial G_1 \cap \partial G_3, \end{cases}
\end{aligned} \tag{33}$$

we can rewrite (30) as

$$DV(x(t)) = D_1 V(x(t)) + D_2 V(x(t)), \tag{34}$$

where

$$D_1 V(x(t)) = \sum_{i=1}^r h_i(\theta(t)) \sum_{j=1}^r h_j(\theta(t)) \left\{ x^T(t) P \pi_{f_i} + x^T(t) P \pi_{A_{ij}} x(t) + x^T(t) P \pi_{\Delta A_i} x(t) \right\}, \tag{35}$$

$$D_2 V(x(t)) = \sum_{i=1}^r h_i(\theta(t)) \left\{ x^T(t) P B_i \pi_d - x^T(t) P B_i \widehat{D} \varphi_D(x(t)) + x^T(t) P B_i \pi_{\Lambda} u(t) - x^T(t) P B_i v(t) \right\} + \frac{1}{\eta_D} \dot{\widehat{D}} + \frac{1}{\eta_{\theta}} \dot{\widehat{\theta}}. \tag{36}$$

Firstly, the analysis of  $\mathcal{D}_1 V(x(t))$  are given. Since  $P$  is nonsingular, it can be proved that  $P \pi_{\Delta A_i} \in [0, P \Delta A_i]$  holds for all  $(t, x(t))$ . Hence, based on Assumption 2, it can be known that, for any  $(t, x(t))$ ,  $x^T(t) P \pi_{\Delta A_i} x(t) \in [0, x^T(t) P \Delta A_i x(t)]$  and

$$x^T(t) P \pi_{\Delta A_i} x(t) \leq \frac{1}{2} x^T(t) P M_i M_i^T P x(t) + \frac{1}{2} x^T(t) N_i^T N_i x(t). \tag{37}$$

For  $(t, x(t)) \in G_k, k = 1, 2, 3$ , it follows from Assumption 1 that

$$\begin{aligned} \pi_{f_i}^T \pi_{f_i} &\leq x^T(t) [U_i^k]^T U_i^k x(t), \\ P\pi_{A_{ij}} &= \frac{1}{2} \left[ P(A_i^k + B_i K_j) + (A_i^k + B_i K_j)^T P \right]. \end{aligned} \quad (38)$$

By combining (35), (37), and (38), we know that, for  $(t, x(t)) \in G_k$ ,  $k = 1, 2, 3$ , the following inequality holds:

$$\begin{aligned} \Phi_{i,j}^k &= \begin{bmatrix} \Phi_{i,j,11}^k & P \\ P & -\frac{1}{\lambda^2} \end{bmatrix}, \\ \Phi_{i,j,11}^k &= P(A_i^k + B_i K_j) + (A_i^k + B_i K_j)^T P + \frac{1}{\lambda^2} [U_i^k]^T U_i^k \\ &\quad + PM_i M_i^T P + N_i^T N_i. \end{aligned} \quad (40)$$

By using (26), it can be checked that, for  $(t, x(t)) \in G_k$ ,  $k = 1, 2, 3$ ,

$$D_1 V(x(t)) \leq -\frac{\alpha}{2} x^T(t) P x(t). \quad (41)$$

where

On the contrary, for  $(t, x(t)) \in \partial G_{k_1} \cap \partial G_{k_2}$ ,  $k_1, k_2 \in \{1, 2, 3\}$ , it can be proved that

$$\begin{aligned} x^T(t) P \pi_{A_{ij}} x(t) &\in [x^T(t) P (A_i^{k_1} + B_i K_j) x(t), x^T(t) P (A_i^{k_2} + B_i K_j) x(t)], \\ \pi_{f_i}^T \pi_{f_i} &\in [f_i^{k_1}]^T f_i^{k_1}, [f_i^{k_2}]^T f_i^{k_2} \in [x^T(t) [U_i^{k_1}]^T U_i^{k_1} x(t), x^T(t) [U_i^{k_2}]^T U_i^{k_2} x(t)]. \end{aligned} \quad (42)$$

Accordingly, the following inequalities can be obtained:

$$\begin{aligned} x^T(t) P \pi_{A_{ij}} x(t) &\leq \max_{k \in \{1,2,3\}} x^T(t) P (A_i^k + B_i K_j) x(t), \\ \pi_{f_i}^T \pi_{f_i} &\leq \max_{k \in \{1,2,3\}} x^T(t) [U_i^k]^T U_i^k x(t). \end{aligned} \quad (43)$$

By combining (35), (37), and (43), we know that, for  $(t, x(t)) \in \partial G_{k_1} \cap \partial G_{k_2}$ ,  $k_1, k_2 \in \{1, 2, 3\}$ ,

$$D_1 V(x(t)) \leq \frac{1}{2} \sum_{i=1}^r h_i(\theta(t)) \sum_{j=1}^r h_j(\theta(t)) \begin{bmatrix} x(t) \\ \pi_{f_i} \end{bmatrix}^T \Psi_{i,j}^k \begin{bmatrix} x(t) \\ \pi_{f_i} \end{bmatrix}, \quad (44)$$

where

$$\begin{aligned} \Psi_{i,j}^k &= \begin{bmatrix} \Psi_{i,j,11}^k & P \\ P & -\frac{1}{\lambda^2} \end{bmatrix}, \\ \Psi_{i,j,11}^k &= \max_{k \in \{1,2,3\}} \left\{ P(A_i^k + B_i K_j) + (A_i^k + B_i K_j)^T P \right. \\ &\quad \left. + \frac{1}{\lambda^2} [U_i^k]^T U_i^k \right\} + PM_i M_i^T P + N_i^T N_i. \end{aligned} \quad (45)$$

Since (26) holds for any  $k \in \{1, 2, 3\}$ , we know that, for  $(t, x(t)) \in \partial G_{k_1} \cap \partial G_{k_2}$ ,  $k_1, k_2 \in \{1, 2, 3\}$ ,  $\mathcal{D}_1 V(x(t)) \leq -\alpha/2 x^T(t) P x(t)$  also holds. Then, by considering (41), it can be concluded that, for any  $(t, x(t))$ ,

$$D_1 V(x(t)) \leq -\frac{\alpha}{2} x^T(t) P x(t). \quad (46)$$

Next texts provide the analysis of  $\mathcal{D}_2 V(x(t))$ . From (33), we know that, for  $(t, x(t))$ ,

$$\begin{aligned} \pi_d &\in [0, \varepsilon_u + d], \\ \pi_{\Lambda_i} &\in [\Lambda_i(t), 1], \end{aligned} \quad (47)$$

where  $\pi_{\Lambda_i}$  and  $\Lambda_i(t)$  represent the  $i$ th component of  $\pi_\Lambda$  and  $\Lambda(t)$  on the diagonal line, respectively. Hence, it can be obtained that, for any  $(t, x(t))$ ,

$$\begin{aligned} \sum_{i=1}^r h_i(\theta(t)) x^T(t) P B_i \pi_d &\in [0, x^T(t) P B (\varepsilon_u + d)], \\ \sum_{i=1}^r h_i(\theta(t)) x^T(t) P B_i \pi_{\Lambda_i} u(t) &\in [x^T(t) P B \Lambda(t) u(t), x^T(t) P B u(t)]. \end{aligned} \quad (48)$$

From Lemma 2, it is easy to know that

$$\begin{aligned}
& \sum_{i=1}^r h_i(\theta(t)) \{x^T(t)PB_i\pi_d - x^T(t)PB_i\widehat{D}\varphi_D(x(t))\} \\
& \leq D\|x^T(t)PB\| - x^T(t)PB\widehat{D}\varphi_D(x(t)) \\
& \leq D \frac{x^T(t)PB[x^T(t)PB]^T}{\sqrt{x^T(t)PB[x^T(t)PB]^T + \varepsilon_D^2}} - x^T(t)PB\widehat{D}\varphi_D(x(t)) + D\varepsilon_D \\
& \leq -\widehat{D}x^T(t)PB\varphi_D(x(t)) + D\varepsilon_D.
\end{aligned} \tag{49}$$

Meanwhile, simple computation shows that

$$\begin{aligned}
& \sum_{i=1}^r h_i(\theta(t)) \{x^T(t)PB_i\pi_{\Lambda}u(t) - x^T(t)PB_iv(t)\} \\
& = -\widehat{\vartheta} \sum_{l=1}^m z_l\pi_{\Lambda,l}\varphi_{\vartheta,l}(x(t), v(t)) - x^T(t)PBv(t).
\end{aligned} \tag{50}$$

Since  $0 < 1/\vartheta \leq \pi_{\Lambda,i} \in [\Lambda_i(t), 1]$ , we can get that

$$\begin{aligned}
& -\widehat{\vartheta}z_l\pi_{\Lambda,l}\varphi_{\vartheta,l}(x(t), v(t)) \\
& = \frac{z_l\pi_{\Lambda,l}\widehat{\vartheta}v_l(t)[z_l(t)\widehat{\vartheta}v_l(t)]}{\sqrt{[z_l(t)\widehat{\vartheta}v_l(t)]^2 + \varepsilon_v^2}} \\
& \leq -\frac{1}{\widehat{\vartheta}} \frac{[z_l(t)\widehat{\vartheta}v_l(t)]^2}{\sqrt{[z_l(t)\widehat{\vartheta}v_l(t)]^2 + \varepsilon_v^2}}.
\end{aligned} \tag{51}$$

Hence, it follows from Lemma 2 that

$$\begin{aligned}
& -\widehat{\vartheta} \sum_{l=1}^m z_l\pi_{\Lambda,l}\varphi_{\vartheta,l}(x(t), v(t)) - x^T(t)PBv(t) \\
& \leq \sum_{l=1}^m \left[ -\frac{1}{\widehat{\vartheta}} \frac{[z_l(t)\widehat{\vartheta}v_l(t)]^2}{\sqrt{[z_l(t)\widehat{\vartheta}v_l(t)]^2 + \varepsilon_v^2}} - z_l(t)v_l(t) \right] \\
& \leq \sum_{l=1}^m \left[ \frac{1}{\widehat{\vartheta}} \left( -\|z_l(t)\widehat{\vartheta}v_l(t)\| + \varepsilon_v \right) - z_l(t)v_l(t) \right] \\
& \leq \sum_{l=1}^m \left[ \frac{\widehat{\vartheta}}{\widehat{\vartheta}^2} z_l(t)v_l(t) - z_l(t)v_l(t) + \frac{\varepsilon_v}{\widehat{\vartheta}} \right] \\
& \leq \frac{\widehat{\vartheta}}{\widehat{\vartheta}^2} x^T(t)PBv(t) + \frac{m\varepsilon_v}{\widehat{\vartheta}}.
\end{aligned} \tag{52}$$

By combining (36) and (49)–(52), it can be obtained that

$$\begin{aligned}
D_2V(x(t)) & \leq -\widehat{D}x^T(t)PB\varphi_D(x(t)) + \frac{\widehat{\vartheta}}{\vartheta}x^T(t)PBv(t) \\
& \quad + \frac{1}{\eta_D}\widehat{D}\dot{\widehat{D}} + \frac{1}{\eta_D\vartheta}\widehat{\vartheta}\dot{\widehat{\vartheta}} + D\varepsilon_D + \frac{m\varepsilon_v}{\vartheta},
\end{aligned} \tag{53}$$

where  $m$  is the dimension of the system input signal  $u(t)$ . Substituting (24) into (53) yields

$$D_2V(x(t)) \leq -\sigma_D\widehat{D}\widehat{D} - \frac{\sigma_D\widehat{\vartheta}\widehat{\vartheta}}{\vartheta} + D\varepsilon_D + \frac{m\varepsilon_v}{\vartheta}. \tag{54}$$

By using the following inequalities,

$$\begin{aligned}
2\widehat{D}\widehat{D} & \leq -\widehat{D}^2 + D^2, \\
\widehat{\vartheta}\widehat{\vartheta} & \leq -\widehat{\vartheta}^2 + \vartheta^2.
\end{aligned} \tag{55}$$

We know that

$$D_2V(x(t)) \leq -\frac{\sigma_D}{2}\widehat{D}^2 - \frac{\sigma_D\widehat{\vartheta}^2}{2\vartheta} + \varepsilon_f. \tag{56}$$

By combining (34), (46), and (56), we know that

$$DV(x(t)) \leq -\frac{\alpha}{2}x^T(t)Px(t) - \frac{\sigma_D}{2}\widehat{D}^2 - \frac{\sigma_D\widehat{\vartheta}^2}{2\vartheta} + \varepsilon_f, \tag{57}$$

which means

$$DV(x(t)) \leq -\beta V(x(t)) + \varepsilon_f, \tag{58}$$

where  $\beta$  and  $\varepsilon_f$  are defined in (29). According to Lemma 1, it can be proved that the Filippov solution of closed-loop fuzzy differential inclusion (25) is bounded and converge to  $\Omega_f$ . The proof is complete.  $\square$

*Remark 4.* It should be noted that the final compact set  $\Omega_f$  can be an arbitrarily small neighborhood of the origin by adjusting the control gains and adaptive parameters. Moreover, in most of the adaptive control results, the ultimate boundness of the closed-loop control system is finally ensured. However, for the differential inclusion systems, the criteria of ultimately boundness have never been provided. Hence, it can be concluded that Lemma 1 lays the mathematical fundamentals for the adaptive control of differential inclusion systems.

Next, we will provide the computation method of control gain  $K$  and matrix  $P$  which is necessary in adaptive laws.

**Theorem 2.** Consider the closed-loop fuzzy differential inclusion (25) under Assumptions 1–4. The fuzzy controller is designed as (20), and the adaptive parameters are updated by (24). Given scalars  $\alpha, \lambda > 0$ . For any  $i, j \in Y$  and  $k \in \{1, 2, 3\}$ , if there exist matrices  $Q, R_j$  such that

$$\begin{aligned}
\Gamma_{i,j}^k & < 0, \quad i = 1, 2, \dots, r, \\
\Gamma_{i,j}^k + \Gamma_{i,j}^k & < 0, \quad 1 \leq i < j \leq r,
\end{aligned} \tag{59}$$

where

$$\Gamma_{i,j}^k = \begin{bmatrix} \Gamma_{i,j,11}^k & Q[U_i^k]^T & QN_i^T & I \\ * & -\lambda^2 I & 0 & 0 \\ * & * & -I & 0 \\ * & * & * & \frac{1}{\lambda^2} I \end{bmatrix}, \quad (60)$$

$$\Gamma_{i,j,11}^k = A_i^k Q + Q A_i^k + B_i R_j + R_j^T B_i^T + \alpha Q + M_i M_i^T,$$

then, for any initial conditions, the Filippov solution of closed-loop fuzzy differential inclusion (25) is bounded and converges to the compact set  $\Omega_f$ . Moreover, if condition (59) is feasible, it can be obtained that

$$\begin{aligned} K_j &= R_j Q^{-1}, \\ P &= Q^{-1}. \end{aligned} \quad (61)$$

*Proof.* Define  $Q = P^{-1}$  and  $R_j = K_j P^{-1}$ . By performing a congruence transformation to with  $\Pi_{i,j}^k$ , we can get the following matrix:

$$\widehat{\Pi}_{i,j}^k = \begin{bmatrix} \widehat{\Pi}_{i,j,11}^k & I \\ I & -\frac{1}{\lambda^2} I \end{bmatrix}, \quad (62)$$

where

$$\begin{aligned} \widehat{\Pi}_{i,j,11}^k &= A_i^k Q + Q A_i^k + B_i R_j + R_j^T B_i^T + \alpha Q + \frac{1}{\lambda^2} Q [U_i^k]^T U_i^k Q \\ &+ M_i M_i^T + Q N_i^T N_i Q. \end{aligned} \quad (63)$$

By performing a Schur complement transformation to (61),  $\Gamma_{i,j}^k$  can be obtained. Since

$$\Gamma_{i,j}^k < 0 \Leftrightarrow \widehat{\Pi}_{i,j}^k < 0 \Leftrightarrow \Pi_{i,j}^k < 0, \quad (64)$$

we know that (26) is satisfied by using (58). According to Theorem 1, the boundedness and convergence of the Filippov solution can be guaranteed. The proof is complete.  $\square$

*Remark 5.* System who involves state-based switching usually has more complex dynamic behaviors which motivates various useful applications, while the construction of rigorous stability for these systems is challenging. Different to classic analysis methods in switching systems such as average dwell time (ADT), differential-inclusion-based approaches provide feasible alternative solutions to the stability analysis of stated-based switching systems. Instead of

analyzing the value of the vector field at individual points, differential-inclusion-based methods focus on the behavior of vector field at the neighborhood of each point. This idea is at the core of constructing continuous Filippov solution which is a general solution to the original differential equations, where the discontinuities is covered by set-valued mapping which is a convex combination of vector field around them. As a result, rigorous stability result can be established for discontinuous vector field as long as the Lebesgue measure of the discontinuities is zero. From the illustration above, it is clear that, for state-based switching systems, the superiority of utilizing differential inclusion is significant.

#### 4. Simulation Study

In this section, we will present a numerical example with two fuzzy subsystems to demonstrate the effectiveness of the proposed control method. The switching regions  $G_i$  of system (1) are defined as

$$\begin{aligned} G_1 &= \{x \in \mathbb{R}^2 \mid \|x\| \geq n1\}, \\ G_2 &= \{x \in \mathbb{R}^2 \mid 0.5t \leq n\|x\|q < h1\}, \\ G_3 &= \{x \in \mathbb{R}^2 \mid \|x\| < n0.5\}. \end{aligned} \quad (65)$$

The system-related matrices are given as follows:

$$\begin{aligned} A_1^1 &= \begin{bmatrix} -2.7 & 1.5 \\ 0.5 & 1.2 \end{bmatrix}, \\ A_2^1 &= \begin{bmatrix} -2.1 & 0.6 \\ 0.2 & 1.8 \end{bmatrix}, \\ A_1^2 &= \begin{bmatrix} -1.9 & 2.3 \\ 1.5 & 2.8 \end{bmatrix}, \\ A_2^2 &= \begin{bmatrix} -3.6 & 2.7 \\ 0.1 & 1.5 \end{bmatrix}, \\ A_1^3 &= \begin{bmatrix} -1.2 & 0.7 \\ 2.1 & 0.5 \end{bmatrix}, \\ A_2^3 &= \begin{bmatrix} -2.8 & 1.7 \\ 3.5 & 1.9 \end{bmatrix}, \\ B_1 &= \begin{bmatrix} -1.9 \\ 3.6 \end{bmatrix}, \\ B_2 &= \begin{bmatrix} -1.5 \\ 2.3 \end{bmatrix}. \end{aligned} \quad (66)$$

The unknown nonlinear functions are set as

FIGURE 1: The trajectories of the system state  $x_1(t)$  under NN-AC, DOBC, and proposed method.

$$\begin{aligned}
 f_1^1 &= \begin{bmatrix} 0.016 \cos(2x_1x_2) \\ 0.022 \sin(x_1 + x_2) \end{bmatrix}, \\
 f_2^1 &= \begin{bmatrix} 0.018 \sin(x_1^2) \\ 0.02 \cos(x_2^2) \end{bmatrix}, \\
 f_1^2 &= \begin{bmatrix} 0.06 \sin(x_1)\cos(x_2) \\ 0.025 \sin(\|x_1\|) \end{bmatrix}, \\
 f_2^2 &= \begin{bmatrix} 0.028 \cos(x_1)\cos(x_2) \\ 0.025 \cos(\|x_2\|) \end{bmatrix}, \\
 f_1^3 &= \begin{bmatrix} 0.024 \sin(x_1)\cos(x_2) \\ 0.025 \cos(\|x_1\| + \|x_2\|) \end{bmatrix}, \\
 f_2^3 &= \begin{bmatrix} 0.01 \sin(x_1x_2) \\ 0.05 \cos(\|x_1\|x_2) \end{bmatrix}.
 \end{aligned} \tag{67}$$

$$\begin{aligned}
 M_1 &= \begin{bmatrix} 0.012 & 0 \\ 0 & 0.08 \end{bmatrix}, \\
 M_2 &= \begin{bmatrix} 0.015 & 0 \\ 0 & 0.06 \end{bmatrix}, \\
 N_1 &= \begin{bmatrix} 0.069 & 0 \\ 0 & 0.087 \end{bmatrix}, \\
 N_2 &= \begin{bmatrix} 0.055 & 0 \\ 0 & 0.072 \end{bmatrix}, \\
 U_1^1 = U_1^2 = U_1^3 &= \begin{bmatrix} 0.25 & 0 \\ 0 & 0.25 \end{bmatrix}, \\
 U_2^1 = U_2^2 = U_2^3 &= \begin{bmatrix} 0.3 & 0 \\ 0 & 0.3 \end{bmatrix}.
 \end{aligned} \tag{68}$$

By letting  $\alpha = 2$  and  $\lambda = 1$ , we can solve (59) and obtain that

$$\begin{aligned}
 P &= \begin{bmatrix} 4.0590 & 6.9122 \\ 6.9122 & 14.0675 \end{bmatrix}, \\
 K_1 &= \begin{bmatrix} -5.6326 & -10.8441 \end{bmatrix}, \\
 K_2 &= \begin{bmatrix} -9.0548 & -17.6541 \end{bmatrix}.
 \end{aligned} \tag{69}$$

To compute the control gains, we take

FIGURE 2: The trajectories of the system state  $x_2(t)$  under NN-AC, DOBC, and proposed method.

FIGURE 3: The trajectories of the adaptive parameters under the proposed method.

TABLE 2: The parameters of the three simulation cases.

|        | Switching regions  | Fault parameters                            | Disturbance parameters                 |
|--------|--|---|--|
| Case 1 | $G_1 = \{x(t) \in \mathbb{R}^2 \mid \ x\  \geq 1\}$<br>$G_2 = \{x(t) \in \mathbb{R}^2 \mid 0.5 \leq \ x\  \leq 1\}$<br>$G_3 = \{x(t) \in \mathbb{R}^2 \mid \ x\  \leq 0.5\}$     | $\Lambda(t) = 0.7 + 0.1 \sin(t/2 + t\pi/3)$ | $d(t) = 20 \sin(2\pi t - \pi/6) + 0.5$ |
| Case 2 | $G_1 = \{x(t) \in \mathbb{R}^2 \mid \ x\  \geq 1.2\}$<br>$G_2 = \{x(t) \in \mathbb{R}^2 \mid 0.5 \leq \ x\  \leq 1.2\}$<br>$G_3 = \{x(t) \in \mathbb{R}^2 \mid \ x\  \leq 0.5\}$ | $\Lambda(t) = 0.5 + 0.1 \sin(t/2 + t\pi/3)$ | $d(t) = 30 \sin(2\pi t - \pi/6) + 0.5$ |
| Case 3 | $G_1 = \{x(t) \in \mathbb{R}^2 \mid \ x\  \geq 1.2\}$<br>$G_2 = \{x(t) \in \mathbb{R}^2 \mid 0.8 \leq \ x\  \leq 1.2\}$<br>$G_3 = \{x(t) \in \mathbb{R}^2 \mid \ x\  \leq 0.8\}$ | $\Lambda(t) = 0.3 + 0.1 \sin(t/2 + t\pi/3)$ | $d(t) = 50 \sin(2\pi t - \pi/6) + 0.5$ |

FIGURE 4: The trajectories of the system state  $x_1(t)$  of the proposed method under three cases.

In the simulation, the initial values of the system states and adaptive parameters are set as  $x_1(0) = 1.2$ ,  $x_2(0) = -0.5$ ,  $\hat{D}(0) = 0$ , and  $\hat{\vartheta}(0) = 1$ . The corresponding adaptive gains and constants are selected as  $\eta_D = \eta_{\vartheta} = 5$ ,  $\sigma_D = \sigma_{\vartheta} = 2$ , and  $\varepsilon_D = \varepsilon_{\nu} = 0.001$ . The disturbance is taken as

$$d(t) = 20 \sin\left(2\pi t - \frac{\pi}{6}\right) + 0.5. \quad (70)$$

The actuator-related settings are

$$\Lambda(t) = 0.7 + 0.1 \sin\left(\frac{t}{2} + \frac{\pi}{3}\right); \varepsilon_u = 0.001. \quad (71)$$

Moreover, to reveal the advantages of the proposed method, the advanced neural network based adaptive control method (NN-AC) and the disturbance observer based control method (DOBC) have been employed in the simulation experiments. The parameters of the NN-AC method are set as  $\eta_{\Theta} = 5$  and  $\sigma_{\Theta} = 2$ . The disturbance observation gain of the DOBC method is selected as  $L = [1.2, 0; 0, 1.2]$ . The control gains of the NN-AC and DOBC methods are set as the same as the proposed method.

The simulation results are provided in Figures 1–3. It is obvious that the proposed method can force both  $x_1(t)$  and  $x_2(t)$  to converge towards zero under switching between  $G_i$

FIGURE 5: The trajectories of the system state  $x_2(t)$  of the proposed method under three cases.

FIGURE 6: The trajectories of the system state  $\hat{D}(t)$  of the proposed method under three cases.

FIGURE 7: The trajectories of the system state  $\hat{\vartheta}(t)$  of the proposed method under three cases.

and finally stay inside a small region near the equilibrium point. Differently, the NN-AC and the DOBC method will cause violent shock, demonstrating that these two methods may possess worse adaptability for the state-dependent switching regions compared with the proposed method. Moreover, it can be found that, by using the proposed method, the adaptive parameters  $\hat{D}(t)$  and  $\hat{\vartheta}(t)$  also converge to a stable value after the initial transient. It can be concluded that, using the proposed method, the closed-loop stability can be guaranteed even under the worst situations (where disturbances and actuator faults both occur). The advantages of the proposed method can be revealed therefore.

Furthermore, to show the robustness of the proposed method, three cases are considered. The parameters of the three cases are given by Table 2.

Under the three cases, the simulation results using the proposed method are given in Figures 4–7. It can be found that although the switching regions, the fault parameters, and the disturbance parameters have changed, the proposed method can still achieve desired control performance.

## 5. Conclusions

A novel robust adaptive controller is given in this paper for solving one of the motivating problems in nonlinear fuzzy systems, that is, to appropriately describe the behavior of the system and to guarantee the stability of the system under discontinuous multiple uncertainties and state-based switching. The proposed differential-inclusion-based

method provides a constructive procedure for the controller design and analysis of a class of heterogeneous T-S fuzzy nonlinear systems with suddenly changing structural parameters and abrupt actuator failures where switching of system dynamics is related with both time and system states. The stability of the resulting closed-loop differential inclusion system is rigorously discussed by virtue of introducing a new fundamental stability lemma for adaptive discontinuous systems, and our results are validated by carefully designed simulations. It should be noted that our control scheme can be easily extended to other T-S fuzzy nonlinear systems with discontinuities and state-based switching, which may provide useful insights for further future research.

Based on the event study method, this paper conducts the analysis on the short-term performance of 1302 major mergers and acquisitions (M&A) in China from 2006 to 2019 and takes the cumulative abnormal return (CAR) as the measurement index. After comparing the five abnormal return (AR) calculation models, it is found that the commonly used market model method and the market adjustment method have statistical defects while the Elman feedback neural network model is capable of good nonlinear prediction ability. The study shows that M&A can create considerable short-term performance for Chinese listed company shareholders. The CAR in window period reached 14.45% with a downward trend, which is the win-win result achieved through the cooperation between multiple parties and individuals driven by their respective rights and interests in the current macro-microeconomic environment in China.

## 1. Introduction

Before 2005, the problem of tradable shares and nontradable shares existed in China's stock market. The controlling shareholders who held nontradable shares were not concerned about the rise and fall of stock price; therefore, the interests of shareholders holding tradable shares cannot be guaranteed. The share-trading reform, launched in 2005 and completed in 2006, made nontradable shares traded, and all shareholders pay more attention to stock prices. 2006 is known as "the year of M&A" [1] because listed companies began to improve the stock price and trading activity through M&A activities.

In 2008, China Securities Regulatory Commission promulgated "Administrative Measures for M&A of Listed Companies," which marked the coming of the era of loose policies of M&A. Since then, a series of policies has been put forward to make the M&A activities more market-oriented.

In the following 10 years, M&A activities of listed companies play an important role in different stages of China's economic development, structural adjustment, transformation, and upgrading. However, the volume and amount of M&A transactions of listed companies increased substantially and attracted the investors to pursue and hype. In 2019, China Securities Regulatory Commission revised "Administrative Measures for M&A of Listed Companies" to strengthen the supervision, prevent arbitrage through M&A, and promote M&A rationality. According to the statistics of Wind, the average amount and number of M&A transactions in China in 2006–2019 were 4.42 trillion Yuan and 5,182, and the number of M&A transactions in the past 3 years exceeded 15,000. M&A has been one of the most important ways of resource allocation for a long time in China's capital market [2].

Since the completion of the share-trading reform in 2006, the discussion about whether M&A can produce

performance and whether it can be used for market value management have never stopped.

## 2. Literature Review

### 2.1. M&A Short-Term Performance Literature

**2.1.1. Synergy Effects Theory.** The synergy effects theory was first proposed by Hermann Haken in 1971 and systematically elaborated in 1976. Since then, it has been applied to the study of M&A motivation theory. According to the efficiency theory proposed by Jensen and Ruback, the important motivation of M&A is that the acquirer and acquiree hope to achieve synergy effects through integration [3], including management, operation, finance, diversification, and other types of synergy [4–7]. M&A gains created by synergy effects will be redistributed among stakeholders, most of which will be transferred to shareholders of both parties during the M&A implementation process [8, 9]. In academic research, the concept of M&A performance is proposed for measuring the synergy effect, and it is divided into long-term performance based on financial index method and short-term performance in view of the event study method [10, 11]. The research object of this paper is the short-term M&A performance of the acquirer. Namely, the CAR on stocks of listed companies in the window period before and after the announcement date is applied as a measure [12].

**2.1.2. Research on Short-Term Performance of Foreign M&A.** The empirical study on the short-term performance of M&A in foreign academics started early (Table 1), and there is no consensus on whether M&A can create short-term performance. Some scholars believe that M&A brings significant positive or negative short-term gains to the acquirer, while others hold that M&A are uncontrollable, which is impossible to bring definite short-term performance to the acquirer.

This paper argues that the inability to reach a consensus conclusion is related to five waves of M&A experienced by Western countries represented by the United States. Scholars have sufficient M&A samples, and the differences in sample scope and time span lead to inconsistent conclusions.

**2.1.3. Research on Short-Term Performance of Chinese M&A.** The empirical research on short-term performance of Chinese M&A started late (Table 2). Due to the speculation and pursue of M&A related stocks by China's stock market for many years, most of the research conclusions focused on the positive short-term performance, and a small number of studies draw different conclusions.

The common feature of short-term M&A performance research in China is that the sample size is small, the coverage period is short, so the sample representativeness and conclusion accuracy are affected, which is related to the objective fact that China's M&A market develops late and the sample of M&A events is small. Zhang empirically analyzed 1,326 M&A events in 1993–2002 based on event study method and concluded that the M&A had a negative

impact on the acquirer with  $-16.76\%$  CAR during the window period. This literature is rare M&A performance research based on larger sample sizes. However, all the event samples occurred before 2005's share-trading reform, and most of them have no exact M&A announcement date. Chen et al. (2017) found that the share-trading reform had a positive impact on China's M&A performance [34], because the improvement of stock liquidity enhanced the reaction speed of stock prices to major decisions of company managers [35]. Therefore, it is necessary to make further researches on the short-term performance of China's M&A after share-trading reform.

### 2.2. Literatures of M&A Short-Term Performance Measurement

**2.2.1. Event Study Method.** Bruner proposed four measurement methods of M&A performance as follows: the event study method, the financial index method, the case-study method, and the management personnel interview method. Among those, the event study method is one of the most important methods for scholars to study M&A performance. The event study method is a general term for a series of methods for measuring the degree of influence of an event on the price of a particular financial asset [36] and has been widely accepted by scholars after improved by Ball and Brown [37] and Fama et al. in the study of market effectiveness [38].

The calculation of the impact of M&A events on stock prices by abnormal return (AR) has become the mainstream method for M&A performance research at home and abroad [39]. AR refers to the return difference between the stock's actual return rate and the normal (predicted) return rate under the assumption without the M&A transactions. The primary task in the calculation of AR is how to design a model to predict normal return.

**2.2.2. Algorithms of AR.** The AR algorithms commonly applied by scholars include the market adjustment method and the market model method [40]. The former assumes that the normal return is the market index return rate, while the latter calculates the normal return based on the capital asset pricing model (CAPM). In addition to utilizing the above traditional methods, foreign scholars have tried other methods to improve the accuracy of AR. For instance, Gregory [41] adopted the market model method, risk- and size-adjusted model, simple size-adjusted model, and value-weighted three-factor model proposed by Fama and French to calculate AR in M&A, finding significant differences in different AR algorithms. Besides, in the study of 1,164 M&A events in the United States from 1955 to 1987, Agrawal et al. [15] utilized the AR algorithms from the studies of Dimson and Marsh [42], Lakonishok and Vermaelen [43], and Ibbotson [44].

Almost all of Chinese scholars adopt the market adjustment method or the market model method, lacking the attempt and exploration of the AR algorithm. Zhang compared the market adjustment method with the market

TABLE 1: Overview of short-term performance research on foreign M&amp;A.

| Conclusion category             | Author                     | Time published | Number of samples | Sample year | Research conclusion  |
|---------------------------------|----------------------------|----------------|-------------------|-------------|--|
| Positive short-term performance | Madden Gerald              | 1981           | 86                | 1997–1979   | One day before and after the M&A announcement, the CAR was significantly positive, but when the window period was extended, the CAR was significantly reduced [13]                                   |
|                                 | Healy and Palepu           | 1992           | 50                | 1979–1984   | Enterprises with highly similar products obtained more positive M&A performance and are the acquirers' capital productivity was raised significantly [14]  |
|                                 | Agrawal et al.             | 1992           | 1,164             | 1955–1987   | About half of the acquirer shareholders were able to obtain a positive CAR, and the CAR gradually decreased with the extension of the window period [15]   |
|                                 | Humphery-Jenner and Powell | 2014           | 17,647            | 1996–2008   | M&A samples from 45 countries showed that the acquirer created positive short-term performance, which decreased with the increasing national governance intensity [16]                               |
| Negative short-term performance | Dodd                       | 1980           | 172               | 1973–1976   | The CAR of the acquirer in about half of the sample during the 2-day window period before and after the M&A announcement was significantly negative [17]   |
|                                 | Higson and Elliott         | 1998           | 830               | 1975–1990   | The CAR of the acquirer in window period was significantly negative [18]   |
|                                 | Hans                       | 2006           | 110               | 1993–2001   | M&A not only brought negative cumulative returns to the acquirer but also continued to decline as the window period increased [19]   |
| Uncontrollability               | Jarrell.                   | 1988           | 663               | 1962–1985   | According to the time of M&A announcement, the samples were divided into three groups; the CAR of the acquirer was inconsistent among the three groups, and there was no significant difference [20] |
|                                 | Bruner                     | 2002           | N/A               | 1971–2001   | After the summary of 130 classics from 1971 to 2001, it was concluded that there was uncertainty in the short-term M&A performance [21]  |
|                                 | Yook                       | 2004           | 75                | 1989–1993   | The short-term performance for acquirer was not significant due to the influence of the premium of the acquisition target [22]   |
|                                 | Uddin                      | 2009           | 373               | 1994–2003   | M&A did not bring significant short-term performance to the acquirer [23]  |

TABLE 2: Overview of short-term performance research on Chinese M&amp;A.

| Conclusion category             | Author          | Time published | Number of samples | Sample year | Research conclusion  |
|---------------------------------|-----------------|----------------|-------------------|-------------|--|
| Positive short-term performance | Li and Chen     | 2002           | 349               | 1999–2000   | M&A brought significant wealth increase to the acquirer shareholders, especially the acquirer shareholders with larger proportion of national or legal person shares [24].       |
|                                 | Liu et al.      | 2009           | 749               | 1998–2004   | During the window period, acquirer shareholders received an average of 1.39% CAR, explaining the conclusion based on the industry cycle theory [25]                              |
|                                 | Deng et al.     | 2011           | 312               | 1997–2000   | Non-associated M&A created significant returns for the acquirers, and the associated M&A did not create wealth for shareholders [26]   |
|                                 | Zhang and Sheng | 2016           | 55                | 2010–2016   | M&A in the Internet finance industry brought significant positive short-term performance, and mixed M&A performance was better than horizontal and vertical M&A performance [27] |
|                                 | Li and Song     | 2017           | 333               | 2010–2013   | M&A created significant short-term M&A gain and increased as risk investor participation grows [28]  |

TABLE 2: Continued.

| Conclusion category             | Author         | Time published | Number of samples | Sample year | Research conclusion   |
|---------------------------------|----------------|----------------|-------------------|-------------|---|
| Negative short-term performance | Zhang and Lei  | 2003           | 216               | 1999–2001   | The wealth of the acquirer shareholders did not increase due to M&A activity, and the CAR rose first and then decreased, and the reduction was greater than the increase [29]                             |
|                                 | Zhang          | 2003           | 1,326             | 1993–2002   | M&A had a negative impact on the acquirer with $-16.76\%$ CAR during the window period [12]   |
|                                 | Zhu and Chen   | 2016           | 517               | 2011–2013   | Technology M&A brought significant negative short-term performance to the acquirer, but the company's establishment period and equity concentration were conducive to improving M&A performance [30]      |
| Uncontrollability               | Chen and Zhang | 1999           | 95                | 1997        | Due to the immature capital market in China, the main M&A stocks did not show significant fluctuations, and the stock market did not respond significantly to M&A [31]                                    |
|                                 | Yu and Yang    | 2000           | 18                | 1993–1995   | In the M&A, the enterprise value of the acquirer did not rise, and the shareholders were not able to obtain returns, which did not benefit the development of the enterprise [32]                         |
|                                 | Yu and Liu     | 2004           | 55                | 2002        | The M&A performance of the acquirer was not significant, and lacked continuity. From the perspectives of M&A motives and methods, the causes for the high failure rate of M&A in China were analyzed [33] |

model method, finding the same conclusion in measuring M&A performance. In addition to adopting the above two methods, Cong made an attempted to utilize the listed company's return on net assets per share to minus the market interest rate to calculate the AR [45], which has become a rare Chinese literature on the AR algorithm research.

The market adjustment method and the market model method have distinct advantages and disadvantages. The former is simple in calculation but lacks theoretical and statistical basis. The latter possesses theoretical basis, but its hypothesis testing results were rarely discussed systematically in previous literatures. The empirical study of this paper shows that the regression equation coefficients cannot pass the significance  $T$  test, which is related to the nonlinear characteristics of the stock price series and is ignored usually due to the passing of  $F$  test with the regression equation. In order to solve the nonlinear problem, this paper designs another two traditional regression models and one artificial intelligence model to calculate AR and compares the fitting effect, prediction accuracy, and significant difference between the five models, which fills in the literature blank about AR algorithm. The accuracy of AR calculation is the basis of all the literatures on the application of event study method, which directly affects the results of events. Therefore, it is necessary and meaningful to carry out the research of AR algorithm.

**2.2.3. Artificial Neural Network Algorithm.** With the continuous improvement of chaos and fractal theory, considerable studies have proved that the stock price series owns nonlinear characteristics [46–50], and scholars have begun to utilize some data mining techniques to solve complex nonlinear problems [51]. Artificial neural network (ANN) is

an adaptive nonlinear dynamic system composed of a large number of neurons through extremely flexible and extensive connections [52], with self-learning, self-organization, and self-adaption functions, which can reveal the complexities contained in data samples [53, 54], and has been widely applied in financial time series studies since the 1990s [55]. Moreover, it has proven to be more suitable for stock forecasting than traditional linear models [56]. Ican and Çelik [57] compared 25 literatures based on neural network predicting stock prices, holding that selecting the appropriate stock data (input information) and neural network structure have an important influence on the fitting effect. According to the topology of neuron connections, neural networks can be divided into forward networks (such as BP neural networks) and feedback networks (such as Elman neural networks). In contrast to forward network, feedback networks can achieve information feedback and have associative memory functions. Weng and Lin [58] compared the short-term prediction effects from stock prices of three neural networks (RBF, BP, and Elman). The empirical results revealed that the prediction ability of Elman feedback neural network was higher than that of the other two forward neural networks.

The core idea of Elman feedback neural network originates from the simple recurrent neural network model proposed by Jeffrey Locke Elman in 1990, consisting of input layer ( $L1$ ), hidden layer ( $L2$ ), connection layer ( $L3$ ), and output layer ( $L4$ ) (Figure 1), which is frequently applied for dynamic modeling or time series prediction [59]. The input information ( $XN$ ) enters the hidden layer neurons through the input layer neurons, and the output information of the hidden layer is calculated and stored by the connected layer neurons and then enters the hidden layer as input information again, repeating iteratively until the error function and the weight reach a stable balance state (Figure 2).

FIGURE 1: Elman neural network structure diagram.

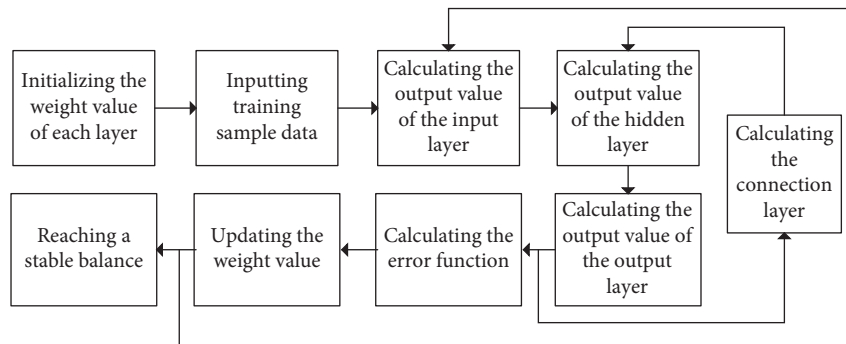

FIGURE 2: Elman neural network operation logic.

Among these, the activation functions of the output layer and the connection layer are linear functions, and the activation function of the hidden layer is a nonlinear function [60].

Since the beginning of this century, Elman neural network has been widely applied in the research on stock trading strategy and trading timing. Sitte and Sitte demonstrated that the S&P500 index can be predicted, through applying the Elman neural network [61]; Huang et al. utilized the Elman neural network to forecast the direction of the stock market and achieved better predictions [62]. Hyun and Kyung introduced the idea of the genetic algorithm based on Elman neural network for financial time series prediction, and the prediction accuracy was further improved [63]. Chinese research on Elman neural network for stock forecasting started late, and scholars have modified the structure or parameters of Elman neural network to study different financial time series predictions. It is agreed that Elman neural network has better nonlinear prediction ability [64–66].

### 3. Data and Methodology

**3.1. The Innovation of This Paper.** Scholars inside and outside China mainly adopt the market adjustment method and market model method to calculate AR. This paper

applies another three models, including the Elman neural network model, to compare and improve the rigor and accuracy of AR calculation, which is the first academic attempt. In addition, this paper takes the Chinese share-trading reform as the starting point and selects almost all M&A events with trading suspension and resumption as research sample to study the changes of M&A performance over the past 14 years, which makes up for the shortcomings of the small coverage period of Chinese M&A samples.

**3.2. Sample Selection.** This paper collects 2,358 major M&A events of listed companies from 2006 to 2019 from the Wind M&A database. The remaining 1,302 M&A events are the total sample, after eliminating 1,056 events failed, unfinished, or in which listed companies as acquiree, or no exact M&A announcement date due to the small transaction volume.

**3.3. Research Model.** The short-term M&A performance indicator adopts the cumulative abnormal return (CAR) of the window period, which is 21 days around M&A announcement, marked as  $(-10, 10)$  with 0 being the announcement day. In this paper, five models are applied to predict the normal return and then calculate the AR. The merits and demerits are compared by three factors: the

determinable coefficient ( $R^2$ ), the root mean-squared error (RMSE), and the significant difference test. The model design adopts Matlab math software [67].

**3.3.1. Market Adjustment Method.** Under the market adjustment method, it is not necessary to determine the observation period. The market index yield is directly subtracted from the stock actual return to calculate the AR. Due to its simple calculation, it is widely applied. As a matter of fact, this model is to assume the constant term and the risk coefficient in the CAPM model as 0 and 1, respectively. This assumption is neither theoretical nor consistent with the reality.

**3.3.2. Market Model Method.** The market model method equation is given as follows:

$$\hat{R}_i = \beta_{im} * R_m + \alpha + \varepsilon. \quad (1)$$

The market model method is a unary linear model based on CAPM theory (equation (1)). It is necessary to predict the constant term  $\alpha$  and the risk coefficient  $\beta_{im}$  according to the linear relationship between stock return and the market yield in the observation period. This paper makes the improvements as follows: first, the observation period of each M&A event is selected by finding trading day range with highest correlation coefficient between the stock return and the market yield before the window period, so as to improve the goodness of fit. The average value of the highest correlation coefficient of all samples in the observation period is 0.6444. If the observation period is set as fixed interval of 50 days before the window period, the average value is 0.5566, which shows that the linear relationship in the observation period is significantly improved. Secondly, on the basis of the first fitting, the noise outliers outside the two standard deviations near the fitted line are eliminated (Figure 3(d)), and then the second fitting is performed. The confidence interval (Figure 3(b)) after eliminating abnormal value is more concentrated than before (Figure 3(a)).

After excluding the outliers, there are only 224 events whose constant term  $\alpha$  and risk coefficient  $\beta_{im}$  both pass the significance test (0.05), and the average coefficient  $R^2$  is 0.5479, indicating that the explanation and prediction ability of market yield to stock return is weak under the unitary linear model, which is consistent with the doubts about the CAPM theory in the previous literature [68]. In this case, this paper attempts the unary nonlinear model.

**3.3.3. Unary Nonlinear Model.** The unary nonlinear model equation is given as follows:

$$y_i = \beta_1 e^{(\beta_2 / (x_i + \beta_3))} + \varepsilon_i, \quad \varepsilon_i \sim N(0, \delta^2). \quad (2)$$

Considering that the distribution of AR is dense with a large fluctuation, the negative exponential function (equation (2)) with the trend of steepness first and then slowness is selected as the unary nonlinear regression model. This paper makes the improvements as follows: First, in order to cover

the stock return history as much as possible and avoid the long-term observation period to damage the goodness of fitting, we take 5 trading days as the step value for each event. From 30 days before the window period, the observation period will be gradually expanded forward for fitting. The observation period with the smallest root mean-squared error (RMSE) is selected as the optimal observation period, and the average observation period of all samples is 51 days. Secondly, the second time fitting is eliminated on the basis of the first fitting, and the improvement effect of the goodness of fit is significant (Figure 4).

After the elimination of the outliers, there are only 83 events whose all the three parameters  $\beta_1$ ,  $\beta_2$ , and  $\beta_3$  pass the significance test (0.05), and the determination coefficient  $R^2$  is 0.5472, which is mainly due to the fact that it is difficult to predict the specific analytical formulae of the nonlinear relationship in practice. In this case, a one-dimensional polynomial model can be tried to gradually fit the measured points.

**3.3.4. Unary Polynomial Model.** Any function can theoretically be approximated by a polynomial model by segmentation (equation (3)). Hence, this paper is fitted from low order to high order, and the improvements are made as follows: first, each observation period of each M&A event is performed to fit from the first order to the tenth order. Secondly, 80 kinds of observation period are selected for each M&A event, which are 21 days, 22 days . . . 100 days before the window period. Each event is fitted for 800 times based on the 1–10 order and 80 observation periods, and the equation with the smallest RMSE is selected as the optimal order and the optimal observation period:

$$y_i = p_1 x_i^n + p_2 x_i^{n-1} + \dots + p_n x_i + p_{n+1} + \varepsilon_i, \quad \varepsilon_i \sim N(0, \delta^2). \quad (3)$$

The optimal order of all samples is 10, the optimal observation period is 33 days, and the average coefficient of  $R^2$  is 0.6790. The fitting effect is greatly improved. However, when the model is utilized to predict AR in the window period, the unreasonable extreme value accounts for 16.70%. The high-order polynomial model can only fit the limited data in observation period, and when data that cannot be covered in observation period appear in window period, the amplification function of the high-order items in the model will destroy the prediction ability. Figure 5(a) illustrates a better approximation fitting of the fitted curve to the limited data in the observation period. When the Y-axis display range is expanded to show the overall trend of the fitted curve, Figure 5(b) reflects the excessive fluctuation characteristics of the high-order fitting curve. Therefore, when the order is limited to the 4th order or less, the extreme value is basically eliminated. However, the coefficient  $R^2$  is reduced to 0.0163.

**3.3.5. Elman Neural Network Model.** The purpose of traditional regression analysis is to find the mapping relationship between independent variables and dependent

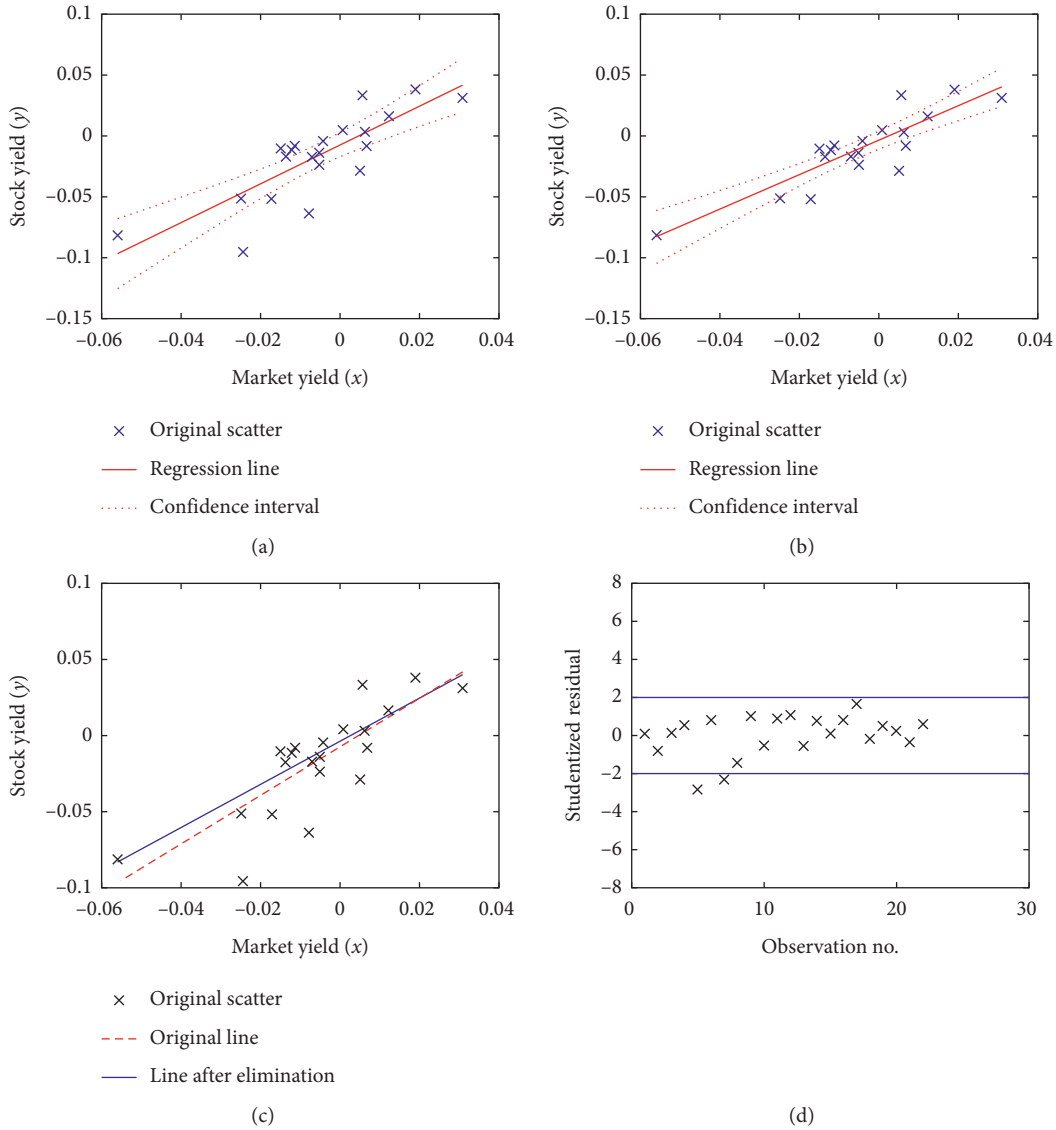

FIGURE 3: Market model method fitting map. (a) Before eliminating abnormal value. (b) After eliminating abnormal value. (c) Before and after eliminating abnormal value. (d) Studentized residual map.

variables. The results of the above four models show that it is difficult to find analytical expressions that satisfy both the hypothesis test condition and the predictive ability in practice. The main cause is that the complex relationship in financial time series is difficult to determine with the function of the analytical expression. As one of the data mining techniques, Elman neural network is widely applied in autonomous learning, associative storage, and high-speed optimization. Theoretically, it can handle arbitrary complex causal relationships, which is suitable for stock return forecasting.

The improvements are made in the Elman model as follows: first, the stock normal return is predicted by input information with individual stock's historical returns ( $E1$ ) and market yields ( $E2$ ), respectively. Secondly, the Elman model memory function is fully applied to cover the stock return history as much as possible with the observation

period selected from 2 months after listing to before the window period. The average observation period of all samples is 1,940 days; the maximum number of iterations is 2,000, and the error tolerance is 0.00001. The iteration process is stopped when the mean-squared error (MSE) reaches the error tolerance. If the error tolerance is not reached after 2,000 iterations, then the parameters, such as the weight and activation function corresponding to the minimum MSE, are taken as the optimal solution. Figure 6 illustrates the process of reducing the MSE to 0.0005 after 2,000 iterations in one of the M&A events.

The  $R^2$  of the Elman model's fitting with individual stock return or market yield is 0.9859 and 0.9958, respectively. The latter is better than the former. This conclusion can also be obtained from the fluctuation of the residual plot (Figures 7 and 8), indicating that the linkage between individual stock return and the market yield is stronger than that between

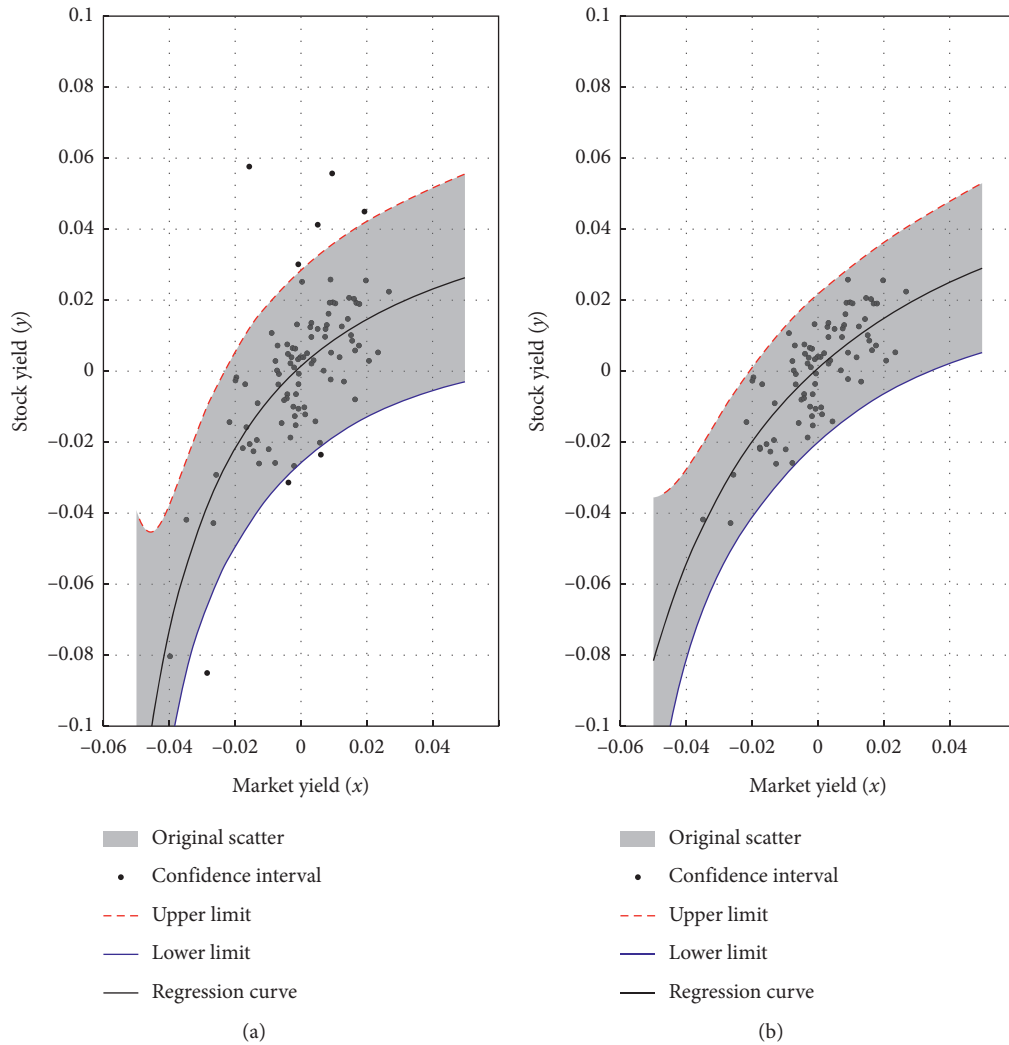

FIGURE 4: Unary nonlinear model fitting map. (a) Before eliminating abnormal value. (b) After eliminating abnormal value.

individual stock return and their own historical return. The fitting effect is shown in Figure 9.

#### 4. Results and Discussions

The five models have different window yields (Table 3). When studying the AR in window period, the following important issues are rarely demonstrated or mentioned: (1) whether the yield rate during the observation period meets the assumptions of the classical theory and the regression model; (2) whether the mean of the AR in the window period is representative; (3) whether there is a significant difference between the window period's AR time series calculated by the five models; (4) whether the overall trend of the AR in each year is significant.

*4.1. Normality Test of the Yield Rate in Observation Period.* The financial time series is supposed to obey the normal distribution, which is almost the common assumption of all classical theories (such as CAPM theory) and the traditional regression model because the normal distribution possesses

good additivity. Based on the central limit theorem, the totality can be considered to obey the normal distribution when the sample size is greater than 30. In this case, the hypothesis that the stock yield rate series obeys a normal distribution is widely dictated with its verification ignored. Considering the advantages as well as disadvantages of various methods, this paper utilizes six common normal distribution test methods (Table 4).

The data period of yield rate series was taken 50 days before the window period. The normality test was carried out for each individual stock and the market yield rate series. The mean skewness of individual stock and the market was  $-0.0242$  and  $-0.8370$ , respectively. The mean kurtosis was  $4.6782$  and  $6.6067$  respectively, indicating that the sequence has a peak fat tail characteristic, which was verified through utilizing the other four methods. Although the results of JB,  $\chi^2$ , and Lilliefors are slightly different, the conclusions are basically the same. Namely, the yield series of large proportion (up to 45.16%) does not obey the normal distribution, and the assumptions of the classical theory and the regression model are not true. Therefore, the statistical

FIGURE 9: Elman model fitting map.

model without normality requirements for the data should be selected and applied.

The K-S test results are quite different from other methods because this paper replaces the population parameters with sample mean and standard deviation like other related literature practices. In essence, it has change the K-S test to Lilliefors test. However, the statistical software (such as Matlab and SPSS) defaults and utilizes the K-S test threshold table, and the mismatch between Lilliefors statistic and K-S test threshold table results in an incorrect conclusion [69].

*4.2. Representative Test for Abnormal Return Mean.* After the representative test, for each model, all the average ARs of every day in the window period (the abnormal return in Table 3) pass the significance test of the 0.005 level.

*4.3. Significant Difference Test between the AR of the 5 Models.* Although the average daily ARs in the window period under the five models are representative, the comparison between average daily ARs cannot infer whether there is a significant difference between AR series under different models. Since AR series do not have normality and homogeneity of variance, the Friedman test (two-factor rank variance analysis) of the nonparametric test method is applied to demonstrate significant differences between AR series of any two models on the same day.

The Friedman test results (Table 5) can be concluded in three aspects as follows: (1) there are 17 days(80.95%) with significant differences in 21 days' window period in AR series between the market adjustment method and the market model method, which means that the substitution of the former for the latter in some literatures is not rigorous and affects accuracy of AR. (2) Because the low-order polynomial method is too gentle and can only reflect the overall trend, there are 0 day with significant differences with the market adjustment method. (3) There are 20 or 21 days' significant difference between Elman model and other four models, which means Elman model is totally different from other models.

*4.4. Significance Test of AR Series' Change in Window Period under Elman Model.* The Friedman test is carried out on the significant difference of AR series in two adjacent days in the window period under the Elman model. The results show that there are significant differences in AR series between 2 days before and 3 days after the announcement date. In Figure 10, the 21 horizontal lines represent the rank and mean confidence intervals (0.05) of the daily AR series, and the vertical axis 11 represents the announcement day. There is no overlap in the projection of adjacent horizontal lines of the ordinate 9–14 in horizontal axis, indicating a significant difference in AR series between the two adjacent days.

The settlement results of the Elman model is shown as follows: (1) M&A news has been transmitted to the stock market at least 2 days before the announcement date, which causes the stock price to fluctuate significantly within 6 days

TABLE 3: The AR in window period and fitting result of the five models.

| Window period  | Actual return (%) | Abnormal return              |                         |                           |                              |           |

around the announcement date. After that, the AR gradually decreases and creates a CAR of 14.45% in the window period; (2) after the announcement day, the AR, which is

significantly different from the previous day, can still continue for 4 consecutive days. The impact of M&A disclosure on the stock market does not disappear immediately, and

TABLE 7: Comparison of advantages and disadvantages of five AR models.

| Model              | Market adjustment method  | Market model  | Unary nonlinearity   | Unary polynomial  | Elman model  |
|--------------------|---------------------------|---|--|---|--|
| Advantage          | Easy calculation          | Simple calculation with theoretical basis   | Simple calculation   | Infinite fitting can be realized theoretically by increasing the order  | Can solve complicated nonlinear causality problem  |
| Disadvantage       | Lack of theoretical basis | Difficult to pass equation parameters' significance test                                      | Difficult to pass equation parameters' significance test                                 | Low-order: Poor fitting; high-order: Poor predictive ability  | The program is complicated; the output layer information is underutilized  |
| Innovation attempt | None                      | Take maximum correlation coefficient's interval as observation period; eliminate the outliers | Selecting the best observation period by step progressive method; eliminate the outliers | Selecting the best observation period by the step progressive method; comparison of low-order and high-order fitting/prediction results | Keep the observation period as much as possible; comparison of closing price and yield rate as input information |

China's stock market has not yet reached the semistrong position according to the semistrong effective judgment standard.

4.5. Significance Test for the Change Trend of AR in Each Year.

The average CAR in window period for each year (Table 6) was calculated by the announcement date of every M&A event based on the Elman model. The Friedman test results ( $P$  value of significance test is 0.0008) showed significant differences among the AR series in the 14 years, indicating that the M&A short-term performance had a significant downward trend and tended to be more reasonable. The low CAR in 2016–2018 was related to the stock market overall

downturn and the regulatory measures to crack down on the speculation of M&A in the past years, and M&A transactions of listed companies tend to be rational.

5. Conclusions

5.1. Comparison of Algorithms for AR. The stock return series does not have normality, and the assumptions of the traditional regression model cannot be established. In the past research, the algorithm for AR mainly adopted the market adjustment method and the market model method. The former lacked theoretical basis, and the latter was short of statistical basis, affecting the calculation accuracy of AR. To achieve the minimum variance, the market model method

has to take the average value of returns in observation period as the fitting result, and the market adjustment method is an extreme case under this rule, which can be reflected from the empirical result of  $R^2$  0.5346 and 0.2813, respectively. Therefore, the smaller the fitting result, the better the fitting effect, which leads to the predicted normal return underestimated and the CAR overestimated. These two methods have CAR 16.28% and 18.03%, respectively, and significantly greater than other three method's CAR.

In the first four traditional regression models, the unary nonlinear model has the best fitting effect with  $R^2$  0.5459, higher than other three models, because it can deal with nonlinear problems in stock yield time series to some extent, which can also be confirmed by the result that its CAR 14.65% is closest to Elman model' CAR 14.45%.

Besides this, the fitting effect of unary polynomial model is inversely proportional to its prediction ability. With the increase of order, the fitting effect is gradually optimized with  $R^2$  rising from 0.0163 in 4th order to 0.6790 in 10th order, while the higher order unary polynomial model' ability to predict is lost due to its huge volatility because the unary polynomial model cannot deal with the data distribution that stock yield time series fluctuates intensively in narrow numerical range.

The empirical results show that Elman neural network model is capable of solving nonlinear complex problems. It can fit the observation period data as well as predict the AR in window period with  $R^2$  0.9950 and CAR 14.45%, which is significantly different from another 4 traditional regression models. However, Elman neural network model has shortcomings. Only the feedback of hidden layer information is considered in the structure, and the output layer information is not relearned [70]. In addition, although the neural network calculation logic is reasonable and easy to understand, the computer operating process is more like a black box, and few researchers have the ability to analyze the model code to explain why the fitting effect is so good.

The advantages and disadvantages among five calculation models for AR are revealed in Table 7.

**5.2. Short-Term M&A Performance.** The M&A short-term performance in the past 14 years has generally declined, which is related with the effectiveness of China's regulatory measures for M&A hype and speculation, leading to M&A short-term performance tending to be reasonable. The M&A of listed companies can create a 14.45% CAR of considerable short-term performance during the window period, indicating that the stock market is generally in recognition of listed companies' M&A activities and the expectations of the company's value is raised and reflected in stock price. However, in the process of stock price fluctuation, there was hype and speculation behavior on M&A, which was reflected in the fact that the M&A news was transmitted to the stock market at least 2 days before the announcement date, causing the stock price to rise significantly in advance. In addition, the significant change of AR has been prominent for 3 consecutive days after the announcement day. The long-term trading suspension (1302 M&A events were

suspended for 111 days on average) did not digest the centralized or excessive response of the stock market to M&A news.

In addition, the AR is significant for 3 consecutive days after the announcement day, and investors can make use of the public information to obtain excess returns, which proves that China's stock market has not reached the semistrong form of efficiency.

**5.3. Explanation of Chinese Short-Term M&A Performance.** Chinese short-term M&A performance is highly related to the characteristics of China's stock markets. In the process of developing the real economy, China endows M&A great potential and space for value creation, which is reflected either in the economic structural adjustment at the macrolevel or in the industrial transformation-upgrading at the microlevel. The China Securities Regulatory Commission, undertaking the economic management functions as a government department [71], have formulated a series of supportive policies for M&A transactions since 2006, which gives M&A activities the crucial role in capital resource allocation. Besides, different from the western stock markets, which are dominated by institutional investors, China's stock market has 160 million individual investors, accounting for 99.76%, who are more likely to interpret M&A as a good signal and chase the stock, which leads to Chinese listed companies more willing to carry out M&A activities.

**5.4. Enlightenments and Recommendations.** For the majority of researchers, it is recommended to make full use of artificial intelligence method to explore nonlinear problems and compare innovation research with previous research in accordance with statistical principles, which will contribute to improving the rigorism of research modeling and the accuracy of the research conclusion.

## Data Availability

Some or all data, models, or code generated or used during the study are available in a repository or online in accordance with funder data retention policies. All M&A events of listed companies between 2006 and 2019 are from the Wind M&A database, and all stock prices come from CITIC Securities Stock Trading Software.

## Disclosure

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

## Conflicts of Interest

The authors declare that there are no conflicts of interest.

At present, the Chinese government is trying to resolve various social contradictions, such as people's ever-growing need for a better life and unbalanced and inadequate development. To do so, urban governance practices including holistic governance, decentralized and interconnected governance, multiple participatory governance, and smart governance have been developed in China. Urban smart governance supported by mobile Internet, the Internet of Things, quantum computing, big data, artificial intelligence, and other information technologies has also entered the field of vision of academics and administrators. However, the research and practice on the integration of organizational structure and smart governance technology for urban governance in China are still insufficient. Hence, this paper proposes the design of the organizational structure of an urban smart governance platform and presents the "1 + N" integrated smart information platform and the "power-sharing linkage, one-center and dual-track" platform construction command system. In this system, the functional module of the information platform for smart urban governance is elaborated. This paper contributes to promoting the modernization of China's urban governance capacity, which can enhance social equity and social order, promote social democracy and rule of law, and enhance the efficiency of urban governance.

## 1. Introduction

On April 19, 2016, Chinese President Xi Jinping stated "In the process of promoting the modernization of the national governance system and governance capacity through information technology, we need to coordinate the development of e-government and build an integrated online service platform to perceive social trends, smooth communication channels and assist scientific decision-making" [1]. Since then, the informatization of urban governance has boomed in China. In addition to the government's active promotion, the rapid development of and changes in Chinese cities and the promotion of information technology have accelerated the informatization of urban governance. This paper aims to identify the trends of China's urban governance transformation to design a governance organization structure and to elaborate on the structure's basic operational logic according

to the information platform of urban smart governance. "1 + n" smart city takes "wisdom, wisdom and efficiency" as the construction concept, relying on the core technologies such as artificial intelligence, blockchain, and cloud computing, to build a "1 + n" smart city platform system, with a set of "smart city cloud" platform to strongly support *n* smart city plates, including smart life, government affairs, transportation, education, health, hospital, food safety, port, environmental protection, pension, law, and community.

## 2. Research Background and Literature Review

At present, many countries have begun to build smart cities, mainly in the United States, Sweden, Ireland, Germany, France in Europe, and China, Singapore, Japan, and South Korea in Asia. The construction of smart cities in most countries is in the stage of limited scale and small-scale

exploration. As the world's fourth largest manufacturer of electronic products, South Korea is one of the leading countries in the formulation of international standards for the Internet of Things, cultivating new industries through the construction of smart city. The United States has raised the construction of smart city to the height of national strategy and made key investment and construction in infrastructure and smart grid. Singapore is recognized as the country with the best government service. Information and communication technology promotes economic growth and social progress. The construction of smart city focuses on serving the public [2].

China's smart city construction has just started, and the urban informatization construction is in an important structural transformation period, that is, from the stage of information technology popularization and application to the stage of information resources development and utilization. China is actively making use of the latest technologies such as the Internet of Things and cloud computing to promote the construction of smart city through the strategic deployment of "integration of industrialization and industrialization," "simultaneous development of five modernizations," and "integration of three networks." At present, there are three construction modes of smart city construction in China, which are the construction mode driven by the development of Internet of Things industry, such as Wuxi; the construction mode guided by the construction of information infrastructure, such as Wuhan; and the construction mode with social service and management application as the breakthrough, such as Beijing and Chongqing.

Analyzing the connotation of the word "smart" is the premise of understanding the concept of "urban smart governance." The word "smart" has different origins and meanings. In Chinese, "smart" [3] means "the ability to distinguish right from wrong and to invent something." In English, it refers to "having or showing a high degree of mental ability" or "witty, clever" [4]. These two definitions convey two meanings: the ability to perceive things and the ability to manage things, respectively. Smartness is the key to government reform strategies worldwide [5].

Smart governance can be defined as "a deployment of the creative mix of emerging technologies and innovation in the public sector" [6] that can cope with complex and difficult challenges to promote innovation, sustainability, and competitiveness in society [7]. In recent years, smart governance has attracted increasing attention.

A team of researchers led by Giffinger of the Technical University of Vienna began a comprehensive assessment of the development of smart cities in Europe in 2007 [8]. The level of smart governance in cities was seen as one of the most important aspects of the assessment, which focused on public participation in decision-making, transparency, and public services. Alenezi et al. [9] regarded smart governance as a governance model based on e-government innovation. Rochet et al. [10] believed that smart governance is business processing and information communication based on information and communication technologies (ICT), with the aim to improve service quality. Some researchers [11–14]

agreed that ICT plays an important role in urban governance. Information technology and many disciplinary approaches, for example, have been adopted to help cities improve the use of services and infrastructure and balance the sustainability of social, economic, and environmental impacts. In addition, Ronan [15] noted that smart governance is a government service that is guided by public services and makes full use of various data, information, and advanced ICT to provide smarter and higher-quality services to the public. Nada et al. [16] defined smart urban governance as smart, intelligent urban public service management and public participation. Lv et al. [17] illustrated that ICT has been used by the government to facilitate interdepartmental data sharing and achieve more open and sustainable government services.

With the implementation of the urbanization strategy, increasing attention has been paid to the level of smart governance in China. Related theoretical research and practice have increased simultaneously. According to Cui and Guo [18], urban smart governance takes the whole urban system as the governance object and constructs a smart decision-making mechanism through information technology to make urban public services more standardized, transparent, and efficient through open interaction between the government, markets, and society. Wang [19] reported that urban smart governance covers both management and service, with an emphasis on smart management and control and smart service. Nie [20] emphasized that the government has made full use of big data, mobilized social forces, and formed a pluralistic cogovernance pattern. Gao [21] believed that the use of modern information technology by the government transforms the relationship among the government, citizens, and society and that various departments within the government can realize power sharing, innovative communication, and supervision methods and shape an efficient modern governance model.

In light of the above literature review, this paper defines urban smart governance as the elimination of information islands between government departments, the full use of advanced ICT to collect data in real time, and data sharing and intercommunication between government departments. By processing and analyzing big data through cloud computing and artificial intelligence, we can offer more accurate, smarter, more efficient, and higher-quality government services oriented to public services and ultimately promote harmonious and sustainable urban development.

Academia generally believes that information platforms of urban smart governance are the key to bridging the gap between technology and governance [22, 23]. However, the unreasonable design of existing information platforms for urban governance leads to a gap between data collection and application [24]. Urban smart governance is not the function of a single department but involves many departments. If the government relied on the promotion of one department alone, it would not be able to succeed. However, the disorderly participation of all departments would lead to difficult coordination. Therefore, a unified deployment of the city government is needed [25]. In the management of the Chinese government's data resources, there are two main

problems: the isomorphism of responsibilities and the highly fragmented and segmentary system. The independence and estrangement between the upper and lower levels of government departments, as well as the conflicts and contradictions between municipal departments at the same level, lead to a situation in which horizontal data can be neither aggregated nor shared and vertical data can be shared neither upward nor downward [26].

At present, the research on urban smart governance is still in the stage of theoretical exploration, and there are relatively few studies and practices related to smart governance considering the characteristics of China's urban governance system. Urban smart governance is a systematic project, and it is urgent to integrate information technology and governance systems, improve the existing governance system through the construction of urban smart governance information platforms, and form an organizational structure and governance model of urban smart governance with clear rights and responsibilities.

### 3. The Trend of Urban Governance Transformation in China

In the academic field, "smart governance" is a concept that has been widely discussed and spread in recent years. It is generally discussed in the context of governance capacity and systems. Therefore, the discussion on urban smart governance must be based on the practical problems of urban governance; otherwise, the academic discussion will lose a practical basis. It not only relates to technical problems but also includes the concept, values, and behavioral process of urban governance.

Correspondingly, the current situation and trend of urban governance in application need to be analyzed in advance in order to clarify the real demand for urban governance and further solve problems.

*3.1. Trend One: Holistic Governance.* The purpose of China's "comprehensive urban management" system is to transform urban governance from decentralized to comprehensive governance. The main characteristics of a comprehensive urban management system are embodied in the functions of "centralization" and "linkage." Centralization aims to provide good services, improve management, enhance law enforcement, and centralize the management and punishment power involved in urban management into one functional department in order to integrate urban management and administrative law enforcement and to improve administrative and service efficiency. Linkage refers to the implementation of interdepartmental joint law enforcement for some urban management law enforcement matters that are temporarily difficult to concentrate on in the process of urban management operation, which is embodied in the linkage between similar or related departments. However, the comprehensive urban management system is only a transitional measure in urban governance. To realize the goal of refined management of diversified subjects in a city, government departments must achieve seamless

professional coordination and smooth information transmission. Therefore, the government should embrace the concept of holistic management guided by the needs of citizens, use information technology as the governance means, and choose coordination, integration, and responsibility as the governance mechanisms to carry out organic coordination and integration of governance levels, functions, public-private relationships, and information systems and to address other fragmentation issues [27].

Urban governance system reform based on the concept of holistic governance will ultimately establish an administrative system coordinated by integrating service, management, and law enforcement [28]. Configuration of power among local government departments should become into notice, and relevant rights and responsibilities need to be clarified to establish a mechanism for information communication among various functional departments. In addition, a multidepartmental coordinated urban governance pattern should be adopted to strengthen the evaluation of and feedback on the effectiveness of urban governance in order to ensure that urban governance meets the needs of all parties. With the development of information technology, holistic management is not only characterized by "concentration" and "linkage" but also emphasizes governance by means of the full use of information technology and the concept of serving the public. Moreover, it coordinates the function and accountability mechanisms of information systems, governance classes, and public and private sectors to promote collaboration among public service subjects and provide seamless public services to the public [29]. Therefore, holistic governance will inevitably facilitate the development of participatory governance and smart governance in practice.

*3.2. Trend Two: Decentralized and Interconnected Governance.* Since the beginning of the 21<sup>st</sup> century, the central government of China has gradually transferred its power to lower levels. "New affairs" generated in the process of urban development have also enabled local governments to naturally acquire power. Thus, city governments have acquired the dominant position of urban governance power. The governance of China's city-level government long used management as its main means, and it has long been featured by comprehensive law enforcement. Local urban management and law enforcement departments belong only to institutions under the jurisdiction of local governments, and even if the government sets up branches, they are basically only at the district level. The function of urban governance of streets and communities, especially their position in the governance system, has not received enough attention. A governance system of decentralization with a unified vertical linkage of "city government-district-street-community" has not been established.

With the development of modern information technology, government reform campaigns have been triggered by the data-opening movement in China. The introduction of information technology has changed the organizational system of the government, thus requiring government

management to change from the previous bureaucratic system to a new organizational framework based on networks and technology [30]. Driven by information technology and the rapid development of cities, the change in the organizational structure is profound; it involves pushing the external boundary of the power structure.

Through our long-term study, we found that in recent years, many city governments have defined the scope of urban management authority because Chinese cities have a principal position in the power of urban governance. City governments have clarified the governance rights and responsibilities of cities, districts, streets, and communities, and the decentralized and interconnected governance model is gradually taking shape in Chinese cities. The reform of urban governance in all parts of China has highlighted the difference in the division of functions between decentralized governance and governments at different levels, with the aim to achieve good coordination between municipal governments and governments at various levels within their jurisdictions based on the division of functions (ref). Municipal governments have systematic plans to promote urban governance within the scope of cities. District governments, street departments, and communities, in accordance with their hierarchical differences, exercise their functions and powers in urban governance within their jurisdiction and cooperate with each other to promote the continuous improvement of urban governance.

*3.3. Trend Three: Multiple Participatory Governance.* Urban refined management needs to be coordinated by scientific and effective governance systems and mechanisms. There are three typical models of urban governance [31]: government-centered, market-centered, and user-centered. The purpose of urban smart governance is to break the previous single-center, hierarchical, and inefficient governance mechanism and build a new system of collaborative governance that includes intergovernmental governance, public-private governance, and government-society governance.

With the advancement of China's urbanization development and the formation of the social multiplication pattern, the demands of different group interests are expressed more strongly, which has prompted the adjustment of government decision-making to meet the demands of the public interest and responses. The concept of participatory governance encourages the public to participate in urban governance [32]. As the public is the owner of a city, the development and change occurring in the city are closely related to public life. Encouraging the public to participate in urban governance is the meaning of reforming urban management and improving the level of urban governance in the new era. To attract public participation, the first step is to stimulate the public's willingness to participate, and the second step is to smooth the channels of public participation and innovate the ways of public participation. At the same time, it is necessary to establish and improve the feedback mechanism and establish a long-term mechanism of public participation. An urban smart governance information platform is undoubtedly the best way to meet the above demands.

*3.4. Trend Four: Smart Governance.* As mentioned above, urban smart governance refers to integrating urban governance resources by constantly innovating digital urban management information platforms; making full use of technologies such as the Internet of Things, big data, cloud computing, and mobile Internet to build smart governance platforms; and constructing appropriate systems to improve the service capability of platforms. Smart governance not only emphasizes the management method of digitization but also focuses on expanding the visual and controllable scope of urban governance by means of informatization and digitalization to provide better urban public services, enhance public participation, and realize public value through coordination from management to service. In terms of the governance system, smart governance emphasizes the combination of the government's instrumental rationality and governance's value rationality and pays attention to the transformation of the urban social economy and environment in overall planning to optimize the urban environment and create more suitable living spaces for citizens [33].

The rapid development of information technology in China has affected all aspects of social life and laid the foundation for the practical application of urban smart governance. China is in the information technology era, accompanied by rapid development. Urban governance systems should actively introduce technologies such as big data, cloud computing, and the Internet of Things. With the support of modern information technology, the government can collect and analyze data to grasp the dynamic change process of urban governance for decision-makers in order to better summarize the development and governance rules of urban problems, clarify the follow-up effects of each urban governance measure, and grasp urban development trends. In addition, it is convenient for the government to find problems at the microlevel to improve the wisdom and refinement of urban governance means [34].

*3.5. Disadvantages of Current Urban Governance.* At present, it is difficult for the data mastered by various departments of the city government to be "open as the normal and confidentiality as the exception." Problems such as lack of data, data closure, and repeated construction of smart platforms are common. This includes not only the external factors such as the lag of the overall urban informatization construction, technical barriers, poor organization, and coordination, but also the internal problems such as the lack of power of the department informatization construction, the data as "private property," and the source of rights. For example, the management foundation of information accounts of a large number of key work such as dismantling illegal and scattered pollution enterprises is weak, the data items and data standards are not unified enough, and the task of multidepartment data aggregation and work standardization is a long way to go; some types of data construction are in the bottleneck position, for example, the existing population signaling data and public security work residence permit data need to be integrated and analyzed to reflect the population characteristics, but there is no

relatively formed solution; a large number of urban and rural planning data need to be integrated into space, but the problem of different base map standards needs to be solved first; some departments, including the development and reform, have done a lot of work in the collection of urban operation data and have strong demands for the cross-sectoral application of data and system. However, there is still a large gap between the barrier-free application of data and the linkage of indicators due to the completion of massive data docking.

*3.6. Coordinated Operation Embodies the Advantages of New Smart City.* “Serving enterprises, government, and citizens” is the original intention of smart city. It can be said that “cooperative operation” is the biggest feature of the new smart city, and the “1+n” platform architecture is the biggest logic of the new-type city intelligent governance. Whether it is government affairs, medical treatment, education, environmental protection, law, pension, community and urban construction, and other more subdivided fields, the new urban intelligent governance has been deeply cultivated for a long time. It is worth mentioning that the new type of urban intelligent governance not only focuses on helping to improve the level of urban intelligence, but also makes continuous investment in smart poverty alleviation, contributing to winning the battle of poverty alleviation in rural areas. The new smart city has improved the end-to-end solution matrix including intelligent medical quality control, intelligent disease prediction, intelligent triage guidance, intelligent medical imaging screening, intelligent auxiliary diagnosis and treatment, intelligent ICU critical management, and intelligent follow-up patient education. It has covered 700+ intelligent disease auxiliary diagnosis and treatment models of common diseases, about 800 million patients, and has a complete medical knowledge map including drugs, diseases, prescriptions, and risk factors.

#### **4. The Design of the Information Platform of Urban Smart Governance**

Based on the previous analysis, the current reform and transformation of urban governance in China are embodied in the framework of decentralized and interconnected governance, where overall governance, participatory governance, and intelligent governance resonate at the same frequency. Such a framework is gradually taking shape. The design of the governance organization structure of an information platform of urban smart governance that meets the actual needs of cities should respond to the transformation trend of urban governance.

*4.1. “1+N” Integrated Intelligent Information Platform.* The methodologies of holistic governance and decentralized interconnected governance are adopted to build an information platform for urban smart governance with the basic characteristics of intelligence, informatization, networking, and precision to realize the goal of a multigoverning model of urban governance.

Rónán et al. [15] pointed out that the connotation of smart government governance includes intelligent public services, intelligent social management, and citizen group participation. The “1+N” integrated intelligent information platform aims to build “1” big data resource center and “N” urban governance platforms. This platform covers the content of smart governance and is an open system that expands and reduces its content according to the actual needs of cities (Figure 1).

The platform includes one center, namely, one big data resource center. The big data center is constructed based on cloud computing technology, which combines virtualization, distributed storage, distributed computing, and other technologies with government affairs to ensure the adaptation of advanced technology and government affair applications. Computing, storage, networks, and other basic resources facilitate capacity expansion according to the needs of the application workload. The overall architecture adopts an open design that is compatible with common equipment, mainstream operating systems, virtualization software, and applications in the industry and reduces development, operation, and maintenance costs. The key point of openness is that the function platform can be increased or decreased with changes in the urban governance function. The platform aims to support multiple users and multiple services to ensure that basic resources can be automatically and dynamically scheduled among different applications and users according to their needs. Meanwhile, different businesses can be isolated from each other to ensure the smooth operation of various businesses. The technology and equipment selected for the construction of the big data resource center are advanced, expandable, mature, open, compatible, reliable, safe, and able to control intellectual property. As the infrastructure and supporting platform of urban smart governance, the big data center integrates urban data resources and enhances governance perception. Its most important task is to serve holistic governance.

In the process of constructing this “1N” comprehensive intelligent information platform, in order to better study the distribution of different types of data information in the system, the machine learning and neural network combination model used on this platform will integrate the characteristics of different data categories. The dynamic feature values are attributed to the same data cluster group. When the data feature values of any two groups in the data are not the same, it means that the two types of data feature information are extremely different, and they will be automatically separated into different levels. The data sets are compared with the eigenvalues of the next data. The actual calculation process of the machine learning model and the neural network algorithm can be regarded as the iterative process of repeatedly decreasing the control parameter value (the unique characteristic information of the data in the database) and performing the machine learning algorithm, as shown in Figure 2. Among them,  $c$ ,  $x$ ,  $u$ ,  $y$ , and  $h$  represent different types of data, and  $F$  represents data processing methods.

In the process of automatically classifying data, the neural network algorithm converts the data feature information predicted by the network traffic into the data

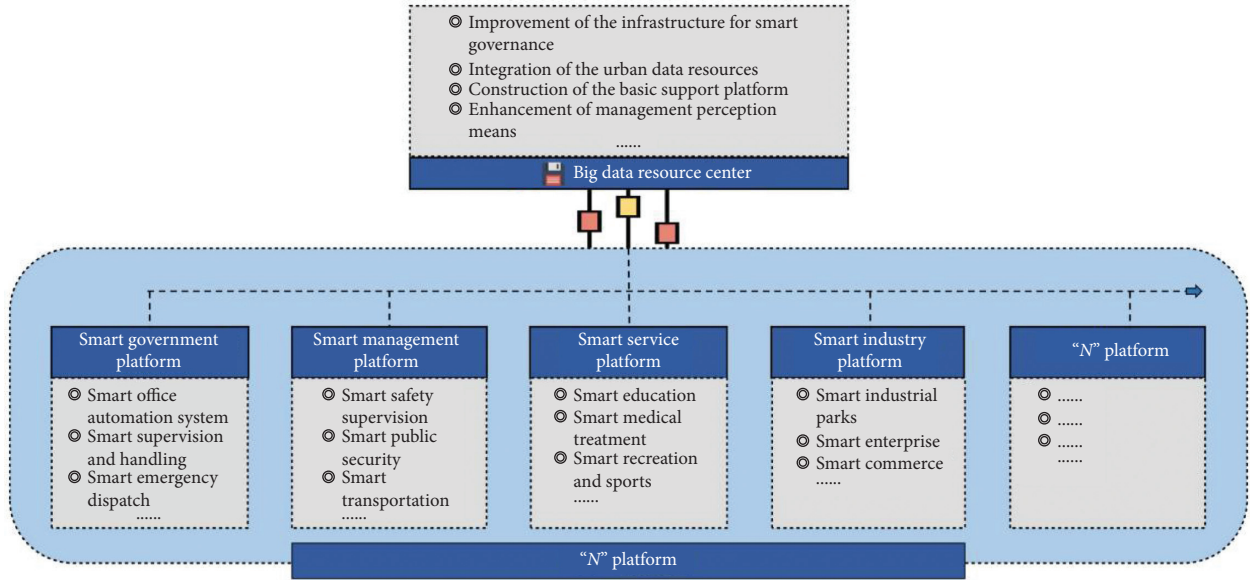

FIGURE 1: "1+N" integrated smart information platform.

