Retracted: Clinical Care of Hyperthyroidism Using Wearable Medical Devices in a Medical IoT Scenario

Journal of Healthcare Engineering

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Retracted: The Role of Health Education in Vaccination Nursing

Journal of Healthcare Engineering

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Wearing a mask greatly reduced the possibility of infection during the COVID-19 pandemic. However, major inconveniences occur regarding patients with upper limb amputations, as they cannot independently wear masks. As a result, bacterial contamination is caused by medical staff touching the quilt when helping. Furthermore, this effect can occur with ordinary people due to accidental touch. This research aims to design an automatic and portable face shield assistive device based on surface electromyography (sEMG) signals. A concise face shield-wearing mechanism was built through 3D printing. A novel decision-making control method regarding a feature extraction model of 16 signal features and a Softmax classification neural network model were developed and tested on an STM32 microcontroller unit (MCU). The optimized electrode was fabricated using a carbon nanotube (CNT)/polydimethylsiloxane (PDMS). The design was further integrated and tested, showing a promising future for further implementation.

1. Introduction

In recent years, the COVID-19 epidemic has been rampant. As a result, face shielding has been effectively used to avoid the spread of the corresponding virus [1]. In the absence of a shelter-in-place strategy, infections, hospitalizations, and deaths were reduced by 37.7%, where the interquartile range (IQR) was 36.1–39.4%, 44.2% (IQR: 42.9–45.8%), and 47.2% (IQR: 45.5–48.7%), respectively, as nonmedical masks were worn by 75% of the population reduced [2]. The use of general facemasks has significant benefits, especially if they are adopted earlier, and at least some benefit is realized across a range of epidemic intensities. Furthermore, masks can be used in addition to other interventions, such as social distancing and hygienic measures, ultimately resulting in a nonlinear decrease in epidemic mortality and healthcare system burden [3]. During the COVID-19 outbreak, many new developments related to healthcare utilized electromyography (EMG) or electroencephalogram (EEG). Setiawan et al. proposed a stroke rehabilitation monitoring method using EEG [4], Bano and Hussain could identify patients that were infected by COVID-19 using the EMG technique [5], and L. Jiang et al. developed an advising device for at-home exercise using sEMG [6].

Some disabled and paralyzed patients, however, who have both arms amputated cannot wear face masks independently. According to the latest survey reported by China Disabled Persons' Federation, in 2010, China had 20.54 billion amputation patients [7], of which 2/3 were upper limb amputees [8]. In addition, there is a nonnegligible group that has a severe impairment of both upper-and triple-limb functions [9]. However, assistance in public places increases the risk of viral infection. Furthermore, cross-infection in hospitals when nurses take care of paralyzed patients and manually wear face shields can also occur. [10] Nevertheless, patients who cannot or have difficulties putting on masks by themselves arrive at hospitals without wearing masks or need to call a nurse for assistance at their home. As a result, the person can get infected if the nurse or people in the hospital are recessive carriers of COVID-19.

Many casual activities, such as dining and drinking, require that masks are constantly put on and off. However, some patients cannot be assisted by nurses all day. In some public places, directly touching the inside of a face shield by hand can contaminate this equipment, reducing its protection against infectious diseases and threatening health. We also believe that a new hand-controlled face-shielding device could be convenient for ordinary people. Hence, a noncontact wearable face-shielding-wearing system is proposed.

Heckendorn [11] and Backers Today [12] separately developed two automated face-shielding-wearing systems controlled through buttons. The automatic face shielding of Heckendorn is promising due to its mechanical structure and portability. Furthermore, the one designed by Backers Today is convenient for drinking water. These designs, therefore, reduce the possibility of contaminating face shields and are conducive for people with disabilities.