FIGURE 2: Algorithm iteration process in this platform.

information (such as vector group or matrix) that can be recognized by the computer through the feedback link in the automatic analysis process. Realize the adverse effect of output on input, and then achieve automatic high-precision classification based on feedback control. The network traffic prediction model based on the neural network algorithm, under normal circumstances, will automatically analyze and process the data classification that needs to be queried based on multiple feedback links. When we perform predictive analysis on the platform based on the more commonly used state probability formulas in neural network algorithms, the specific formulas are as follows:

$$P_j(T_k) = \frac{\sqrt[k]{KC_k}}{C_{k+1}}, \quad (1)$$

where  $P$  represents the prediction result and  $C$  represents the different types of data analysis. There is also the influence of data  $T_k$  in data eigenvalues on probability  $P_i(T_k)$ .

When the  $T_k$  is very large, the probability of each state is almost equal. At this time, the neural network algorithm began to perform wide-area search, and the  $P_i(T_k)$  difference expanded as the course data predicted by the network traffic decreased.

$$E_i = \frac{K}{T_K}, \quad (2)$$

where  $E$  represents different dimensional data and  $K$  represents different data selection rules at this time:

$$\sigma_\theta(x) = \sum_{i=1}^n P_i(T_\theta). \quad (3)$$

The validity and error of the problems involved in this study are related to the set error confidence  $h$ , and the correlation with the initial solution is also relatively large. In order to only examine the numerical method itself, usually only the stability of the numerical method used to solve the model equation is tested. The model equation is given by

$$\begin{cases} y' = \lambda y, \\ y(a) = y_0. \end{cases} \quad (4)$$

Among them,  $\lambda$  is a complex number, this equation is also called the test equation, and its true solution is as follows:

$$y(x) = y_0 e^{\lambda(x-a)}. \quad (5)$$

When using the random probability model to solve different practical problems, the result is

$$(1 - h\lambda\beta_k)y_{n+k} = \sum_{i=0}^{k-1} (\alpha_i + h\lambda\beta_i)y_{n+i}. \quad (6)$$

Let the solution be

$$y_n = r^n. \quad (7)$$

Then, there is

$$(1 - h\lambda\beta_k)r^{n+k} = \sum_{i=0}^{k-1} (\alpha_i + h\lambda\beta_i)r^{n+i}. \quad (8)$$

Its equivalent form is given by

$$(1 - h\lambda\beta_k)r^k = \sum_{i=0}^{k-1} (\alpha_i + h\lambda\beta_i)r^i. \quad (9)$$

We call the above formula the feature confidence solution formula based on probability random variables and their numerical features. Remember

$$\pi(r; h\lambda) = (1 - h\lambda\beta_k)r^k - \sum_{i=0}^{k-1} (\alpha_i + h\lambda\beta_i)r^i. \quad (10)$$

And take the above formula as the limit characteristic error degree in solving the probability distribution model.

Therefore, when the optimal solution of the network traffic prediction system needs to be solved, the output image of the function when the parameter  $\theta$  is 1 and 2 is shown in Figure 3 (using different ST functions for simulation), where the horizontal axis  $N$  represents different sizes in the dataset and the vertical axis  $T$  represents the accuracy calculation operator.

The platform includes  $N$  platforms, namely, all platforms for building smart government affairs platforms, such as the Smart Government Platform, the Smart Management Platform, the Smart Service Platform, and other platforms required by holistic governance. For example, (1) the Smart Government Platform takes handling documents, meetings, and affairs as the core, and it meets the needs of the Party and government for coordinating government affairs. Paperless office and mobile approval support and data visualization make decision-making more scientific. (2) Through the Smart Management Platform, the government adopts the combination of the Cell Grid Management Method and the Urban Component and Event Management Method and the tools of real-time information collection and transmission to reconstruct the urban management process in order to realize accurate, agile, efficient, and multidimensional urban management. (3) The Smart Service Platform, adhering to the concept of Internet + government services, aims to improve the level of social governance refinement and comprehensively promote networked and highly informationized public management and services from a higher starting point. This platform innovates the government management model, clarifies responsibilities, and integrates resources to achieve “zero distance in social services, full coverage in social governance, and prompt responses to residents” demands. It

FIGURE 3: Function output image during simulation.

realizes the transformation of urban governance from prevention and control to humanized and service-oriented governance and from extensive governance to refined governance.

**4.2. “Power-Sharing Linkage, One-Center and Dual-Track” Platform Construction Command System.** As shown in Figure 4, power-sharing linkage refers to the distribution of jurisdiction according to the functions of different levels and departments. The smart governance system can automatically allocate and fully link public affairs notifications and governance data between different levels and functional departments within the scope of law. “One center” refers to the “Urban Smart Control Service Command Center,” and “dual track” refers to two tracks. The first track is from the Municipal Government Command Center to the Municipal Departments Command Center to the District Departments Command Center to the Street Departments Command Center and finally to the Community Service Center, which serves as the control service command information channel in ordinary times. The other track is from the Municipal Government Command Center to the Street Command Center and finally to the Community Service Center, which is mainly used as an emergency joint command information channel and auxiliary information channel in ordinary times. Accordingly, a “one-center and dual-track” operation carrier with high efficiency is formed to ensure a city’s control and command linkage. The vertical hierarchy and horizontal organizations are closely integrated and integrated through information technology [35].

## 5. Operation Logic of Urban Smart Governance Information Platform

**5.1. Functional Module of Information Platform for Urban Smart Governance.** Urban smart governance is the reform and innovation of traditional government governance under

FIGURE 4: “Power-sharing linkage, one-center and dual-track” platform construction command system.

the framework of smart city construction. Gil-Garcia et al. [6] believed that with the help of modern information technology development, smart governance has made creative breakthroughs in government strategy and investment to make governance sustainable and flexible. On this basis, the Smart Information Platform of Urban Governance aims to bridge the islands of information formed by the decentralized storage and management of departments and to form a computer room, a server cluster, a network, and a data center to realize big data collection, access, integration, management, application, and release. Based on the data center, the smart information platform will command and coordinate administrative affairs and urban operation monitoring (Table 1).

## 5.2. Operational Logic of Urban Smart Governance Information Platform

### 5.2.1. Data Integration

(1) *Data Integration.* Driven by the rapid development of information technology, big data has been integrated into people’s lives; it has not only profoundly changed the political-ecological environment of cities but also promoted the transformation of democratic politics from passive participation to active participation. Every governance body is the source of data, and fairness for actors is based on the deep

integration of networks and data. In view of democracy, Decker [36] regarded big data as a “disruptive innovation.” Democratization of data has been quietly taking place, and government construction will develop towards efficiency, innovation, and transparency.

As shown in Figure 5, the platform integrates urban infrastructure, resources, the environment, municipal management, and commerce into a holistic system through the analysis and sharing system and the application of intelligent delivery, communication, Internet, and data processing technology. In addition, it forms a data center through the Internet, cloud computing, data discovery and analysis, and other technical means and constructs subsystems, such as the urban population, transportation, energy, trade, telecommunications, and environmental resources, to perceive, transmit, process, and share data intelligently in the urban system. Urban governance can realize the real-time exchange of data from the system according to different permissions; this enables the quick coordination and arrangement of resources to make governance decisions that allow a harmonious and sustainable city and enable an effective response to unexpected urban security issues.

(2) *Data Collection.* Deutsch [37] explained that information communication is as important to the government as nerves are to the human body. The collection and processing of social information and data assist the government in making scientific and efficient decisions, and the exchange of information inside and outside the system promotes the sustainable operation of government work. Based on the current situation of China’s urban governance transformation, it is recommended that two halls and two centers be adopted as the concrete means of smart governance. It will serve administrative examination and approval of items to achieve the objectives of one window of acceptance, interconnection, and information sharing and to carry out two goals (100% online declaration and 100% online approval). Similarly, the platform is used to reform the administrative system (Figure 6).

All-natural persons, legal persons, and other entities have unique identifiers. That is, legal persons and other organizations have a unified national ID code so that government affairs can be handled with one code, which is conducive to improving the management level of public administration, reducing transaction costs, and improving social work efficiency (Figure 7).

Paperless offices, electronic declarations, and approval are implemented in the process of providing administrative services. For example, when a legal person declares matters, government staff actively search and check the certification materials through the database of the government service exchange platform to avoid trouble for the applicant and to prevent the need for a large amount of paper-version materials and certificates, as shown in Figure 8. The further development of information technology and urban management models is expected to further expand the coverage and efficiency of online services. “More data and less public running” will no longer be a slogan but will be gradually realized in more fields in the future.

TABLE 1: The functional module of information platform for smart urban governance.

| Data integration  | Public affairs allocation processing   | Urban operation monitoring   |
|---|--|--|
| (i) Data acquisition<br>(ii) Real-time data input<br>(iii) Data integration and management<br>(iv) Data applications and services | (i) Network management and unified distribution and disposal center<br>(ii) Three steps: first time to find, first time to deal with, first time to solve<br>(iii) Two separation: patrol separation and handling separation<br>(iv) Five systems: comprehensive inspection, diversified participation, intelligent governance, scientific law enforcement, good credit construction | (i) Government affairs operation monitoring<br>(ii) Urban safety operation monitoring<br>(iii) Economic operation monitoring |

5.2.2. Allocation Processing of Public Affairs

(1) *Basic Framework of Distribution Processing Operation.* Although unprecedented social changes have effectively promoted the progress of urban development, they have also created contradictions and challenges at the critical stage of city transitions. To solve different problems efficiently, unified scheduling and distribution processing are needed. The Smart Allocation Processing Platform, based on the principle of separation of inspection and treatment, uses GIS, remote sensing, apps, and other information technologies to realize smart governance for administrative affairs. As shown in Figure 9, the closed-loop processing

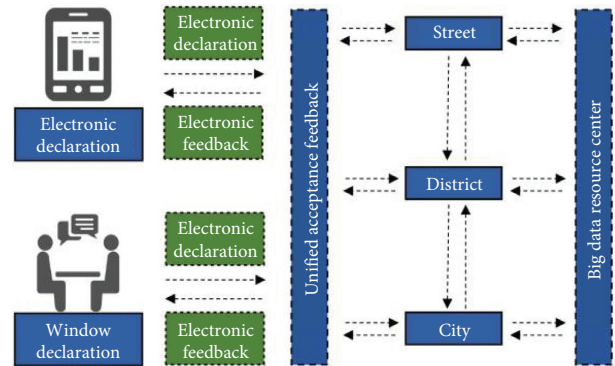

FIGURE 8: E-government service framework and operational logic.

mechanism of “event collection, allocation, disposal, verification, evaluation, and settlement” is formed to establish the information support capability for first-time discovery, first-time disposal, and first-time solutions for urban governance events to promote the refined and scientific development of social governance. The whole operation design combines service classification, spatial information service chain, workflow, and other technologies to ensure clear business logic and convenient operation of transaction processing according to a specific business logic.

(2) *Support System for Allocation Processing Operation.* Relying on the Smart Information Platform of Urban Governance, urban governance areas are divided into community cell grids according to certain standards to form grid governance. Through the inspection and monitoring of

FIGURE 9: Smart distribution processing operational framework.

the community cell grid, unified scheduling, allocation, and disposal, the form of separation of supervision and disposal is established.

Comprehensive inspection forms a comprehensive and professional patrol team at the street level. Through a comprehensive patrol in which one person is in charge of one space and a professional patrol in which one person is responsible for a large patrol network, the whole coverage patrol is formed to identify problems for the first time. This can achieve the target of proactive discovery and timely treatment to improve governance efficiency and solve urban problems in the germination stage. Diversified participation means actively mobilizing the wide participation of society, such as NPC Members, Party Deputies, CPPCC Members, retired cadres, volunteers, and residents' representatives, to enrich the forces for large-scale inspection and renovation. Intelligent governance, the "brain" of urban governance, aims to strengthen the operation and application of digital management means such as data integration, operation monitoring, distribution processing, and collaborative command in the grid management system to integrate all relevant data on people, events, and objects into the system. In addition, it will strengthen commands with big data technology to achieve instantaneous distribution and real-time processing. Scientific law enforcement, forming strong synergy through self-inspection by enterprises, government supervision, and law enforcement investigations to focus on solving problems at the first line, will continue to improve and reform the law enforcement mechanism. Good credit construction, the foundation of management and control, will strengthen the data application of grid management and integrate the credit records of enterprises and individuals into a united credit database and achieve the first correlation in the application and approval of administrative matters. In

this way, each responsible subject is forced to fulfill its own responsibilities (Figure 10).

**5.2.3. Urban Operation Monitoring.** Due to the influence of multiple factors of physical society and virtual society, cities in the information age are faced with increasingly complex unexpected events, and city operation and management are also facing great challenges. As governments attach increasing importance to data governance, they should consider how to change decentralized data management into comprehensive data management using a unified structure, organization, and process. Accordingly, the management and service mechanism using data for decision-making, management, and services will be formed. Urban operation monitoring and early warning play an important role. The application of the Smart Information Platform of Urban Governance in urban operation monitoring will directly or indirectly affect the processes and results of emergency management. The concept of deep integration of technologies such as the Internet of Things, big data, cloud computing, and spatial geographic information technology with business domains of comprehensive emergency management has been accepted and recognized by many municipal governments and academics in China. As shown in Figure 11, City Operational Visualization is the exhibition of real-time situational awareness, collection, sharing, and information about multidimensional interagency collaboration for emergencies and responses to events. This will connect relevant departments, agencies, and command centers at all levels of the emergency response to realize the communication and sharing of real-time situation information in order to ensure joint responses and coordinated emergency responses and to

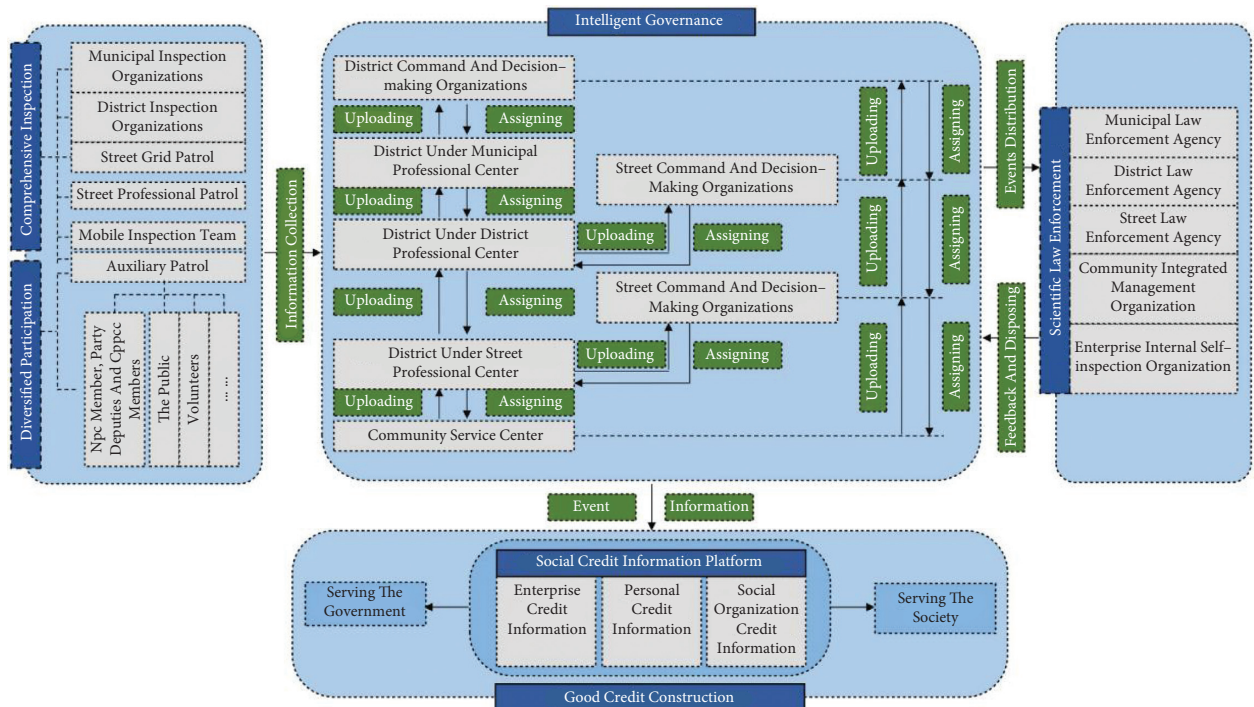

FIGURE 10: Smart distribution processing operational support system.

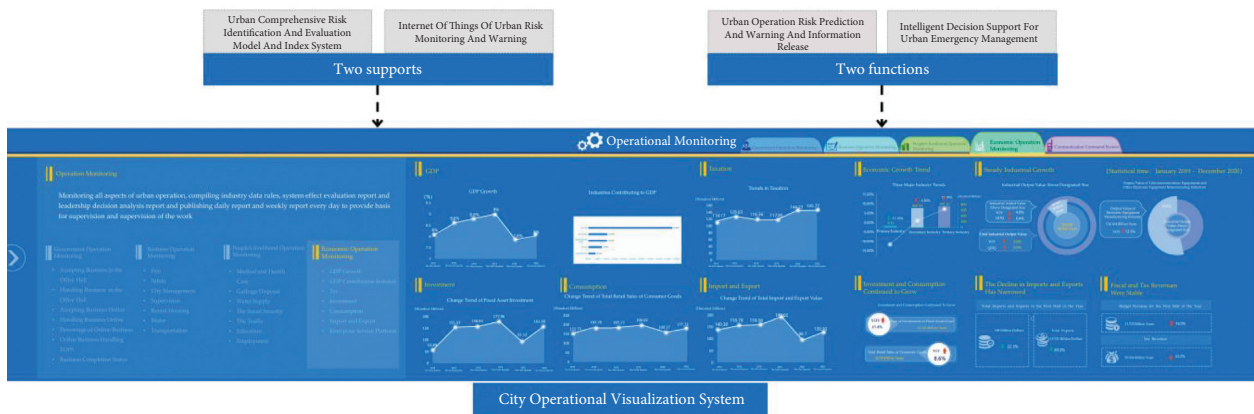

FIGURE 11: City Operational Visualization system.

realize the sharing of emergency resource information and visual command.

Two major supports are as follows:

**Urban Comprehensive Risk Identification and Evaluation**

The risk evaluation model and index system of government affairs, city safety, the economy, and other fields of operation will be established to realize the risk evaluation and analysis of a single field. Hence, machine learning and other technologies are used to continuously learn and train real-time data to realize the automatic optimization of risk analysis models and

intelligent risk prediction. Finally, risk prevention and control measures will be generated automatically.

**Internet of Things of Urban Risk Monitoring and Warning**

The monitoring and early warning system covering all levels, services, and processes in urban governance through the Internet of Things will be constructed. The most significant goal is to strengthen the monitoring areas closely bound to people’s lives, such as urban lifelines, traffic, the environment, flood prevention, and fire control and develop comprehensive application systems for monitoring urban operational signs, risks and hidden dangers, risk assessment,

prediction, and early warnings in order to provide application support for various subjects of urban governance.

Two functions are as follows:

#### Urban Operation Risk Prediction and Warning and Information Release

Artificial intelligence and other information technology are used to achieve higher government efficiency and the scientific analysis of disaster development trends, accident impacts and consequences, economic operations, and so on. First, the early-warning information from various departments will be integrated and strengthen the research and application of precise early-warning release technology to realize the targeted release of urban operation. Second, different responses to early warning persons and the public should be used, and innovation should be developed in the mechanism of early warning information release. The channel of early warning information release should be unblocked, and the effectiveness of early warning information transmission should be improved.

#### Intelligent Decision Support for Urban Emergency Management

According to the types and evolution trends of urban operation emergencies, this paper conducts in-depth mining and analysis of relevant data under multisource data fusion technology for event information and relevant cases to intelligently provide decision-making support for emergency event disposal.

**5.3. Operational Performance Evaluation Mechanism.** Evaluating the process and results of urban governance based on the Smart Information Platform for Urban Governance is important for promoting the modernization of urban governance in the new era. This platform can quickly process acquired data and realize the sharing and linkage of real-time data. It provides the possibility for relevant subjects of urban governance to supervise, evaluate, provide timely feedback, and adjust the content of urban governance. Moreover, the efficient, scientific, and credible modern system of urban governance must rely on the establishment of a performance evaluation mechanism.

On the one hand, the establishment of a sound performance evaluation mechanism can give full play to the external evaluation and supervision role of society and the public in urban governance to adjust governance decisions and to improve government credibility. At the same time, it can improve the sense of participation of social organizations and the public as the main body of urban governance and stimulate the enthusiasm of social organizations and the public [38].

On the other hand, a perfect performance evaluation mechanism can improve the scientific level of urban governance and guarantee the effectiveness of the platform. Due to the real-time and rapid characteristics of information means, policy feedback is timely and convenient for the timely adjustment of urban governance policies and means to make decision-making more scientific and accurate. At

the same time, the serious consequences of decision-making mistakes need to be reduced or prevented.

Therefore, in the era of smart urban governance, it is necessary to build a scientific and perfect performance evaluation mechanism and to build a performance evaluation system during the construction of the Smart Information Platform for Urban Governance to ensure the smooth progress of modernization of urban governance and make urban governance more scientific, more refined, and smarter. Meanwhile, the data resources of various intelligent systems are integrated to analyze the occurrence characteristics, trends, and changes in events. Various kinds of data will be adopted to perform a comprehensive evaluation of the work efficiency of inspection and rectification, to supervise abnormal situations in specific event handling processes, and to provide reference data for the evaluation and evaluation of inspectors.

**5.4. Experimental Results and Analysis.** Table 2 and Figure 12 show the results of 6 sets of data during the work process of the platform's database under the network traffic prediction. According to Table 2 and Figures 12–15, the horizontal axis  $N$  represents different flow data lengths, and the vertical axis  $R$  represents the calculated complex rate.

We can know that in the 5 sets of data, due to the different processing speeds of different types of data, the method based on the combined model of machine learning and neural network is better in terms of accuracy. In terms of computational complexity, we propose an optimization algorithm based on neural network. The complexity of the traffic prediction system is lower, and the difficulty of condition tracking is also lower.

It can be seen from the results that the accuracy of the model proposed in this paper is 0.984, 0.966, 0.967, and 0.932 in terms of data analysis and information extraction. Compared with 0.875, the accuracy of this model can be greatly improved.

On the other hand, in the process of 5 sets of experiments, it can be found that with the different number of experiments, the error of the experiment also shows a regular change, that is, the more the number of experiments, the smaller the prediction error.

## 6. Research and Analysis

### 6.1. Suggestions on Application and Construction of Urban Intelligent Management Platform in China

**6.1.1. Realizing Platform Building and Data Sharing from Top to Bottom.** It is the integration of many data chains within the city that are really concerned about the data links between different departments. Therefore, the construction of the whole platform must be led by the city managers, from top to bottom to strengthen department cooperation, government enterprise cooperation, and government people interaction. Based on the connotation of urban operation and development and urban management, the complete logic chain from macrocontrol to microgovernance is sorted out, and various complex problems involved in urban

TABLE 2: 5 sets of experimental data results.

| Enterprise   | Data 1 | Data 2 | Predicting fit (%) |
|--------------|--------|--------|--------------------|
| Enterprise 1 | 93     | 97     | 87.5               |
| Enterprise 2 | 94     | 94     | 93.2               |
| Enterprise 3 | 89     | 83     | 92.1               |
| Enterprise 4 | 93     | 98     | 96.7               |
| Enterprise 5 | 92     | 97     | 96.6               |

FIGURE 12: Image output of 5 sets of experimental data results A.

FIGURE 13: Image output of 5 sets of experimental data results B.

management are collected to realize intelligent perception and event response through the platform. The construction of the platform is the work of coconstruction and sharing of multidepartments and social institutions. On the basis of

FIGURE 14: Image output of 5 sets of experimental data results C.

“data fusion,” the decision-making of each department needs to comprehensively consider the data and work of relevant departments, and the multiobjective comprehensive decision-making across departments can be realized through data sharing.

**6.1.2. Effectively Improving Data Quality through Data Governance.** The value of data governance lies in standardizing information transmission between systems, improving data quality, and improving the level of data sharing and sharing between business and systems. Scientific data quality rules should be established, and data quality management should be run through all aspects of platform construction and use to meet the needs of business operation and management analysis. Meanwhile, data redundancy and infrastructure investment in storage, hardware, operation, and maintenance should be reduced to improve application system performance and reduce the burden of later maintenance. For some sensitive data, the data items should also be divided into specific sensitive levels, and according to this level, the data items can be properly protected in the whole life cycle, and the protection of residents’ privacy data and key urban infrastructure should be strengthened.

**6.1.3. Designing Scientific Urban Operation Monitoring Index System.** The construction of urban operation monitoring index system should follow the principles of importance, guidance, and systematicness. The selection of indicators should be in line with the urban development strategy and social governance objectives and closely related to the scope of responsibility of urban managers; the construction of the index system must be based on the accurate understanding and linkage analysis of urban governance system, department business, social institutions, and related disciplines, so as to achieve effective coordination among

FIGURE 15: Image output of 5 sets of experimental data results  $D$ .

departments and minimize the negative effects and external costs of work.

#### 6.1.4. Building Clear and Practical Application Scenarios.

The application scenarios of urban intelligent management platform should be able to quickly show the city operation status and display the data change trend through the “one plug to the bottom” data granularity and space-time coordinates, so as to effectively support urban management decision-making. The real-time monitoring of abnormal points should be clear at a glance, and the analysis function should be provided according to the needs of users to help them accurately determine the causes of abnormal information. The simulation of urban development scenarios is also one of the government’s key needs for platform capability. Supported by the complex background model, it simulates the development of the city and society, providing the basis for evaluation and decision-making. On the premise of meeting the content, the application scenario design should be clear and concise, the operation function should be simple and practical, and it can provide appropriate personalized customization according to the needs of users and can be used anytime and anywhere by portable devices.

**6.2. Research Contribution.** Technological change and innovation promote the full integration of ICT into the system of political power and urban governance. The superposition and combination of technological elements and other elements are a strong driving force of reform, which has become the catalyst for the development and progress of modern society in China. Wherever it goes, the original power structure system will be deeply changed and form a unique logic of technological governance and development.

Specific technologies and specific governance goals and trends are closely linked to promote the mutual service and promotion of urban governance and information technology in a new and radical way [39]. In this paper, emerging Internet technology and urban governance are integrated for achieving smart urban governance, reengineering business processes, and transforming institutional advantages into governance efficiency.

**6.2.1. Improving Social Equity and Social Order.** The core concept of smart governance is people-oriented, and data-oriented instrumental rationality coexists with humanistic care. The transformation of urban governance from extensive management to precision governance will be promoted by this platform to improve the accurate supply capacity of various public services. Relying on big data acquisition and mining technologies, this platform can seize the demand characteristics of the public, enterprises, and other organizations and improve the matching, precision, and validity of governance to satisfy increasingly diversified and personalized demands and realize the public service of active response to the supply side. In no way does this paper propose conducting urban governance through methods other than science. The research of this paper is based on the existing social system, organizational structure, and urban problems. The famous scholar Hu [40] once pointed out sternly, “We do not deserve to reject science under the background of the chaotic altar monastery, underdeveloped communications, underdeveloped industry.” There is no reason to reject science and technology in China in the present study and application, and even in urban governance, there should not be a one-sided emphasis on the human elements. Instead, we should construct the contemporary value order by means of technology, paying attention to the survival status of all social strata so that the

public can truly share the fruits of development and the problem of social equity can be solved.

**6.2.2. Promoting Social Democracy and the Rule of Law.** It is necessary to establish the operation rules of government data, rebuild the operation rules of government affairs, and reform government institutions and before applying the platform to meet the system and business process requirements of smart urban governance. In this way, the modern urban governance mechanism of adopting data to make decisions, manage public affairs, and innovate will be constructed to adapt to the demand of smart urban governance. Through the integration of business, technology, and data, the government will reshape the government process, organizational structure, functional positioning, and responsibilities, break down organizational and information barriers, and improve the government's governance capacity and public service quality [41]. The platform will work with the new system to promote the participation of all citizens in urban governance to objectively promote the application of democracy. The extensive participation of the public in governance can pool the wisdom of the public to the greatest extent in order to improve the scientific nature of urban governance and establish good governance in the actual urban governance practice that conforms to the fundamental interests of the public.

**6.2.3. Building a Chinese Sample of City Governance.** It is indispensable to improve the efficiency of urban governance in the information age by ICT. The application of the urban smart governance information platform will be conducive to improving the efficiency of government operations, promoting economic development, social governance, and cultural development, and enabling all of society to run like clockwork. The application of the platform, which conforms to the transformation trend of urban governance in China, will set a governance example for Chinese cities.

**6.3. Discussion.** The smart governance concept further promotes the city governance path of innovation. The urban smart governance information platform, an effective means of implementing intelligent management, will constantly improve the management network at the city, district, street, and community levels in practice to form a unified intelligent information platform for the governance of the whole city. Platform governance includes matters in various areas of urban social life and information on people, places, things, events, and organizations within the jurisdiction into the database management. The establishment of a long-term mechanism for data updating and the realization of dynamic monitoring and management should be established to discover and process problems in a timely manner; this enables effectively realizing the government's public management and services to social units. However, it needs to be emphasized that the formation of any urban order cannot be achieved without the participation of people. It is difficult for the government to form a flexible order by means of strong

administrative regulation or wishful planning. Urban governance transformation must be built and operated under the guidance of a people-oriented concept, gathering diverse subjects and various social forces and jointly promoting the modernization of the urban governance capacity.

## Data Availability

The raw/processed data required to reproduce these findings cannot be shared at this time as the data also form part of an ongoing study.

## Conflicts of Interest

The authors declare no conflicts of interest.

The green development level reflected in the green finance index and the evaluation of the degree of green development in smart cities have important practical effects on economic transformation. For promoting the transformation and upgrading of finance, we select 2013–2019 data and construct a distributed lag model to analyse the important role played by green finance and financial technology in the construction of smart cities. In the paper, we find green finance promotes the construction of smart cities, and only it will not appear until nine months late. Financial technology has an opposite impact on the construction of smart cities, this is mainly because the research and marketization of financial technology are higher, and the cost is also higher. This influence will appear in the next 14 months.

## 1. Introduction

The severe destruction of the global ecological environment is accompanied by the rapid development of the global economy. Therefore, many countries attach great importance to achieving “green growth” of their economies while vigorously developing their economies. The green upgrading of traditional industries and the growth of strategic green emerging industries require the effective empowerment of the financial sector, and the supply of green physical industries by the financial sector is a significant manifestation of green finance. Finance is the core of the modern economy. If we want to promote the economy, we must develop high-quality finance and use finance to avoid economic uncertainty. For China’s current development, green finance is the way to circumvent this uncertainty and is an important driving force for promoting supply-side structural reforms. The green development level reflected in the green finance index and the evaluation of the degree of green development in a region have important practical effects on economic transformation, reducing investment risks, and

helping traditional enterprises improve their sustainable development capabilities.

Fintech refers to financial innovation brought by new technologies. It can create new business models, applications, processes, or products, which has a significant impact on the way financial markets, financial institutions, or financial services are provided. The business scenarios where technology and finance are combined mainly include financial supervision, payment settlement, financing products and services, insurance, smart investment advisory, and energy trading. The underlying technologies include artificial intelligence, blockchain, cloud computing, big data, and the Internet of Things. In the global sustainable financial development process, financial institutions and fintech companies in various countries in the world, especially in Europe, the United States, and China, have tried to integrate fintech and financial technology by actively using blockchain, artificial intelligence, big data, and the Internet of Things, combining green finance to carry out green finance technology exploration and practice.

Smart cities are inseparable from the joint construction of all sectors of society. In the financial field, the close cooperation of the banking industry is required. With China's rapid economic and social development, the production and life of urban residents can no longer be separated from financial activities, and letting the development of financial technology benefit each inhabitant is an important part of the construction of a smart city. Correspondingly, in the era of the mobile Internet, technological means have fundamentally restructured people's behaviour habits, and banks must also change the financial services they provide in time. The construction of smart cities has been closely integrated with the development of banks. The People's Bank of China has repeatedly called on commercial banks to continuously strengthen the innovative use of financial technology to inject new vitality into urban construction. Local governments have also actively sought to cooperate with banks. The cooperation between the government and the bank has made great progress in various fields such as people's livelihood, education, and public utilities.

The specific contributions of this paper include the following:

- (1) A literature survey about various existing distributed lag models and analysis of their advantages and disadvantages.
- (2) An effective distributed lag model for green finance and fintech in the smart city is proposed.
- (3) It can be seen that there is a relatively obvious correlation between the two in the seventh lag and the twelfth lag, indicating that the two models are affected to some extent by other common variables.

The rest of this paper is organized as follows: Section 2 discusses related work, followed by the empirical analysis in Section 3. Estimation of parameters for smart cities by green finance is discussed in Section 4. Section 5 shows the discussion of the distributed lag model empirical results. Section 6 concludes the paper with a summary and future research directions.

## 2. Related Work

In foreign studies, green finance is also known as environmental finance, which is a definition of financial greening derived from environmental issues and the need to promote sustainable development. From an economic point of view, environmental issues have significant externality characteristics, which can produce positive externalities and negative externalities. Related theories include externalities, Coase's theorem, government intervention, and Pareto improvement. The development of green finance has a driving role in environmental protection, energy conservation and emission reduction, and sustainable development, so it will bring good external effects. However, good external effects directly lead to higher costs for financial institutions to implement green finance, which ultimately leads to a lack of incentives and insufficient effective supply

for the private sector to implement green finance, and it is almost impossible to achieve Pareto optimal asset allocation.

Green finance is to support sustainable development, that is, sustainable finance; it is a path of innovation in finance in environmental protection, and it is a link between the financial industry and the environmental industry [1]. Green finance is a financial tool based on market research to improve environmental quality and transfer environmental risks. As a method and means to promote sustainable development, green financial services have become the mainstream trend of financial development. Although the concept of green finance is widely recognized, it lacks a complete evaluation system, which makes it slow to develop. Some scholars have established evaluation index systems to analyse the performance problems of bank green service channels in operations and use real data from well-known banks. Based on the evaluation and analysis of their sustainable development concept and specific practices, they constructed a five-dimensional index evaluation system. Through a series of studies, it was found that although the cost of implementing the "equatorial principle" is higher, the credit risk generated by loans is lower [2-4].

The international understanding of green finance can be roughly divided into two categories: the first category regards green finance as investment and financing activities that improve the environment, that is, green investment. The starting point of this understanding is to "make up the investment gap" [2]. Another type of understanding directly incorporates environmental factors into the field of financial investment, including changes in environmental costs, changes in risk coefficients, and changes in returns and returns caused by engaging in business. It is believed that the development of green finance is based on the mutual constraints between finance and the environment [5]. For example, green finance incorporates environmental factors into financial services, such as bank investment or reception decisions, postloan monitoring, and participation in environmental assessment during risk management [6]. The above two categories are both different and related.

Over time, overseas scholars have also elaborated a series of issues in the development of green finance. Further analysis shows that the return on investment of such funds is longer with the cycle, and the overall investment income is not worse than other mutual funds.

Fintech is a modern concept and so far, no unified definition has been formed. However, in 1993, the term "fintech" appeared in the relevant report of Citibank. Attempts to enable technology to finance have gradually begun, and it has been intensified with the increasing enrichment of Internet financial practices and the continuous upgrading of the transformation of the financial sector. It can be said that fintech has quietly integrated into people's lives before society has realized it. The Financial Stability Board (FSB) believes that fintech refers to technological innovation that can significantly affect financial markets, institutions, and services and is mainly accomplished through innovative business models, application methods, process methods, and product types.

The definition of fintech has been gradually clarified in continuous research. Most scholars define fintech as a technological solution that can realize the transformation of the financial service industry. They believe that fintech is a new industry that uses technological innovation to improve the quality of financial services. Science and technology are a disruptive emerging financial industry. It mainly uses digital and information technology to achieve innovation in the existing economic model [7, 8]. In summary, fintech refers to financial innovation driven by technological innovation. Through the deep integration of finance and technology, big data, blockchain, artificial intelligence, and cloud computing are the main technical support, which has changed financial business processes. And business models challenge traditional financial thinking. Fintech has given impetus to various industries in finance-related fields by expanding the service boundaries of financial institutions and improving service methods while increasing financial efficiency and while minimizing risks [9–11]. However, fintech cannot be simply understood as the superposition of the two. It is more a process of gradual integration and deepening of emerging technologies and financial services to continuously promote the transformation and upgrading of traditional financial services.

The definition of “smart city” comes from the vision of “Smart Earth.” IBM released the theme report of “Smart Earth: Next Generation Leadership Agenda” in New York in 2008. The report mentioned “Smart Earth,” which actually refers to the full use of IT technology and sensors in various industries to embed in hospitals, power grids, railways, bridges, tunnels, highways, buildings, and other objects in the corners of the world, connect various objects to form the Internet of Things, then integrate the Internet of Things with the Internet, and finally use supercomputers and cloud computing to integrate the Internet of Things.

The construction of a smart city is not a process with clear boundaries, so there is no unified interpretation of its concept. The concept of early smart cities is mainly related to the operational functions, management, and planning efficiency of smart technology solutions in energy, transportation, physical infrastructure, distribution and communication networks, economic development, and service delivery. With the development of smart cities, more and more emphasis is placed on the use of information technology to achieve the purpose of urbanization, and a definition of a focused and operable smart city is gradually given. Invest in social capital, traditional, and modern communications infrastructure to promote sustainable economic growth and high-quality living, and wise management of natural resources. Emphasize the role of information technology. Think of smart cities as transforming productivity, to achieve the prosperity of the city and benefit the people [12–15]. Some scholars have begun to define smart cities from the perspective of the Internet. They believe that smart cities are a complex system containing multiple visions [16, 17]. Recently, with the development of information technology, more and more foreign scholars have begun to focus on sustainable development incorporating into the concept of smart cities, emphasizing the

improvement of environmental issues through technological development.

In addition, scholars have also made related research on smart city assessment. From different perspectives, they built innovative cities, regional green cities, quality of life, digital government, and so forth as evaluation indicators and carried out evaluation work on smart cities in different countries around the world [18] to promote the sustainable development of smart cities. Later, scholars carried out evaluations of smart city performance, proposed models for measuring smart city performance, and conducted empirical research.

Fintech itself is based on “science and technology,” its purpose is to promote the transformation and upgrading of finance, and it is an important force to promote the development of green finance [19]. This study explores the impact of finance on the construction of smart cities from an innovation-driven perspective and analyses the important role played by green finance and financial technology in the construction of smart cities.

### 3. Empirical Analysis

*3.1. Data Source.* The starting year of the time series data selected in this article is 2013 because 2013 is called “the first year of Internet finance.” In the study of green finance, fintech, and smart cities, this article selected seven-year data from 2013 to 2019, which can more clearly rely on the latest year’s data to understand the specific impact between the three [20]. The data are constructed through an index system. Green finance indicators include seven aspects: green credit, green bonds, green development funds, green insurance, green stocks, green investment, and carbon finance. The city index is constructed from four perspectives: smart technology, smart economy, smart society, and smart environment.

*3.2. Model Setting and Identification.* Since the independent and explanatory variables involved in this study are time series data, the structure of a commonly used linear regression model is as follows:

$$Y_t = C + \sum_{i=1}^k \beta_i X_{it} + \varepsilon_t, \quad (1)$$

in which  $Y_t$  is the time series of the dependent variable,  $X_{it}$  is the time series of the  $i$ -th independent variable,  $\varepsilon_t$  is the random disturbance term (disturbance term), and  $C$  is the constant term. In order to use the least square method (ordinary least square) for estimation, it is usually assumed that the random perturbation term and independent variable are independent of each other, and the random perturbation term is independent and identically distributed. However, the above model itself and the basic assumptions about the random perturbations have three problems: they ignore the lag effect of the independent variables, cannot handle the autocorrelation of the perturbations, and are misleadingly related [21].

In view of the above problems, this article considers the use of the dynamic regression model (dynamic regression) and introduces the lag term in the initial dynamic regression model [22]. According to the different representations of the lag term, there are two kinds of dynamic regression models: Linear Distributed Lag Model (LDL) and Rational Distributed Lag Model (RDL) [23]. Since the actual data has only a limited number of data samples, it is not possible to directly estimate the parameters of the LDL model. So this research uses the RDL model; the specific expression is as follows:

$$Y_t = C + \frac{\omega(B)B^b}{\delta(B)}X_t + \varepsilon_t = C + \frac{(\omega_0 + \omega_1 B + \dots + \omega_h B^h)B^b}{1 - \delta_1 B - \delta_2 B^2 - \dots - \delta_r B^r}X_t + \varepsilon_t. \quad (2)$$

The RDL model can describe more complex changes in impulse response weights through the combination of multiple backshift operators, thereby better fitting the data, in which  $B^b$  is used to reflect the dead time, that is, the time interval when the independent variable starts to affect the dependent variable;  $\delta(B)$  represents the Decay Pattern; and  $\omega(B)$  reflects the absence of the impulse response weight.

This article will use the Box–Jenkins dynamic model construction strategy, namely, model identification, parameter estimation, and model diagnosis [24]. When the Box–Jenkins dynamic model construction strategy is officially started, according to the actual operation experience, the following preprocessing tasks will be performed on the original data in order, which will help the subsequent modelling process to proceed smoothly [25].

- (1) Perform differential processing on the independent and dependent variable sequences and convert them into stationary sequences  $\{X'_t\}$  and  $\{Y'_t\}$ .
- (2) Prewrite independent variable sequence to obtain the perturbation sequence  $\{a_t\}$  of the autoregressive moving average model (hereinafter referred to as ARMA model) of the independent variable sequence, which is a white noise process; its ARMA model is as follows:

$$a_t = C + \frac{\varphi(B)}{\theta(B)}X'_t. \quad (3)$$

- (3) Apply the filter expression obtained in (2) to the dependent variable sequence to obtain another sequence of perturbed terms. The process is as follows:

$$\beta_t = \frac{\varphi(B)}{\theta(B)}Y'_t. \quad (4)$$

- (4) Calculate the cross-correlation function of the sequences  $x$  and  $y$  (hereinafter abbreviated as CCF), and perform a Ljung–Box population test on the given number of lag terms  $k$ . If the null hypothesis is rejected, explain the first  $k$  lags of the independent

variable sequence. At least one of the terms has a significant nonzero correlation with the dependent variable; that is, the independent variable has explanatory power to the dependent variable and should be added to the RDL model.

Firstly, clarify three key parameters in the polynomial ratio form of the impulse response function—the molecular polynomial order  $h$ , the dead time  $b$ , and the denominator polynomial order  $r$ .

Secondly, the ARIMA model expression of the perturbation term is as follows:

$$\varepsilon_t = \frac{\Theta(B^s)\theta(B)}{\Phi(B^s)\varphi(B)}\nabla_s^D \nabla^d a_t, \quad (5)$$

in which  $a_t$  is a normally distributed white noise with a mean of 0 [26].

This paper chooses the linear transfer function method (the LTF method) to complete the entire model identification task. The LTF method requires the establishment of the following free-form distribution lag model (the FFDL model):

$$Y_t = C + v_0 X_t + v_1 X_{t-1} + \dots + v_k X_{t-k} + \frac{1}{(1 - \varphi_s B^s)(1 - \varphi_1 B)} a_t, \quad (6)$$

in which  $k$  is the number of lag effect terms chosen arbitrarily, generally the values that can be considered are  $-5$ ,  $10$ ,  $15$ , and  $20$ , and  $k$  is selected in this paper; for the disturbance term, this paper chooses a low-order autoregressive model (the AR model) to improve the accuracy of impulse response weight estimates. In the presence of seasonal effects, the AR (1) can usually be considered [27].

**3.2.1. Model Estimation.** After the model recognition task is completed, the following complete model expression can be obtained:

$$Y_t = C + \frac{\omega(B)B^b}{\delta(B)}X_t + \frac{\Theta(B^s)\theta(B)}{\Phi(B^s)\varphi(B)}\nabla_s^D \nabla^d a_t. \quad (7)$$

**3.2.2. Model Diagnosis.** Then, perform a maximum natural estimation on (6). It should be noted that both  $\{X_t\}$  and  $\{Y_t\}$  are sequences that satisfy weak stationary after performing the difference.

**3.2.3. Model Comparison.** In the process of model identification, there may be multiple candidate models. If multiple models are diagnosed through the model, they will face the problem of choosing between multiple models. There are two commonly used criteria for model comparison: Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC). The definition formula of AIC is as follows:

$$\text{AIC} = n \log(\hat{\sigma}^2) + 2M, \quad (8)$$

in which  $M$  is the number of parameters in the model,  $\hat{\sigma}^2$  is the maximum likelihood estimate of the variance of the disturbance term, and  $n$  is the amount of data. The definition formula of BIC is as follows:

$$\text{BIC} = n \log(\hat{\sigma}^2) + \log(n)M. \quad (9)$$

From the above definitions, when the amount of data is large ( $n > 10$ ), compared with the AIC criterion, the BIC criterion will impose a larger penalty term on the amount of model parameters. According to the Principle of Parsimony of model selection (Principle of Parsimony), this article will use BIC as the selection criterion—the model with the lowest BIC value is optimal.

**3.2.4. Construct LTF Model and Specify RDL Model Parameters.** Specify  $K$  as 20 and the perturbation term is approximated by a low-order AR model. Figures 1 and 2 show the changes in the impulse response weights of the two independent variables.

As can be seen from Figure 1, the three key parameters of the green financial independent variables in the RDL model are  $b = 4, r = 0, h = 0$ . The impulse response weight only slightly exceeds the threshold. As can be seen from Figure 2, the parameters of the RDL model part of the fintech independent variable are  $b = 14, r = 0, h = 0 + 1 - 1 = 0$ .

Figure 3 shows the residuals SACF and SPACF exhibit white noise characteristics, so the disturbance term partially retains the AR (1) model.

## 4. Results

### 4.1. Model Estimation

**4.1.1. Estimation of Parameters for Smart Cities by Green Finance.** According to the parameters specified in the model identification stage, the parameters of the RDL model are estimated based on the maximum likelihood estimation method. The results are shown in Table 1.

As can be seen from Table 1, the seasonal part of the disturbance term is not significant, and the molecular polynomial parameter of the independent variable part of RDL is not significant, so try to specify another set of alternative parameters:  $b = 9, r = 0, h = 1 + 0 - 1 = 0$ . The estimated results of the revised RDL model are shown in Table 2. It can be seen from this that each parameter passed the significance test.

According to the parameters specified in the model recognition stage, the parameters of the RDL model are estimated based on the maximum likelihood estimation method. The results are shown in Table 3. As can be seen from the figure, the seasonal part of the disturbance term is not significant, and the parameters of the fintech independent variable part are not significant, so an alternative RDL model is selected. The estimated results of the revised RDL model are shown in Table 4, which shows that each parameter passed the significance test.

FIGURE 1: Impulse response weights for green finance.

FIGURE 2: Impulse response weight map of fintech.

**4.2. Model Diagnosis and Analysis.** The first step is to perform residual diagnosis on the RDL model. As can be seen from Figures 4 and 5, the residuals of the modified RDL model can pass the autocorrelation and normality tests.

The second step is to perform residual diagnosis on the independent variable ARIMA model. The results are shown in Table 5 and Figure 6. Table 5 shows that each parameter passed the significance test, and it can be seen from Figure 6 that IACF and PACF show that the residuals pass the autocorrelation test, but they are not white noise.

In the third step, a Ljung–Box test is performed on the two residual sequences CCF, and the result is shown in Figure 7. It can be seen that there is a relatively obvious correlation between the two in the seventh lag and the twelfth lag, indicating that the two models are affected to some extent by other common variables.

From the model estimation and diagnosis results, we can know that green finance has a significant positive impact on the construction of smart cities, and this impact will occur after nine months. Fintech has a significant negative impact

## 5. Discussion

The first is to innovate financial institutions and vigorously develop technology banks, technology microcredit companies, and financial leasing companies. On the premise of following the law of development of technology innovation, expand diversified financing channels, and, at the same time, use mechanism innovation as a driving force to strengthen internal incentives. Improve fair and objective assessment mechanisms and improve protection systems such as risk compensation. The second is to innovate financial products, efficiently use differential risk tolerance to support scientific and technological credit, promote high-yield bond and equity bond financing methods, and comprehensively promote intellectual property pledge financing and repayment. Innovation in financing methods: the third is innovative financing methods, breaking through the traditional service model of indirect financing, financial team and equity, and venture capital investment and loan linkage; the fourth is focusing on the development opportunities of Internet financial technology innovation, fostering "Internet thinking," and actively promoting "networks" "Process" model; creating Internet banking, high-quality service platforms, electronic banking, online revolving loans, and other IT banks; effectively solving the "gap" in funds faced by high-tech projects; promoting the output and diffusion of technological innovation; and promoting the development of information technology in smart cities.

The core of the development of green finance lies in financial intermediaries. The market's actual demand for green finance requires financial institutions to continuously improve their awareness of social responsibility and environmental protection, and carry out targeted green finance promotion and education for internal staff. When making business decisions, we must coordinate the relationship between social responsibility and self-interest. We must always consider environmental protection and sociality in daily operations. Strict environmental protection social responsibility runs through all daily business activities. The financial community must maintain the concept of developing green finance at all times. It must take a dialectical and unified view of the social responsibility and self-realized benefits of enterprises when they conduct green financial business and promote the development of green finance as a long-term strategy to operate, financial institutions. The government should actively carry out green finance publicity work, publicize the government's ideas and measures in developing green finance, and explain the positive changes that green finance development will bring to the lives and work of the general public. On this basis, companies can actively participate in promoting the development of green finance.

One of the major obstacles facing the development of China's green finance is the incomplete information sharing mechanism between different institutions in green finance and the problem of information asymmetry in different sectors, especially the financial and environmental protection sectors that are closely related to green finance. The information asymmetry between the two departments lays

hidden dangers for the occurrence of financial risks. Through the application of fintech, a green financial information database can be established between departments, thereby forming a stable communication and coordination mechanism and achieving information sharing between the two parties. At the same time, regulators can also use real-time tracking and monitoring of enterprises participating in green credit through the application of fintech and update related information in real time. In addition, a mature information disclosure system should also be established through the application of fintech, the disclosure procedures for financial institutions to provide green financial services to enterprises, the role of the public and groups in supervision, and the strengthening to cooperate with each other to create a system of vertical supervision and horizontal supervision.

## 6. Conclusions

Starting from the relationship between green finance, fintech, and smart city construction, this study selects data from 2013 to 2019 and uses a distributed lag model to demonstrate it. The following conclusions are obtained: first, green finance promotes smart city construction and green credit. The promotion effect of green financial indicators composed of seven aspects including green bonds, green bonds, green development funds, green insurance, green stocks, green investment, and carbon finance on the construction of smart cities will not appear until nine months later. The honey lake fintech index has verified that it has a reverse effect on the construction of smart cities through models. This is mainly due to the high cost of fintech research, marketization, and profitability, which hinders the construction of smart cities to a certain extent. The effect of this effect will appear after 14 months.

Classification and gradation system adopts different security protection schemes for different types of data by implementing classification and gradation management of data, which is an important pretechnical means for data security protection and prevention of data leakage. This paper introduces artificial intelligence classification, machine learning, and other means to learn and train enterprise documents according to the characteristics of enterprise sensitive data. The generated training model can intelligently identify and classify file streams, improving work efficiency and accuracy of classification and gradation. At the same time, the differences, advantages, and disadvantages of K-NN (K-Nearest Neighbors), DT (Decision Tree), and LinearSVC algorithms are compared. The experimental data shows that LinearSVC algorithm is applicable to high-dimensional data, with discrete, sparse data features and large number of features, which is more suitable for classification of sensitive data of enterprises.

## 1. Introduction

With the advent of Internet plus era, the status of data as a basic strategic resource has become increasingly prominent [1–3]. As network security threats become increasingly prominent, data face many security risks during storage, processing, and transmission. The challenges of management and monitoring which accompany it are increasingly severe [4, 5], so the establishment of a data classification and gradation system environment is the basic premise for the rapid development of enterprises [6, 7]. According to the results of data classification and gradation and the company's policy requirements, efficiently matching the collated data with security strategies is an important means for enterprises to improve their core competitiveness. For large enterprises, data security faces many problems and challenges. According to the international standards of information security [8], the importance of different data is different, and high-value data requires stricter protection mechanisms. Therefore, data is used as the security protection target, and the intricate enterprise data assets are divided into various categories and multiple levels according

to the classification and gradation method. According to the type and value of data, different protection strategies are formulated [9, 10], and the continuous strengthening and improvement of sensitive data security management have become more prominent and important.

At present, the state has promulgated laws and regulations such as the "Network Security Law of the People's Republic of China" [11], clearly stating that "network operators should comply with the requirements of the network security level protection system, perform the following security protection obligations to protect the network from interference, destruction, or unauthorized access, prevent network data from being leaked, stolen, or tampered," and "take measures such as data classification, important data backup, and encryption". The data combining work has the following problems. First, for the sensitive data of enterprises, due to the lack of strict management of the computer network by the managers and their lack of awareness of network security, it is easy for the computer to leak information, which causes a series of subsequent security risks to damage the computer network [12]. Second, most of the understanding of policies, regulations, and standards also

relies on manual combining. There is a possibility that the understanding and interpretation of policies, regulations, and standards may be artificially expanded or reduced. Third, at the same time, with regard to the characteristics of large data business types and large data volumes of large enterprises [13, 14], business personnel cannot quickly identify which sensitive data is based on standards, and the level of confidentiality corresponding to sensitive data is not easy to define. Therefore, establishing a classification and gradation protection catalogue for the corresponding trade secrets of large enterprises, establishing a more detailed classification and gradation process specification and implementation guide according to the business data, improving the efficiency and accuracy of classification and gradation management, providing reference for confidentiality of documents for business personnel, and forming compliance management measures are imperative [15, 16].

By integrating artificial intelligence classification technology [17], this paper carries out automatic classification and gradation of documents. This paper compares three classification algorithms and shows the feasibility and effect of LinearSVC algorithm in the classification and gradation system, so as to improve the accuracy of data classification and gradation [18].

## 2. Classification and Gradation System Architecture and Deployment

The classification and gradation management of enterprise information can enable various sensitive data information of the enterprise to be grasped in a timely, efficient, and accurate manner [19]. It is an important pretechnical means for large-scale enterprises to protect data security and prevent data leakage. According to the data privacy standards and management systems of enterprises, classification and gradation management of sensitive data of enterprises is more convenient for the formulation of data security policies and the protection of sensitive data.

Figure 1 shows the deployment of classification and gradation. As the core part of classification and gradation, AI server can predict the classification and gradation of enterprise documents through artificial intelligence classification and machine learning and provide users with a higher level of intelligent application services; the role of the load-balancing server is to distribute the user to the web server group; the file server and the database, respectively, provide storage for the file and relational data for the classification and gradation system; and the report server provides a comprehensive display for the classification and gradation information.

The DLP system continuously captures and analyzes the traffic on the network by placing a monitor at the outlet of the enterprise's external network and detects sensitive data and important traffic elements [20] through protocols such as SMTP, FTP, and HTTP to prevent the transfer of sensitive data to the outside. It can be seen from Figure 2 that the classification and gradation system integrates with the DLP (data leakage prevention) system to obtain network or terminal data leakage event information and displays related

information for organizations with data permissions on the basis of strict authority control design. The user data protection requirements can be collected from the information or security management department to provide a basis for the data security policy. At the same time, the DLP system interacts with the classification and gradation system to compare the fingerprint of the outgoing file with the fingerprint database of the classification and gradation system to predict which category the file belongs to.

## 3. Materials and Methods

Data intelligent classification mainly uses intelligent classification technology to form different categories of data to be classified [21]. As shown in Figure 3, the AI intelligent classification function is mainly divided into two modules: AI training and AI classification. The AI training module is processed by a stand-alone server. Through the full amount of learning from classification and gradation information source uploaded by users, generating the system model, and uploading it to AI classification module, AI classification will classify documents according to the model. In the AI classification module, when the user enters the classification and gradation information, the platform intelligently classifies and gives the user a classification prompt to provide a reference for the user.

*3.1. Data Preprocessing.* To be able to calculate the accuracy of the classification algorithm, before the model training, the system needs to automatically classify and annotate the data sample files and then classify the inaccurate files automatically into the correct classification through manual proofreading. The manual proofreading step is very important and has a great impact on the final accuracy. For the calibration document after proofreading, if obtaining higher quality corpus data is needed during model training, the data should be preprocessed in advance [22]. The data preprocessing flow chart is shown in Figure 4.

The original text is first cleaned. This is the last procedure to find and correct identifiable errors in the data file. It reexamines and verifies the data, removing duplicate information, correcting existing errors, and providing data consistency. After that, the word segmentation process is performed, the Chinese characters are divided into individual words, and the continuous word sequences are recombined into word sequences according to certain specifications. Finally, the stop words are removed. The words that do not contribute to the text features are roughly divided into two categories. One kind of stop words is characterized by a wide range of applications and can be found everywhere in various documents; for example, the word "company" appears in almost every document, and the characteristics of the document cannot be reflected for such words. Another kind of stop words includes a modal particle, an adverb, a preposition, and a conjunction, which usually has no clear meaning. These words will not have specific meaning until they are put into a complete sentence, such as the common "the," "in," and the like. After the data is

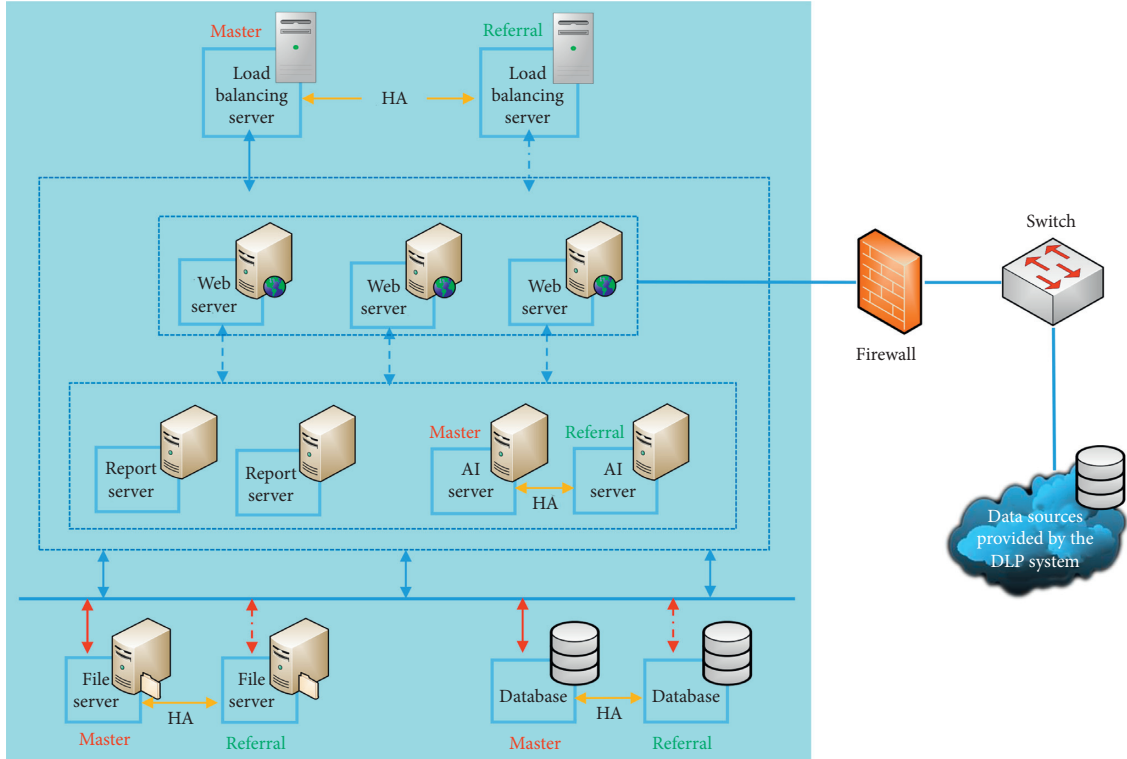

FIGURE 1: Classification and gradation system architecture diagram.

FIGURE 2: Interaction diagram of classification and gradation system and DLP system.

FIGURE 3: AI intelligent classification module diagram.

preprocessed, the original text is expected to have higher quality prediction data for the next model training.

**3.2. Model Training.** Dividing all training data into two parts, one for the training model is called the train set, and the other for the accuracy test of the model is called the test set. Then the TF-IDF (term frequency-inverse document frequency) [23] calculation on the two data sets is carried out. The calculation process is as follows: for the word  $t_i$  in each parsed.txt file  $d_j$ , the term frequency (TF) can be expressed as in the following equation:

$$tf_{i,j} = \frac{n_{i,j}}{\sum_k n_{k,j}}, \quad (1)$$

where  $n_{i,j}$  is the number of occurrences of the term  $t_i$  in the document  $d_j$  and the denominator is the sum of the occurrences of all the terms in the document  $d_j$ . The main idea of IDF (inverse document frequency) is that if there are fewer documents containing the word  $t_i$ , the IDF value is larger, indicating that the word  $t_i$  has a good class discrimination ability at the level of the entire document set. IDF is expressed as follows:

$$idf_i = \log \frac{|D|}{|\{j: t_i \in d_j\}|}, \quad (2)$$

where  $|D|$  is the total number of all documents in the corpus and the denominator is the number of all documents containing the term  $t_i$ . The TF-IDF weight is actually the product of two parameters. That is,  $tf_{i,j} \times idf_i$ .

TF-IDF is a commonly used weighting technique for information retrieval and data mining. It is a statistical method used to evaluate the importance of a word to a document set or one of the documents in a corpus [24]. The importance of a word increases in proportion to the number of times it appears in the document, but at the same time it decreases in inverse proportion to the frequency of its appearance in the corpus. If in a specific type of test set document the TF-IDF value of the word  $t_i$  is high but that in other categories is very low or even 0, indicating that the word is of greater importance to this type of document and has a strong ability to classify this type of document, it can be

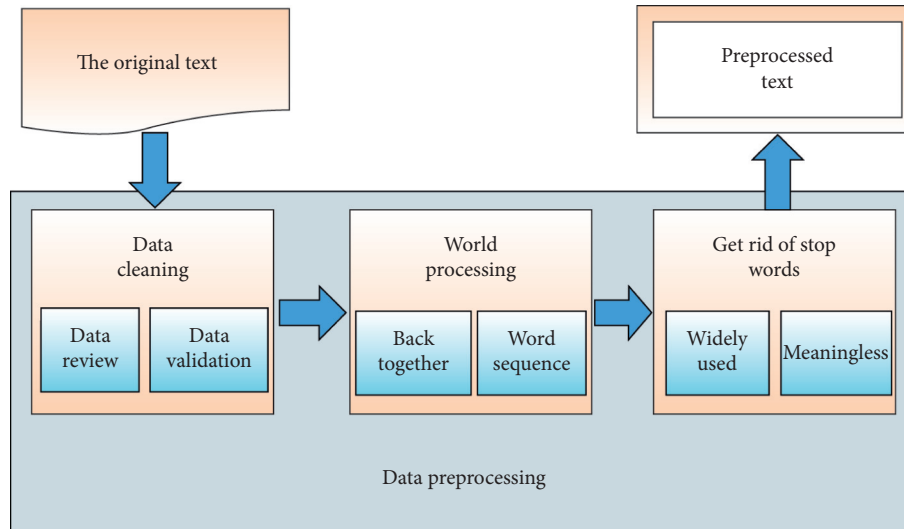

FIGURE 4: Data preprocessing flow chart.

regarded as the characteristic word of this kind of file. The specific model training process is as follows: TF-IDF calculation is performed on the words in the file data in each category of the training set; then the words with the strongest classification ability are selected as the feature words of the type of file. So, the classifier training is performed using these features. In the end, a classification model is generated. After each training of the model, the test data set needs to be used to verify the accuracy of the model. When the accuracy reaches the requirement, the model can be saved. If the higher accuracy is not achieved, it is necessary to classify the annotation data to confirm whether there is a data classification error and then adjust the parameters of the model, evaluate the model, and iterate the process until a higher accuracy is obtained. The model training process is shown in Figure 5.

**3.3. Learning Function of Classification Model.** In view of the numerous and intricate features of the documents in the enterprise, with the change of the enterprise system and the continuous increase of documents, it is sometimes necessary to make changes to the classification standards and adjust the data file categories. The AI intelligent classification model learning framework is shown in Figure 6. The framework consists of model learning services, file parsing services, and model training. With the corpus and new standard of classification reuploaded, the file parsing service is called to convert the data file into a txt file, and the corpus is initially automatically classified based on the new classification criteria. After manual proofreading, the model training module is invoked for training. The result is repeated iterations to achieve the learning function of the model.

## 4. Results and Discussion

**4.1. Several Common Classification Algorithms.** Logistic Regression (LR) [25], a generalized linear regression analysis model, is based on the Sigmoid function to deal with large-

scale data by giving the probability that the sample belongs to each category. Logistic regression algorithms are often used to solve the two classification problems; Naive Bayes (NB) [26], a method for calculating posterior probabilities from prior probabilities, requires a hypothetical premise. In the actual data classification analysis process, this premise assumption is often too idealistic, and it is not established in the actual situation. So the above two algorithms are not suitable for use in the enterprise data multiclassification system.

Decision Tree (DT) [27] creates a tree node by calculating the information gain of each attribute and selecting the attribute with the highest information gain as the test attribute of the given data set, and marks with this attribute, and then creates a separate branch for each value of the attribute and divides the sample accordingly; K-Nearest Neighbors (K-NN) [28] classification, an analogy-based learning method, works by storing all training samples in an N-dimensional model space, calculating sample files by calculating the K training samples closest to a given unknown sample using the Euclidean distance formula; LinearSVC [29] is one of the SVM (Support Vector Machine) classification algorithms. By using kernel function techniques, linearly inseparable features are mapped into high-dimensional space, so that features can be divided in high-dimensional space. Based on the limited sample information, the complexity of the model (the learning accuracy of a particular training sample) and the learning ability (the ability to identify any sample without error) maximize the maximum separation between the separate categories to achieve good classification predictions for the sample file.

**4.2. Experimental Scheme and Results.** Intelligent classification and gradation module is essentially a module of text classification. Text classification refers to the automatic classification process of the input text according to a certain categorization system by the computer through algorithms. The algorithm of this classification and gradation module is implemented by a more mature machine learning algorithm.

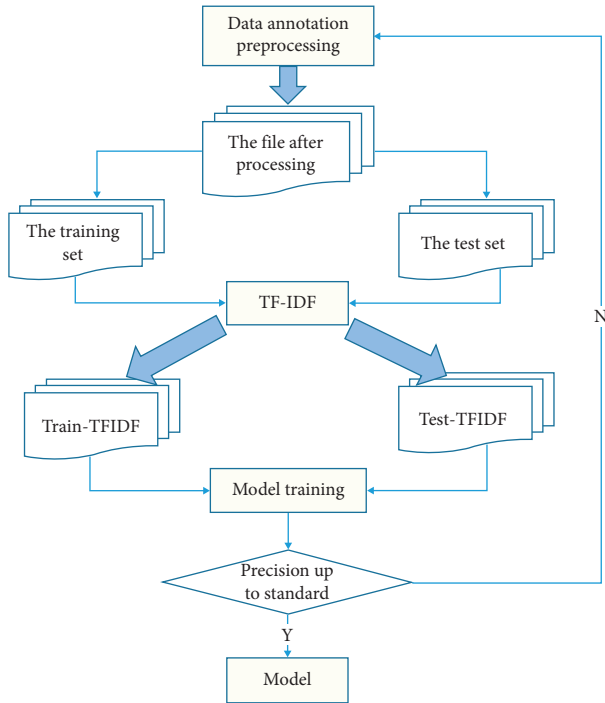

FIGURE 5: Model training flow chart.

In machine learning, there are many algorithms that can be used for text classification. After comparing the advantages and disadvantages of different algorithms, combined with the sparse and discrete features of the enterprise text data, three algorithms (Decision Tree, K-NN, and LinearSVC) that are suitable for enterprise text classification are selected for experiment.

For the experimental work of exploring the data volume of the model training on the accuracy and modeling time of the three classification algorithms, according to most enterprise systems and organizational components, the enterprise data can generally be roughly divided into 12 categories including personnel, auditing, legal affairs, material procurement, production and management, technology management, discipline inspection and supervision, maintenance of letters and visits, comprehensive office, planning, finance, international cooperation, and policy research. For the discrete, sparse, and feature-rich characteristics of the enterprise data, if there are too many training samples, some abnormal feature values will appear inside for the discrete and sparse enterprise data, which will affect the accuracy of the model. At the same time, the amount of training data should not be too small; otherwise, it will also affect the accuracy. In view of the fact that the number of training samples would affect the accuracy of the classification model, this experiment fixed the size of the sample categories into 12 to explore the changes in the accuracy and modeling time of the three classification algorithms when the amount of training data for each classification file is 40, 60, 80, 100, 120, 140, and 160. It is worth noting that, in order to avoid the influence of other factors on the experiments, all experiments were conducted on the same hardware configuration server. The results are shown in Figure 7.

Due to the characteristics that the enterprise data are discrete, sparse, and numerous, the more categories are classified, the higher the degree of feature coincidence among each category is, which makes the accuracy of the model more easily affected. In general, the enterprise documents are roughly divided into 12 categories: company personnel, finance, and so on. According to the different nature and the different system of the enterprise, the data category species will slightly change.

When exploring the influence of the number of training samples on the model accuracy and modeling time, it can be seen from Figure 7 that the modeling time increases with the increase of the number of training samples, while the accuracy of the model built by the three algorithms peaks within the range of local sample size (75–100). Therefore, as for the experimental work to explore the influence of the number of enterprise data classification types on the accuracy and modeling time of the three classification algorithms, in order to facilitate the calculation of experimental parameters, the fixed training sample size for this experiment is 100 files. Therefore, this experiment explores the changes in the accuracy and modeling time of the three classification algorithms when the number of classification types is 8, 10, 12, 14, 16, 18, and 20 in sequence for servers with the same hardware configuration. The variations of the three algorithms are displayed in Figure 8.

**4.3. Analysis of Experimental Results.** It can be seen from the data and the line graph obtained from the two experiments that, for different numbers of training samples, the model training time of each algorithm is almost the same for the three algorithms. But the training time of the Decision Tree algorithm model is generally over 1s, while the other two algorithms K-NN and LinearSVC have slightly faster speed, with the over 1s training time when the training sample size is more than 100. However, in the view of the accuracy, LinearSVC classification algorithm is superior to the other two kinds of algorithm; its accuracy can reach 95% or so. The LinearSVC classification algorithm has the highest accuracy when the number of training samples is about 100 files. For the experiments for different types of enterprise data classification, the training times of all algorithms are still similar, but the accuracy of the LinearSVC classification algorithm is still the highest, which can reach about 95%. According to the results of the two experiments, it can be seen that, when considering the time used for modeling, the three classification algorithms are not much different, but the LinearSVC classification algorithm still has a far better accuracy than the other two algorithms in the two experiments and therefore is most suitable for application in the enterprise data classification and gradation system.

## 5. Application Verification and Summary

**5.1. Analysis of Experimental Results.** Taking a petroleum enterprise as an example, the AI intelligent classification composed of the LinearSVC algorithm is applied in the classification and gradation system of the enterprise. Then,

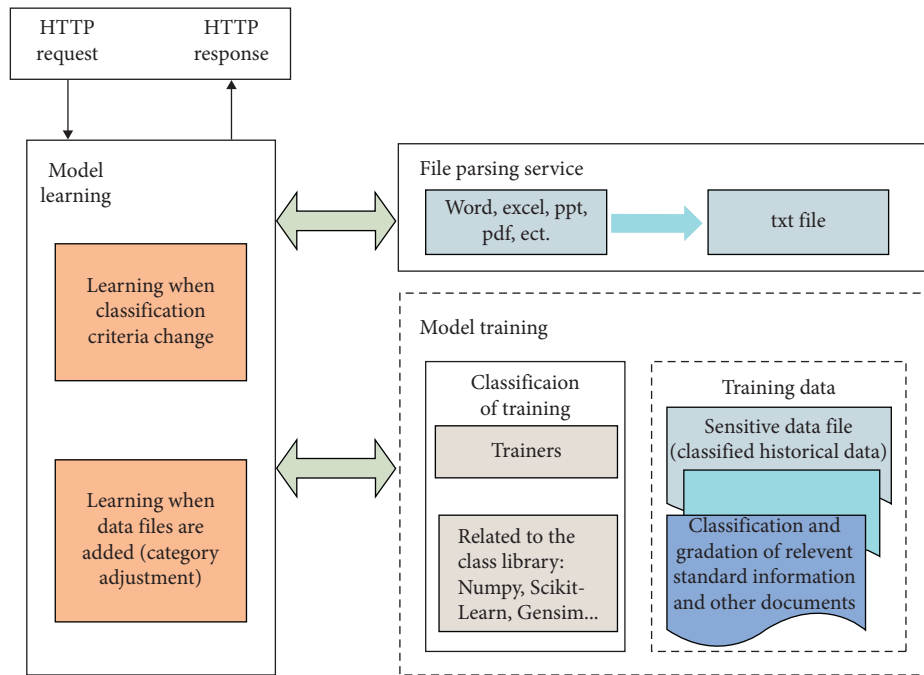

FIGURE 6: AI intelligence classification model learning frame diagram.

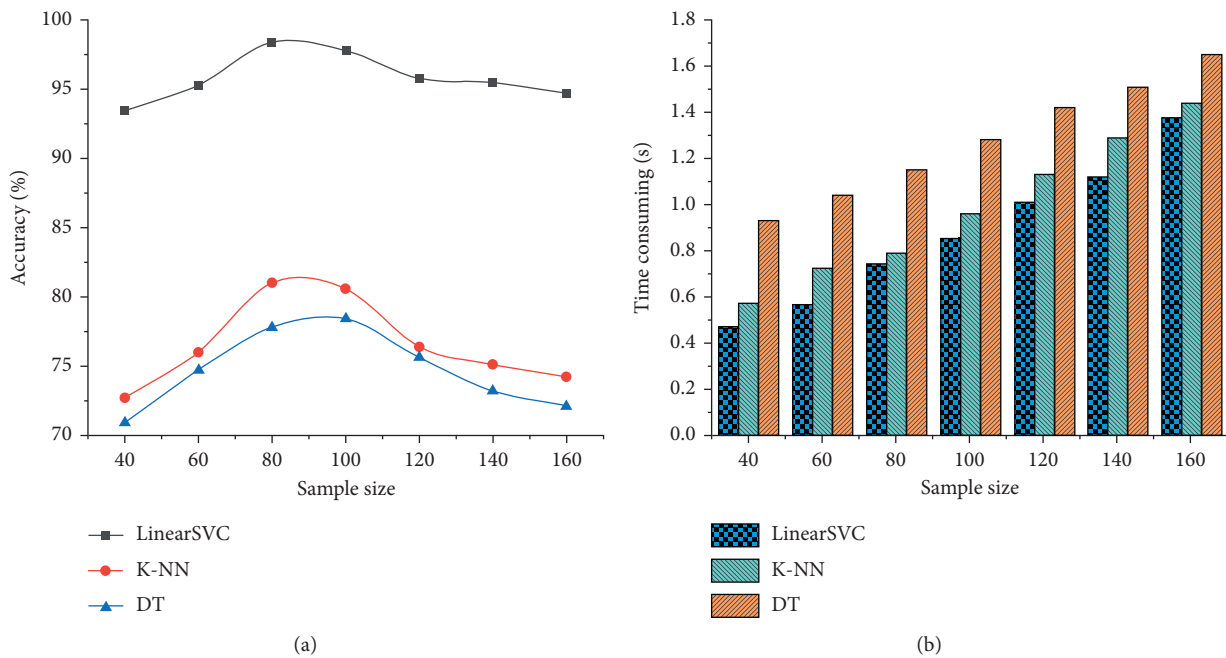

FIGURE 7: The relationship between different number of training samples and accuracy and time. (a) Accuracy line graph. (b) Modeling time diagram.

according to the nature and system of the oil company, the company roughly divides the data into 19 categories: personnel, auditing, legal affairs, and so on. At the same time, we found 19 types of documents from within the oil company, and the number of each type of documents is about 100. The various documents are divided into two parts: training set and test set. The number of the two text

sets can be flexibly set, usually set as the ratio of training set and test set is 4 : 1, but the slight increase or decrease of this ratio will not affect the accuracy of model training results.

The numbers of data files for the training and test sets of each classification category are shown in Tables 1 and 2.

The supervised model training is carried out in the enterprise classification and gradation system. When the

accuracy reaches the required level, the model is generated. Table 3 shows the accuracy and time taken for the training of the enterprise classification and gradation system model.

It can be seen from Table 3 that when the training accuracy reaches 100%, the time spent in the model training is less than 1s, and when tested, the accuracy of the model can reach 94%, exceeding 90%. Therefore, the trained model shows the advantages of short training time and high accuracy.

**5.2. Application Verification.** In order to verify the accuracy of the classification model of the system for the classification of sensitive data documents of enterprises, 3000 data files are randomly selected as test files in a petroleum enterprise. The test files were randomly divided into three groups, and the system was tested three times in succession and verified by three indicators: (3), (4), and (5).

TABLE 3: Model training results.

| Category     | Accuracy (%) | Model training time (s) |
|--------------|--------------|-------------------------|
| Training set | 100          | 0.85                    |
| Test set     | 94.8         | ×                       |

|-------------|---------------|------------|--------|
| Test 1      | 94.9          | 95.3       | 95.1   |
| Test 2      | 95.2          | 95.4       | 95.3   |
| Test 3      | 94.3          | 95.0       | 94.6   |

$$\text{precision} = \frac{\text{Num}_{\text{correct}}}{\text{Num}_{\text{total}}}, \quad (3)$$

$$\text{recall} = \frac{\text{Num}_{\text{correct}}}{\text{Num}_{\text{actual}}}, \quad (4)$$

$$F1 = \frac{2 \times \text{precision} \times \text{recall}}{\text{precision} + \text{recall}}. \quad (5)$$

In the previous equations,  $\text{Num}_{\text{correct}}$  is the correct number of documents in the various types of data identified by the classification model,  $\text{Num}_{\text{total}}$  is the number of documents predicted by the model, and  $\text{Num}_{\text{actual}}$  is the total number of actual samples.

Table 4 clearly reveals that, in the three random testing experiments, the generated model shows great classification effect: the recall rate reaches 95% and above, and the classification accuracies are all higher than 94%. The results are consistent with the conclusions drawn in the test section, indicating that the model has good stability and can be well applied to the classification of enterprise sensitive data documents.

Regarding the part of the misclassified data that has not been verified, although the data is not classified into the correct category, it will not affect the detection of sensitive files in actual scenario. The reason is as follows: With the increase in the classification categories of sensitive documents, the difference in classification standards between the categories will gradually decrease. Therefore, in this case, it is easy to cause the misclassification of data. But, in fact, even if the data is misclassified into other categories, due to the fact that these different categories also belong to the category of sensitive documents, the purpose of preventing the leakage of sensitive documents can still be achieved.

## 6. Conclusion

This paper introduces intelligent classification technology to realize automatic classification and gradation of sensitive data of enterprises. Through the intelligent management of enterprise data, enterprises can quickly grasp the specific quantity and distribution of the information held by the enterprise, greatly reducing the learning cost of the system users and improving the efficiency of work and the accuracy of data classification and gradation. The enterprise data

classification and gradation system compensates for the problem of insufficient technical support and system adaptability of the diversified system of sensitive data classification and management through the integration of AI intelligent classification technology. But, when referring to the enterprise document classification accuracy, there is still some misclassification. Inaccurate classification will affect the accuracy of detection of sensitive documents. In the future, the accuracy of document classification should be improved in the classification and gradation system, and the misclassification should be minimized to the greatest extent to provide a more accurate pretechnical means for the enterprise data security protection and data leakage prevention.

In order to study drag reduction mechanism in mud parts' operation of surface machine tools for paddy field, this paper takes floating plate, the main working part of laminating mechanism, as the research object and systematically analyzes the mechanism of action of elevation angle, curved angle, penetrating angle, and local microstructure of floating plate on working resistance and local fluid flow characteristics of the laminating structure based on VOF model in Fluent. Using ship mechanics theory and fluid lubrication theory, the drag reduction mechanism under different structural parameters of the floating plate is analyzed. The results show that, compared with the ordinary floating plate, the pressure difference resistance can be reduced by increasing the elevation angle by 60°, curved angle by 20°, and mud separation angle by 20°. The increase of the concave nonsmooth bottom surface structure can reduce viscous frictional resistance, and the total working resistance after structural optimization is comparatively reduced by 48.3%, with lowered hilling height in the forward direction and improved lubrication condition of the bottom surface, forming liquid lubrication effect. This study can provide theoretical references for the optimization design of muddy soil mud parts, mud-machine interaction research, and the development of paddy field laminating mechanism.

## 1. Instruction

The paddy soil treated by field steeping forms a working layer and a hard underlayer structure, and the working layer is composed of water body and mud. The presence of mud makes the paddy field machine tools bear a large working resistance during the movement. Studies have shown that 40% of the total power consumption of rice transplanters, boat tractors, etc., is used to overcome the mud resistance in the forward process [1]. Therefore, a study on the action law of the machine tool with different surface morphology and structural parameters and paddy mud means great significance for the optimization design of paddy soil mud tools.

In recent years, scholars have carried out abundant experiments and simulation studies on drag reduction mechanism in agricultural machinery. Guo Zhijun et al. studied resistance characteristics of nine bulldozing plate models by the orthogonal test of indoor soil troughs. The

results show that, compared with the traditional curved surface structure, the parabolic bulldozing plate can reduce working resistance by 4.6%, and field mouse claw bionic curved surface structure can reduce the resistance by 16.0% [2]. Under soil moisture content of 20% and with traction resistance and soil adhesion amount as investigation indicators, Tong Jin compared 9 rib-type press rollers, finding that, compared with ordinary press roller, reasonable rib-type press roller has a visbreaking ratio up to 41.08% and a drag reduction rate up to 11.75%~39.4% [3]. Onwualu studied the effect of speed on tillage tool forces by test method and evaluated the experimental results based on three theoretical models. The results show that the second model had a more general agreement with experimental observations [4]. Ucgul et al. simulated interaction between noncohesive soil and plowing machine by EDEM. When soil particle size was 10 mm, the model could accurately predict the traction and vertical force received by the plow in a

certain speed range [5]. Using the discrete element method, JB Barr et al. simulated the effect of opener rake angle on groove profile parameters, ridge height, inclined area, trench backfill, and lateral sling silt of the sandy loam soil and compared the simulation results with the soil trough test. The relative errors were 9%, 16%, 14%, 0.8%, and 9%, respectively [6]. Woodiga and Salazar et al. installed a tail plate behind a generic tractor-trailer truck model to reduce the pressure drag. The effect of the backward-facing step height between the top surface of the trailer and the tail plate on the drag reduction is studied [7]. Skonieczny established the model of soil and farming tools by DEM and showed that excavation forces due to soil accumulation are especially sensitive to cohesion in planetary excavation with various levels of cohesion [8]. Liyan et al. established a soil particle model of paddy field using discrete element software EDEM and designed the mechanical mud parts' surface with a fish scale simulative microstructure. The motion trajectory and different distribution law of mud particles were obtained by numerical simulation, and it was calculated that the total resistance of the bionic sample is 49.84% lower than that of smooth surfaces under paddy soil conditions [9].

In summary, there are many researches on drag reduction mechanism in agricultural machinery at home and abroad, and the application methods are diverse with remarkable results achieved. However, most of them study dry field operation machinery, and there are a few researches on the drag reduction mechanism of paddy field machinery. At the same time, due to the complex fluid characteristics of paddy field mud, the research method for dry field machinery is not applicable to paddy field machinery. Based on the previous studies, this paper analyzes drag reduction mechanism of the floating plate in mud operation and provides a reference for the optimization design of related mud parts, which means great significance for reducing resistance in paddy machinery forward operation and improving the working efficiency of the unit.

## 2. Physical Model and Numerical Simulation Method

*2.1. Physical Model Establishment Method.* The actual operation on the paddy field is more complicated; it is a viscous

flow field. For this reason, the physical properties of the paddy field are first considered in the simulation process, and the mud viscosity is measured. The parameters of the mud model are shown in Table 1. The clay viscosity and geometrical characteristics of the floating plate are the most important factors in generating and affecting resistance. When the floating plate travels in the paddy mud at a certain speed, the floating plate is in contact with the mud, causing the local mud to turn, forming a vortex at the head end and the bottom of the floating plate. Moreover, the boundary layer separation occurs and the mud forms a wake flow region in progression at the tail of the floating plate under the extrusion of the floating plate, which causes a pressure change in the pressure field at the tail of the floating plate and results in a pressure difference between the head end and the tail, that is, viscous pressure resistance. Therefore, according to the working characteristics of the laminating mechanism and by virtue of the relative motion principle, the floating plate can be viewed as static, and the mud makes constant turbulence movement relative to the floating plate for numerical simulation. After the mud hits the floating plate, a turbulent flow will form in the floating plate, which is essentially a turbulent process. The mud particles affect each other, while velocity and pressure vary with time and space. Due to the severe turbulence at the head end of the floating plate, the overall flow pattern is considered as a turbulence model according to the definition of classic flow Reynolds number (Re), and wall boundary is selected in the real model. Since there is no heat transfer in the actual operation and energy form is mechanical energy, continuous equation and momentum conservation equation are selected for the governing equation, as shown in equation (1) and equation (2) [10, 11]. Eddy viscosity model is used in the numerical solution process. The standard k-model is used to solve the RANS equation, and RNG k-model with the average strain rate in reaction mainstream is introduced into equation to correct the small vortex in motion [12, 13]:

$$\frac{\partial \rho}{\partial t} + \frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho v)}{\partial y} + \frac{\partial(\rho w)}{\partial z} = 0, \quad (1)$$

$$\begin{aligned} \frac{\partial(\rho u)}{\partial t} + \frac{\partial(\rho uu)}{\partial x} + \frac{\partial(\rho uv)}{\partial y} + \frac{\partial(\rho uw)}{\partial z} &= \frac{\partial}{\partial x} \left( \mu \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( \mu \frac{\partial u}{\partial y} \right) + \frac{\partial}{\partial z} \left( \mu \frac{\partial u}{\partial z} \right) - \frac{\partial p}{\partial x} + S_u, \\ \frac{\partial(\rho v)}{\partial t} + \frac{\partial(\rho vu)}{\partial x} + \frac{\partial(\rho vv)}{\partial y} + \frac{\partial(\rho vw)}{\partial z} &= \frac{\partial}{\partial x} \left( \mu \frac{\partial v}{\partial x} \right) + \frac{\partial}{\partial y} \left( \mu \frac{\partial v}{\partial y} \right) + \frac{\partial}{\partial z} \left( \mu \frac{\partial v}{\partial z} \right) - \frac{\partial p}{\partial y} + S_v, \\ \frac{\partial(\rho w)}{\partial t} + \frac{\partial(\rho wu)}{\partial x} + \frac{\partial(\rho wv)}{\partial y} + \frac{\partial(\rho ww)}{\partial z} &= \frac{\partial}{\partial x} \left( \mu \frac{\partial w}{\partial x} \right) + \frac{\partial}{\partial y} \left( \mu \frac{\partial w}{\partial y} \right) + \frac{\partial}{\partial z} \left( \mu \frac{\partial w}{\partial z} \right) - \frac{\partial p}{\partial z} + S_w, \end{aligned} \quad (2)$$

TABLE 1: Mud model parameters.

| Moisture content (%) | Mud viscosity (Pa·s) | Mud solid phase particle size ( $\mu\text{m}$ ) | Soil density (g/ml) | Travel speed (m/s) |
|----------------------|----------------------|---|---------------------|--------------------|
| 36.1                 | 4.53                 | 100   | 2.34                | 1.44               |

where  $S_u$ ,  $S_v$ , and  $S_w$  are generalized source terms.

**2.2. Two-Phase Flow Model Establishment Method.** VOF method (Volume of Fluid) determines the free surface tracking fluid change by studying the fluid and mesh volume ratio function in the grid unit [14, 15]. In the solution, the volume fraction of a fluid in a single grid is usually kept updated without changing the interface height in interface tracking. With the advantages of no topological constraints, it is suitable for stratified flow, surface flow, and large bubble flow, thus widely used in multiphase flow models [16]. In the solution process, the volume fraction of liquid in each grid varies from 0 to 1, with 0 representing no such fluid in the grid, 1 representing the liquid filling the grid, and 0.5 representing the interface of the two liquids. The corresponding volume fraction expression is as follows [17, 18]:

$$\frac{\partial \alpha}{\partial t} + \frac{\partial}{\partial x_j} (\alpha u_j) = 0. \quad (3)$$

**2.3. Meshing Method.** The floating plate model has a complicated structure. In order to eliminate the influence of the grid itself, the same size fluid domain is used to divide the grid, but only local encryption is performed. At the same time, to deal with the interface problem of segmentation interval, workbench is adopted for direct 3D modeling [19, 20]. Wall surface partition and meshing are performed via space claim. Since the model thickness is 10 mm, according to the boundary layer characteristics, to accurately reflect the model features, the inner wall mesh is set to a minimum of 3 layers of mesh, so the grid size of the floating plate is 4 mm, the surrounding of the floating plate is filled with 15 mm grid, and area away from the stamping is set to 25 mm. The mesh generation diagram is shown in Figure 1(a). The maximum number of grids is about  $101 \times 10^4$ . The model grid computing domain is shown in Figure 1(b).

**2.4. Grid Independence Verification.** In order to avoid the influence of the size of the grid on the simulation results, four different grid division schemes were selected in turn to verify the grid independence. The model of the stamping board is established by Solidworks. Mesh preprocessing is generated by mesh. High precision grid structured grid and local encryption. The corresponding grid numbers are 851914, 1013400, 1329640, and 1720592 and the entry angle is  $50^\circ$ . Using the grid of fluid motion in the process of membrane plate in contact with soil conditions was analyzed, and the resistance change with iterative is shown. It is seen from Figure 2 when the number of meshes more than 1,013,400, the stable flow field, the calculated resistance is almost the same, the error  $< 2\%$ . Therefore, the number and

degree of encryption of the mesh calculation are the same as before.

**2.5. Boundary Condition Setting and Geometric Model Construction.** The floating plate has a movement state in the mud similar to that of the boat in the sea. The common feature of both is that small objects move in a large space. In the calculation domain and initialization model, the distance from the entrance to the model is 5 times that of board length, and the distance from the exit to the model is 3.5 times that of board length. The air zone model has a set height of 1.5 L and a lower water disturbance depth of 400 mm (equal to the board length). The immersion depth is also a value that needs special consideration, which affects the resistance value of the flow process. It can be calculated by the Baker formula, as shown in equations (4) [21, 22]. According to the field operation requirements, the immersion depth of the floating plate is generally 10~30 mm, which is affected by parameters such as mud, transplanting equipment, and degradable film weight. Therefore, the immersion depth is set to 20 mm, which can reflect the resistance value in a larger range:

$$H = \left[ \frac{G}{BL(k_c / (B + K_\phi))} \right]^{(1/n)}, \quad (4)$$

where  $H$  is the immersion depth of the floating plate,  $G$  is the weight of the floating plate (including hydraulic equipment and degradable film),  $B$  is the grounding width of the floating plate,  $L$  is the grounding length of the floating plate,  $k_c$  is the cohesive deformation modulus of the soil,  $k_\phi$  is the soil friction deformation modulus, and  $n$  is the soil deformation index.

During the simulation, the position corresponding to the immersion depth is the free interface. According to the VOF model, there is a two-phase flow interface when volume fraction is 0.5, and mud foundation depth is generally 20~40 cm when the paddy field is steeping, so the rationality and accuracy of the simulation can be guaranteed [23, 24]. The free interface height set in this paper is 400 mm and the movement speed of the floating plate is up to 6 km/h. Using a variable reference frame, the mud and air move relative to the floating plate, and the speed at the muddy water inlet and air inlet is set to 1.44 m/s. At the same time, to save the grid, both the floating plate and the air domain adopt symmetric boundaries. The remaining boundary conditions are set as follows:

- (1) The air and muddy water inlets are velocity inlets with a speed of 1.44 m/s.
- (2) The outlet is a restricted pressure outlet.
- (3) There are four wall surfaces, the rear sidewall surface, the bottom wall surface, the upper wall surface, and the wall surface of the floating plate respectively.

FIGURE 1: Grid division. (a) Mesh generation. (b) Convex hull local mesh refinement.

FIGURE 2: Grid independence verification.

- (4) The symmetry boundary is set in a symmetrical boundary condition for free energy and mass transfer.

### 3. Results and Discussion

Figure 3 shows a dynamic evolution diagram of the volume fraction during the movement of the floating plate. It can be seen from the figure that, with the flow of muddy water, the original static soil begins to move forward, and the soil moving in the horizontal direction hits the bottom of the floating plate. As the floating plate has a certain width and height, after blocked by the floating plate, the muddy water near the bottom of the floating plate is first decelerated, with the velocity dropped to zero. Subjected to inertia and viscosity, the subsequent muddy water cannot be stopped. Therefore, a detour convex hilling is formed at the bottom of the floating plate. Subsequent muddy water cannot continue to move in the horizontal direction, so a detour flow is formed from the bottom and the sides. The height of the hilling will continue to increase for a long time, until the hilling does not rise and stabilizes under the combined effects of gravity, viscous force, and bypass flow on both sides. Due to the influence of gravity during the ascending process of hilling, the angle of the front end boat deck affects

the rising height of the hilling. Therefore, this paper first studies the influence of the angle and height of the boat deck on the hilling height and analyzes the influencing factors affecting hilling and forward resistance.

*3.1. Influence of the Front End Angle of the Floating Plate on the Hilling.* Because of the space size limit, the floating plate is fixed; a too long length will cause inconvenience. Therefore, in the study of this paper, the floating plate front end length is selected as 160 mm with reference to analyzing the evolution law of hilling height with angle after stabilization. For a too small angle, the floating plate size will be greatly increased, and the too large volume is not conducive to operation. Therefore, the paper studies from the angle which is  $35^\circ$ . It can be seen from Figures 4 and 5 that when the boat deck angle is  $35^\circ \sim 50^\circ$ , the tilling will flow over the entire front end boat deck. After the angle reaches  $60^\circ$ , tilling is only partially piled up and will not flow over the front end boat deck. This is because, while the muddy water hits the floating plate, the splash height is affected by the angle and height of the front end boat deck of floating plate. The muddy water after the collision will continue to move forward due to inertia, which will produce a significant pressure on the surrounding boat deck.

It can also be seen from the partial pressure cloud map that the pressure here is significantly higher than that in other places, and the pressure will make the muddy water climb along the boat deck. During the climb, the muddy water decelerates and falls under the action of gravity. When the energy for the upward movement is exhausted, hilling will stop. On the one hand, as the angle increases, the component force of gravity increases along the boat deck, which will cause the climbing height to decrease. On the other hand, under the same boat deck length, for a larger angle, the vertical height is higher, the potential energy required for the climb is larger, and the initial kinetic energy is larger. Therefore, there will be a tendency that hilling height decreases with the increase of the angle under the same height of the deck boat.

However, the front end angle of the floating plate is not better as it is higher. From the total resistance variation chart (Figure 6), it can be seen that as the angle increases, the resistance increases and the floating plate travels difficultly. Hence, a lower angle should be selected for an appropriate length. It can be seen from the volume fraction cloud diagram that when the angle is less than  $60^\circ$ , the boat deck will

FIGURE 3: 65° floating plate simulation results: (a) 0 s, (b) 0.5 s, (c) 0.1 s, and (d) 2 s.

FIGURE 4: Simulation results of 50° floating plate. (a) 50° free waveform diagram. (b) 50° volume fraction diagram.

FIGURE 5: Simulation results of 60° floating plate. (a) 60° free waveform diagram. (b) 60° volume fraction diagram.

be submerged, and the hilling will turn over the floating plate, which is unfavorable for operation. Nevertheless, when the angle is greater than 60°, the hilling will not turn over the boat deck. Therefore, the angle should be 60° in the design and this angle is maintained for subsequent designs. It can be seen from the simulation results that the resistance of the floating plate is divided into differential pressure resistance and frictional resistance. Due to the high viscosity muddy water characteristics, the differential pressure resistance is slightly larger than the frictional resistance. It can be known from classical fluid mechanics that viscous resistance is directly related to the contact area, so reducing the contact area may be an effective factor for lower total resistance; the front end bottom of the floating plate is subjected to a large pressure, so optimization on it can reduce

the differential pressure resistance, thus overall reducing travel resistance of the floating plate and improving the working efficiency of the laminating machine.

*3.2. Influence of the Curved Angle of the Floating Plate on the Hilling Effect.* The influence of different curved angle on the resistance of the floating plate is studied by ship theory. The angle range is 5~20°. Figure 7 shows a variation chart of the floating plate resistance under different curved angles. It can be seen from the figure that the frictional resistance basically does not change with the increase of the curved angle, while differential pressure resistance is significantly reduced. Compared with an ordinary floating plate of 0°, the total resistance is reduced by about 11.90~18.18%, where the

FIGURE 6: Total resistance variation chart.

FIGURE 7: Resistance variation chart.

differential pressure resistance is significantly reduced when the curved angle is  $20^\circ$ . It can be seen from the static pressure diagram (Figure 8) that the front end boat deck of the floating plate has a big pressure drop, there is a low-pressure zone at the tail end, and the pressure difference between the two becomes pressure drop resistance. The curved surface boat deck increases the local contact area, buffers the local flow field, reduces the local pressure drop, and reduces the resistance. The pressure decrease also causes the lifting height of muddy water to drop. It can be seen from the volume fraction cloud diagram that, compared with Figure 5, the hilling height has decreased significantly, and the vortex caused by the gas-liquid two-phase separation at the edge is reduced.

It should be pointed out that, from the simulation results, it can be seen that the curved floating plate has a significant effect on the hilling effect, although a smaller

FIGURE 8: Static pressure distribution diagram: (a) static pressure distribution diagram of floating plate and (b) static pressure distribution diagram of floating plate with 20 degrees of curved angle.

angle can play a certain role and the smaller curved angle has little effect on the real situation. Therefore, it is recommended that the surface angle should be designed at around  $20^\circ$ . This is because the resistance will be increased when the angle exceeds a certain value, and at the same time, an excessively large curved surface also increases the cost and difficulty of processing. Excessive annealing will reduce the service life of the floating plate and the floating plate angle should be set to about  $20^\circ$  based on comprehensive consideration.

**3.3. Influence of the Penetrating Angle of the Floating Plate on the Hilling Effect.** In the ship dynamics, in order to reduce the resistance during the ship movement, the front end of the boat deck is usually in sharp angle to increase the momentum of the ship in the forward direction, breaking the waves and increasing the ship speed [23, 24]. In view of this, a similar penetrating angle of the floating plate structure was designed, and the penetrating angle is in the range of  $5^\circ \sim 20^\circ$  considering the paddy field working environment. Figure 9 shows the influence law of different penetrating angles on hilling height above the middle symmetry plane of the floating plate. It can be seen from the figure that hilling height is reduced with the increase of the penetrating angle, and the surface penetrating angle has a significant effect on reducing hilling height. This is because after the muddy water hits the floating plate, under the sharp interface cut, the fluid is easily split and easily flows to both sides. In this way, hilling flows around the floating plate from both sides, thus reducing the forward resistance. At the same time, in the case of a high penetrating angle, it is found that typical

FIGURE 9: Simulation results of different penetrating angle: (a) penetrating angle is  $5^\circ$ , (b) penetrating angle is  $10^\circ$ , (c) penetrating angle is  $15^\circ$ , and (d) penetrating angle is  $20^\circ$ .

hilling is reversed back to the front, and the hilling is completely broken.

It can be seen from the local velocity cloud diagram (Figure 10) that the downward impact speed of the fluid along the floating plate is significantly higher than that of an ordinary floating plate, which also indicates that the floating plate breaks the muddy water on the one hand and accelerates fluid's downward movement on the other hand, thus reducing the hilling height. As can be seen from Figure 11, the pressure difference resistance is maximally reduced by about 21.96% as compared with the maximum of the floating plate without a penetrating angle. The calculation results also show that when the penetrating angle is  $5^\circ$ , great changes occur as compared with ordinary curved surface floating plate, with a drop of about 5.89%, and when the penetrating angle is increased, the effect becomes more and more obvious, but there is abnormal rise when the penetrating angle is 10 degrees, which may be caused by the muddy water break distance at that time.

It can be seen that the viscous resistance does not change basically. It can also be seen from Figure 12 that, with the presence of a penetrating angle, the local maximum pressure distribution changes, which changes from basically uniform distribution to a distribution with the highest static pressure at the position of the penetrating angle. This is consistent with the basic physical common sense, indicating that the result is correct. It is also necessary to point out that the tip of the penetrating angle must be sufficiently strengthened. Otherwise, there will be damage under frequent pressure impact. Therefore, it is recommended to add reinforcing structures such as ribs inside.

**3.4. Influence of Local Microstructure of Floating Plate on Resistance.** Figure 13 shows the volume fraction cloud diagram of the symmetry plane position. It can be seen from the above

figure that the surface of the three nonsmooth structures does not have a significant effect on the hilling height, but only slight difference exists. It can be seen from the total resistance distribution diagram (Figure 14) that the groove structure resistance has a decrease of 23.05 N compared with the  $20^\circ$  penetrating angle surface, and the concave structure has a decrease of nearly 45 N, while the convex groove structure not only has no resistance drop but instead shows the abnormal phenomenon of increase in resistance. The pressure drop of the three nonsmooth surfaces is basically the same in a detailed analysis, and the convex hull structure has a slight rise, but the rise is not obvious. This is because it can also be seen from the partial pressure cloud diagram of the convex hull structure that the front end facing muddy water of the convex hull structure has a pressure significantly larger than that of the tail. Under the action of a plurality of convex grooves (18), the pressure drop is significantly increased. Although the groove has small increased pressure in the impact surface facing the muddy water, the overall pressure value does not change much. At the same time, it is found that the viscous resistance of the three has a clear difference, the obvious viscous resistance drop of the concave envelope contributes to almost all the resistance drop, indicating that the drag reduction effect is obvious, the viscous resistance of the groove has a slight decline, and the downward trend is not obvious; at the same time, the pressure of the convex hull increases significantly, rising by about 5.2%. Therefore, under the joint action of the two, the resistance of the concave envelope is significantly reduced, while the resistance of the convex hull is significantly increased. The nonsmooth structure at the bottom of the surface primarily reduces the total resistance by reducing the viscous resistance.

Figure 15 is a streamline diagram of three different surfaces. It can be seen from the figure that the flow fields of the three nonsmooth surfaces are completely different. The convex hull surface will show obvious bypass flow

FIGURE 10: Velocity nephogram of 20.

FIGURE 11: Drag distribution picture.

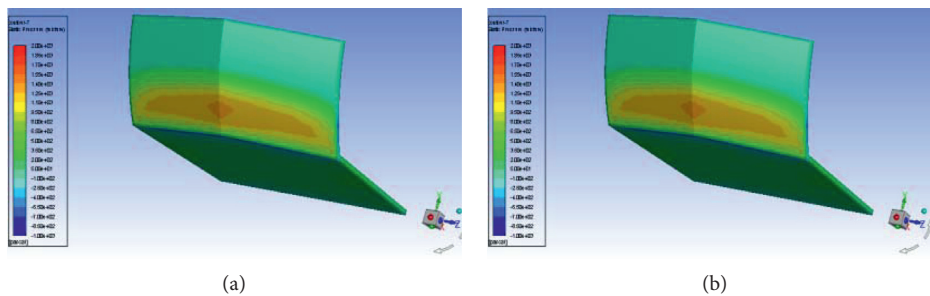

FIGURE 12: Pressure cloud diagram under different penetrating angles: (a) pressure cloud diagram when penetrating angle is 5° and (b) pressure cloud diagram when penetrating angle is 20°.

when hit by the muddy water. A wake flow is formed at the rear after the bypass. Similar to the Carnot vortex, it increases local eddy current, but since there is no local rectification structure, the superimposed disturbance of multiple vortices will inevitably increase the pressure

drop, thereby improving the running resistance. At the same time, the formation of the convex hull increases the contact area of the floating plate at the bottom. For mud flow process with great viscosity, the increase of the contact area means an increase in the viscous resistance,

FIGURE 13: Hilling and pressure cloud diagram of nonsmooth bottom: (a) partial hilling and pressure cloud diagram of concave envelope, (b) partial hilling and pressure cloud diagram of groove, and (c) partial hilling and pressure cloud diagram of convex hull.

FIGURE 14: Drag distribution picture.

so the overall running resistance of the convex hull increases.

According to the simulation of the groove structure, although the contact area is increased on the surface, since the groove is long, the muddy water moves into the grooves on both sides after the impact, which accelerates the movement in the groove and reduces the viscous resistance.

For the nonsmooth structure of the concave envelope, it can be seen from the local flow field that the flow velocity near the concave envelope is extremely low, and the muddy water almost slips over the concave surface, which means that this is a typical liquid lubrication phenomenon. The muddy water filled in the concave envelope provides a lubricating effect, so that the muddy water slides down the wall surface

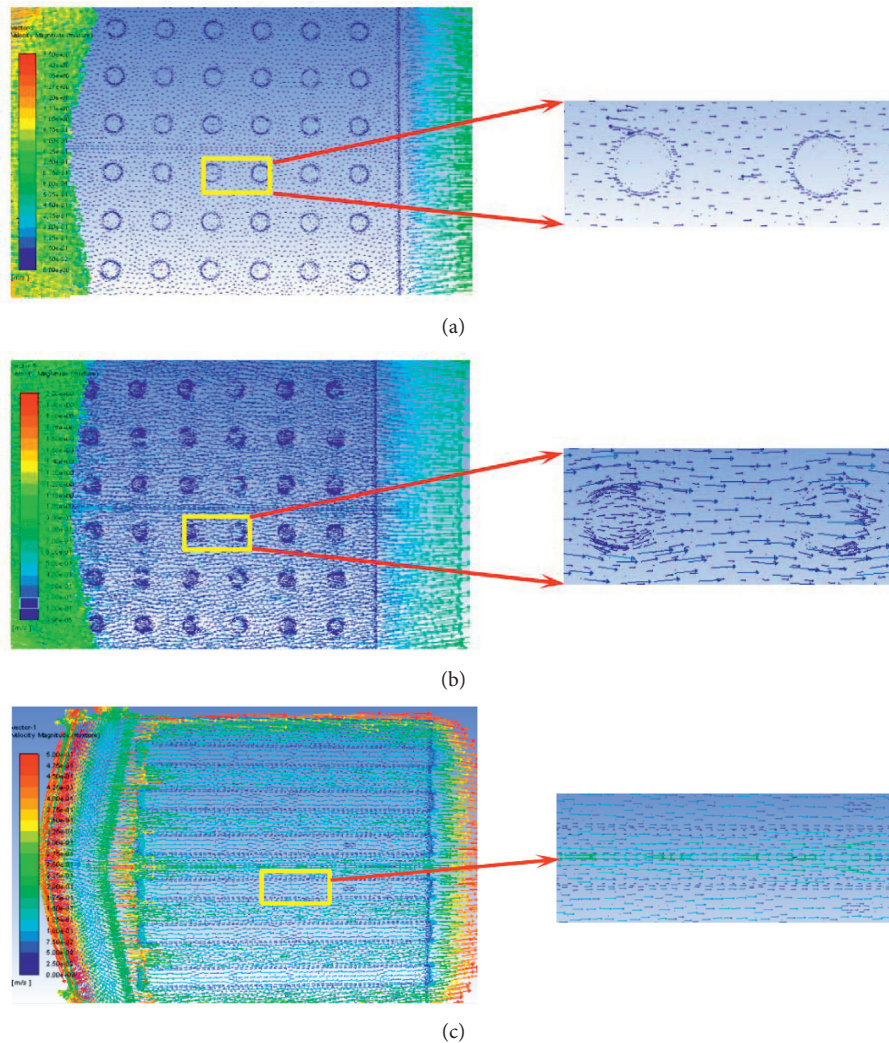

FIGURE 15: Streamline diagram of different bottom structures: (a) Velocity distribution and partial enlargement diagram of concave envelope at 365 mm. (b) Velocity distribution and partial enlargement diagram of convex hull at 365 mm. (c) Velocity distribution and partial enlargement diagram of groove at 365 mm (enlarged as groove superficial zone).

with almost no wall shearing, reducing the overall viscous resistance. Nonsmooth structures are not necessarily conducive to the reduction of total resistance but may also lead to an increase in overall resistance, such as convex hull structure. The reasonable design will reduce the resistance to a certain extent and improve the overall operating efficiency of rice laminating machine, such as concave envelope structure. In summary, we obtained the optimal design parameters for laminating machine under high viscosity in this study. The boat deck angle is  $60^\circ$ , the curved surface radian is  $20^\circ$ , the penetrating angle is  $20^\circ$ , and the bottom is in concave envelope structure.

#### 4. Experimental Verification

In order to verify the accuracy of the simulation results, this paper measures the resistance of different structures of floating plate in the indoor soil trough as Figure 16 shows. The main types of equipment for the test included

electric tractor, suspension mechanism, MIK-LCS1 tension-compression sensor, paddy soil, and floating plate model. Other types of equipment included ruler, stopwatch, marking pen, soil moisture detector, insulating tape, and assembly tools (wrench, screwdriver, plier, etc.).

During the test, the three models were moved from one end of the soil tank at a constant speed, and the moving distance was 1.5 m. Observe and measure the depth of the model sinking into the mud. After moving the model to 1.5 m, we observe the front, back, and two sides of the model, then record the measured results, and smooth the mud surface. Each model was repeated three times, and the results were averaged.

**4.1. Test Results.** Table 2 shows the traction resistance values measured after different optimization mechanism parameters. It can be seen from the table that the traction resistance

FIGURE 16: The test soil bin.

TABLE 2: Test results of traction resistance of floating plate.

| Floating plate structure type | Traction resistance (N) |              |              | Average value | Simulation result (N) |
|-------------------------------|-------------------------|--------------|--------------|---------------|-----------------------|
|                               | Test value 1            | Test value 2 | Test value 3 |               |                       |
| Common structure              | 377.3                   | 381.9        | 351.1        | 370.1         | 312.8                 |
| Curved structure              | 284.0                   | 270.1        | 262.8        | 272.3         | 236.2                 |
| Penetrating angle structure   | 240.3                   | 250.5        | 235.8        | 245.2         | 210.0                 |
| Baseplate microstructure      | 203.5                   | 195.6        | 209.6        | 202.9         | 172.7                 |

of the other three improved structures is significantly lower than that of the common structure.

On the basis of the curved structure, the traction resistance is reduced by about 27 N after the addition of the penetrating angle structure. The average traction resistance decreases to 202.9 N after adding the bottom concave envelope microstructure on the basis of the addition of a penetrating angle structure. This shows that, after several structural optimizations, there is a drag reduction effect on the working resistance of the floating plate. At the same time, the relative errors of the simulated and experimental values in the structural resistance of the four types of floating plates were 18.3%, 15.27%, 16.76%, and 17.47%, respectively. In summary, the test results are consistent with the simulation analysis results, and the simulated values are well fitted with the experimental values. Therefore, it is considered that the established interaction model between the mud parts and paddy soil based on the VOF model is reasonable.

## 5. Conclusion

In this paper, the VOF-coupled level-set model in Fluent is used to systematically study the drag reduction mechanism of the design parameters for the floating plate of the paddy field laminating machine. By investigating the influence mechanism of floating plate angle, curved angle, penetrating angle, and local nonsmooth structure on the running resistance and flow pattern of the floating plate, the research

shows that (1) the angle and height of the floating plate affect the hilling height. Although a smaller angle means small resistance, hilling will easily turn over the boat deck, reducing the effect. Comprehensively considering the hilling effect and resistance, better design angle is  $60^\circ$  under high viscosity; (2) the change of the curved surface shape reduces the pressure difference resistance. Combining theoretical model analysis values, the optimal resistance operation range can be obtained when the floating plate curved angle is  $20^\circ$ ; (3) the increase of the penetrating angle reduces hilling height, lowers running resistance, and improves the operation efficiency. Comprehensively considering local strength, the better design value of penetrating angle is  $20^\circ$ ; (4) the local nonsmooth structure has a significant influence on the viscous resistance. Comparing the three nonsmooth structures, concave envelope has the best drag reduction effect due to the local liquid lubrication. The simulation results were verified through an indoor soil trough test, which realized the innovation of the research method for the drag reduction mechanism of paddy field mud parts. The established model and the data obtained by the simulation result will contribute to the research and optimization design of the drag reduction mechanism of paddy field tools.

In order to reduce the misoperation of submersible pilots in the complex environment of deep sea and improve human reliability, it is a very important method to optimize the cabin space of manned submersible. In this paper, manned submersible Jiaolong is taken as an example to describe the breakthrough of traditional modes for optimizing the cabin layout of manned submersible with an aesthetic perspective of deconstruction and reconstruction thinking; the layout is optimized based on deconstruction and reconstruction from the cultural perspective of interdisciplinary. The experimental results show that the layout of manned submersible cabin is optimized by combining the theory of deconstruction and reconstruction aesthetics and human factors engineering, and the feasibility and effectiveness of this method are verified by multiobjective genetic algorithm. Deconstruction and reconfiguration layout optimization improves the human reliability of divers. It is a new method for the optimization of manned submersible cabin layout and also provides a reference for studies on the layout of similar small space.

## 1. Introduction

Since the 21st century, human beings have entered a new era of ocean exploration. Currently, the “blue territory” with deep-sea resources and military strategic significance is being developed, utilized, and protected by numerous coastal countries. The first choice for ocean exploration is manned submersible, which is called “an important cornerstone of oceanographic research.” Manned submersible refers to a type of diving device with the capacities of underwater observation and operation, which can be mainly used to carry out the tasks such as deep-sea investigation, exploration, development, and salvage, and is usually taken as a base for underwater activities by submersible pilots. Deep-sea manned submersible, as the forefront and commanding height of ocean exploitation, will reflect the comprehensive strength of a country [1]. However, in the complex deep-sea environment over thousands of meters

deep, several submersible pilots shall perform the high-intensity and high-precision scientific investigation for more than ten hours in a manned submersible cabin with an inner diameter of about only 2 meters, which is almost an impossible mission. Therefore, the matter of how to optimize the space layout of a manned submersible cabin and improve the human reliability of submersible pilots has always been a hot topic in maritime powers [2].

The manned submersible cabin layout has been performing better and better through continuous upgrading and transformation by means of function orientation, ergonomics, space segmentation, and algorithm based on the preliminary design [3]. Foreign and domestic manned submersibles, such as Ross/Consul and Peace I/II of Russia, Alvin and Nadir/Deep Rover of the United States, Deep Sea 6500 of Japan, Nautilie of France and Jiaolong, Deep Sea Warrior, and Fendouzhe of China, as shown in Table 1, have been transformed as planned in recent years; they have

TABLE 1: Main technical parameters of domestic and foreign manned submersibles.

| Jiaolong      | China             | 7000      | 8.2        | 3.4        | 3.0       | 23.5             | Ti alloy              | 2.1                      |

accepted continuous and planned upgrades in aspects of cabin layout, and all have achieved great success [4].

The optimized layout of manned submersibles, aerospace, and aircraft enclosed cabins usually takes the operator as the center to build simulators to optimize the layout. For example, Boeing’s BOEMAN, NASA’s A3I program, and NATO’s AGARD Aircraft Cockpit program all use simulators to study how to optimize space layout and reduce the misoperation caused by human factors. The space layout of manned submersible cabin adopts the traditional cut-and-trial manner; later, they turned to adopt 3D modeling with computer software for layout cut and trial, which was not materially different from a model and could not reach a satisfactory result either. The layout based on ergonomics, such as muscle fatigue of submersible pilots, would also cause a series of problems; therefore, it is a trend to optimizing cabin layout with multiple technologies oriented by manned submersible functions and ergonomics. With the increase of diving depth of manned submersibles, the cabin space will be smaller and smaller, the interference between equipment and equipment becomes greater and greater, the working hours of submersible pilots become longer and longer, and the multidisciplinary optimization design system will be highlighted during the research of cabin layout. In this system, visual simulation, virtual reality technology, and mathematical algorithm model will be introduced [5].

The optimization of manned submersible cabin layout has been continuously explored to seek new design methods and means to optimize the layout, thus improving human reliability. In this paper, the manned submersible cabin layout is optimized based on deconstruction and reconstruction thinking from the cross-disciplinary cultural perspective and then verified in combination with multi-objective genetic algorithm. It will provide a new method for the research on cabin layout of manned submersibles and also provide a reference for the research on the layout of small cabins of aircraft, ships, and space ships [6].

## 2. Application of Deconstruction and Reconstruction Thinking in Optimization of Cabin Layout of Manned Submersible Jiaolong

*2.1. Deconstruction and Reconstruction Thinking.* Deconstruction (structural decomposition) is a term proposed by Derrida, a French poststructuralist philosopher,

which was derived from “deconstruction” in Sein Und Zeit. Reconstruction refers to the rationalization of design pattern and architecture through adjusting and improving quality and performance, thus improving the scalability and maintainability. In short, deconstruction is the decomposition of the original structure into basic units, while reconstruction is the restoration of such basic units to parts for recombination, thus obtaining a brand new and different structure.

Deconstruction and reconstruction thinking is a way of thinking for getting new objects by recombination in a new way based on representative elements taken from the basic units decomposed from a specific object, such as overall appearance, local morphology, or microfeatures. Basic deconstruction methods include planarization, geometrization, symbolization, and abstraction. Reconstruction has the following types and methods: reconstruction of the concrete form: reality and superreality; and reconstruction of the abstract form: geometric abstraction (cool abstraction) and free abstraction (hot abstraction).

*2.2. Symbolic Deconstruction of Static Space in the Cabin of Manned Submersible Jiaolong.* The cabin of the manned submersible Jiaolong is approximately an oval sphere with an inner diameter of 2.1 m, which can accommodate three people, including an operator and two scientists, as well as the corresponding seats, monitors, manipulators, batteries, and the related electronics. First, qualify the ergonomic parameters of people and facilities, and evolve the objects in the spherical cabin into simple symbols based on the tasks to be performed, as shown in Table 2; later, take these symbols as the constituent elements of space layout, which is the symbolic expression of deconstruction and reconstruction thinking, as shown in Figure 1; three submersible pilots (⊙round) are arranged in the middle of the cabin, with the grey dotted circle and rectangular boxes as their range of activity; workbenches (∟lines), monitors, and maneuvering devices (□square) are arranged around, for taking full advantage of the spherical cabin wall.

As shown in Figure 1, the objects in the cabin are symbolically deconstructed, and the displays and monitors are combined with the spherical wall. As shown in Figure 2(a), the operating table and monitoring equipment shall be reconstructed in combination with Figure 2(b) by making full use of spatial features of the spherical wall

TABLE 2: Objects in the spherical cabin and occupied area.

| Name                        | Parameters                                  | Quantity | Occupied area A (m <sup>2</sup> ) | Area          | Symbolization |

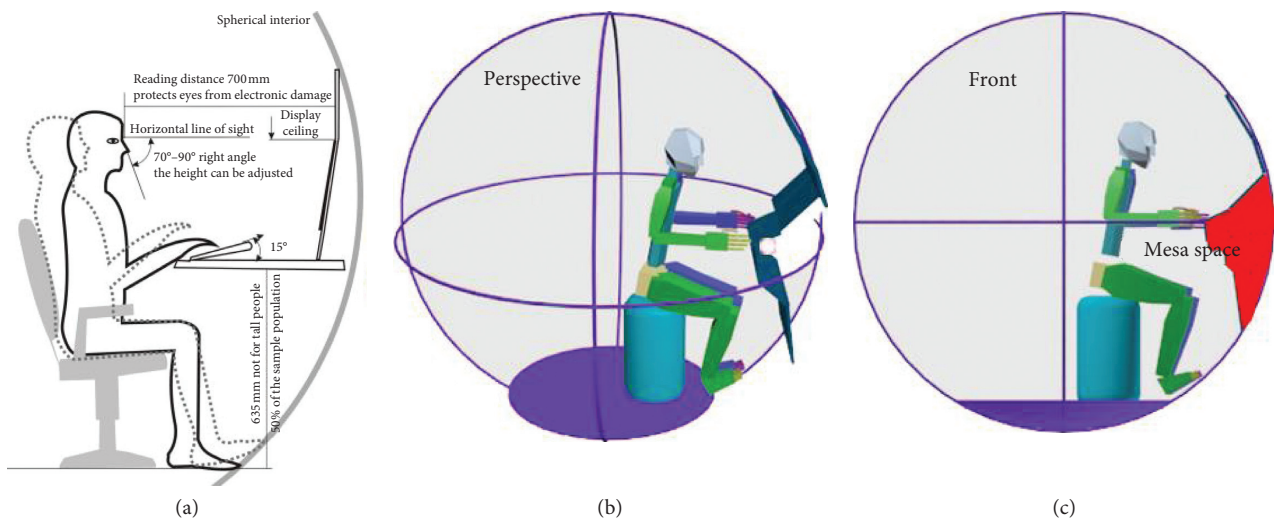

FIGURE 2: Reconstruction and optimization of the working table and display system of manned submersible cabin.

according to the ergonomic requirements for submersible pilots under the conditions of meeting the strong constraint requirements of visibility, accessibility, and comfort and then form the red space as shown in Figure 2(c), to place electronic devices and personal belongings of submersible pilots.

*2.3. Geometric Deconstruction of Active Regions in the Cabin of Manned Submersible Jiaolong.* The manned submersible cabin consists of the master control area, display area, life support area, working area, and area of other facilities. Its spatial relation can be decomposed into several geometric planes, which may be taken as basic modeling elements for performing geometric deconstruction combining with the tasks of manned submersible, the underwater environment, and working area in the cabin [7].

The layout of objects in the cabin can be divided into three parts, and most destructive collisions would be concentrated in the front and lower parts of manned submersible, so it is suggested placing energy and electronic devices in the lower part of manned submersible and back area of the cabin with great structural strength. In addition, according to the tumbler principle, the batteries shall be placed at the bottom for easy maintenance and maintain the balance of manned submersible. Due to few collisions on the top of the cabin, the upper part is relatively safe, so it can be taken as the last line of defense for the safety of submersible pilots and the place for storing life support materials, as shown in Figure 3(a). The active region mainly refers to the working area of the three submersible pilots in the middle of the spherical cabin, as shown in Figure 3(b). Through geometric deconstruction and reconstruction for submersible pilots and objects in the cabin, the display and monitoring devices shall be fixed on the spherical inner wall, so as to ensure the visibility and the operability within the control range of upper limbs, thus ensuring the accessibility of control [8].

The seats are usually reconstructed in a similar manner, which may be set as the integrated or folded geometry with geometric construction surface as the basic modeling element. The integrated seat can increase the storage space, while the folded one can increase the activity space after being folded and allow 3 people to seat after being unfolded. In this case, the integrated seat is adopted. Through graphic reconstruction of the storage space shown in Figure 3 in combination with the seats for 3 submersible pilots, the lower storage space is increased as much as possible while meeting the seating requirements of submersible pilots, as shown in Figure 4. While designing the integrated seat, the man-machine ergonomic parameters such as visibility and comfort of submersible pilots, the accessibility, and comfort of manned submersible equipment shall be constrained in strict accordance with the ergonomic requirements, so as to construct the model of the integrated seat and working table for submersible pilots as shown in Figure 4.

*2.4. Reconstruction and Optimization of Overlapping Area in the Cabin of Manned Submersible Jiaolong.* The operation of manned submersible can be simplified into five stages:

diving, sitting on the sea bed, cruising, operating, and ascending, which involve the tasks of photo taking, camera shooting, surveying, and sampling [9]. Surveying, sampling, and manned submersible manipulation would basically overlap in pairs; therefore, we should freely and abstractly reconstruct the overlapping work area and arrange movement areas for submersible pilots undertaking the overlapping tasks, thus meeting the requirements for simultaneous working by submersible pilots without interference, as shown in Figure 5. Take sampling; for example, reconstruction and optimization of overlapped areas can save the activity space for one submersible pilot and ensure that the operation and observation space are sufficient for two operators without mutual interference, and another scientist may only need to stand in front of the monitor and direct the operations while monitoring.

The working areas of the three submersible pilots are overlapped, with the activity space in the front, as shown in Figure 5. Their activities are concentrated in the front, one may perform operations, the second one may provide observation and assistance, and the third one may monitor the working status. The weight of space overlapping is the lowest at the wall and the rear half, as shown in Table 3. After deconstruction, the rear part of the cabin is used to place equipment, and through optimization and reconstruction of the integrated seat, the seat and rear space can be designed in a model conforming to ergonomics. The lower part in the rear is provided with a certain space for a submersible pilot to lie down and relax (for they will work for more than ten hours in the cabin with a diameter of only 2.1 m). The upper part of the spherical cabin is separated, the middle part is vacated, and the top is set with a passageway, thus obtaining the space layout as shown in Figure 6.

### **3. Establish the Optimization Model of Cabin Layout of Manned Submersible Jiaolong under the Deconstruction and Reconstruction Thinking**

In this paper, we consider the basic elements of the reconstruction as modules and seek the sources of manned submersible cabin module, the function of each part of the cabin represented by the module, and the form of each module in the cabin by the deconstruction and reconstruction thinking, so as to reconstruct the space layout of the cabin module system under different thinking [10].

The abstract module system is a logical system with coherent design, so there is a close relationship between task decomposition modules, and the matching of different modules may have different meanings. The module elements applying deconstruction thinking are qualified (sample population is selected for submersible pilots), as shown in Figure 2; as for cabin layout, the space of each qualified module has an exact range, and the modules can be freely replaced under the condition that the occupied space does not exceed the maximum range of activity. The overlapping weight grade is set between modules, as shown in Table 3, to further optimize the layout of cabin space.

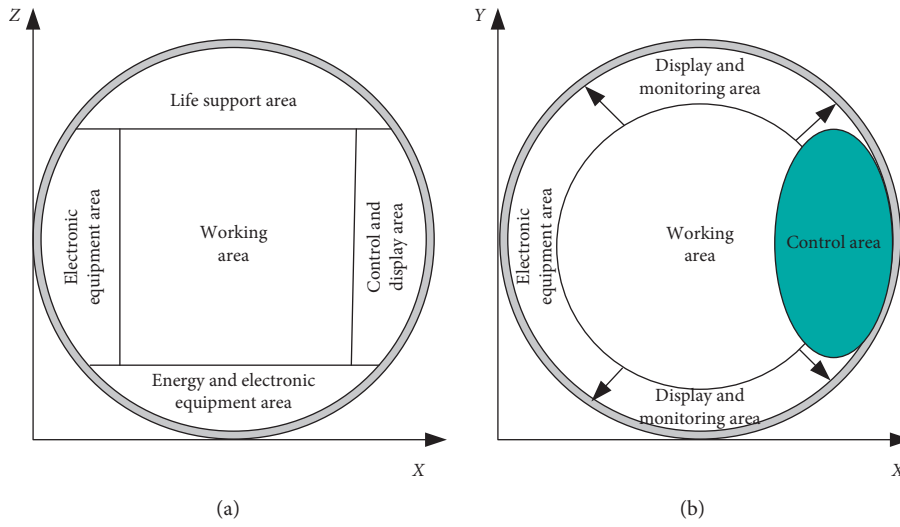

FIGURE 3: Geometric deconstruction of space in manned submersible cabin.

FIGURE 4: Reconstruction and optimization of the seat for three submersible pilots.

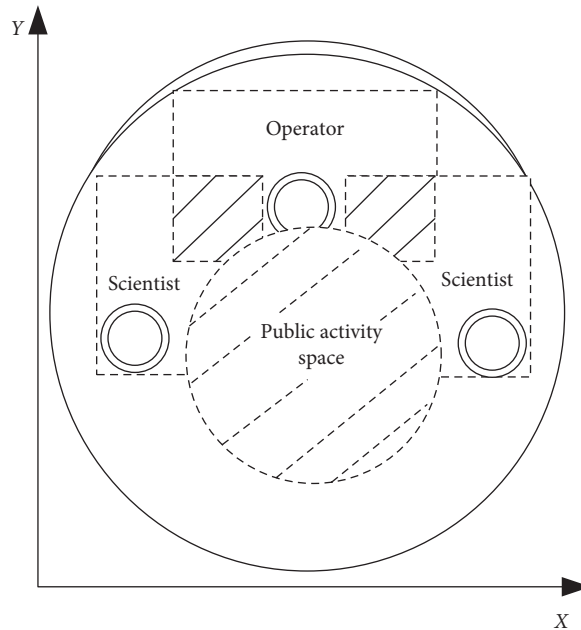

FIGURE 5: Reconstruction optimization of overlapping working areas in manned submersible cabin.

TABLE 3: Overlapping weight grade and definition of coefficients.

| Grade | Weight | Meaning   |
|-------|--------|---|
| 1     | 1      | Regional overlap demand is quite high or the regions must be overlapped |
| 2     | 0.7    | Overlap demand is relatively high                                       |
| 3     | 0.4    | Overlap demand is general   |
| 4     | 0.1    | Overlap demand is relatively low  |

FIGURE 6: Abstract reconstruction and optimization of overlapped space for submersible pilots in the spherical cabin.

**3.1. Cabin Layout Optimization Model of Manned Submersible Jiaolong.** Suppose that  $m$  target objects (including 3 submersible pilots) shall be placed in the spherical cabin; the design variable of  $m$  objects is  $X = (x_1, x_2, \dots, x_m)^T$ , representing the spatial position of each object;  $F$  refers to the objective function, representing the design requirements of each object;  $r$  refers to the radius of the spherical cabin;  $v_i$  refers to the space occupied by objects in the spherical cabin;  $v_j$  refers to the space occupied by objects during movement;  $i$  refers to the variable of objects occupying space in the spherical cabin;  $j$  refers to the variable of objects with mutual interference of active space; and  $k$  refers to the equipment overlapping weight coefficient, as shown in Table 3:

$$\begin{cases} \max F = \{f_1(X), f_2(X), \dots, f_m(X)\}, \\ \text{Vol}_F = \sum_{i=0}^m V_i + \sum_{j=0}^m kV_j, \\ \text{s.t. } 0 \leq i, j \leq m, \\ \text{Vol}_F \leq \frac{4}{3}\pi r^2. \end{cases} \quad (1)$$

According to the ergonomic quantitative data of the cabin model, we perform preliminary deconstruction and reconstruction of the targets in the cabin and get the model of cabin layout (Figure 7) according to the requirements of noncollision between objects in manned submersible cabin, between equipment and equipment, and between equipment and cabin wall.

**3.2. Optimization of Cabin Layout under Noninterference Constraint.** Noninterference refers to the zero probability of collision between equipment and equipment in the cabin and between the equipment and cabin wall, which is the first condition for the optimization of cabin layout [11]. According to calculation formula (2), the metrics can be used to measure noninterfering collisions, where  $f_I$  refers to the total interference of space layout in the cabin,  $I_1(x)$  refers to the interference amount between the equipment and cabin wall, and  $I_2(x)$  refers to the interference amount between equipment and equipment. In summary, the mathematical model can be expressed as follows:

$$\begin{cases} \max F = \{f_1(X), f_2(X), \dots, f_m(X)\}, \\ f_I = \sum I_1(x) + \sum I_2(x), \\ \text{s.t. } |X_i| \leq R, \quad i = 1, 2, \dots, m, \\ f_I = 0. \end{cases} \quad (2)$$

#### 4. Pareto Multiobjective Optimization Genetic Algorithm

Optimization refers to getting better items through certain rules or algorithms. In a given area, the optimization of multiple numerical targets is called the multiobjective optimization. In this paper, the genetic algorithm, combined with the parallel selection strategy, is mainly used to solve the multiobjective optimization in the cabin of manned submersible Jiaolong after deconstruction and reconstruction [12].

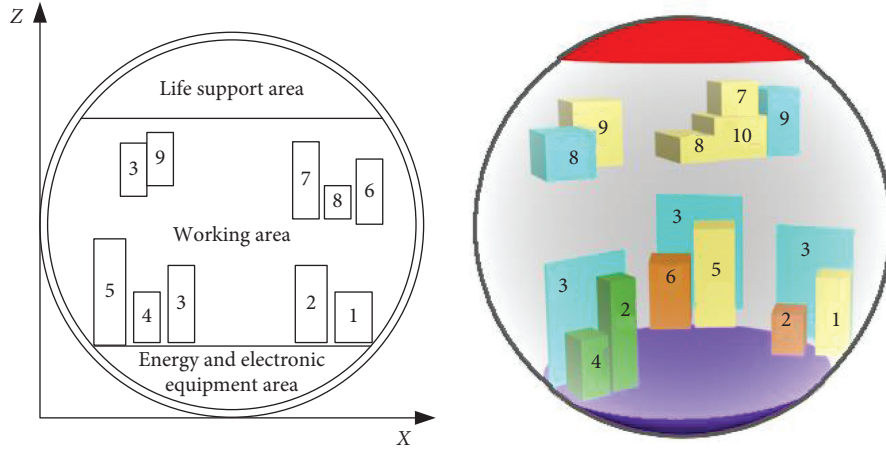

FIGURE 7: Model of space layout of equipment in the cabin.

**4.1. Improved Genetic Algorithm.** The manned submersible cabin group (all kinds of equipment) is divided into different subgroups based on the number of objective functions of cabin layout category after deconstruction and reconstruction, and the corresponding objective function is provided for each subgroup; later, the optimal subfunctions are independently selected under the constraint conditions of cabin layout and formed into the corresponding new subgroups, thus combining into new groups; and then the cross-mutation operation is performed; finally, the group of the next generation is generated, and the Pareto optimal solution will be obtained after cycling [13], as shown in Figure 8. The flowchart of parallel selection genetic algorithm after deconstruction and reconstruction is shown in Figure 9.

After deconstruction and reconstruction, the genetic algorithm can be improved from the following aspects: maintain the Pareto optimal items in the subgroups of the next generation, without participating in crossover calculation and mutation calculation. The area to be searched, such as the integrated seat and the rear item placement area after deconstruction and reconstruction, can be taken as the final search result, as shown in Figure 10; the search trajectory of Figure 10(a) improved genetic algorithm is more effective than that of Figure 10(b) random search, based on which, the fitness function value is established for guiding the fast and stable search.

**4.2. Coding and Fitness Function.** The solution variable is the coordinate of each of the types of equipment in the cabin of manned submersible Jiaolong, which can be taken as the chromosome for coding.  $X$  refers to a certain layout scheme.  $x_{ic}$ ,  $y_{ic}$ , and  $z_{ic}$  refer to the center-of-mass coordinate of each equipment:

$$X = (x_{1c}, y_{1c}, z_{1c}, x_{2c}, y_{2c}, z_{2c}, \dots, x_{mc}, y_{mc}, z_{mc}). \quad (3)$$

Fitness function value is usually used to evaluate the individual performance and guide the search in genetic algorithm, and it directly determines the stability and speed of the genetic algorithm. Take the space layout in the cabin of

manned submersible Jiaolong as an example;  $R$  of the spherical cabin is 2,000 mm, so in order to find an optimal layout scheme of the cabin of manned submersible Jiaolong, the first condition is that the devices cannot collide with each other (i.e.,  $f_I = 0$ ). The fitness function is

$$F(p) = k \times \sum_{i=1}^m Q_i \times f_i(p), \quad (4)$$

where  $P$  refers to the layout scheme of manned submersible cabin;  $Q_i$  refers to the prior layout index of the cabin after deconstruction and reconstruction;  $f_i(p)$  refers to the optimal individual value of the equipment in manned submersible layout scheme;  $k$  refers to the equipment overlapping weight coefficient.

**4.3. Main Parameters of the Optimization Algorithm.** The manned submersible group size  $N=50$ . According to formula (3),  $n$  is 10; crossover probability  $P_c=0.8$ ; mutation probability  $P_m=0.1$ ; generation gap of subgroup  $G_{Gap}=0.8$  (each generation has 20% of outstanding individuals inherited into the next generation); the maximum number of evolution generation  $G_{max}=500$ . The initial individuals are randomly arranged and automatically optimized during the operation of the algorithm. The objective function values of the subgroups are all subject to dimensionless and normalization processing [14].

**4.4. Analysis of Case Results.** In this case, the results of 20 calculations are basically consistent, verifying that the optimized layout of manned submersible cabins constructed after deconstruction and reconstruction has a better stability. A set of calculation results (only part of the results) is extracted for analysis, as shown in Figure 11.

As for Figure 11(a), optimization of equipment with low overlapping weight in the cabin, the initial objects are randomly arranged, the movement trajectory of equipment in the cabin is chaotic, and there are many collisions in the activity space, which are mainly the collisions between equipment and inner wall of the spherical cabin and between

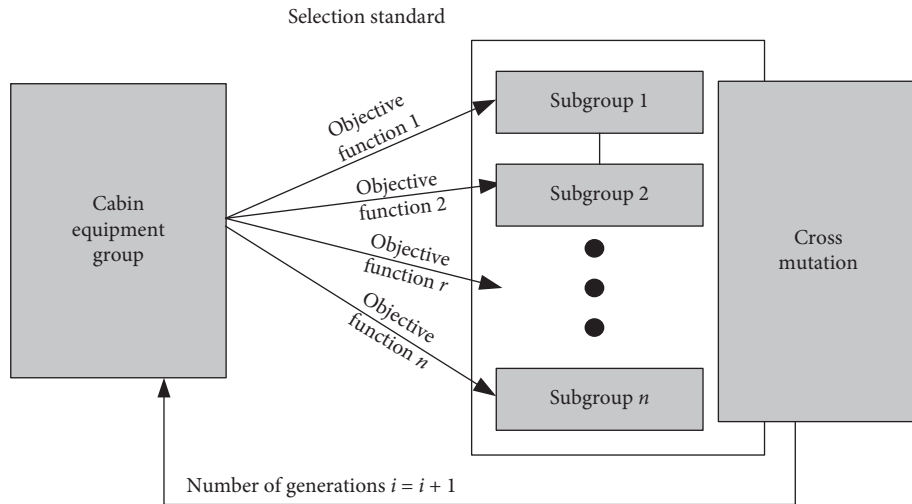

FIGURE 8: Diagram of parallel selection genetic algorithm after deconstruction and reconstruction.

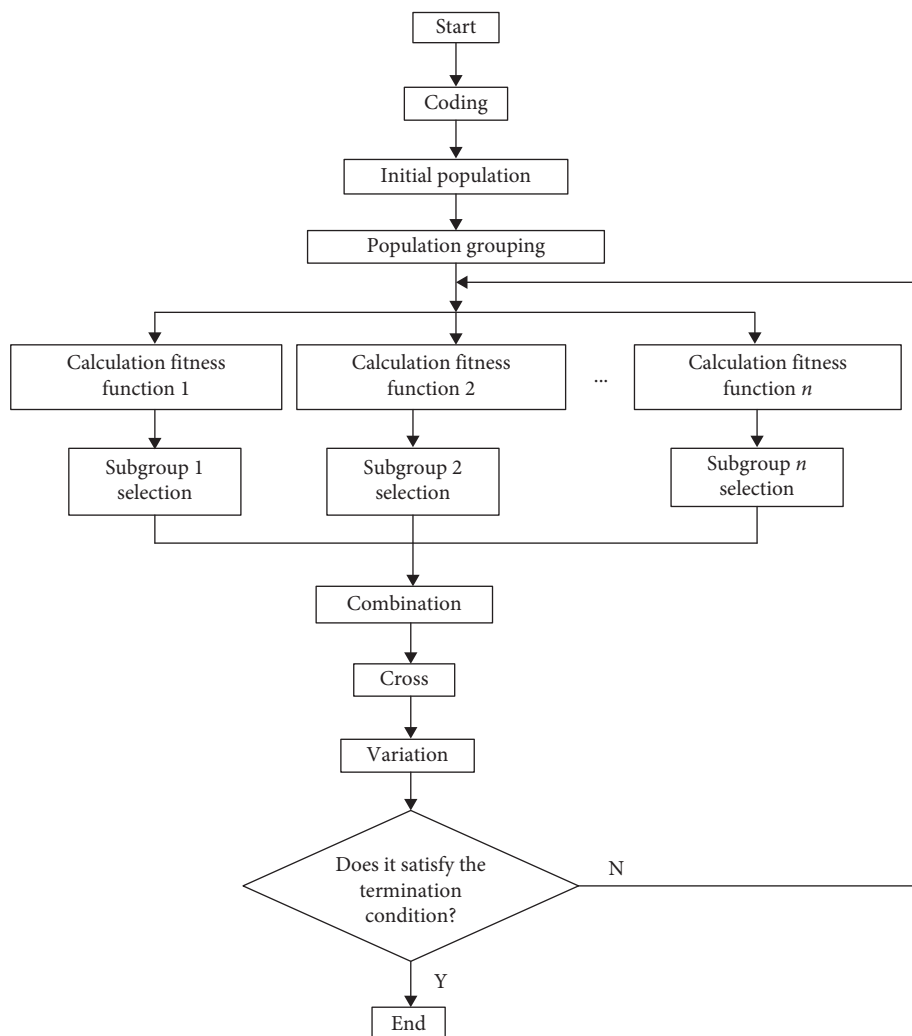

FIGURE 9: Flowchart of parallel selection genetic algorithm after deconstruction and reconstruction.

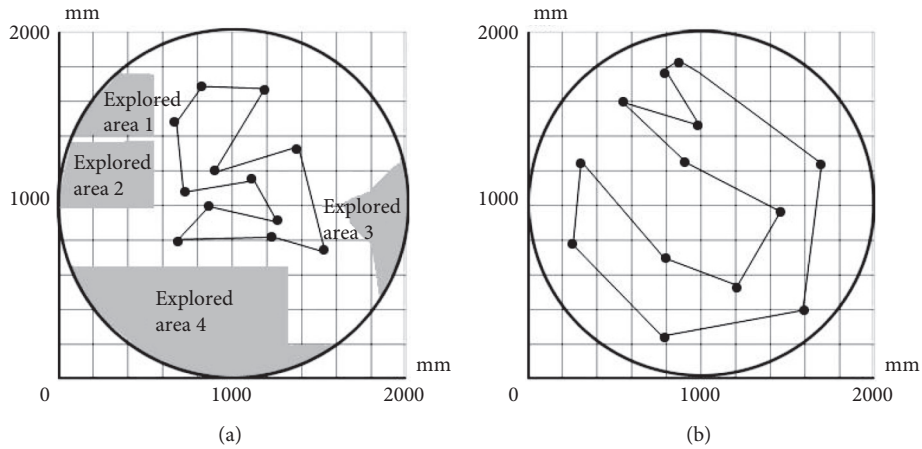

FIGURE 10: Comparison of search area after deconstruction and reconstruction with the random search area. (a) Search trajectory of improved parallel selection genetic algorithm. (b) Search trajectory of random search.

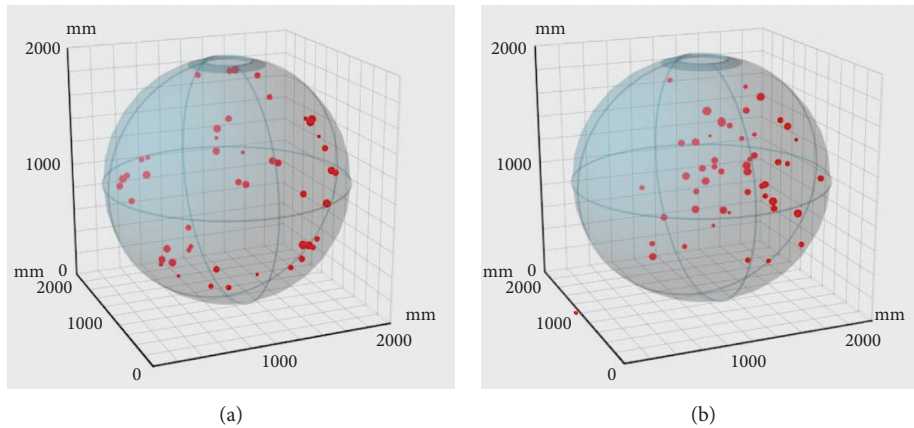

FIGURE 11: Results of multiobjective genetic algorithm for manned submersible cabin layout. (a) Optimization of equipment with low overlapping weight in the cabin. (b) Optimization of equipment with high overlapping weight in the cabin.

equipment and equipment. With the progress of the multiobjective genetic algorithm, the number of collisions (interference amount) in the cabin is gradually reduced, the equipment (small red dots) gradually moves to the center of the sphere and the inner wall, and the distance between equipment and equipment becomes larger, making the activity space of equipment with low overlapping weight scatter on the spherical wall; Figure 11(a) proves that the multiobjective genetic algorithm conforms to the rationality of optimized layout of equipment with low overlapping weight after deconstruction and reconstruction.

As for Figure 11(b), optimization of equipment with high overlapping weight in the cabin, the initial objects are randomly arranged with large activity space, so there is a large amount of interference between equipment and equipment, such as the interference between the activity space of the three submersible pilots and the equipment in the cabin, and between the tasks and the equipment. After deconstruction and reconstruction, with the progress of the multiobjective genetic algorithm, the equipment

(small red dots) gradually moves to the front of the cabin, and the amount of interference decreases after optimization of the distance between equipment and equipment, thus making the equipment with high overlapping weight move in the front of the cabin. Figure 11(b) proves that the multiobjective genetic algorithm conforms to the rationality of the optimized layout of equipment with high overlapping weight after deconstruction and reconstruction.

The results of multiobjective genetic algorithm indicate that when the total interference of equipment in the cabin ( $f_I$ ) is 0, the equipment with low overlapping weight should be fixed on the wall of the cabin; those with high overlapping weight should be fixed in the front of the cabin. In the Jiaolong manned submersible cabin, energy and common tools are arranged in the rear and lower parts of the cabin, the submersible pilots are arranged in the front part of the cabin, and those with high operating and viewing frequency should be placed within the accessibility and visibility range of the 3 submersible pilots.

FIGURE 12: Cabin layout optimized by genetic algorithm after deconstruction and reconstruction.

Figure 12 is an effect diagram of cabin layout optimized by genetic algorithm after deconstruction and reconstruction; Pareto optimal solution of the optimized mathematical model is the one obtained with the total interference of equipment  $f_I = 0$ . The human-machine integrated evaluation system for manned submersibles can select a relatively reasonable layout scheme from the optimal solution. As shown in Figure 12, there is no interference in cabin layout optimized by genetic algorithm after deconstruction and reconstruction, indicating a reasonable optimization process.

## 5. Conclusion

The optimization of the cabin layout of manned submersible is of great importance to improve human reliability. In this paper, the manned submersible cabin layout is optimized based on deconstruction and reconstruction thinking from the cross-disciplinary cultural perspective in accordance with the design requirements of manned submersible Jiaolong, combined with ergonomic to constraint conditions on the space layout, so as to establish an optimized mathematical model for cabin layout of manned submersible Jiaolong. After deconstruction and reconstruction, this paper finally obtains a better layout scheme combined with the multiobjective genetic algorithm; the main conclusions are as follows:

- (1) Deconstruction and reconstruction of manned submersible cabin space from an interdisciplinary cultural perspective is a new method of cabin layout optimization, which reflects the advantages of cross-field and multidiscipline combination optimization.
- (2) The manned submersible cabin layout is optimized by combining the aesthetic principles of deconstruction and reconstruction with man-machine ergonomics and other conditions. The same type of

activities and equipment with the same nature are combined to save the cabin space; at the same time, weight combined with multiobjective genetic algorithm is introduced to provide a more scientific scheme for the layout of cabin equipment.

- (3) Based on the aesthetic principle of deconstruction and reconstruction and multiobjective genetic algorithm, the cabin layout optimization model of manned submersible reduces the random search area and finally makes the total interference of cabin equipment approach zero as soon as possible, which can accelerate the progress of the scheme.

However, the optimization mathematical model needs to be further refined in more in-depth subject analysis and calculation tool research. In the next step, static and dynamic dimensions of submarine pilots are added, and virtual simulation and bionic algorithm are applied to improve its engineering practicality.

With the rapid development of Internet of Things (IoT) technology, the energy consumption of service composition in the IoT environment is a key problem to be studied. At present, the problems of service composition in the IoT environment mostly focus on the evaluation research based on quality of service (QoS), ignoring the overall energy consumption in the process of dynamic configuration of service composition. Therefore, we construct the service composition structure for the IoT and propose the QoS evaluation model and energy evaluation model for the service composition in the IoT environment. Considering that the service composition in the Internet of things environment is NP hard, moth algorithm (MFO) is successfully applied to the QoS evaluation model and energy evaluation model. The simulation results reveal that MFO has good optimization effect in the abovementioned models, and the optimization effect of MFO is improved by 8% and 6% compared with the genetic algorithm and particle swarm optimization, so as to realize the green energy strategic management of QoS composition in the environment of IoT.

## 1. Introduction

In recent years, the development of embedded devices has been rapid along with the growth of Internet of Things (IoT) [1–3]. The service-based information system connects the physical reality world and the network virtual world, making the boundary between them gradually blurred [4]. In the IoT, the service-oriented method is widely used and accepted in the development and integration of information [5]. More and more network resources can be freely obtained, such as public data and applications [6]. The traditional information publishing platform is gradually transformed into an open distributed computing infrastructure. With the wide acceptance of service-oriented, service has become the core resource in the network environment [7].

Web services provide the mechanism of service description, service publishing, and service discovery, forming an open, independent, and autonomous distributed environment [8]. In order to ensure the reusability of services, the function of a single service is relatively simple, but in the real application

environment, a simple single service cannot meet the needs of users. When a single service cannot meet the complex needs of users, it is necessary to combine a large number of services with simple functions to form a powerful service that can meet the needs of users. Therefore, scholars hope to create new and more powerful service functions by combining the existing service integration, so as to make full use of the previous resources, expand and extend the original services, fully tap the potential of Web services, and make them play a greater role [9]. From the perspective of task planning, service composition decomposes complex large-scale tasks and then selects atomic services that can complete the subtask for each subtask. With the continuous development of IoT and Web services technology, more and more functions and processes are packaged into standard Web services and published to the Internet, which leads to the exponential growth of the number of services. In order to ensure the interoperability of various information systems, researchers at home and abroad directly apply the service-oriented framework and Web service standards to physical devices. However, it is not appropriate to apply Web service standards directly in the IoT environment [10].

At present, most of the research studies on the quality of service (QoS) composition focus on the optimization of QoS indicators, and some preliminary results have been achieved [11]. However, how to realize the QoS-based green energy strategic management is still an open problem [12]. In reference [13], hybrid integer linear programming (MILP) is proposed for service selection, in which energy consumption is used as an indicator of QoS attributes. However, the time complexity of ILP increases exponentially with the size of the problem. In view of the limitations of integer linear programming (ILP) [14], service selection is formulated to solve the service composition quality problem with multiple constraints. References [15, 16] break through the bottleneck of the classical service composition method which can only select a single candidate service and propose to allow multiple candidate services from a given service class to execute sequentially to improve the QoS of composite services [17]. The advantage of this method is to improve the selection time of the traditional multiconstrained shortest path by introducing the potential path of QoS requirements [18]. In reference [19], service composition is modelled as a path search problem of a directed acyclic graph, and heuristic ant colony algorithm is adopted to search the optimal path in a directed acyclic graph under global constraints [20].

However, the abovementioned research does not fully consider the dynamic nature and the complexity of service state in the optimization process [21, 22]. In reference [23], K-means clustering technology is used to divide candidate services into clusters with roughly the same attributes. These different clusters can be used to determine the best service composition under the condition of satisfying global QoS constraints [24]. Firstly, the QoS value is defined as a discrete random variable with probability quality function, and then, simulated annealing algorithm is used to select service composition satisfying global QoS constraints [25, 26]. The advantage of the abovementioned method is that it can be optimized according to the QoS attributes that users are interested in, for searching the QoS composition path that satisfies the actual needs of users [27, 28]. In references [29, 30], the paper proposes the service composition selection by minimizing the weighted sum of energy consumption and response time.

To solve the abovementioned problems, this paper models the QoS evaluation and energy consumption of the QoS-based composition problem in the IoT environment and applies MFO algorithm to the abovementioned model successfully. Considering the quality of service composition and energy consumption, this paper puts forward the QoS evaluation model and energy evaluation model in the IoT environment and applies MFO (month flame optimization) algorithm to the QoS evaluation model and energy evaluation model successfully. The experimental results show that compared with PSO (particle swarm optimization) and GA (genetic algorithm), MFO can obtain the best QoS and effectively reduce energy consumption, so as to realize the green energy strategic management of service composition quality in the Internet of Things environment. The main contributions of this paper are as follows: (1) most of the

service composition problems in the Internet of Things are focused on the evaluation of quality of service (QoS), ignoring the overall energy consumption in the dynamic configuration of service composition. The service quality evaluation model and energy evaluation model of service composition in the Internet of Things environment are proposed to solve the abovementioned problems; (2) the month algorithm (MFO) is successfully applied to the QoS evaluation model and energy evaluation model. In addition, good optimization effect has been achieved.

The rest of this article is designed as follows. Section 2 gives the structure and model design of QoS composition in IoT. In Section 3, the QoS-oriented green energy management model for IoT is studied. Section 4 conducted simulation experiments and analysed the results. Section 5 summarizes the full text.

## 2. Structure and Model Design of QoS Composition in IoT

How to realize the optimal selection of QoS composition in the IoT environment to meet the actual needs of users for services is an NP hard problem. At present, a large number of literature research mainly focuses on QoS-based service selection. However, with the increase of service categories, each candidate service generates energy consumption, which makes the overall energy consumption increase. Therefore, QoS evaluation and energy consumption evaluation are of great significance for the optimization of service composition. Therefore, structure and model design of QoS composition in IoT is the core research.

*2.1. Multilayer Architecture Design of IoT.* IoT is closely related to a ubiquitous network, and its hierarchical structure is also very similar to a ubiquitous network. The multilayer structure of IoT includes a perception layer, access layer, network layer, support layer, and application layer, which is shown in Figure 1. The perception layer mainly realizes the collection and information processing. The research content of the sensing layer is how to achieve the goal of miniaturization and intellectualization of nodes while saving energy and how to use renewable energy. At the same time, multihop and other research contents of the traditional WSN can be reflected in this layer. The access layer mainly completes the Internet access of all kinds of devices. The network layer is the original Internet, which mainly completes the function of long-distance transmission of information. There are still many contents to be further studied in this layer, such as Internet of Things content distribution technology. The support layer, also known as the middle layer or business layer, mainly completes three parts of functions: the lower needs cognitive network resources and then achieves the purpose of adaptive transmission; its core content is to complete the expression and processing of information and ultimately achieve the purpose of information sharing; this layer also needs to provide a unified interface and virtualization support; virtualization includes computing virtualization and storage virtualization;

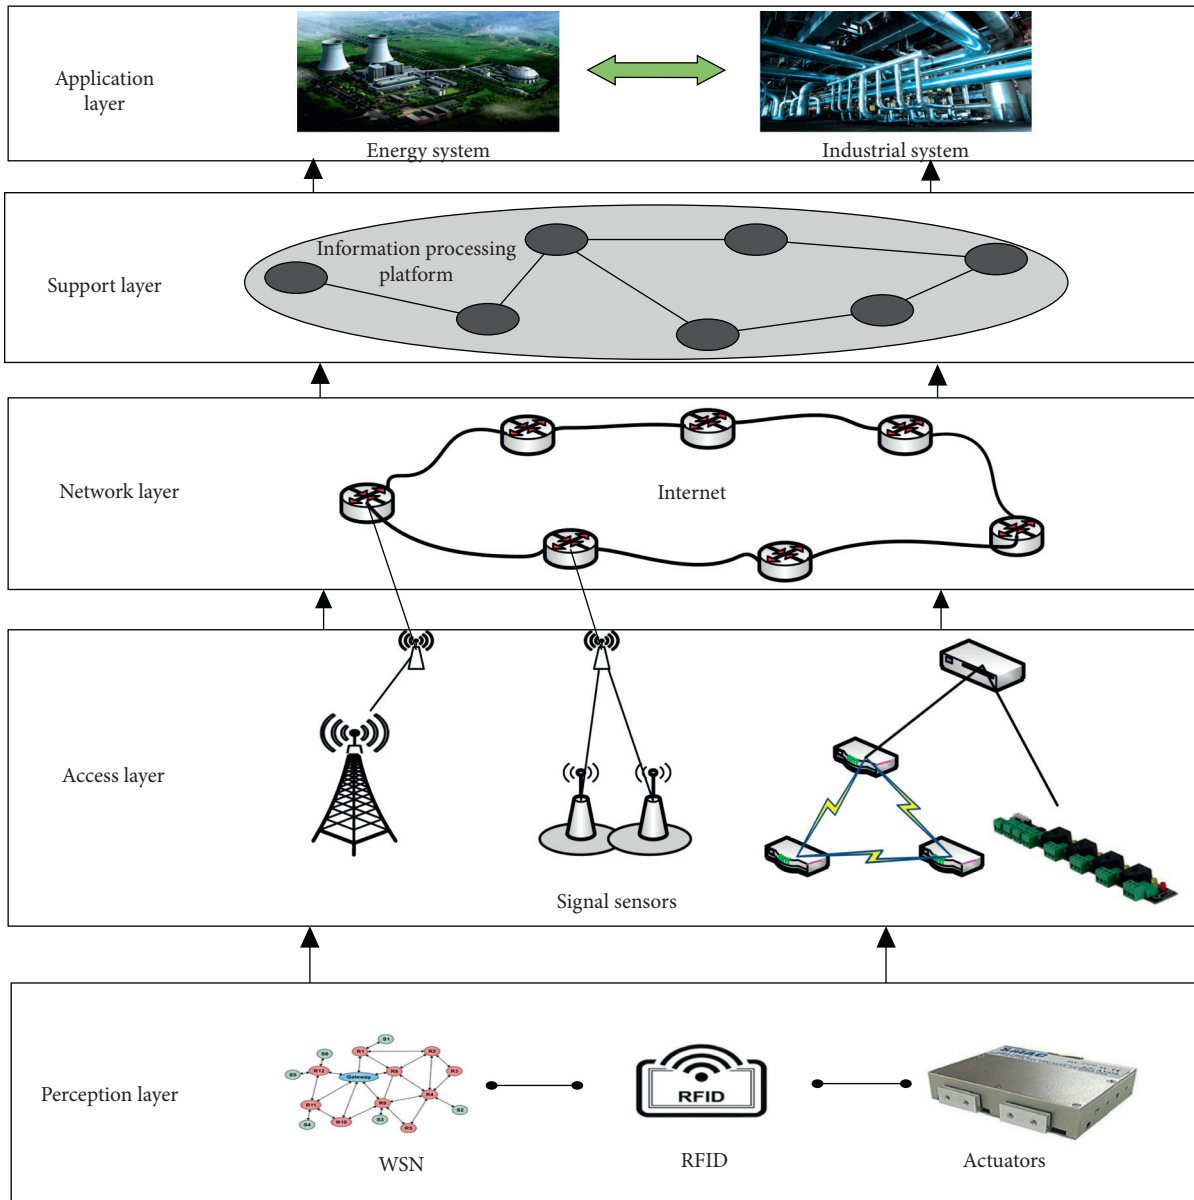

FIGURE 1: Multilayer architecture of IoT.

the more typical technology is Cloud Computing. The application layer is the comprehensive utilization of information to provide help for users.

**2.2. QoS Constraint Model in IoT.** Based on the new features of context adding QoS ontology and semantic IOT services, a QoS constrained service model in IOT is proposed, as shown in Figure 2. Among them, the interaction model shows the relationship between IOT services, service producers, and service consumers; the state model shows the state transition of services; the function model shows the behaviour of services; the three and the relationship between them are marked by the QoS ontology of relevant ontology in the knowledge base.

In the service model based on the Internet of Things shown in Figure 2, the protocol of the underlying sensor may

be quite different from the transmission protocol of the Internet, so there is a home gateway between the two network protocols. Home gateway is responsible for the access of nodes in a small range. Either ID or home protocol are not supported at the same time. In addition, objects may use a variety of physical layer transmission methods, such as wired, WiFi, ZigBee, or Bluetooth, so the home gateway must also have the function of heterogeneous network access. In the case of coexistence of various heterogeneous and same frequency wireless transmission modes, how to reduce the interference between various wireless transmission modes is particularly important, such as the interference problem when ZigBee and WiFi coexist.

After the introduction of object mobility, the network architecture may also need to introduce an access gateway (located between the home gateway and the regional server), which

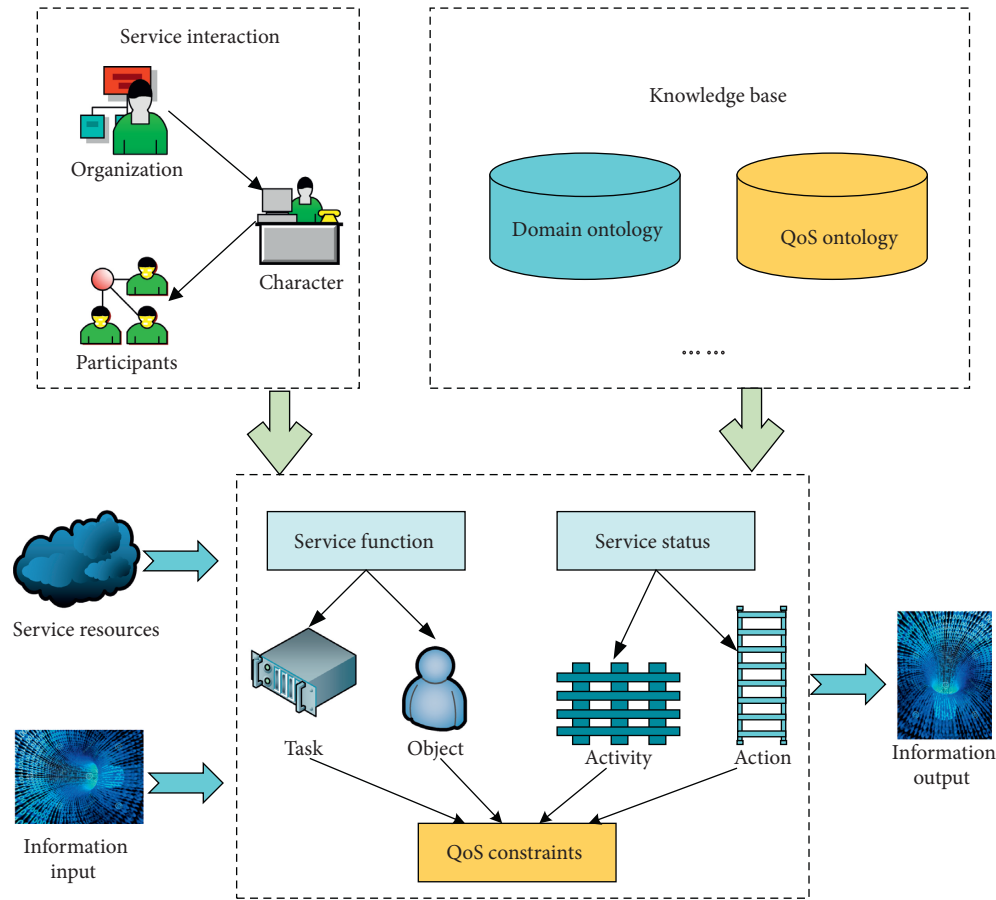

FIGURE 2: Service model based on IoT.

is mainly responsible for the mobility management of nodes in a larger range and the management of existing IOT devices. Of course, if the home gateway is powerful enough, the mobility management of objects can be completed directly in the home gateway under the guidance of a network flattening idea. From the networking technology of the Internet of Things discussed before, the gateway based on DTN is more suitable for architecture of the IoT, so the home gateway discussed here can be implemented in the way of DTN. However, in order to meet some real-time applications (such as actuator control and alarm), the home gateway must have the priority-based data transmission function.

**2.3. Dynamic Composition Framework of Internet of Things Services Based on QoS.** Figure 3 shows the core functions of the dynamic composition framework of QoS-based semantic IoT services; it also shows the dynamic composition model based on QoS and how to optimize the combination mainly including the following modules:

(1) **Service preliminary screening module:** the module analyses the user's direct request for the target service, and the related domain ontology forms the standard service request description file, carries on the preliminary matching with the service in the service library, and obtains the candidate service set.

(2) **Restricted service description file generation module:** the module senses the context information related to users and physical devices through the sensing devices around the physical devices mapped by users and candidate service sets. With the support of context-added QoS ontology, the module calculates the impact of context information changes on the QoS information of services required by users and services provided by physical devices and forms a standard Q without a semantic conflict service description file of OS restriction.

(3) **QoS-based service selection module:** after dimensionless processing of QoS parameter values of the request service description file and each service description file in the candidate service set, atomic matching and aggregate matching are carried out, respectively, and compared with corresponding atomic threshold and aggregation threshold, and one or more subservices that meet some or all requirements of users are selected to form the service set to be combined.

(4) **Service composition module based on graph search:** the module dynamically constructs the directed graph of the service and the input/output data of the service set to be composed and obtains one or more new services that meet the specific conditions. The

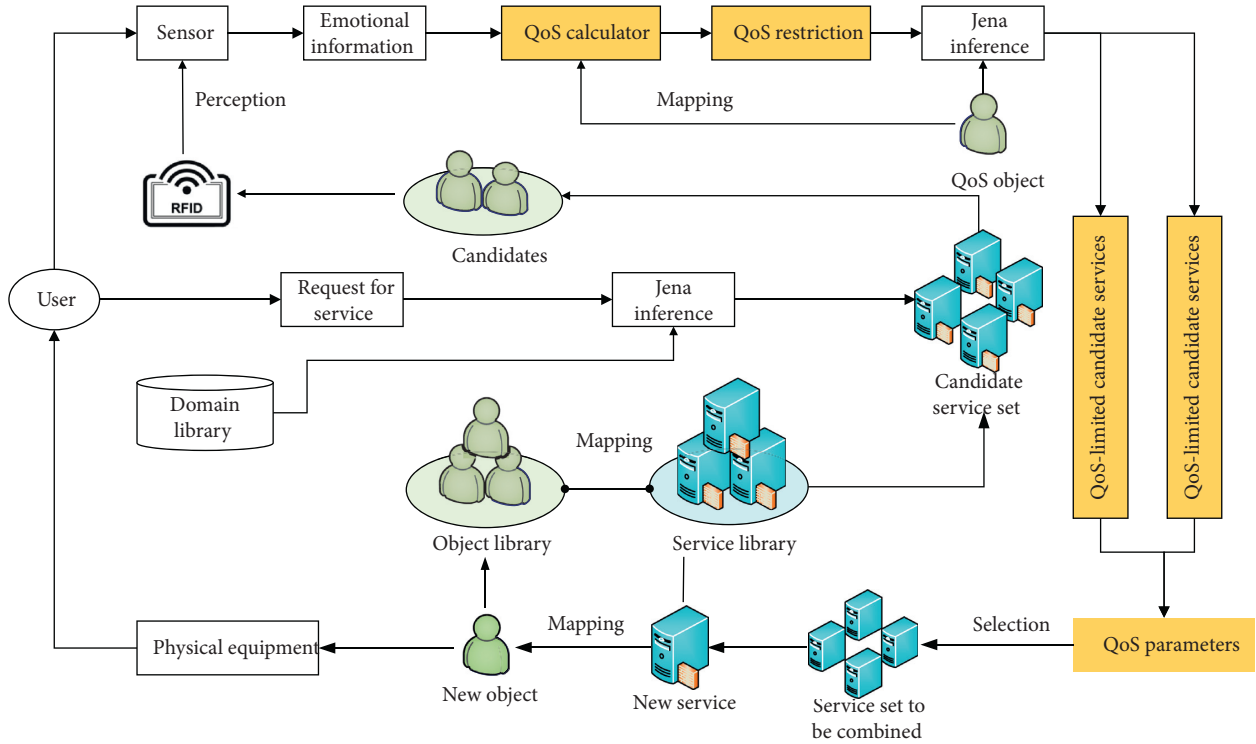

FIGURE 3: Dynamic composition diagram of IoT services based on QoS.

method of combining the depth first algorithm with the breadth first algorithm is used to select the most suitable service.

- (5) Service mapping module based on the object net: through the service ID of each subservice in the new service, the module maps the new service to the corresponding virtual object to form a virtual object network. Finally, the service results are fed back to the user through the corresponding physical settings of the object network.

### 3. QoS-Oriented Green Energy Management Model for Internet of Things

**3.1. QoS Evaluation Model in the Environment of IoT.** Assuming that a composite service can be composed of  $N$  services with different functions, all services can be divided into  $n$  classes according to their corresponding functions, which are called service classes. Assuming that there are  $m$  atomic services in each service class, each service is called a candidate service. The core processing idea of the QoS-driven service composition model is based on the corresponding QoS attribute requirements, and a candidate service is selected from each service class, so as to find a service sequence that can make the QoS attribute optimal or better.

We pay attention to the QoS evaluation model in the Internet of Things environment.  $T = \{T_1, T_2 \dots T_i \dots T_D\}$  is defined as a complex Internet of Things service, where  $D$  means the service categories for a service.

Each service category  $T_i$  contains  $C_i$  specific service  $S_i^j$ , where  $i$  is the service category,  $j$  means the number of following services, and  $j = 1, 2, \dots, C_i$ , the set of QoS metrics used to evaluate each candidate service.

Figure 4 describes the main process of service composition of IoT. As can be seen from Figure 1, the goal of IoT service composition is to select the best path to satisfy the service requirements of customers. Theoretically, there are  $\prod_{j=1}^D C_j$  service composition paths. The path of QoS composition simplifies as  $x = \{x_1, x_2, x_i, \dots, x_D\}$ , where  $x_i$  is the candidate service for executing the  $i$ -th service category, where  $1 \leq i \leq C_i$ . Generally, according to several reduction principles, serial, parallel, and circular structures can be converted into sequential structures when evaluating paths with QoS metrics.

We suppose that the QoS parameter value of each service  $CS_i$  is  $q\{CS_i^j\} = \{q_1, q_2, q_3\}$ , that is,  $q\{CS_i^j\} = \{t, c, r\}$ . The QoS is defined as  $Q = Q\{Q_1, Q_2, Q_3\} = \{T, C, R\}$ , and indicators are estimated, considering the specific rules and the characteristics of the QoS indicator. The target is defined as

$$\min f_1(x_1) = w_1 T(x_1) + w_2 C(x_1) + w_3 R(x_1),$$

$$s.t. \begin{cases} 1 \leq j \leq C_i, \\ 1 \leq i \leq D, \\ \sum_{i=1}^D W_i = 1, \end{cases} \quad (1)$$

where  $\{w_1, w_2, w_3\}$  corresponds to the weight of each QoS indicator, which is set to 1/3 in this paper.

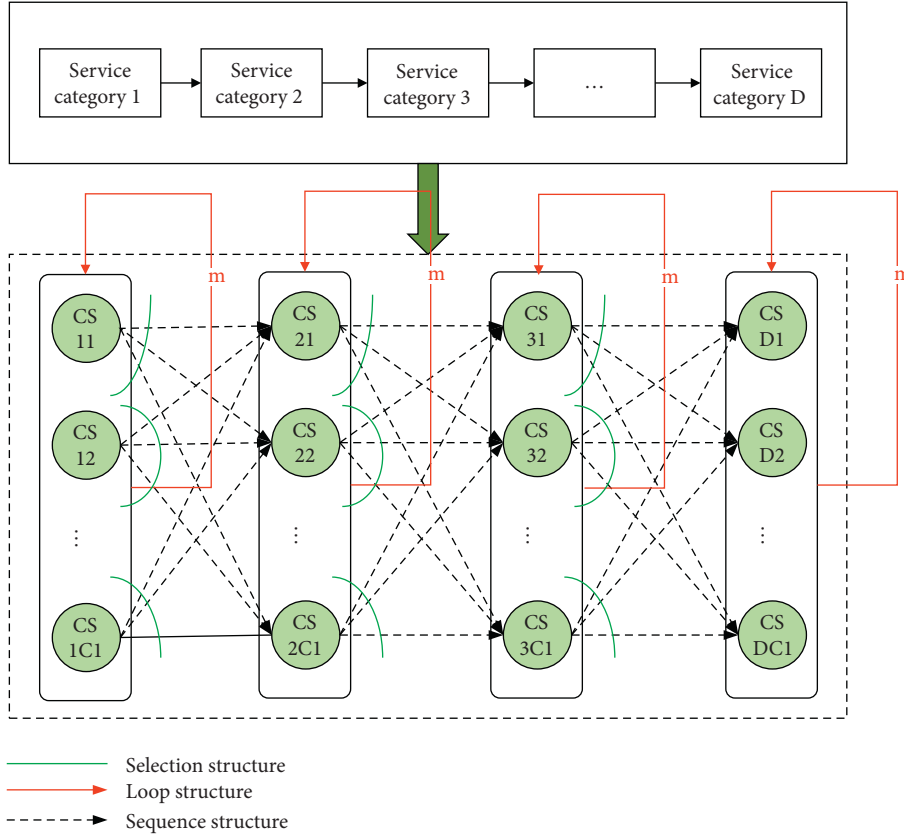

FIGURE 4: The QoS composition process of IoT.

3.2. *Energy Assessment Model Based on IoT.* The objective function of the energy evaluation model is defined as follows:

$$\min f_2(x_2) = \sum_{i=1}^{N_{ES}} \left( \frac{P_i(t)}{\eta_i} C_{run}(i) + P_i(t) C_{om}(i) + P_{Grid}(t) \right), \quad (2)$$

where  $T$  and  $N_{ES}$  are number of system segments and energy services (ES). ES includes various kinds of power generation services, such as photovoltaic (PV) service, wind turbine (WT) service, battery (BAT) service, and fuel cell (fuel cell) service (FC) service, and microturbine (MT) service;  $i$  is the number of ES categories.  $P_i(t)$  is the power generation at time  $t$ , and  $\eta_i$  is the generation efficiency of the  $i$ -th ES.  $C_{run}$  is the operating cost of each ES;  $C_{om}$  is the maintenance cost of each ES.  $C_{Grid}$  is the power price grid, and  $P_{Grid}$  is the exchanged power.

The power balance constraint equation is as follows:

$$\sum_{i=1}^{N_{ES}} P_i(t) + P_{Grid}(t) = P_{Load}(t) + \sum_{n=1}^{N_{ESO}} P_{ESO}(t), \quad (3)$$

where  $P_{Load}(t)$  is the load power at time  $t$  and  $P_{ESO}(t)$  is the discharge power of ES at time  $t$ . Equation (3) illustrates that the IoT-based energy management must meet the total power balance conditions in the whole period.

The power constraint equation is as follows:

$$\begin{cases} P_{ES,min} \leq P_{ES}(t) \leq P_{ES,max}, \\ \Delta P_{ES,down} \leq P_{ES}(t) - P_{ES} \leq \Delta P_{ES,up}, \end{cases} \quad (4)$$

where  $P_{ES,min}$  and  $P_{ES,max}$  are minimum and maximum limits of the ES output;  $\Delta P_{ES,down}$  and  $\Delta P_{ES,up}$  are the maximum reduction and increase of power per unit time of ES.

3.3. *Green Energy Model of Internet of Things by Adopting Moth Algorithm.* Because the QoS composition in IoT is an NP hard problem, the traditional mathematical methods have some problems such as high computational complexity and low efficiency. The intelligent optimization algorithm has better optimization effect in solving the abovementioned problems. The references show that MFO has better optimization effect and higher stability than the traditional intelligent optimization algorithm in single peak function, multimodal reference function, and composite reference function. Therefore, this paper selects MFO to simulate QoS evaluation model and energy evaluation model.