Huang developed an automask utilizing an ultrasonic sensor and an sEMG sensor that allowed the wearer to actuate when sneezing by contracting the abdominal muscle while manually covering the ultrasonic sensor [13]. This design could detect and avoid the sneeze spreading; however, the situations in which such devices can be applied are limited. Furthermore, the mask is not suitable for patients with upper limb amputations, as it can only be actuated by contracting the abdominal muscle while covering the ultrasonic sensor by hand. The utilization of an HC-SR04 ultrasonic distance sensor would significantly harm the cost efficiency of the design. The HC-SR04 module is an active measurement instrument [14] that continuously emits an echo pulse at a 40 kHz frequency [15]. Owing to the active detection limit, the power consumption of the HC-SR04 module is incessant during wearing. In contrast, the sEMG module is a passive measurement instrument whose power consumption is much lower; therefore, it is more suitable for casual wearing. Moreover, the ultrasonic distance sensor can be accidentally triggered from the outer environment, such as the clothing of the user or the impact caused by passing-by pacers. Furthermore, the signals of ultrasonic distance sensors commonly fluctuate (fluctuation phenomenon) [16], even though a threshold value is set to avoid accidental triggering. In addition, the control algorithm of the design involved no signal classification, increasing the risk of accidentally triggering the mechanism. The actuation and control of the servo motor without a signal classification are usually achieved by manually setting the threshold of the triggering voltage amplitude. [15] However, unwanted spike signals that trigger the actuators can be generated. For example, accidental pressing on the sEMG sensors or external force-induced position shift of the electrodes would create spikes and noise. Furthermore, the fluctuation phenomenon of the ultrasonic distance sensors contributes to more accidental actuation in Taliyah Huang's design. Finally, controlling the mask based on the abdominal muscle is not feasible, as the body fat at a selected abdomen position significantly varies depending on the person; therefore, the EMG signal cannot be commonly applied. Different factors, such as epidermal body fat, significantly influence the sEMG measurement, [17]. As lipids easily accumulate in the abdomen, the abdominal muscle EMG could be weak to be detected when facing thick abdominal fat tissue.

To solve these problems, we designed a portable, noncontact, and automatic face-shielding-wearing device that considers the EMG signals.

2. Background Knowledge

An electromyography instrument is used in EMG to record muscle bioelectric signals. These electrical signals can describe some characteristic behaviors of the human muscles. EMG signals can be used in many fields, such as clinical applications [18] and human-computer interaction [19]. More direct monitoring of the human body can be achieved through the analysis, processing, classification, and various signal analysis methods of these signals [20]. New implementations of EMG, such as muscular paralysis disease prediction using EMG, have been developed during the pandemic [21].

However, people who are inconvenienced by wearing masks often need to adapt themselves to EMG devices for a long time. Commercial electrodes are generally Ag/AgCl electrodes; however, these components should be avoided, as they cause damage to human skin [22]. As a result, we used carbon nanotubes, which are nontoxic, harmless, and pollution-free [23], as the primary material for the electrode, increasing its stronger skin affinity and allowing it to be more suitable for long-term use.

The proposed device collects and analyzes the human body EMG signal, realizing thereafter, through machine learning, the wearing and removal of the face shield according to the human body EMG signal. As a result, it does not need to be manually controlled. This study used the specific location of the muscle signal of a dual-channel sEMG detector. We also improved the electrode material in contact with the human body, resulting in a more suitable material for long-term use. Based on the corresponding signal feature processing and machine learning classification, noncontact automatic face shielding and wearing could be realized.

3. System Architecture and Methodology

The main objective of this study was to design a portable face-shielding device based on sEMG. The user of the proposed device could wear/undress the mask by contracting two specific muscles, fulfilling the noncontact demand for paralyzed patients with amputated upper limbs or ordinary people, therefore avoiding the accidental touch of the inner surface of the face shield. By selecting two independent muscles that do not usually form a synergic pattern, the device can be precisely actuated based on the corresponding gesture, thereby avoiding accidental triggers. To realize this purpose, at least three primary components were involved: data acquisition units, portable data processing units, and automatic face-shielding mechanisms.

A data flow chart of the designed system, composed of these primary components, is shown in Figure 1. We use a 2 MyoWare™ Muscle Sensor (AT-04-001) [24] to achieve

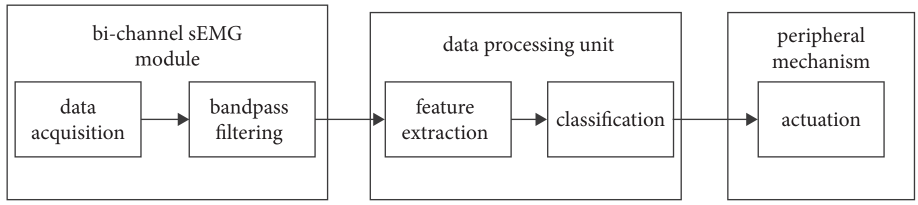

Figure 1: Data flow chart of the proposed device.