The population size of moth is  $n$ , and its flight space is  $d$  dimension, which is the same as the number of service categories. Initial population  $\{x_1, x_2, \dots, x_n\}$  where  $X_i$  is the position of the moth.  $x_i$  is produced by the following equation:

$$x_i^d = [lb^d + (ub^d - lb^d) \times \text{rand}(0, 1)], \quad (5)$$

where  $ub$  and  $lb^d$  are the upper and lower limits of  $d$ -dimension, respectively, and  $\text{rand}(0, 1)$  is a value randomly generated between  $(0, 1)$ . FMO defines the moth population and the corresponding fitness value, the flame population, and the corresponding fitness value by combining the specific trajectory of moth tending to artificial light. By updating the moth population in the form of helix and calculating the fitness value of the evolutionary moth population, the optimal fitness value and corresponding solution are obtained. In this algorithm, the update of moth position is as shown in the following equations:

$$s(M_i, F_j) = D_i \times e^{bt} \times \cos(2\pi t) + F_j, \quad (6)$$

$$D_i = |F_j - M_i|, \quad (7)$$

where  $F_j$  means the moth position,  $M_i$  is the flame position, and  $D_i$  shows the distance between the position of the moth and the position of the flame. It can be seen from formula (7) that the position update of the moth is relative to the position of the flame. Let  $t$  in formula (8) be a random digit between  $[r, 1]$  in the iterative process. In this way, the moth can make better use of the corresponding flame in the iteration process.

## 4. Simulation Results and Analysis

**4.1. Simulation Parameter Setting.** Due to the lack of a common data set, the service composition problem in the IoT environment is simulated by using the data set with composite QoS attributes according to the references. In order to verify the effectiveness of the algorithm, MFO is compared with PSO and GA. Software environment: Microsoft Windows 10 professional edition (64 bit), version number 16299, Matlab r2015a. Hardware environment: inter (R) core (TM) i7-6700 CPU @ 3.40 GHz, 3408 mhz, 4 cores, 8 logical processing units, 8.00 gb physical memory, 1 t hard disk.

The experimental parameters are set as follows: for the QoS evaluation model, the QoS attribute value of each service is randomly generated, and the service category  $D$  and candidate service  $C$  increase from a small value. For the energy consumption evaluation model, the duration of sample interval  $\Delta t$  is 1 h, and total duration was 24 hours.  $i$  is the category of energy services, and the initial population  $N$  is the number of candidate services. In the experiment, two cases were selected:  $i$  fixed at 72,  $N$  increased from 100 to 1000;  $n$  fixed at 100,  $I$  changed from 72 to 720. The parameters of GA are shown as follows: the population number is 100, iterations are 200, fitness normalized elimination acceleration index is 2, crossover probability is 0.8, and mutation probability is 0.05. The initial position is random. The main parameters of PSO are as follows: the max iterations are 800; number of independent variables of objective function is 2; particle swarm size is 50; and individual learning factor and social factor of each particle are 2.

**4.2. Validation of the QoS Evaluation Model.** In order to verify the change of an individual's maximum fitness with population algebra, firstly, the number of service classes in

composite service is set to 45, and the number of candidate services in each service class is 35. The corresponding test data are generated by the range of QoS attribute generation.

As is revealed from Figure 5, the performance of MFO algorithm is obviously better than that of GA and PSO algorithms under different number of alternative services. The difference is smaller and more stable. We can obtain that MFO has better global optimization ability and can find the global optimal solution of the service composition problem with greater probability.

At the same time, the fitness function value of the QoS evaluation model in Figure 5(b) decreases with the increase in the number of iterations. With the increase in iteration times, the error of fitness function gradually decreases, which shows that the optimization efficiency of MFO is higher than that of particle swarm optimization and genetic algorithm. MFO algorithm can reach the convergence state after 1000 iterations, which is more efficient than 1300 and 2200 times of PSO and GA. This also indirectly shows that the optimization strategy based on moth algorithm is better than particle swarm optimization and genetic algorithm. The sharp increase of GA results is mainly caused by three reasons: the multisolution genetic algorithm does not converge, the initial feasible solution has problems, and the evaluation function is not distinguished enough.

**4.3. Validation of the Energy Evaluation Model.** In order to obtain the best combination of QoS, the method of choosing proper parameters is the same as that in the QoS model. In this simulation, MFO, PSO, and GA are selected to estimate the energy consumption under different parameters. Figure 6(a) shows that the optimization effect of MFO on the energy consumption evaluation model is significantly better than PSO and GA.

In Figure 6(b), simulation results reveal that the energy consumption of MFO-based service combination in the Internet of Things environment is significantly less than that of PSO and GA algorithm. In addition, Figure 6(b) shows that, with the increase of candidate services, energy consumption also increases because each service category selection will generate energy consumption, and a linear relationship existed. Also, the optimization effect of MFO is improved by 8% and 6% compared with the genetic algorithm and particle swarm optimization.

**4.4. Comparison of QoS Energy Consumption in Internet of Things.** In order to verify the design advantages, we compare the performance and energy utilization of the hierarchical management data centre and the UN optimized hybrid data centre. We use professional precision power and energy meters to detect the energy consumption and power consumption of the server in real time and monitor the number of requests waiting for the queue to accumulate to analyse its performance.

Figure 7 shows the change in tasks number in queue with time. The larger the value, the more serious the task accumulation, the lower the performance of the data centre, and the more difficult it is to meet the computing requirements.

(a)

(b)

FIGURE 5: Relationship between QoS and number of services. (a) QoS changes with the number of candidates; (b) error change with the number of iterations.

(a)

(b)

FIGURE 6: Relationship between energy consumption and services quantity. (a) Energy consumption under services quantity. (b) Energy consumption under different service categories.

Figures 7(a) and 7(b) shows the change in the length of the task waiting queue with time under the traditional and QoS-oriented strategies, respectively. The traditional task-scheduling mode lacks the control and allocation of random arriving tasks, so the data centre has the phenomenon of uneven task allocation and certain task accumulation. Compared with Figure 7(a), the tasks in the waiting queue in Figure 7(b) can be very fast. On the one hand, it shows that the hierarchical organizational structure can improve the performance of the hybrid data centre, that is, the waiting time of tasks; on the other hand, it also shows that there is free space for

computing resources in the case of layering. Even if some computing resources are shut down, some of them may still meet the computing needs, and there is a potential to trade performance for energy efficiency.

In Figure 8, we compare the overall energy-saving effect of the data centre under different sleep states. We directly measured that the power consumption of all servers (hybrid data centre system) is about 8% of the maximum power in Figure 8, the ordinate represents the percentage of energy saved under  $4 \times 3$  different dynamic sleep strategies under QoS positioning, and the abscissa

FIGURE 7: Performance monitoring results. (a) QoS-oriented energy consumption. (b) Traditional energy consumption.

FIGURE 8: Energy consumption monitoring results under different parameters.

represents the sleep ratio of servers in the central data centre. It can be seen that, with the growth of dynamic sleep time, the data centre can save more energy, but this energy efficiency advantage is also affected by the data centre performance constrained, that is, when the closed computing resources are too much or the data centre computing resources are not enough, leading to a serious decline in the QoS. In the experiment, moderate load integration and collective sleep strategy for all levels of IOT data centre can bring more than 12% energy saving. In conclusion, in view of the IOT environment, the hierarchical organization structure of service composition can be realized reasonable management and planning of computing resources, and the reasonable collective sleep strategy in this hierarchical structure can further improve energy efficiency with low performance impact.

## 5. Conclusions

In this paper, aiming at the deficiency of traditional methods only based on QoS evaluation to optimize services in the IoT

environment, this paper proposes a QoS evaluation model and energy evaluation model of QoS-based composition and successfully applies MFO to the QoS evaluation model and energy evaluation model. Simulation results reveal that MFO algorithm has more remarkable optimization effect than PSO and GA. Therefore, when MFO is used to solve the service composition problem, it can not only satisfy the requirements for QoS in the Internet of Things but also achieve optimal energy efficiency. It is proved that MFO has better large-scale processing ability and global optimization ability than traditional genetic algorithm and PSO and can find the global optimal solution of the QoS composition problem with greater probability. In the next step of research, we can obtain real data sets from experiments to evaluate the QoS of composition and energy consumption under the IoT. In addition, MFO has strong performance, but it is possible to fall into local optimum. Therefore, we can consider combining MFO with other intelligent optimization algorithms to improve MFO for overcoming the local optimization for the QoS problem.

Starting from the virtual reality technology, the characteristics of its most suitable combination with the library are explored, so as to lay a foundation in theory and practice to promote the development of virtual reality in the library. In the concentration camp of the latest advanced technology, the relevant technologies used in the various levels of models in the smart library are extracted, and their functional principles and applications are systematically introduced; Chapter 4 builds the level of the smart library information retrieval technology model. The structure diagram, various levels of functions, and related smart service models are discussed. Research is on context construction of extended resources of knowledge service in smart libraries. The elements and content of the resource context are introduced, and the strategy of constructing the resource context for the extension of the knowledge service of the smart library is proposed. Research is on the construction of the context of the extension and interconnection of knowledge services in smart libraries. The relevant elements and contents of the technical context and the spatial context are introduced, and a strategy for constructing a connected context for the extension of the knowledge service of a smart library is proposed. Research is on the context construction of knowledge service extension of smart library. The elements and contents of the service context are introduced, and the strategy of constructing the service context of the knowledge service extension of the smart library is proposed. A visual model of information retrieval is constructed. The model integrates the core steps of the information visualization process and introduces the information space and functional system (navigation, organization, indexing, and retrieval) in the information construction theory into it and through five mapping layers (functional space mapping, visualization space mapping, visualization mapping, view mapping, and interactive mapping) and six spatial layers (role space, information space, functional space, visualized information space, visualized object space, and visualized view space), which describe visualization applications that target the user experience model in information construction build process.

## 1. Introduction

With the advent of the big data era, a large amount of data continues to emerge, and there is a phenomenon of abundant information but there is a lack of useful information. Information overload has caused problems such as lack of information and a significant reduction in user information utilization. As an indispensable part of society, libraries should bring forth the new and avoid working behind closed doors. They need to adapt to the development of the times and integrate the latest technology into the library to achieve personalized services for users. But no matter how the library changes and how the technology is updated alternately, its core value of “people-oriented” has

not changed. How can the library realize the transformation from the passive and stereotyped model to the intelligent service model in the new intelligent environment and realize the transformation from single-library service to cross-library service? The construction of the technical model of China's smart library studied in this paper provides technical support for the above problems. Relying on the construction of this model, the library can realize transparent management of user services, mine users' useful information needs, and intelligently predict user personalized services trend, accurately integrating the value density of library management, scientific services, and librarian decision-making.

Research on smart libraries can suggest that it is a difficult and tedious task for readers to accurately find the

books and materials they need in the library environment, but location-aware technology can help readers solve such problems and achieve the purpose of accurate search [1, 2]; it is proposed that a smart library is a mobile library that can transcend space limitations and can be noticed by people [3, 4]. The fact that a smart library uses a large number of software quality projects to reduce users and libraries is emphasized. The goal of error is in the process of use, classification, configuration, installation, or processing by technical personnel [5]. Research is on the application of data mining technology in smart libraries. Through this interactive platform system, the library uses EAI technology to construct the underlying architecture, exchange heterogeneous systems, data, and platforms, realize seamless integration within the system and between multiple systems, and then uses scene graph, data mining, and data analysis technology which intelligently perceives, mines, captures, analyzes, and integrates information to achieve collaboration and sharing of data processing [6, 7]. In the era of big data, data mining technology is of great significance to the development of libraries. It not only can extract hidden and potentially valuable knowledge information from a large amount of disordered and vague practical application data but also can be used to support a wide range of business smart applications, such as directional marketing [8, 9]. Smart library mobile visual search service architecture diagram, and display mobile visual search services, visualization services, knowledge services, social services, social recommendations, one-stop navigation services, and other service functions in the smart service module [10, 11]. Innovative service models have distinctive features, and these accompanying features have evolved based on new technologies and intelligent facilities. Research is on location-based information push services and private customization and other service models, and the research and innovative development of smart libraries by expanding social networks and expanding publicity camps have increased [12]. Guided by relevance learning theory, service models of context-aware services, social services, cloud services, and mobile information services are constructed [13]. The deep integration of "Internet +" and the library has realized the interconnection between the physical world and the virtual world, making the library rich and diverse, and the library community is also actively studying this direction [14]. Under the background of the deep integration of traditional industries and the Internet, it is proposed that libraries should establish user thinking and Internet thinking to build a smart library. Internet thinking is the technical basis of user thinking, and user thinking is the manifestation of Internet thinking, include two complement segmentation [15, 16]. In the "Internet +" environment, the service content of the smart library is introduced in detail [17]. Information technology plays an important role in the transformation and upgrading of the library. The use of Internet of Things, cloud computing, wearable technology, virtual reality technology, artificial intelligence, and other technologies can realize the optimization of the library's literature, equipment, personnel, and buildings [18, 19]. Based on the problems in the application of the Internet of Things

identification technology in the smart library, the improvement measures for the construction of the smart library are proposed [20, 21]. The three relationships between wearable technology and smart library, the specific application of wearable technology in reader navigation, and help for disadvantaged groups and personalized services are analyzed [22, 23]. Using the effect of virtual reality to present pictures, models, or videos in the book, the reading method and interest are increased [24, 25]. A three-dimensional book of virtual reality is made, and the pictures in the book are carried out by using mobile devices. The scanning function can present the actual scene of the corresponding 3D model, change the interactive way of parent-child reading, and promote the establishment of the reading sharing relationship between parent and child [26]. Mobile learning is most effective only when it connects the real environment with related resources [27, 28]. Mobile AR technology provides a channel for the establishment of this connection, and library resources make the connection possible. In the research of the library personalized service system based on virtual reality, there is a detailed introduction to the realization of personalized service related functions, including the following: real-time scanning of QR codes, real-time calculation of projection matrix, projection of three-dimensional objects and location-based book retrieval and book recommendation functions of [29, 30]. In the research on the application of virtual reality technology in the library personalized service platform, it is found that the library information browsing system based on QR code and virtual reality can present different information interfaces to different users according to the information displayed by scanning the QR code. It guides readers to browse the information of books on the bookshelf in an intuitive way and at the same time recommends various resources of interest to readers [31]. The Android-based virtual reality library service platform is a platform that combines new technologies such as the mobile Internet and data mining technology to provide users with personalized services such as book query, book recommendation, and book location navigation [32]. The impact of various frontier technology developments is on libraries, including virtual reality technology. The ideas and countermeasures to innovate the library service model for reference from the Internet are put forward [33]. In the exploration of the application of virtual reality technology in the library, starting from the practical application direction of the library, the foundation of virtual reality is introduced in detail, the important role of this technology in the library business is explored, and the effect of virtual reality in the library is initially explored [34]. The application status of mobile virtual reality technology in the library, combined with the characteristics of various services of the library, is analyzed and the application prospects of mobile virtual reality technology in the library are also explored in order to further utilize the mobile virtual reality technology in the library. The application value in the library provides reference [35]. From the perspective of bookshelf and resource integration, virtual reality multimedia books, virtual reality library navigation, virtual reality optical character recognition, and virtual reality personalized

services, the application of mobile virtual reality technology in modern libraries is discussed [36, 37]. Through research and analysis, the necessity of using virtual reality technology in smart libraries is analyzed, and the application form, workflow, and image recognition mechanism of virtual reality in smart libraries are pointed out, and the innovative service mode of smart libraries based on virtual reality technology is explored [38]. The current situation of library business at this stage is analyzed, and, according to the characteristics of virtual reality, the application of virtual reality technology in intelligent libraries from three aspects is discussed: library personalized intelligent navigation service, resource integration service, and personalized recommendation push service [39, 40].

In view of the research on the information retrieval technology model of the smart library, a detailed analysis is made on the specific construction content of the smart perception layer, network transmission layer, data resource layer, and smart application layer. This article mainly focuses on personalized and scenario-based recommendation, and virtual research is carried out on six service dimensions of reality, multimedia, smart space, and visualization. From a new perspective, virtual reality technology has been widely popularized in certain fields and has brought about certain benefits to those fields. One of the evaluation criteria for the effect of the integration of new technology is whether it has improved the industry, and the application of virtual reality in the library is consolidated through various practical improvement effects, so as to lay the foundation for the popularization of the library industry, as well as theory and practice to be prepared for in-depth research. It also proposes a strategy for constructing a resource context for the extension of knowledge services in a smart library to introduce the elements and content of a resource context, a strategy for constructing a context for the extension of knowledge services in a smart library, and a strategy for constructing a context for extension services of a smart library. The application of augmented reality, virtual reality, and integrated reality provides a new way for libraries to carry out innovative services and a new perspective for libraries to better serve readers. With the passage of time, the technologies of virtual reality, augmented reality, and integrated reality will continue to develop, and the applications full of surprises will continue to change the way readers work, communicate, and entertain themselves and further expand the functions of libraries, so as to promote the construction and development of smart libraries.

## 2. Information Retrieval Model of Smart Library Based on Virtual Reality

With the current rapid development of intelligence and Internet of Things technology, a technical platform has been created for the bold use of virtual reality technology in libraries, and it has also provided technical innovation and service concept transformation for the diversified transformation of library services. Virtual reality technology is to reflect virtual information into the real world with the help of computer processing technology to realize the integration

of virtual objects, scenes, actions, and other objects and apply them to real scenes. The introduction of virtual reality technology in the smart library creates a comfortable smart virtual space for readers, allowing readers to enhance their desire to enjoy library services in the context of services. Virtual reality technology is a special form of reality technology. It has the characteristics of strong interaction, integration of virtuality and reality, and three-dimensional positioning. It introduces three-dimensional registration and virtual compatibility. At present, if libraries want to efficiently broaden the scope of public cultural services, they should introduce AR virtual reality technology as soon as possible, show the service model to readers in a brand new form, and use high-quality resource construction to burst out the library's own advantages.

*2.1. Construction of the Technical Hierarchical Model of Smart Library.* The library uses its own obvious resource advantages and integrates the advanced service performance of smart libraries, combines the library models built by predecessors, and introduces smart modern technology based on the theory of integration and collaboration to build a technical-level technical-service model that meets user needs. As shown in Figure 1, the current situation that libraries use a general service mode to meet user needs is broken, and the stable development of the library's service concept of "serving users and satisfying users" is promoted.

The architecture shown in Figure 1 is mainly composed of four parts: smart perception layer, network transmission layer, data resource layer, and smart application layer. The smart perception layer in the smart library is mainly composed of wearable devices, sensors, storage devices, RFID, and video. It consists of monitoring equipment and network monitoring equipment. Users visit the library under the information demand target. The intelligent equipment in the intelligent perception layer perceives, screens, and extracts the data traces generated during the reader's enjoyment of the library's application mode and services. Through the network transmission layer, according to the distance between the geographic location of the sensing device and the library collection data, the large amount of data collected by the intelligent sensing layer can be safely, efficiently, and quickly transmitted through the wireless network, triple play technology, and computer communication network.

The data resource layer is at the center of the technical model. It consists of data warehousing, data mining, cloud computing, information push, and semantic analysis technologies. It is mainly responsible for user data storage and format conversion, user data resource mining and calculation, and user personalized information needs. Task functions include prediction, recommendation, and management. The smart application layer relies on the data analysis provided by the data resource layer and is mainly constructed by virtual reality technology, multimedia, data visualization, and other technologies to realize library scene-based recommendation services, user personalized services, virtual reality services, and multimedia services. The improvement of smart space services and visualization services

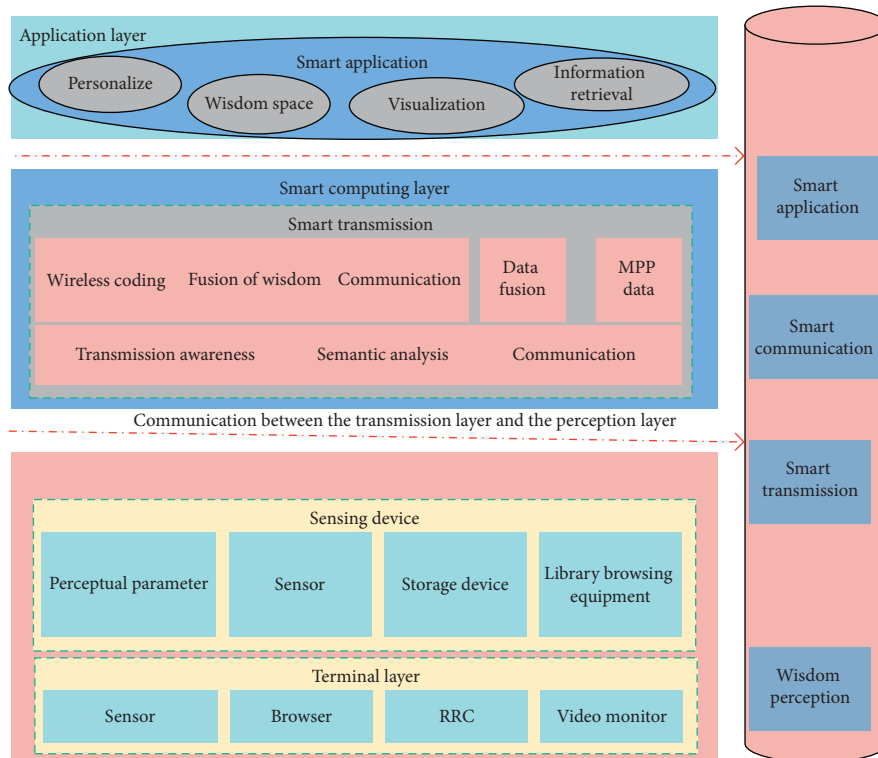

FIGURE 1: Architecture of the intelligent library information retrieval technology model construction system.

and the innovative development of smart libraries have realized the service process from sensing information to digging information, processing information, and finally discovering wisdom.

Virtual reality technology has computer-generated three-dimensional effects that integrate visual, tactile, and olfactory functions, allowing users to enjoy interactive services immersively with realistic and visual scenes. The multiple senses, visibility, permeability, and immersion characteristics of virtual reality technology make it popular in the library field. At present, virtual reality technology is mainly used in the virtual official buildings of libraries, allowing users to “walk” among them, freely associate with the virtual space, and obtain a three-dimensional and realistic user experience. When users “walk into” the virtual space of the library, they can understand the overall layout of the library and can also obtain information consulting services and browse the operation mode of the library in the most direct way of expression, allowing them to understand at a glance and fully embody the superiority of the smart library. It also appropriately compensates for the one-sided and localized information obtained on the library website and increases the user’s affinity for the virtual reality of the smart library. The application of visualization technology in smart libraries can realize the service functions of explicit tacit knowledge, clarification of fuzzy knowledge, and concrete abstract knowledge. In the process of smart library services, the collection of knowledge and the organization of knowledge are inseparable from the service criteria of “knowledge visualization.” Therefore, the smart library must achieve the visual effect of vivid knowledge services. Data

visualization technology is conducive to processing intricate data relationships, transforming data dimensions into visual dimensions, and then mining the knowledge structure and development trends hidden in the data.

*2.2. Application of Virtual Reality Technology in Smart Library.* In the actual application process, the manifestation of virtual reality technology can be divided into three types according to the user’s “immersion” and “interaction.”

*2.2.1. Virtual Reality Technology Display Mode Based on Computer Screen Display.* The real-world image or video captured by the camera equipment is input to the computer, synthesized with the virtual scene generated by the computer graphics system, and output to the screen display. The user sees the final enhanced scene picture or video on the screen. This form of expression is simple, in the enlightenment stage of the concept of virtual reality technology, and most of the things shown to users are display attributes, unable to operate and interact, and cannot bring much immersion to users. The implementation scheme of the virtual reality technology system based on computer screen display is shown in Figure 2.

*2.2.2. Display Mode Based on Optical Perspective.* This type of virtual reality technology needs to use display devices that emphasize the user’s vision and tactility, mainly helmet and glasses-type displays, to enhance the visual immersion by being close to the user’s body. Early AR products produced

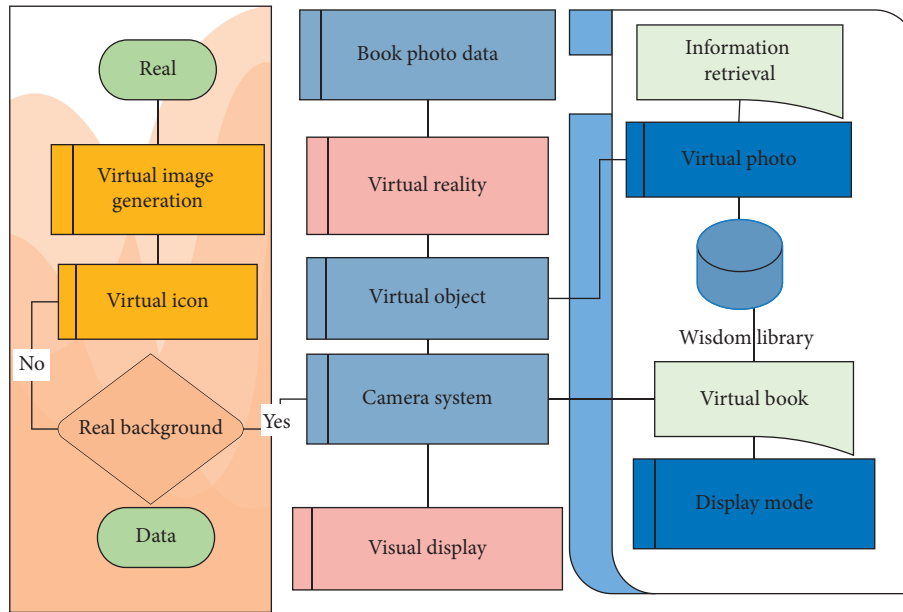

FIGURE 2: Operating principle model of virtual reality technology display mode based on computer screen display.

by electronic product companies such as Sony and Google are geared towards users in the form of helmets and glasses. Different from the computer screen display, the user can directly see the external real world. In fact, it uses a transparent optical synthesizer to project the signal of this virtual image to the eyes, and then because the real world is clearly visible, there is no way through shooting processing and artificial display. Its operating system is shown in Figure 3.

User experience design includes information construction, user interface design, human factor configuration design, and user experience evaluation. In order to complete these designs, they must be carried out in stages according to the requirements of user experience design, namely, the discovery of information needs based on user experience, the construction of user-oriented services based on resource integration, and feedback control based on information integration and service integration. These three aspects can be subdivided, as shown in Table 1.

The integration of information resources based on user experience directly faces users, highlights needs and services, and allocates limited resources to the service businesses that users care about most to ensure the efficiency of resource utilization. To do this, you need to analyze the information needs of users. The discovery process is to understand and analyze users' information needs from multiple angles. The measures taken include analyzing the current environment, understanding the real needs of users through surveys or interviews, deep mining and using the acquired user information, and coordinating user needs with the service organization's strategy and environmental requirements and then enter the design phase of user experience construction.

Construction design is the main part of user experience design, including information architecture, user interface design, human factor research, and user experience evaluation. Information architecture is a high-level information

design that focuses on the organization and presentation of information, and its purpose is to provide users with clear and understandable information. User interface design requires reasonable arrangement of interface elements on the basis of information construction, distinguishing the importance of information, expressing information in an easy-to-understand manner, and enabling users to interact with system functions. Human factor research and user experience evaluation are generally combined. Their responsibilities include user experience testing, researching user development, communicating with users, and passing these results to designers. The feedback control design requires the specification and description of the design process and user-oriented business, listening to opinions in many aspects, and designing a user-oriented integrated service feedback control system to ultimately improve the user experience design.

*2.3. Virtual Reality Technology Improves the Effectiveness of Information Retrieval Services and Management of Smart Libraries.* As the current popularity of virtual reality technology is not very high and it is not currently included in the development plan of the library business, the survey of this technology in the questionnaire must first start with the cognitive level of the surveyed, and it is easy to be surveyed. The questionnaire was designed based on the expression of the reader's understanding, and the cognitive results are shown in Table 2.

The survey results showed that 35 people did not understand the concept of virtual reality technology at all, accounting for 36.55% of the total number of people in the survey. Because the cognitive problem of the survey is also an important reference data, I do not think that choosing this option will lead to a whole answer. This questionnaire is invalid, which also reflects the current state of understanding of this technology in the industry to a certain

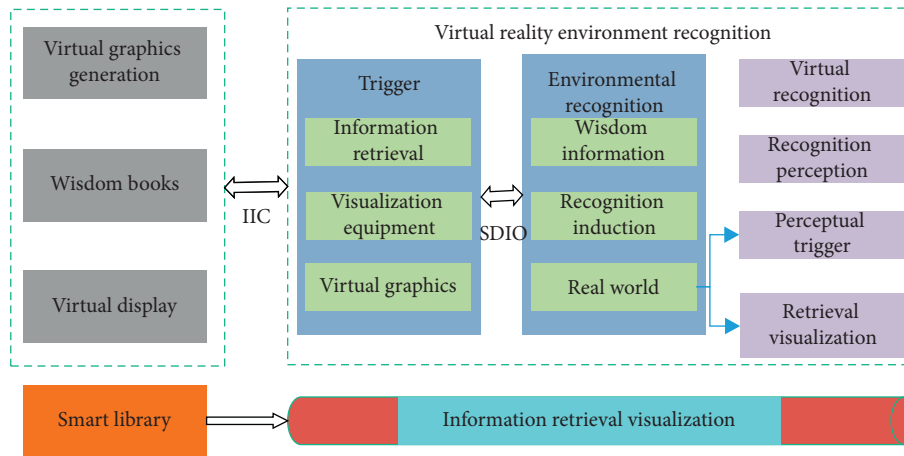

FIGURE 3: Display mode based on optical perspective.

TABLE 1: User experience design process.

| User needs                 | Experience building            | Feedback control    |
|----------------------------|--------------------------------|---------------------|
| Background analysis        | Concept + first prototype      | Design description  |
| User interview             | Site map                       | Process feedback    |
| User role and plot setting | Interactive model              | Performance control |
| Brainstorming              | Idea refinement                |                     |
| Group design practice      | User interface + visual design |                     |
|                            | User experience evaluation     |                     |

TABLE 2: User perception statistics.

| Variable  | Types of                 | Quantity | Percentage |
|-----------|--------------------------|----------|------------|
| Awareness | Don't understand         | 35       | 36.55      |
|           | Scan the QR code         | 34       | 38.71      |
|           | Sweep the reality object | 34       | 35.47      |
|           | Electronic games         | 28       | 31.17      |
|           | For life                 | 35       | 36.58      |

extent, and even if you do not understand the concept of virtual reality technology, you can express the expectations of the surveyed in the subsequent survey options. At the same time, I set the option of "scan QR code" in the research options. In fact, although the method of using QR code is similar to virtual reality technology, the two are not in a mutually compatible relationship. Codes do not belong to virtual reality technology. In the survey results, 14 people chose the QR code option alone, accounting for 14% of the total number of people. It can be understood that these users do use QR codes but they are still familiar with virtual reality technology. If combined with users who do not know anything about it, the proportion of respondents who have a weak awareness of virtual reality technology reaches 50.6%, which accounts for about half. This ratio reflects the current use of virtual reality technology in books. Among the remaining options, "scanning reality" is one of the main features of virtual reality technology, "electronic games" is a hot development field of current virtual reality technology, and "available for life services" means that all types of technologies including virtual reality technology are available. The selected development goals and those that

chose these options also accounted for the other half of all surveyed objects, reflecting the controversy of virtual reality technology in libraries.

The combination of virtual reality technology and library management and services has not only obtained theoretical support in the previous chapters but also should find the advantages of the combination of the two in real applications to enrich theoretical research and lay a foundation for popularization of practice. This section summarizes specific advantages by combining the results of the questionnaire survey and the author's reasonable assumptions. The survey results are shown in Table 3.

In the questionnaire survey on the advantages of virtual reality technology in library applications, 83 people think that virtual reality technology can provide more comprehensive services for library readers, accounting for 90.31%, and 73 people think it will enhance the interaction between the library and readers' sex, accounting for 77.43%, 57 people think that this will make paper books break the limit of paper media, accounting for 60.23%, 50 people think that virtual reality technology in the library will help library management, accounting for 55.9%, and 5 people think the advantage is not obvious, accounting for 4.4%. From the analysis of the above survey results, it can be seen that service is the primary consideration in the application of virtual reality technology in smart libraries, and its advantages can be better reflected in services. There is a certain gap between the research objects in management and the selection of services. This also shows that the proportion of virtual reality technology in the development of smart library services and management may also fit the selection of this survey.

TABLE 3: User advantage selection.

| Variable       | Types                            | Quantity | Percentage |
|----------------|----------------------------------|----------|------------|
| Advantage type | Full service                     | 83       | 90.31      |
|                | Improve interactivity            | 73       | 77.43      |
|                | Breakthrough paper media         | 57       | 60.23      |
|                | Improve management effectiveness | 50       | 55.9       |
|                | The advantage is not obvious     | 5        | 4.4        |

The number of users of smart libraries is large, and the level of information retrieval service is at the forefront of the times. It is the basis for smart libraries to adopt and popularize new technologies, and it is the main advantage. Compared with the more expensive and fixed-location navigation machine in the library, the virtual reality technology can be realized on the user's mobile phone, and the service can be provided through the design of the program, and the user's use method is flexible, easy to learn, and fast. As far as the development of smart libraries is concerned, the introduction of intelligent information services such as virtual reality technology improves service efficiency and implements the reader-centered concept. In the questionnaire survey, more than 75% of the respondents believe that virtual reality technology has improved the interaction between the library and the reader, and the smart library has the interaction between the reader and the smart library in each part. The application of virtual reality technology will make the way of interaction more intelligent. In terms of social value, if the use of virtual reality technology is promoted by the smart library of colleges and universities and the concept of new technology is popularized among young users, it will make college students who are good at using computers and mobile phones take advantage of this technology. The strong impression will also affect their future scientific and technological concepts and thus they will have a sense of dependence on the smart library and become loyal users. The group of young people is a group with a rapid popularity and a large number. It can also achieve certain effects in public libraries with evenly distributed age groups. Providing virtual reality technology services for older and traditional library user groups can achieve the effect of narrowing the social technological gap and completing large-scale technical literacy.

Any new technology may be a double-edged sword in the initial stage of application. Through the understanding of the functional characteristics of virtual reality technology, combined with the learning and understanding of the library, and the questionnaire survey and analysis, it is also found that the following points may limit its development, and user survey results are shown in Table 4.

In the questionnaire survey on the limitations of the application of virtual reality technology in libraries, 61 people think that the equipment of virtual reality technology is more expensive, accounting for 64.53%, 44 people think that the utilization rate of virtual reality technology in libraries is low, accounting for 48.38%, 28 people think that virtual reality technology is difficult to popularize as a new thing, accounting for 31.17%, 25 people think that virtual reality technology is complicated and difficult to use,

accounting for 25.82%, and 5 people think there are other reasons, accounting for 4.5%. Therefore, it can be seen from the survey results that the cost issue is the main issue in the application of virtual reality technology in the library. This is not only in the aspect of virtual reality technology. The library's funding is based on the overall consideration of each part of the library, so virtual reality of the cost of technical equipment should be carefully considered. Without experiments, the utilization rate is also worthy of attention. The low utilization rate of advanced and expensive equipment after the introduction will cause great losses to the library. The limitations are discussed in detail below.

### 3. Knowledge Service Extension and Information Retrieval Visualization of Smart Library

As a valuable and high-quality high-level knowledge service product, smart service is a perceptible, calculable, and visualized creative service, which will drive the technological upgrading, conceptual innovation, management reform, and service transformation of smart libraries. The library becomes an incubator for technological innovation and creativity and promotes the burst of imagination and creativity of users.

*3.1. Characteristics of Knowledge Service Extension of Smart Library.* The ultimate goal of the extension of the knowledge service of the smart library is to improve the knowledge service capability and level of the smart library and meet the increasingly diverse and individual needs of users. Specifically, the extension of the knowledge service of the smart library is to use the Internet of Things technology to realize the digitization of resources, the application of metadata harvesting, and the establishment of a data warehouse; as well as the storage and calculation of big data on the basis of data interconnection, forming a first-hand reliable information resources; on the basis of information collection, resources are reorganized, a knowledge base system through resource reengineering is built, and the knowledge of information is realized; a precise service platform based on situational awareness is built, and personalized knowledge service products is provided; the intelligence of knowledge is realized, and finally big data analysis tools are used to perform machine learning, mine user preferences, recommend personalized knowledge products, and achieve precise services. The goal of the extension of the knowledge service of the smart library is shown in Figure 4.

TABLE 4: Users' views on limitations.

| Variable             | Types                                  | Quantity | Percentage (%) |
|----------------------|--|----------|----------------|
| Types of limitations | Expensive                              | 61       | 64.53          |
|                      | Low utilization                        | 44       | 48.38          |
|                      | New things are difficult to popularize | 28       | 31.17          |
|                      | Complex operation                      | 25       | 25.82          |
|                      | Other reasons                          | 5        | 4.5            |

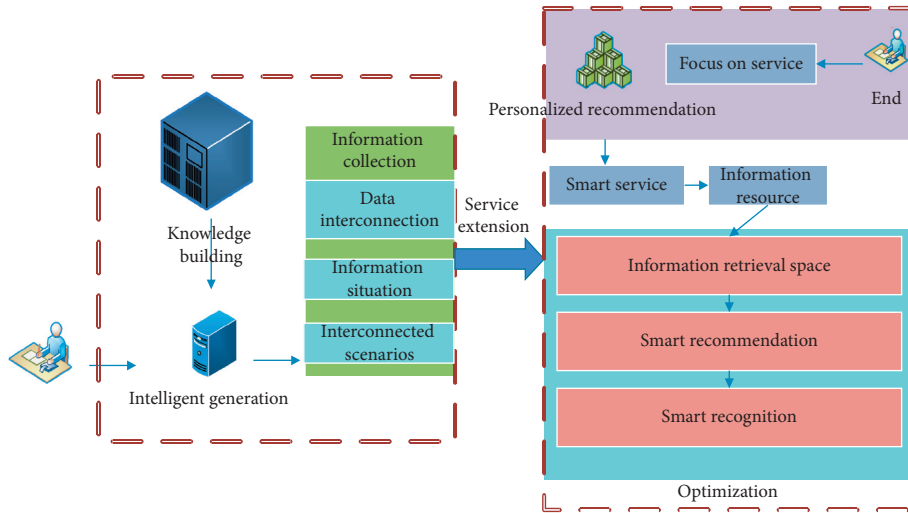

FIGURE 4: Goal-oriented diagram of the knowledge service extension of the smart library.

As shown in Figure 4, the interconnected context is the technical guarantee for the knowledge service context function of the smart library. The accessibility and popularization of the interconnected context depend on the supportive context technology of the Internet of Things and the ease of use and audience perception of the knowledge service platform. Resource context is the material basis of knowledge services in smart libraries. Resource reorganization and resource reengineering to improve the quality of resource content are related to the smooth development of user knowledge mining, knowledge association, knowledge utilization, and knowledge creation. In particular, human resources have become the first resource for the extension of knowledge services in smart libraries. It is the key to applying emerging technologies in the process of knowledge services and carrying out resource reengineering, knowledge creation, and smart services. The service context is the integration of the elements of the knowledge service field of Unicom's smart library under the combined effect of the technology interconnection context and the resource context. The personalized service and precise adaptation incentive function reflect the final performance of the knowledge service of the smart library. The interconnected context, resource context, and service context are cross-integrated and interacted in the knowledge service extension mechanism of the smart library, which together influence and determine the knowledge service level and users' perceived experience and satisfaction.

*3.2. Endogenous Power Mechanism Model of Knowledge Service Extension of Smart Library.* Based on the mechanism of interaction between the user and the smart library knowledge service system and the influence of the interaction function of the smart library knowledge service system on user behavior, this model is constructed from the different context dimensions of the interaction process between the user and the smart library knowledge service system. Users are the most basic and active force in the extension of knowledge services. The function of the knowledge service system of the smart library and the influence mechanism of user behavior are the user context, which mainly includes user needs and user experience. The three knowledge service context factors of the smart library are interconnection context, resource context, and service context. The corresponding ones are the ease of use, usefulness, and motivation of the correlation between the knowledge service function of the smart library and the user information interaction behavior. They include the ease of use of the space-time system, the ease of use of the supporting system, the usefulness of the resource construction system, the usefulness of the resource reengineering system, the standardized incentives of the service system, and the personalized incentives of the service system. The extension of the knowledge service function of the smart library and the construction of the mechanism model of user behavior are shown in Figure 5.

It can be seen from Figure 5 that user experience interaction and user demand promotion are accompanied by

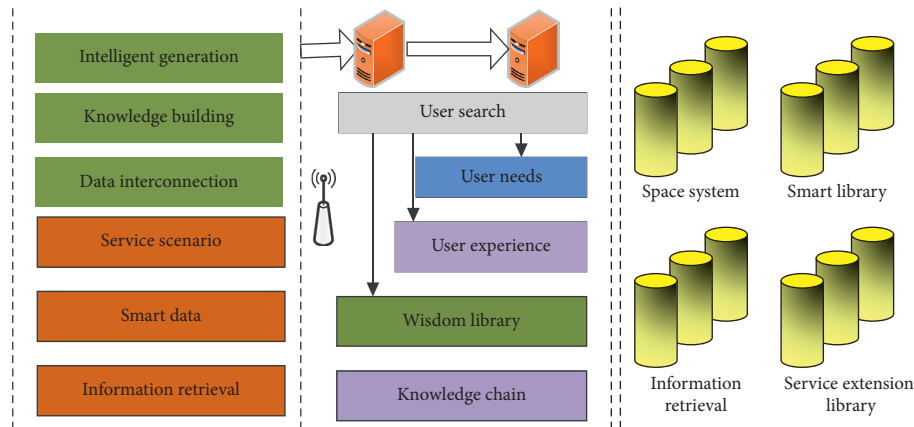

FIGURE 5: Mechanism model of endogenous power and user behavior of the extension of knowledge service in smart libraries.

both service experience characteristics and demand promotion functions. The interactive function of the knowledge service system of the smart library and the user's information interactive behavior work are through the following mechanism: the information of the knowledge service is presented to the user, and the user confirms the occurrence of the interactive behavior through self-perception. The psychological feelings of cognition, emotion, value, and so forth obtained by users through interactive behaviors are the result of comparison between user interaction perception and expectations, which directly affect the evaluation of knowledge service system functions and service incentive levels. In the process of information interaction, the user's impressive experience is accompanied by use and operation behavior, including the mastery of the knowledge service context function and the realization of needs; the user will always be based on the interactive experience and perception of the received customized information feedback and adjust their information interaction behavior. The functional elements of the knowledge service interconnection context, resource context, and service context of the smart library enhance and promote the data interconnection, knowledge construction, and wisdom generation of users, which have an impact on users' information interaction behavior, stimulate users' interactive interest at any time, and induce users' information interaction. The result of its interactive experience is changed. Users' knowledge needs to have new characteristics such as interconnection, sharing, knowledge integration, ubiquity, intelligence, and innovation. The user's interactive behavior in the knowledge service coincides with the ease of use of the knowledge service interconnection context, the usefulness of the resource context, and the motivation of the service context; that is, the user's psychological feelings and satisfaction with the knowledge service and reflecting a good experience of knowledge service quality is the whole process of the effect of the endogenous power of the knowledge service extension of the smart library.

The application of virtual reality technology in smart libraries has certain feasibility. First, the integration of the "three networks" and the construction of the Internet of Things provide networks and traditional equipment and

provide hardware support for the use of virtual technology. The integration of the "three networks" has achieved a high level of resource sharing, with higher communication speed, higher communication quality, and stronger communication security. As an important part of the new generation of information technology, the Internet of Things has realized the real connection of things with the help of the Internet. The development of the Internet of Things will greatly promote the development of smart libraries and VR technology. Second, the development of libraries requires the integration of virtual reality technology. Smart library is a new type of library facing the future and facing science and technology. It is an extension and expansion of traditional libraries. With the development of smart libraries, more and more information technology will be widely used in its function realization and service improvement. When VR technology has shown great advantages and potentials, its integration has improved the way of information services and enhanced the visibility and influence of smart libraries. Third, the characteristics of virtual reality technology are applicable to smart libraries. The immersion of virtual reality technology enables participants to exist in the virtual environment as subjects. The sense of interaction allows participants to get feedback from the virtual environment and realize interaction. Imagination will enable participants to expand more knowledge content through logical judgment, reasoning, and association based on the information they have obtained. It can be analyzed from the above three points that the application of virtual reality technology in smart libraries is very feasible.

### 3.3. Visualization of Information Retrieval in Smart Library.

For the design of the information visualization model of the smart library, it must not only conform to the basic system structure of the smart library but also fully meet the various requirements of information visualization. Therefore, for the design of the model, the following principles must be met:

- (1) Meeting the individual needs of users. The design of the model should be able to meet the needs of various users of the smart library, and different users have different preferences for the choice of visualization

methods. The personalization of user preferences is mainly in the results, that is, the way to provide personalized visualization results through the icon library.

- (2) Universality. The information resources contained in a smart library are massive, and there are many types of these information resources, including text, graphics, images, sounds, and videos. In the process of model design, it should be classified according to the information resources contained in the smart library to avoid the phenomenon that only information in a specific field is effective, so that the model can be used in a wider range of fields.
- (3) Convenience. Convenience here means that when the user visits the smart library, its visual interface is friendly and there is good interaction between the user and the system.
- (4) Interoperability. Information visualization technology faces the massive collection of information in smart libraries. This information is stored in various databases in different formats. The visualization system should be able to achieve undifferentiated access to information. In addition, the information contained in the smart library comes from different application fields, and the system should also implement interoperability between them.
- (5) The flexibility of the structure. The development prospects of visualization technology are unpredictable. Both information technology and computer technology are developing rapidly, and it is impossible for any technician to fully predict the future development.

Fuzzy C-means clustering algorithm is a typical information retrieval partitioning algorithm; its idea is to make the similarity between objects classified into the same category is the largest, and the similarity between different objects is the smallest. In the iterative optimization process, the FCM algorithm continuously updates the values of the various centers and the elements of the membership matrix until it approaches the minimum value of the following criterion function:

$$T_n(O, P) = \sum_{j=1}^N \sum_{i=1}^c o_{ij} w_{ij}^2. \quad (1)$$

Regarding feature extraction, in the test sample data set, there are a total of 988 keywords, and the number of keywords that are different from each other reaches 628.  $w$  is the weight of the number of keywords. After the data dimensionality reduction process, the remaining unique keywords are 113, which greatly reduces the aggregation. The data dimension of the class algorithm in the document space vector matrix  $R$  is stored in a text file as the data source of the FCM algorithm in Matlab. The number of iterations of running the FCM algorithm is 100, and the clustering result when the clustering objective function value is the smallest is taken out as the final result output. The results of the five experiments are shown in Table 5.

The clustering results of the third run in Table 5 are the best, and only 2 documents are misclassified in each of the three categories. In general, when the number of FCM documents is small, the clustering quality is better, with an average correct rate of 97.4%. But sometimes the result is not very stable, mainly due to the limitations of the FCM algorithm itself; that is, the random initialization of the center point has a greater impact on FCM.

Since keywords can directly indicate the subject of the literature and the characteristics of the subject, the similarity of the literature can be directly reflected by the similarity of the keywords. In order to cluster the documents, the document similarity matrix is first defined, and the similarity is expressed by Euclidean distance. The following definition is based on the following assumptions: suppose that the total number of documents to be clustered is  $n$ , the total number of different keywords in all documents is  $m$ , the keyword set is  $S$ , and the number of categories is  $k$ . The document similarity matrix ( $n * n$ ) is defined as

$$\begin{bmatrix} W_{11}, W_{12}, \dots, W_{1n} \\ W_{21}, W_{22}, \dots, W_{2n} \\ \dots \\ W_{n1}, W_{n2}, \dots, W_{nm} \end{bmatrix}. \quad (2)$$

The similarity of two keywords is defined as

$$W(\lambda_i, \lambda_j) = \begin{cases} \frac{\kappa}{\kappa_i + \kappa_j - \kappa}, & k \geq 4, \\ 0, & \kappa < 4. \end{cases} \quad (3)$$

The components of the literature keyword matrix are defined as

$$Q_{ij} = \max(W(\lambda_i, \lambda_j)). \quad (4)$$

The clustering objective function is defined as follows:

$$E = \frac{\sum_{j=1}^k \sum_{i=1}^m (y_i - y_j)^2}{m_j}. \quad (5)$$

The selection operation is adopted to select good individuals from the current group and decide which individuals can enter the next generation. First, the individuals are sorted according to the fitness function from large to small, and the first  $h$  individuals are copied as new individuals directly into the next generation, and the fitness of the remaining individuals is calculated as follows:

$$P(D) = \left[ c + (d - c) \frac{M - \text{rand}(D)/M - d}{(M - c)} \right]. \quad (6)$$

In order to test the feasibility and effectiveness of the information retrieval of the smart library, the value of 207 documents in the life is taken as the test data set. The genetic algorithm parameter is 50, the probability of mutation is represented by  $P$ , the value is 0.15, and the intersection value is 0.0002. The value is 0.76, and the maximum number of iterations is represented by  $T$ , with a value of 100. After 50

TABLE 5: FCM clustering results.

| 2                     | 48                       | 4     | 71             | 2     | 83                   | 3     | 100.4342           |
| 3                     | 51                       | 2     | 69             | 2     | 84                   | 2     | 98.9119            |
| 4                     | 48                       | 3     | 67             | 2     | 83                   | 3     | 102.5346           |
| 5                     | 51                       | 2     | 67             | 3     | 84                   | 2     | 99.2325            |

experiments, the result of the average objective function is shown in Figure 6.

It can be seen from Figure 6 that, in the iterative process of the FCM algorithm, the objective function can converge quickly, and the value of the objective function is greater than that of the GA algorithm, indicating that the convergence accuracy of the FCM algorithm is inferior to the GA algorithm. GA algorithm converges slowly, but the average accuracy of classification can reach more than 99%, which is better than FCM algorithm. As the GA algorithm draws on the idea of genetics in biology, it searches for the optimal solution through repeated iterations of “survival of the fittest.” Therefore, the optimization ability of GA is better than the FCM clustering algorithm, but the disadvantage is that the GA calculation speed is slow and many parameters need manual intervention.

**3.4. Information Retrieval Visualization Construction.** For the design of the information visualization model of the smart library, it must not only conform to the basic system structure of the smart library but also fully meet the various requirements of information visualization. Therefore, for the design of the model, the following principles must be met:

- (1) Meeting the individual needs of users. The design of the model should be able to meet the needs of various users of the smart library, and different users have different preferences for the choice of visualization methods. The personalization of user preferences is mainly in the results, that is, the way to provide personalized visualization results through the icon library.
- (2) Universality. The information resources contained in a smart library are massive, and there are many types of these information resources, including text, graphics, images, sounds, and videos. In the process of model design, it should be classified according to the information resources contained in the smart library to avoid the phenomenon that only information in a specific field is effective, so that the model can be used in a wider range of fields.
- (3) Convenience. Convenience here means that when the user visits the smart library, its visual interface is friendly and there is good interaction between the user and the system.
- (4) Interoperability. Information visualization technology faces the massive collection of information in

FIGURE 6: Comparison of the relationship between objective function and evolutionary algebra.

smart libraries. This information is stored in various databases in different formats. The visualization system should be able to achieve undifferentiated access to information. In addition, the information contained in the smart library comes from different application fields, and the system should also implement interoperability between them.

- (5) The flexibility of the structure. The development prospects of visualization technology are unpredictable. Both information technology and computer technology are developing rapidly, and it is impossible for any technician to fully predict the future development. Therefore, when designing a visualization system, full consideration should be given to the standardization of the database and the expansion of the system.

The information visualization model of the smart library designed in this paper is shown in Figure 7, which is based on the combination of the basic architecture of the smart library and the reference model of information visualization. As shown in Figure 7, the proposed smart library information visualization model includes a total of six modules: source data module, original database module, feature

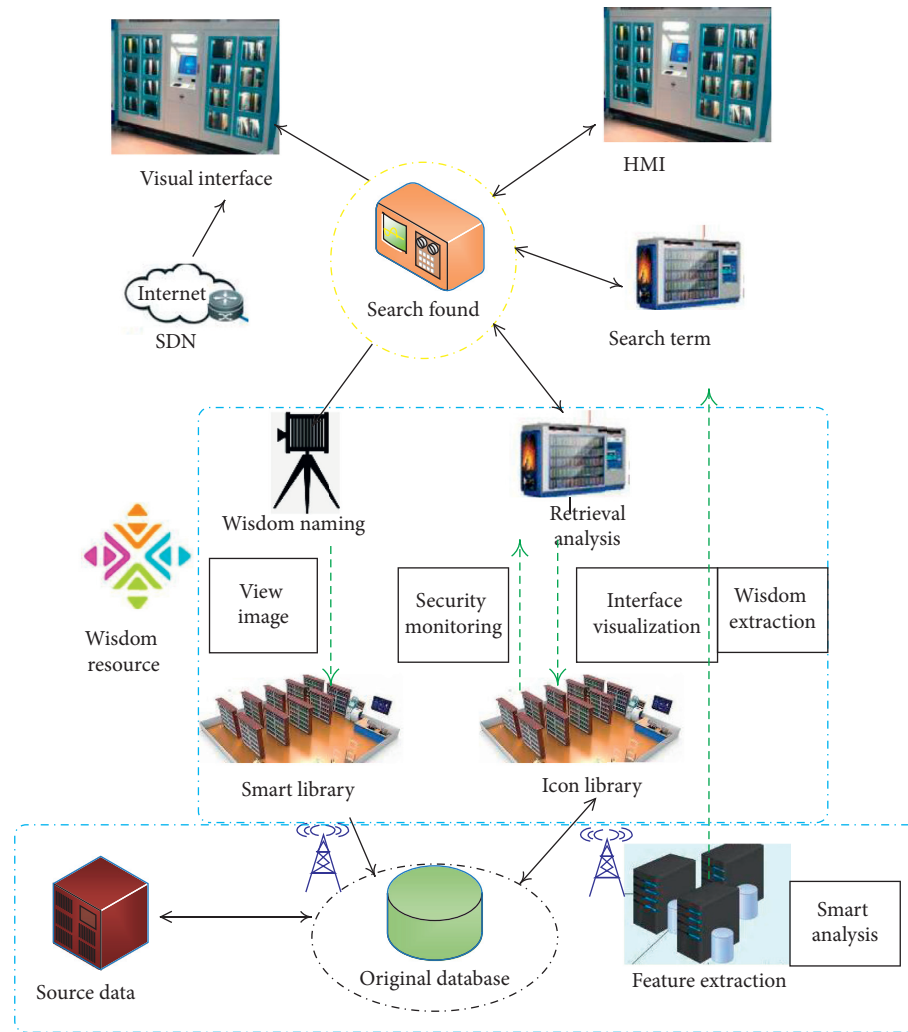

FIGURE 7: Information visualization model of smart library.

database module, view object module, visualization interface module, and extended function slot module.

Based on the above considerations, the L-Apriori algorithm is described as follows:

- (1) Classify the collection of books, combine the book classification method, and divide the collections into professional books and cross-professional books according to their professional background. Professional books for each profession are definitely different.
- (2) Preprocess the historical borrowing data, and set up subdatabases according to profession and year. Each subdatabase only contains the historical borrowing data of previous students in the major, which relates to the borrowing information of professional books and cross-professional books.
- (3) Data association rule mining of professional books: data mining is performed on subdatabases through Apriori algorithm; then the frequent item set A of each subdatabase must be the borrowing information of this professional book, and association rules can be extracted for recommendation; at the same time, get the frequent item set B of cross-professional books.
- (4) Prune the frequent itemsets obtained by Apriori algorithm mining, delete the frequent itemsets of professional books, and keep only the frequent itemsets of cross-specialties.
- (5) Compare the frequent itemsets A of the first subdatabase a and the frequent itemsets B of the second subdatabase b, find out the same parts, and put the same parts into the frequent itemsets C of the merged new data category c.
- (6) For frequent itemsets, scan b to obtain the support degree  $sup_x$  in b and  $sup_x$  plus the support degree  $sup$  in A; if the sum of the two is greater than or equal to the minimum support degree, put them in C. Similarly, for frequent itemsets, scan a and recalculate its support; and if it is greater than or equal to the minimum support, put it in C.
- (7) Repeat steps 5 and 6 until all the subdatabases are merged to form a new frequent itemset and

association rules, and the extracted association rules are recommended to users in a visual way.

#### 4. Experimental Verification

In order to verify the efficiency of the L-Apriori algorithm, a comparative test was conducted with the Apriori algorithm. The test data is the student borrowing data of a smart library from 2011 to 2012 in the last semester. The test results and the required time are observed through different mining algorithms. The required software and hardware environments are the same. The performance comparison of the two algorithms is shown in Figure 8.

Through the comparison and analysis of the test results and the required time, L-Apriori is more effective than April in the frequent itemset mining of library borrowing data, and the result is simpler, mainly because the L-Apriori algorithm pruned some of the frequent items of professional books in the process of subdatabase frequent itemset integration, and the pruned frequent items of professional books directly extracted the association rules and recommended them to users in the form of knowledge. The frequent items of cross-professional books are integrated one by one to form a frequent itemset of cross-professional books, which is much less than the frequent itemset obtained by April and naturally requires less time. Both the cross-professional book association rules obtained by the L-Apriori algorithm and the professional book association rules obtained by the Apriori algorithm can be recommended to users.

The recommendation service methods of the interviewed smart libraries that provide recommendation services can be divided into two types: personalized recommendation and nonpersonalized recommendation. As shown in Figure 9, about 56% of the interviewed smart libraries provide nonpersonalized recommendation services, such as “new book recommendation,” “borrowing ranking,” “hot review books,” “librarian recommendation,” and “reader recommendation.” Only about 23.5% of the provincial smart libraries have achieved personalized recommendations, but about 72% of them need to rely on third-party search systems to complete personalized search recommendations. Personalized search recommendations mainly rely on user search content to make recommendations, with similar recommendation forms and relatively single content, such as “Guess you like,” “Related Borrowing,” “Related Collection,” “Other Works by Authors of the Same Name,” and “Borrowing Relationship Diagram.” The survey found that the third-party systems that provide personalized search recommendations are mainly the ILAIII knowledge portal search system and the Interlib system. The smart library has completed personalized recommendation under its own recommendation system. When a user logs in to the service platform of the smart library, the recommendation system can analyze the user’s interest and preferences based on the user’s historical data, provide personalized recommendations of “Guess you like” on the homepage, and provide nonpersonalized recommendations of “everyone cares” or dynamic recommendation.

Using the information retrieval visualization API, event processing of the visualization interface can be performed, and interactive control can be added. This means that multiple visualization views can be coordinated, and data flow and control flow can be managed with the server through event processing. Information retrieval visualization provides more than 20 chart types, including the chart type that comes with the API and many visualization chart types developed by third parties, such as tag clouds. Therefore, with the increase of the API applications, the optional visualization types will gradually increase. As shown in Figure 10, the view elements are manipulated by responding to mouse click events. The information retrieval visualization API can also call the information retrieval visualization API to update the visualization view through asynchronous interaction with the server without updating the entire page.

However, from the perspective of the types of visualization, there is a lack of many classic views in the field of information visualization, such as graph-based visualization types and many tree-based visualization views (e.g., hyperbolic trees, radial trees, etc.). It lacks focus + context and overview + detail visualization.

The implementation of questionnaire survey mainly includes two parts: questionnaire survey and individual interview. All the users who participated in the questionnaires selected in this article are those who have used mobile virtual reality technology and are between 20 and 40 years of age. The author first explained the basic concepts of mobile virtual reality technology and then briefly introduced the mobile virtual reality technology prototype system and its functions designed and implemented. Finally, the software was installed on the mobile phone with the Android operating system and the subjects personnel conduct operation and experience. A total of 55 questionnaires were distributed in the survey and 55 were returned, of which 48 were valid questionnaires, with an effective rate of 95%. After collecting the questionnaires, the author randomly selected several questionnaires and conducted individual interviews with the corresponding subjects to discuss related issues that need to be understood.

It can be seen from Figures 11 and 12 that the four categories of user experience scores are not high, the highest score is behavioral experience, with 55 points, and users are basically satisfied. Since the designed mobile virtual reality technology prototype does not involve a social module, users will basically not have a social experience, so the social experience score is low and users are very dissatisfied.

In order to verify the clustering performance of the information retrieval visualization algorithm, the International Standard (IRIS) classification data is used for testing. The data set uses the characteristics of the Orioles as the data source. The data set contains 150 data sets, divided into 3 categories, each with 50 data, and each data contains 4 attributes. It is very commonly used in data mining and data classification for test set and training set. In the PSO algorithm, the inertia weight and learning coefficient adopt linear change strategy. In the information retrieval visualization algorithm, the number of IS-PSO iterations is 20, and

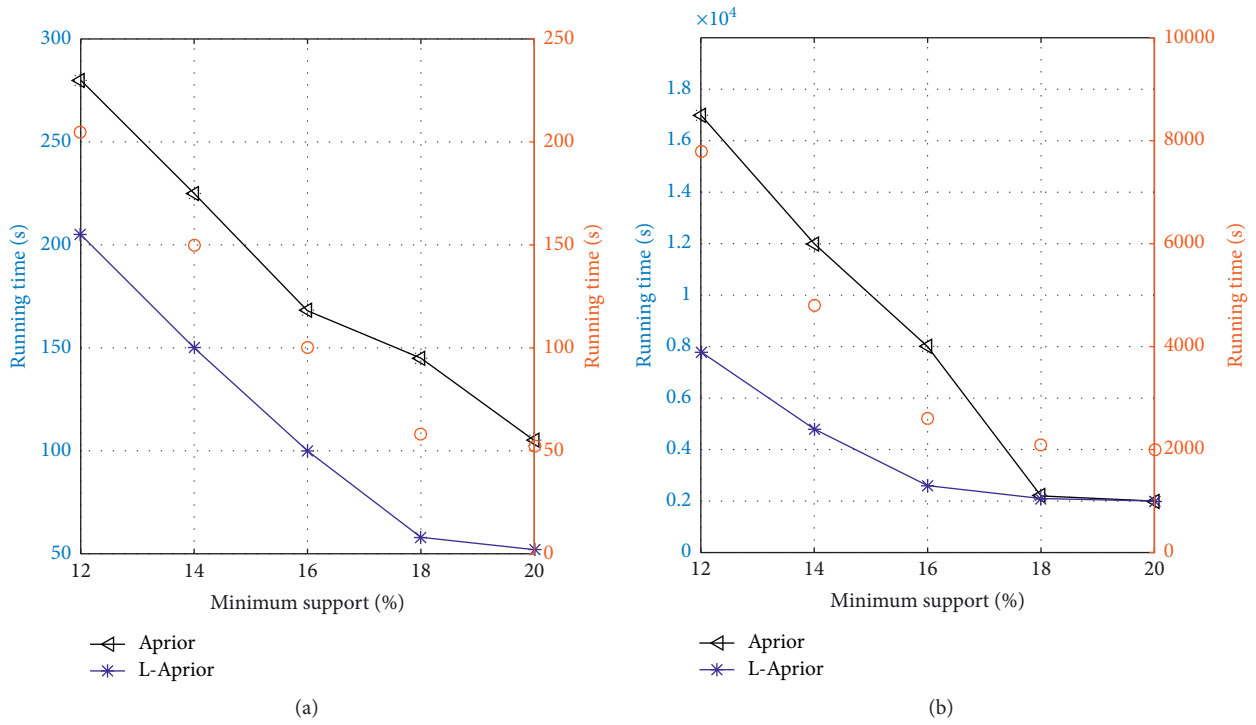

FIGURE 8: Performance analysis of L-Apriori algorithm.

FIGURE 9: Specific content of the recommendation service provided by the smart library.

FIGURE 10: Pie chart (view events responding to mouse click).

FIGURE 11: Histogram of satisfaction with various elements of user experience.

FIGURE 12: Histogram of user experience category satisfaction.

the number of FCM iterations is 80. The results are compared with the results of IS-PSO algorithm and FCM algorithm at 100 iterations. The results of multiple tests of the two algorithms on the same data set are relatively stable. Table 6 shows the comparison of the average performance of the three algorithms.

From the perspective of the correct rate of classification, the correct rate of FCM algorithm classification is only 88.68%, while IS-PSO and information retrieval visualization algorithms have reached a higher accuracy rate; from the perspective of running time, IS-PSO runs the most due to the complexity of the algorithm. The shortest running time of the FCM algorithm is more than 17 seconds, while the running time of the information retrieval visualization algorithm is in the middle. From the objective function, the

information retrieval visualization algorithm is the basis for finding a better center point in the PSO algorithm. On the other hand, with the advantage of fast convergence of FCM, the optimization accuracy is the best, while the IS-PSO algorithm could not exceed the information retrieval visualization algorithm in the optimization accuracy due to the limitation of running algebra.

Figure 13 shows a simulation diagram of the objective function optimization of the two algorithms. The FCM algorithm has the fastest convergence speed but is premature. The IS-PSO algorithm has the slowest convergence speed and the worst optimization performance within the range of 100 iterations. The information retrieval visualization algorithm is consistent with the IS-PSO algorithm in the first 20 generations, but in 20 after the first generation, due to the

TABLE 6: Comparison of average performance of algorithms.

| Algorithm             | Correct rate (%) | Operation hours | Objective function |
|-----------------------|------------------|-----------------|--------------------|
| FCM algorithm         | 88.68            | 0.138668        | 0.0515             |
| IS-PSO                | 94.66            | 18.358748       | 0.0485             |
| Information retrieval | 96.2             | 3.964959        | 0.0384             |

FIGURE 13: Simulation diagram of objective function.

FCM algorithm, the convergence speed is accelerated, and a better optimization effect can be quickly achieved.

As shown in Figure 13, although the efficiency of information retrieval visualization algorithm is slower than FCM, its optimization performance is better than FCM. The information retrieval visualization algorithm combines the advantages of higher optimization accuracy of PSO and the characteristics of fast convergence of FCM, so the information retrieval visualization algorithm can be better applied to document clustering in smart libraries.

## 5. Conclusion

Inner motivation is the decisive force to promote the increase of contextual functions of new knowledge services. The key to exploring the extension and sustainable development of knowledge services is to explore the intrinsic motivation of new knowledge service enhancements. Therefore, it is necessary to comprehensively consider the development and changes of user experience and perception in the knowledge service process, continuously improve the user's interactive experience and perception, continuously improve the new knowledge service context function of the smart library, and comprehensively and evenly improve the new knowledge service context function design and development to better meet the multidimensional applications and individual needs of users. External motivation is the driving force and supporting force to promote the contextual function of new knowledge

services, which mainly comes from the improvement of resource content quality and basic conditions. Resource context is an important force that determines the function of the new knowledge service, and the maximization of resource content attributes and value is the basic force to promote the interactive function of the new knowledge service context. According to the internal mechanism of knowledge service extension of smart library, the internal power and external power are actively and effectively used to form a dynamic and balanced situational state in order to promote the improvement of the overall function of the library's new knowledge service. By building a smart technology system of smart perception layer, network transmission layer, data resource layer, and smart application layer, with the help of various sensing devices in the perception layer, network technology in the network transmission layer, data mining and cloud computing in the data resource layer technology, virtual reality and augmented reality technology at the smart application layer complete the collection, distribution, and organization of user data and collection data and realize user personalized recommendation services, scene-based services, multimedia services, smart space services, visualization services, and virtual realistic service. However, smart libraries also need diversified smart countermeasures to solve various problems in the construction process and establish an interactive smart platform for the multifunctional smart library system to check for deficiencies and make up for the lack of public welfare services. Under the banner of advocacy, we can focus on user needs and implement the service standards of "precise demand and high-quality services" to create a smart space, to realize the interconnection of physical space, to increase the comfort and humanistic care of the space, and to embody the concept of a smart library for the convenience of readers and green development. In addition, the integration of online and offline libraries, libraries and bookstores, libraries and logistics companies, integrated service solutions, and other integrations are also being further explored, and integration is becoming the main form of the development of smart libraries.

Big data has brought about opportunities for landscape architecture, changing the design thinking of layout optimization simulation, expanding the platform for public participation in layout optimization simulation design, reflecting social and humanistic care, and promoting the integration of discipline cooperation and data. At the same time, it also brings about challenges. The proposal of data theory, the acquisition and analysis of data, and the protection of privacy are all issues that we need to face and solve. First, build a layout optimization simulation program under the background of big data. Follow the procedures of conventional layout optimization simulation, add big data analysis technology to the preliminary analysis, layout optimization simulation design, and later evaluation management, introduce new data processing methods, and build a theoretical framework of landscape optimization simulation methods that integrate new and traditional data. Second, studying the evolution of the landscape image layout of the three-dimensional pastoral complex is different: the overall landscape image layout of the three-dimensional pastoral complex shows a trend of fragmentation and heterogeneity. Among them, the arable land is gradually fragmented, the wetland and water area are simplified in form, the woodland and grassland patches are gradually distributed, the fragmentation is reduced by 76.19%, and the connectivity index is gradually increased. From a spatial perspective, the edge area outside the Fourth Ring Road becomes the most obvious area of fragmentation tendency. Finally, by introducing big data into the landscape layout optimization simulation, a layout optimization simulation method based on big data is constructed and used in the layout optimization simulation of the landscape image layout of the three-dimensional pastoral complex to guide the participatory layout optimization simulation.

## 1. Introduction

Three-dimensional landscape image layout of pastoral complex is an important guarantee for urban ecological environment. By the urban green land, farmland, forestland, and wetland and the waters together form a complex three-dimensional rural landscape image layout that has important ecological service function, in the maintenance of ecological safety and delay species, reducing the heat island effect and maintaining the social and economic sustainable development playing an important role, and has a decisive influence on land ecological environment. A complex three-dimensional rural landscape image layout of ecological benefit, economic benefit, and social benefit also caused the country to attach great importance to

the construction of urban forest and green space construction as the main content; emphasizing the urban forest ecosystem plays an important part in urban development and together with the urban green space system affects the ecological landscape of the city. Farmland, wetland, and water area are also indispensable parts of urban ecosystem, which play an important role in ecological protection and material circulation. Therefore, it is urgent to study the three-dimensional landscape image layout of urban green space, farmland, forestland, and water area and put forward the optimization strategy for the overall urban ecological environment construction and the improvement of ecological benefits.

Theoretical research mainly focuses on the impact of big data on subject teaching, landscape layout optimization

simulation process, and the guidance of data analysis on layout optimization simulation. The actual cases mainly focus on spatial structure analysis, human behavior characteristics, and users' emotional evaluation under the background of big data, mainly using remote sensing, bus ride record, taxi GPS track, Weibo positioning data, network text, and so forth. The research scope involves large-scale scenic spot layout optimization simulation, as well as small- and medium-sized green space system and greenway layout optimization simulation. It can be seen that studies on big data in landscape layout optimization simulation are concentrated in local areas, and no complete system has been proposed for the application of big data technologies and methods in layout optimization simulation program. For example, the concept and characteristics of big data are introduced, and the characteristics of big data are linked with the simulation content of landscape layout optimization [1–3].

Combined with practical cases, the application of location service data in landscape layout optimization simulation in various periods was introduced, and the simulation design method of landscape layout optimization based on location service big data was drawn, providing a good reference and research direction for subsequent researchers [4–6]. In the study of population activity, the quantitative analysis method of thermal diagram was used, which provided a practical reference case for the application of big data in the simulation of landscape layout optimization [7, 8]. Taking Beijing forest park as the research object, the word frequency analysis software is used to collect and analyze the network text, so as to obtain the social service value of different forest parks and introduce the network text into landscape evaluation [9, 10]. By collecting mobile phone location data in scenic area, the behavior rules of tourists are studied to provide a basis for layout optimization simulation management and decision-making in scenic area, and the research on tourists' behavior characteristics based on positioning data is a hot research topic at present [11, 12]. Big data plays a prominent role in the study of urban issues, and it is commonly used to study urban internal space, urban activity space, and urban hierarchy. For example, according to the global Internet map, the world's Internet cities are graded by using domain names and number of users [13, 14]. Use Twine: firewall cracking programs to extract the geographic coordinates and text data, and combined with time series model analyzed in different cities of Twitter posts characteristics and distribution of keywords, found that only a few cities that can offer more time keyword search the information they need and get the city level of network activity and the relationship between 15th and 16th. By analyzing the communication information of 25 million users provided by the Belgian mobile phone operator, the social network was established by using the zip code corresponding to the user's mobile phone bill address, and the communication intensity was studied by using the gravity model, and finally the communication connection and hierarchy system between cities were obtained [15, 16]. By combining mobile network traffic data (directional switching vector and overall network traffic data) with social networking site data (Flickr), the spatial analysis method is adopted to

reveal the activity hotspots of cities and the travel activities and change characteristics of cities and suburbs in different seasons [17, 18]. Through 8 million Flickr locations and image information the central border in London and Chicago metropolitan areas is determined, using GPS and web tools (can record the time and latitude and longitude, speed, distance, and direction) and connecting with Google maps, to simulate the two cities, 76 tourists in Canberra and Sydney, and the action of trajectory, as well as analysis of tourists travel path, change to the mode of transportation, travel, obstacles, and other characteristics [8, 17, 18]. However, there are few studies on landscape development under the background of big data, and the research on big data focuses on the application exploration and decision support of big data and the application of various big data in landscape layout optimization simulation. Big data has brought about new types of technology and equipment to other industries. For landscape architecture, big data has brought about more changes in planning thinking, allowing professionals to rely more on rational analysis of problems. Planning and design is a problem-solving process. Aiming at complex problems, by analyzing a large number of multiple types of data, it proposes a more suitable solution than traditional data analysis. Only in this way can the planning be more objective and rational.

The types of big data involved include cellphone signaling data, satellite positioning data, social network data, and landscape photos. How to mine relevant data under the nonstationary characteristics of big data? Through the investigation of 4950 interviewees on the relationship between the acquisition of high-quality urban green space and the level of leisure and sports activities, it is found that there is no clear relationship between activities and access to green space [19, 20]. Publicly available via the Internet social produce or provide the geographic mark photos, collected from 2100 tourists, 29,443 photographs, with pictures of these geographic staggered build datasets, can help them address these challenges, as well as, for example, destination, traffic layout optimization simulation, and the management development of series of problems such as providing practical use value [21]. Research on the connotation is of three-dimensional rural complex landscape image layout and the relationship between development mode, layout optimization simulation mode and path, industrial layout optimization simulation, and rural revitalization. Based on the analysis of the new urban-rural relationship, the value content, operation mechanism, and guiding strategy of the three-dimensional landscape image layout of pastoral complex are discussed [22, 23]. Layout of a complex three-dimensional rural landscape image, the concept of value, the tertiary industry relations, and operation mode are analyzed in detail; at the same time, summarizing their participation in three-dimensional rural process of landscape image layout project strategy is complex and difficult, and the complex three-dimensional rural landscape image layout in the advantages and problems in the domestic development is demonstrated [24, 25]. The importance of the development of the landscape image layout mode of 3D pastoral complex in

the layout optimization simulation design is listed, and the characteristics of the landscape image layout of 3D pastoral complex are systematically analyzed [26]. The construction contents of the “seven systems” and “seven projects” in the layout of three-dimensional pastoral complex landscape images are introduced in detail, and the layout optimization simulation strategies in terms of industrial system, building rural communities, and joint mechanism of interests are proposed [27, 28].

By learning the data collection and processing technology of big data, the processing mode and guiding method of big data are introduced into the landscape layout optimization simulation, and the processing method of big data is added to the conventional layout optimization simulation program, so as to influence the thinking of layout optimization simulation design and improve the objectivity and scientificness. The main procedure is to introduce the technology of big data collection and processing on the basis of field investigation and site data collection, screen and process the data, and establish a database. By quantifying different types of influencing factors, the thousand-layer cake analysis method is adopted to overlay different data to guide the simulation of landscape layout optimization. The landscape layout optimization simulation method based on the influence of big data was applied to the landscape image layout of 3D pastoral complex, and the similarities and differences were found by comparing the traditional layout optimization simulation method and the layout optimization simulation program of the data-based layout optimization simulation method. The layout optimization simulation design of 3D pastoral complex landscape image layout was studied, focusing on the simulation of road, spatial structure, ecological pattern, and industrial layout optimization of 3D pastoral complex landscape image layout under the premise of ecological environmental protection.

## 2. Big Data Analysis of Three-Dimensional Rural Complex Image Layout Prediction Analysis

The core of landscape pattern optimization of three-dimensional pastoral complex is to realize the optimization of quantity and space. Through quantitative and qualitative research, specific macro and spatial strategies are provided to provide policy and data support for realizing the ideal landscape pattern of three-dimensional pastoral complex. In this study, the system dynamics model and cellular automata model are mainly used as the land simulation and prediction model to carry out the area and space simulation of the landscape pattern optimization of three-dimensional rural complex [29, 30].

### 2.1. Image Layout Predictive Analysis Modeling

- (1) Understand the problem, define the problem, confirm the target, and determine the macro variable factors that affect its change according to the modeling purpose and prediction object. In this

study, the three-dimensional pastoral complex is affected by policy regulation and social economy at the macro level, specifically manifested as economic development, population growth, industrial adjustment, land expansion, and so forth. Therefore, the variable factors of the system dynamics model of three-dimensional pastoral complex should reflect these macro factors, and we call these macro social factors and the system that reflects the area of various three-dimensional pastoral as the complex system of three-dimensional pastoral complex.

- (2) Draw the causal feedback diagram of the system according to the logical relationship between the target and parameters; the causal feedback graph is mainly expressed as arrows and diagrams according to the interaction between variable factors. In addition, positive and negative signs are used to show the interaction between the two factors. That is to say, we need to visualize the relationship between factors in the complex system of three-dimensional pastoral complex in graphical ways such as arrows and signs.
- (3) Describe the relationship between parameters by mathematical formula and establish the system dynamics model. Through debugging in Vensim PLE software, the quantitative relationship between different factors in the 3D pastoral complex system was simulated. By analyzing the interaction mechanism between social economy and the change of the number of covers in three-dimensional pastoral complex, the relationship between them is analyzed mathematically and logically, so as to realize the influence relationship in the whole system.
- (4) Test and verify the model. In order to verify the reasonability of the model, it is necessary to debug the model, compare the relationship between the simulated value and the real value, and usually simulate the data of a certain historical period with the data of the past several stages until the simulation results meet the 10% error range.
- (5) Establish a system mechanics simulation and prediction simulation platform to predict the future area change of the three-dimensional rural complex, design multiple scenarios, and use the model to select and simulate strategies. That is, by changing the parameters of the model and testing the posteffects of various scenarios, the opportunity and approach to improve the behavior of the complex system of three-dimensional pastoral complex are sought. Through the prediction analysis and comprehensive comparison under different scenarios, the relative optimal scheme for the coordinated development of social economy and three-dimensional pastoral complex is sought.

Cellular automata modeling process can be understood as actual three-dimensional rural complex, construction land, and unused land allocation process, refer to previous

high citation rate research, at the same time combined with three-dimensional rural complex in the evolution of the space characteristics, mainly on the basis of land unit is converted to other types of land suitability, neighborhood unit on its transformation, the inheritance of land unit itself and random interference factors to determine, and focus on the transformation between the Mosaic and the three-dimensional rural construction land. The specific modeling process of cellular automata is as follows, as shown in Figure 1.

The statistical results of stakeholders' power dimension of pastoral complex projects are shown in Table 1. It can be seen that the government, social capital, operators, and farmers' cooperatives rank the top four in the power of pastoral complex projects construction, while users, scientific research institutions, financial institutions, and suppliers of materials and equipment rank the bottom four. It is worth noting that financial institutions and users bear more risks in project construction but have less power. This part of project stakeholders is the vulnerable group mentioned in many studies. Farmer cooperatives rank the third in the risk dimension, but their power somewhat decreases. This is because the resources invested by farmer cooperatives may not reach equilibrium with their power, which will lead to the problem of uneven distribution of benefits in the process of project construction and operation. Since the operation stage of the project is relatively important, the operator has more power over the project. The mean and variance are calculated using the formulas in [19].

Pastoral complex is a multifunctional spatial gathering and combination of agricultural production, residence, leisure, and entertainment in a certain regional space and realizes integrated management of spatial layout optimization simulation, construction, and operation. Urban government is the main body of simulation and construction management of spatial layout optimization of pastoral complex. It mainly guides and restricts each participant through policy support and simulation management of spatial layout optimization, as shown in Figure 2.

*2.2. Spatiotemporal Evolution Analysis of Three-Dimensional Pastoral Complex Pattern.* Normalized difference vegetation index (NDVI) is defined as the ratio of the difference between the values of near-infrared band and visible red-light band and the sum of the values of the two bands:  $NDVI = (IR - r) / (IR + R)$ . For TM data, the numbers of near-infrared bands and visible red-light bands correspond to the fourth band (TN4: 0.76–0.9  $\mu m$ ) and the third band (TN3: 0.63–0.69  $\mu m$ ), respectively. NDVI calculation formula is as follows [31]:

$$NDVI = \frac{TN4 - TN3}{TN4 + TN3} \quad (1)$$

As the NDVI value calculated by the above formula is between 0 and 1, in order to match the 8-bit radiation resolution of Landsat, the result is transformed and stretched, so that its gray value is within [0, 255].

Through to the central city in 1992, 2000, 2008, and 2016, four times each type of three-dimensional rural complex remote sensing interpretation results, by Arcmap statistics, get the three-dimensional rural complex interpretation data statistics (Table 2, construction land and unused land) and the three-dimensional rural complex area change contrast figure (Figure 3, construction land and unused land).

It can be seen from Table 2 and Figure 3 that, during the research period from 1992 to 2016, the total area of the three-dimensional pastoral complex in the central city and the area of a single three-dimensional pastoral complex such as grassland, woodland, cultivated land, wetland, and water area all changed to different degrees, and the overall change was relatively obvious. In general, during the study period, the cultivated land and woodland area of the central city always ranked first and second in the area of the three-dimensional pastoral complex, while the wetland, water area, and grassland always ranked second. In 1992, cultivated land was the dominant type of three-dimensional pastoral complex in the central city, but in 2000, the dominant position of cultivated land was slightly reduced. In 2008, woodland became the dominant type of three-dimensional rural complex in the central city, but the advantage was not obvious. In 2016, woodland has become an obvious dominant type of three-dimensional pastoral complex.

Overall, Table 3 shows that, from 1992 to 2016 (study period), the central city's total area of the three-dimensional rural complex had a declining trend; the reason is that forestland, arable land, grassland, and wetland and water appear in different periods of time, and the three-dimensional rural complex type area reduction is higher than the increase, so the total area of the three-dimensional rural complex declined from 1992 to 2016. From the analysis of the area change of different types of three-dimensional pastoral complex, the area of three-dimensional pastoral complex in the central city of Beijing has been undergoing significant dynamic change. The continuous decrease of the overall area of the three-dimensional pastoral complex, the decrease of the large area of cultivated land, the fluctuation of woodland area, and the increase and decrease of the small area of grassland, wetland, and water area have become the typical characteristics of the area evolution of the three-dimensional pastoral complex in the central city since 1992. In the past 24 years, people have changed the way of land use in the central city through urban construction, which will affect the three-dimensional rural complex pattern of the central city. With the expansion of construction land area, the cultivated land area in the central city of Beijing decreases, and the land productivity decreases. With the increase of grassland area and fluctuation of woodland area, the landscape of the study area will become more fragmented, which will not be conducive to the maintenance of biodiversity in the study area and even affect a series of ecological functions such as heat island mitigation and stormwater retention. Therefore, it is necessary to further study the three-dimensional rural complex pattern in the central city of Beijing.

### 3. Image Layout Optimization Method for Three-Dimensional Rural Landscape Based on Big Data

As an emerging research direction, big data attracts increasing attention. In 2018, there were 25,745 Chinese literatures with big data as the theme, with a sequential growth rate of 21.40%. The study covered ten disciplines, and landscape architecture was not surprisingly affected. Big data in landscape architecture caused a wave of simulations and researches on layout optimization through quantitative information and played a role in providing new technologies or new methods in each stage of landscape layout optimization simulation. In the early analysis of landscape layout optimization simulation, big data mainly introduces new survey methods, expands the data collection methods, and broadens the data collection scope. The additional relevant information provides the foundation for comprehensive, high-precision, and high-granularity research. For example, the data about the characteristics of the users and the emotional information were added to the data collection, and the positioning information was collected through the network. The research of layout optimization simulation

stage focuses on the analysis stage, which is mainly used to discover and mine the relationship between related elements. New data commonly used in layout optimization simulation include location communication data, network text data, and network photos. Positioning because traffic data can reflect the space location and individual behavior, widely used in space function of identification, analysis and use of space structure, road layout optimization simulation of space related problems, such as analysis, as well as the crowd gathers the characteristics of space and time, population distribution, behavior related to human activities such as analysis. Social network is an important channel for public participation layout optimization simulation design due to its wide coverage, fast propagation speed, and good interoperability. Network text data is generated with the development of social networks. By quantifying text and seeking public attention, interest points, and emotional evaluation, it can be used to analyze the advantages and disadvantages of site management and to build an evaluation system. Online photos could not only reflect location data but also reflect the current situation of the site. Superimposing this kind of big visual data on the map can evaluate the space quality, street greening, and road landscape, which is of positive significance to improve the landscape. In the later stage of layout optimization simulation design, big data mainly enriches the feedback platform of the public and establishes an online communication network for the public, layout optimization simulators, and decision-makers through social networks and mobile terminals. Based on the above research, the simulation design framework of landscape layout optimization under the background of big data can be simplified as shown in Figure 4.

First, draw a CAD axis Map, import the CAD Map into the space syntax Depthmap software, use the Convert Drawing Map function to transform the Graph into a layer of Axial Map that can be recognized by the software, and then use the software's Run Graph Analysis function to perform topological calculation on the axis Graph and finally obtain the accessibility Analysis Graph (See Figure 5).

FIGURE 3: Comparison chart of land use area change in the central city from 1992 to 2016.

The area of each land type within the layout optimization simulation range provided by multiple planning is

summarized. According to the ecological capacity of each land type provided by the layout optimization simulation standard of scenic and historic interest areas, the ecological capacity of the land type within the site is defined as shown in Table 4. According to the above formula, the daily space capacity is about 58,100 people, and the annual space capacity is 21,218,500 people.

The area algorithm is adopted to obtain the following formula of tourist mental capacity:

$$Cd = \frac{B}{B_s} \times \frac{R}{r} \quad (2)$$

In the previous equation,  $Cd$  is the psychological capacity of tourism,  $B$  is the total area of sightseeing,  $B_s$  is the per capita area of sightseeing, and  $R$  and  $r$ , respectively, represent the service time and visitor's stay time. The minimum sightseeing area per capita is 50 people. The total area of the site is 9,986,900  $m^2$ , so the daily psychological capacity is 459,300 people, and the annual psychological capacity is 167.68 million people.

It can be seen from Table 5 that, among the three factors, ecological capacity is the smallest, which becomes the determinant to limit the environmental capacity of the site. In layout optimization simulation, the development red line

should be the ecological capacity of 54,700 people per day and 20,309,900 people per year.

#### 4. Experimental Verification

Based on the use of big data, this paper conducts a questionnaire to collect basic information of people and their concerns about the pastoral complex. This survey was conducted by WeChat. A total of 65 questionnaires were received, and respondents were distributed in 11 provinces and 1 municipality directly under the central government. The survey content is divided into two parts: one is the basic information of respondents, and the other is the detailed investigation of the construction of pastoral complex. The first part includes basic information such as gender, age, education, occupation, and income and also registers basic information related to tourism, such as the frequency of travel, destination, duration of travel, and fellow travelers. According to the survey results, as shown in Figure 6, the gender distribution of the respondents is more women than men, mainly between 30 and 60 years of age. Most of them have a bachelor's degree and a graduate's degree, and most of them are college students and company employees. Most people go out for an average of two to three times a year, three to four days each time, mainly to scenic spots and tourist cities, and most people go out with friends and family.