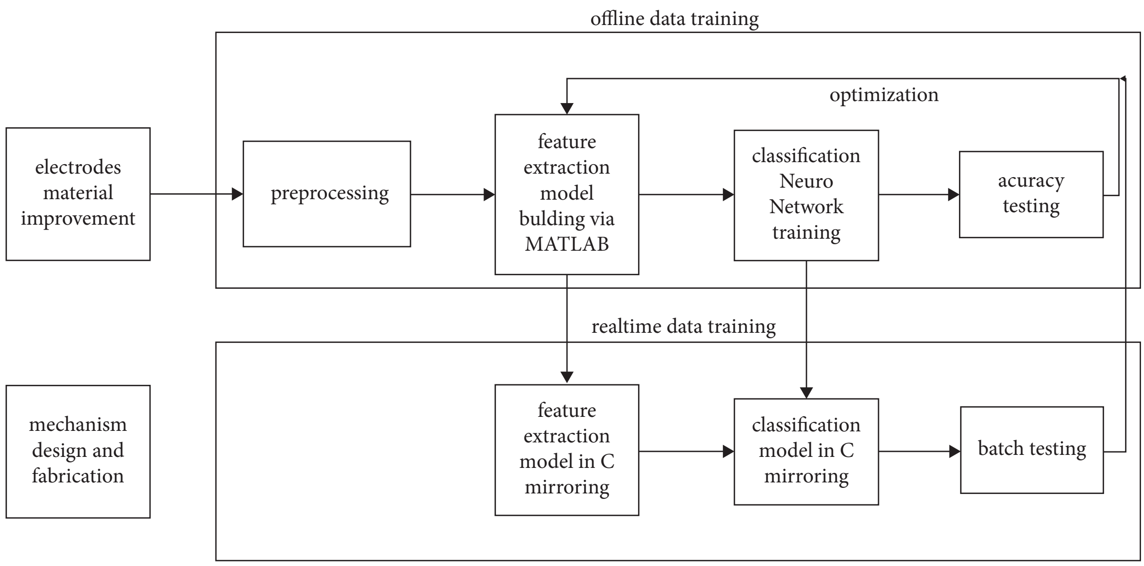

Figure 2: Research methodology diagram.

bichannel input of the sEMG signals, as the EMG signals of two independent muscles were detected. A hardware bandpass filtering circuit and rectifying and amplifying procedures were integrated into the MyoWare module. The analog sEMG signal was further converted to a digital signal through an analog to digital converter (ADC) on a STM32F103ZET6 microcontroller unit (MCU), which is a portable data processing unit. Based on the received data, our algorithm yields a decision that fulfills the user demand. Accordingly, the triggering signal is sent to the automatic face-shielding mechanism via IIC based on the corresponding gesture.

Many studies, among which the methodologies are profound examples of our research, have been conducted on implementations utilizing sEMG. References [25–28] investigated muscle selection for sEMG electrode placement or gesture selection. References [26–30] analyzed the sEMG signal preprocessing or segmentation. References [25–29] studied a feature extraction procedure of the signal and a classification method utilizing neural networks or a support vector machine (SVM), which was integrated into [25–29]. Based on the methodologies investigated, our research methodology can be summarized as indicated in Figure 2.

To increase the dermotropic property and electrical conductivity of the electrodes, we have investigated the improvement of the electrode material. The mechanical structural design targets a lightweight and conciseness compatible wearable mechanism. As shown in Figure 2, the model training of the EMG data flow can be divided into an offline data training process and a real-time model training.

In the offline model training procedure, the data were, first, preprocessed. Afterward, serial feature extraction based on the segmented data batches was conducted. The classification process was based on artificial neural networks (ANN) in this research.