The investigation on the content and interest points of pastoral complex is carried out from eight aspects, namely, tourism motivation, types of pastoral complex, elements of pastoral complex, tourism commodities, activities, accommodation forms, simulation points of layout optimization, and regional location. Among the 65 respondents, 64 indicated that they would like to travel to the countryside or take a vacation. Most of them travel to the countryside mainly for rural sightseeing, entertainment, relaxation, and cultural experience. Among the six different types of pastoral complexes, sightseeing and comprehensive and cultural communication pastoral complexes are favored by people. In the nine different elements, natural scenery, local food, farmland landscape, local culture, and living environment are the key points of people's attention. Local specialties, folk customs products, creative

cultural products, and agricultural products account for more than 60% of the tourism commodities. Among the 8 kinds of activities, pastoral tourism, folk custom activities, cultural experience, and farming experience account for up to 50 percent. In the form of accommodation, the proportion of home stay, shared farm, and characteristic hotel is more than 50%. For the elements of pastoral complex, tourism commodities, activities, accommodation forms, and tourism motivations, the proportion of person-time is adopted, as shown in Figure 7.

As for the project positioning of building a healthy and nourishing rural complex with urban backyard garden, all respondents expressed that it was reasonable, as shown in Figure 8. The project positioning of the survey rationality evaluation highlights the characteristics of the site, mainly because the project positioning combines local resources; in response to national policies, development under environmental protection conditions can also drive local development: implementation feasibility is higher.

According to the classification of S and R, public participation can be divided into three types and eight levels, from false (nonfalse) participation to substantive participation, and the degree of participation gradually increases (see Table 6). At present, the level of conventional participation is mainly informed participation, and the level of participation is relatively shallow. In this paper, a participatory layout optimization simulation design program is established by collecting big data and investigation. In the preliminary analysis, the opinions of villagers and netizens were investigated. In the layout optimization simulation fully consider the opinions; after the layout optimization simulation is completed, people's ideas will be understood in the form of video and questionnaire. The level of public participation includes informed participation, cooperative participation, and decision-making participation, which greatly improves the level of participation.

The participatory layout optimization simulation method is introduced in the layout optimization simulation of rural complex, which is helpful to build the communication platform. Everyone has different choices due to

FIGURE 7: Distribution of tourism motivation and distribution of pastoral complex types.

|                               |                           |                              |
|-------------------------------|---------------------------|------------------------------|
| Level of public participation |                           |                              |
|                               | False participation       | Operational participation    |
|                               |                           | Educational participation    |
| Public participation          | Symbol in                 | Informed participation       |
|                               |                           | Consultative participation   |
|                               | Substantial participation | Restricted participation     |
|                               |                           | Cooperative participation    |
|                               |                           | Representative participation |

different living environment, education level, working environment, and so forth. Participatory layout optimization simulation can provide a platform for communication,

which can be used to express ideas and guide layout optimization simulation. It is also a platform for mutual learning. Professionals have professional knowledge reserves

but lack the understanding of site information. Although the public have no professional knowledge, they have a good grasp of the site information, especially the cultural aspects that cannot be consulted on the Internet or in the literature. The communication between the two is conducive to a comprehensive understanding of the site, as well as layout optimization simulation design with cultural characteristics of the scheme.

## 5. Conclusion

The landscape layout optimization simulation design based on the background of big data can apply big data and big data technology to every stage of layout optimization simulation. In the preliminary analysis, big data provides layout optimization simulation with a wider range of more comprehensive basic data and information about crowd concerns. In addition to the new data, it also introduces a lot of analysis methods, such as regression analysis, factor analysis, emotion analysis, time series analysis, and nuclear density analysis, providing a channel for in-depth mining of the information behind the data. In the late stage of layout optimization simulation, the visual presentation mode enables more people to understand the intention and effect of layout optimization simulation. In combination with the public feedback platform of big data, modification suggestions are provided for layout optimization simulators. In the process of constructing layout optimization simulation framework, the authors found that although big data brought about changes in layout optimization simulation thinking, update of analysis methods, new technologies, and other influences, big data mainly played the role of supporting analysis in the whole layout optimization simulation. We should embrace the impact of big data with an open mind and at the same time be rational in its use. Rationally view the positioning of big data in layout optimization simulation; Face up to the difference between rational and perceptual analysis methods and combine them; only in this way can the power of big data be brought into play. Against the background of big data, a simulation program for layout optimization of pastoral complex is constructed, in which the application of big data in pastoral complex mainly focuses on the early analysis and the late feedback. In the early analysis, the global consciousness of big data plays a huge role in the analysis of the overall layout, which enables the layout optimization simulator to consider the site in a larger scope. At the same time, based on big data analysis, it can understand and master the interest points and basic features of the public, which is conducive to providing targeted activities. On the basis of previous analysis, the influence of big data on layout optimization simulation is mainly focused on spatial analysis and layout optimization simulation, such as function partition, spatial structure layout optimization simulation, and spatial quantization. Big data plays a guiding role. The greater influence of big data on layout optimization simulation of rural complex lies in that it provides a communication platform for layout optimization simulation designers, farmers, and decision-makers, deepening the degree of participatory layout optimization simulation.

Affected by professional optimization of the 3D pastoral landscape, research time and way of thinking, the depth and breadth of model construction, research methods, and problem-solving ideas are obviously insufficient, and the angle of innovation is not enough, which may lead to certain problems in research bias.

Fractal art graphics are the product of the fusion of mathematics and art, relying on the computing power of a computer to iteratively calculate mathematical formulas and present the results in a graphical rendering. The selection of the initial value of the first iteration has a greater impact on the final calculation result. If the initial value of the iteration is not selected properly, the iteration will not converge or will converge to the wrong result, which will affect the accuracy of the fractal art graphic design. Aiming at this problem, this paper proposes an improved optimization method for selecting the initial value of the Gauss-Newton iteration method. Through the area division method of the system composed of the sensor array, the effective initial value of iterative calculation is selected in the corresponding area for subsequent iterative calculation. Using the special skeleton structure of Newton's iterative graphics, such as infinitely finely inlaid chain-like, scattered-point-like composition, combined with the use of graphic secondary design methods, we conduct fractal art graphics design research with special texture effects. On this basis, the Newton iterative graphics are processed by dithering and MATLAB-based mathematical morphology to obtain graphics and then processed with the help of weaving CAD to directly form fractal art graphics with special texture effects. Design experiments with the help of electronic Jacquard machines proved that it is feasible to transform special texture effects based on Newton's iterative graphic design into Jacquard fractal art graphics.

## 1. Introduction

Fractal geometry is often used to describe irregular things in nature. The well-known Euclidean geometry describes objects composed of points, straight lines, common polygons and curves in two dimensions, and boxes and surfaces in three dimensions [1, 2]. Most common man-made objects can be described by Euclidean geometry, such as books, desks, lighthouses, houses, and other buildings. However, many natural objects in nature cannot be described by conventional geometric figures, such as clouds and coastlines [3]. The emergence of fractal geometry provides a new perspective for describing natural objects. In fact, it is difficult to judge the difference between two clouds and two coastlines only from the structure and shape, because these natural objects have self-similarity. Fractal geometry uses the idea of fractal dimensions to describe the difference in this

characteristic and maps objects with different dimensions [4].

In foreign countries, the research on fractal art is mainly based on scientists, and artists' attention to this field is not very common [5]. The research of fractal art has always had its own system and development history, which is particularly prominent in design education [6]. Reason education has been mentioned in art education for a long time, and geometry is even regarded as one of the foundations of art design teaching [7]. Joseph Albers, Max Bill, and others have cited many geometric principles in graphic design to guide operation and design [8, 9]. A large part of their courses are graphic creation based on mathematical prototypes. In China, the research on fractal art mainly focuses on artists, and scientists pay little attention [10]. This is a manifestation of the different understandings of fractal art research at home and abroad. Relevant scholars explained how Julia set,

Mandelbrot set, and Newton fractal set adjust the number and shape of petals in clothing design and extracted texture information of different flower types, focusing on analyzing the relationship between Julia set flower types and various parameters [11]. Researchers proposed that works of art should represent nature and work like nature [12]. Science is also trying to explain the laws that determine nature. Technology provides appropriate tools for both parties to achieve common goals [13]. Fractal art is at the core of the triangular relationship between art, science, and technology. Fractal geometry and chaos theory bring new perspectives to art. The study of fractal features provides broad possibilities for art development [14]. Relevant scholars have used artificial neural networks to realize the fusion of natural scene image content and classic painting style and transfer the classic painting style to the content image [15]. Through parameter adjustment, the generated image meets people's aesthetic standards. As an important branch of deep learning, style transfer has been favored by many scholars [16]. In terms of practical application, because theory and practice have not been well integrated and due to lack of understanding of fractals, there are very few researches on the rules of graph generation and the application of the rules [17]. Only the clothing and textile industry is involved and requires fractal technology. Higher industries such as movies and 3D games have no real substantive applications for the time being. In addition, due to the disconnection between science education and art education in China, the domestic understanding of fractal graphics is still at the initial stage. Scientists are not paying enough attention to this kind of artistic performance, so it has not attracted more attention. The research on fractal art lacks knowledge not only in theory but also in material support. Therefore, the road to popularization of fractal theory is still very difficult [18–20]. How to further promote fractal theory to make people realize its material value and economic benefits, or to use fractal art image as a new art form, requires our further efforts.

Newton's iterative graph is generated from nonlinear dynamics theory by changing its mathematical model and related parameters. In the calculation process, the Gauss-Newton iteration method is used to optimize the selection of the initial value of the Gauss-Newton iteration method. The optimization method makes full use of the characteristics of the actual problem of target positioning and combines the advantages of the Gauss-Newton method to perform local fast search. The situation where the Gauss-Newton method does not converge or only converges to the local optimal solution is avoided, and a more ideal positioning result is obtained. Four Newton iterative transformation forms are proposed to produce different shapes of graphics, which can affect the texture effect of the fractal art graphics surface. Mathematical morphology processing of Newton's iterative graphics with the help of MATLAB makes the pixel points of the graphics directly correspond to the tissue points, making them directly into fractal art graphics and presenting a variety of special texture effects, and we design experiments with the help of electronic Jacquard machines. In order to

design special texture effects of fractal art graphics, a new way for reference is explored.

The rest of this article is organized as follows. Section 2 analyzes the related theories of fractal art graphics. Section 3 constructs an improved Newton iteration algorithm. Experiments and discussions were conducted in Section 4. Section 5 summarizes the full text.

## 2. Theories Related to Fractal Art Graphics

*2.1. Characteristic Analysis of Fractal.* A fractal is a collection of some "complex" points in some simple spaces. This collection has some special properties. First, it is a compact subset of the space where it is located and has the typical geometric characteristics listed below:

- (i) The fractal set has proportion details at any small scale, or it has a fine structure.
- (ii) The fractal set cannot be described by traditional geometric language. It is neither the trajectory of points that satisfy certain conditions nor the solution set of some simple equations.
- (iii) The fractal set has a certain self-similar form, which may be approximate self-similar or statistical self-similar.
- (iv) The "fractal dimension" (defined in some way) of a fractal set is generally greater than its topological dimension.
- (v) In most interesting situations, the fractal set is defined by a very simple method and may be generated by iterations of transformations.

For a variety of different fractals, some may have all the above properties at the same time, some may only have most of them, and some have exceptions to certain properties, but this does not affect us calling this set a fractal. It should be pointed out that most of the fractals involved in nature and various applied sciences are approximate. When the scale is reduced to the size of the molecule, the fractality disappears, and strict fractal exists only in theoretical research.

Fractals are generally divided into two categories, deterministic fractals and random fractals. If multiple iterations of the algorithm still produce the same fractal, this fractal is called a deterministic fractal. Deterministic fractals are repeatable. Even though some randomness may be introduced in the generation process, the final graph is deterministic. Random fractal refers to the fact that although the rules for generating fractals are determined, they are affected by random factors. Although the fractals generated by each generation process can have the same complexity, the shape will be different. Although random fractals also have a set of rules, the introduction of randomness during the generation process will make the final graph unpredictable. That is, the graphics generated by the two operations at different times can have the same fractal dimension, but the shape may be different, and random fractals are not repeatable. The frame diagram of the fractal graphic design program is shown in Figure 1.

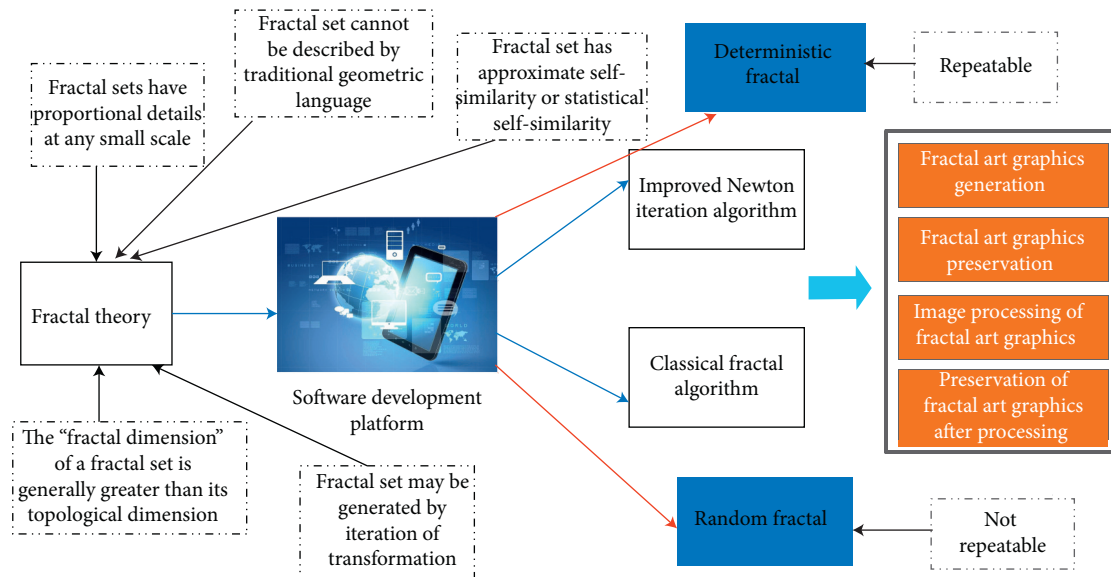

FIGURE 1: Framework diagram of fractal graphic design program.

**2.2. The Difference between Fractal Geometry and Euclidean Geometry.** To explain the difference between fractal geometry and Euclidean geometry, first we introduce the characteristics of Euclidean geometry. Euclidean geometry is a study of regular geometric figures. The so-called regular geometric figures are familiar points, straight lines, and line segments; squares, rectangles, trapezoids, rhombuses, various triangles and regular polygons on planes, and planes; and cubes, cuboids, and regular tetrahedrons in space. The other type is geometric figures composed of curves or surfaces, circles and ellipses on a plane, spheres, ellipsoids, cylinders, cones, and truncated cones in space. The dimensions (Euclidean dimension) of these points, lines, screen graphics, and space graphics are 0, 1, 2, and 3, respectively. The geometric measurement of regular geometric figures refers to the measurement of length, area, and volume.

The graphics studied by fractal geometry are more complex or more realistic than those studied by Euclidean geometry. Its important feature is that it has no characteristic length, and the lines or surfaces that make up its shape are not smooth and nondifferentiable. For example, clouds are not spherical, mountains are not conical, coastlines are not arcs, tree bark is not smooth, and even lightning does not traverse the sky in a straight line. These irregular geometric shapes are difficult to describe with straight lines, smooth curves, and smooth curved surfaces in Euclidean geometry. Therefore, the research object of fractal geometry is a kind of irregular geometric shapes with no characteristic length. Although this kind of object cannot be processed by classical Euclidean geometry, it has “good” properties. To facilitate research, important idealized assumptions are often made; that is, it is assumed to be self-similar. Self-similarity means that if a part of the figure to be considered is enlarged, its shape is the same as the whole. Although these assumptions are too simplistic, only then can we study them while still being suitable for the purpose of the

application. Of course, no real structure will remain the same after an infinite number of repeated amplifications. In principle, self-similarity is only approximately reflected in the application.

There is no strict definition of the characteristic length. Generally, the length that can represent the geometric characteristics of an object is called the characteristic length of the object, such as the radius of a sphere, the side length of a cube, and the height of a person; these are the characteristic lengths of various objects, and they well reflect the geometric characteristics of these objects. For the shapes of objects with characteristic lengths, even if they are slightly simplified, as long as their characteristic lengths remain unchanged, their geometric properties will not change much. In other words, for this type of object, you can use geometrically well-known simple shapes such as rectangles, cylinders, and spheres to combine them, and they can closely resemble their structures. For objects that do not have a characteristic length, the characteristic is that they cannot or are difficult to measure with conventional geometric scales.

**2.3. Fractal and Chaos.** Fractals often show irregular representations, but this does not mean that they are absolutely irregular. Fractals have the characteristics of “self-similar”; that is, they take any part of the fractal figure and enlarge it appropriately, and you can still get a similar image to the original whole figure.

The object described by chaos has an infinite self-similar structure and also has an irregular representation but actually has an infinite self-similar nested structure. In this way, the research on “fractal” and “chaos” has moved towards convergence. We can see the fact that there is a chapter on “fractal” in the book titled “Chaos,” but in the book titled “Fractal,” there is another chapter on “Chaos.” “Fractal” and “Chaos,” the two theories developed from different angles, converge on “self-similarity.”

Nonlinear scientific research turns people's understanding of "normal" things and "normal" phenomena to the exploration of "abnormal" things and "abnormal" phenomena. "Multimedia" technology is a new "unconventional" method used to encounter a large number of "unconventional" phenomena in the process of information storage, compression, conversion, and control. Chaos breaks the various "singular attractors" phenomenon that the deterministic equation determines the motion of the system by the initial conditions.

Chaos comes from a nonlinear dynamic system, and the dynamic system describes an arbitrary process that develops and changes over time. Such systems arise from all aspects of life. The research purpose of the dynamic system is to predict the final development result of the "process." However, even the simplest dynamic system with only one variable will have an essentially random characteristic that is difficult to predict. The sequence produced by successive iterations of a point or a number in a dynamic system is called an orbit. If a small change in the initial conditions causes the corresponding orbit to change only slightly within a certain number of iterations, the dynamic system is stable. At this time, the orbit arbitrarily close to the given initial value may be far from the original orbit. Therefore, it is extremely important to understand the set of unstable points in a given dynamic system. The set of all points whose orbits are unstable is the chaotic set of this dynamic system, and small changes in the parameters of the dynamic system can cause rapid changes in the structure of the chaotic set. This kind of research is extremely complicated, but, with the introduction of a computer, you can visually see the structure of this chaotic set and see whether it is a simple set or a complex set and how it changes as the dynamic system itself changes. It is from here that fractal enters the chaotic dynamic system research.

Chaos mainly discusses the unstable divergence process of a nonlinear dynamic system, but the system always converges to a certain attractor in the phase space, which is very similar to the generation process of fractals. Chaos mainly discusses the behavioral characteristics of the research process, while fractal pays more attention to the study of the structure of the attractor itself. At the same time, chaos and fractal rely heavily on the advancement of computers, which poses a challenge to the traditional concept of pure mathematics. It also greatly stimulated the interest and understanding of scientists and the public and played a role in promotion. The consistency of fractal and chaos is not accidental. In the computer image of chaos set, it is often the set of points with unstable orbit that forms the fractal. So these fractals are given by an exact rule. They are a chaotic set of dynamical systems and various strange attractors. Therefore, the beauty of fractal images is the beauty of chaotic collections, and the study of fractal images is part of the study of chaotic dynamics.

*2.4. Method of Generating Fractal Graphics.* The  $L$  system is a set of methods to describe plants and trees proposed from the perspective of plant morphology. At the beginning, it only focused on the topological structure of plants, that is,

the neighboring relationship between plant components. After years of research, geometric explanations were added to the description process. The high simplicity and multilevel structure of this system provide an effective theory and method for describing the morphological and structural characteristics of the growth and reproduction process of plants and trees. Not only can the  $L$  system describe plants but also its composition method can be used to draw all kinds of regular fractal curves and other shapes. Figure 2 shows the calculation framework of the fractal dimension value generated by fractal graphics.

Iteration Function System (IFS) is an important branch of fractal geometry, and it is also one of the most vital and promising fields in fractal images. IFS is a fractal configuration system. Aiming at this system, a set of theories was proposed, a series of algorithm rules were developed, and they were used in many aspects. The theory of IFS includes compression mapping, metric space, existence of invariant compact sets, and measurement theory. The iterative function system has great advantages in the modeling of a large class of objects, especially the advantages of computer simulation of natural scenery. Because of this, IFS has a wide range of applications in graphics. Among them, the research of visualization technology has been extended from 2D fractal to 3D fractal objects; the self-similar fractal image researched by IFS expands its application range, and the IFS transformation need not be limited to affine transformation. For the geometric transformation of the original graphics, the linear transformation in IFS is extended to the nonlinear transformation; for the discussion of the computer generation of natural scenery, the modeling method is also extended from two-dimensional to three-dimensional.

The fractal set of complex dynamical system mainly includes Mandelbrot set and Julia set. Mandelbrot set is the most famous fractal set in fractals. Julia sets are an iteration of polynomials and rational functions. Both the Mandelbrot set and the Julia set are sequences of points obtained by repeated iterations in the complex plane.

The Mandelbrot set is a general outline of the Julia set, and the Julia set is the boundary of the Mandelbrot set. The beautiful images presented in front of people by Mandelbrot and Julia impressed the artists. The benefits have broad application prospects. People's research on Julia set and its extension includes generation algorithm, related demonstration, three-dimensional fractal graph generation, and its further extension; the research on the mapping of Julia set also has further development, including high-order Julia set generation. The study of methods extends the quadratic complex mapping to higher-order complex mapping; the second-order Julia set algorithm-escape time algorithm, random inverse function algorithm, and rotating escape time algorithm are extended to higher-order and generalized Julia sets and the fractal image of Julia set. Through computer experiment method, the research of Julia set has been extended to transcendental function; this research field of artistic design based on fractal and Julia set image has set up another pass for people.

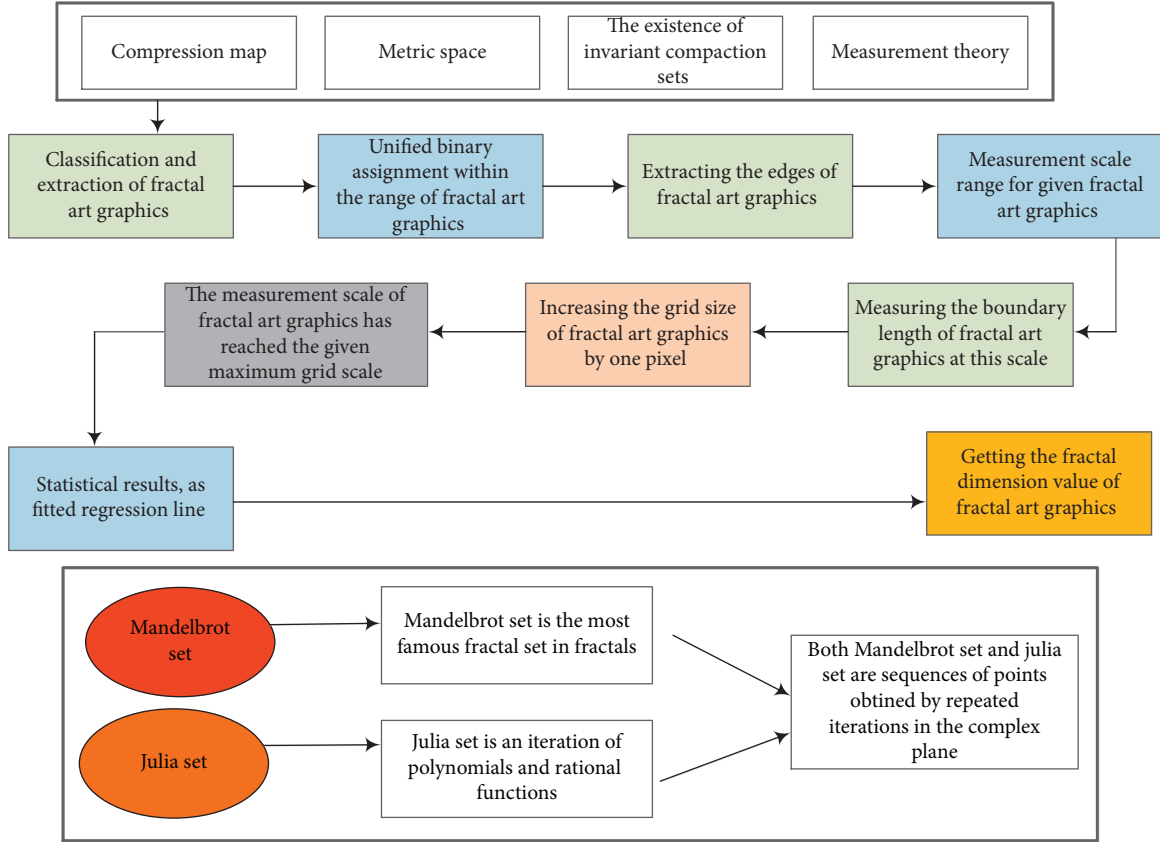

FIGURE 2: The calculation framework of fractal dimension values generated by fractal graphics.

### 3. Improved Newton Iteration Algorithm

**3.1. Gauss-Newton Iteration Method.** Gauss-Newton iteration method is used to solve nonlinear regression problems. After setting the initial value, through multiple iterations, the regression coefficients are modified to obtain the optimal solution of the equations. The basic idea of the Gauss-Newton iterative method is to use Taylor series expansion to approximately replace the nonlinear regression model, and then, after several iterations, the regression coefficients are constantly revised to make the regression coefficients constantly approach the best regression coefficients of the nonlinear regression model. The goal is to minimize the residual sum of squares of the original model. The Gauss-Newton algorithm is an algorithm for solving nonlinear least squares problems. It can be seen as Newton's method to find a minimum function variant. It is used to minimize the sum of the square values of the function. In nonlinear regression, the parameters in the model are sought after, making the model consistent with existing observations, such as nonlinear least squares problems.

Given  $m$  functions  $R = (R_1, \dots, R_m)$  of  $n$  variables  $\alpha = (\alpha_1, \dots, \alpha_n)$ , where  $m \geq n$ , the Gauss-Newton iterative algorithm finds the least square sum:

$$s(\alpha) = \sum_{i=1}^m r_i^2(\alpha). \quad (1)$$

We iterate from the set initial value

$$\alpha^{(s+1)} = r\alpha^{(s)} J_r^T (J_r J_r^T)^{-1} + \alpha^{(s)}. \quad (2)$$

Among them, the Jacobian matrix is

$$J_r = \frac{\partial r_i(\alpha^{(s)})}{\partial \alpha_j}. \quad (3)$$

We set the system of equations to

$$f_i(x, y) = [(x - x_i)^2 + (y - y_i)^2]^{1/2} - [(x - x_{i+1})^2 + (y - y_{i+1})^2]^{1/2} + vt_{i,i+1}. \quad (4)$$

Its Jacobian matrix is

$$G(x, y) = \begin{pmatrix} \frac{\partial f_1}{\partial x} & \frac{\partial f_1}{\partial y} \\ \frac{\partial f_2}{\partial x} & \frac{\partial f_2}{\partial y} \\ \frac{\partial f_3}{\partial x} & \frac{\partial f_3}{\partial y} \end{pmatrix} = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \\ C_{31} & C_{32} \end{pmatrix}. \quad (5)$$

When the Jacobian matrix is a nonsingular matrix (the determinant is not zero), the target coordinate iteration formula is

$$\begin{pmatrix} x^{(k+1)} \\ y^{(k+1)} \end{pmatrix} = \begin{pmatrix} f_1(x^{(k)}, y^{(k)}) \\ f_2(x^{(k)}, y^{(k)}) \\ f_3(x^{(k)}, y^{(k)}) \end{pmatrix} \cdot \begin{pmatrix} \frac{\partial f_1}{\partial x} & \frac{\partial f_1}{\partial y} \\ \frac{\partial f_2}{\partial x} & \frac{\partial f_2}{\partial y} \\ \frac{\partial f_3}{\partial x} & \frac{\partial f_3}{\partial y} \end{pmatrix} + \begin{pmatrix} x^{(k)} \\ y^{(k)} \end{pmatrix}. \quad (6)$$

**3.2. Selection of Initial Value.** The Gauss-Newton iteration method is greatly affected by the initial value. The three-node set in the target positioning system used in this article can form a triangular array, and the function value of the Jacobian matrix in the corresponding direction is calculated by calculating the points on the outer extension line of each side of the triangle. The function value no longer changes.

At points on the straight line, the value of the Jacobian matrix is 0. At this time, the Jacobian matrix function takes the extreme value. The Jacobian matrix function takes the minimum value on the left side of the point and the maximum value on the right side, but the value of the Jacobian matrix function remains unchanged. Therefore, when the Gauss-Newton iteration method is used to solve the problem and when the initial value and the real calculation result are in the same range (referring to the same side of the extreme value point), the optimal solution can be obtained after several iterations. When the initial value and the true value are not in the same range, more accurate calculation results cannot be obtained, and only iterative convergence can lead to a local optimal solution.

Based on the idea of genetic algorithm, the selection of the initial value of Gauss-Newton iteration method is optimized. Genetic algorithm is a nondeterministic quasi-natural algorithm. Genetic algorithm is a random algorithm that uses natural selection and genetic mechanism in nature. The main idea of the algorithm is to simulate heredity, mutation, and crossover in natural selection. We select ideal individuals and recombine them through genetic operators to generate a new set of candidate solution groups, until the optimal solution or better solution that meets the setting is obtained. Genetic algorithm provides a new method for the selection of the initial value of the Gauss-Newton iteration method. In the calculation of the Gauss-Newton iteration method, a group of candidate points are selected to participate in the iteration, and the reasonable selection parameters are selected according to the fitness function to select the candidate points that minimize the error of the calculation result as the initial value of the Gauss-Newton iteration method. The point with the highest fitness is selected as the initial value. The probability of selection is

$$P = \frac{fit(i)}{\sum_{j=1}^n fit(j)}. \quad (7)$$

The two-by-two connection of three nodes in this fractal design system can divide the points in the entire positioning area into seven ranges. Therefore, when selecting the initial value, one point in each of the seven regions can be randomly selected as a candidate point for the initial value. We use these seven points as the initial values in the Gauss-Newton iteration method to perform iterations and limit the number of iterations to 10. Within the specified number of times, the point where the fitness function takes the smallest value is taken as the final true initial value. This initial value is calculated iteratively, and a better initial value is selected for the iterative process. Each iteration corrects the calculated solution to obtain the optimal solution.

The final result obtained will be returned as the calculation result of target positioning. This ensures that the optimal result can be obtained conveniently in the locatable area. Figure 3 illustrates the calculation steps in detail.

## 4. Experiment and Discussion

**4.1. Optimization Results of Newton Iterative Algorithm.** The value of the Jacobian matrix obtained in the process of calculating the representative points of different regions is different, so the correction amount that determines the iteration is different. As a result, convergence and non-convergence occurred in the iterative calculation. The final result of iterative calculation of the initial values of different artistic graphic candidates is shown in Figure 4.

It can be seen from Figure 4 that the error of the calculation results of the initial values of different art graphics is less than 7%. This verifies that selecting the initial iterative value by region is effective in improving the traditional Gauss-Newton iteration method. Compared with the method of randomly selecting the initial value, selecting the initial value by region can improve the calculation accuracy of the Gauss-Newton iteration method. Most of the results obtained by the iterative process of randomly selecting initial values have large errors. The positioning result is largely limited by the distance between the randomly generated initial value position and the actual sound source. The smaller the distance between the randomly generated initial value of the iteration and the actual far sound point, the smaller the error of the calculation result and the more ideal calculation result. When the randomly selected initial value is far away from the actual sound source point, the calculation result has a large error. The positioning method of randomly generating initial values is limited to the range of generating random numbers, and, at the same time, due to its randomness, it is not suitable for practical systems.

**4.2. The Influence of Iterative Function and Parameter Changes on the Generation of Newton Iterative Graph.** The factors affecting the generation of Newton iterative graphics mainly include the type of the iterative function and the value of the parameters  $p$  and  $q$  and the selected Newton iterative graphics part in the design of fractal art graphics.

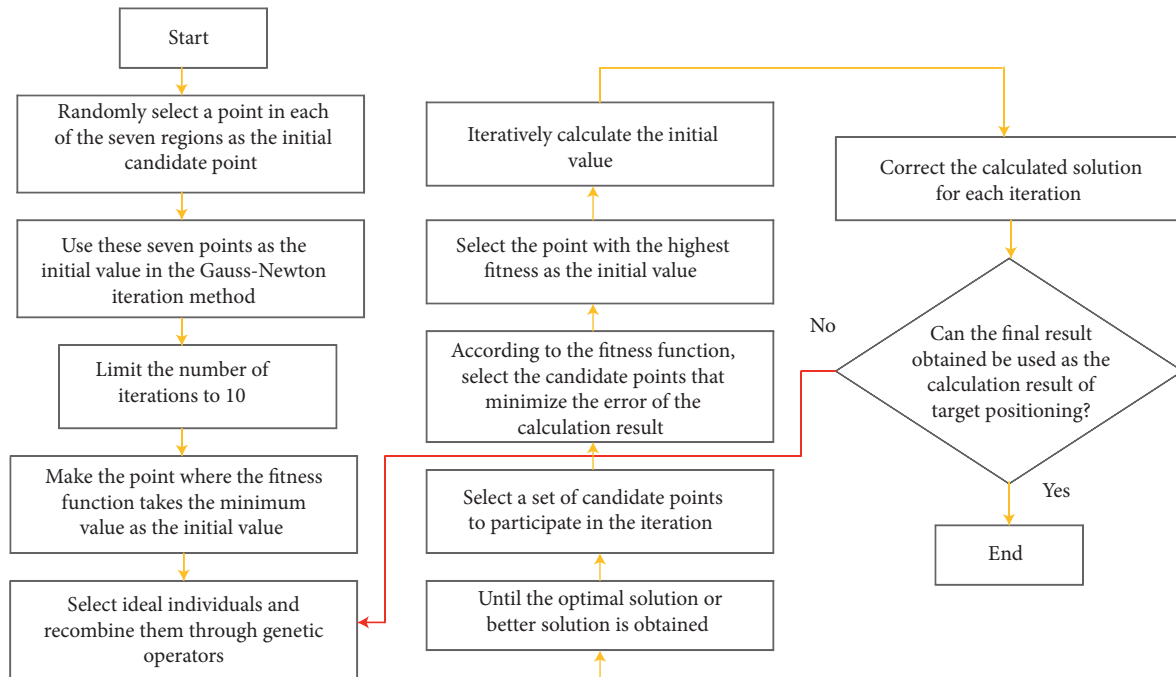

FIGURE 3: Flowchart of initial value selection.

FIGURE 4: Calculation results of the initial values of different artistic graphics.

Through experiments and analysis and summary, some regular trends of Newton iterative graph changes can be grasped, and Newton iterative graphs with special texture effects can be generated.

According to the definition of Newton's iteration and its computer visualization principle, it can be known that the type of iteration function has a decisive effect on the formation of Newton's iterative graph fractal art. The iterative function can choose trigonometric function, power function, exponential function, hyperbolic function, absolute value function, and so forth. Selecting different iterative functions can get  $N$  set graphics with different shapes. Among them, trigonometric functions are divided into sine, cosine, tangent, cotangent, and other trigonometric

functions and can also include the power exponent change of the trigonometric function. This article mainly chooses trigonometric functions, power functions, exponential functions, and hyperbolic functions as the iterative functions of Newtonian iterative graphs. The Newton iteration graphs generated by different iteration functions are shown in Figure 5.

In the same type of iterative function, changing the iterative mapping function means changing the numerator and denominator of the real and imaginary parts of the iterative formula, and the reconstructed Newton iterative graph will also have a kaleidoscopic structure. This article has proposed a variety of methods to reflect the texture of Newton's iterative graphs in the design. Among them, the

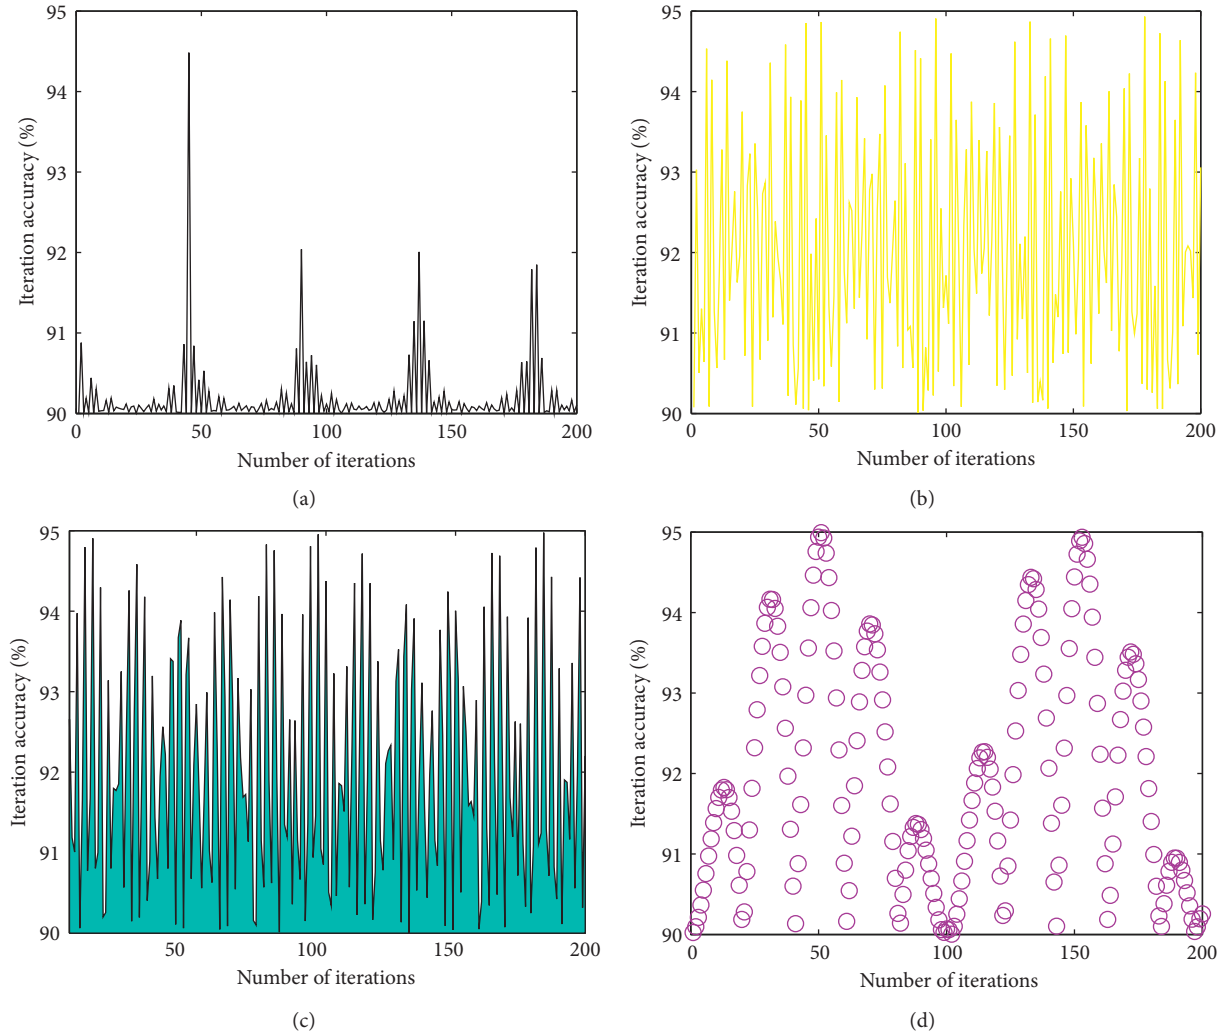

FIGURE 5: The accuracy of Newton iteration generated by different iteration functions. (a) Power function Newton iteration accuracy rate. (b) Trigonometric function Newton iteration accuracy rate. (c) Exponential function Newton iteration accuracy rate. (d) Hyperbolic function Newton iteration accuracy rate.

power function Newton's iterative graph and the trigonometric function Newton's iterative graph change greatly because of the change of the iterative function.

It is found through experiments that the power exponential Newton iteration graph and the trigonometric function Newton iteration graph are more sensitive to the changes of parameters, while the exponential function Newton iteration graph and the hyperbolic function Newton iteration graph have little adjustment to the graph structure caused by the change of the parameters.

*4.3. The Influence of Mathematical Morphology Image Processing Methods on Newton Iterative Graphs.* Through Matlab software, we have performed a variety of mathematical morphological processing on Newton's iterative graphs, including two operations, expansion and erosion. Figure 6 in this article is a sample of Newton's iterative graphics processed by mathematical morphology as fractal art graphics.

By comparison, it can be found that when the two structural elements of diamond and square are selected, the image effect after the corrosion operation is clearer, and the style of Newton's iterative graphics is more obvious. However, there are many block structures after image processing of structural elements, which will cause uneven tension in the warp and weft directions during design, which is not conducive to design.

*4.3.1. Selection of Structural Elements.* Choosing appropriate structural elements plays an important role in better expressing the special texture effects of Newton iterative graphics. Structural elements include spherical, linear, diamond, square, and disc. Through multiple experiments and comparisons, this article mainly uses two structural elements, diamond-shaped and square-shaped, in the experiment.

As shown in Figure 7, it is found through experiments that, with the increase of structural elements, Newton's

FIGURE 6: Comparison of Newton iteration graphs after corrosion calculation of different structural elements. (a) Original image. (b) Binary image after dither processing. (c) Corrosion of diamond structural element. (d) Corrosion of square structural element.

FIGURE 7: The Newton iteration graph after the expansion operation of the diamond structure element in different units. (a) Original image. (b) 1-unit diamond structural element expansion. (c) 2-unit diamond structural element expansion. (d) 3-unit diamond structural element expansion.

iterative graphics gradually turn from delicate to rough style, and their inherent texture effect gradually disappears.

**4.3.2. Application of Expansion Calculation.** The expansion operation is more suitable for nonscattered Newton iterative graphs. For scatter Newton iterative graphs, after the expansion operation processing, the scattered points will be combined with the scattered points of the attachment to become a block, and as the structural elements increase, the scattered points disappear quickly, and the unique texture effect also disappears.

**4.3.3. Application of Corrosion Calculation.** By comparison, it can be found that the erosion operation is more suitable for Newton iterative graphs of scatter points. When selecting the two structural elements of diamond and square, the image effect after the corrosion operation will be clearer than before, and the style of Newton's iterative graphics will be more obvious. With the increase of structural elements, the more blocky structures appear after image processing.

**4.4. The Influence of Fractal Art Graphic Organization and Fractal Art Graphic Density on Experimental Results.**

Traditional fractal art graphics are divided into flower parts and ground parts. Different colors are used to express in the weaving design, and the organization is corresponding; that is, one color corresponds to one organization. Newton iteration graphics are all composed of scattered points and thin lines, which determine that the flower parts are composed of scattered points and thin lines, and the rest are all ground parts, which need to be properly organized. In the experimental design of this paper, the same fractal art graphics are matched with 2–4 organizations, so that the warp and weft yarns of the fractal art graphics are more complex, the surface of the fractal art graphics reflects more details, and the texture is more complex and delicate.

The fractal art graphics used in this topic are inherently complex and delicate, which require delicate materials, better gloss, and the highest possible density of yarns. The density of cotton fractal art patterns can reach up to 70–85 pieces/cm, and the density of silk fractal art patterns can reach up to 190 pieces/cm. Therefore, it can be seen that real silk has a great advantage in reflecting the delicate structure of fractal art graphics. For this reason, we choose real silk as raw material, and we can also try to use cotton yarn, chenille, polyester, and other raw materials to obtain different style effects. The fractal accuracy rate of art graphics of the improved Newton iterative algorithm is shown in Figure 8.

FIGURE 8: The fractal accuracy of artistic graphics of the Newton iterative algorithm before and after the improvement.

## 5. Conclusion

This paper analyzes the basic principles of the Gauss-Newton iteration method and we found that the Gauss-Newton iteration method is greatly affected by the initial value of the iteration. If the initial value is not properly selected, the iteration may not converge to the wrong result. Conversely, selecting appropriate initial values can efficiently calculate accurate results and reduce positioning errors. A representative point is selected from the seven regions as the candidate initial value and substituted into the equation for iterative calculation. We use the value with the smallest error as the final calculation result. The method of selecting the initial value in the Gauss-Newton iteration method is optimized. We construct a new fractal art graphic design and form model based on Newton's iterative theory. Specifically, it includes changing various factors that affect the generation of Newton iterative graphs, continuously transforming the factors that affect the generation of Newton iterative graphs and summarizing the regularity of their changes. In order to find a special type of Newton iterative graphics, we design fractal art graphics and then select the appropriate organization to reflect the unique mechanism of Newton's iterative graphics. We use MATLAB to perform morphological transformation on the designed fractal art graphics to obtain the transformed fractal art graphics. We use this kind of fractal art graphics to design fractal art graphics with special texture effects with the help of weaving CAD and Jacquard design technology. Through factors such as the selection of fractal art graphic organization and the change of the size of the fractal art graphic cycle, we design fractal art graphic textures with different effects.

Smart city is a brand-new city form, in which information and communication technologies are utilized to sense, analyze, and integrate the key information of city operation core system, so that intelligent responses can be immediately and effectively taken to various demands including people's livelihood, environmental protection, public safety, city services, and industrial and commercial activities. Digital economy is a mixed economy with the coexistence of multiple business models and diversified value creation models based on the information and communication technologies and in the digital economy, many things are undergoing huge changes, and their corresponding economic rules also need to be adjusted. On the basis of analyzing previous research works, this paper expounded the research status and significance of smart city's resource scheduling and strategic management, elaborated the development background, current status, and future challenges of digital economy, introduced the methods and principles of city-level spatiotemporal data model and spatial full factor coding, formulated resource scheduling strategies for smart city based on digital economy, explored the dynamic fusion, storage, and update of smart city's multisource heterogeneous data, conducted the information display and analysis of multilevel smart city, proposed strategic management approaches for smart city based on digital economy, analyzed the integrated implementation model of shared resource scheduling and people-oriented social management, and discussed the economic growth factors and standardization mechanism of smart city under the background of digital economy. The results of this study provide a reference for further research studies on the resource scheduling and strategic management of smart city under the background of digital economy.

## 1. Introduction

Smart city is a brand new city form which builds a smart and intelligent environment to support the city development; it utilizes cutting-edge information technology methods, such as the Internet of Things, cloud computing, optical networks, and mobile Internet, to integrate the scattered and fragmented information systems in a city into an organic whole with better synergy and regulation capabilities, so as to intelligently respond to various needs of public services, social management, industrial operations, and other activities [1]. The essence of a smart city is to make use of advanced information technology to realize smart management and operation of the city, thereby creating a better life for people in the city and promoting the

harmonious and sustainable growth of the city [2]. The security of a smart city is a key indicator of its information-awareness layer. The analysis of city security characteristics is the basis for the construction of a smart city model, but this analysis model does not take into account factors such as the city environment, government services, and infrastructure. The construction of a new type of smart city includes four key elements of the open architecture of the Internet of Things, the city's open information platform, the city operation command center, and cyberspace security. The development of the concept of smart city and related applications can promote the realization of a consumption-driven economic development mode from the three aspects of increasing household consumption, corporate consumption, and government consumption [3]. In addition,

the information, the Internet of Things, and related industry development brought by the development of smart city can also promote industrial structure adjustment from the three aspects of coordinating the proportion of the three industries, improving industrial quality, and developing emerging industries and these three aspects reflect to varying degrees rationalization and advanced industrial structure [4].

Digital economy is a mixed economic system, in which information technology and computer technology are widely used. The use of information technology and computer technology has fundamentally changed the mode and situation of economic environment and economic activities [5]. The management system and multiple departments are indeed very important for the overall deployment and construction planning tasks of a smart city. In the digital economy, the transactions of management system usually have the characteristics of digitization, virtualization, concealment, and electronic payment in its multiple departments, which make it difficult to judge the consumption of trading venues and provide goods and services. In addition, the digital economy can provide better support for production, distribution, sales, and other goods and services, thereby creating a win-win environment for businesses and consumers [6]. The essence of the digital economy lies in informatization, which is a completely new social and political and economic system that fully digitizes information and business activities, including the development of information technology such as information technology, traditional industries, infrastructure, and social life [7]. The era of the digital economy is an era of globalized market competition, knowledge, and convergence and knowledge is spreading, accumulating, and updating more quickly due to the development of information technology and communication networks. The smart city is the main carrier of the development of the digital economy; digital economy is also the main feature of the development of the industrial economy of the smart city and the two are mutually reinforcing and mutually dependent relationships [8].

On the basis of analyzing previous research works, this paper expounded the research status and significance of smart city's resource scheduling and strategic management, elaborated the development background, current status, and future challenges of digital economy, introduced the methods and principles of city-level spatiotemporal data model and spatial full factor coding, formulated resource scheduling strategies for smart city based on digital economy, explored the dynamic fusion, storage, and update of smart city's multisource heterogeneous data, conducted the information display and analysis of multilevel smart city, proposed strategic management approaches for smart city based on digital economy, analyzed the integrated implementation model of shared resource scheduling and people-oriented social management, and discussed the economic growth factors and standardization mechanism of smart city under the background of digital economy. The detailed section arrangement is as follows: Section 2 introduces the methods and principles of city-level spatiotemporal data model and spatial full factor coding; Section 3 formulates resource scheduling strategies for smart city based on digital

economy; Section 4 proposes the strategic management approaches for smart city based on digital economy; Section 5 discusses the economic growth factors and standardization mechanism of smart city; Section 6 is conclusion.

## 2. Methods and Principles

*2.1. City-Level Comprehensive Spatiotemporal Data Model.* Due to the different dimensions of the indicators in the evaluation index system for digital economy development, the orders of magnitude differ greatly and they tend to increase [9]. Therefore, the initial data of the basic data is transformed into a comparable sequence and the calculation method is as follows:

$$P_{ij} = \frac{X_{ij}}{Y_{ij}}, \quad (1)$$

where  $P_{ij}$  is the data of the  $i$ -th index at the beginning of the  $j$ -th year;  $X_{ij}$  is the original data; and  $Y_{ij}$  is the value of the  $i$ -th index at the  $j$ -th year and the weight of each index is calculated as follows:

$$S_{ij} = -k \cdot \sum_{i,j=1}^n p_{ij} \ln p_{ij}, \quad i = 1, 2, \dots, n, \quad (2)$$

where  $k$  is the fractal coefficient of the digital economy;  $p_{ij}$  is the proportion of the value of the  $i$ -th index in the  $j$ -year value of the indicator; and  $S_{ij}$  is the information entropy of the  $i$ -th index in the  $j$ -th year.

According to the characteristics and basic structure of smart city, the intelligent system of city public facilities based on digital economy is designed and the model of building smart buildings can be expressed as

$$S_{ab} = \frac{\alpha(a_1 - b_2) + \beta(a_1 + b_2)}{S_a^\beta \cdot S_b^\alpha} + X_{ab} \cdot Y_{ab}, \quad (3)$$

where  $a_1$  and  $b_2$  are the factors of the digital economy system;  $\alpha$  is the feature space factor of the smart city;  $\beta$  is the dimension of the divergence matrix;  $S_a^\beta$  and  $S_b^\alpha$  are the inter-class divergence matrix and intra-class divergence matrix, respectively; and  $X_{ab}$  and  $Y_{ab}$  are the city dimension spatial data sample set and feature attribute points, respectively.

Constraint equations that use the digital economy to optimize city-level spatiotemporal data are

$$W(S_{ij}) = \begin{cases} w_1, & 0 < S_{ij} \leq h_1, \\ w_2, & d_1 < S_{ij} \leq h_2, \\ \vdots & \vdots \\ w_k, & h_{k-1} < S_{ij} \leq 1, \end{cases} \quad (4)$$

where  $W(S_{ij})$  is the constraint condition that the average dimension of the parameters of smart optimization system needs to meet;  $w_k$  is the interference caused by the digital economy background to city construction problems; and  $h_k$  is the global information feature vector of the smart city. So the city-level spatiotemporal comprehensive data model is calculated as

$$Q_x = P_{ij} \cdot W(S_{ij}) + \xi \cdot \frac{f(X_{ij}, Y_{ij}) \cdot S_{ab}}{\gamma \cdot (x_i + y_j)}, \quad (5)$$

where  $Q_x$  is the equipment mark of the digital economy;  $\xi$  is the correlation factor;  $f(x_{ij}, y_{ij})$  represents the regression basis function;  $x_i$  is the principle of minimizing the intelligent use of digital resources;  $y_j$  is the city optimization factor; and  $\gamma$  is the minimum value of the constraint.

**2.2. City-Level Spatial Full Factor Coding.** The digital economy's impact on the current tax system is comprehensive, involving multiple aspects of the impact on the elements of the tax system itself, the division of tax jurisdiction, and the impact on the current tax collection and management system [10]. When the digital economy shows extremely complex shapes, it cannot be expressed by simple mathematical expressions, but only approximate mathematical functions can be used to approximate the actual situation. According to its coding requirements for city spatial elements, its fitting function  $P(x_i, y_i, z_i)$  can be expressed as

$$P(x_i, y_i, z_i) = \sum_{i=1}^n S_i \left( \frac{x_i^2}{Q_x^2} \cdot \ln \frac{y_i^2}{Q_x^2} + \frac{z_i^2}{Q_x^2} \right). \quad (6)$$

In the formula,  $Q_x^2$  is the influence radius of discrete points;  $Q_x^2 = (x - x_i)^2 + (y - y_i)^2 + (z - z_i)^2$ ;  $x_i$ ,  $y_i$ , and  $z_i$  ( $i = 1, 2, \dots, n$ ) are the sampling data of discrete points on the digital system; and  $S_i$  is the undetermined coefficient, given by the information of the known points.

The city-level spatial all-elements group is updated synchronously; that is, after  $m$  elements complete their respective traversal searches, the digital information is updated and adjusted uniformly. If  $k_{ij}(n)$  is assumed as the information factor after the  $n$ th cycle, the following formula can be obtained:

$$k_{ij}(n) = (1 - \lambda)k_{ij}(n-1) + \sum_{i,j=1}^m \Delta k_{ij}^n, \quad (7)$$

where  $\lambda$  is the volatility coefficient of the total space factor,  $(1-\lambda)$  is the digital information, and it is also the pheromone residual factor, and  $\Delta k_{ij}^n$  is the digital increment of the  $k$ -th space full factor on the path in this cycle.

In order to calculate the coding time required for each spatial element of a smart city under different digital economic conditions, the execution matrix is defined as

$$H(i, j) = \begin{bmatrix} h_{11} & h_{12} & \cdots & h_{1m} \\ h_{21} & h_{22} & \cdots & h_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ h_{n1} & h_{n1} & \cdots & h_{nm} \end{bmatrix}, \quad (8)$$

where  $k_{ij}$  represents the encoding time required to represent the digital economic conditions  $h_i$  to process the full space elements  $h_j$ . If  $H(i, j)$  is assumed as the gradient value of the previous feature point, and  $J(i, j)$  is the gradient value of the

neighboring features centered on the current feature point, the gradient discrimination factor  $R(i, j)$  can be defined as

$$R(i, j) = \max\{|J(i, j)| - |H(i, j) \cdot J(i, j)|\}. \quad (9)$$

It can be known from the above formula that the gradient discrimination factor  $R(i, j)$  is the minimum value of the difference between the gradient modulus value of the current element and the  $n$  neighboring point modulus values in the digital economic model; then, the adaptive fractional order expression is defined as

$$A(i, j) = \begin{cases} \frac{J(i, j) - H(i, j)}{\max\{J(i, j)\} - \nu \cdot R(i, j)}, & R(i, j) \geq K, \\ 0, & R(i, j) < K. \end{cases} \quad (10)$$

In the formula,  $\nu$  is the adjustment coefficient of spatial full-element coding;  $\max\{G(i, j)\}$  is the maximum gradient of  $n$  feature points; and  $K$  is the threshold value selected according to different smart city models. When the required gradient value of the processed space and the gradient value of the surrounding elements change greatly, that is, when the gradient discrimination factor is greater than a given threshold value, it is considered that the encoding of the spatial full factor is successful.

### 3. Resource Scheduling of Smart City Based on Digital Economy

**3.1. Dynamic Fusion, Storage, and Update of Multisource Heterogeneous Data.** The spatial and temporal characteristics are the obvious characteristics of each element in the city. The information analysis of the smart city should straighten out the relationship between different elements, find similarities among them, and centrally process the information of all parties. The city-level spatiotemporal comprehensive data model can not only complete the establishment of a city-level spatiotemporal comprehensive data conceptual model from the perspectives of multiple dimensions, multiple temporalities, multiple dimensions, or even the four dimensions of multiple topics. The intangibility and mobility of the digital economy make the connection factors that determine tax jurisdiction disappear or become obscured, which brings challenges to the traditional standards for determining tax jurisdictions of residential places and source jurisdictions. In the application of comprehensive information, comprehensive analysis of multisource heterogeneous business, and integration sorting, processing and clarification of data are analyzed to determine the dwelling form of information collection and construction of judgment paths to provide multitopic information service. The framework of resource scheduling of smart city under the background of digital economy is shown in Figure 1. The information system design indeed needs to be continuously adjusted and updated as the environment changes. The digital economy mainly presents the economic process of manufacturing and supplying electronic products and services for commerce or trading activities caused by commerce. In this process, production and

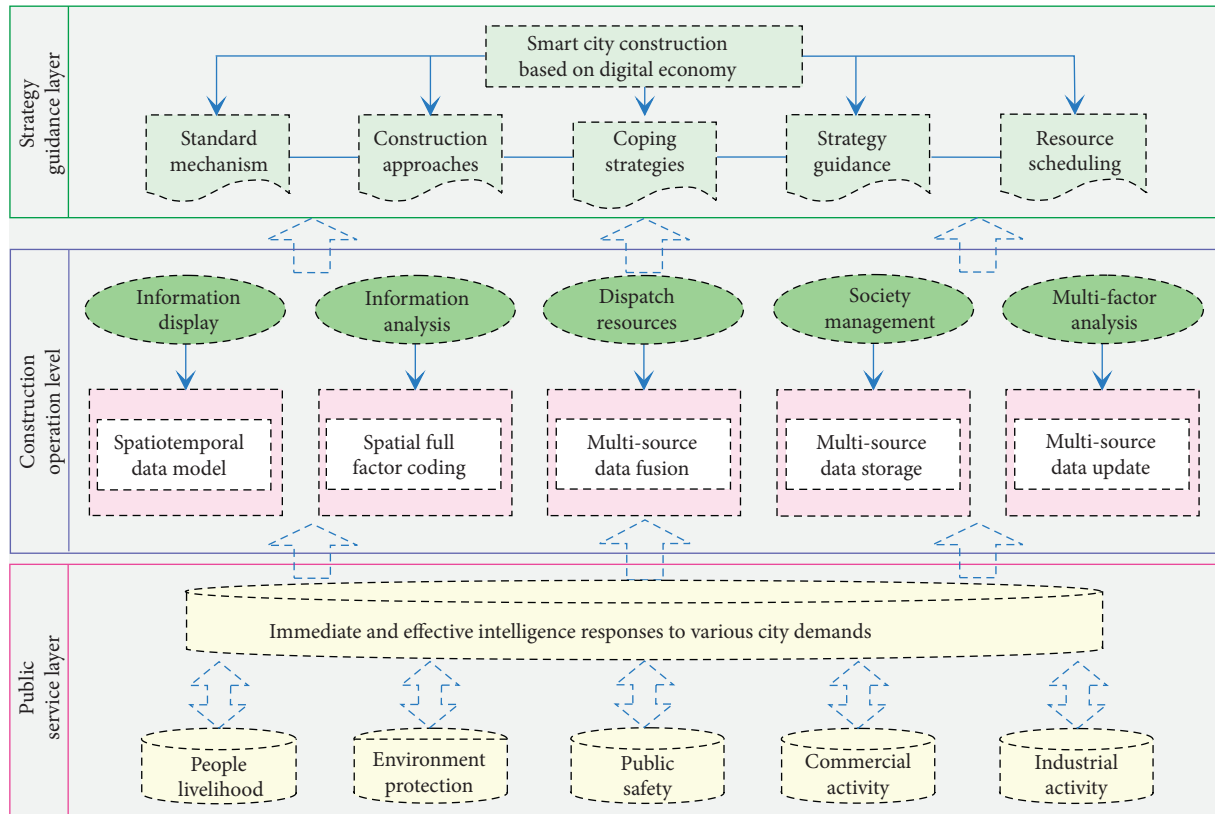

FIGURE 1: Framework of resource scheduling of smart city under the background of digital economy.

management are electronic as the environment changes, in which various suppliers and consumers and related activities are connected through the information analysis technology.

A smart city is of comprehensive structural design, technology integration, and three-dimensional services. Technical cooperation in the areas of city governance, city planning, industrial informatization, and architecture is required to achieve a high degree of integration, resource optimization, and highly interconnected technology and functions. At the same time, it is also a strategy for advancing smart city, which is different from the core of the previous informatization and digital cities. It also emphasizes the organic connectivity and functional realization of city households between different industries, internal industries, and other factors. Therefore, the coordination of the smart city industry has become a key path to accelerate the landing of the smart city industry. Most of the key projects in the areas of smart life, smart city management, and smart government affairs are invested and led by the government. The starting point is mainly from serving city management and administrative approval and there is a certain misalignment between project design, business services, and citizen demand. From supply to demand, the model is usually not timely, accurate, and comprehensive to meet the needs of citizens, and the government has not established an information-based active service mechanism for the needs of social entities. Smart city construction funds are mainly used in transportation, security, and other fields that have an important impact on city construction and management,

not at the community level, which is closely related to people's livelihood; social capital investment has not formed an effective business model [11].

In order to complete the overall deployment and construction planning tasks of a smart city, the management system must be first improved and multiple departments should be involved in the implementation of the planning and design process. Therefore, a dedicated smart city department must be established to form the smart city's affairs and materials. The management mechanism of talents and people is followed by effective planning and top-level design of a smart city to effectively adapt to modern development, and then the construction of a city performance evaluation system, to effectively ensure the healthy development of the city [12]. In order to enhance the driving force of smart city planning and design, it must actively implement innovation, rely on the latest science and technology to achieve effective docking with smart city, and ensure the source of power for smart city planning and design. The technological innovation environment must be first optimized and the public integrated process of the service platform then should be improved to guide the whole society to actively innovate and start businesses. The smart home function can be added, and city residents can centrally control the homes at home and they can also understand the price and quality of different home products in a unified interface. At the same time, they can set up corresponding merchant connection services to ensure that merchants can integrate the latest home products and push residents to build a contact platform for merchants and residents.

*3.2. Multilevel City Comprehensive Information Display and Analysis.* An information system cannot be successfully designed at one time, which is necessary to improve the design incompletely during operation and continuously adjust and update as the environment changes and the self-improving ability is the core of the system's vitality. The long-acting system is not a static system, but an adaptive system with a self-regulating improvement mechanism, and the project management mechanism is the key point. Choosing an appropriate management model is a guarantee for the long-term benefits of the project and projects that do not fully consider the management model are not feasible. The selectable management mode of the city's intelligent system which includes government, cause and non-profit organization and enterprise. The different management modes and mechanisms have their own advantages and should be selected according to the characteristics of the service business [6]. The key to the sustainability of an information sharing system is to establish a quality assurance mechanism for data resource providers. Innovative ideas need to be reflected through project optimization, and planning attention should be focused on policy design and project selection. Table 1 shows the rating system of smart city resource scheduling based on digital economy. The smart city is not expected to bring shortcuts to information construction and information is only a tool for city development and the benefits of the tools need to be matched with the environment. The transformation and reconstruction of the environment must not be abrupt, and the smart city cannot bring sudden changes; mentality does not always want to leapfrog development and there are many benefits achieved by reducing the scale of the project.

The core of a smart city is a smarter way to change the way governments, communities, or companies and people interact with each other through a new generation of information technology to improve the clarity, efficiency, flexibility, and responsiveness of interactions with basic characteristics of perception, interconnection, and intelligence. From a technical perspective, the basic structure of a smart city mainly includes the Internet of Things, data center, city management, and operation levels, which correspond to the smart city intelligent sensing network, information resource center, operation management application layer, and public service center. Figure 2 shows the relationship between encoding relative time and index system rating in the resource scheduling and strategic management of smart city. The core technologies of smart city include intelligent identification, mobile computing, cloud computing, and information fusion and the public information services usually refer to the process of implementing open and developing services for public information. It includes two levels of open services and development services, including information on public affairs management activities, as well as information related to public interests, public policies, and arrangements and implementation of public management systems. Under the strategic guidance of the top-level design, starting from the core function of public information service push, the innovation of the value supply of the platform and the business model is

achieved, driving the innovation of smart city form through the integration of multistakeholders.

The construction of a smart city is a complex and systematic project and building specific smart projects to meet the objective needs of the city is the basic principle for completing the construction. The existing city characteristic analysis models analyze different cities by using population, economic scale, traffic conditions, industrial strength, service industry strength, and innovation capacity as analysis factors. Among them, the population factor is calculated using the number of city populations; the economic scale is calculated using the regional gross domestic product; the traffic conditions are calculated using the turnover of goods or the turnover of tourists; the authorization calculation of industrial strength is calculated using the added value of the industry or the added value of the secondary industry. The analysis of city characteristics is the basis for the construction of a smart city model, but this analysis model does not take into account factors such as the city environment, government services, infrastructure, etc. The resulting analysis results may not meet the needs of actual work and there are certain limitations in a city which can be regarded as an organization, and a smart city is the result of the development of city informatization to a certain stage. To this end, the theoretical model applicable to the development of organizational informatization can theoretically also be used to build a smart city development path and city informatization. By analyzing the stage of each city's informatization, combined with the city's development goals and needs, it can better build the development path of smart city [13].

## **4. Strategic Management of Smart City Based on Digital Economy**

*4.1. Integrated Management of Sharing Scheduling City Resources.* Market demand is the driving force behind the sustainable development of smart city. The focus of smart city construction is to give play to the role of the market in allocating resources, to create various personalized smart applications that meet market needs through price, competition, and other factors, to foster a good state of emerging markets, and to promote new growth in the smart city economy. Technological innovation and the development of strategic emerging industries are important foundations for the construction of smart city. First of all, the construction of public service platforms must be strengthened in technology research and development, application testing, evaluation, and inspection, and the technological innovation environment also needs to be improved (Figure 3). The second is to promote the transformation of the dynamic mechanism of city development, improve the city industrial structure, and promote the emergence of new industrial forms with smart technological innovation. Finally, the key to strengthening technological research and development is to cultivate professional talents and make them the intellectual resources for smart city development. The construction process needs to make a reasonable top-level design based on the nature, characteristics, and functions of the city and establish a long-

TABLE 1: Rating system of smart city resource scheduling based on digital economy.

| Rating index system          | Smart foundation operation | Smart management services | Smart economy humanity | Smart integrated support |
|------------------------------|----------------------------|---------------------------|------------------------|--------------------------|
| Network connection level     | 0.836                      | 0.623                     | 0.735                  | 0.838                    |
| Service interaction platform | 0.783                      | 0.416                     | 0.511                  | 0.769                    |
| Technology infrastructure    | 0.804                      | 0.327                     | 0.850                  | 0.642                    |
| City marking technology      | 0.735                      | 0.020                     | 0.255                  | 0.523                    |
| Operation management         | 0.843                      | 0.134                     | 0.146                  | 0.114                    |
| Personal consumption         | 0.632                      | 0.463                     | 0.347                  | 0.745                    |
| Society environment          | 0.957                      | 0.032                     | 0.966                  | 0.758                    |
| Culture environment          | 0.362                      | 0.217                     | 0.675                  | 0.483                    |
| Government policy            | 0.235                      | 0.948                     | 0.107                  | 0.956                    |
| Business application         | 0.145                      | 0.566                     | 0.524                  | 0.046                    |
| Business environment         | 0.521                      | 0.211                     | 0.122                  | 0.919                    |
| Analysis function            | 0.165                      | 0.925                     | 0.694                  | 0.544                    |
| Cloud management             | 0.238                      | 0.866                     | 0.437                  | 0.312                    |

FIGURE 2: Relationship between encoding relative time and index system rating in the (a) resource scheduling and (b) strategic management of smart city based on digital economy.

term institutional guarantee. At present, the construction of smart city is mainly to give full play to advantages or solve shortcomings. Depending on the focus of city construction, the common goal is to identify obstacles to their own development; in some cities, the focus of construction is to give play to their advantages and promote economic development in a targeted manner.

A smart city is a complex large-scale system project, and its security problems will manifest in the system's information-awareness layer, access and transmission layer, application layer and terminal layer, intelligent processing, and collaborative platform layer. If sudden safety problems are encountered, the impact will involve the entire city, which may lead to factory shutdowns, store shutdowns,

electrical interruptions, traffic paralysis, water cuts, etc., which will have extremely serious consequences [14]. Therefore, they should be practically paid more attention to and dealt with and its heterogeneous interconnection, multihop, and distribution characteristics will make it more difficult to integrate and integrate its security system due to the use of a heterogeneous system platform. The different methods of equipment, storage, processing, and detection make information security, information transmission, and processing, which are also difficult to unify; the equipment is often in unattended, adaptive management, self-disconnection, and self-connecting states, which also increases the difficulty of designing and implementing security systems. Specifically, the integrity, authenticity, confidentiality,

FIGURE 3: Integrated and people-oriented strategic management of smart city based on digital economy.

availability, fault tolerance, and self-organizing ability of massive data collection should be guaranteed for the ubiquitous network sensing layer with self-organizing characteristics. For this reason, special attention should be paid to solving physical-level attacks for obtaining stored passwords and data, and to handle encryption, decryption, identity authentication and signature, and key security issues.

In the future, the data of smart city will be aggregated and dispersed and convergence means that public information platforms gather, extract, and analyze various heterogeneous and heterogeneous data. The dispersion means that data from vertical industries or different government agencies and enterprises will be separated due to their natural nature which may be distributed across different private and public cloud data centers. According to the city's budget and planning, the solution can be based on three key platforms: infrastructure platform, centralized management, and flexible scheduling of network resources, allowing more embedded infrastructure. The intelligent processing platforms can consolidate and improve service delivery, intelligent innovation platform, and modular service channels, including user self-service, social networking sites, application incubation, and service support call centers by identifying service priorities, expanding [15]. The key business capabilities of smart city should move closer to the trends of cloud computing and mobile and social networks. As cloud computing deployments and the number of users increase, vendors will inevitably transition to service providers or choose the right partners. The social networks can not only capture and analyze user data in real time, but also

provide important feedback mechanisms that the public can use socially software or feedback to the government and manufacturers on services and suggestions at any time through social media, promote the improvement of service quality, and create more business opportunities.

#### 4.2. Realization of People-Oriented Social Management Model.

The smart city is supported by spatiotemporal information and relies on modern information technologies such as the Internet of Things and cloud computing to materialize human knowledge into various activities such as city planning, design, construction, management, operation, and development under informative conditions. The industry sector proportion of digital economy in smart city construction is shown in Table 2. A smart city should include real-time information sensing devices like human senses, two-way transmission of information and instructions like human nervous systems, ubiquitous network systems, and cloud computing service centers like human brains, and response and human behavior organs. A smart city cannot be separated from the support of the geospatial framework [16]. The geospatial framework is the responsibility of the geographic information department of mapping, and it is also the infrastructure for city informatization. In the digital city phase, the main content of the geospatial framework is presented as a basic geographic information database and a public geographic information platform. With the development of the Internet of Things and cloud computing technologies, the basic geographic information database has become a spatiotemporal information database, and the

TABLE 2: Industry sector proportions of digital economy in smart city construction.

| Catering         | 0.365                         | 0.466               | 0.370               | 0.428            |
| Information      | 0.812                         | 0.354               | 0.421               | 0.397            |
| Communication    | 0.764                         | 0.265               | 0.304               | 0.143            |

public geographic information platform has become a spatiotemporal information cloud platform. In the smart city stage, the geospatial framework has spatiotemporal characteristics and has evolved into a spatiotemporal information framework. The core content includes a spatiotemporal information database and a spatiotemporal information cloud platform.

For information, it is mainly to use language, characters, numbers, symbols, and other media to form special symbols to represent the content and characteristics of objective things; for data, it is mainly the carrier of information. In building a smart city, different methods need to be used to collect information, organize information, and analyze information. There are many types of information, such as natural information, social information, humanistic information, geographic information, etc. The transformation of digital cities into smart city is an inevitable requirement for the development of digital cities and an important way for cities to realize informatization (Figure 4). In the construction of digital cities, a variety of information has been gathered to ensure the normal construction, planning, management, and operation of the city. When building a smart city, the results of digital cities should be fully used to apply the information and data of digital cities. In the construction of smart city, this will promote the construction of smart cities. The construction of a smart city is to better and more scientifically manage the city, so as to improve people's living standards and let people feel the results brought by the smart city. Therefore, when building a smart city, the management decision-making platform should be optimized and improved on the basis of a digital city, so as to promote the application of smart city in transportation, medical treatment, and public safety spatial geographic information [17].

The smart city will multiply the city economy to some extent. Firstly, the research and development, manufacturing, and application of the Internet of Things, the Internet, supercomputers, and data processing and computing technologies and these high-tech capital-intensive industries will become new engines of economic growth and industrial upgrading and will generate a wide range, large markets, smart industrial chain, and industrial clusters with long chains and multiple connections. Secondly, while promoting the upgrading of city operating systems, a smart city will also make the wealth creation activities based on city

operating systems more convenient and efficient. A smart city is a product of the combination of a virtual economy and a real economy, and it will bring profound changes to city development. The construction of a smart city, through the widespread application of smart technologies, can increase the contribution of knowledge, technology, and information resources to economic growth. It can not only save material resources, reduce resource and energy consumption, reduce environmental pollution, and improve resource allocation efficiency, but also promote the transformation of economic development from labor-intensive and capital-intensive to knowledge-intensive and technology-intensive and accelerate the optimization and adjustment of economic structure. As a result of transformation and upgrading, some intelligent industrial chain and industrial groups with a wide range, large market, long chain, and many connected have been born; economic development is more intelligent, which in turn enhances the city's innovation and competitiveness.

## 5. Discussion

*5.1. Multifactor Analysis of Economic Growth in the Context of Smart City Construction.* The foundation of a smart city is a digital city, which can innovate in a measurable and visualized management and operation form of the digital city and create a networked comprehensive city decision-making and city management platform in the city's data and information infrastructure. The wireless network and the data network constitute a wireless sensor network, which is data-centric and designed for a certain requirement. The wireless sensor network refers to the realization of real-time monitoring of each node based on the wireless network for a certain characteristic application and can collect the information of the detection object and the environment information in the network and then process it to pass it to the user in more detail and comprehensive information (Figure 5). The network must have the ability to autonomously organize and reconfigure; when a node in the layout fails due to changes in the environment, the network topology changes over time. Therefore, the network is required to have the function of maintaining dynamic routing. Failures can occur due to node failure. Intelligent transportation systems can improve the efficiency of transportation systems, realize intelligent, networked, information and integrated transportation systems, and intelligently collect traffic flow, information, noise, and traffic accidents. The

FIGURE 5: Multifactor analysis of economic growth in the context of smart city construction.

environments can communicate with each other to improve the safety and economy of the transportation system.

The intelligent applications will facilitate the management of the city and the life of citizens, while also collecting extensive user information, which will become the basis for planning, resource deployment, research, and analysis by government and other decision-making agencies. In the field of a smart city, data has a very important status, including geospatial data, industry data, census data, sensor monitoring data, etc., which are the basis of smart city construction [18]. The market demand is analyzed from infrastructure of enterprises, electronic business, electronic commerce, and computer network. The technological innovation environment of market demand must be first optimized and the public integrated process of the service platform then should be improved to guide the whole society to actively innovate and start businesses. The proposal of the integration of cities and industries is an inevitable requirement for responding to the transformation of industrial functions and the improvement of comprehensive city functions. It also reflects the trend of city planning from functionalism to humanism. From the focus on functional zoning and industrial structure, the focus is on integration and development and also is on people's initiative and the transformation of innovation and development. The smart cities emphasize the high degree of integration of industrialization and informationization and rely on the development of highly developed information infrastructure to create conditions for the extensive interconnection and

interconnection of city big data. The digital economy will build a smart park into a comprehensive high-tech park that integrates technology research and development, public platforms, demonstrations, system integration, and consulting services. With the help of geographic information technology, the citizen information terminal integrates city management information and establishes a precise, efficient, comprehensive, and visual city management model.

The smart city construction is a systematic project that requires a large amount of funds to support it. Therefore, it is necessary to broaden the financing channels, especially to promote the participation of social capital. The government should accurately convey the value information of smart city construction and, for social capital investors, then accelerate the financing of smart city construction through energy-saving bonds, green bonds, etc. (Figure 6). This is a feasible strategy to promote the development and development of smart city. Information and communication are two key technologies in the construction of smart city, so they cannot be measured according to a specific technical term. Instead, they should be judged based on value functions. For example, in the process of clarifying water standards, network speed and coverage of the scope, penetration rate, timeline, etc. are clearly defined so as to better meet the needs of functional parameters in the construction of smart city under clear technical standards to achieve convergence with the development of future cities [9]. In addition, the smart city construction is a systematic project, so during the construction process, a management system that can be used

FIGURE 6: Realization of people-oriented social management model based on digital economy.

by decision-makers to judge success or failure should be established first, so as to continuously evaluate the plan progress, and it should also provide a certain early warning function, so as to ensure the steady progress of smart city construction.

### 5.2. Standardization Construction Mechanism of Smart City.

The competition for smart city development includes competition for industries, markets, talents, and investment and development opportunities; and the development has the corresponding effect, and resources will quickly gather to the core. When a place is successful, it will close the possibility of neighboring cities to follow the same road and an area cannot form two centers with the same characteristics. The success of regional development strategies is often not entirely determined by their own wishes and the development strategies of surrounding cities will affect the implementation of established strategies. The behavior of other regions is unpredictable and these uncertainties make static city planning extremely risky. At present, the emergence of industrial development plans in cities will inevitably greatly reduce the success rate of the plans. Because city information industry development planning is the field with the highest isomorphism, localities generally lack ideas and innovations in planning software, service outsourcing, digital content industry, Internet industry, and Internet of Things industry. The generation of isomorphic planning is based solely on the results of digital analysis and the same trend data can only lead to the same recommendations. The information industry planning is a risk decision in the face of uncertainty (Figure 7). The engineering logic cannot give innovative power, which suggests that the regional industrial planning must be independent and take risks [19].

The information service providers in the middle of the industry chain mainly include various information technology companies and network operation providers. The information service providers include software and application development, information integration and transmission, large-scale data processing, and cloud computing. The network operation provider is mainly responsible for project investment, construction, and operation and then resells or leases it to the government to provide basic communication and broadband network operation functions. The operation and service providers are important links in the industrial chain and midstream smart city construction system integrators present a trend. They have begun to move from the field of smart applications to the top-level design of smart city and from small integration of some applications to large integration of smart city construction, trying to establish standards and seize the right to operate a smart city (Figure 8). The industrial chain for the construction of a smart city contains all the content for the development of a smart economy industry and becomes an operating platform to realize data monetization. The key to smart economy is the development and integration of the smart city construction industry chain and the key to the latter lies in the coordinated and innovative development of the industry. Through the penetration, crossover, and reorganization of information, technology, talents, funds, and other resources, the entire wisdom is reconstructed. The industrial chain of city construction and even the city system promotes the development of smart industries and forms a smart economy.

The smart cities are digitally networked, intelligent, interactive, and synergistic at the technical level and they are especially demanding for the level of interconnection and interoperability of various city systems, at the social, economic, cultural, and educational levels. This emphasizes people-centered sustainable innovation and focuses on the collaborative sharing of a knowledge-based society, which involves a wide range of aspects, which determines that the construction of a smart city urgently requires the comprehensive use of various information technologies and products, as well as the innovation of business operations and public service models [20]. Therefore, the best order function of standard formulation can be used to solve problems such as data fusion and sharing in the construction of smart city, and the use and reuse of standardized activities to build, innovate, and promote related models of smart city construction. The mechanism between the two relationships can be developed from the following aspects and the construction of a smart city is a new thing, and it is necessary to constantly explore and accumulate experience in the construction. Among them, the promotion of replication and demonstration pilots is an effective way. In this process, standardization can transform the valuable and fully available results of the pilot into standard specifications in a timely manner, form a standardized working model for smart city construction, and promote the demonstration pilots to be carried out in a wider and deeper field.

## 6. Conclusions

This paper formulated resource scheduling strategies for a smart city based on digital economy, explored the dynamic fusion, storage, and update of a smart city’s multisource heterogeneous data, conducted the information display and analysis of multilevel smart city, proposed strategic management approaches for a smart city based on digital economy, analyzed the integrated implementation model of shared resource scheduling and people-oriented social management, and discussed the economic growth factors and standardization mechanism of a smart city under the background of digital economy. In the digital economy,

digital networks and communication technology facilities provide a global platform for individuals and organizations around the world to achieve mutual communication, communication, and cooperation. In the digital economy, transactions usually have the characteristics of digitization, virtualization, concealment, and electronic payment, which make it difficult to judge the consumption of trading venues and provide goods and services. The focus of smart city construction is to give play to the role of the market in allocating resources, to create various personalized smart applications that meet market needs through price, competition, and other factors, to foster a good state of emerging markets, and to promote new growth in the smart city

economy. The core of a smart city is a smarter way to change the way governments, communities, or companies and people interact with each other through a new generation of information technology to improve the clarity, efficiency, flexibility, and response speed of interactions and the characteristics are perception, interconnection, and intelligence. The results of this study provide a reference for further researches on the resource scheduling and strategic management of a smart city under the background of digital economy.

In the article titled “Explosion Resistance of Three-Dimensional Mesoscopic Model of Complex Closed-Cell Aluminum Foam Sandwich Structure Based on Random Generation Algorithm” [1], there was an error in

Figures 1(c) and 2 due to the incorrect version of the code being used. The authors confirm that this does not affect the results and conclusions of the article, and the corrected Figures 1(c) and 2 are as follows:

FIGURE 1: The real structure and numerical simulation structure of aluminum foam.

FIGURE 2: Comparison of different sections of the model with the real structure.

The complexity of language is usually reflected in the complexity of sentences. At present, the research of sentence complexity mainly focuses on the analysis of syntactic complexity. In this paper, from the perspective of Leech's theory of sentence semantic structure, the predication structure is taken as the semantic unit to explore the sentence semantic complexity. The predication structures are extracted based on the result of sentence-based syntactic analysis, and then the linear expression sequence of a sentence is converted into a semantic hierarchy based on predicate semantic frameworks; the universality of predicate semantic frameworks is obtained by using the spectral clustering algorithm; and the sentence semantic complexity depends on the universality of predicate semantic frameworks at various layers. The experimental results show that the measurement method of sentence semantic complexity based on predicate semantic frameworks is more effective by comparing with the method that only considers the semantic categories of words in the sentence.

## 1. Introduction

Language complexity refers to a property or quality of a phenomenon or entity in terms of (1) the number and the nature of the discrete components that the entity consists of and (2) the number and the nature of the relationships between the constituent components [1]. The complexity of language is embodied in vocabulary, pronunciation, grammar, and other subsystems. Among them, each plane subsystem (syntax, semantics, and pragmatics) within the grammar subsystem also has complexity [2]. This paper will focus on the semantic complexity, especially the measurement of sentence semantic complexity.

According to Leech's theory of sentence semantic structure, the predication structure is the main semantic unit of a sentence [3]. A predication structure can be divided into arguments and the predicate connecting arguments. Among them, the predicate is the main component of the predication structure, which determines the number and nature of arguments. Moreover, there are subordinate predication structures and degraded predication structures, and the difference between them lies in their different layers and

positions in sentences [4]. Yushu Hu pointed out the sentence semantics should not be sought from the lexical semantics in the sentence, but from the form or structure of the sentence. "Only by structural analysis can we summarize the common semantics from the same structures, and only by structural analysis can we find different semantics in different structures" [5].

According to the existing theory and analysis method of sentence semantic structure, this paper starts from the sentence structure and converts the linear expression sequence of the sentence into semantic hierarchy based on the results of sentence-based syntactic analysis. That is, the predication structure is used as the analysis unit. The predication structures of a sentence that need to be expressed preferentially are selected as the important parts, and the unimportant predication structures are selected as the additional components. The predication structures are arranged in layers according to the direct or indirect relationship between the various sentence components. Secondly, combined with the definition of words in HowNet [6], the arguments of the predication structures are further abstracted and generalized to obtain predicate semantic

frameworks (PSFs). In this way, the linear expression sequence of a sentence is converted into a semantic hierarchy, and the sentence semantic complexity is converted into the complexity of PSFs which are measured by the universality of PSFs. Spectral clustering is used to cluster the PSFs of a predicate, and the universality of PSFs in a large class is relatively higher. Finally, the sentence semantic universality depends on the universality of PSFs at each layer, and different weights are given to PSFs at different layers. The sentence semantic universality reflects the sentence semantic complexity. The sentences with high semantic universality are frequently used and the learning order is in the front. Sentences with low semantic universality make it difficult for learners to learn and understand [7, 8]. That is, the higher the sentence semantic universality is, the lower the sentence semantic complexity is.

The main innovations of this paper are as follows: one is to propose a measurement method of the universality of PSFs based on the predication structure, so as to obtain the universality of different PSFs of a predicate; the second is to propose an assessment method of sentence semantic universality based on PSFs, and the sentence semantic complexity is reflected by the sentence semantic universality.

## 2. Related works

At present, sentence complexity is mainly analyzed from structure and syntax. In [9], it is considered that two kinds of commonly used operations to complicate the content of clauses are parallel compound structure and nesting clause structure. Among them, the parallel compound structure takes the total number of commas and parallel conjunctions appearing in clauses as the quantitative estimation basis for difficulty, and the nesting clause structure takes the number of core verbs appearing in clauses as the estimation basis for difficulty. The mean of the difficulty estimation value of all clauses is taken as the difficulty estimation value of the sentence. In [10], a linear comprehensive evaluation model is used to calculate the complexity of Chinese structure. The indicators used in the model include the total number of clauses, the number of embedded or subordinate clauses in clauses, and the ratio of the word number to the clause number.

In addition, in the field of second language teaching, syntactic complexity is mainly used to measure the syntactic usage of learners' language output, which is an important indicator of learners' language level and language development trajectory. L2SCA is a syntactic complexity analysis tool for English second language, which covers 14 indicators including 5 dimensions of syntactic length, dependency, collocation, phrase complexity, and sentence overall complexity [11, 12]. Paper [13] also selects 14 measurement indicators from three categories and five subcategories for the syntactic complexity of Chinese as a second language, namely, the number of characters, words, syntactic components, phrases, clauses, consortiums, partial relations, complement structures, conjunctions, disjunctions, disposals, and passive, existential, and relative clauses in a basic unit. Papers [14–19] also study sentence complexity, and

researchers try to use various quantitative indicators to quantify sentence complexity.

Most of the existing researches on syntactic complexity focus on the analysis of sentence structure and formal features. Biber believes that simply considering sentence complexity from the perspective of structure does not really reflect its essence [20]. Ortega also believes that the semantic, function, and communicative value of sentence complexity should be analyzed and studied [21]. In addition, according to Bulté and Alex Housen, the complexity of language learning cognition consists of at least three parts: proposition complexity, discourse interaction complexity, and language complexity [1]. Among them, proposition refers to the semantics expressed in the text, not just the statement itself. The semantic structure of a proposition can be expressed as a “predication structure.” Proposition complexity is a relatively new concept, which has received far less attention than language complexity [22, 23].

Therefore, this paper attempts to analyze the sentence semantic complexity based on the basic proposition. In Section 3, the extraction of predication structures, the acquisition of PSFs, and the calculation method of the universality of PSFs are introduced. In Section 4, the calculation method of sentence semantic universality is introduced. The experimental results are introduced and analyzed in Section 5. Finally, the conclusion and limitations of this study are discussed in Section 6.

## 3. Universality of PSFs

The calculation method of the universality of PSFs is shown in Figure 1. Based on the results of sentence-based syntactic analysis, the predication structures are extracted layer by layer, and the PSFs are obtained by combining the definition of words in HowNet. All the PSFs of a predicate are clustered to get the universality of the PSFs. In addition, it is necessary to calculate the similarity of PSFs through lexical similarity and sememe similarity in order to cluster PSFs.

*3.1. Extraction of Predication Structures.* The extraction of predication structures is based on the result of syntactic analysis in the sentence-based treebank [24, 25]. The analysis and annotation of sentences in the sentence-based treebank are in the form of visual diagram, as shown in Figure 2. The horizontal line is the benchmark to observe the sentence layer. The subject, predicate, object, attribute, adverbial, complement, and other sentence components attached to the same horizontal line belong to the same layer. The subject, predicate, and object are located above the line, which are the “main components” of the sentence pattern; the attribute, adverbial, and complement are located below the line, which are the “additional components” of the sentence pattern; for the complex additional components, the syntactic analysis goes deep layer by layer. The annotation results are stored in XML form. The diagram and XML can be transformed in both directions.

Based on the results of sentence-based syntactic analysis, the long horizontal line with predicate component is taken

FIGURE 1: The calculation method of the universality of PSFs.

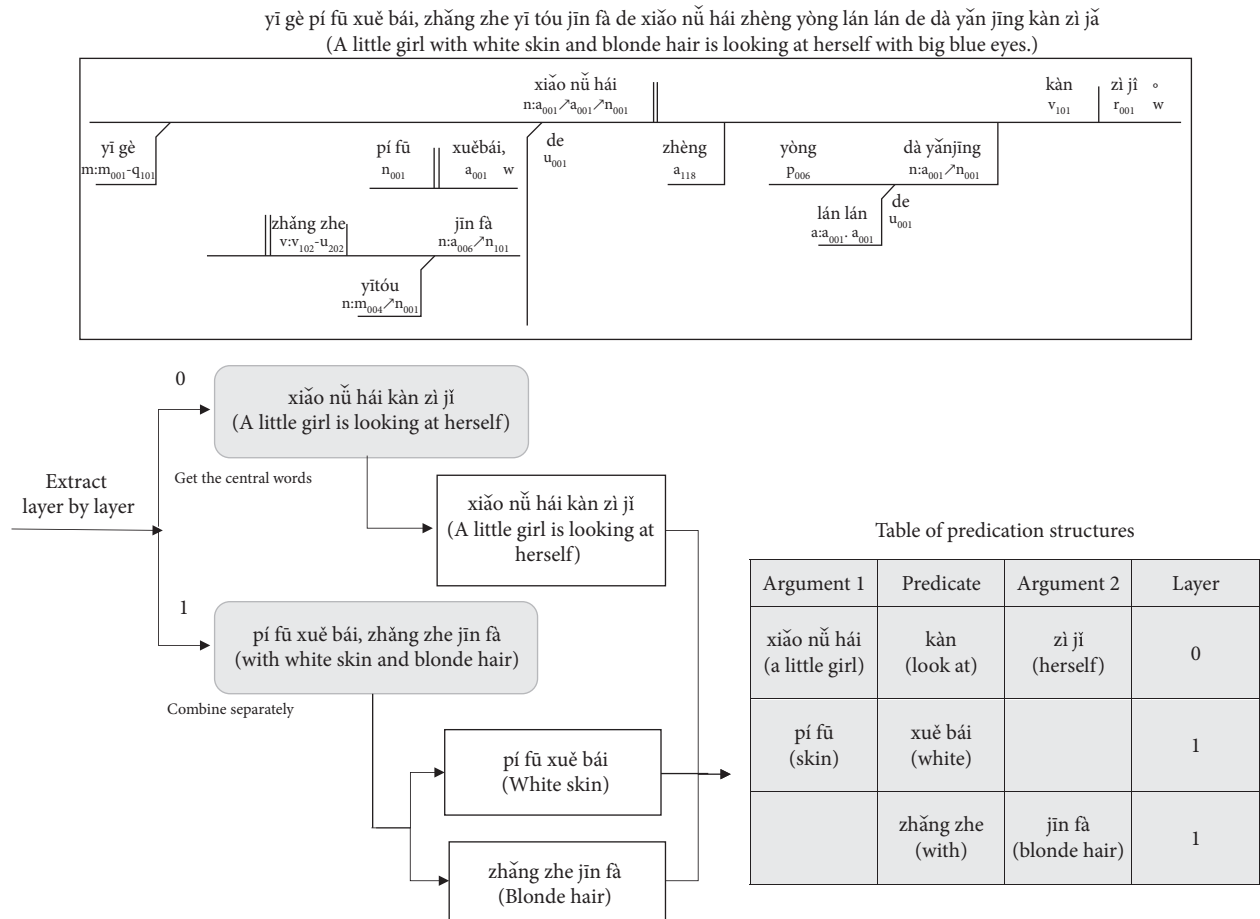

FIGURE 2: The extraction of predication structures.

as the baseline to extract the central word sequence directly related to the predicate. After the central word sequence of each layer is obtained, the predication structures are obtained by splitting and combining multiple predicates, and the process is shown in Figure 2.

It is possible that there are juxtaposed components in the subject or object. At this time, each component needs to be combined with core predicate separately. For example, in the sentence “yán sè, yàng zi dōu bǐ gāng cái kàn de qí páo hǎo (The color and style are better than those of the cheongsam I saw just now),” the subject includes juxtaposition, namely, “yán sè (color)” and “yàng zi (style).” The

predication structures of layer 0 are “yán sè hǎo (The color is good)” and “yàng zi hǎo (The style is good).”

The sentences with multiple predicates need to be split. Table 1 lists the split methods of the compound predicates, joint predicates, linked predicates, and pivotal sentence.

Considering the complexity of Chinese language, sentence components not only are acted by words, but also may contain a new predication structure, which is directly identified by the “VP.” For example, in the predication structure at layer 0 of the sentence “lì shǐ yǐ jīng zhèng míng tā zhǔ zhāng huáng quán shì cuò de (The history has proved that he is wrong in claiming imperial power),” “zhèng

TABLE 1: The split methods of multipredicates.

| Type                | Sentence  | Split results                             |
|---------------------|---|---|
| Compound predicates | wǐ shì fú nǐ le(I follow you!)                              | wǐ  shì<br>wǐ  fú  nǐ                     |
| Joint predicates    | mǔ qīn qiú shén bài fó(Mother prays for God and Buddha)     | mǔ qīn   qiú  shén<br>mǔ qīn    bài fó    |
| Linked predicates   | tā zhuā zhù wǐ de shǒu bù fàng (He held my hand)            | tā    zhuā zhù   shǒu<br>tā     bù   fàng |
| Pivotal sentence    | wǐ qǐng nǐ chī zhōng cān (I invite you to eat Chinese food) | wǐ    qǐng   nǐ<br>nǐ    chī   zhōng cān  |

míng(proof)” is the predicate and “lǐ shǐ(history)” and “VP” are arguments.

3.2. *Acquisition of PSFs.* Based on HowNet, the predicate structures are transformed into the PSFs. HowNet is a common sense knowledge base, which takes the concepts represented by Chinese and English words as the description object, and reveals the relationship between concepts and their attributes. HowNet defines a word as follows:

$$\textcircled{1} \text{wǐ:}\{\text{human}|\text{rén:PersonPro} = \{\text{1stPerson}|\text{wǐ}\}\}$$

$$\textcircled{2} \text{wǐ:}\{\text{specific}|\text{tè dìng:PersonPro} = \{\text{1stPerson}|\text{wǐ}\}\}$$

The first sememe in the definition of a word is the basic sememe, which points out the most basic meaning of the concept, such as “wǐ” referring to “human” or “specific.” The colon is followed by a detailed explanation of the basic sememe.

Combined with the semantic definition of words in HowNet [6], the PSFs can be obtained by abstracting and generalizing the arguments of predication structures, as shown in Table 2. Each word only takes the first basic sememe of each definition. Since it is impossible to know the exact semantics of each argument, if a word has multiple definitions in HowNet, all definitions in HowNet will be listed here for use in subsequent steps. If the word is not defined in HowNet, the word is used directly.

3.3. *Sememe Similarity.* Sememe similarity is the basis of calculating lexical similarity. Sememe similarity can be obtained by calculating sememe distance [26]. The most classical calculation method is as follows:

$$\text{sim}(s_1, s_2) = \frac{\alpha}{\text{dis}(s_1, s_2) + \alpha} \quad (1)$$

$\text{dis}(s_1, s_2)$  is the distance between  $s_1$  and  $s_2$  in the sememe tree. If  $s_1$  and  $s_2$  are in the same tree, the distance is the sum of the path lengths from  $s_1$  and  $s_2$  to their minimum common sememe. If  $s_1$  and  $s_2$  are not in the same tree, the distance will take a maximum of 20;  $\alpha$  is an adjustable parameter.

In the above calculation method, the weight of all paths is set to 1, but in HowNet, the difference between the top classes is large; the difference between the bottom classes is small. In view of this situation, [27] not only considers the depth of sememe tree, but also considers the regional density

TABLE 2: PSFs.

| Argument 1        | Predicate       | Argument 2  | Layer |
|-------------------|-----------------|---|-------|
| {human <br>rén}   | kàn(look at)    | {human rén}<br>{inanimate  wú shēng wù}<br>{self  jǐ} | 0     |
| {part bù<br>jiàn} | xuě bái(white)  |   | 1     |
|                   | zhǎng zhe(with) | {AppearanceValue <br>wài guān zhí}<br>{part bù jiàn}  | 1     |

of sememe tree. The calculation method of sememe similarity is as follows:

$$\text{sim}(s_1, s_2) = \frac{\alpha}{d + \alpha},$$

$$d = \delta \cdot \frac{\text{dis}(s_1, s_2)}{\text{con}(s_1) + \text{con}(s_2)},$$

$$\text{con}(s_1) = \gamma \text{deep}(s_1) + \eta \text{desity}(s_1) (\gamma < \eta \text{ and } \gamma + \eta = 1),$$

$$\text{desity}(s_1) = \frac{nc(s_1)}{\beta},$$

(2)

where  $\text{dis}(s_1, s_2)$  is the distance between  $s_1$  and  $s_2$  in the sememe tree.  $\text{deep}(s_1)$  is the depth of  $s_1$  in the sememe tree, that is, the path length from the root node to the sememe  $s_1$ .  $nc(s_1)$  is the sibling node number of  $s_1$ . The parameters are set as follows:  $\alpha = 1.6, \beta = 50, \gamma = 0.3, \eta = 0.7, \delta = 3$ .

3.4. *Similarity of PSFs.* There may be  $n$  parts (arguments) in a PSF. For two different semantic frameworks of a predicate ( $F_1$  and  $F_2$ ), if  $n$  is different, the possibility of similarity is small, and the similarity of the two PSFs is taken as 0. If  $n$  is the same, each framework has  $\text{ar}_1, \text{ar}_2, \dots, \text{ar}_n$  parts (arguments), and  $\text{sim}(F_1, F_2)$  is determined by the similarity of each part.

$$\begin{aligned} \text{sim}(F_1, F_2) &= \alpha_{\text{ar}_1} * \text{Sim}_{\text{ar}_1}(W_{F_1,1}, W_{F_2,1}) + \alpha_{\text{ar}_2} \\ &* \text{Sim}_{\text{ar}_2}(W_{F_1,2}, W_{F_2,2}) + \dots + \alpha_{\text{ar}_n} \\ &* \text{Sim}_{\text{ar}_n}(W_{F_1,n}, W_{F_2,n}). \end{aligned} \quad (3)$$

$\alpha_{ar1}, \alpha_{ar2}, \dots, \alpha_{arn}$  are the adjustable parameters, namely, the weight of each part, and  $\alpha_{ar1} + \alpha_{ar2} + \dots + \alpha_{arn} = 1$ . If  $W_{F_1,k}$  has  $m$  definitions in HowNet:  $S_{11}, S_{12}, \dots, S_{1m}$  and  $W_{F_2,k}$  has  $l$  definitions in HowNet:  $S_{21}, S_{22}, \dots, S_{2l}$ ,  $\text{sim}(W_{F_1,k}, W_{F_2,k})$  is the maximum value of similarity between definitions:

$$\text{sim}(W_{F_1,k}, W_{F_2,k}) = \max_{i=1\dots m, j=1\dots l} (\text{sim}(S_{1i}, S_{2j})). \quad (4)$$

For each part of a PSF, the first basic sememe of each definition is obtained from HowNet, so the similarity between definitions is the similarity between sememes.

The subject is the person or thing to be described in a sentence. It is the statement object of the predicate. The predicate and the object are generally combined to describe the subject. In view of the closer relationship between the predicate and the object, the parameters are set as follows:

- predicate + object + object(VOO) structure:  $\alpha_{ar1} = 0.5$ ,  
 $\alpha_{ar2} = 0.5$   
 subject + predicate + object(SVO) structure:  $\alpha_{ar1} = 0.2$ ,  
 $\alpha_{ar2} = 0.8$   
 subject + predicate + object + object(SVOO) structure:  
 $\alpha_{ar1} = 0.2, \alpha_{ar2} = 0.4, \alpha_{ar3} = 0.4$

**3.5. Clustering of PSFs.** The similarity matrix of PSFs is obtained by calculating the similarity between the semantic frameworks of each predicate. The method of spectral clustering is used to cluster the semantic frameworks of each predicate, and PSFs in large classes have a high universality.

Spectral clustering is a kind of clustering method based on graph theory [28–30]. All data vertices  $V = \{v_1, v_2, \dots, v_n\}$  form undirected weighted graph  $G(V, E)$ . Vertices can be connected by edges, and the weight  $w_{ij}$  on each edge represents the relationship between  $v_i$  and  $v_j$ . Because  $G$  is an undirected graph, the weight on the edges is independent of the direction of the two points,  $w_{ij} = w_{ji}$ . The matrix composed of the weights between any two points is the adjacency matrix  $W$  of a graph. For any point  $v_i$  in a graph, its degree  $d_i$  is defined as the sum of the weights of all the edges connected with it, that is,  $d_i = \sum_{j=1}^n w_{ij}$ . The degree matrix can be expressed as  $D$ .  $D$  is a diagonal matrix whose value is the degree of each vertex.

Each semantic framework of each predicate can be regarded as a vertex in graph  $G$ . The relationship between the semantic frameworks of each predicate is represented by the adjacency matrix  $W$ , that is, the PSFs similarity matrix of a predicate. Clustering is to cut the graph  $G$  into  $k$  subgraphs, so that the sum of edge weights between different subgraphs is as low as possible, while the sum of edge weights within subgraphs is as high as possible, as shown in Figure 3. The number of vertices contained in each subgraph is the universality of this kind of PSF  $u_i$ .

## 4. Sentence Semantic Universality

According to Levy, there are two different ways to understand sentences: one is based on memory; the other is based on expectation. Because of the need to complete the timely

FIGURE 3: Clustering of PSFs.

storage, synthesis, and extraction of input information, it is difficult to understand based on memory [31]. The text that meets reading expectation is relatively easy to understand. For example, the following two sentences have the same number of words, but the premodifiers in the first sentence are juxtaposed, which meet reading expectation and are easy to understand. However, the second sentence is not easy to understand because of its multiple nesting of modifiers [10].

- (1) zài chù dǎngwěi de dà nǎo hóng 9 yuè, gēxīn 2 qiān jiàn, bǎozhèng bǎi mǐ jǐng, guóqīng bǎ lǐ xiàn de xíngdòng kǐuhào xià (25 words; under the slogan of the party committee's campaign to make a big splash in September, to innovate 2000 pieces, to ensure the 100-meter well and to present gifts on National Day).
- (2) duǎnduǎnde guānyú shìjiè shàng de zhǐngzhǐng de lǐshǐ de zōngjiào duìyú rénlèi de sǐwáng hòu de shēngmíng suǐ céngjīng qǔ guò de tàidù de xùshù (25 words; a short narrative about the attitudes of various historical religions in the world to human life after death).

Based on the above theory, the sentence semantic complexity can be divided into two parts: the complexity of the main PSFs and the complexity of the additional PSFs. Only by understanding the main PSFs can we grasp the central idea of the sentence. Only by clarifying the additional PSFs can we get a complete understanding of sentence semantics. Different weights are given to PSFs at different layers, and the semantic universality of a sentence ( $U_{sen}$ ) with  $n$  structures is the synthesis of the universality of PSFs ( $u_i$ ) in every layer.

$$U_{sen} = \sum_{i=0, \dots, n} \alpha_i u_i, \quad (5)$$

where  $\alpha_i$  is an adjustable parameter, that is, the importance of different PSF, which will be determined later by experiments.

## 5. Experiments and Discussion

**5.1. Experimental Data.** 244 volumes of international Chinese textbooks in the sentence-based treebank are selected to obtain the universality of PSFs, which includes 4,695 documents and 91,526 sentences (separated by · ? !).

*Boya Chinese* is selected to complete experiments of sentence semantic complexity. *Boya Chinese* contains 9

volumes of textbooks. The difficulty of these textbooks increases in turn, and they can be divided into primary, intermediate, and advanced. The details are shown in Table 3.

5.2. *Universality of PFSs*. Based on 91,526 sentences, 231,020 predication structures are extracted. 1,138 predicates with a frequency greater than 20 are clustered. The contour coefficient is used to measure the density and dispersion of the classes, so as to automatically select the number of clusters. The calculation method of the contour coefficient is as follows:

$$S = \frac{b - a}{\max(a, b)}. \quad (6)$$

For a predication structure,  $a$  is the average distance from other predication structures in the same category, and  $b$  is the average distance from the predication structures in the different categories closest to it. The overall contour coefficient is the average value of all the contour coefficients. The larger the contour coefficient is, the better the dispersion between classes is; the smaller the contour coefficient is, the worse the clustering effect is.

After clustering, the percentage of a kind of predication structure can be obtained. As shown in Table 4, in the predication structures of “*tí gāo* (improve)”, the first class of predication structures accounts for 6.7%, and the second class of predication structures accounts for 24.6%. Combined with the occurrence frequency of the predicate, the universality of each predication structure can be obtained. For predicates whose frequencies are less than or equal to 20, the universalities of their predication structures are set to 1.

5.3. *Sentence Semantic Universality*. This paper analyzes the sentence semantic universality of *Boya Chinese*. At the same time, the setting methods of adjustable parameter in the calculation formula of sentence semantic universality are compared in this experiment.

Method 1: the sentence universality takes the lowest universality of PSFs in the sentence.

$$\alpha_i = \begin{cases} 1, & \text{if } \min(u_i), \\ 0, & \text{other.} \end{cases} \quad (7)$$

Method 2: if there is only one layer of syntactic structure in a sentence, the weights of all the predication structures are the same; otherwise, the weight of predication structures at the backbone layer is 0.8, and the weight of predication structures at the additional layer is 0.2.

First of all, method 1 is used to set adjustable parameters. Table 5 shows the distribution of sentence semantic universality in textbooks at all levels. It can be seen intuitively that, with the increase of text difficulty, the proportion of sentences with low universality gradually increases, from 26.6% to 82.6%, and the proportion of sentences with high universality is declining sharply.

Method 2 is used to calculate the sentence semantic universality, and the distribution of sentence semantic universality in each textbook is shown in Table 6. From the results in the table, the distribution of sentences with semantic universality between 1 and 20 in the textbooks of Book 1 to Book 9 is not rising steadily. The distribution of sentences with semantic universality more than 1000 has not achieved the expected effect, and the distribution law is not obvious in all levels of textbooks.

In order to compare the difference of sentence semantic universality between the two methods on text difficulty, the relative entropy (KL distance) between adjacent level texts is calculated based on sentence semantic universality. KL distances are shown in Table 7. It can be seen that the sentence semantic universality calculated by Method 1 can better distinguish texts at all levels, and the KL distances between textbook texts at adjacent levels are larger, so Method 1 is used to obtain sentence semantic universality. The effect of Method 2 is not as expected. This may be because the split of the sentence is too detailed when obtaining the predication structures, resulting in the frequencies of synthetic predicates being higher, which affects the calculation of sentence semantic universality. For example, the sentence “*wǐ néng qù yóu yǐng*(I can go swimming)” is divided into “*wǐ néng*(I can),” “*wǐ qù*(I go),” and “*wǐ yóu yǐng*(I swim).” In this case, the frequencies of predicates such as “*néng*(can)” and “*qù*(go)” have increased a lot.

#### 5.4. Comparative Experiment

5.4.1. *Baseline*. From the above experiments, it can be seen that when sentence semantic universality is used to represent sentence semantic complexity, sentence semantic complexity has obvious distribution law in all levels of texts (Method 1). The method in this paper closely connects structure and semantic, extracts the predication structures layer by layer based on the results of syntactic analysis, and synthesizes the complexity of the predication structures at all levels of a sentence.

In order to further verify the effectiveness of this method, the following method does not consider sentence structure and only measures the sentence semantic complexity from the diversity of lexical semantics. The calculation method is given as an example below [32].

If there is a dialogue below:

- (A) *wǐ de bà bà yán jiū de shì shù xué, nǐ de bà bà ne?*  
(My dad studies mathematics, what about your dad?).
- (B) *wǐ de bà bà shì shū fǎ.* (My father studies calligraphy).

So, although the structure of the following two sentences is the same, it is clear that the first sentence is easier to understand than the second sentence, because the semantics of “*bà bà*(daddy)” and “*jūn rén*(military)” are the same [32].

- (1) *wǐ de bà bà shì jūn rén* (My father is a soldier).
- (2) *wǐ de bà bà shì shū fǎ* (My father studies calligraphy).

TABLE 3: Boya Chinese.

| Title                 | Character | Level        | Chapter | Sentence | Average of character in a sentence | Average of word number in a sentence |
|-----------------------|-----------|--------------|---------|----------|------------------------------------|--------------------------------------|
| <i>Boya Chinese 1</i> | 5876      | Primary      | 66      | 1075     | 12.244                             | 7.46                                 |
| <i>Boya Chinese 2</i> | 7259      |              |         |          |                                    |                                      |
| <i>Boya Chinese 3</i> | 11560     | Intermediate | 67      | 2549     | 24.774                             | 14.519                               |
| <i>Boya Chinese 4</i> | 17390     |              |         |          |                                    |                                      |
| <i>Boya Chinese 5</i> | 14475     |              |         |          |                                    |                                      |
| <i>Boya Chinese 6</i> | 28344     |              |         |          |                                    |                                      |

TABLE 7: KL distances between textbooks of adjacent level.

| Text                    | Method 1 | Method 2 |
|-------------------------|----------|----------|
| Primary & intermediate  | 0.10832  | 0.011571 |
| Intermediate & advanced | 0.00822  | 0.005318 |

The semantics of each word in the sentences obtained from HowNet are as follows (because the semantic classification dictionary in [32] cannot be obtained, we count the number of semantic categories in the sentence based on HowNet):

- ①wǐ:human| rén
- ②wǐ:specific| tè dìng
- ③de:FuncWord| gōng néng cí
- ④bà bà: human| rén
- ⑤shì:be| shì
- ⑥shì:exist| cún zài
- ⑦shì:expression| cí yǔ
- ⑧shì:specific| tè dìng
- ⑨jūn rén: human| rén
- ⑩shū fǎ: method| fāng fǎ

Only the number of semantic categories is considered, and the occurrence number of semantic categories is not counted. The number of semantic categories in the first sentence (wǐ de bà bà shì jūn rén) is 6 (①②③⑤⑥⑦). The number of semantic categories in the second sentence (wǐ de bà bà shì shū fǎ) is 7 (①②③⑤⑥⑦⑩). In order to offset the influence of sentence length, the sentence semantic complexity = the number of semantic categories in the sentence / the number of words in the sentence [32]. The semantic complexity of the first sentence =  $6/5 = 1.2$ , and the semantic complexity of the second sentence =  $7/5 = 1.4$ . It can be seen that the second sentence has a higher complexity and is more difficult to understand.

**5.4.2. Results.** The summary of semantic complexity of sentences in *Boya Chinese* textbooks is shown in Table 8. The sentence complexity metrics obtained by the method in [32] and the method proposed in this paper are different. Using the method in [32], the representation of the sentence semantic complexity is ratio, the minimum is 0.5, the maximum is 12, and the median is 2.42. The representation of the sentence semantic complexity in this paper is frequency, with a median of 7.45.

In order to compare the two methods, the mapping functions of sentence semantic complexity are constructed firstly, and the sentence semantic complexity is divided into 1–6. The larger the value is, the more difficult the sentence is. After statistics and analysis of the distribution of sentence semantic complexity, the constructed mapping functions are shown in Table 9 (it should be noted that, after the analysis of the sentences in texts, it is found that the diversity of lexical semantics is less in the sentences of the more difficult texts, so monotonic decreasing function is also constructed).

The two methods are used to analyze the sentences in the textbooks (*Boya Chinese*) and calculate the average, standard deviation, and confidence interval of the sentence semantic complexity of each level of text (assuming that the distribution of sentence difficulty in each level of text follows Gaussian distribution, a 95% confidence interval is constructed). The results are shown in Table 10. It can be seen that as the difficulty of the text increases, the average of the sentence semantic complexity obtained by the two methods increases, but relatively speaking, the sentence semantic complexity obtained by the method proposed in this paper is better distinguished in all levels of text.

TABLE 11: Correlation analysis of sentence semantic complexity and the text level.

| Parameters                      | Paper [32] | This paper |
|---------------------------------|------------|------------|
| Pearson correlation coefficient | 0.11       | 0.31       |
| T                               | 26.03      | 43.81      |
| Critical value (99%)            | 2.33       | 2.33       |

Due to the lack of Chinese sentence complexity tagging corpus, Pearson correlation coefficient is used to analyze the correlation between sentence semantic complexity and the text level. The results are shown in Table 11. The correlation coefficient of the method proposed in this paper is 0.31, which is significantly improved compared with the method of [32]. By constructing  $T$  to analyze the significance of correlation coefficient,  $T$  is not within the critical value ( $-2.33 < T < 2.33$ ), which indicates that there is a significant positive correlation between sentence semantics complexity and the text level at 99% confidence level.

The effect of measurement method based on predicate semantic frameworks is better than that only considering the number of semantic categories in sentences. The reason should be that the measurement method based on PSFs combines structure and semantics and takes predication structure as semantic unit, which not only measures the semantic collocation relationship and quantity between sentence elements from a horizontal perspective, but also examines the hierarchical system and the primary secondary relationship from a vertical perspective. It is a comprehensive analysis of the number and nature of elements in a language system, as well as the number of connections between these different elements.

## 6. Conclusion

Based on the results of sentence-based syntactic analysis, this paper extracts the predication structures and converts the predication structures into PSFs. The spectral clustering method is used to cluster the semantic frameworks of each predicate to obtain their universality. Then according to the number and importance of PSFs at different layers of the sentence, the sentence semantic universality is obtained. Experiments show that the sentence semantic universality can well reflect the sentence semantic complexity. Furthermore, the method is compared with the method that only considers the semantic categories of words in the sentence. Experimental results show that the proposed method in this paper can effectively measure the sentence semantic complexity.

In this paper, the universality of PSFs is only considered from the collocation universality of subject, object, and predicate, ignoring the relationship between adverbial, complement, and predicate. However, adverbial is the grammatical component that modifies the predicate, and complement is the component that complements and explains the predicate. They are closely related to the predicate. In addition, a predication structure is a reflection of the basic propositional semantic of the sentence. In addition to the basic propositional semantic, the sentence semantics also contain the superpropositional semantics, such as modal semantic, tense and aspect semantic, and degree semantic, which will be considered in the subsequent work.

## Data Availability

Sentence-based treebank and text corpus of international Chinese textbooks supporting this study have not been made available because the sentence-based treebank cannot be published until the relevant intellectual property protection application is completed. In addition, these textbooks belong to third party rights; the authors have no right to publish the data source.

## Conflicts of Interest

The authors declare that they have no conflicts of interest.

Solid-state processing of metal material is a very complex physical and chemical process, which is coupled by a series of variations including heat transfer, momentum transfer, mass transfer, and phase change. Applying three-dimensional (3D) finite element numerical method to the simulation of solid-state processing can perform analysis of metal material's forging processes before production trial production, can obtain their relevant information such as material flow law, temperature field, and strain field under the minimum physical test conditions, thereby predicting metal material's forming defects and improving their forging quality. On the basis of summarizing and analyzing previous research works, this paper expounded the current status and significance of solid-state processing of metal materials, elaborated the development background, current status, and future challenges of 3D finite element numerical simulation, introduced the discrimination method and free surface solution method of numerical simulation calculation, conducted finite element model's geometric assumptions, material selection, element division, model establishment, parameter selection, and initial and boundary condition determination, and simulated and analyzed rheological casting, remelting heating, thixoforming, and rotary piercing processes of metal materials. The results show that the 3D finite element numerical method can not only simulate various processes of flow field, temperature field, stress field, and microstructure in solid-state processing but also can provide a reliable basis for effectively obtaining a reasonable description and finding a more optimized design plan for metal material processing in a short time, which plays an important role in understanding and analyzing solid metal forming process, controlling and optimizing process parameters, guiding and mastering rheological casting, and secondary heating and rotary piercing of metal materials.

## 1. Introduction

Solid-state processing of metal material is a very complex physical and chemical process, which is coupled by a series of variations including heat transfer, momentum transfer, mass transfer, and phase change. The simulation of temperature field and strain field in the solid-state processing of metal materials is to simulate the process of metal transforming from liquid to solid from the perspective of heat transfer, and the numerical solution of the thermal differential equation is obtained in the presence of phase change [1]. With the help of numerical simulation technology of temperature field and strain field, the formation mechanism of major casting defects, such as shrinkage

cavity, shrinkage porosity, thermal cracking, and macro-segregation, optimizes the design of the casting process, ensures the quality of castings, shortens the trial production cycle, and reduces production costs [2]. Solid-state processing of metal material refers to the deformability that a material can achieve without damage during plastic processing and is an important indicator of the material's bulk forming ability [3]. Material processing includes two aspects and the first one is stress state processing, which is related to the processing technology, mold and friction state, and can be controlled by changing the geometric size of the deformation area and the applied stress state; the other is internal workability, which reflects the decisive microstructure evolution under certain temperature, strain

rate, and strain conditions through the flow stress curve of the material and is very sensitive to the initial state of the material [4].

Applying three-dimensional (3D) finite element numerical method to the simulation of solid-state processing can perform analysis of metal material's forging processes before production trial production, can obtain their relevant information such as material flow law, temperature field, and strain field under the minimum physical test conditions, and thereby predicting metal material's forming defects and improving their forging quality [5]. The accurate simulation of these processes requires the constitutive equation of the liquid-solid mixture, and the contribution of the liquid to the deformation mechanism of mixture needs to be accurately described. Stress and strain field analysis is the basis for optimizing the rolling process. The key to accurate simulation is the establishment of solid material models and the optimization of simulation parameters, and the 3D simulation has further increased the difficulty [6]. Through numerical simulation, researchers can answer questions that cannot be answered in empirical design and understand the whole process of metal plastic forming, including the filling of materials at each stage of the metal forming process, the trend of material deformation, the stress, strain, and strain rate and forming inside the material load and velocity vector field [7]. This has great practical significance for the metal plastic forming process design, mold design, metal blank design, press selection, and forming quality control. Therefore, scholars have conducted a lot of research studies on the numerical simulation of metal material's solid-state processing and have obtained many research results [8].

On the basis of summarizing and analyzing previous research works, this paper expounded the current status and significance of solid-state processing of metal materials, elaborated the development background, current status, and future challenges of 3D finite element numerical simulation, introduced the discrimination method and free-surface solution method of numerical simulation calculation, conducted finite element model's geometric assumptions, material selection, element division, model establishment, parameter selection, and initial and boundary condition determination, and simulated and analyzed rheological casting, remelting heating, thixofforming, and rotary piercing processes of metal materials. The study results of this paper provide a reference for further research studies of 3D finite element numerical simulation and analysis of solid-state processing of metal material. The detailed chapters are arranged as follows. Section 2 introduces the discrimination method and free surface solution method of numerical simulation calculation. Section 3 conducts finite element model's geometric assumptions, material selection, element division, model establishment, parameter selection, and initial and boundary condition determination. Section 4 simulates the rheological casting and remelting heating processes of metal materials. Section 5 analyzes the thixofforming and rotary piercing processes of metal materials. Section 6 is conclusion.

## 2. Methods and Principles

*2.1. Discrimination Method of Numerical Simulation Calculation.* Rheological casting is actually a 3D heat conduction process, but the rheological casting used for solid-state processing of metal materials mainly prepares cylindrical billets, which is a symmetric problem. The differential equations for solving the thermal field problem of continuous casting semisolid cylindrical ingots can be written as follows:

$$\begin{aligned} & \frac{\partial(r_a T_x)}{\partial x} + \frac{\partial(r_b T_y)}{\partial y} + \frac{\partial(r_c T_z)}{\partial z} \\ & = f_s(x) \frac{\partial T_a}{\partial t} dL + f_s(y) \frac{\partial T_b}{\partial t} dL + f_s(z) \frac{\partial T_c}{\partial t} dL, \end{aligned} \quad (1)$$

where  $T_x$ ,  $T_y$ , and  $T_z$  are the thermal conductivity in the  $x$ ,  $y$ , and  $z$  directions, respectively;  $d$  is the material density;  $L$  is the latent heat of crystallization; and  $T_a$ ,  $T_b$ , and  $T_c$  are the specific heat;  $a$ ,  $b$ , and  $c$  are the axial displacement,  $f_s(x)$  The above differential equation can be solved by applying the finite element method or the difference method as the power consumption function.

According to the general viscosity model of early suspensions, the correlation between apparent viscosity and solid phase ratio and microstructure is

$$w = f_s \left[ 1 + \frac{-dL}{2(\lambda_k + 1/Cp)} \right], \quad (2)$$

where  $w$  is the apparent viscosity of the liquid alloy;  $\lambda_k$  is the critical solid phase rate, which mainly depends on the cooling rate and shear rate; and  $Cp$  is the specific surface area of the solid phase particles.

The central content of the theory of plasticity of metallic materials is the establishment of yield criterion. Since the complex physical characteristics of metal material deformation are difficult to describe with a very accurate mathematical model, the yield criterion based on the relationship between equivalent stress and equivalent strain increment is expressed as follows:

$$K = \frac{1}{\gamma} \sqrt{\frac{m}{2} \sigma + \frac{d^2 L^2}{w}} - P, \quad (3)$$

where  $K$  is the uniaxial yield stress;  $m$  is the stress component tensor;  $P$  is the hydrostatic pressure; and  $\sigma$  is the function of relative density, which can be obtained through uniaxial compression experiments and 3D compression experiments.

Previous studies have shown that the viscosity  $\eta$  and the shear rate of the alloy melt continuously cooled at a certain shear rate are [9]. The relationship of  $\gamma$  can usually be expressed as follows:

$$\eta = \left( K - \frac{f_s}{Cp} \right)^{-mr} \left\{ 1 + \left[ \frac{b(f_s)}{a} \right]^n \right\}^{n/k}, \quad (4)$$

where  $a$  and  $b$  are the critical solid fraction and instantaneous solid fraction related to the cooling rate and the shear

rate, respectively, and  $m$  and  $n$  are the consecutive times; the other parameters are empirical constants.

The thermal strain  $\delta_{ij}$  is related to the temperature and the thermal expansion coefficient of the material, and its expression is

$$\delta_{ij} = \begin{cases} \alpha_{ij}(T - T_\eta), & i = j, \\ \alpha_{ij}(T + T_\eta), & i \neq j, \end{cases} \quad (5)$$

where  $\alpha_{ij}$  is the thermal expansion coefficient of metal material;  $T$  is the temperature; and  $T_\eta$  is the reference temperature and one is the direct coupling unit. In addition to the displacement freedom of the ordinary unit, the unit also has the temperature freedom. After being affected by the local temperature, the temperature field in the unit is first calculated according to the heat conduction theory, and the temperature is taken as the temperature field. The external load is applied to the element and then combined with the element force and displacement constraints, and the internal force distribution of the element is obtained.

**2.2. Free Surface Solution Method.** The change of the free surface of liquid metal belongs to the category of interface dynamics, which is a difficult problem to deal with in the simulation of the metal flow process. In this method, the coordinate system is established on the fluid mass, and the grid moves with the mass, so the calculation method is simple and the determination of the free surface is more convenient. However, the flow and deformation of the mass will inevitably cause the grid to be distorted and distorted so that they are kinked with each other and even the grids may intersect, making the calculation impossible [10].

Since it is assumed that the solid material is equivalent to the porous material, the elastic deformation can be ignored. From the relationship between the strain rate tangent and the instantaneous stress, the rigid-constitutive equation of the solid material can be obtained as follows:

$$V_I = \gamma(I) \frac{\partial T}{\partial r}, \quad (6)$$

where  $V_I$  is the yield function and  $r$  is the material constant. The rheological behavior of solid metals is mainly affected by factors such as shear rate, solid phase volume fraction, solid phase particle morphology, and agglomeration degree, which can be expressed as follows:

$$h(x, y, z) = \eta(\gamma, f_s, m, c), \quad (7)$$

where  $\eta$  is the apparent viscosity,  $\gamma$  is the shear rate,  $m$  is the morphology parameter of solid particles, and  $c$  is the parameter of the degree of agglomeration of solid particles.

Therefore, when calculating the rolling force during the forming process, generally only the average total rolling force is calculated. The calculation formula is as follows:

$$B_e = h_a \sigma_b V_I (D + D_c) \sqrt{n \frac{\sigma_b}{V(D)}} e^{-n/L}, \quad (8)$$

where  $B_e$  is the average total rolling force,  $h_a$  is a parameter related to the taper of the core and uneven deformation,  $\sigma_b$  is a parameter that depends on the degree of hardening of the metal or alloy,  $D$  is the outer diameter of the rolled tube,  $D_c$  is the outer diameter of the tube,  $n$  is the amount of feed, and  $L$  is the length of the working part of the groove excluding the sizing section. If expressed in terms of heat capacity based on unit mass, the equation can be expressed as follows:

$$dW = mCp dT, \quad (9)$$

where  $m$  is the mass of the object and  $Cp$  is the heat capacity per unit mass, that is, the specific heat capacity of the object. The total power absorbed by the material per unit volume during thermal processing can be expressed by the sum of two complementary functions:

$$U = \int_0^v \sigma dv + \int_0^\sigma v d\sigma. \quad (10)$$

The  $U$  value in the formula represents the power consumption due to plastic deformation, most of which is converted into heat. The dissipation margin is the power consumption related to the change of the structure during the deformation of the material, so the change also represents the change of the microstructure.

### 3. Finite Element Model and Parameter Selection

**3.1. Basic Assumptions of the Geometric Model.** The assumptions for the solid-state processing of metal materials are as follows: the metal material is a compressible continuum; the elastic deformation of the material is ignored during the forming process of the metal material; the solid material is a non-Newtonian fluid. Thixoforming is to cool and solidify the semisolid billet obtained by special processes such as stirring, then cut the material according to the required size, then reheat it to the semisolid temperature, and then place it in the mold cavity for forming. The heating and conveying of semisolid metal blanks are very convenient, the forming process is easy to control, and it is convenient to realize automated production [11]. At present, most processes use thixoforming. After holding the alloy melt for a certain period of time near the liquids temperature, it is cast to obtain a semisolid slurry method suitable for thixoforming, and liquid casting alloy has a low melt temperature, almost no overheating, and a uniform temperature field. During the casting process, a large number of crystal nuclei are uniformly generated in the melt to form small, uniform, and semisolid slurry, and the method is simple, efficient, energy saving, and material saving. The alloy ingot with the structure is heated and sheared during the transportation process through a heating source and a special spiral propulsion system so that it has importance and is injected into the mold cavity to form injection molding which is essentially a kind of rheological technology.

**3.2. Material Selection and Unit Division.** This paper chooses TC11 alloy as the experimental metal material. TC11 alloy is a

kind of  $\alpha$ - $\beta$ -type heat-strength alloy with good comprehensive properties, which has excellent heat-strength properties below 500°C and high room temperature strength. The alloy is mainly used to manufacture parts such as compressor discs, blades, and drums of aero engines, as well as aircraft structural parts.

From the perspective of forging, the upper boss of the forging is not easy to be filled, so the upper boss is placed on the upper die. Although the shape of the bottom of the forging is complex, it is easy to fill. The size of the blank is obtained according to previous calculations and experiments and the initial heating temperature is 950°C. Considering the heat loss during the transfer process, the blank temperature is set to 930°C in the simulation. The size of the material is obtained according to previous calculations and experiments with its size of 400 mm × 120 mm. The blank is divided into 40,000 tetrahedral units (Figure 1).

**3.3. Establishment of Geometric Model.** Finite element software is used to simulate the forming process, and two kinds of blanks, cylindrical and stepped, are used for forming research, respectively. At the same time, in order to reduce the number of unit divisions and increase the calculation speed and time, only a certain proportion of the blank is taken as the simulation research object. Tetrahedral elements are used to discriminate the blank and redraw according to the grid distortion at any time during the calculation process to ensure the accuracy and convergence of the calculation. The points on the symmetry plane are constrained so that their normal velocity along the symmetry plane is zero (Figure 2). The deformation of the mold is not considered during the simulation, and its material property is a rigid body. In this paper, a simple and convenient parent element method is used to generate the grid of the initial blank. That is to say, the blank must be divided into simple sub-blocks and coordinate transformation, then transformed into a unit rectangle or a unit parallelepiped in the local coordinate system, and finally the grid is divided according to the specified grid division ratio in each direction.

During the deformation process, high temperature and large deformation are often generated in a local area to cause mesh distortion, which will reduce the accuracy of the solution or cause the mold to be embedded in the blank and penetrate, so adaptive mesh re-partitioning technology is required. As the deformation intensifies, the initial grid of the blank will be severely distorted, which may result in the inability to continue the calculation. Therefore, in order to overcome the computational difficulties and low accuracy caused by grid distortion, when the finite element grid is distorted to a certain extent, the calculation must be stopped, the grid suitable for the calculation must be redivided, and the modified boundary conditions must be determined and then continued to calculate. The automatic mesh redraw technology can correct the distorted or distorted mesh caused by excessive deformation. According to a certain set criterion, such as mold penetration, plastic strain, and incremental step criterion, it can automatically regenerate a

good-shaped mesh. The state variables in the original old grid are mapped to the newly divided grid to ensure subsequent calculations and improve calculation accuracy. Grid redrawing is generally divided into three steps of judgment of grid distortion, new grid generation, and data conversion between old and new grids [12].

### 3.4. Determination of Initial and Boundary Conditions.

The processing of the boundary conditions is the determination of the representative section of the tool and work-piece shape in the calculation, taking into account the geometric conditions, thermal effects, and other aspects. Such as work-piece cooling caused by tools or temperature rise caused by plastic deformation, as well as mechanical effects, including elastic flattening and bouncing of metal materials, are not considered. These simplifications are made to reduce the required calculation time, and the basic assumption makes the physical influence not play a major role when analyzing the influence of the equipment structure on the uneven flow of materials. These steps apply boundary condition constraints on geometric objects or finite element meshes, apply symmetric boundary conditions to corresponding symmetric nodes, and establish a set of two boundary nodes:  $Y=0$  node  $X$  displacement and  $Y$  and  $Z$  rotation is 0 and  $X=0$  node  $Y$  displacement and  $X$  and  $Z$  rotation is 0.

The metal material processing process mainly involves the heat transfer during the plastic deformation of the sheet surface. During the processing, the upper surface of the sheet material in contact with the air is a free surface, and the initial temperature of the sheet material and room temperature during the simulation is 24°C. The main heat exchange model is expressed as follows:

$$-k \frac{\partial T}{\partial x} = \lambda_c (T - T_0), \quad (11)$$

where  $k$  is the heat transfer coefficient between the metal material and the air and  $T$  is the absolute temperature. When calculating the temperature field, it is necessary to impose thermodynamic boundary conditions, including constant temperature boundary conditions and thermal convection boundary conditions. The constant temperature boundary condition simulates the surrounding external ambient temperature; the thermal convection boundary condition simulates the heat exchange on the contact surface between the structure and the air, assuming that the convective heat transfer coefficient is constant.

In the model, the speed of the contact surface with the cooling boot is 0, that is,  $v_x = 0$ ,  $v_y = 0$ , and  $v_z = 0$ . The speed of the contact surface with the work roll is the work roll speed:

$$\begin{aligned} v_{xi} &= v_0 \cos \alpha_i, \\ v_{yi} &= v_0 \sin \alpha_i, \end{aligned} \quad (12)$$

where  $v_0$  is the rotation speed of the work roll and  $i$  is the number of the node in the heat conduction matrix. The convective heat transfer coefficient on the entire contact

FIGURE 1: Metal material model and unit division for simulation and analysis of solid-state processing.

FIGURE 2: Establishment of the geometric model and its unit division of the metal material in solid-state processing.

surface changes with the temperature of the alloy and the mold and the contact state between the two, and it is accurately determined quite difficult. The metal material moves down at a constant speed, and the die adopts a floating structure, that is, during the pressing process of the metal material, the metal material forces the die to move downward together at the same speed. In the simulation process, it is assumed that the mold does not undergo plastic deformation and is a rigid body; in the incremental calculation, each reduction is taken as a certain value of the initial blank height.

## 4. Simulation Results and Analyses

**4.1. Rheological Casting Simulation of Solid-State Processing of Metallic Materials.** A closed die is used to actively load the isothermal extrusion to form a curved metal material. By optimizing the cavity structure of the concave mold, the nondevelopable surface can be directly forged to achieve a net shape or an approximate net shape processing. The simulation results show that the metal flows smoothly, the forming effect is good, and there are no defects such as folding and dissatisfaction with the filling, which proves that the isothermal extrusion forming of curved metal materials is feasible. As shown in Figure 3, when the load is 2 kPa, the vector change of the true radial plastic strain of the working cone is mainly deformed by wall reduction and the amount of wall reduction is evenly distributed; when the load is 3 kPa, the true radial plastic strain has remained unchanged and its value is the largest in the entire forming process because this stage is in the sizing stage of the cold rolling process; when the load is 6 kPa, the residual deformation of the short-side simply supported plate is similar to that of the

free plate, which is greater than the deformation of the short-side fixed plate. It can be seen from the simulated load curve that the deformation process is roughly divided into three stages, namely, the initial deformation, cavity filling, and final forming [13]. In the initial stage of deformation, the load curve rises gently and the deformation force is small; the upward trend of the load curve increases with the increase of displacement, which shows that deformation is becoming more and more difficult.

In the process of multistroke cold rolling of metal materials, the vector change of the true radial plastic strain of the working cone is divided into three stages. From the beginning to the section, the true radial plastic strain gradually increases, and its increasing trend is the largest. This is because at this stage, the working cone is mainly reduced in diameter and the amount of reduction is the largest, while the reduction in wall deformation is not obvious, which is usually called the empty reducing stage, so the value of this stage is relatively small. The radial plastic true strain also gradually increases, but the increasing trend decreases. This is because at this stage the working cone is mainly deformed by wall reduction and the amount of wall reduction is evenly distributed, while the reduction deformation carried out with the wall reduction is relatively large. The true radial plastic strain has remained unchanged and its value is the largest in the entire forming process because this stage is in the sizing stage of the cold rolling process, and the value remains unchanged. The axial length of the outer surface of the rolled tube is greater than the axial length of the neutral layer, and the axial length of the neutral layer is greater than the axial length of the inner surface, which indicates that the degree of anisotropy of the rolled tube ranges from the outer surface to the neutral layer and to the inner surface. The wall-reducing deformation of the material in the final stage is much greater than the diameter-reducing deformation, and the degree of anisotropy of the rolled tube decreases from the outer surface to the neutral layer to the inner surface.

Under different constraint conditions, the magnitude of the residual stress and the residual deformation are different. The boundary constraint of the short-side fixed plate is the strongest and the deformation inside and outside the plane is restricted, the deformation amount is the smallest, but the residual stress is the largest. The residual deformation of the short-side simply supported plate is similar to that of the free plate, which is greater than the deformation of the short-side fixed plate, but the residual stress is smaller. Comparing the calculation results with or without heat preservation after

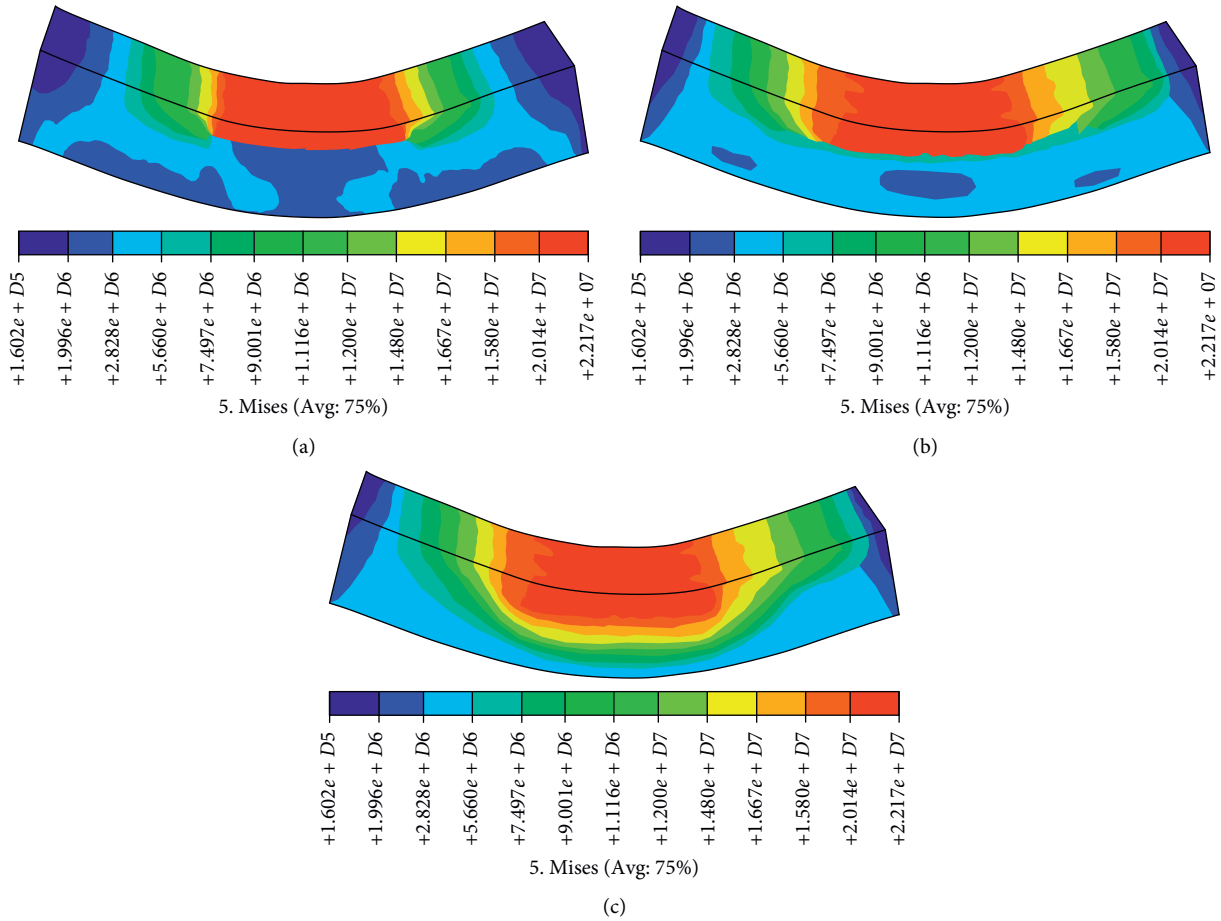

FIGURE 3: 3D finite element numerical simulation results of rheological casting processing of metal material. (a) Load = 2 kPa. (b) Load = 3 kPa. (c) Load = 6 kPa.

processing, whether in terms of residual deformation or residual stress, the performance with heat preservation conditions is significantly better than that without heat preservation. When there is heat preservation, after the material is cooled to the heat preservation temperature, the temperature field is distributed uniformly through heat transfer, and the temperature difference gradient is small. After the heat preservation is removed, the whole material can be uniformly cooled to the on-site ambient temperature; compared with the case of no heat preservation, the material with heat preservation. The degree of uneven cooling is small so that the residual deformation and residual stress are small, indicating that heat preservation measures are indispensable for controlling the residual deformation and residual stress. During the processing and construction of the material shear wall, lateral supports are often set on the two wall panels that need to be processed to limit the effect of the out-of-plane deformation of the material during the processing. After the processing is completed, the support is removed, and the out-of-plane deformation of the material increases [14].

**4.2. Remelting and Heating Simulation of Solid-State Processing of Metal Materials.** In the process of metal deformation, the deformation temperature has a great influence

on the metal deformation. The temperature change during the piercing process has a great influence on the plastic deformation resistance of the metal. When the temperature increases, the plasticity of the metal increases, the deformation resistance weakens, and the metal is easily deformed. On the contrary, the metal deformation resistance increases and the metal are difficult to deform. In addition, temperature is also the key influencing factor for the phase transition of metals, and the phase transition structure is the determining factor for the final mechanical properties of metals and the temperature distribution during the sample rolling process is not uniform. In the direct contact area between the roll and the sample, due to the relative sliding friction between the roll and the sample, it is mainly back slip, causing the temperature in the contact area between the sample and the roll to be higher than the rest (Figure 4). The temperature in the area is tens of degrees higher. The metal equivalent strain in the cross-rolling piercing deformation is the highest near the roll transition cone, and gradually decreases to both sides. The largest deformation occurs in the contact area between the sample and the roll, which corresponds to the stress distribution. During the piercing process, the surface of the plug is subject to high temperature, high pressure, and high shear stress and is prone to wear, melt loss, and steel sticking, which shortens the service

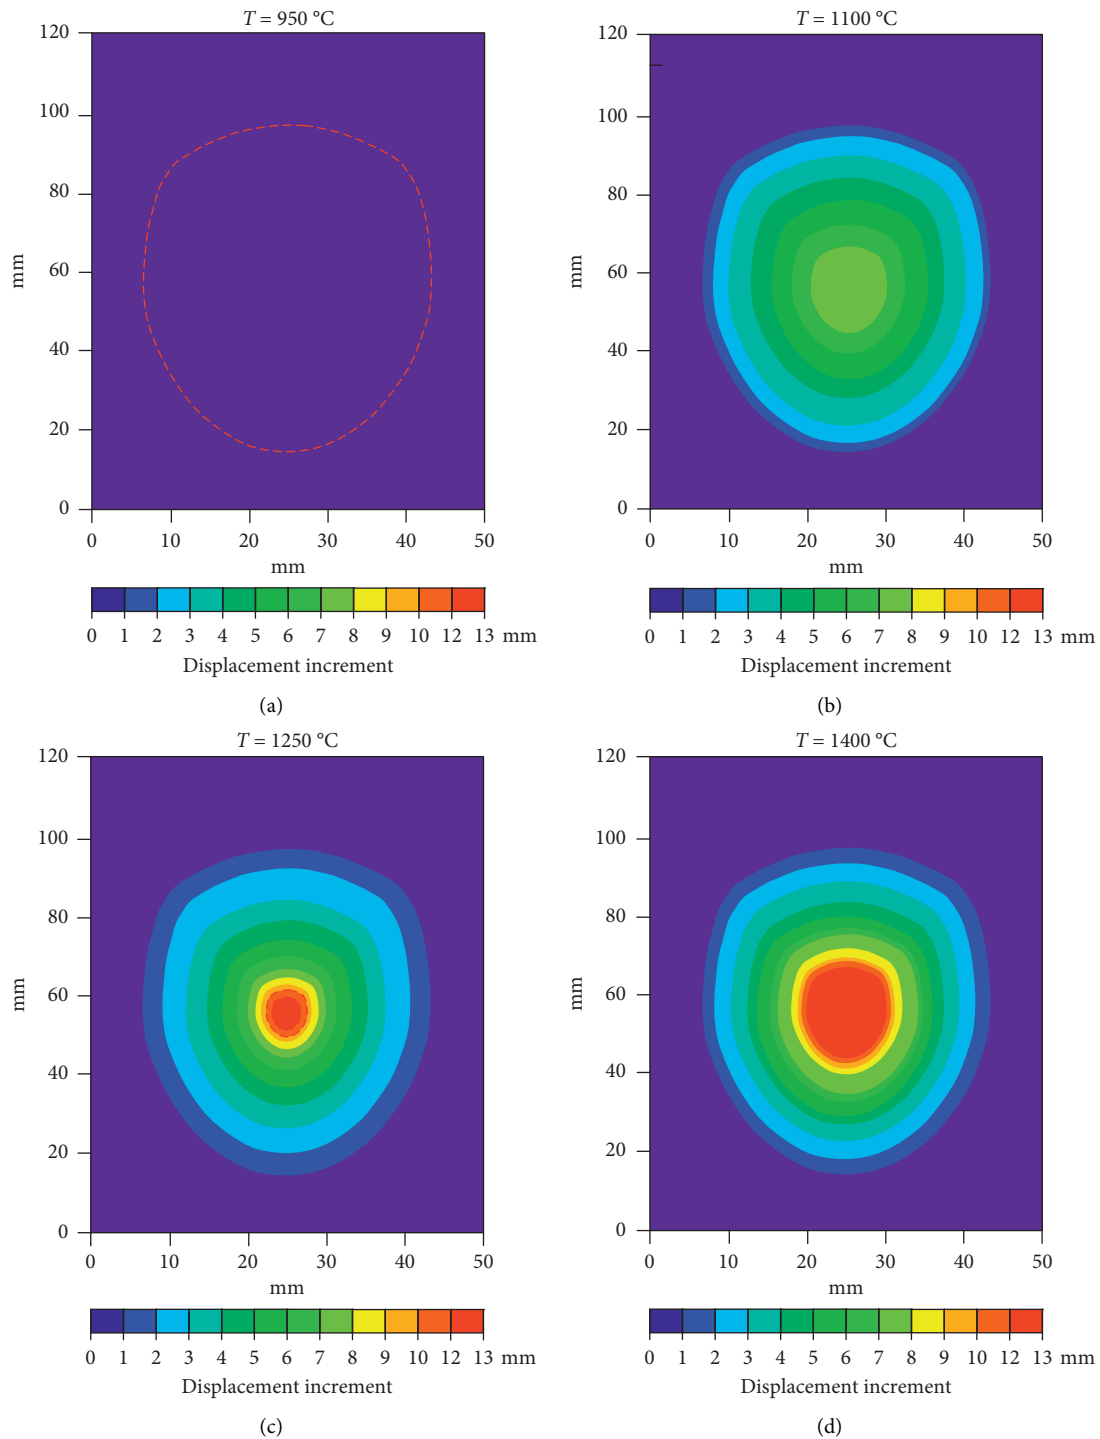

FIGURE 4: Numerical simulation results of displacement increment for mental material at different remelting temperature in solid-state processing.

life of the plug and deteriorates the inner surface quality of the steel pipe. During the cross-rolling and piercing process, the maximum stress on the outer surface of the tube blank occurs in the contact area between the tube blank and the roll and the contact area with the guide plate.

This is because the plastic deformation of the semisolid slurry of the granular structure is mainly achieved by liquid

flow. As the deformation temperature increases, the volume fraction of the liquid phase increases, and the liquid phase is gradually connected into a network to separate the solid particles and the particle rotation and movement are easier to proceed. The solid phase ratio is a key factor affecting the deformation characteristics of the semisolid slurry. Generally speaking, the longer the opening and drawing time, the

closer the position of the crack is to the lower opening of the mold, that is, the length of the retained layer in the mold becomes longer with the extension of the opening and drawing time [15]. The greater the heat flux density, the closer the crack position is to the lower mouth of the crystallizer, that is, the length of the retention layer in the crystallizer increases as the heat flux density increases. The greater the heat flux density, the closer the crack position is to the lower mouth of the crystallizer, that is, the length of the retention layer in the crystallizer increases as the heat flux density increases (Figure 5). The longer the opening time or the greater the heat flux density, the greater the thickness of the solidified shell at the crack, which is consistent with common sense. From the perspective of the corresponding relationship between the crack position and the crack thickness, in general, the lower the crack position, the thicker the thickness of the solidified shell at the crack. If a crack occurs due to excessive drawing resistance, the position of the crack will be lower. Figure 5 concludes that during repeated grinding and deformation, since it is a new deformation based on the plastic deformation of the last pass, the surface metal has undergone work hardening after plastic deformation, so the deformation resistance is greater.

The finite element analysis of solid-state rolling is a highly nonlinear problem. Considering material nonlinearity, boundary nonlinearity, and temperature nonlinearity, the use of simple geometric models is a means to make research progress. In order to study the change of solid state during rolling, two rolling methods, flat rolling and closed pass rolling, were used; in flat rolling, the solid slurry is simplified into a round bar. In the pass rolling, under the restriction of the pass and side sealing tools, the solid slurry has better fluidity and will form a small hole above the hole; therefore, the solid slurry can be simplified into cuboids. Because flat rolling has no restriction on the side of the rolled piece, the horizontal extension is large. At the same time, due to the friction force of the rolling, the contact part of the rolling piece head and the rolling piece extends in the longitudinal direction to form a spiral depression [16]. The downward pulling force causes the remaining part of the rolled piece to shrink and become thinner. Because the solid material has low flow stress and good fluidity, it can be rolled with a large amount of deformation, but at the same time, it is easy to cause uneven stress distribution on the cross-section. The stress distribution on the cross-section of the deformation zone is uneven, decreasing from the core to the side on the same cross-section; the longitudinal changes of the stress gradient on the surface of the deformation zone are inconsistent.

## 5. Discussion

*5.1. Thixoforming Simulation of Solid-State Processing of Metallic Materials.* From the relationship between volume change rate and pressing time under different load conditions, it can be seen that, in the initial stage of pressing, the volume changes more drastically. This is mainly due to the rapid decrease of the void density between the compact particles and the gradual compaction of the metal material

particles. As the pressing progresses, the volume change trend is relatively gentle. At this stage, the metal material particles are rearranged and plastically deformed. From the comparison between the experimental value and the simulated value, it can be seen that the change of the average density goes through three stages with the increase of the load: the rapid growth stage, the gentle growth stage, and the saturation stage. The density distribution is in a stepped layered distribution that gradually increases from bottom to top in parallel to the movement direction of the die punch (Figure 6). The maximum and minimum relative density of the compact are located at the end corners of the upper and lower surfaces, respectively, inside the press. The density distribution is more uniform than the outer surface, and the density distribution is a contour surface, which indicates that the radial flow and axial flow of the metal material are in a balanced state on this surface. The density distribution is layered parallel to the movement direction of die punching, and the density distribution on the outer surface is basically gradually increasing from bottom to top, and is basically parallel to the top surface. In the interior of the press, the density distribution is stepped. Gradually, except for the upper and lower corners, the density distribution inside the pressing piece is more even than the outer surface [17].

The flow velocity of the melt in the longitude direction is much larger than the axial casting velocity. The electromagnetic field in the velocity field presents a distribution and reaches its maximum value on the middle surface of the stator. The equivalent flow trajectory length of all solidified particles increases with the progress of casting, and the residence time of solid particles in the solidification zone is also significantly different. This method can accurately process free surfaces, effectively track the deformation history of fluid masses, conveniently realize grid optimization, obtain local accurate physical images, and can handle larger grid deformations. Numerical simulation technology can not only simulate the changes in the flow field, temperature field, stress field, and microstructure of the metal processing process but also predict the formation of defects in the metal processing process. Therefore, it has control over the understanding and analysis of the solid metal forming process, and optimization of process parameters can play an effective guiding role for rheological casting, secondary heating, and near-net thixoforming of parts. However, solid metal forming is a solid-liquid two-phase flow process and has importance, and its deformation resistance or apparent viscosity is not only related to the shear rate but also closely related to time. Therefore, the numerical simulation method must be able to track the fluid deformation process.

Under the same reduced pressure condition, the surface of the plate is milled by single milling and repeated milling. The comparison of the effective strain shows that the cumulative effect of repeated milling on the effective strain is very obvious [17]. The reason for this result is that the deformation of the metal material during processing consists of two parts: elastic deformation and plastic deformation. The elastic deformation is restored after each grinding process, and the plastic deformation remains in the

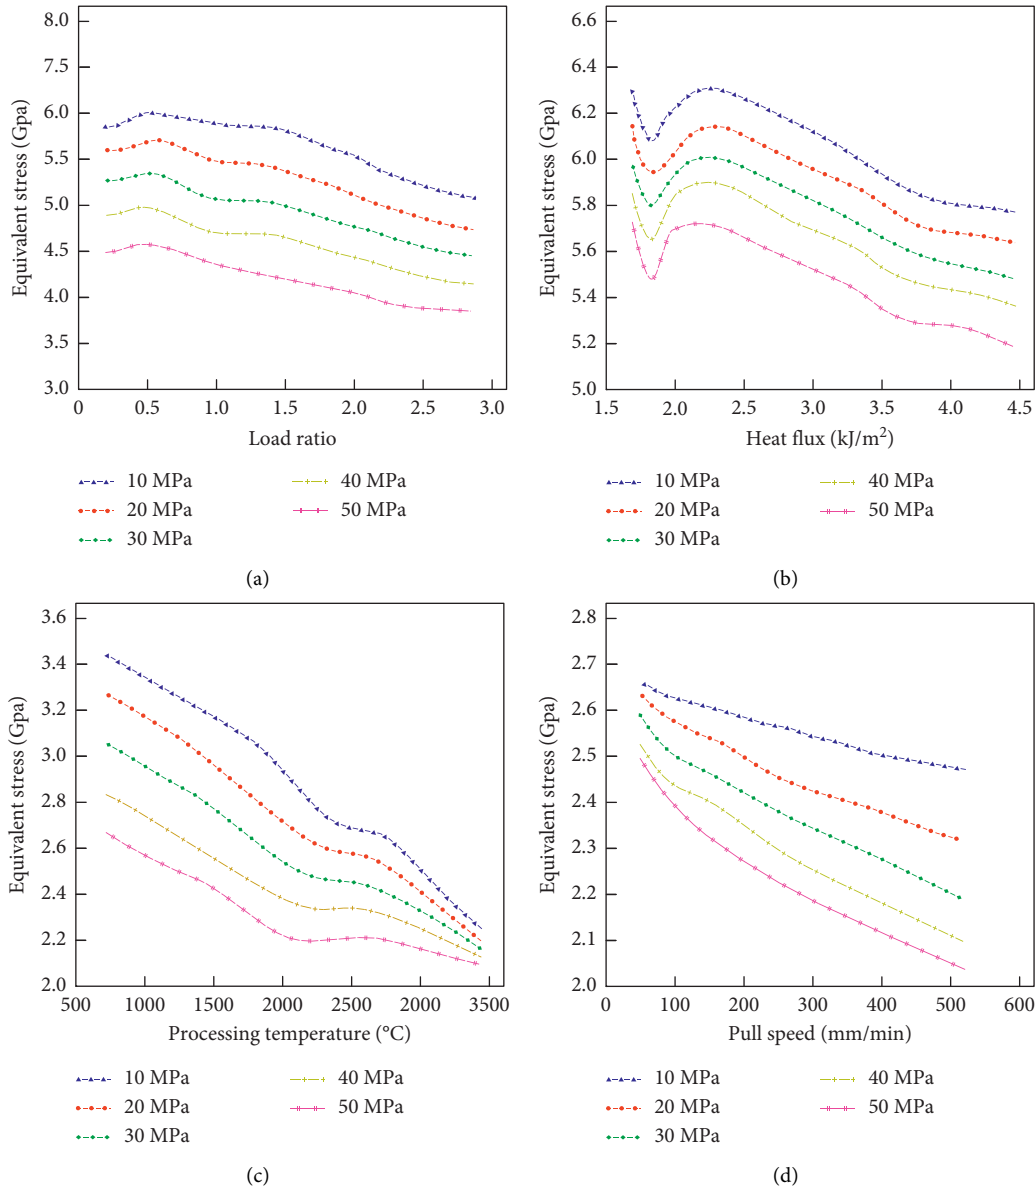

FIGURE 5: Relationship between equivalent stress and load ratio. (a) Heat flux. (b) Processing temperature. (c) Pull speed. (d) Different processing effects.

deformation area. During repeated grinding and deformation, since it is a new deformation based on the plastic deformation of the last pass, the surface metal has undergone work hardening after plastic deformation, so the deformation resistance is greater. In order to continue the deformation, the plate must be the material exerts greater compressive stress, which is also the reason why more effective strain can be obtained by multipass grinding under the same lower pressure condition. With the increase of milling passes, the maximum effective strain gradually increases. When the number of milling passes exceeds the second, even if the number of milling passes increases, the maximum effective strain does not increase much, indicating that the strengthening effect produced by strong plastic deformation tends to be saturated. No matter which milling method is used, the effective strain increases with the

increase of milling times, and the curve is close to the linear change law.

*5.2. Rotary Piercing Simulation of Solid-State Processing of Metal Materials.* The alloy ingot with the structure is heated and sheared during the transportation process through a heating source and a special spiral propulsion system so that it has importance and is injected into the mold cavity to form injection molding which is essentially a kind of rheological technology. As shown in Figure 7, in stage (1), wall thickness changes everywhere are not gradually and slowly, and the change at the beginning quickly reaches the final change result; in stage (2), the bending part of the tube gradually moves to the rear end of the tube as the bending angle increases; in stage (3), the wall thickness is still the initial

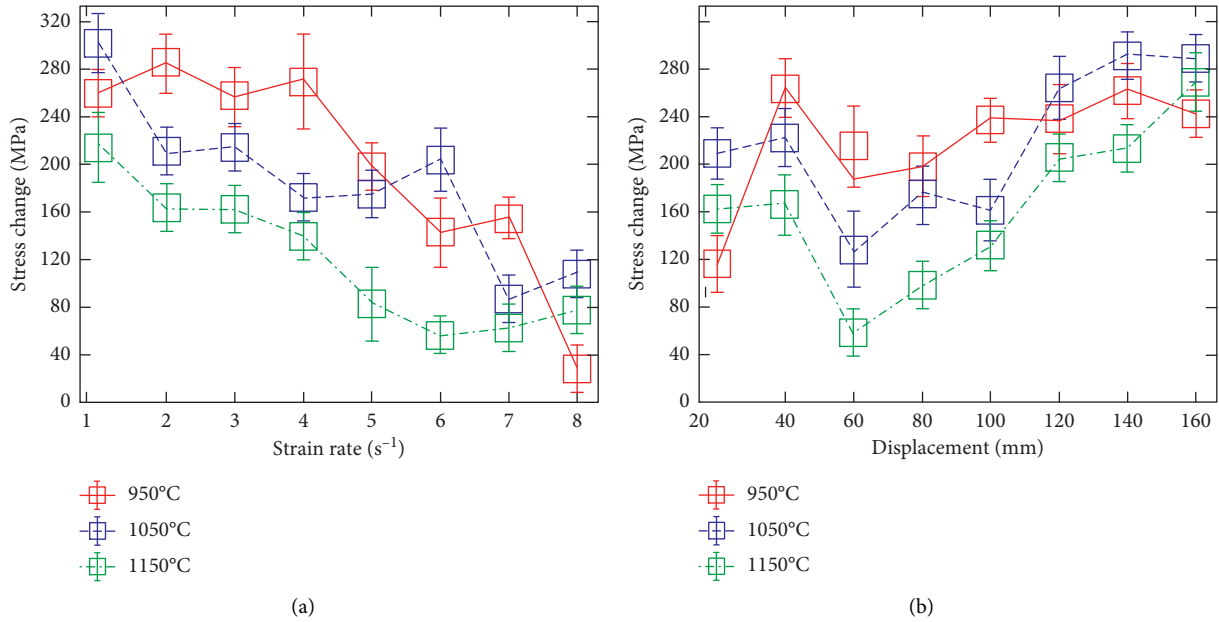

FIGURE 6: Relationship between stress change and strain rate. (a) Displacement. (b) Mental material in the solid-state processing.

FIGURE 7: Rotary piercing simulation results of solid-state processing of metal materials. (a) Stage (1). (b) Stage (2). (c) Stage (3). (d) Stage (4). (e) Stage (5). (f) Stage (6).

value; as the bending angle increases, the deformation zone moves to this point; in stage (4), tensile and compressive stresses are generated on the pipe wall, resulting in a change in the wall thickness; in stage (5), no bending deformation occurs, and the wall thickness at this time remains basically unchanged; in stage (6), the inner concave edge of the elbow is compressed to increase the wall thickness, while the outer

convex edge is stretched to reduce the wall thickness. The total change of the equivalent stress value during the bending deformation process of the pipe fitting increases with the increase of the bending angle, and the stress value of the inner concave side pipe wall of the curved pipe fitting is larger than that of the outer convex side pipe wall. The inner wall is subjected to compressive stress and the outer wall is

subjected to compressive stress. The equivalent strain value of the inner pipe wall is larger than the outer pipe wall. In the bending process, due to the small bending radius and large bending deformation, the inner concave edge of the elbow is compressed to thicken the inner wall, while the outer convex edge is stretched to make the outer wall thinner [18].

When the strain rate is low, driven by the pore pressure gradient, the liquid seeps out of the free surface, and the resulting pore pressure is much smaller than the total macroscopic pressure. At the other extreme, if the deformation is fast, the liquid does not have enough time to migrate to low pressure zone and causes the accumulation of pressure and the deformation in this case is nondraining [19]. In the nondraining deformation, the increased pressure reduces the pressure component of the equivalent stress, resulting in a reduction in the three-way equivalent stress because the reduction of the cohesive force is directly related to the partial stress of the applied stress. In the case of no drainage, the solid skeleton is destroyed, which easily causes deformation concentration. Without ignoring the pressure of the liquid, there is a lack of understanding of the behavior of metals in liquid-filled porous media both theoretically and experimentally. Because these relationships are not only theoretical, technological processes such as continuous casting and solid forging are likely to generate a large amount of liquid pressure. The accurate simulation of these processes requires the constitutive equation of the liquid-solid mixture, and the contribution of the liquid to the deformation mechanism of the mixture needs to be accurately described. The asymmetry of the metal solid down-compression deformation behavior and the use of liquid compression experiment, nondraining liquid compression experiment, and shear experiment verified the correctness of the model [20].

In the actual forming process, the size range of different partitions is constantly changing, and the related areas are also constantly transformed. When they are in the stable deformation stage, the metal volume from the force transmission zone into the deformation zone and transfer from the deformation zone to the deformed volume of the zone is equal. With the progress of the deformation process, the force-transmitting zone keeps decreasing; the deformed zone keeps increasing, while the size of the deformed zone and the numerical distribution of stress remain unchanged [21]. During the deformation process, the degree of deformation, the diameter, thickness, length of the tube blank, and the adjustment of the structural parameters of the rotary wheel will all have a direct impact on the deformation state. When the feed depth is constant, the deformation resistance is reduced when the working angle is small, which is more conducive to metal deformation, but on the contrary, the distance of metal flow increases, and the deformation zone is correspondingly elongated, which increases the contact area between the blank and the surface of the rotary wheel. When the working angle of the rotary wheel is large, the contact area between the blank and the rotary wheel is reduced, and the deformation of the metal is more difficult, resulting in an increase in the deformation force. In the process of necking forming, the deformation zone is mainly affected by radial

and axial compressive stresses, which reduces the diameter and increases the wall thickness and length. For thin-walled cylinders, when the radial compressive stress is too large, it is easy to cause wrinkling and instability in the deformed thin-walled area.

## 6. Conclusions

This paper conducted finite element model's geometric assumptions, material selection, element division, model establishment, parameter selection, and initial and boundary condition determination and simulated and analyzed rheological casting, remelting heating, thixoforming, and rotary piercing processes of metal materials. From the relationship between volume change rate and pressing time under different load conditions, it can be seen that, in the initial stage of pressing, the volume changes more drastically. This is mainly due to the rapid decrease of the void density between the compact particles and the gradual compaction of the metal material particles. At this stage, the metal material particles are rearranged and plastically deformed and the density distribution is in a stepped layered distribution that gradually increases from bottom to top in parallel to the movement direction of the die punch. The maximum and minimum relative density of the compact are located at the end corners of the upper and lower surfaces, respectively, inside the press. The density distribution is more uniform than the outer surface, and the density distribution is a contour surface, which indicates that the radial flow and axial flow of the metal material are in a balanced state on this surface. The results show that the 3D finite element numerical method can not only simulate various processes of flow field, temperature field, stress field, and microstructure in solid-state processing but also can provide a reliable basis for effectively obtaining a reasonable description and finding a more optimized design plan for metal material processing in a short time, which plays an important role in understanding and analyzing solid metal forming process, controlling and optimizing process parameters, guiding and mastering rheological casting, and secondary heating and rotary piercing of metal materials.

The structure of the deep artificial neural network is similar to the structure of the biological neural network, which can be well applied to the 3D visual image recognition of aerobics movements. A lot of results have been achieved by applying deep neural networks to the 3D visual image recognition of aerobics movements, but there are still many problems to be overcome. After analyzing the expression characteristics of the convolutional neural network model for the three-dimensional visual image characteristics of aerobics, this paper builds a convolutional neural network model. The model is improved on the basis of the traditional model and unifies the process of aerobics 3D visual image segmentation, target feature extraction, and target recognition. The convolutional neural network and the deep neural network based on autoencoder are designed and applied to aerobics action 3D visual image test set for recognition and comparison. We improve the accuracy of network recognition by adjusting the configuration parameters in the network model. The experimental results show that compared with other simple models, the model based on the improved AdaBoost algorithm can improve the final result significantly when the accuracy of each model is average. Therefore, the method can improve the recognition accuracy when multiple neural network models with general accuracy are obtained, thereby avoiding the complicated parameter adjustment process to obtain a single optimal network model.

## 1. Introduction

Aerobics is a kind of gymnastics, it is a kind of gymnastics that can change people's physical and psychological feelings. As an independent event, the sport joined the International Gymnastics Federation in September 1994. In recent years, with the call of the global fitness craze and happy sports, the recognition of aerobics has become more and more widespread. The development of fitness aerobics and competitive aerobics conforms to the trend of the times [1, 2]. The essence of aerobics is to let people enjoy the feeling of joy through the beauty of athletes' wonderful performances. This is a manifestation of high-grade spiritual civilization and wealth. It is precisely because of the fact that it attracts more people to participate.

The three-dimensional visual image of aerobics is the basis of human perception of the world and provides people with rich and diverse information [3]. People have a strong ability

to recognize the three-dimensional visual images of aerobics movements and are not even restricted by the sensory channel [4, 5]. People can not only recognize words with their eyes, but also when they write on the back of a person. Through the study of eye activity during the 3D visual image recognition of aerobics, it is found that changing the distance of the 3D visual image of aerobics and the position on the sensory organs will cause the size and shape of the 3D visual image of aerobics to change on the retina [6]. In the current 3D visual image recognition system for aerobics movements, the recognition of complex 3D visual images of aerobics movements can be realized mainly through different levels of information processing [7, 8]. For the familiar three-dimensional visual image of aerobics movements, once you have mastered its main features, you can use this main feature as a recognition unit without paying attention to its details [9]. The 3D visual image recognition of aerobics movements is an important application of artificial intelligence. Its main function is to compile

a computer program that imitates the human brain to recognize the three-dimensional visual image of aerobics movements, process the three-dimensional visual image of aerobics movements, and extract effective information from it to realize the recognition of people or things [10, 11]. The development process of 3D visual image recognition of aerobics movements has mainly experienced three stages: text recognition, 3D visual image information processing, and recognition of aerobics movements and object recognition [12]. Now some of the relatively mature aerobics 3D visual image recognition technologies have been applied to the commercial field [13]. Due to the diversity of problems in the process of 3D visual image recognition of aerobics movements, the methods of 3D visual image recognition of aerobics movements can only adopt different methods for specific problems [14]. Therefore, many recognition systems require a lot of research to improve the performance of breakthroughs on specific issues (such as improving the efficiency of recognition and reducing the time required for system training). The method of machine learning is a method that can get better recognition results on different recognition problems [15]. Relevant scholars have adopted sparse coding that is more suitable for the three-dimensional visual image representation of aerobics to identify and recognize the target object, instead of vector quantization coding that has a large loss of accuracy [16]. The 3D visual image recognition technology of aerobics has been continuously improved. But we have to say that there are still many unresolved problems. The quality of the 3D visual image of aerobics action determines the effect of 3D visual image recognition of aerobics action, and the effect of 3D visual image recognition of aerobics action of poor quality is not good [17, 18]. There are still many issues that need to be studied further [19, 20]. In general, the 3D visual image recognition of aerobics movements is an extremely challenging task. It is difficult to achieve the desired effect with only one method. How to improve the accuracy of the 3D visual image recognition of aerobics movements and reduce the algorithm complexity of the system and how to make it practical are all worth studying.

This paper improves on the mainstream convolutional neural network model VGG and builds a new CNN network model, which is called N-VGG. Combined with this model, a simple aerobics action three-dimensional visual image target positioning and recognition model is constructed. The activation function used in the traditional convolutional neural network model is analyzed, and a new activation function is introduced into the N-VGG network model. In the N-VGG network model, the spatial pyramid pooling technology (SPP) is introduced to improve the recognition accuracy of the model. This paper conducts multiple comparative experiments on convolutional neural networks and deep neural networks and shows that a single neural network can be adjusted with different parameters to improve its accuracy, but its parameter adjustment process is complicated and random. By comparing the experimental results of convolutional neural network and deep neural network fusion in single and different methods, it can be concluded that the model fusion method based on the improved AdaBoost algorithm can improve the neural

network's ability to improve the 3D visual image of aerobics movements to a certain extent.

The rest of this article is organized as follows. Section 2 studies the 3D visual image recognition technology and related algorithms of aerobics. Section 3 designs a convolutional neural network recognition model. In Section 4, simulation experiments and result analysis are carried out. Section 5 summarizes the full text.

## 2. Aerobics 3D Visual Image Recognition Technology and Related Algorithms Research

*2.1. 3D Visual Image Processing of Aerobics.* Aerobics 3D visual image processing refers to the use of a computer to process the 3D visual image of aerobics to be recognized to meet the subsequent needs of the recognition process. It is mainly divided into two types: aerobics 3D visual image preprocessing and aerobics 3D visual image segmentation. The preprocessing of 3D visual image of aerobics mainly includes restoration of 3D visual image of aerobics and transformation of 3D visual image of aerobics. Its main purpose is to remove the interference and noise in the 3D visual image of aerobics and enhance the 3D vision of aerobics. The useful information in the image improves the detectability of the target object. At the same time, due to the real-time requirements of the three-dimensional visual image processing of aerobics, it is necessary to re-encode and compress the three-dimensional visual image of aerobics to reduce the complexity and complexity of subsequent algorithms. The segmentation of aerobics 3D visual image is the process of segmenting the 3D visual image of aerobics to be recognized into several subregions. The features of each region have obvious differences, and the internal features of each region have certain similarities.

The method based on edge segmentation is to segment the 3D visual image of aerobics by detecting the area where the gray value of the pixel changes suddenly, or the place where the texture structure changes suddenly. The edge is usually located at the connection between two different areas. Because in a 3D visual image of aerobics action, the gray values of different areas are often different, and there will be obvious gray discontinuities at the junction of the two areas, that is, the edge. Because the gray value of each pixel at the edge is discontinuously distributed, differential or second-order differential can be used for detection. They calculate the first-order differential of the gray value of each pixel distributed in the edge area; then the pixel corresponding to the place where its extreme value appears is the edge point of the three-dimensional visual image of aerobics action. The gray value of a point is calculated for the second-order differential, and the pixel point with a differential value of zero is also the edge point of the three-dimensional visual image of aerobics. Therefore, the edge detection of the three-dimensional visual image of aerobics can be performed by the method of differential operators.

Because the Roberts differential detection operator uses an even number of templates, the gradient amplitude value at  $(x, y)$  is actually the value at the intersection shown in Figure 1, which is offset by the pixel from the real position, so

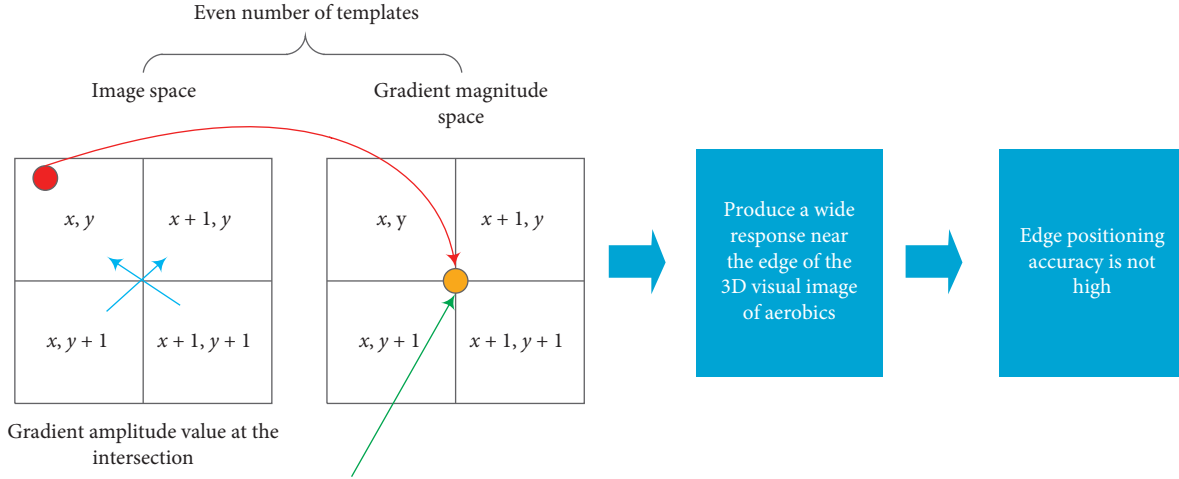

FIGURE 1: Schematic diagram of Roberts operator algorithm.

this method will produce a wider response near the edge of the 3D visual image of aerobics, and the edge positioning accuracy is not high.

### 2.2. Feature Extraction of the 3D Visual Image of Aerobics.

The feature extraction of the 3D visual image of aerobics is the key step in the three steps of 3D visual image recognition of aerobics. It refers to the 3D vision of aerobics that remains unchanged after the interference of factors such as scaling, translation, scale transformation, or illumination. Image information is extracted as features, and the three-dimensional visual image of aerobics is abstracted into some concrete mathematical representations or vector descriptions. The feature extraction of aerobics action three-dimensional visual image can be divided into global features and local features according to the different extraction ranges. The global features of the three-dimensional visual image of aerobics refers to all the features that describe the overall information of the three-dimensional visual image of aerobics, such as the color feature, shape feature, and texture feature of the three-dimensional visual image of aerobics. The local features refer to the partial features of the 3D visual image of aerobics movements in a specific area. It is only a representation of the local features in a certain area in the 3D visual image of aerobics movements. It is only suitable for matching the 3D visual image of aerobics movements.

The color histogram is the most widely used color feature in the 3D visual image retrieval of aerobics. It mainly uses the statistical distribution and basic tones of different colors in the entire 3D visual image of aerobics. It does not care about each color in aerobics. Each aerobics action 3D visual image can find its unique color histogram, so it is especially suitable for describing the 3D visual image of aerobics action that cannot be automatically segmented. The color histogram can be divided into two description methods: feature statistical histogram and feature cumulative histogram.

Suppose the total number of pixels in the three-dimensional visual image  $P$  of aerobics action with feature value  $x_i$  is  $s(x_i)$ , and  $N$  is the total number of pixels in the

three-dimensional visual image of aerobics action. The proportion of the total pixels in the 3D visual image is

$$h(x_i) = \frac{s(x_i)}{\sum_j s(x_j)}. \quad (1)$$

That is to say, the feature histogram with feature  $x$  in the three-dimensional visual image  $P$  of aerobics can be expressed as

$$H(P) = [h(x_1), h(x_2), h(x_3), \dots, h(x_{n-1}), h(x_n)]. \quad (2)$$

Among them,  $n$  represents the number of features  $x$ . The cumulative histogram with feature  $x$  in the three-dimensional visual image  $P$  of aerobics movements can be expressed as

$$u(P) = [u(x_1), u(x_2), u(x_3), \dots, u(x_{n-1}), u(x_n)]. \quad (3)$$

Therefore, the feature statistical histogram and feature accumulation histogram of the three-dimensional visual image of aerobics can be regarded as two one-dimensional discrete functions, that is, to obtain the probability distribution of a certain feature in the three-dimensional visual image of aerobics. The feature histogram is the probability distribution of the grayscale of the three-dimensional visual image of aerobics.

**2.3. Discriminant Deep Recognition Structure.** The main function of discriminative depth structure is to distinguish pattern recognition and describe the posterior probability distribution of data. Because CNN contains multiple levels of network structure, it can ensure the minimization of preprocessed data, rely on shared weights to reduce the complexity of the model structure, and use spatial relationships to reduce the number of parameters. It is a learning algorithm that can perform better training. Unlike the DBN network, it is a discriminative deep structure. The CNN algorithm model structure is mainly composed of convolutional layer, pooling layer, and fully connected layer, as shown in Figure 2. Using the CNN model structure to

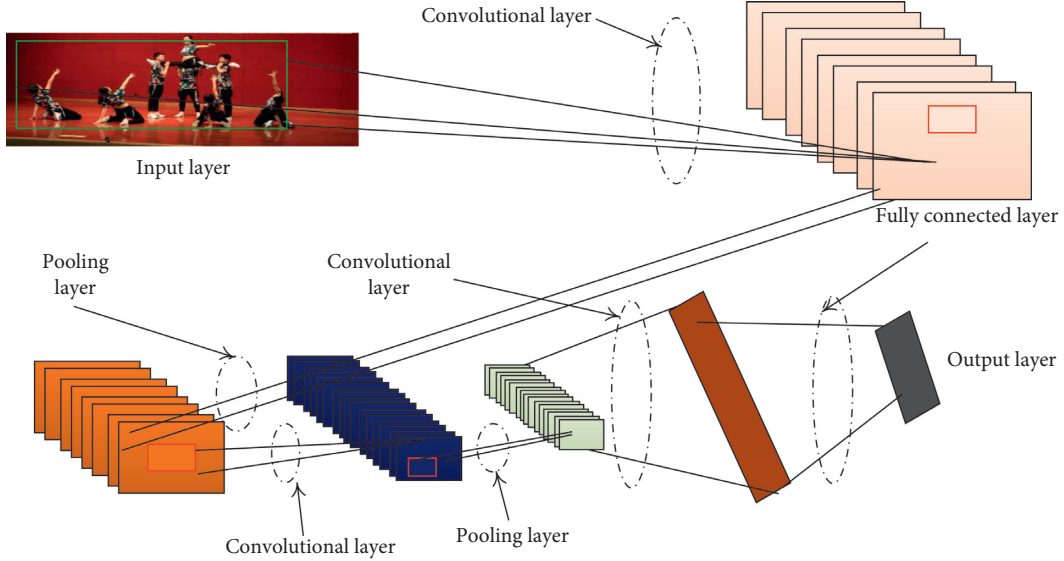

FIGURE 2: Model diagram of 3D visual image recognition of aerobics based on CNN.

process the three-dimensional visual image of aerobics can make full use of the two-dimensional structure of the three-dimensional visual image data of aerobics to perform good feature extraction on the three-dimensional visual image of aerobics. Therefore, compared with other deep learning models, CNN has a higher accuracy in the recognition of 3D visual images of aerobics.

CNN first convolves the input aerobics action three-dimensional visual image with the convolution kernel of the convolution layer and the bias that can be added. The basic mathematical expression of convolution in calculus is

$$S(t) = \int w(a) \cdot x(t-a) da. \quad (4)$$

The discrete form is expressed as

$$s(t) = \sum_a w(a) \cdot x(t-a). \quad (5)$$

For the two-dimensional convolution operation in the CNN network, the mathematical expression is

$$s(i, j) = \sum_m \sum_n w(m, n) \cdot x(i+m, j+n). \quad (6)$$

Among them,  $W$  is the convolution kernel in the convolution layer, and  $X$  is the input data. If  $X$  is a two-dimensional input matrix,  $W$  is also a two-dimensional matrix. If  $X$  is a multidimensional vector, then  $W$  is also a multidimensional vector. When the convolution layer performs a convolution operation on the input aerobics action three-dimensional visual image, it is the convolution kernel matrix and the input aerobics action three-dimensional visual image. The elements in each position of the different local matrix are multiplied and then added, but the operation is a kind of linear operation, while the neural network requires that each neuron in the network can adapt to complex nonlinear operations, which requires the introduction of nonlinear factors, namely, activation functions.

In the CNN model, there are multiple convolution kernels in the convolutional layer. After each convolution kernel performs the convolution operation, the feature map of the input aerobics action 3D visual image can be obtained. These feature maps share the same weight matrix and bias. After the convolution results are averaged, the 3D visual image of the characteristic aerobics action is output, namely,

$$Y_j = \frac{\sum_{i=1}^N X_i \cdot W_j}{N}, \quad (7)$$

where  $X_i$  represents the feature map extracted by the  $i$ th input,  $W_j$  represents the weight matrix of the  $j$ th convolution kernel,  $N$  represents the total number of input feature maps, and  $Y_j$  represents the output  $j$ th feature map.

After the 3D visual image of aerobics moves through the convolutional layer to obtain the feature map of the 3D visual image of the aerobics movement, it is sent to the pooling layer to aggregate and count each feature. The pooling layer is mainly responsible for the aggregation of the three-dimensional visual images of the characteristic aerobics actions, using statistical features to obtain the average or maximum value of the three-dimensional visual images of the aerobics actions in the characteristic area, and removing irrelevant feature samples to further reduce the number of parameters. The use of pooling operations on the continuous areas in the 3D visual image of aerobics can reduce the effect of translation, rotation, and other factors on the 3D visual image of aerobics and prevent overfitting.

The fully connected layer is the “recognizer” of the entire CNN network. Its main function is to map the feature representation after operations such as convolution and pooling to the corresponding sample label space. Its essence is to use several  $1 \times 1$  volumes. The product core performs convolution compression on the upper layer feature map, transforms the two-dimensional feature expression into a one-dimensional vector representation, and maps the original feature to each implicit semantic node.

### 3. Design of the Convolutional Neural Network Recognition Model

*3.1. Design of Activation Function.* One problem with the traditional activation function is the disappearance of the gradient. From the previous back propagation algorithm derivation process, it can be seen that when the error value is reverse gradient descent, it must be multiplied by the current input  $x$ -value. Taking the sigmoid function as an example,  $\text{Grad} = \text{Error} * \text{Sigmoid}'(x) * x$ . Both types of functions have the characteristic of double-ended “saturation”; that is, the value range is limited. If the derivative value is in the  $(0, 1)$  interval, the derivative value is scaled, and if the  $x$ -value is in  $(0, 1)$  or  $(-1, 1)$ , the saturation value is scaled. In this way, the error value in the propagation process of each layer is reduced at a double speed. After multiple recursive back propagations, the gradient continues to attenuate and disappear, making the process of network model learning gradually slow. This is the vanishing gradient problem caused by sigmoid-like functions.

At this stage, the most commonly used activation function in neural network models is ReLUs. This function was created in a restricted Bozeman machine and has been used extensively in neural network models. The ReLUs activation function is the parameter entity itself when the parameter is positive and has a value of 0 when the parameter is negative, and its positive gradient is 1, and only one end is saturated. Based on this feature, the ReLUs function has two main characteristics: one is that the neurons output from it are more sparse; the other is that it can reduce the problem of gradient disappearance to a certain extent.

However, ReLUs is a nonnegative function, and its output activation average value is greater than zero. The mean value of the neural unit is nonzero, and as the input of the next layer, there will be an offset difference. In this way, with the gradual accumulation, the higher the layer of neurons, the greater the offset difference. The effect of too large offset difference is to reduce the learning speed of the neural network model. Some solutions are to adjust the weight update during the gradient descent process, such as the SReLU's function.

In order to make the average output of neurons tend to 0 as much as possible, some variants of ReLUs activation function are produced. For example, the function Leaky ReLUs replaces the 0 value part of ReLUs with a linear function  $f(x) = ax$ , and other similar methods such as parameterized ReLUs and random leaky ReLUs approximate linear changes. Although the activation functions LReLU's, PReLU's, and RReLU's can make the average output of neurons 0, they still do not guarantee that neurons are in a noise-robust activation state.

*3.2. Design of Convolution and Pooling.* In the existing convolutional neural network model, the convolution operation is an indispensable operation, and there is no fixed requirement for the design of the convolution kernel size. In

general, the size of the convolution kernel is related to the “depth” design of the model. In the case of the same input size of the 3D visual image of aerobics, the larger the convolution kernel of each layer, the faster the size of the feature map will shrink. This paper proposes that the N-VGG network is based on the VGG network transformation, in which the fixed value of the convolution kernel is set to the size of  $3 * 3$ , and the moving step is 1. There are some feature maps at the edge of the  $3 * 3$  visual image of aerobics movements that cannot just meet the size of the  $3 * 3$  sliding window. At this time, a “patch” operation is required; that is, the last few pixels of the 3D visual image of aerobics movements are insufficient.

Existing convolutional neural network models generally use maximum pooling or average pooling. The difference between maximum pooling and mean pooling is the value of the function evaluation. There are also some pooling methods that are somewhat different in operation, such as overlapping pooling, which only sets the moving step of the sliding window to be smaller than the side length of the window. Therefore, adjacent pooling windows will have some overlapping areas, and the corresponding overlapping pooling generated features maps are also larger. Overlapping pooling can improve the recognition accuracy of CNN to a certain extent for the three-dimensional visual images of aerobics with tight final features. Here we introduce a new pooling method: Spatial Pyramid Pooling (SPP). The SPP pooling method utilizes the multiscale information of the pooled area and can solve the problem of different input sizes of the three-dimensional visual image of aerobics.

The SPP pooling method comes from a defect in the traditional CNN model; that is, the size of the input aerobics action 3D visual image in the traditional CNN model is fixed, and the 3D visual image of aerobics action of different sizes is usually scaled. The zooming operation will cause the distortion of the three-dimensional visual image of the aerobics action to a certain extent, which may lose some pixel spatial information, and the recognition accuracy of the model will be affected. SPP pooling can map different sizes of aerobics 3D visual images to the same feature dimension. Since SPP can process 3D visual images of aerobics movements of any size, it can also avoid the zooming operation of feature maps or original maps, which can reduce the information loss of 3D visual images of aerobics movements to a certain extent, thereby improving the 3D visual images of aerobics movements characteristic expression ability. The specific operation is relatively simple, as shown in Figure 3.

The feature map is pooled into three feature maps, corresponding to 1, 4, and 16 feature points. The middle connection layer contains 256 feature points. These 256 feature points and the previous 21 feature points are, respectively, fully connected, and after being fully connected, they are cascaded into a 5376-dimensional feature vector. We perform the next step on this feature vector. Spatial pyramid pooling is to map feature maps of different scales to feature vectors of the same dimension in this way.

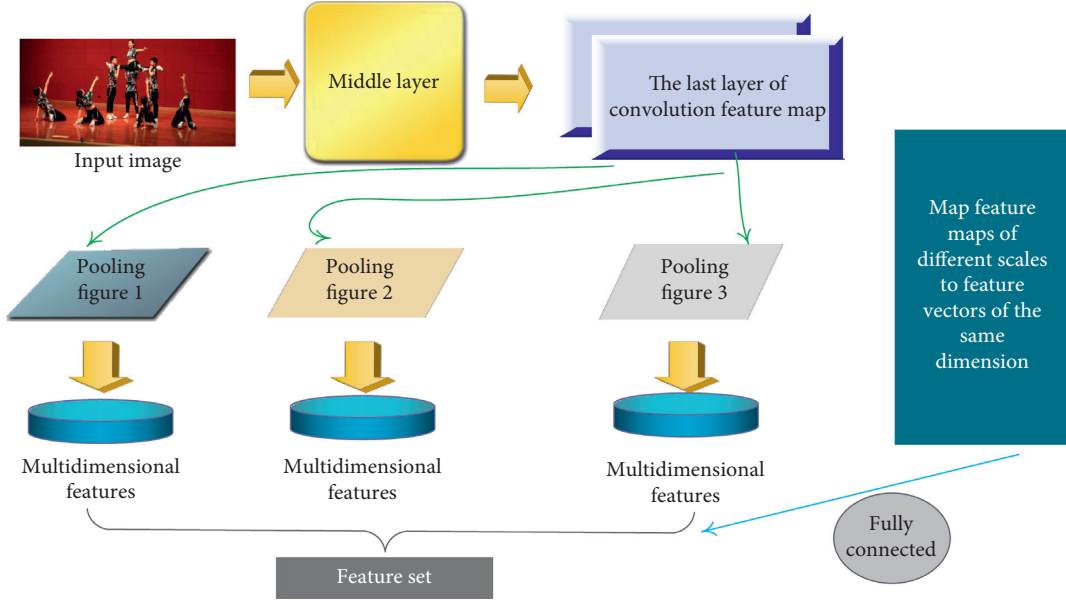

FIGURE 3: Schematic of spatial pyramid pooling.

3.3. *Recognizer Design.* Support vector machine is a very classic recognition algorithm in the field of machine learning. “Machine” in the field of machine learning usually refers to algorithms, and support vectors refer to variables that can affect decisions.

Suppose there are several training samples  $(x_i, y_i)$ , which can be separated by the hyperplane  $L3: wx + b = 0$ . At this time, the distance between  $L3$  and the closest sample point of the two categories is maximized. In the above linearly separable case, the parallel hyperplane line defining the support vector point is  $L1: w * x + b = 1$  and  $L2: w * x + b = -1$ , then the distance between the two is  $2/\|w\|$ ; at this time, the maximum identification interval is maximized; that is,  $\|w\|$  is minimized. At this time, all sample points are satisfied:

$$\begin{cases} x_i \cdot w \geq -b + 1, & y_i = 1, \\ x_i \cdot w < -b - 1, & y_i = -1. \end{cases} \quad (8)$$

At this point, the problem is equivalently defined as

$$\begin{aligned} & \min_{w,b} 0.5\|w\|^2, \\ & \text{s.t. } y_i(x_i \cdot w + b) > 1, \quad i = 1, 2, \dots, n-1, n. \end{aligned} \quad (9)$$

The above problem becomes a minimum value solving problem under several inequality constraints, that is, an optimization problem of convex quadratic programming. To construct the Lagrange function for the above problem, we get

$$L(w, a, b) = 0.5w^T \cdot w - \sum_{i=1}^n a_i \cdot y_i (x_i \cdot w + b - 1). \quad (10)$$

Among them,  $a_i$  is the Lagrange multiplier. According to the Lagrange duality theory, the dual problem of the original problem can be obtained. This problem can be solved by the SMO algorithm, and the solution of  $w$  can be obtained as

$$w = \sum_{i=0}^{n-1} a_i \cdot x_i \cdot y_i. \quad (11)$$

The decision function at this time is

$$f(x) = \text{sgn} \left[ \sum_{i=0}^{n-1} a_i \cdot y_i \cdot (x, x_i) + b \right]. \quad (12)$$

In this paper, the improved N-VGG convolutional neural network model based on the VGG network model is basically the same as the original VGG network model. The difference in the framework includes the introduction of the IRPN network at the last shared convolutional layer, which is used for model segmentation. The pooling layer after the convolutional layer is changed from the original maximum pooling layer to the spatial pyramid pooling layer.

In addition, inspired by the IRPN network, a bounding box regression layer is also introduced in the recognition layer. The function of the bounding box regression layer is the same as the bounding box regression method in IRPN. Its main function is to correct the bounding box of the target during the test phase. The bounding box regression at this time is the regression correction of the original target and the predicted target, so the loss function is

$$L(p, u, v, t^u) = L_{\text{loc}}(t^u, v) + L_{\text{cls}}(p, u). \quad (13)$$

The pooling of the SPP layer is performed on the cells after cutting. Considering that the pixel space of  $2 * 2$  cells is small enough, fully connected mapping is used for  $2 * 2$  cells. Here, only  $7 * 7$  and  $4 * 4$  cells are pooled in spatial pyramid. Among them, the size of the intermediate connection layer is changed to 179 dimensions. At this time, the dimension of the first fully connected layer is 4053.

## 4. Simulation Experiment and Result Analysis

*4.1. Convolutional Neural Network Aerobics 3D Visual Image Recognition Simulation.* By adjusting the configuration parameters of the convolutional neural network to improve the recognition accuracy of the network, we obtain relevant experimental data and analyze and discuss the ways and costs of improving the recognition results of the convolutional neural network.

Since the 3 data sets of the experiment are all grayscale images with small pixels, according to the principle of convolutional neural network, suppose the image size is  $n * n$ , the size of the first convolution kernel is  $c1 * c1$ , and the size of the downsampling area is  $s1 * s1$ ; the output feature map size after processing by the first convolutional layer and downsampling layer is  $o1 = (n + 1 - c1) / s1$ . The division operation also needs to be divided. Therefore, in order to ensure that the convolution kernel and sampling area have the appropriate size, the designed convolutional neural network has only 2 convolutional layers and 2 downsampling layers. A small number of network layers can also prevent the back-propagation algorithm from transmitting the error update value from back to front without becoming too small due to too many layers. The final fully connected layer will be adjusted for the number of categories of different data sets.

In the training method of the convolutional neural network, this experiment uses the BP algorithm for training; that is, first, we randomly initialize the convolution kernel matrix and then update the convolution kernel according to the error between the training result and the real result. Different from the BP algorithm, this experiment uses a method called min-batch for iteration. This method does not calculate the error of all training samples and update the weight parameters in each iteration; instead, the training samples are divided into multiple blocks. (Batch); each iteration only trains a sample of one block and adjusts the weight according to the error of the sample of the block. Since the weight update is performed for some samples, the learning rate can be increased appropriately to increase the update range of the weight on the partial samples, so that it can quickly adapt to all samples. Training the training samples in blocks helps to speed up the update speed of weights and improve training efficiency. The network structure (6, 5) – 2 – (12, 5) – 2 shows that the convolutional neural network has a total of 2 convolutional layers and 2 downsampling layers. There are 6 convolution kernels in the first convolutional layer. The size of each convolution kernel is  $5 * 5$ , and the size of the first downsampling area is  $2 * 2$ ; there are 12 convolution kernels in the second convolution layer, and the size of each convolution kernel is  $5 * 5$ . The size of the two downsampling areas is  $2 * 2$ .

Some parameters of the convolutional neural network are adjusted to obtain network configurations with different structures. Experiments were performed on these network models with different configurations to obtain experimental results. We conducted a total of 10 sets of experiments. Figure 4 shows the test results of the convolutional neural network on the aerobics dataset.

The convolutional neural network is trained in the min-batch method, and each block has a size of 50, which means 50 training samples are included. Before the experiment, the

training samples were randomly shuffled to ensure that the sample distribution in each block is random. The training data set has a total of 80,000 samples, and parameter updates are performed after each block is trained. Therefore, a total of  $80,000 / 50 = 1600$  parameter updates are required for one iteration. Figure 5 is the training error graph of experiment 1.

It can be seen from the error curve in Figure 5 that the min-batch method of training makes the error of the network model fluctuate, but all are within a certain range. Because the update parameters are performed after each small sample of training, the sample is not global, so it is not ruled out that there may be jitter when the error drops, but the error is still acceptable from the overall situation.

The network parameters used in experiment 1 and experiment 2 are exactly the same; the only difference is the sampling method. Experiment 1 uses mean sampling; experiment 2 uses maximum sampling. Experiment 2 is more advantageous in terms of efficiency. Because only the maximum value is taken, experiment 2 avoids the mean value calculation process. If the sampling area is large, the running time advantage of experiment 2 will be more obvious. And the maximum value sampling can well represent the difference of the data in the sampling area, reflect the most characteristic data in the area, reduce information loss, and improve the recognition accuracy. Therefore, in experiments 2 to 10, maximum sampling is used.

Experiments 2, 5, and 6 used 3, 6, and 12 convolution kernels in the first convolution layer when the size of the convolution kernels was the same. As the running time becomes longer, the experimental results are not gradually improved. The specific relationship is shown in Figure 6.

It can be seen from Figure 6 that when the size of the convolution kernel is constant, the recognition accuracy shows a wave trend as the number of convolution kernels increases. This shows that the increase in the number of convolution kernels is beneficial to the extraction of more features, thereby improving the recognition effect. However, when a certain number of convolution kernels is reached, the recognition effect is not the highest. The reason is that the extracted features are so many that redundant noise is also extracted, resulting in an overfitting phenomenon, resulting in a reduction in the recognition result.

When the number of the first layer of convolution kernels is certain, increasing the size of the convolution kernel can improve the recognition result because the increase of the convolution kernel can enlarge the area of the extracted features, so that the associated features in the area can be better extracted. However, a too large convolution kernel will also cause a decrease in results because the expansion of the extraction area leads to a loss of information. The comparative experiments 2, 3, and 4 are shown in Figure 7.

Comparing experiments 3, 7, and 8, the network structures used by them are exactly the same, but experiment 2 is iterated once during training; experiment 7 is iterated 5 times, a total of  $1600 * 5 = 8000$  parameter updates; and experiment 8 iterates 50 times, a total of  $1600 * 50 = 80000$  parameter updates. Figure 8 shows the relationship between training time and recognition accuracy. According to the curve, we can find that increasing the training time in the first part can

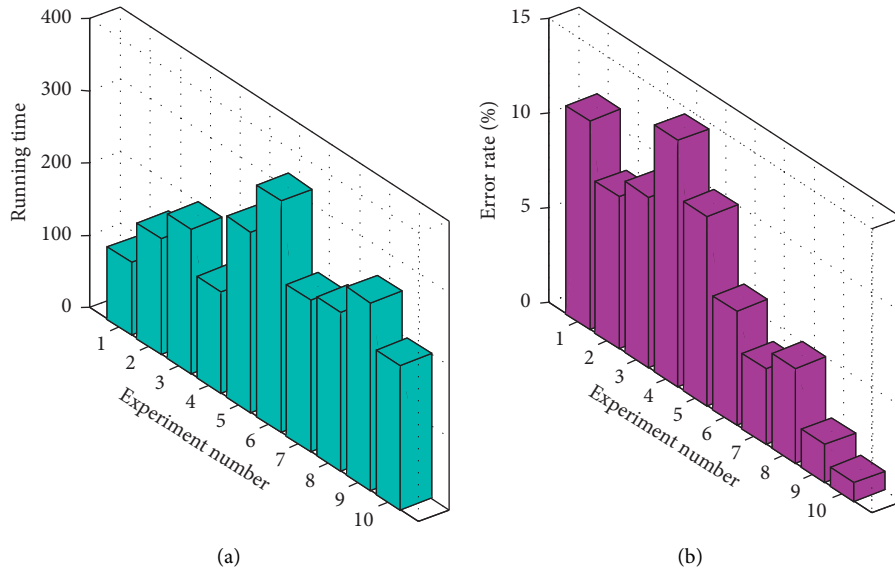

FIGURE 4: Test results of convolutional neural network on the data set. (a) Running time. (b) Error rate.

FIGURE 5: 3D visual image experiment of aerobics movement 1 training error.

FIGURE 6: The relationship between the number of convolution kernels and the recognition results.

effectively improve the accuracy of the model, but the accuracy of the latter part will increase slowly or even decrease. Therefore, increasing the training time does not produce a

significant improvement in accuracy. Due to the limitations of hardware conditions, this experiment did not conduct a higher number of iterations, but it is theoretically expected that as the number of iterations increases, the network may overfit the training data set, thereby affecting the results on the test data set.

**4.2. Deep Neural Network Aerobics 3D Visual Image Recognition Simulation.** The deep learning neural network designed in this section is based on an autoencoder, stacking multiple autoencoders, and the hidden layer of the previous encoder is used as the input of the latter encoder, thus forming a multi-autoencoder deep neural network. Because the hidden layer of the autoencoder extracts the potential features of the data, using it as the input of the subsequent autoencoder can further extract the features to obtain more abstract high-level features. The results of the 3D visual image recognition of aerobics by the deep neural network are shown in Figure 9.

By adjusting the structure and configuration of the deep neural network, we got the following experimental results. Figure 10 shows the test results of the network model on the data set.

Increasing the number of hidden layers can also increase the final accuracy to a certain extent, but the accuracy will decrease when it reaches a certain number. The reason for the analysis is that increasing the number of hidden layers means increasing the number of abstractions of shallow features, which makes the later features more advanced, thus improving the recognition results. However, the autoencoder used in the experiment will minimize the error when extracting features of each layer, but this does not mean that no error will be generated. The increase in the number of layers will lead to the accumulation of errors, so that the error will be reduced to a certain extent. According to Figure 11, we can observe that when the number of features

FIGURE 7: The relationship between the size of the convolution kernel and the recognition result.

FIGURE 9: Recognition result of 3D visual image of aerobics action by deep neural network.

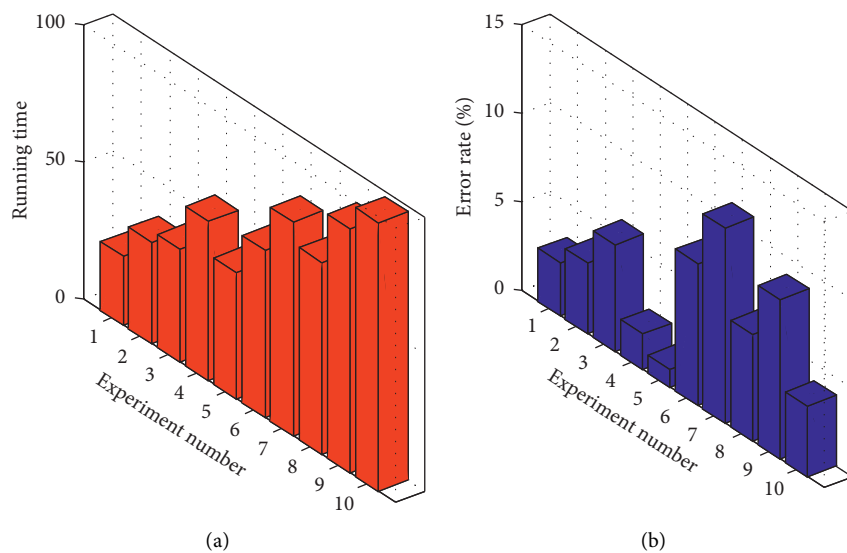

FIGURE 10: Test results of the deep neural network on the data set. (a) Running time. (b) Error rate.

FIGURE 11: Comparison of the number of hidden layers and the number of nodes of the autoencoder.

is relatively large, the increase in the number of hidden layers can significantly improve the recognition accuracy.

## 5. Conclusion

This paper, through the research of aerobics action 3D visual image recognition and deep learning technology, introduces in detail the aerobics action 3D visual image recognition and deep learning theory, summarizes the description of common algorithms for feature extraction, and elaborates common aerobics such as R-CNN. The action 3D visual image recognition algorithm model and performance indicators verify the performance of the algorithm model. This paper introduces a new activation function ELU to replace the traditional functions such as ReLU. In addition, the maximum pooling layer of the last layer of the N-VGG model becomes spatial pyramid pooling. We train an SVM recognizer in the test phase to compare the recognition performance of the softmax recognizer. Convolutional neural network and autoencoder-based deep learning neural network are used as experimental objects, and they are applied to the benchmark data set for recognition testing. By adjusting the network configuration parameters and conducting multiple comparison experiments, the accuracy of the neural network model is improved. In the experiment, the model fusion method based on the improved AdaBoost algorithm is implemented and the above neural network model is fused. By comparing the experimental results of the model, we conclude that the model fusion method based on the improved AdaBoost algorithm is not accurate in the fusion model. In the case, when there is only a high accuracy model, there is also an improvement, but the effect is not as obvious as the first case.

In the intelligent transportation system, the license information can be automatically recognized by the computer and the vehicle can be tracked. Red light running, illegal change of lanes, vehicle retrograde, and other illegal driving events are reasonably recorded. This is undoubtedly an effective help for the traffic police to relieve the huge work pressure. However, in China, a considerable number of vehicle tracking methods have certain limitations in resisting complex external environmental influences. The external environmental factors include but not limited to variable factors such as camera movement, jitter, and severe rain and snow. These factors cannot be controlled well, so the tracking accuracy is greatly reduced. In regard to this, this paper proposes an optimization method for moving vehicle tracking based on SPF. First, according to the size of the overlapping area of the motion area between the two images, the researcher can construct and simplify the vertex adjacency matrix that reflects the characteristics of the undirected bipartite graph. Then according to the corresponding relationship between the vertex adjacency matrix and the regional behavior and vehicle behavior, the researcher completes the regional behavior analysis and vehicle behavior analysis. On this basis, a particle filter vehicle tracking algorithm based on segmentation compensation is introduced, and the vector sum of the tracked segmentation area is used as the final position of the target vehicle. In this way, as many scattered particles fall on the target area as possible, which will greatly improve the efficiency of particle utilization, enhance tracking accuracy, and avoid the problem of tracking failure caused by too fast vehicle movement. Through experimental simulation, it can be seen that the method proposed in this paper can greatly enhance the vehicle tracking ability when tracking vehicles in “complex environments.”

## 1. Introduction

In the application of target tracking that involves getting close to people's livelihood, one of the most critical areas is vehicle tracking. Vehicles on the roads in China have gradually transitioned from being dominated by bicycles to being dominated by automobiles with the continuous improvement of related technologies in the industry and the great optimization of residents' quality of life. Family ownership of cars is about to leap forward, and more and more families own their own cars, making road traffic more and more burdensome. On the other hand, urban construction has been finalized, and roads in the city have nowhere to be repaired. The limited number of roads corresponds to the increasing number of cars, causing frequent traffic accidents. These problems put forward more stringent

requirements on road traffic management and gradually formed the concept of an intelligent transportation system. Intelligent transportation can use the sensitivity of the computer to identify the information of passing vehicles and record the route of the vehicle in real time. In this way, any traffic violations such as running a red light, illegally changing lanes, and vehicles going backward will be recorded. It will greatly reduce the work pressure of traffic police, improve driving safety, and reduce traffic accidents.

Academic research in the field of vehicle tracking is very complicated. With the rapid development of information technology, video surveillance has penetrated into all areas of people's production and life and naturally attracted the attention of scholars from all over the world. There are many countries that have invested a lot of manpower, material, and financial resources to in-depth research and solved problems

in the field of vehicle tracking, which better promotes the rapid development of the transportation field. The 8<sup>th</sup> literature introduced the Kalman filter algorithm and related mathematical theories into the target tracking algorithm, which promoted the development of vehicle tracking technology during this period. However, this method is difficult to adapt to the weather, environment, and external light factors, which will lead to the problem of low vehicle tracking accuracy. The 9<sup>th</sup> literature made outstanding contributions in several aspects such as mean shift theory, probabilistic multihypothesis tracking, variable structure multimodel, and distributed target fusion, which had pushed the field of vehicle tracking forward. But this method was subject to fall into the optimal solution. The 10<sup>th</sup> literature proposed a vehicle tracking method based on feature extraction of vehicle edges. In this method, the target edge information was obtained by detecting the changing gray value, then the vehicle characteristics were proposed, and the tracking of the vehicle was completed on this basis. This method had high stability to external factors such as light. But there is a problem that tracking takes a long time.

For this reason, an SPF-based optimization method for moving vehicle tracking is proposed in this paper. Particularly for the background failure due to the influence of weather interference, changing the optical fiber and other dynamic factors on the background, according to the size of the overlapping area of the moving area between the two frames of images, this paper constructs and simplifies the vertex adjacency matrix reflecting the characteristics of the undirected bipartite graph. Then, according to the corresponding relationship between the vertex adjacency matrix and the regional behavior and vehicle behavior, a particle filter algorithm (SPF) based on segmentation compensation is proposed for the problem that the vehicle tracking model is easy to fall into the optimal solution [1]. During the process of tracking the target vehicle, this algorithm divides the target into multiple regions. Based on the local features of the selected target in these regions, if the tracked target is partially occluded or the shape changes, other regions of the target can be used instead of tracking, which can make the particle filter more accurate and applicable. Regarding the time-consuming problem of the vehicle tracking process, this paper adds the resampling calculation after calculating the weight of the particles. The particles are resampled according to the weight of the particles, and particles with small weights are deleted, which reduces the amount of calculation time.

## 2. Behavior Analysis of Moving Vehicles Based on Directionless Two-Part Graph

**2.1. Principles of Vehicle Behavior Analysis.** The directionless two-part graph is a very useful mathematical model, which has important applications in many scientific fields. The directionless two-part graph can be used to describe many problems, for example, “data allocation,” “work arrangement,” “time allocation,” and “personnel selection.” This paper combines the directionless two-part graph with the behavior analysis of the vehicle in the video and uses the

vertex adjacency matrix representing the directionless two-part graph to determine the behavior of the moving area. Besides, by combining the relationship between regional behavior and vehicle behavior, this paper completes vehicle behavior analysis. The overall flowchart of the algorithm is shown in Figure 1.

The biggest advantage of applying the directionless two-part graph to vehicle behavior analysis is that the method does not require high accuracy for moving target extraction. Even if the extracted moving regions are not continuous, vehicle behavior analysis can be performed.

**2.2. Vehicle Analysis Model Based on Directionless Two-Part Graph.** The directionless two-part graph is expressed by the vertex adjacency matrix, the essential meaning and function of the two are the same, but the vertex adjacency matrix can better reflect the association relationship of each area and is more suitable for programming. The following paper will introduce the basic principles and implementation of vertex adjacency matrix construction. The flowchart of vertex adjacency matrix construction can be seen in Figure 2.

On the basis of extracting the moving vehicle area, the researcher can transform the behavior analysis of the vehicle into the behavior analysis of the area. The behavior analysis of the region is obtained by analyzing the vertex adjacency matrix constructed below.

This paper extracts the moving area in each frame of the traffic surveillance video and replaces the original moving area with the smallest bounding rectangle of each area [2]. The change of the motion area between two adjacent frames of images can be defined as four behaviors: appearance, disappearance, merging, and decomposition, as shown in Figure 3. Figure 3(a) describes the three motion regions extracted in the frame as R1, R2, and R3; Figure 3(b) describes the three motion regions extracted in the first frame, denoted as R4, R5, and R6. From Figures 3(a) and 3(b), the relationship between the motion areas in two adjacent frames can be obtained intuitively, as shown in Figure 3(c). In Figure 3(a), part of R1 is decomposed into R5, and the other part is merged with R2 to form R4. R3 disappears because there is no associated motion area, and R6 is the newly appeared area in Figure 3(b).

The directionless two-part graph can describe the relationship between the motion areas in adjacent frames. Within the frame  $k - 1$  and  $k$  in the image, this paper takes the upper left vertex of each motion area as the vertex sets  $U = \{U_1, U_2, \dots, U_m\}$  and  $V = \{V_1, V_2, \dots, V_n\}$ , respectively. Each vertex represents a motion area; that is, the vertex set  $U = \{U_1, U_2, \dots, U_m\}$  corresponds to the motion area set  $Ru = \{Ru_1, Ru_2, \dots, Ru_m\}$  in the frame  $k - 1$ ; the vertex set  $V = \{V_1, V_2, \dots, V_n\}$  corresponds to the motion area set  $Rv = \{Rv_1, Rv_2, \dots, Rv_n\}$  in the frame  $k$ .

Each edge represents the association relationship ( $i = 1, 2, \dots, m; j = 1, 2, \dots, n$ ) between the motion regions  $Ru_i$  and  $Rv_j$  of adjacent frames, and  $E$  is the set of all edges in  $G$ . The vertex adjacency matrix  $A_{n \times m}$ , which is equivalent to the directionless two-part graph  $G(U, V, E)$ , can clearly describe the edge set  $E$ . In vertex adjacency matrix  $A_{n \times m}$ , row  $m$

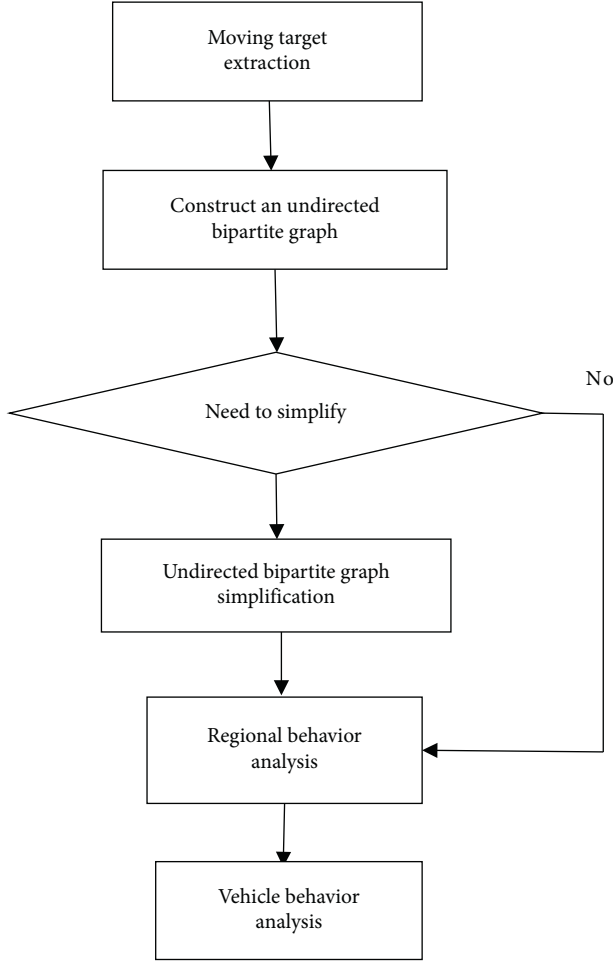

FIGURE 1: Flowchart of vehicle behavior analysis.

correspond to  $m$  vertices in vertex set  $U = \{U_1, U_2, \dots, U_m\}$ , that is, the  $m$  motion regions contained in the frame  $k-1$ ; the  $n$  columns correspond to the  $n$  vertices in the vertex set  $V = \{V_1, V_2, \dots, V_n\}$ , that is, the  $n$  motion regions contained in the frame  $k$ . Then the meaning of the element  $a_{ij}$  of the vertex adjacency matrix can be expressed as follows:

If  $a_{ij} = 1$ , it means that there is an edge between the vertices  $U_i$  and  $V_j$ ; that is, there is a correlation between the motion areas  $Ru_i$  and  $Rv_j$ .

If  $a_{ij} = 0$ , it means that there is no edge between the vertices  $U_i$  and  $V_j$ ; that is, there is no correlation between the motion regions  $Ru_i$  and  $Rv_j$ .

It can be seen from the above definition that whether or not there is a correlation between each motion area in the two images before and after determines the value of the vertex adjacency matrix element  $a_{ij}$ . The literature gives a method to determine the relationship between motion areas; that is, it is determined by calculating the overlap area between the motion areas  $Ru_i$  and  $Rv_j$ . The specific algorithm is shown in formula (1).

$$S(u_i, v_j) = \frac{\min(S(u_i), S(v_j))}{2} \quad (1)$$

In formula (1),  $S(u_i)$  represents the area of the motion area  $Ru_i$  in the frame  $k-1$ ,  $S(v_j)$  represents the area of the motion area  $Rv_j$  in the frame  $k$ ,  $S(u_i, v_j)$  represents the overlapping area of  $Ru_i$  and  $Rv_j$  in the motion area, and the relationship between  $S(u_i, v_j)$ ,  $S(u_i)$ , and  $S(v_j)$  is shown in Figure 4.

If equation (1) is satisfied between the movement areas  $Ru_i$  and  $Rv_j$ ,  $Ru_i$  and  $Rv_j$  are considered to be related,  $a_{ij} = 1$ .

If equation (1) is not satisfied between the movement areas  $Ru_i$  and  $Rv_j$ , then  $Ru_i$  and  $Rv_j$  are considered unrelated,  $a_{ij} = 0$ .

After constructing the vertex adjacency matrix according to the above algorithm, the behavior of the moving area can be analyzed through the simplification of the vertex adjacency matrix, and then the behavior analysis of the vehicle can be completed according to the conversion relationship between the area behavior and the vehicle behavior.

### 2.3. Optimization Analysis of Vehicle Behavior Based on Directionless Two-Part Graph

**2.3.1. Improvement of Directionless Two-Part Graph.** Theoretically, four behaviors such as merging, decomposing, appearing, and disappearing may occur in the motion area of adjacent frames. However, in a video stream with a sampling frequency of 25–30 frames/sec, the probability of simultaneous decomposition and merging of the same motion area is very small. This actual experience is reflected in the region relationship graph and vertex adjacency matrix and can be expressed as follows: the degree of the two vertices connected by each edge of  $G$  (i.e., the number of edges derived from each vertex) is at most one greater than or equal to 2. The sum of the number of “1” in the row and column where element  $a_{ij}$  is located cannot be greater than or equal to 2. So, in this paper, the edge with the degree of both vertices greater than or equal to 2 is called the interference edge, which will cause errors in regional behavior analysis. Therefore, before the regional behavior analysis, these interference edges must be removed by simplification of the directionless two-part graph.

In the actual surveillance video, there are noise interference and changes in the external environment. These factors will inevitably cause interference edges in  $G$ . And there may be multiple interference edges connected to a vertex, as for which one to delete, researchers need to follow the principle of simplification of the directionless two-part graph described below [3].

The improved logic of directionless two-part graph can be expressed as follows. First, by scanning the vertex adjacency matrix  $A_{m \times n}$ , the researcher records all interference edges, assuming that there are interference edges in  $M$  vertices. Then, for a certain vertex  $a_{ij}$  that has  $N$  interference edges connected to it, the researcher deletes  $l$  ( $l = 1, 2, \dots, N-1$ ) interference edges in turn to obtain  $C_N^1 C_N^2, \dots, C_N^{N-1}$  different subgraphs. In order to find the subgraph that is most consistent with the actual situation and define the matching function  $C$ , see the following

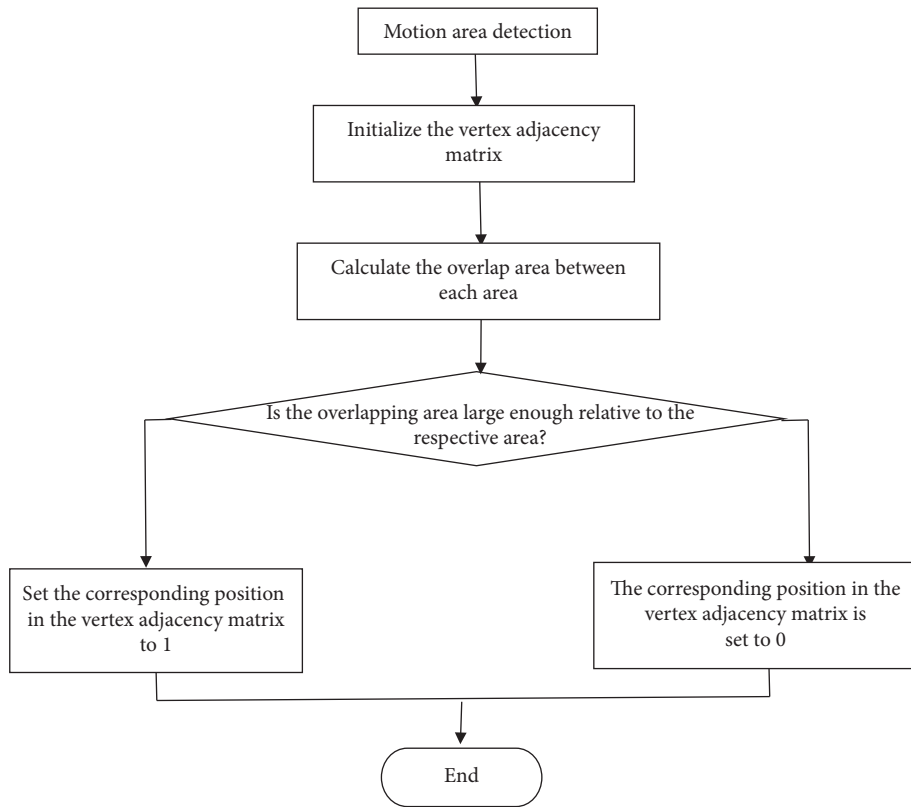

FIGURE 2: Flowchart of the construction of the vertex adjacency matrix.

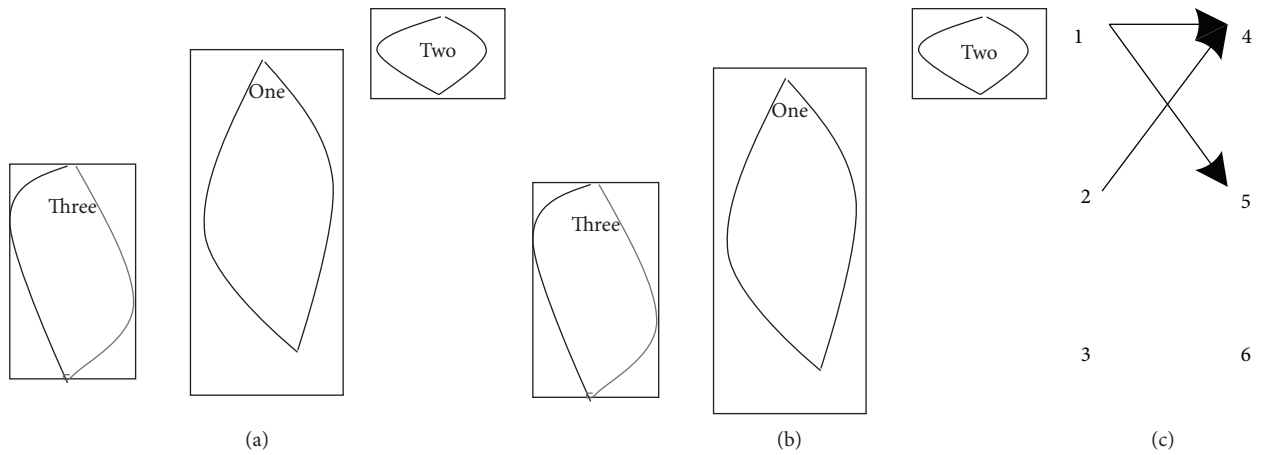

FIGURE 3: Four kinds of transformation in the region. (a) The area in frame  $k - 1$ . (b). The area in frame  $K$  (c). Correspondence between regions.

FIGURE 4: Calculation of the regions' relation.

formula (2); the researcher takes the subgraph with the smallest function value as the result of the vertex  $a_{ij}$ ; that is, deletes its interference edges according to the subgraph with the smallest function value and simultaneously updates the element values in the rows and columns of  $a_{ij}$  in the vertex adjacency matrix. In the same way, other vertices  $M - 1$  with interference edges also delete their interference edges and update the vertex adjacency matrix according to the same algorithm. When all  $M$  vertices are processed, the behavior of the motion area can be obtained according to the vertex adjacency matrix obtained by the simplification.

$$C(G) = \sum_{u \in P_k} \frac{|S(u_i) - A(u_i)|}{\max(A(u_i), S(u_i))}. \quad (2)$$

As for the directionless two-part graph, first, all vertices can be divided into “father vertices” and “subvertices.” The “father vertices” include all vertices with degree greater than 1 and degree equal to 0 in frame  $k - 1$  (the previous frame), and other vertices are “subvertices.” Assuming that the set of “father vertices” is  $P_k$ ,  $S(u_i)$  represents the area of the region  $Ru_i$  represented by the vertex  $U_i$  in the set  $P_k$ , and  $A(u_i)$  represents the sum of the areas of the motion regions represented by all vertices connected to the vertex  $U_i$ . Calculate the  $C(G)$  value of each subpicture, and take the subpicture with the smallest function value to describe the behavior of the motion area of the two adjacent frames [4].

Based on the above basic principles, the flowchart of the algorithm is shown in Figure 5.

**2.3.2. Vehicle Behavior Analysis.** Because there is a corresponding relationship between the vehicle and the moving area, the behavior analysis of the vehicle can be transformed into the behavior analysis of the moving area. However, there is not a simple one-to-one relationship between sports areas and vehicles. One car can correspond to multiple sports areas, and the same area may be shared by multiple vehicles. Table 1 summarizes the relationship between the features of the vertex adjacency matrix and the regional behavior and vehicle behavior.

From the vertex adjacency matrix, the logic of regional behavior and vehicle behavior can be expressed as follows. In the image of frame  $k - 1$ , assuming that the corresponding relationship between the vehicle and the moving region  $Ru_i$  is known, the final vertex obtained by simplification in the adjacency matrix  $A_{n \times m}$ , look for elements that meet the conditions in the first column of Table 1, then follow the rules in Table 1 to obtain the region behavior from frame  $k - 1$  to frame  $k$ , and then summarize the two-vehicle behavior between frames [5].

### 3. SPF-Based Vehicle Optimization Tracking

In the process of tracking a moving vehicle, because the vehicle is in constant motion, in addition to analyzing the behavior of the vehicle, it is also necessary to track it in real time. On the basis of understanding the relationship between the vertex adjacency matrix and the regional behavior and vehicle behavior, if the target is occluded during the

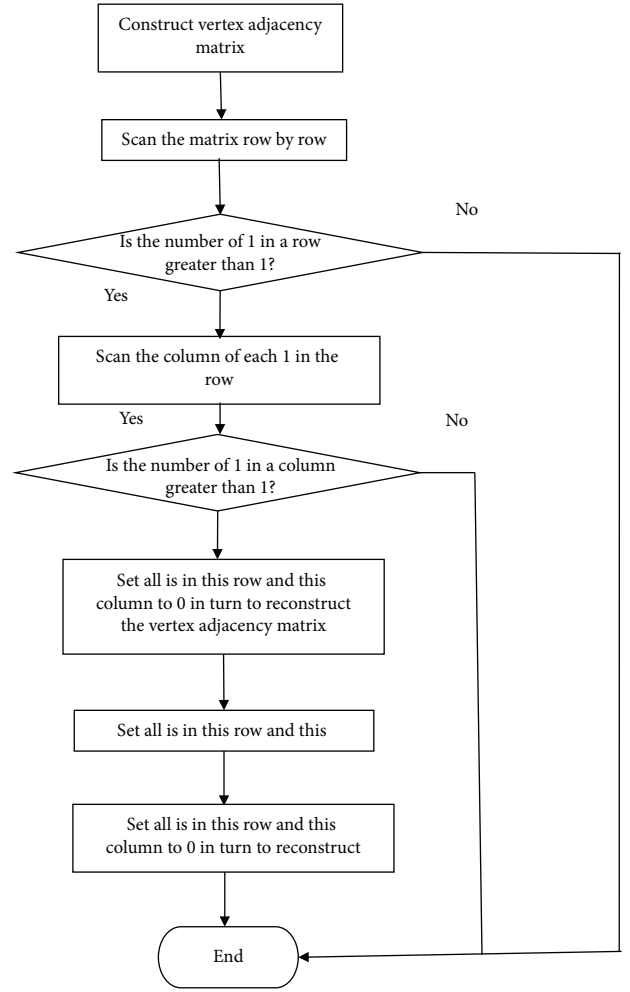

FIGURE 5: Flowchart of the simplification of the directionless two-part graph.

movement of the vehicle, it is necessary to grasp some unique characteristics of the vehicle itself. Tracking these features will achieve better tracking results.

#### 3.1. Moving Vehicle Tracking Based on SPF

**3.1.1. Principle of Particle Filter Algorithm.** As far as SPF and IPPF are concerned, they mainly extract effective tracking schemes by improving the correlation distribution on the standard particle filter. MC-JPDAF is the particle filter technology applied to the standard JPDAF, so as to effectively overcome the dimensionality problem by dividing the state space [6].

Based on Monte Carlo methods, the concept of standard particle filtering is proposed. It mainly uses particle sets to represent probability, which can be used in any form of state-space model. Its core idea is to express its distribution through random state particles drawn from the posterior probability, which is a kind of sequential importance sampling. To put it simply, the particle filter method refers to the process of approximating the probability density function by finding a set of random samples propagating in the

TABLE 1: Relation between the vertex adjacency matrix and the behaviors of region and vehicle.

| $a_{ij} = 1$ , exists $a_{hj} \neq 1 (h \neq i)$ | $Ru_i$ and $Ru_h$ merge into $Rv_j$         | Obstructed entry (area in frame $k$ , both $Ru_i$ and $Ru_h$ are single vehicles)  |
| $a_{ij} = 1$ , exists $a_{ih} = 1 (h > j)$       | Decompose $Ru_i$ into $Rv_j$ and $Rv_h$     | Split (area $Ru_i$ in frame $k$ is a single vehicle)<br>Occlusion separation (occlusion exists in area $Ru_i$ in the frame $k$ ) |

state space and replacing the integral operation with the sample mean to obtain the state minimum variance distribution. The sample here refers to the particle. When the number of samples is  $N \rightarrow \infty$ , any probability density distribution can be approximated.

The basic principle of Monte Carlo method is as follows.

In a high-dimensional space, it is required to solve the following integral:

$$I(f) = \int_x f(X)p(X)dX. \quad (3)$$

In the above formula,  $p(X)$  is a probability distribution,  $f(\cdot)$  is any integrable function of  $p(X)$  and satisfies  $f: X \rightarrow R^n$ ,  $N$  independently distributed random sample functions  $p(X)$  are drawn from the probability distribution  $\{X^{(i)}\}_{i=1}^N$ , and then the probability distribution function  $p(X)$  can be approximated by the sample functions of these independent distributions as

$$p_N(X) = \frac{1}{N} \sum_{i=1}^N \delta(X - X^{(i)}). \quad (4)$$

Among them,  $\delta(X - X^{(i)})$  is the Dirac-Delta function, so the integral formula to be solved can become the following summation problem:

$$I_N(f) = \frac{1}{N} \sum_{i=1}^N f(X^{(i)}) \xrightarrow{N \rightarrow \infty} I(f) = \int_x f(X)p(X)dX. \quad (5)$$

This transformation from integration to addition is the Monte Carlo method. It is not difficult to conclude from the theorem of large numbers that  $I_N(f)$  is unbiased, and the Monte Carlo method converges to  $I(f)$ .

*Definition.*  $\sigma_f^2 \triangleq E_p(X)(f_2(X)) - I^2(f)$ , so the variance of  $I_N(f)$  is  $(\sigma_f^2/N)$ , and the following formula can be obtained from the central limit theorem:

$$\sqrt{N}(I_N(f) - I(f)) \xrightarrow{N \rightarrow \infty} N(O, \sigma_f^2). \quad (6)$$

If the probability distribution function  $p(X)$  obeys the Gaussian distribution, the random sample  $p(X)$  can be obtained directly through the sampling of  $\{X^{(i)}\}_{i=1}^N$ . However, in practical applications, in many cases  $p(X)$  does not satisfy the Gaussian distribution, so the Monte Carlo method can be used to solve this problem.

For discrete-time stochastic systems, in the known prior state distribution  $p(X_0)$ , the solution of  $p(X_{0:k}|Z_{1:k})$  can be obtained according to the Bayesian estimation method:

$$p(X_{0:k}|Z_{1:k}) = \frac{p(Z_k|X_k)p(X_k|X_{k-1})}{p(Z_k|Z_{1:k-1})} p(X_{0:k-1}|Z_{1:k-1}). \quad (7)$$

The posterior distribution  $p(X_{0:k}|Z_{1:k})$  can be solved by Monte Carlo method. In the case that the random process does not satisfy the Gaussian distribution, the mathematical expression of the posterior distribution is difficult to give intuitively, so it is difficult to directly obtain the posterior distribution. Defining  $q(X_{0:k}|Z_{1:k})$  is a conditional probability distribution that satisfies the non-Gaussian state, and it has a larger support set than the posterior distribution. Select  $N$  random samples from the recommended distribution to get a sample set  $\{X_{0:k}^{(i)}\}_{i=1}^N$ , which can get the following formula:

$$q(X_{0:k}|Z_{1:k}) = \frac{1}{N} \sum_{i=1}^N \delta(X_{0:k} - X_{0:k}^{(i)}). \quad (8)$$

Similarly, the expression of the posterior distribution can be written as

$$p(X_{0:k}|Z_{1:k}) = \frac{p(X_{0:k}|Z_{1:k})}{q(X_{0:k}|Z_{1:k})} q(X_{0:k}|Z_{1:k}) = \sum_{i=1}^N w_k^{(i)} \delta(X_{0:k} - X_{0:k}^{(i)}). \quad (9)$$

Among them,  $w_k^{(i)} = (\tilde{w}_k^{(i)} / \sum_{i=1}^N \tilde{w}_k^{(i)})$  is the normalized sample, which meets

$$\tilde{w}_k^{(i)} \propto \frac{p(X_{0:k}^{(i)}|Z_{1:k})}{q(X_{0:k}^{(i)}|Z_{1:k})}. \quad (10)$$

From the above mathematical reasoning, it can be seen that, in the non-Gaussian case, the posterior probability  $p(X_{0:k}^{(i)}|Z_{1:k})$  can be approximated by a set of random samples  $\{X_{0:k}^{(i)}, W_k^{(i)}\}_{i=1}^N$ . These random samples are called particles. The method of obtaining the posterior probability distribution through particle sampling is called importance sampling method.

When calculating the Bayesian state estimation, the above proposal distribution can be converted into a recursive form, with the following formula:

$$q(X_{0:k}|Z_{1:k}) = q(X_k|X_{0:k-1}, Z_{1:k})q(X_{0:k-1}|Z_{1:k-1}). \quad (11)$$

According to the Bayesian state estimation equation, the following formula can be obtained:

$$p(X_{0:k}|Z_{1:k}) \propto p(Z_k|X_k)p(X_k|X_{k-1})p(X_{0:k-1}|Z_{1:k-1}). \quad (12)$$

Put these two expressions into equation (12), it is not difficult to get

$$\begin{aligned} \tilde{w}_k^{(i)} &\propto \frac{p(Z_k^{(i)}|X_k^{(i)})p(X_k^{(i)}|X_{k-1}^{(i)})p(X_{0:k-1}^{(i)}|Z_{1:k-1})}{q(X_k^{(i)}|X_{0:k-1}, Z_{1:k})q(X_{0:k-1}^{(i)}|Z_{1:k-1})} \\ &= \tilde{w}_k^{(i)} \frac{p(Z_k^{(i)}|X_k^{(i)})p(X_k^{(i)}|X_{k-1}^{(i)})}{q(X_k^{(i)}|X_{0:k-1}, Z_{1:k})}. \end{aligned} \quad (13)$$

Adding a normalization factor to formula (13) can normalize  $\tilde{w}_k^{(i)}$ , so that, for the recursive Bayesian filtering problem,  $\tilde{w}_k^{(i)}$  can be rewritten as

$$\tilde{w}_k^{(i)} \propto \tilde{w}_{k-1}^{(i)} \frac{p(Z_k^{(i)}|X_k^{(i)})p(X_k^{(i)}|X_{k-1}^{(i)})}{q(X_k^{(i)}|X_{k-1}, Z_k)}. \quad (14)$$

In this way, the posterior probability  $p(X_k|Z_{1:k})$  can be approximately written as

$$p(X_k|Z_{1:k}) = \sum_{i=1}^N w_k^{(i)} \delta(X_k - X_k^{(i)}). \quad (15)$$

At this time, if the proposed distribution function is a state prior distribution, it can be derived as

$$q(X_k^{(i)}|X_{k-1}, Z_k) = p(X_k^{(i)}|X_{k-1}). \quad (16)$$

Bring the above formula into (15) is

$$\tilde{w}_k^{(i)} \propto \tilde{w}_{k-1}^{(i)} p(Z_k^{(i)}|X_k^{(i)}). \quad (17)$$

The process described above is the process of particle filtering. The entire process of particle filtering can be described as follows:

- (1) Initialization: at  $k = 0$ , according to the prior distribution  $p(X_0)$ , the initial particle set  $\{X_0^{(i)}, w_0^{(i)}\}_{i=1}^N$  is obtained, where  $w_0^{(i)} = (1/N)$ .
- (2) Sampling: for  $k = 1, 2, \dots$ , sample from the state transition probability relationship  $p(X_k^{(i)}|X_{k-1}^{(i)})$  to calculate a new particle set  $\{\tilde{X}_k^{(i)}\}_{i=1}^N$ .
- (3) Calculate the weight: calculate the weight  $\tilde{w}_k^{(i)}$  of the particle  $\tilde{X}_k^{(i)}$  according to  $\tilde{w}_k^{(i)} \propto \tilde{w}_{k-1}^{(i)} p(Z_k^{(i)}|X_k^{(i)})$ , and normalize the weight to obtain a new weight  $\{w_k^{(i)}\}_{i=1}^N$ .
- (4) Calculate the estimated state: according to the particle set  $p(X_k|Z_{1:k}) = \sum_{i=1}^N w_k^{(i)} \delta(X_k - X_k^{(i)})$  obtained in (17), the estimated state posterior

distribution can be calculated, and the state estimate is

$$\hat{X}_k = E(X_k) = \sum_{i=1}^N w_k^{(i)} \tilde{X}_k^{(i)}. \quad (18)$$

- (5) Resampling: according to the particle weight  $w_k^{(i)}$ ,  $N$  particles  $\{X_k^{(i)}\}_{i=1}^N$  are retrieved from the particle set  $\{\tilde{X}_k^{(i)}, w_k^{(i)}\}_{i=1}^N$ , and the new particle weight is  $(1/N)$ , thereby establishing a new particle set  $\{X_k^{(i)}, (1/N)\}_{i=1}^N$ .

**3.1.2. Particle Filter Sampling Method.** In the process of particle filtering, the sampling method of particles will greatly affect the performance of the algorithm. Therefore, choosing a good sampling method is the key to the success of the overall algorithm. The Markov chain-Monte Carlo sampling (MCMC) method is to sample a specific sample  $X^{(i)}$  from the proposed distribution  $q(X)$  and obtain the state probability in the state space of  $X$  Markov chain of distribution  $p(X)$  so that high-dimensional distribution, invariant distribution, and Gibbs distribution are sampled through Markov chain samples, and the method of random simulation of sampled samples is Markov chain-Monte Carlo Sampling method. This sampling method is widely used in many aspects of random simulation evaluation [7]. The more important and outstanding sampling method is the Metropolis-Hastings (MH) algorithm, which was first proposed by Metropolis and later improved and improved by Hastings on its basis. It becomes the current MH algorithm. Its sampling method is

$$p_a(X, \tilde{X}) = \min \left\{ 1, \frac{p(\tilde{X})q(X|\tilde{X})}{p(X)q(\tilde{X}|X)} \right\}. \quad (19)$$

$X$  is the current system state,  $\tilde{X}$  is the sample value obtained by sampling,  $p(X)$  is the invariant distribution of the Markov chain,  $q(\tilde{X}|X)$  is the recommended distribution, and  $p_a(X, \tilde{X})$  is the acceptance probability of the required Markov chain to transfer to  $\tilde{X}$ .

The flow of the M-H algorithm is briefly described as follows:

- (1) Initialization: give the initial state  $X^{(0)}$  of the system.
- (2) Sample extraction: according to the previous system status  $X^{(i-1)}$ , candidate samples are sampled from the recommended distribution.
- (3) Acceptance probability: calculate the acceptance probability  $p_a(X, \tilde{X})$  according to  $p_a(X, \tilde{X}) = \min\{1, (p(\tilde{X})q(X|\tilde{X})/p(X)q(\tilde{X}|X))\}$ .
- (4) Calculating the state transition: generate a uniform random number  $u$  on the distribution of  $[0, 1]$ , compare the acceptance probability with  $u$ , if it is greater than  $u$ , and complete the state transition, namely,  $X^{(i)} = \tilde{X}$ ; otherwise, do not transfer, namely,  $X^{(i)} = X^{(i-1)}$ .

**3.1.3. Solution to the Problem of Particle Degradation.** In the particle filter algorithm described above, after multiple recursive operations, it is likely that only a few particles have large weights, while the rest of the particles have small weights. There are many particles with these small weights, and they have very little impact on the overall particle filter. In the calculation process, they take up a lot of time and greatly increase unnecessary computing time. In extreme cases, there may be only a few particles with very large weights left, while the weights of a large number of other particles are close to 0. Scholars call this phenomenon the degradation of particles [8].

The phenomenon of particle degradation is due to the narrow support set of the particle's proposed distribution  $q(X_k|X_{0:k-1}, Z_{1:k})$  and the particle's posterior distribution  $q(X_k|Z_{1:k})$ , and there is only a small amount of overlap. In the sampling calculation, only a small number of particles are concentrated in the support. In this way, after Bayesian estimation, the weight of these particles becomes very small. After many times of this process, the weight of the particles gets smaller and smaller and finally approaches 0. Since its calculations have not changed, it still takes a lot of time. In order to solve the problem of particle degradation, Liu et al. proposed the concept of effective particle number and defined a relation:

$$T_s \approx \sum_{i=1}^k w_k \rho_k. \quad (20)$$

Since the above formula is more complicated to calculate, the following simple formula is often used instead of the above formula:

$$\hat{N}_{\text{eff}} = \frac{1}{\sum_{i=1}^N (w_k^{(i)})^2}. \quad (21)$$

The degradation phenomenon of particles makes the weight of only a few particles larger, and the accuracy of using a few particles to express the probability distribution is low. Therefore, the degradation phenomenon of particles greatly compromises the reliability of particle filtering. How to avoid particle degradation or how to improve particle degradation had become the focus of research by many scholars. The more effective and efficient algorithm is the resampling method. This method is to add the resampling calculation after calculating the particle weight and resample the particles according to the particle weight. Particles with small weights are deleted to avoid taking up a lot of calculation time, and particles with large weights remain. At the same time, in order to ensure the number of particles, the particles with large weights are divided, and multiple sampling algorithms are used. The sampling variance is  $\text{Var}(N_i) = N w_k^{(i)} (1 - w_k^{(i)})$ . In order to improve the effectiveness of sampling, the sampling variance must be reduced. At this time, system sampling can be used. It is a sampling method with a very small sampling variance.

The process diagram of particle resampling is shown in Figure 6 as follows.

Figure 6 clearly illustrates the whole process from particle generation to weight change and resampling, that is, the overall implementation process from the posterior probability  $p(x_{k-1}|z_{1:k-1})$  at time  $k-1$  to the posterior probability density  $p(x_k|z_{1:k})$  at time  $k$ . The black solid dots represent the particles in the particle filter, and its size reflects the relationship between the particle weights. The particle weight represented by the large black dot is greater than the particle weight represented by the small black dot. The researcher initially assumed that there are ten particles, and the weights of these ten particles are all equal to  $(1/N)$ . The curve in the figure above represents the distribution state of all particles. The particles passing through the peak have a greater weight than those passing through the trough.

- (1) After ten particles with equal weights have passed the first curve, the weights of the ten particles have changed correspondingly due to the different positions of the crests and troughs of the passing curves. The weight of the particle passing through the wave crest is larger, and the weight of the particle passing through the trough is relatively smaller. The schematic diagram of the particle weight at  $k-1$  shown in the figure above is obtained.
- (2) After step 1, the weights of ten particles have changed. At this time, the resampling algorithm is used to keep the particles with larger weights. Particles with small weights are discarded and no longer participate in calculations, reducing the amount of subsequent calculations and leaving the number of effective particles.
- (3) After step 2, the particles with larger weights are retained, and they are repeatedly sampled to ensure that the number of particles does not decrease after sampling, and it is still ten particles. And the weights of ten particles are the same as the initial ones, and the prior probability density of particle  $k$  is obtained.
- (4) The number of resampled particles and the weight of each particle are exactly the same as the moment  $k-1$ . At this time, ten particles are observed to obtain the posterior probability density of the particles, and the entire process of particle resampling is completed.

Through the above calculation, the influence of small weight particles on the filtering algorithm is well eliminated. On the premise of ensuring the diversity of particles, the researchers remove particles with smaller weights, which greatly improves the utilization of calculations and the accuracy of filtering.

The aforementioned algorithm to avoid particle degradation can be briefly described as follows:

- (1) Weight calculation: for the sampled particle set  $\{\tilde{x}_k^{(i)}, w_k^{(i)}\}_{i=1}^N$ , set the initial weight  $c_1 = w_k^{(1)}$ , and use this to calculate the cumulative weight  $c_i = c_{i-1} + w_k^{(i)}$ .

FIGURE 6: Schematic diagram of particle resampling.

- (2) Calculating the random number: calculate the uniformly distributed random number on  $[0, N^{-1}]$ , namely,  $u - U[0, N^{-1}]$ .
- (3) Resampling: for the range of  $j = 1: N$ ,  $u_1 = u + N^{-1}(j - 1)$ , if  $u_1 > c$ , then calculate the next weight; otherwise  $X_k^{(j)} = \tilde{X}_k^{(j)}$  and  $w_k^{(j)} = N^{-1}$ .

The flowchart of particle filtering is shown in Figure 7.

### 3.2. Vehicle Tracking Algorithm Based on Improved SPF

**3.2.1. Segmentation of Moving Vehicles.** Particle filter algorithm (SPF) is based on segmentation compensation [9]. In the process of tracking the target vehicle, this algorithm divides the target into multiple regions and selects the local features of the target from these regions. If the tracked target is partially occluded or morphologically changed during the tracking process, other areas of the target can be used instead of tracking, which can make the particle filter more accurate and applicable. After the target is located, the target to be tracked needs to be segmented, and the tracking frame is equally divided into the following nine regions as shown in Figure 8.

Similarly, segmentation methods such as  $2 \times 2$  or  $4 \times 4$  can also be selected, but  $2 \times 2$  segmentation has less effect on the segmentation of the target frame and loses the meaning of tracking frame segmentation. When the video resolution is not high, dense segmentation such as  $4 \times 4$  or even  $5 \times 5$

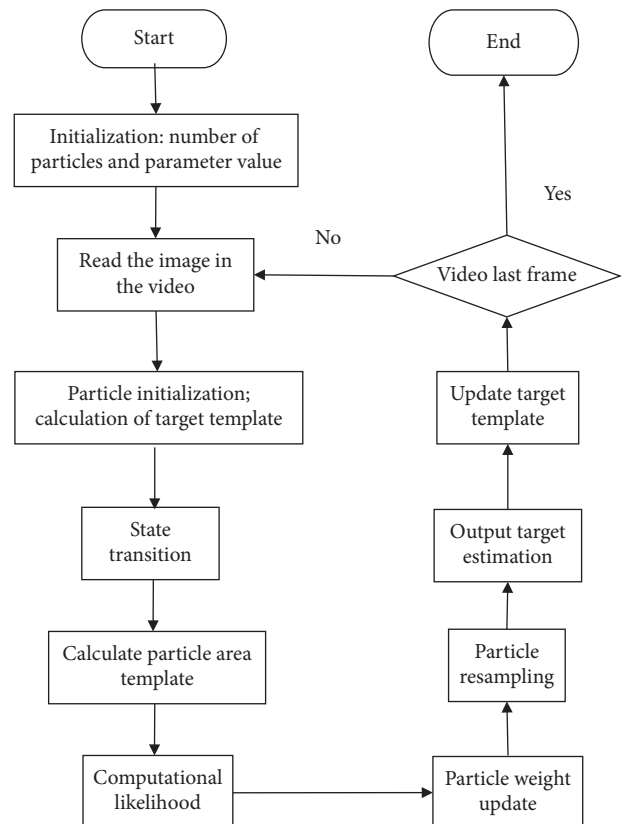

FIGURE 7: Particle filter target tracking flowchart.

FIGURE 8: Schematic diagram of target segmentation.

makes the resolution of the segmented area too small and fewer features are extracted from it, which is not conducive to the continuous tracking. The segmentation of the  $3 \times 3$  region selected in this paper is more practical and has no emphasis on the global average distribution. It can be applied to most target tracking situations, and the region with the best local features can be selected from these nine segments for vehicle track.

After the segmentation area is obtained, it is necessary to select a suitable segmentation area for tracking during the tracking process. For the 1-9 segmented regions defined in the above figure, the researcher defines the concept of segmentation adjacent. The adjacent bits of segment 1 are segment 2 and segment 4, and the adjacent bits of segment 5 are segment 2, segment 4, segment 6, and segment 8, and so on. After obtaining the relationship of adjacent bits, the selection rule for segmentation is defined as follows: the feature histogram of the segmented block and the feature histogram of adjacent bits are better if the Bhattacharyya coefficient is smaller. The Bhattacharyya coefficient is the similarity coefficient, which is defined as

$$\rho[\hat{p}(\hat{y}_0), \hat{q}] = \sum_{u=1}^m \sqrt{\hat{p}_u(\hat{y}_0) \hat{q}_u}. \quad (22)$$

The value range of its value is between 0 and 1, and the value of  $\rho$  reflects the similarity of the calculated two models. The larger the  $\rho$  value is, the higher the similarity of the two models. For the segmented region, the larger the  $\rho$  value of the adjacent bits, the higher the similarity between the two adjacent bits. In other words, the correlation is large and can be replaced by adjacent bits. Therefore, we take the segmentation area with a small  $\rho$  value, that is, the segmentation area with low similarity to the neighboring bits, and discard the segmentation area with a large  $\rho$  value.

After obtaining the segmentation area with small correlation, find the mean value of the Bhattacharyya coefficients of all the adjacent positions of the segmentation area; that is,

$$\rho_{\text{mean}} = \frac{\sum_i^k \rho_i}{k}. \quad (23)$$

For example, for segment 5, it is to find the Bhattacharyya coefficients of segment 2, segment 4, segment 6, and segment 8 and then add the sum and average.

After calculating the  $\rho$  values of all 9 segments, select the smaller segmentation area, and perform target tracking on the selected area.

*3.2.2. Motion Compensation for Segmented Areas.* Figure 9 is the particle distribution map formed by the segmented area at a certain time  $t$  during the vehicle tracking process. It can be clearly seen that the particles are distributed around the center of the segmented area.

The following figure shows the position A where the segmented area A moves at  $t + 1$  during the target tracking process. The particle distribution shown in the figure is still the particle distribution at time  $t$ .

Figure 10 shows the position where the segmented area A moves at  $t + 2$  during the target tracking process. The particle distribution shown in the figure is the particle distribution at  $t + 2$ .

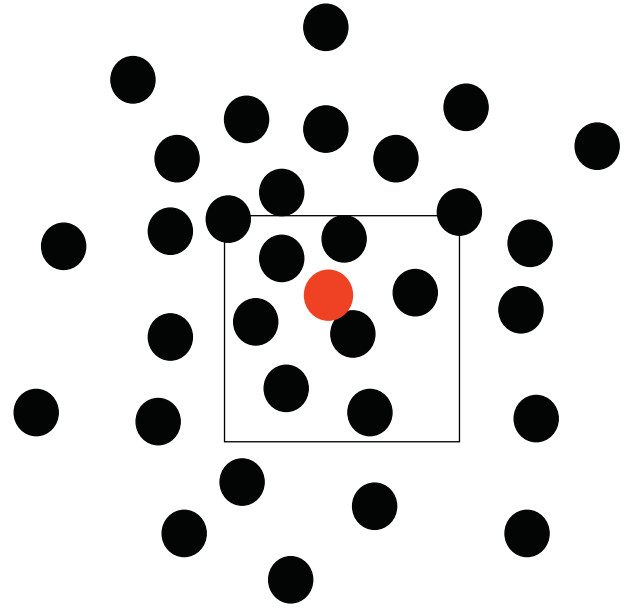

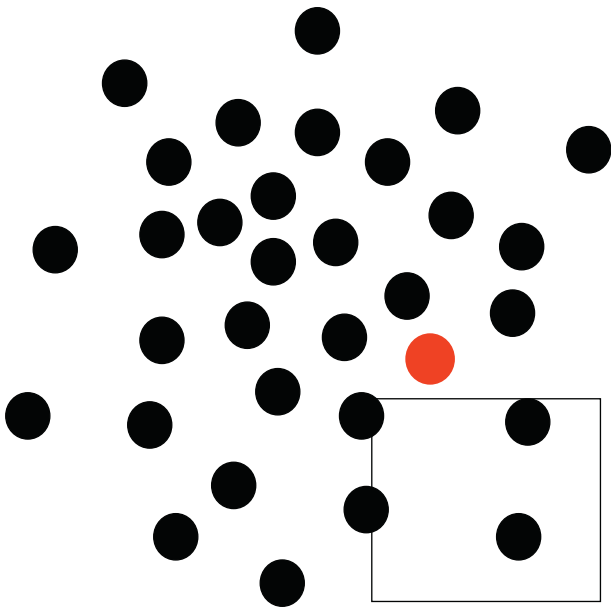

The situation in Figure 10 is exactly the same as that in Figure 11. Due to the faster movement of the segmented area, there are fewer particles at the location of the segmented area at  $t + 1$ , and the target is located at the position of the small red dot in Figure 11. At this time, if the researcher adds an offset to these particles to make the position of the particles shift to the direction of the target movement, the particles at  $t + 1$  can be shown in Figure 10, and the particle distribution at  $t + 1$  can be obtained. It is not the distribution centered on the position of the small red dot, but there is some deviation in the direction of the target movement, which is closer to the true position of the target in Figure 11. In this way, the segmented area tracked at  $t + 2$  after offset compensation is shown in (D).

Comparing the tracking frames in Figures 11 and 12, we can see that the target position is closer to the real one. The problem of tracking failure in Figure 10 does not occur.

The particle center is represented by the following formula:

$$P_p = P_p + \theta T_s. \quad (24)$$

$P_p$  represents the current position of the particle,  $T_s$  represents the movement displacement of the vehicle in the previous frame, and  $\theta$  represents the weighted value. The value of  $\theta$  is generally between 0.3 and 0.7 according to the movement form of the tracking target. In this paper, the median value is 0.5. In the application process, the particles scattered in the segmented area are added with an offset to improve the problem of large target positioning deviation caused by rapid target movement.

FIGURE 9: Particle distribution diagram at time  $t$ .FIGURE 11: Particle distribution diagram at time  $t + 2$ .FIGURE 10: Particle distribution diagram at time  $t + 1$ FIGURE 12: Particle distribution diagram at time  $t + 2$ .

### 3.2.3. Optimized Vehicle Tracking Based on SPF Algorithm.

Assume that the segmentation area with a smaller  $\rho$  value obtained in the previous section is segment 1, segment 5, and segment 9 and the center of the tracking frame is the black spot position, as shown in Figure 13.

Then, this paper uses the target tracking results of these three segmented regions to locate the overall target motion and obtains segment 1, segment 5, and segment 9 target tracking results as shown in Figure 14.

The final motion position of the target is the vector sum of segment 1, segment 5, and segment 9, which can be expressed by the following formula:

$$T_s \approx \sum_{i=1}^k w_k \rho_k. \quad (25)$$

$T_s$  represents the motion displacement of the overall target,  $\rho_k$  represents the motion displacement of the segmentation, and  $w_k$  is the weight of each segmentation. If there is no special target tracking situation,  $w_k$  can be set to the same value and the researcher only normalize the motion of all segmented regions. The final target tracking and positioning result is shown in Figure 15.

The advantage of such segmentation tracking is that, firstly, the segmented areas with greater correlation are eliminated, and they can be replaced with segmented areas

FIGURE 13: Schematic diagram of selecting partition area.

FIGURE 14: Schematic diagram of tracking results of segmented regions.

related to them, which reduces the amount of calculation accordingly. On the other hand, each small segmented area is equivalent to the target tracking of a small object, and the particle filter method is used to track it to ensure the accuracy of its tracking. In this way, the positive and negative errors of the target tracking result of the entire tracking frame obtained from the vector sum of the vehicle tracking results in a plurality of small segmented regions are offset, the tracking error is reduced, and the tracking accuracy is improved.

## 4. Test Analysis of Vehicle Tracking

*4.1. Comparison of Tracking Performance of Different Algorithms.* In order to verify the performance of the improved algorithm proposed in this chapter for vehicle

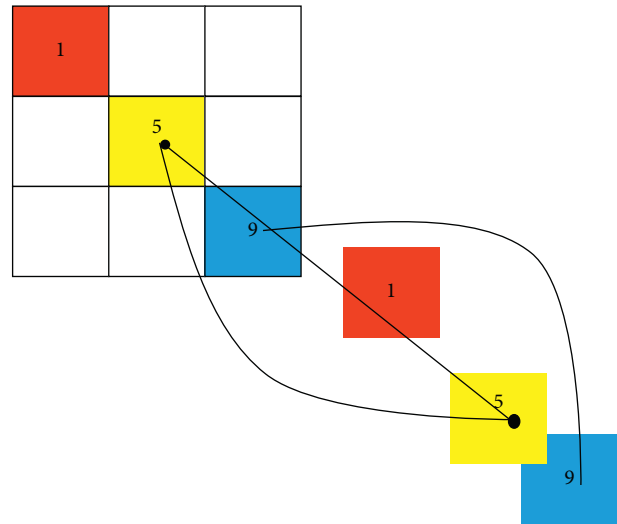

FIGURE 15: Schematic diagram of target tracking results.

tracking, this article uses the mainstream domestic Monte Carlo and convolutional neural network vehicle tracking algorithms to compare and first process the video 05 accident. The size of the video in Figure 16 is  $432 \times 240$ , and the number of frames is 125. This video is a video of a vehicle driving on a highway shot in a helicopter. In the video, a black car rolls over when it collides with another car while driving at a high speed. The tracking success rate, tracking accuracy, and algorithm time-consuming of the two algorithms are compared by tracking the target vehicle [10].

The tracking results of the three algorithms are shown in Figures 17–19, the red box represents the real tracking that passed the algorithm, and the blue box represents the false tracking that the algorithm failed to track.

The comparison results in the above figure can be divided into three sections to analyze:

- (1) Vehicle driving at high speed: Both Monte Carlo algorithm and SPF algorithm can accurately track vehicles, but SPF algorithm tracking is more accurate.
- (2) Vehicle collision: The tracked vehicle suddenly occludes and rotates, and at the same time, it is accompanied by the appearance of similar objects. The other two algorithms get wrong tracking results, while the SPF algorithm tracks accurately.
- (3) Vehicle out of control: Large-scale rotation and deformation of the vehicle. At this time, because similar vehicles leave the screen, the other two algorithms cannot track the target, the tracking frame turns blue, and the SPF algorithm still successfully tracks the target.

### 4.2. Analysis of Tracking Results

- (1) The vehicle is traveling at high speed: Both algorithms in the first segment of the video successfully track the target vehicle, but due to the high-speed movement of the target vehicle, the Monte Carlo

FIGURE 16: Original video frame.

FIGURE 17: The tracking results of the particle filter algorithm for segmentation compensation in this paper.

FIGURE 18: Monte Carlo tracking results.

FIGURE 19: Convolutional neural network vehicle tracking.

FIGURE 20: Comparison of vehicle offset distances with different algorithms.

TABLE 2: Average error comparison.

|  | Average error |
|--|---------------|
| Monte Carlo algorithm                  | 4.7204 pixels |
| SPF algorithm                          | 1.7354 pixels |
| Convolutional neural network algorithm | 3.6781 pixels |

algorithm is successful in tracking the target. The targets at  $t + 1$  are always scattered at the edge of the target area at  $t$ , leading to tracking deviation problems. In this case, there will be an error rate of tracking deviation of 4.7204.

This video has a total of 28 frames. The method in the previous section is used to compare the deviation between the target tracked by the three algorithms and the real target. The results are shown in Figure 20.

Table 2 also shows the advantages of the SPF algorithm proposed in this chapter in tracking high-speed moving vehicles, and the average error is reduced by 16.48%.

## 5. Conclusion

In regard to the road traffic environment, this article focuses on moving vehicle target tracking technology to complete the research. It is the future development trend to flexibly solve road traffic problems through intelligent transportation systems. Among them, the vehicle target tracking algorithm is one of the key technologies, which is also an important research direction of image processing and computer vision. Vehicle tracking technology is a subject that combines many advanced technological achievements such as image processing, pattern recognition, and automatic control.

The following innovations are worth noting:

- (1) Through the corresponding relationship between the vertex adjacency matrix and the regional behavior and vehicle behavior, this paper constructs the vertex adjacency matrix that reflects the characteristics of the undirected bipartite graph and simplifies the logic to complete the regional behavior analysis and vehicle behavior analysis.
- (2) By dividing the target area, this paper selects the local features of each part of the target and draws the conclusion. If the tracked target is partially occluded or changed in shape during the tracking process, other areas of the target can be used instead of tracking, which optimizes the accuracy and applicability of particle filtering.

In spectrum sharing cognitive radio networks, unauthorized users (secondary users) are allowed to use the spectrum of authorized users (primary users) to improve spectrum utilization. Due to limited spectrum resources, how to formulate a reasonable spectrum allocation scheme is very important. As a mathematical analysis tool, game theory can solve the problem of resource allocation well. In recent years, it has been applied to the research of resource allocation in spectrum sharing networks by some literatures. In a cellular network consisting of multiple cellular users and full-duplex end-to-end communication users D2D (device-to-device), the self-interference caused by full-duplex communication and the interference caused by the D2D users to the cellular users will significantly reduce system throughput. In order to reduce the interference in the network, this paper introduces a power control algorithm based on Stackelberg game, which sets the cellular users and D2D users as the leaders and followers, respectively. The cellular users and the D2D users compete with each other to minimize the cost, and we propose new utility functions. We build an optimization problem under the outage probability constraint and power constraint and the transmission power of the users is obtained by using the Lagrangian dual decomposition method. The simulation results show that the proposed game algorithm improves network performance compared with other existing schemes.

## 1. Introduction

With the rapid development of 5G technology, more and more mobile devices are required to access, making spectrum resources even poorer. The traditional spectrum sharing scheme is a static spectrum allocation mode. It is to allocate some fixed frequency bands to users of some specific networks. These specific users are authorized users (primary users). Users in networks that have not been allocated spectrum resources are unauthorized users (secondary users). In the past, these unauthorized users (such as Wi-Fi users) could only use a small number of users.

Crowded public open unauthorized spectrum, while most authorized frequency bands are sometimes idle (such as TV frequency bands). In order to improve the utilization rate of radio spectrum and make good use of radio spectrum

resources reasonably, a dynamic sharing scheme must be proposed to allocate radio spectrum resources more efficiently. Therefore, cognitive radio (CR) technology is proposed in this environment. As a new concept, cognitive radio technology promotes the development of wireless communication industry, improves the utilization efficiency of spectrum resources, and provides a brand-new idea for realizing the sharing of spectrum resources.

The high transmission rate of 5G cellular network can effectively promote the realization of Internet of Things (IoT) and smart city. However, the big data brought by the Internet of Things and smart cities may overload 5G cellular networks due to limited spectrum resources, and mobile communication networks gradually cannot meet people's exponential demand for wireless mobile data traffic. D2D technology can relieve the pressure of the upcoming core

network traffic and is considered as a promising way to solve this problem. D2D communication allows direct communication between devices without using base stations for relay, and the transmission distance of D2D pairs is short. Spectrum efficiency can be significantly improved through spectrum multiplexing of cellular users. Therefore, D2D communication has the advantages of reducing the network burden of cellular users, reducing the power consumption of mobile terminals, improving the robustness of network infrastructure, improving spectral efficiency and system capacity, reducing user network delay and power consumption, expanding network coverage, etc. D2D technology can be used in machine-to-machine communication, car-to-car communication, content distribution, location-aware services in smart cities, social networks, proximity online games, electronic health care, and public safety services. However, in order to realize D2D communication, several challenging problems need to be solved, such as equipment discovery, spectrum resource allocation, interference management, power control, communication security, etc.

With the popularization of the fifth-generation mobile communication network and terminal equipment, the requirement for high-speed transmission of the network is becoming higher and higher. Traditional LET network technology cannot meet the requirements of high communication services, especially high-speed services. Thus, device-to-device (D2D) mode of direct communication between close-range terminals and terminals has been proposed in this context. This communication mode shares spectrum resources with cellular users in cellular networks to improve the capacity and spectrum utilization of network systems. It has become one of the most popular research technologies recently. At the same time, simultaneous full-duplex D2D communication technology can support two communication devices to transmit and receive at the same frequency band in the wireless cellular network, and further improve the spectrum utilization [1]. However, how to reduce power interference among users is a key problem, such as D2D user interference, D2D user interference to cellular users, and D2D user self-interference.

## 2. Related Work

In order to solve the resource management problem in D2D cellular network, some non-cooperative or cooperative game theory schemes are proposed in [2–5], which are used to control the power problem of DD users and cellular users in D2D cellular network, reduce the interference between users, and maximize the capacity of users in the network. In addition, the convergence of user transmit power is also analyzed in this paper. However, these works basically only consider half-duplex D2D communication mode. Therefore, the scheme of user power control and interference management in D2D full-duplex communication mode is proposed in [6–8]. Literature [6] proposes a rate maximization model to improve the total rate of full-duplex D2D communication network and minimize the interference of D2D users to cellular users. In [7, 8], a power optimization scheme

is proposed to maximize the total rate of cellular subscribers and D2D pairs in the presence of two directional interference. In addition, the paper [9, 10] proposes an efficient adaptive user power control scheme, which further reduces the interference between users and improves the system performance. In document [11], in order to reduce user interference, an interference cancellation scheme of cell network selection model is designed. However, most of the existing work neglects studying the power control of multiple cellular users and multiple D2D users in full-duplex D2D communication networks. In addition, the user's requirement for interruption probability has not been taken into account in the establishment of the model. Although reference [3] considers the interruption probability constraints of the network, it only considers the half-duplex communication mode, and its utility function does not consider the network power saving in order to maximize the network throughput. Zulhasnine et al. proposed a greedy algorithm based on the maximum throughput of the system and proposed an optimization strategy from two aspects of D2D communication users multiplexing the uplink and downlink resources of cellular users. The allocation problem of D2D to users' cell radio resources was summarized as a mixed integer nonlinear programming problem [12]. Min et al. proposed a D2D mode selection scheme for users in downlink, which reduced the interference between communication users [13]. Yu et al. proposed a joint mode selection and resource allocation algorithm, which achieves the effects of maximum capacity and minimum communication interference of the communication system [14]. Xiao et al. studied the algorithm of D2D on the transmission power of users and cellular users and proposed a scheme to adjust the transmission power of users under different communication modes to control the interference between communication users [15]. Hassan et al. proposed a two-stage resource allocation algorithm to minimize system interference while maintaining the total rate of the target system. Firstly, a weighted two-part matching algorithm is used to minimize interference and obtain a feasible initial solution, and then local search technology is used to improve the solution [16]. Nguyen et al. and others studied from the geographical location of the cell where the users are located, established communication restricted areas according to the interference between users, and implemented different communication mode strategies in different areas, thus improving the overall communication quality of the system [17]. Ningombam and Shin proposed a radio resource allocation and power control scheme to reduce D2D interference to multiplexed uplink cellular resources [18]. A radio resource allocation scheme is proposed by using a cell sectorization method to reduce interference in D2D communication of LTE-A uplink cellular network. Jaheon et al. proposed a scheme combining resource allocation and power control. The scheme firstly coordinates the interference introduced by D2D to a certain extent by allocating reasonable multiplexing resources for D2D users and appropriately adjusts the transmission power of D2D users to ensure controllable cellular link interference [19]. Fodor et al. proposed a solution to share spectrum resources

between cellular mobile devices and D2D, thus improving the spectrum efficiency and energy efficiency of traditional cellular networks [20]. Doppler et al. explained the session and management mechanism of D2D communication and how to limit the interference of D2D communication to cellular networks [21]. Kim et al. proposed a D2D link radio resource allocation strategy for interference between D2D users and cellular users [22]. Li et al. proposed a radio resource allocation scheme to minimize the interference between communication users [23, 24], aiming at the interference problem generated in the communication system where D2D communication users coexist with cellular users and D2D technology is combined with Multi-User Multiple-Input Multiple-Output (MU-MIMO) technology.

Therefore, this paper proposes a power control algorithm for multiple cellular users and D2D users in full-duplex D2D communication with channel interruption constraints based on Stackelberg game. Considering the interference and self-interference in two directions among D2D users, we set cellular users and D2D users as leaders and followers, respectively. Cellular users and D2D users compete with each other to minimize their cost effectiveness (network power consumption), and propose a new utility function. Under the condition of channel interrupt constraint and power constraint, the optimization problem is constructed, and the transmission power of users is obtained by using Lagrange dual decomposition method. The simulation results show that the proposed game algorithm improves network throughput and reduces bit error rate. The second part introduces related work; the third part introduces the system model; the fourth part introduces the Stackelberg game theory method; the fifth part introduces the Stackelberg game solution; the sixth part introduces simulated experimentally.

### 3. System Model

The system model of cellular network is shown in Figure 1. A single base station is located in the cell center of the network. It has  $K$  cellular users. Cellular users have the priority to use the base station to allocate the channel.  $M$  D2D user's pair and D2D users pair are allowed to share the communication channel of cellular users, and D2D users adopt full-duplex communication mode. Suppose each D2D user has two antennas, one for transmitting signals and the other for receiving signals. Define the path loss and multipath fading channel coefficients of the cellular subscriber  $K$  and its receiver between the base stations as  $L_{mk}$  and  $h_{kk}$ ; for the path loss and multipath fading between the  $m$ -th D2D user pair and the  $k$ -th cellular subscriber and the base station, respectively, the channel coefficients are  $L_{mk}$  and  $h_{mk}$ , respectively; the path loss and multipath fading channel coefficients between the  $m$ -th D2D pair are  $L_m$  and  $h_{mm}$ ,

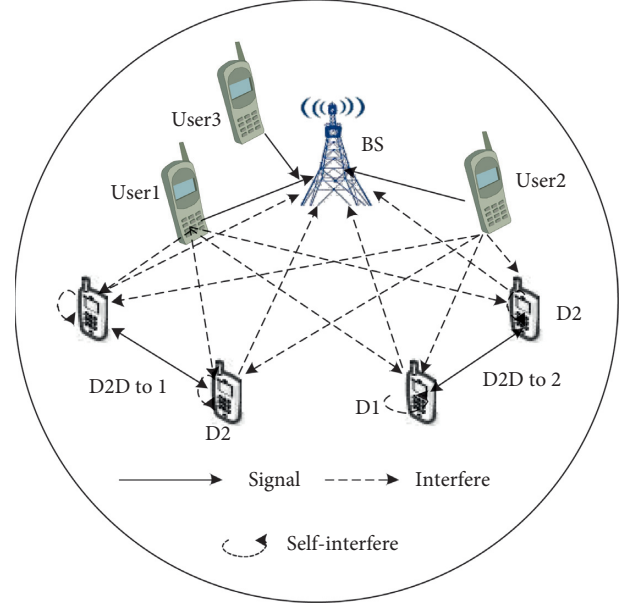

FIGURE 1: Cellular network model.

respectively, and for the path loss and multipath fading channel between the  $m$ -th D2D pair and the  $i$ -th user, the coefficients are  $L_{im}$  and  $h_{im}$ , respectively. The fading coefficient obeys the  $CN(0, 1)$  independent Gaussian distribution. Cellular user  $k$  has a transmit power of  $P_k$ . On the  $k$ -th cellular user channel, the powers of the first user (D1) and the second user (D2) of the  $m$ -th D2D pair are  $p_m^k$  and  $\alpha_m p_m^k$ , respectively, where  $\alpha$  is defined as the coefficient of the transmit power between D1 and D2. We assume that each cellular user transmits simultaneously on a single channel and that each cellular user's channel can simultaneously transmit all D2D pairs to the user.

The signal-to-interference and noise ratio (SINR) received by the  $k$ -th cellular subscriber at the base station is defined as

$$\gamma_k = \frac{p_k L_k |h_{kk}|^2}{\sum_{m=1}^M (1 + \alpha_m) p_m^k L_{mk} |h_{mk}|^2 + N_0}, \quad (1)$$

where  $L$  represents the path loss factor and  $L = d^{-3}$ , where  $d$  represents the distance between the user's transmitter and receiver, and  $N_0$  represents the noise power.

Since the current self-interference suppression technology cannot completely eliminate self-interference [9], the power of residual self-interference is defined as  $p_{SI} = \eta p$ , where  $p_{SI}$  is the power of residual self-interference,  $\eta$  ( $0 \leq \eta \leq 1$ ) is the cancellation coefficient of self-interference, and  $p$  represents the transmitting power of the transmitting end. On the  $k$ -th cellular user channel, the SINR received by D2 is defined as

$$\gamma_m^{k,D1 \rightarrow 2} = \frac{p_m^k L_m |h_{mm}|^2}{\sum_{i \neq m}^M (1 + \alpha_i) p_i^k L_{im} |h_{im}|^2 + \eta_{m,2} \alpha_m p_m^k L_{m,SI} |h_{m,SI}|^2 + p_k L_{km} |h_{km}|^2 + N_0}, \quad (2)$$

where  $L_{m,SI}$  and  $h_{m,SI}$  represent the self-interference path loss and fading channel coefficients of the  $m$ -th D2D pair to the user, respectively. Similarly, we can get the SINR of D2 to D1 on the  $k$ -th cellular user channel as  $\gamma_m^{k,D_2 \rightarrow 1}$ .

When the cellular user  $K$ 's SINR value is lower than the threshold  $\bar{\gamma}_k$ , its communication will be interrupted, and the cellular user's outage probability  $P_{k,out}^C(p_k, \mathbf{P}_{-k})$  is expressed as [13]

$$P_{k,out}^C(p_k, \mathbf{P}_{-k}) = 1 - \exp\left(-\frac{\bar{\gamma}_k N_0}{P_k L_k}\right) \prod_{m=1}^M \left(1 + \frac{\bar{\gamma}_k (1 + \alpha_m^k) P_m^k L_{mk}}{P_k L_k}\right)^{-1}, \quad (3)$$

where  $\mathbf{P}_{-k}$  represents the power vector of the user other than the cellular user on the channel of the  $k$ -th cellular user. Since the cellular user  $k$  has the constraint  $\xi_k$  of the channel outage probability,  $P_{k,out}^C \leq \xi_k$ , it can be obtained by formula (3):

$$1 - \xi_k \leq \exp\left(-\frac{\bar{\gamma}_k N_0}{P_k L_k}\right) \prod_{m=1}^M \left(1 + \frac{\bar{\gamma}_k (1 + \alpha_m^k) P_m^k L_{mk}}{P_k L_k}\right)^{-1}. \quad (4)$$

Similarly, on the channel of the cellular user  $k$ , when the SINR value  $\gamma_m^k$  of the D2D to the user is less than the target threshold  $\bar{\gamma}_m^k$  of the SINR, the probability of the interruption of the  $m$ -th D2D pair (from D1 to D2) can be defined as

$$P_{m,out}^{D_1 \rightarrow 2}(p_m^k, \mathbf{P}_{-m}^k) = 1 - \exp\left(-\frac{\bar{\gamma}_m^k (N_0 + \eta_{m,2} \alpha_m P_m^k L_{m,SI} |h_{m,SI}|^2)}{P_m^k L_m}\right) \cdot \prod_{i \neq m}^M \left(1 + \frac{\bar{\gamma}_m^k (1 + \alpha_i) P_i^k L_{im}}{P_m^k L_m}\right)^{-1}, \quad (5)$$

where  $\mathbf{P}_{-k}$  represents the transmit power vector of all other users except the  $k$ -th D2D on the first channel. If the probability of break  $\gamma_{m,out}^{k,D_2 \rightarrow 1}$  is less than the interrupt threshold  $\xi_m$ ,  $\gamma_{m,out}^{k,D_2 \rightarrow 1} \leq \xi_m$ , the constraint of the probability of interruption can be obtained:

$$1 - \xi_m \leq 1 - \exp\left(-\frac{\bar{\gamma}_m^k N_0}{P_m^k L_m} - x_m^{D_1 \rightarrow 2}\right) \prod_{i \neq m}^M \left(1 + \frac{\bar{\gamma}_m^k (1 + \alpha_i) P_i^k L_{im}}{P_m^k L_m}\right)^{-1}, \quad (6)$$

where  $x_m^{D_1 \rightarrow 2} = ((\bar{\gamma}_m^k \eta_{m,2} \alpha_m L_{m,SI} |h_{m,SI}|^2) / L_m)$ .

Similarly, the probability of the first D2D pair (from D2 users to D1 users) can be defined as

$$1 - \xi_m \leq 1 - \exp\left(-\frac{\bar{\gamma}_m^k N_0}{\alpha_m P_m^k L_m} - x_m^{D_2 \rightarrow 1}\right) \prod_{i \neq m}^M \left(1 + \frac{\bar{\gamma}_m^k (1 + \alpha_i) P_i^k L_{im}}{\alpha_m P_m^k L_m}\right)^{-1}, \quad (7)$$

where  $x_m^{D_2 \rightarrow 1} = ((\bar{\gamma}_m^k \eta_{m,1} L_{m,SI} |h_{m,SI}|^2) / (\alpha_m L_m))$ .

## 4. Stackelberg Game Theory

**4.1. Traditional Noncooperative Game Model.** In cognitive radio network system, it is considered that secondary users are access users who will not cooperate with each other; then there must be conflicts between secondary users, which plays an extremely important role in analyzing complex and competitive cognitive radio networks with noncooperative game theory. Let  $\Theta = \{\kappa, \{P_k\}\{U_k(p)\}\}$  be NPG model and  $\kappa = [1, 2, 3, \dots, K]$  be the set of perceived users.  $P_k$  is the power set of secondary user  $k$ ; its revenue function is  $U_k(*)$ . In order to solve the problem that the game model cannot obtain the global optimal transmission power solution, a linear cost function is introduced into the utility function of the secondary user, and the benefit function expression of NPGP model [25] is defined as follows:

$$\text{NPGP: } \max_{p_k \in P_k} U_k(p_k, P_{-k}) = \frac{\text{LR}}{M P_k} \left(1 - e^{(-\gamma_k/2)}\right)^M - c_1 p_k, \quad k \in \kappa. \quad (8)$$

In the formula,  $M$  is the total number of bits per frame;  $L$  is that number of valid information bit ( $L$  & lt;  $M$ );  $R$  is transmission rate;  $c_1$  is a penalty factor;  $P$  is secondary user transmit power vector:  $p = (p_1, \dots, p_k)$ ,  $P_{-k}$  is the power of other users besides perceiving user  $k$ .

Utility function  $U_k$  represents the final income of users after the game in bits/joules. However, the above penalty factor is a constant, and due to different interferences caused by users, it is unfair to set it in this way. Through the introduction of the above-mentioned related game schemes, the improved penalty function [26] is expressed as follows:

$$\text{NPGP - MSFLA: } U_k(p_k, P_{-k}) = \frac{\text{LR}}{M P_k} \left(1 - e^{(-\gamma_k/2)}\right)^M - c_1 e^{p_k} - c_3 (\gamma_k - \gamma_k^{\min}). \quad (9)$$

In the formula,  $c_2$  and  $c_3$  are constant cost factors.

Let  $f_1(\gamma_k)$  be an effective function when data transmission is successful. Generally, it is modulated by frequency shift keying. The expression is defined as follows:

$$f_1(\gamma_k) = \left(1 - e^{(-\gamma_k/2)}\right)^M. \quad (10)$$

In the game model of [27], a new benefit function is designed, in which the penalty function is a nonlinear function set according to the interference of users and the signal-interference-noise ratio, and the utility function is defined.

$$\text{NPGP - ESIA: } U_k(p_k, P_{-k}) = \frac{\text{LR}}{M P_k} \left(\frac{1 - e^{-\gamma_k}}{1 + e^{\gamma_k - \gamma_k^{\min}}}\right) - \alpha e^{\beta((\gamma_k / \gamma_k^{\min}) - 1)} \frac{P_k}{p^{\text{th}}}. \quad (11)$$

In the formula,  $\alpha$  is that trim factor of the penalty function and is constant;  $\beta$  is that trim factor of the penalty function and is constant;  $p^{\text{th}}$  is threshold of average power.

**4.2. Stackelberg Game Model.** Stackelberg's game model is actually an orderly game model; that is, some actors can act first and are called leaders. However, the users who act later make corresponding action strategies according to the users who act earlier, which are called followers. This is the Stackelberg game. At the top of the game, leaders will choose the best action to maximize their benefits when they know the relevant information of followers. At the bottom of the game, followers make the best strategy through noncooperative game under the condition of understanding the relevant behaviors of leaders. The Nash equilibrium solution of Stackelberg game is called Stackelberg equilibrium (SE). The game leader will formulate his own optimal response function considering the follower's response information, which is defined as follows:

$$S_F^* \leq \arg U(S_L). \quad (12)$$

Leaders get their best action strategy  $S_F^*$  when maximizing their own benefit function. At this time, followers choose the best action strategy  $S_F^*$  according to the leader's response  $S_L^*$  to maximize their own interests.

$$S_L^* \leq \arg U(S_L). \quad (13)$$

After many games, Stackelberg equilibrium solutions ( $S_F^{\text{SE}}, S_L^{\text{SE}}$ ) can be obtained. Both parties change their strategies according to the information of other participants to further improve their income. Stackelberg equilibrium solution: the behavioral strategy set ( $S_F^{\text{SE}}, S_L^{\text{SE}}$ ) is the strategic equilibrium solution of Stackelberg's game. For any leader  $\forall i \in K$ ,

$$\begin{aligned} U_i(S_1, \dots, S_i^{\text{SE}}, \dots, S_K, \dots, S_L^{\text{SE}}) \\ \geq U_i(S_1, \dots, S_i, \dots, S_K, \dots, S_L^{\text{SE}}), \quad \forall i. \end{aligned} \quad (14)$$

For any one of the followers  $\forall j \in N$ ,

$$\begin{aligned} U_i(S_1, \dots, S_j^{\text{SE}}, \dots, S_K, \dots, S_F^{\text{SE}}) \\ \geq U_i(S_1, \dots, S_j, \dots, S_K, \dots, S_F^{\text{SE}}), \quad \forall j. \end{aligned} \quad (15)$$

The power control model can adopt Stackelberg game algorithm to control the transmission power of cognitive users according to the different order of primary and secondary users' strategies. In addition, since most literatures do not consider the outage probability constraints of primary users and secondary users into the system model, taking the constraints into account will improve the practicability of the algorithm, and Lagrange optimization method and KTT scheme are used to obtain the optimal transmission power of each user on the corresponding channel.

The power control strategy between cellular users and D2D to user can use the Stackelberg game model to solve power control problems. Specifically, cellular users are leaders, first taking action, setting the market price to sell the spectrum resources they use; D2D pairs are followers, observing the leader's actions and taking appropriate actions, by paying the main user's corresponding fees to share the licensed band of cellular users. Both cellular users and D2D pairs are selfish, and they are designed to minimize their own costs under outage constraints, thereby building a corresponding benefit function.

We first analyze the leader subgame of cellular user power control issues. Cellular users aim to minimize their cost by providing interference prices to D2D pairs. The cost utility of the leader (cellular users) can be defined as their own transmit power minus the gain from the D2D pair by sharing resources with all D2D pairs. The utility cost function for cellular users is expressed as

$$Q_k(p_k, \mathbf{p}_{-k}, c_k) = p_k - c_k \sum_{m=1}^M \left( (1 + \alpha_m) p_m^k L_{mk} |h_{mk}|^2 \right), \quad (16)$$

where  $c_k$  represents the interference price of the cellular user  $k$ .

The optimization issues for cellular users are as follows:

$$\begin{aligned} \min Q_k(p_k, \mathbf{p}_{-k}, c_k) \\ \text{s.t.} \quad (4). \end{aligned} \quad (17)$$

For a follower's subgame, the cost function for each D2D pair is the total power allocated on the channel of all cellular users plus the cost paid for using the cellular user's channel. Therefore, the cost function of the first D2D to the user can be expressed as

$$\begin{aligned} U_m(\mathbf{p}_m, \mathbf{p}_{-m}, \mathbf{c}) = \sum_{k=1}^K \left( (1 + \alpha_m) p_m^k \right) \\ + \sum_{k=1}^K \left( c_k (1 + \alpha_m) p_m^k L_{mk} |h_{mk}|^2 \right), \end{aligned} \quad (18)$$

where  $\mathbf{p}_m$  represents the power vector of the  $m$ -th D2D pair to users on all  $k$ -cellular user channels,  $\mathbf{p}_{-m} = (\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_{m-1}, \dots, \mathbf{p}_{m+1}, \dots, \mathbf{p}_M)$  represents the transmit power matrix of all other D2D pairs, and  $\mathbf{c} = (c_1, c_2, \dots, c_k)$  represents the price vector that the  $m$ -th D2D user pays to all cellular users.

Therefore, the first D2D pair is intended to solve the problem of multi-channel power control. The specific problems are

$$\begin{aligned} \min U_m(\mathbf{p}_m, \mathbf{p}_{-m}, \mathbf{c}) \\ \text{s.t.} \quad (6) (7). \end{aligned} \quad (19)$$

Since constraints (4), (6), and (7) are nonconvex, the games (17) and (19) under constraints are nonconvex. Therefore, we can optimize problems (17) and (19) by using

the logarithm of the variable:  $\tilde{p}_k = \log(p_k)$ ,  $\tilde{p}_m^k = \log(p_m^k)$ . Therefore, the optimization problems in (17) and (19) are translated into

$$\min Q_k(e^{\tilde{p}_k}, e^{\tilde{p}_{-k}}, c_k) = e^{\tilde{p}_k} - c_k \sum_{m=1}^M \left( (1 + \alpha_m) e^{\tilde{p}_m} L_{mk} |h_{mk}|^2 \right), \quad \forall k \quad (20)$$

$$\text{s.t.} \quad \frac{\bar{Y}_k N_0}{e^{\tilde{p}_k} L_k} + \sum_{m=1}^M \left( \log \left( \frac{\bar{Y}_k (1 + \alpha_m) e^{\tilde{p}_m} L_{mk}}{e^{\tilde{p}_k} L_k} \right) \right) \leq \log \left( \frac{1}{1 - \xi_k} \right), \quad \forall k,$$

$$\min U_m(e^{\tilde{p}_m}, e^{\tilde{p}_{-m}}, \mathbf{c}) = \sum_{k=1}^K \left( (1 + \alpha_m) e^{\tilde{p}_m} \right) + \sum_{k=1}^K \left( c_k (1 + \alpha_m) e^{\tilde{p}_m} L_{mk} |h_{mk}|^2 \right), \quad \forall m$$

$$\frac{\bar{Y}_m^k N_0}{e^{\tilde{p}_m} L_m} + x_m^{D_1-2} + \sum_{i \neq m}^M \left( \log \left( 1 + \frac{\bar{Y}_m^k (1 + \alpha_i) e^{\tilde{p}_i} L_{im}}{e^{\tilde{p}_m} L_m} \right) \right) \leq \log \left( \frac{1}{1 - \xi_m} \right), \quad \forall k \quad (21)$$

$$\text{s.t.} \quad \frac{\bar{Y}_m^k N_0}{\alpha_m e^{\tilde{p}_m} L_m} + x_m^{D_2-1} + \sum_{i \neq m}^M \left( \log \left( 1 + \frac{\bar{Y}_m^k (1 + \alpha_i) e^{\tilde{p}_i} L_{im}}{\alpha_m e^{\tilde{p}_m} L_m} \right) \right) \leq \log \left( \frac{1}{1 - \xi_m} \right), \quad \forall k.$$

In the system herein, the cellular user's channel is fixed. For example, each cellular user occupies one subchannel, and then the D2D user selects whether to share the cellular user's channel for communication according to the cellular user channel condition. Therefore, this paper introduces the Stackelberg game theory to control the user power and manage the D2D user access cellular user channel; that is, the cellular user performs its own transmit power according to its own utility function (equation (16)), while the D2D user selectively accesses the cellular user's channel and controls its own transmit power according to its utility function (equation (18)).

The solution to the Stackelberg game is to analyze the existence and uniqueness of the Nash equilibrium. The tree constraint functions of (20) and (21) have  $\tilde{P}_{m,\text{out}}^c(\tilde{p}_k, \tilde{p}_{-k})$ ,  $\tilde{P}_{m,\text{out}}^{D_1-2}(\tilde{p}_m^k, \tilde{p}_{-m}^k)$ , and  $\tilde{P}_{m,\text{out}}^{D_2-1}(\tilde{p}_m^k, \tilde{p}_{-m}^k)$ . The performance problem of Nash Equilibrium can be expressed as follows.

**Theorem 1.** *The subgame of D2D to the user (follower) is the existence of Nash equilibrium and is unique.*

*Proof.* For each D2D pair,  $\forall m \in M$ , the interrupt constraint functions  $\tilde{P}_{m,\text{out}}^{D_1-2}(\tilde{p}_m^k, \tilde{p}_{-m}^k)$  and  $\tilde{P}_{m,\text{out}}^{D_2-1}(\tilde{p}_m^k, \tilde{p}_{-m}^k)$  are strictly convex functions and are monotonically decreasing in  $\tilde{p}_m^k$ . The power vectors  $\mathbf{P}^k = \{p_m^k; \forall m \in M\}$  in the Hessian matrices  $\tilde{P}_{m,\text{out}}^{D_1-2}$  and  $\tilde{P}_{m,\text{out}}^{D_2-1}$  are both non-negative. Therefore, problem (21) is obviously an optimization problem of strictly convex constraints, NE always exists, and there is a unique optimal solution.

**Theorem 2.** *The subgame of a cellular user (leader) is the existence of Nash equilibrium and is unique.*

*Proof.* For each cellular user, the  $\forall k \in K$ , the  $k$ -th cellular user's interrupt constraint function is  $\tilde{P}_{m,\text{out}}^c(\tilde{p}_k, \tilde{p}_{-k})$ ; the interrupt constraint function is a strict convex function and is about the  $\tilde{p}_m^k$  monotonically decreasing function. Therefore, problem (20) is an optimization problem of strict convex constraints, and there is a unique optimal solution.

The Nash equilibrium of the Stackelberg game consists of the Nash equilibrium of the follower subgame and the Nash equilibrium of the leader subgame and analyzes the existence and uniqueness of the Nash equilibrium of the Stackelberg game. The Nash equilibrium of the leader's subgame exists and is unique. For a given power allocation scheme, the Nash equilibrium of the follower subgame exists and is unique.

## 5. Stackelberg Game Solution

Since the optimal power control problems of (20) and (21) have constraints, if the complexity of solving the subproblem is higher with the distributed algorithm, we use the Lagrangian dual decomposition method to solve problem (20). And (21) optimizes the problem with the most transmit power.

**5.1. D2D Solves the User's Optimal Transmit Power.** D2D minimizes its cost utility by observing the interference price vector  $\mathbf{c}$  set by all cellular users and controlling its own transmit power. Thus, the Lagrangian function of equation (22) can be expressed as

$$\begin{aligned}
L_m(\tilde{p}_m, \tilde{p}_{-m}, \mathbf{c}, \lambda_m, \omega_m) &= \sum_{k=1}^K \left( (1 + \alpha_m) e^{\tilde{p}_m^k} \right) + \sum_{k=1}^K \left( c_k (1 + \alpha_m) e^{\tilde{p}_m^k} L_{mk} |h_{mk}|^2 \right) \\
&+ \sum_{k=1}^K \lambda_m \cdot \left( \frac{\tilde{\gamma}_m^k N_0}{e^{\tilde{p}_m^k} L_m} + x_m^{D_1-2} + \sum_{i \neq m}^M \left( \log \left( 1 + \frac{\tilde{\gamma}_m^k (1 + \alpha_i) e^{\tilde{p}_i^k} L_{im}}{e^{\tilde{p}_m^k} L_m} \right) \right) - \log \left( \frac{1}{1 - \xi_m^k} \right) \right) \\
&+ \sum_{k=1}^K \omega_m \left( \frac{\tilde{\gamma}_m^k N_0}{\alpha_m e^{\tilde{p}_m^k} L_m} + x_m^{D_2-1} + \sum_{i \neq m}^M \left( \log \left( 1 + \frac{\tilde{\gamma}_m^k (1 + \alpha_i) e^{\tilde{p}_i^k} L_{im}}{\alpha_m e^{\tilde{p}_m^k} L_m} \right) \right) - \log \left( \frac{1}{1 - \xi_m^k} \right) \right),
\end{aligned} \tag{22}$$

where  $\lambda_m$  and  $\omega_m$  are the dual variables of the constraints. The optimal solution for the Lagrangian dual function is  $\min L_m(\tilde{P}_m, \tilde{P}_{-m}, \mathbf{c}, \lambda_m, \omega_m)$ . According to the convex optimization theory,  $L_m(\tilde{P}_m, \tilde{P}_{-m}, \mathbf{c}, \lambda_m, \omega_m)$  is a concave

function with respect to  $\lambda_m$  and  $\omega_m$ ; therefore, the optimal dual variable that can be obtained by the subgradient method is as follows:

$$\begin{aligned}
\lambda_m^* &= \lambda_m^* + \varepsilon \left( \frac{\tilde{\gamma}_m^k N_0}{e^{\tilde{p}_m^k} L_m} + x_m^{D_1-2} + \sum_{i \neq m}^M \left( \log \left( 1 + \frac{\tilde{\gamma}_m^k (1 + \alpha_i) e^{\tilde{p}_i^k} L_{im}}{e^{\tilde{p}_m^k} L_m} \right) \right) - \log \left( \frac{1}{1 - \xi_m^k} \right) \right)^+, \\
\omega_m^* &= \omega_m^* + \phi \left( \frac{\tilde{\gamma}_m^k N_0}{\alpha_m e^{\tilde{p}_m^k} L_m} + x_m^{D_2-1} + \sum_{i \neq m}^M \left( \log \left( 1 + \frac{\tilde{\gamma}_m^k (1 + \alpha_i) e^{\tilde{p}_i^k} L_{im}}{\alpha_m e^{\tilde{p}_m^k} L_m} \right) \right) - \log \left( \frac{1}{1 - \xi_m^k} \right) \right)^+,
\end{aligned} \tag{23}$$

where  $\varepsilon$  and  $\phi$  represent small enough steps and are positive.

Since the  $L_m(\tilde{P}_m, \tilde{P}_{-m}, \mathbf{c}, \lambda_m, \omega_m)$  function is a concave function on  $\lambda_m$  and  $\omega_m$ , (15) iteratively converges to the optimal  $\lambda_m$  and  $\omega_m$ . Substituting the obtained optimal  $\lambda_m$  and  $\omega_m$  into (23), we derive it to obtain

$$\frac{\partial L_m(\tilde{P}_m, \tilde{P}_{-m}, \mathbf{c}, \lambda_m, \omega_m)}{\partial \tilde{p}_m^k} \Big|_{\lambda_m^*, \omega_m^*} = 0. \tag{24}$$

By solving (24), we can derive the optimal solution  $\tilde{p}_m^{k*}$  in (22). Then, by the exponential change of the  $p_m^{k*} = \exp(\tilde{p}_m^{k*})$ , the optimal transmit power  $p_m^{k*}$  of D1 in the  $m$ -th D2D pair and the optimal transmit power  $\alpha_m p_m^{k*}$  of D2 can be obtained. Therefore, we can get the optimal transmit power of each D2D to the user.

## 5.2. Cellular User (Leader) Optimal Transmit Power Solution.

In order to minimize the cost utility of cellular users, each cellular user needs to adaptively update the market interference price set to the user to the D2D based on the transmit power response of the user  $\tilde{P}_m^*$  (or  $\mathbf{P}_m^*$ ) by D2D. The subgame problem of the leader in the optimization problem (20) can be decomposed into two subproblems: by correcting the price factor  $c_k$ , the optimal transmit power of each cellular user  $k$  can be obtained, and then the optimal  $c_k$  is obtained. The solution of the optimal transmit power of the cellular user  $k$  can be obtained by the Lagrangian dual decomposition method.

Therefore, for the subgame problem of the leader in (20), the corresponding Lagrangian function can be obtained:

$$L_k(\tilde{p}_k, \tilde{p}_{-k}, c_k, \nu_k) = e^{\tilde{p}_k} - c_k \sum_{m=1}^M \left( e^{\tilde{p}_m^k} L_{mk} |h_{mk}|^2 \right) + \nu_k \left( \frac{\tilde{\gamma}_k N_0}{e^{\tilde{p}_k} L_k} + \sum_{m=1}^M \left( \log \left( \frac{\tilde{\gamma}_k (1 + \alpha_m) e^{\tilde{p}_m^k} L_{mk}}{e^{\tilde{p}_k} L_k} \right) \right) - \log \left( \frac{1}{1 - \xi_k} \right) \right), \tag{25}$$

where the dual variable  $\nu_k$  represents the constraint in (20); the optimal solution for the Lagrangian dual function is  $\min L_k(\tilde{p}_k, \tilde{p}_{-k}, c_k, \nu_k)$ .

$L_k(\tilde{p}_k, \tilde{p}_{-k}, \mathbf{c}, \lambda_m, \omega_m)$  is a concave function for  $\nu_k$ . Similarly, we can use the gradient method to get the optimal dual variable:

$$\begin{aligned}
\nu_k^* &= \nu_k^* + \theta \left( \frac{\tilde{\gamma}_k N_0}{e^{\tilde{p}_k} L_k} + \sum_{m=1}^M \left( \log \left( \frac{\tilde{\gamma}_k (1 + \alpha_m) e^{\tilde{p}_m^k} L_{mk}}{e^{\tilde{p}_k} L_k} \right) \right) - \log \left( \frac{1}{1 - \xi_k} \right) \right)^+ \\
&- \log \left( \frac{1}{1 - \xi_k} \right) \Big)^+,
\end{aligned} \tag{26}$$

where  $\theta$  is a sufficiently large positive real number. The iteration in (26) will converge to the optimal  $v_k^*$ . Thus, we can derive the optimal solution ( $\tilde{p}_k^*$ ) of the problem in (20) by solving the following problem. The solution of the problem is as follows.

Then, we can get the transmit power  $p_m^{k*} = \exp(\tilde{p}_m^{k*})$  of the cellular user  $k$  by the exponential change of the formula  $\tilde{p}_k^*$ .

Based on the analysis of the optimal transmit power of D2D to the user subgame and the cellular user subgame, it is discussed how the cellular user sets the optimal price according to the transmit power policy response of all D2D pairs.

If the  $m$ -th D2D interference price to the user is greater than the payment threshold, the D2D pair of users will stop renting the channel of the  $k$ -th cellular user. In other words, for each D2D pair user, if it is transmitted on the channel of the  $k$ -th cellular user, its cost utility cannot be greater than the maximum cost threshold  $U_m^{k, \max}(e^{p_k})$ . Thus, the cost for the  $m$ -th D2D pair of users should satisfy the constraint:

$$(1 + \alpha_m)e^{\tilde{p}_m^{k*}} + c_k(1 + \alpha_m)e^{\tilde{p}_m^{k*}} L_{mk} |h_{mk}|^2 \leq U_m^{k, \max}(e^{\tilde{p}_m^{k*}}). \quad (27)$$

Therefore, we can get the constraint of the price  $c_k$ , expressed as follows:

$$c_k \leq Z_m = \frac{U_m^{k, \max}(e^{\tilde{p}_m^{k*}}) - (1 + \alpha_m)e^{\tilde{p}_m^{k*}}}{(1 + \alpha_m)e^{\tilde{p}_m^{k*}} L_{mk} |h_{mk}|^2}. \quad (28)$$

As can be seen from (28), if the cellular subscriber wants the  $m$ -th D2D pair to communicate on its channel, the price set by the cellular subscriber  $k$  should not be higher than the upper limit price in (28). Therefore, the optimal interference price  $c_k^*$  is  $c_k^* = Z_m$ .

According to the above analysis, the  $k$ -th cellular user will minimize  $Q_k(e^{p_k})$  by paying the threshold vector  $\mathbf{Z} = (Z_1, Z_2, \dots, Z_M)$  and then select the appropriate overall price  $c_k^*$ .

In order to achieve Nash equalization and to converge to the optimal transmit power, we propose the following iterative power control algorithm.

- (i) Step 1: let  $t = 0$ ; for all cellular users  $k$ , initialize its transmit power  $p_k(t)$  and price  $c_k(t)$ ; for all D2D pairs, initialize  $\mathbf{P}_m(t)$
- (ii) Step 2: for each D2D user, calculate the price vector paid by the  $m$ -th D2D to all cellular users
- (iii) Step 3: update  $\lambda_k^*$  and  $\omega_k^*$  according to formula (23), respectively
- (iv) Step 4: for a given cellular user  $p_k(t)$  and  $c_k(t)$ , each D2D pair user  $m$  is solved according to equation (24) to obtain  $\mathbf{P}_m^*(t+1)$ . If  $c_k(t) > Z_k(t)$ , D2D terminates the channel using cellular user  $k$  for user  $m$
- (v) Step 5: for each cellular user  $k$ , update  $v_k^*$  according to formula (18)

- (vi) Step 6: at a given D2D user transmit power  $\mathbf{P}_m^*(t+1)$ , the cellular user  $k$  updates its transmit power  $p_m^*(t+1)$  by solving equation (19)
- (vii) Step 7: according to formulas (28) and  $\mathbf{Z}$ , the cellular user updates its price  $c_k^*(t+1)$
- (viii) Step 9: let  $t = t + 1$  repeat steps 2 to 8 until convergence

## 6. Simulation Results and Performance Analysis

This paper uses simulation to analyze the performance of the Stackelberg game power control. Assuming the radius of the cell is 500 meters, the maximum transmit power of the cellular user and D2D to the user is  $P_m^{\max} = 24$  dBm and  $P_m^{\max} = 20$  dBm, the noise power  $N_0 = 10^{-10}$  w, and the maximum distance of each cellular user from the base station is 300 meters, and the maximum communication distance of each D2D pair is 50 meters. For each D2D pair user, we set  $\alpha_m = -1$ ; self-interference relief coefficient  $\eta_1 = \eta_2 = -100$  dB.

Figure 2 shows the interrupt performance of three cellular users and five D2D pairs at different target SINR values. The outage probability of the two users becomes larger as the target SINR threshold increases. However, the terminal probability of the proposed game scheme is significantly lower than the other two power control schemes, especially at the low SINR threshold. This is because the proposed scheme takes into account the user's minimum SINR requirement and builds an optimization problem under the outage probability, which effectively reduces the probability of interruption of users in the network. The other two schemes do not consider the outage probability into the system optimization problem, so the interrupt performance is lower than the proposed scheme.

Figure 3 is a comparison of the three algorithms for cellular users and D2D throughput performance for users. As can be seen from Figure 4, as the signal-to-noise ratio increases, the total throughput of the user also increases. When the signal-to-noise ratio is low, the three algorithms can get better performance, and the performance of the proposed algorithm in this case is almost the same as other algorithms mainly because of the constraints. However, as the signal-to-noise ratio increases, the performance of the proposed scheme is improved and higher than the other two schemes. In addition, it can be seen that the performance of D2D to the user's throughput performance is not significantly improved in the case of high signal-to-noise ratio. This is because the interference power to the cellular user is less than a certain value, so the transmission power of the D2D to the user is limited. However, compared with the other two schemes, D2D still has higher throughput for users.

Figure 4 compares the three algorithms for the total cost utility of cellular users and D2D to users. As can be seen from Figure 4, as the background noise increases, the total cost utility of the user also increases. This is because, in the case of large background noise, the user only increases his own transmission power to improve the signal-

FIGURE 2: Convergence of cellular users (a) and D2D to users (b).

FIGURE 3: Cellular user (a) and D2D outage probability to user (b).

to-interference ratio of the receiving end to meet the requirement of the outage probability, and the cost increases. The algorithm proposed in this paper can reduce

the power cost of the network to a certain extent compared with other algorithms. In addition, it can be seen that the cost required by the greedy algorithm is the

FIGURE 4: Cellular user and D2D throughput to users. (a) Cellular user. (b) D2D user.

FIGURE 5: Total cost utility of cellular users and D2D to users. (a) Cellular user. (b) D2D user.

largest, because the algorithm causes the user to self-increase the transmission power to satisfy the performance in the network, and ignores the interference caused to other users. The details are shown in Figure 5.

## 7. Conclusions

This paper studies the problem of uplink power control in a full-duplex D2D communication network under interrupt

constraints. In order to effectively control the users transmit power, this paper introduces the Stackelberg game power control algorithm, setting up cellular users and D2D users as leaders and followers, respectively. Cellular users and D2D users compete with each other to minimize the cost utility and a new utility function is proposed. Under the condition of channel interruption constraint and power constraint, the optimization problem is constructed and the Lagrange dual decomposition method is used to obtain the user's

transmitting power. Finally, the performance of the proposed game scheme is analyzed and the Nash equilibrium can be converging. Future work will focus on the construction of intelligent algorithm research for D2D competition in the case of multi-users and assigning solutions through user weights.

This paper proposes a new system whose potential function is with three types of asymmetric potential wells, driven by trichotomous noise. Firstly, the three types of asymmetric bistable system are described in detail, and the changes of asymmetric bistable system potential function under different asymmetric factors are analyzed. Secondly, the effect of potential function parameters, asymmetric factor  $\alpha$ , noise intensity  $D$ , and the probability of particle transition  $q$  is discussed, using numerical simulation. The detection effects of traditional symmetric SR and three types of asymmetric SR are observed and compared under the driving of trichotomous noise and periodic signals. The mean of signal-to-noise ratio gain is the indicator of the system's effectiveness on enhancing weak signal. The results indicate that it can make the detection effect of the asymmetric system better than that of the traditional bistable system by adjusting the parameters of the asymmetric stochastic resonance system and trichotomous noise.

## 1. Introduction

Asymmetry is a ubiquitous phenomenon which has been a widespread concern for researchers for a long time due to its potential applications in physical and natural systems, such as neural networks [1, 2], wireless communications [3], optical metamaterials [4], and medical imaging [5]. In addition, as demonstrated in a number of studies, the effect of stochastic resonance can be enhanced in the case that the potential function is not symmetric [6–10]. However, there are relatively few studies devoted to the asymmetric system SR driven by trichotomous noise.

It is generally accepted that noise has a negative effect on the extraction and detection of weak signals. However, if the noise is used reasonably, the weak signal can be enhanced according to the stochastic resonance theory. Stochastic resonance is regarded as a method of weak signal detection [11–14] since it was firstly proposed to express the periodic alternations between the Earth's ice age and the warm

climate period in 1981 [15]. Later, various potential function models of stochastic resonance were proposed based on the model of traditional bistable stochastic resonance [16, 17], such as monostable models [18–20], tristable models [21–23], and two metastable models [24]. Then, the underdamping SR system [25–27] that is different from the traditional systems (overdamped system [28–30]) has been paid much attention by researchers. In addition, in the research of SR, the driving noise is various, including Gaussian white noise [31–33] and colored noise [34–37]. And it can be divided into multiplicative noise and additive noise [32, 38–40], according to the action mode of driving noise to the system.

Much work so far focusing on stochastic resonance always takes the Gaussian white noise as the driving noise. However, it should be noted that most of the noise in a physical system is not gaussian white noise. Trichotomous noise is a function of the time variable  $t$  that is converted between the three values of  $a$ ,  $b$ ,  $c$ . Considerable research

efforts have been devoted to SR phenomenon driven by trichotomous noise [41–44]. However, SR systems with asymmetric potential function driven by trichotomous noise have not been realized yet. Hence, the combination of trichotomous noise and asymmetric SR system presents a wide range of possibilities for the further development of weak signal detection.

## 2. Models and Methods

The Langevin equation of asymmetric stochastic resonance system is considered as follows:

$$\frac{\partial x(t)}{\partial t} = -\frac{\partial U(x)}{\partial x} + A \cos(2\pi ft) + \xi(t), \quad (1)$$

where  $A \cos(2\pi ft)$  is the system input signal to be measured,  $A$  is the amplitude of the input signal to be measured,  $f$  is the frequency of the input signal to be measured,  $\xi(t)$  is the trichotomous noise, and  $U(x)$  is the potential function of asymmetric systems.  $U(x)$  is given as follows:

$$U_i(x) = \begin{cases} \frac{a_0 x^2}{2} + \frac{b_0 x^4}{4}, & x \geq 0, \\ \frac{a_0 A_i x^2}{2} + \frac{b_0 B_i x^4}{4}, & x < 0, \end{cases} \quad (2)$$

where  $m, n, A_i,$  and  $B_i$  are the structural parameters of asymmetric systems, and these parameters meet such inequalities:  $a_0, b_0, A_i, B_i > 0$  and  $i = 1, 2, 3$ .

### 2.1. Three Kinds of Asymmetric Stochastic Resonance Systems

**2.1.1. The Bistable System with Asymmetric Depth of Potential Well.** When  $A_1 = B_1 = \alpha$ , ( $\alpha$  is asymmetric factor) and there is no input signal, the potential function contains two minima in the potential well:  $x_{\min\pm} = \pm\sqrt{(a_0/b_0)}$  (stable points) and maxima in the potential barrier  $x_{\max} = 0$  (unstable point). The widths of left and right potential well are both  $\sqrt{(a_0/b_0)}$ . Then, the depths of the wells can be obtained as follows:

$$\Delta U_L = \frac{\alpha a_0^2}{4b_0}, \quad (3)$$

$$\Delta U_R = \frac{a_0^2}{4b_0}. \quad (4)$$

As can be seen from formulae (3) and (4), only the depth of the left well is controlled by the asymmetric factor  $\alpha$ . Figure 1(a) shows the different depths of potential function caused by  $\alpha$  when  $a_0 = 1$  and  $b_0 = 1$ , where the depths of the left potential well increase with  $\alpha$  increasing.

**2.1.2. The Bistable System with Asymmetric Width of Potential Well.** When  $A_2 = (1/\alpha^2)$ ,  $B_2 = (1/\alpha^4)$ , the potential function contains two stable points,  $x_{\min+} = \sqrt{(a_0/b_0)}$  and  $x_{\min-} = -\alpha\sqrt{(a_0/b_0)}$ , and an unstable point  $x_{\max} = 0$ . The

depths of left and right potential well are both  $(a_0^2/4b_0)$ . Then, the widths of the wells can be obtained as follows:

$$\Delta W_L = \alpha\sqrt{\frac{a_0}{b_0}}, \quad (5)$$

$$\Delta W_R = \sqrt{\frac{a_0}{b_0}}. \quad (6)$$

As can be seen from formulae (5) and (6), the width of the left well is controlled by the asymmetric factor  $\alpha$ . Figure 1(b) shows the different widths of the potential function caused by  $\alpha$  when  $a_0 = 1$  and  $b_0 = 1$ , where the widths of the left potential well increase with  $\alpha$  increasing.

**2.1.3. The Bistable System with Both Asymmetric Width and Asymmetric Depth of Potential Well.** When  $A_3 \neq B_3, A_3^2 \neq B_3$ , the bistable system has potential wells with both asymmetric width and depth. In this research,  $A_3 = 1, B_3 = (1/\alpha^4)$  (the combination of  $U_1(x)$  and  $U_2(x)$ ) are selected as typical and the potential function contains two stable points,  $x_{\min+} = \sqrt{(a_0/b_0)}$  and  $x_{\min-} = -\alpha^2\sqrt{(a_0/b_0)}$ , and an unstable point  $x_{\max} = 0$ . Then, the depths and widths of the wells can be obtained as follows:

$$\Delta U_L = \frac{\alpha^4 a_0^2}{4b_0}, \quad (7)$$

$$\Delta U_R = \frac{a_0^2}{4b_0}, \quad (8)$$

$$\Delta W_L = \alpha^2\sqrt{\frac{a_0}{b_0}}, \quad (9)$$

$$\Delta W_R = \sqrt{\frac{a_0}{b_0}}. \quad (10)$$

As can be seen from formulae (7)–(10), the left well is controlled by the asymmetric factor  $\alpha$ . Figure 1(c) shows the differences of the potential function caused by  $\alpha$  when  $a_0 = 1$  and  $b_0 = 1$ , where the widths and depths of the left potential well increase with  $\alpha$  increasing.

**2.2. Method of Generating Trichotomous Noise.** In (1),  $\xi(t)$  is trichotomous noise, and the method of generating it will be introduced in this section. Trichotomous noise belongs to colored noise. The transitions state of trichotomous noise is between three values ( $a, b,$  and  $c$ ) [42] and it is divided into symmetry trichotomous noise ( $a = -c, b = 0$ ) and asymmetry trichotomous noise ( $a \neq -c, b \neq 0$ ) according to the fluctuation values. The trichotomous process is a Poisson process, and the jump between the three values occurs with the constant probabilities:

$$\begin{aligned} P_s(a) &= P_s(c) = q, \\ P_s(b) &= 1 - 2q. \end{aligned} \quad (11)$$

The transition probabilities between the three states can be obtained as follows:

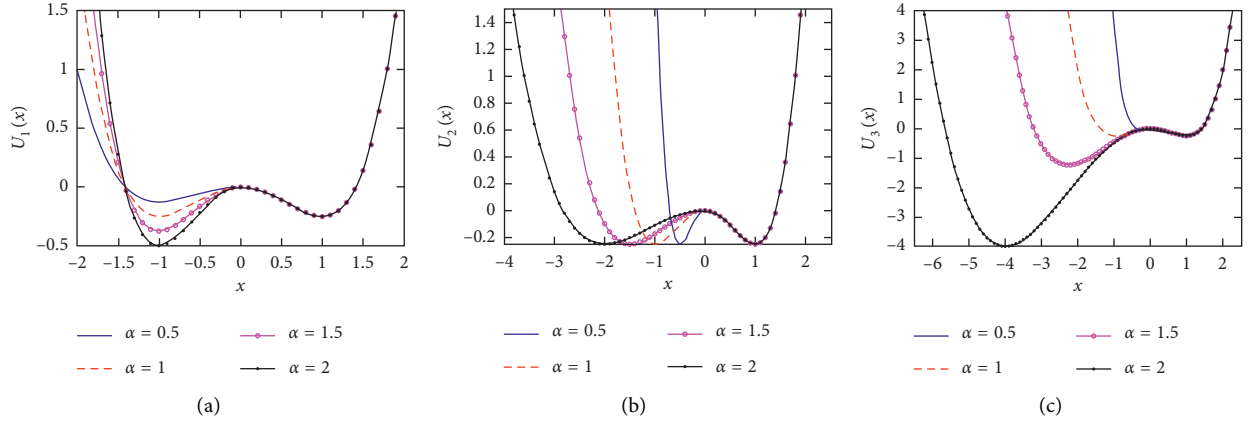

FIGURE 1: (a) Potential  $U_1(x)$  for different values of  $\alpha$ . (b) Potential  $U_2(x)$  for different values of  $\alpha$ . (c) Potential  $U_3(x)$  for different values of  $\alpha$ .

$$\begin{aligned}
 P_{aa} &= P(a, t + \tau | a, t) = q - (q - 1)e^{-\nu\tau}, \\
 P_{ba} &= P_{ca} = P(a, t + \tau | b, t) = P(a, t + \tau | c, t) = q(1 - e^{-\nu\tau}), \\
 P_{bb} &= P(b, t + \tau | b, t) = 1 - 2q(1 - e^{-\nu\tau}), \\
 P_{ab} &= P_{cb} = P(b, t + \tau | a, t) = P(b, t + \tau | c, t) = (1 - 2q)(1 - e^{-\nu\tau}), \\
 P_{cc} &= P(c, t + \tau | c, t) = q - (q - 1)e^{-\nu\tau}, \\
 P_{ac} &= P_{bc} = P(c, t + \tau | a, t) = P(c, t + \tau | b, t) = q(1 - e^{-\nu\tau}).
 \end{aligned} \tag{12}$$

Here,  $\tau > 0$ ,  $0 < q < (1/2)$ ,  $\nu > 0$ ,  $\tau > 0$ ,  $\nu = (1/\tau_{\text{cor}})$ , and  $\tau_{\text{cor}}$  is the noise correlation time. The trichotomous process is completely determined by (11) and (12). Thus, the mean value  $\langle \xi(t) \rangle$  and correlation function  $\langle \xi(t + \tau)\xi(t) \rangle$  of the trichotomous noise in the steady state can be calculated as

$$\langle \xi(t) \rangle = aq + b(1 - 2q) + cq, \tag{13}$$

$$\langle \xi(t + \tau)\xi(t) \rangle = \langle \xi(\tau) \rangle_s^2 + \frac{D\nu}{2}e^{-\nu\tau}. \tag{14}$$

Here, the noise intensity  $D$  is defined as

$$\begin{aligned}
 D &= \int_0^\infty (\langle \xi(\tau)\xi(0) \rangle_s - \langle \xi(\tau) \rangle_s^2) d\tau, \\
 &= \frac{2}{\nu} (a^2q + b^2(1 - 2q) + c^2q - [aq + b(1 - 2q) + cq]^2).
 \end{aligned} \tag{15}$$

According to the description above, the numerical method is used to generate trichotomous noise. Firstly, the function  $\xi(t)$  starts at  $a$ ,  $\xi(0) = a$ . Then, The uniformly distributed random function  $R(t)$  with value range  $[0, 1]$  is used to compare with the conditional probability given in (12) in order to determine the value of  $\xi(0 + \Delta t)$ . If  $R(0) < P_{aa}$ , the value of function  $\xi(0 + \Delta t)$  is  $a$ , and if  $P_{aa} < R(0) < P_{aa} + P_{ab}$ , the value of function  $\xi(0 + \Delta t)$  is  $b$ ; otherwise, the value of function  $\xi(0 + \Delta t)$  is  $c$ . And then, if the value of function  $\xi(0 + \Delta t)$  is  $b$ ,  $R(0 + \Delta t)$  will be used to determine the value of  $\xi(0 + 2\Delta t)$ . If  $R(0 + \Delta t) < P_{ba}$ , the value of function  $\xi(0 + 2\Delta t)$  is  $a$ , and if

$P_{ba} < R(0) < P_{ba} + P_{ba}$ , the value of function  $\xi(0 + 2\Delta t)$  is  $b$ ; otherwise, the value of function  $\xi(0 + 2\Delta t)$  is  $c$ . The case where the value of  $\xi(0 + \Delta t)$  is  $c$  is similar to the case where the value of  $\xi(0 + \Delta t)$  is  $b$ . By repeating the procedure, we can obtain the trichotomous noise  $\xi(t)$ .

Figures 2(a) and 2(b) show the profiles of the asymmetric trichotomous noise with parameters  $a = 3$ ,  $b = 1$ ,  $c = -2$ . Figures 2(c) and 2(d) show the profiles of the symmetric trichotomous noise with parameters  $a = 2$ ,  $b = 0$ ,  $c = -2$ . By comparing Figures 2(a) and 2(b), it is considered that the residence time extends with the increase of noise intensity  $D$ . When  $q = (1/2)$ , it shows that the trichotomous noise reduces to dichotomous noise in Figure 2(d).

### 3. Performance Index

There are many kinds of indexes to measure stochastic resonance, such as signal-to-noise ratio (SNR) [45, 46] and signal-to-noise ratio gain (SNRG) [47], and mean first-passage time (MFPT) [46]. In practical engineering, people are more concerned about the gain of the output SNR compared with the input SNR, so the SNR gain is chosen in this paper, given as

$$\text{SNRG} = \frac{(S_{\text{out}}(f_0)/\xi_{\text{out}}(f_0))}{(S_{\text{in}}(f_0)/\xi_{\text{in}}(f_0))}, \tag{16}$$

where  $S_{\text{out}}(f_0)$  and  $S_{\text{in}}(f_0)$  represent the output and input power of the signal at input frequency  $f_0$ , and  $\xi_{\text{out}}(f_0)$  and  $\xi_{\text{in}}(f_0)$  represent the output and input power of the noise at input frequency  $f_0$ . Due to the randomness of the noise, it is usually necessary to conduct numerous experiments and take the average value of them to ensure the reliability of the experimental results. Therefore, the average value of signal-to-noise ratio gain is defined as

$$A - \text{SNRG} = \frac{1}{n} \sum_{j=0}^{j=n} \text{SNRG}_j, \tag{17}$$

where  $n$  is the time of simulation and  $n = 20$  in this paper.  $\text{SNRG}_j$  is SNRG of the  $j$ -th simulation.

FIGURE 2: (a, b) The asymmetric trichotomous noise with parameters  $a=3$ ,  $b=1$ ,  $c=-2$ . (a)  $D=1$ ,  $q=0.3$ . (b)  $D=4$ ,  $q=0.3$ . (c, d) The symmetric trichotomous noise with parameters  $a=2$ ,  $b=0$ ,  $c=-2$ . (c)  $D=0.5$ ,  $q=0.3$ . (d)  $D=1$ ,  $q=0.5$ .

#### 4. Stochastic Resonance of Asymmetric Bistable System Driven by Trichotomous Noise

The purpose of this research is to cover the impact of system parameters and refer to the stochastic resonance of the asymmetric bistable system driven by trichotomous noise system parameters. The input sinusoidal signal is  $s(t) = A \cos(2\pi f_0 t)$ , where  $A = 0.3$ ,  $f_0 = 0.01$  Hz. The parameters of trichotomous noise distribution are set to be  $a = 1$ ,  $b = 0$ ,  $c = -1$ ,  $q = 0.3$ , and  $D = 0.5$ . A-SNRG is chosen to be the indicator. Simulation time is  $n = 50$ , for each simulation experiment, the calculation step is set as  $h = (1/f_s)$ , where the sampling frequency is  $f_s = 5$  Hz, and the sampling number is  $N = 4096$ . The optimal parameter pair  $(a, b)$  is discovered by using the adaptive algorithms in Figure 3. Figure 3 shows a three-dimensional plot of the traditional bistable adaptive optimization in which the asymmetric factor is  $\alpha = 1$ . Figure 4(a) shows the time-domain diagram of the noisy signal which contains the trichotomous noise and sinusoidal signal. It is obvious that the input signal is completely submerged by trichotomous noise. Figure 4(b) is the power spectrum diagram of the noisy signal. It could be seen from the figure that the frequency ( $f_0 = 0.01$  Hz) of the input signal cannot be identified easily.

Therefore, both passing the stochastic resonance system and the addition of noise are used to enhance the weak signal to be measured. Figure 5(a) shows the time-domain diagram of the output signal through the traditional bistable system SR system and the power spectrum of it. Figures 5(b)–5(d) show the diagram of the output signal through the bistable system with asymmetric depth, asymmetric width, and both asymmetric depth and width of potential. The peak of the asymmetric system power spectrum at  $f_0 = 0.01$  Hz is higher than the symmetric system. So, the conclusion is that the asymmetric system which contains trichotomous noise and the periodic signal has a better detection effect than the symmetric systems, by changing the depth and width of one potential well.

Next, the parameter of noise and potential function are explored under different values of the asymmetric factor in order to obtain better detection parameters.

**4.1. Influences of Asymmetric Factor  $\alpha$  for SR with Asymmetric Depth of Potential Well.** The parameters of the input signal contain  $A_0$ ,  $f_0$  and trichotomous noise contains  $a$ ,  $b$ ,  $c$ ,

FIGURE 3: Three-dimensional diagram of the traditional symmetric bistable system SR adaptive optimization driven by trichotomous noise.

consistent with the above results. The parameters of the potential function are  $a_0 = 1.9$ ,  $b_0 = 2.3$  from the adaptive algorithms. The influence of the noise intensity  $D$  is shown in Figure 6. The influence of  $a_0$  and  $b_0$  with the noise intensity fixed  $D = 0.5$  is shown in Figure 7. Then, the influence of  $q$  with the noise intensity fixed  $D = 0.5$  and  $a_0 = 1.9$ ,  $b_0 = 2.3$  is shown in Figure 8.

Figure 6(a) shows that with the increase of the noise intensity  $D$ , the curves of A-SNRG first increase and then decrease for different values of  $\alpha$  and it means that stochastic resonance with asymmetric depth of the potential well is generated under the drive of trichotomous noise. To see more clearly, the values of the asymmetric factor are 0.6, 1.0, and 1.4 given in Figure 6(b), respectively. The maximum of A-SNRG increases with an increase in depth of the potential well, but the deeper the well, the greater the noise intensity needed to reach the peak and the reason for this is the particles need larger noise intensity  $D$  to cross the barrier. The value of A-SNRG when  $\alpha > 1$  is larger than it when  $\alpha < 1$ . Figures 6(c) and 6(d) show the SR curves for  $\alpha > 1$  and  $\alpha < 1$ , respectively. Figure 6(c) shows that the value of A-SNRG is the maximum for  $\alpha = 1.4$  and starts to decrease from 1.4. When  $\alpha = 2$ , the system cannot produce SR. Figure 6(d) shows that the curve has no peaks which means the system cannot produce SR when  $\alpha = 0.4$  and the value of A-SNRG is starting to increase. These four figures demonstrate that a

FIGURE 4: (a) The time-domain diagram of noisy signal and (b) the power spectrum diagram of the noisy signal.

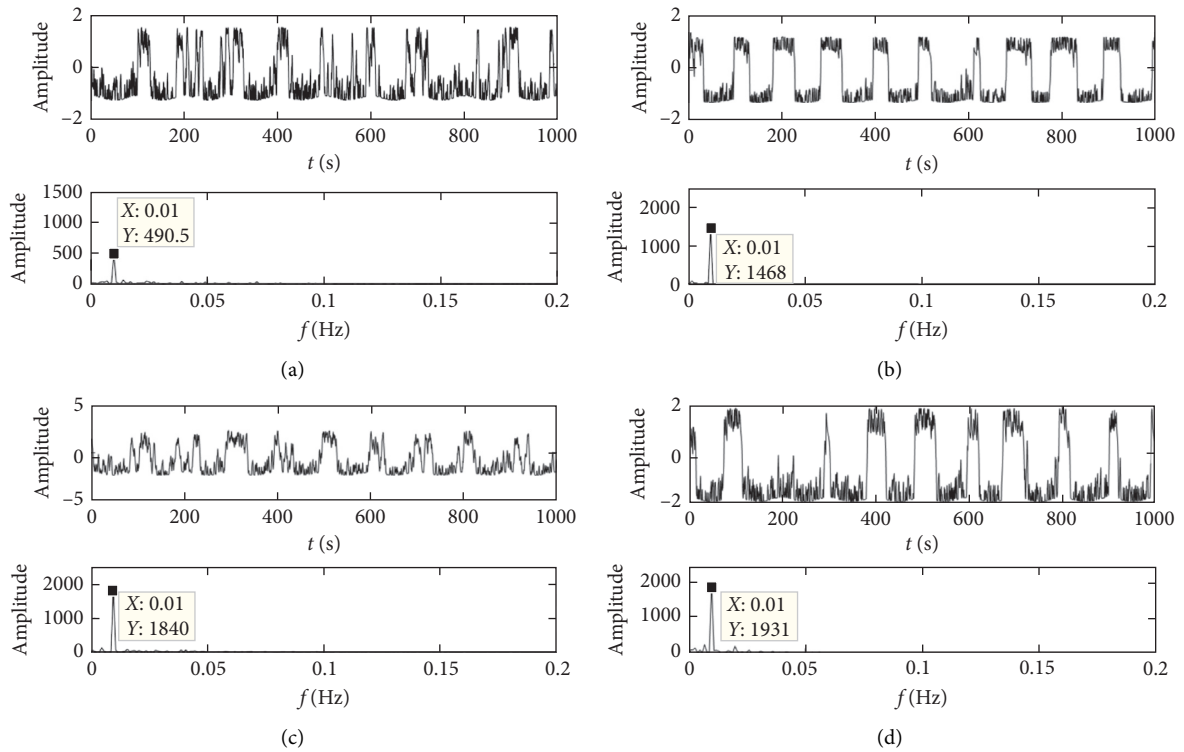

FIGURE 5: (a) Output of the symmetric system SR model and its power spectrum. (b) Output of SR model with asymmetric depth of the potential well ( $u_1(x)$ ) and its power spectrum. (c) Output of SR model with asymmetric width of potential well ( $u_2(x)$ ) and its power spectrum. (d) Output of SR model with asymmetric depth and width of potential well ( $u_3(x)$ ) and its power spectrum.

larger depth of a single potential well has a positive effect on enhancing the A-SNRG in the case that SR can be produced.

Under the condition that SR can be produced, in Figure 7(a), with the increase of parameter  $\alpha$ , the peaks of A-SNRG curves increase and the values  $a_0$  corresponding to the peak decrease. In Figure 7(b), with the increase of parameter  $\alpha$ , the peaks of A-SNRG curves increase and the values  $b_0$  corresponding to the peak increase at the same time. That is to say, there is a pair of optimal system parameters which can enhance the effect of SR.

In Figure 8, when  $\alpha < 1$ , the value of A-SNRG increases with  $q$  increasing. When  $\alpha > 1$ , the value of A-SNRG increases first and then decreases with  $q$  increasing. That is to say, for the case of shallow potential well depth, the longer

the residence time of particle is, the better the effect of stochastic resonance will be. However, when the potential well is deep, there is an optimal  $q$  for the stochastic resonance system and the value of  $q$  does not enhance the effect of the SR system significantly.

**4.2. Influences of Asymmetric Factor  $\alpha$  for SR with Asymmetric Width of Potential Well.** The parameters of the input signal contain  $A_0$ ,  $f_0$  and trichotomous noise contains  $a$ ,  $b$ ,  $c$ ,  $q$  consistent with the above results. The parameters of the potential function are  $a_0 = 1.9$ ,  $b_0 = 2.3$  from the adaptive algorithms. The influence of the noise intensity  $D$  is shown in Figure 9. Then, the influence of  $a_0$  and  $b_0$  with the noise

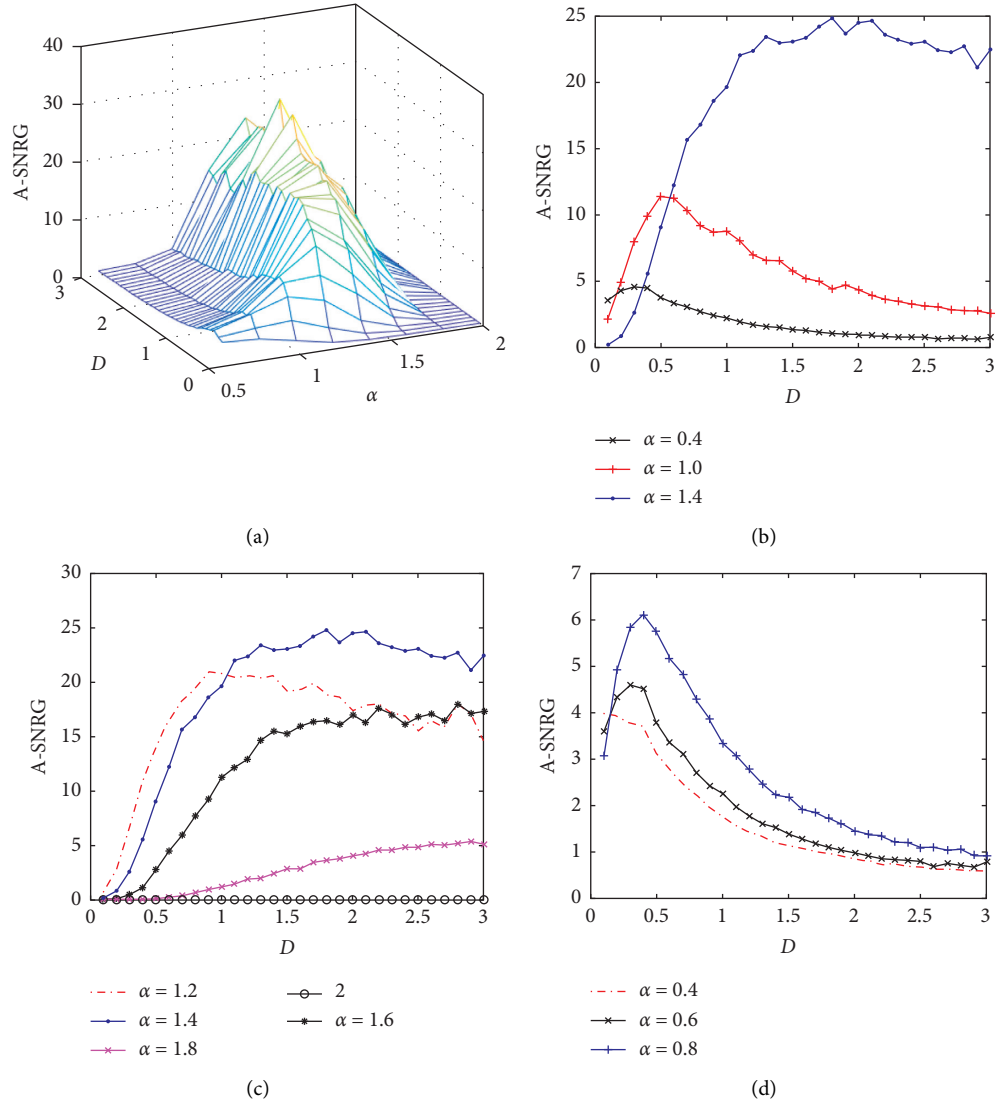

FIGURE 6: (a) A-SNRG of SR with asymmetric depth of potential well as a function of noise intensive  $D$  and asymmetric factor with different values of  $\alpha$ . (b) A-SNRG of SR with asymmetric depth of potential well as a function of noise intensive  $D$  for different values of the asymmetric factor with  $\alpha$ . (c)  $\alpha > 1$  and (d)  $\alpha < 1$ .

intensity fixed  $D = 0.5$  is shown in Figure 10. After that, the influence of  $q$  with the noise intensity fixed  $D = 0.5$ ,  $a_0 = 1.9$ ,  $b_0 = 2.3$  is shown in Figure 11.

Figure 9 shows that, with the increase of the noise intensity  $D$ , the curves of A-SNRG first increase and then decrease for different values of  $\alpha$  and it means that stochastic resonance with asymmetric width of the potential well is generated under the drive of trichotomous noise. The values of the asymmetric factor are 0.5, 0.8, 1.0, 1.2, and 1.5 given in Figure 9, respectively.

The maximum of A-SNRG decreases with an increase in width of the potential well, and the wider the well is, the greater the noise intensity will be needed to reach the peak. Compared with Figure 6(a), the changes in noise intensity which is needed to reach the peak for different depth of the potential well are larger than those of different widths. That is to say, the depth of the potential well has more effect on the

SR systems than the width. Obviously, the A-SNRG for the small  $\alpha$  is always larger than the big  $\alpha$  and the result exhibits the system with a smaller asymmetric factor  $\alpha$  which means the potential function with narrower width has a better detection effect. The value of A-SNRG when  $\alpha > 1$  is much larger than it when  $\alpha < 1$ . So the smaller width of one potential well in an asymmetric bistable system has a positive effect on stochastic resonance.

In Figure 10(a), with the increase of parameter  $\alpha$ , the peaks of A-SNRG curves increase and the values  $a_0$  corresponding to each peak decrease. And it indicates that the smaller the value of  $a_0$  is, the better the detection effect will be with a certain  $b_0$ . In Figure 10(b), with the increase of parameter  $\alpha$ , the peaks of A-SNRG curves increase and the values  $b_0$  corresponding to each peak increase at the same time. And it indicates that the greater the value of  $b_0$  is, the better the detection effect will be with a certain  $a_0$ . That is to

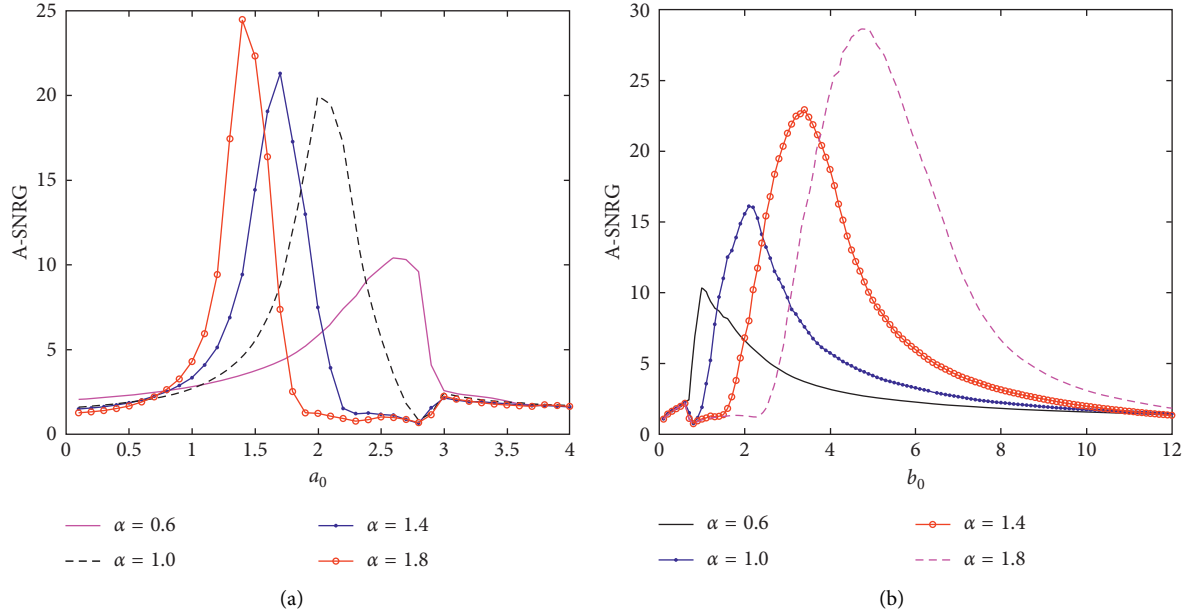

FIGURE 7: A-SNRG of SR with asymmetric depth of potential well as a function of the potential function parameter. (a)  $a_0$  and (b)  $b_0$ .

FIGURE 8: A-SNRG of SR with asymmetric depth of potential well as a function of potential function parameter  $q$ .

say, there is a pair of optimal system parameters which can enhance the effect of SR.

In Figure 11, the value of A-SNRG increases with  $q$  increasing for different values of  $\alpha$ . It means that the longer the residence time of particle is, the better the effect of the stochastic resonance will be with different widths of a single well. Compared with Figure 8, the width of the potential well has no effect on the trend of the curve for  $q$ -A-SNRG.

FIGURE 9: A-SNRG of SR with asymmetric width of potential well as a function of noise intensive  $D$  for asymmetric factor with different values of  $\alpha$ .

4.3. Influences of Asymmetric Factor  $\alpha$  for SR with Asymmetric Depth and Width of Potential Well. The parameters of the input signal contain  $A_0$ ,  $f_0$  and trichotomous noise contains  $a$ ,  $b$ ,  $c$  consistent with the above results. The parameters of the potential function are  $a_0 = 1.9$ ,  $b_0 = 2.3$  from the adaptive algorithms. The influence of the noise intensity  $D$  is shown in Figure 12. Then, the influence of  $a_0$  and  $b_0$  with the noise intensity fixed  $D = 0.5$  is shown in Figure 13. After

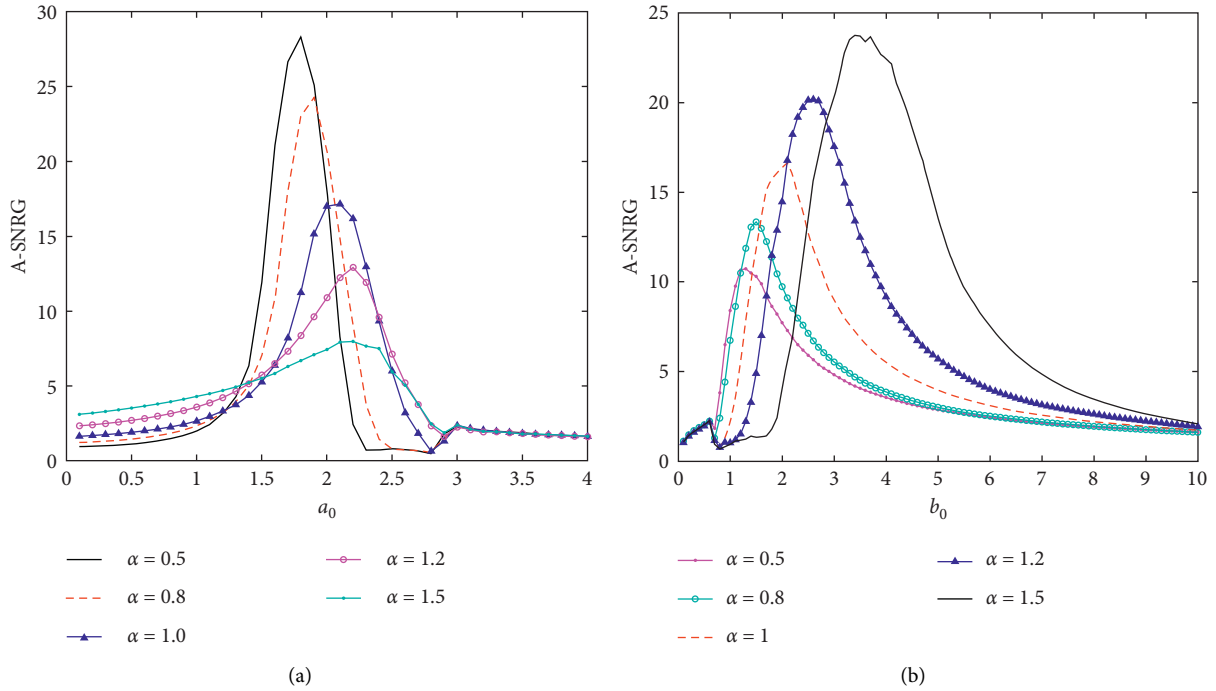

FIGURE 10: A-SNRG of SR with asymmetric width of potential well as a function of a potential function parameter. (a)  $a_0$  and (b)  $b_0$ .

FIGURE 11: A-SNRG of SR with asymmetric width of potential well as a function of potential function parameter  $q$ .

that, the influence of  $q$  with the noise intensity fixed  $D = 0.5$  and  $a_0 = 1.9$ ,  $b_0 = 2.3$  is shown in Figure 14.

Figure 12(a) shows that when  $\alpha \in (0.8, 1.1]$ , with the increase of the noise intensity  $D$ , the curves of A-SNRG first increase and then decrease for different values of  $\alpha$  and it means that stochastic resonance with asymmetric depth and width of the potential well is generated under the drive of

trichotomous noise. To see more clearly, the values of the asymmetric factor are 0.8, 1.0, and 1.2 given in Figure 12(b), respectively. When  $\alpha = 0.8$ , the curve of A-SNRG shows a downward trend in all the values of  $D \in (0, 3]$  which means the system cannot produce SR. When  $D > 1$ , the value of A-SNRG for  $\alpha = 1.2$  is larger than that for  $\alpha = 1$ . In the case that other parameters are the same and with the appropriate

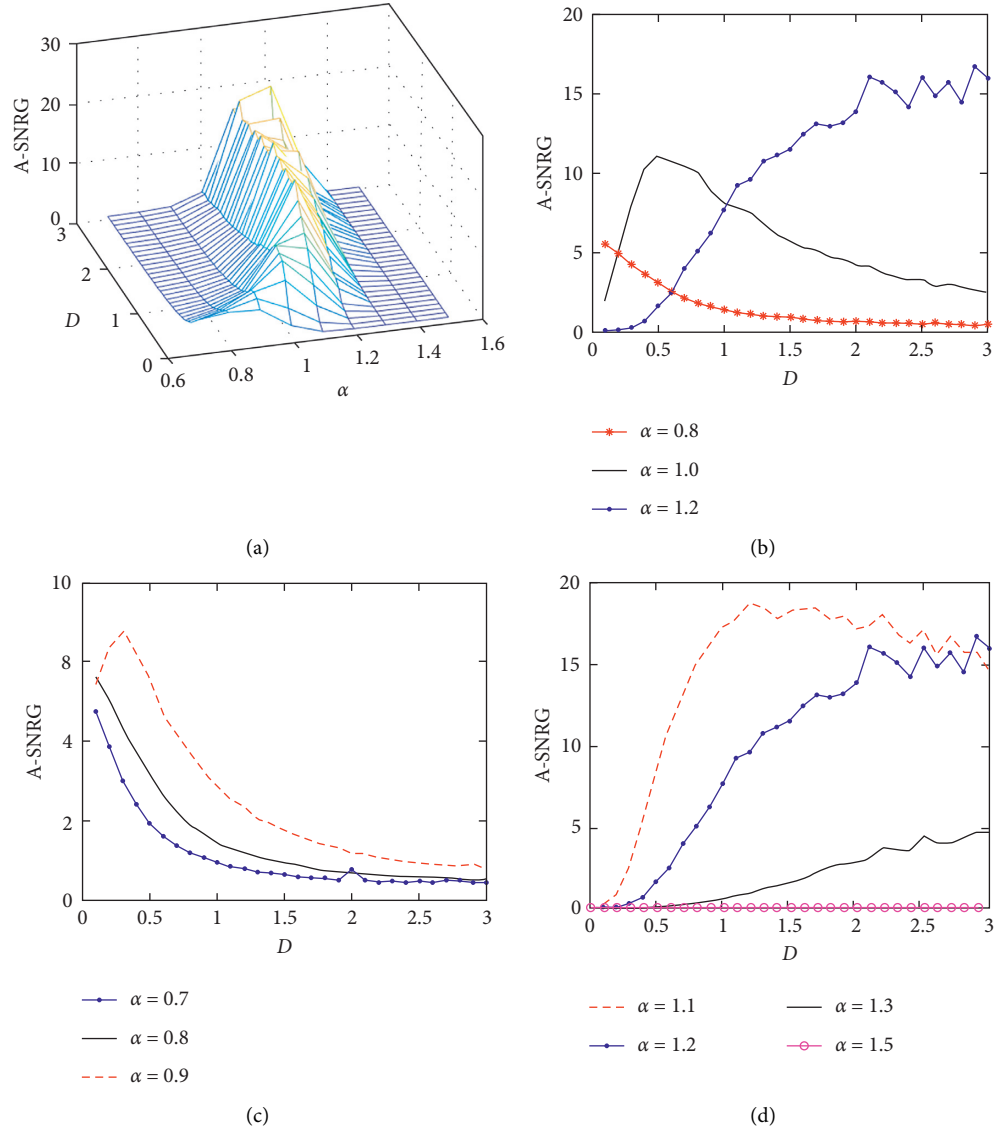

FIGURE 12: (a) A-SNRG of SR with asymmetric depth and width of potential well as a function of noise intensive  $D$  and asymmetric factor with different values of  $\alpha$ . (b) A-SNRG of SR with asymmetric depth and width of potential well as a function of noise intensive  $D$  for different values of asymmetric factor with  $\alpha$ , (c)  $\alpha < 1$  and (d)  $\alpha > 1$ .

noise intensity, the system with the asymmetric well has a more positive effect on the SR than the traditional one. The value of A-SNRG when  $\alpha > 1$  is larger than that when  $\alpha \leq 1$  under the condition that SR can be produced in Figure 12(b), and it means a larger asymmetric factor may have a better detection effect. Next, SR curves for  $\alpha < 1$  and  $\alpha > 1$  will be analyzed more clearly and Figures 12(c) and 12(d) show the SR curves for  $\alpha < 1$  and  $\alpha > 1$ , respectively. Figure 12(c) shows that the curves have no peaks which means the system cannot produce SR until  $\alpha = 0.9$ . Figure 12(d) shows that the value of A-SNRG is maximum for  $\alpha = 1.1$  and it decreases from  $\alpha = 1.1$ . When  $\alpha = 1.5$ , the values of A-SNRG are all under 1, so the system cannot produce SR with  $\alpha = 1.5$ . These four figures demonstrate that there is an

optimum asymmetric factor that has a better detection effect than the traditional system.

Under the condition that SR can be produced, in Figure 13(a), with the increase of parameter  $\alpha$ , the peaks of A-SNRG curves decrease and the values  $a_0$  corresponding to the peak decrease at the same time. In Figure 13(b), with the increase of parameter  $\alpha$ , the values  $b_0$  corresponding to the peak increase at the same time. The peaks of A-SNRG curves remain stable when  $\alpha \in [0.9, 1.1]$  and then decrease. That is to say, when  $\alpha$  is around 1,  $b_0$  is meaningless to enhance the effect of SR.

In Figure 14, when  $\alpha < 1$ , the value of A-SNRG increases with  $q$  increasing. when  $\alpha > 1$ , the value of A-SNRG increases first and then decreases with  $q$  increasing. According to

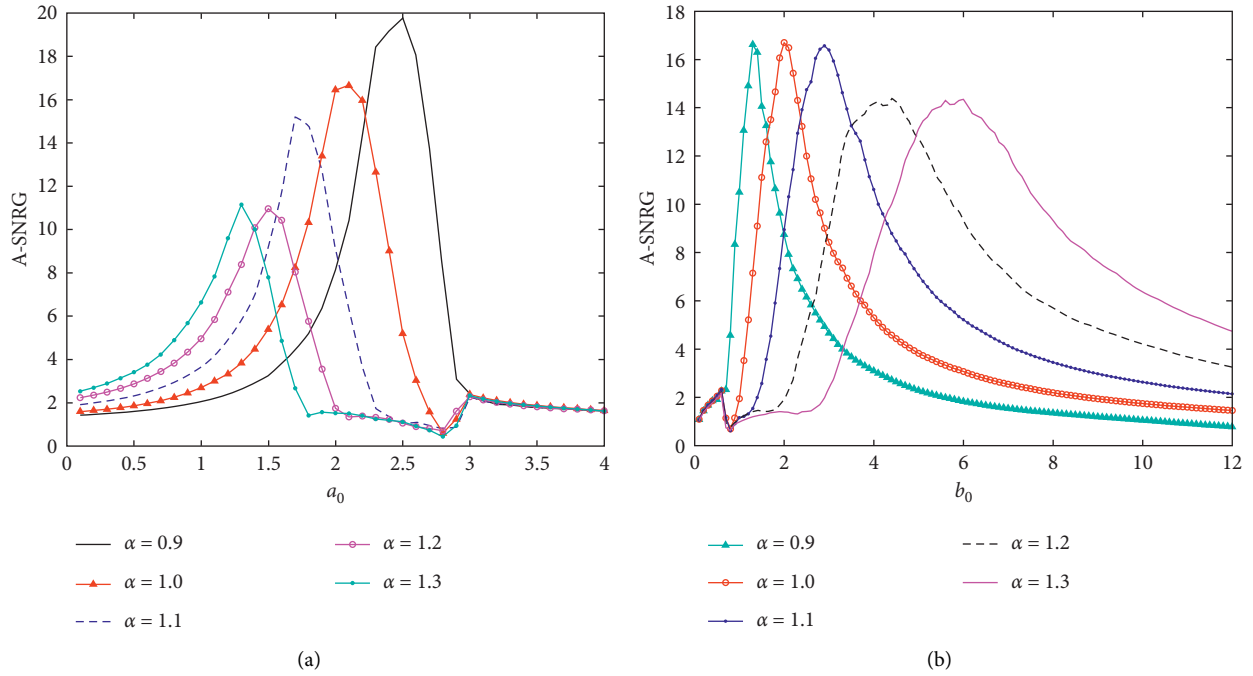

FIGURE 13: A-SNRG of SR with asymmetric depth and width of the potential well, as a function of the potential function parameter. (a)  $a_0$  and (b)  $b_0$ .

FIGURE 14: A-SNRG of SR with asymmetric depth and width of potential well as a function of potential function parameter  $q$ .

Figures 8 and 11, the trend of the curve when  $\alpha > 1$  is determined by the depth of the well only.

## 5. Conclusion

In this paper, we have focused on the SR phenomenon in three types of the asymmetric bistable system driven by trichotomous noise. The following conclusions can be drawn

from the above research: (1) when the system parameters of the potential function are different functions of an asymmetric factor, the depth and width of a single potential well can be changed. (2) When the noise intensity  $D$  is relatively large, a better detection effect can be obtained by making the depth of a single well deeper. It can improve the detection effect by making the width of the potential well smaller for different noise intensities  $D$ . (3) Parameters  $a_0, b_0$  of the potential function always have the optimal value regardless of the form of asymmetry. (4) The effect of particle residence time on the stochastic resonance system is affected by the depth of the potential well.