Models are obtained through offline training, regardless of the real-time control of the mechanism and considering datasets stored on a personal computer (PC). Further development of these idealized models needs to be achieved and calibrated in the real-time training procedure. Their parameters were, therefore, carefully adjusted based on the actual performance of the device to achieve the optimized conditions.

Our experimental setups of the data flow model training are shown in Figure 3, which indicates the key components for the feature extraction model and the classification neural network training. The red arrows represent the power supply directions; the blue lines stand for data flows from the peripheral devices to the MCU. In contrast, the yellow arrows represent the opposite data flow. Both data flow represented by the yellow and blue arrows should be omitted during the real-time optimization to achieve the portability of the design. The green and grey arrows indicate the data flow between the MCU and peripherals.

To illustrate the hardware selection, two MyoWare™ muscle sensors (AT-04-001) were selected for the sEMG

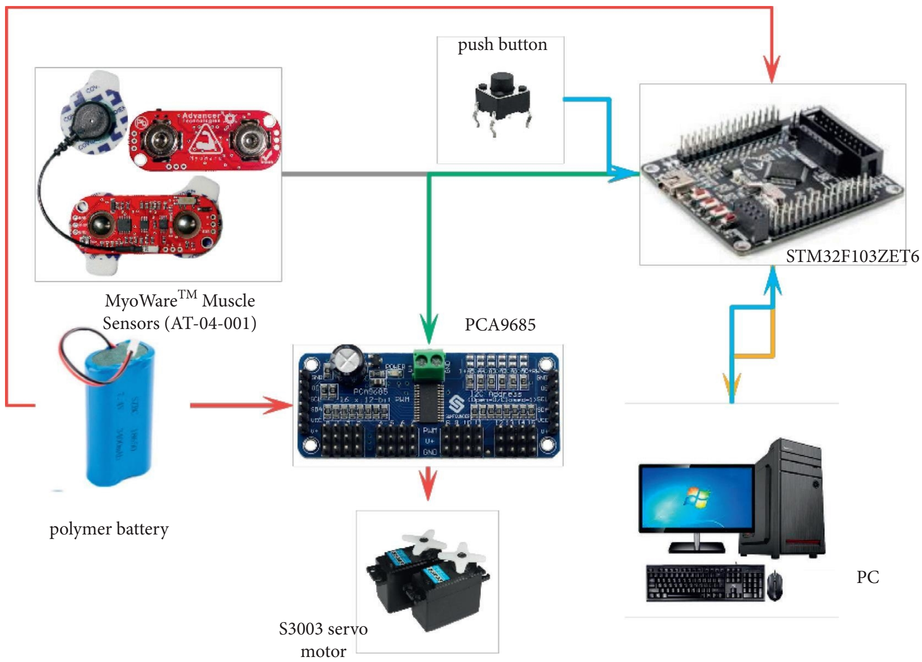

Figure 3: Experiment setups for feature extraction and classification model training.

signal detection. A 32-bit microcontroller composed of an ARM Cortex-M3 core STM32F103ZET6 [31] MCU module was selected to execute the computational tasks of this portable device, owing to its computational performance and stability. A push button, which was pressed to indicate the need for the shielding mask, was used for signal labeling. A 5 V polymer battery was needed for the power supply. The PCA9685 module is a 16-channel PWM output motor control module [32]. In this study, we realized control of a FUTABA Corp. S3003 servo motor through IIC communication and PCA9685.

4. Design of Mechanism

The mechanical design of the face-shielding device should promote function, reliability, and economic characteristics. To achieve a functional design, the basic motion form, as well as the main measurement of the device, should be analyzed based on practical applications. After completing the overall design of the device, which is usually idealistic and abstract, its reliability must be evaluated; therefore, specific parts, such as rockers and connectors, should be selected, and mechanical calculations and analyses are necessary to ensure the feasibility of movement. Certain elements might also be modified and optimized. Finally, the material and manufacturing process are were selected based on a limited budget.

Our face-shielding device must successfully take the face shield on and off. To simplify this situation, it can be assumed that the shield is moving around a fixed point. As this is the only movement required, the device can be designed as a planar mechanism, as shown in Figure 4(a). To further simplify the system, a rigid four-bar linkage was used as the basic structure.

As the only movement of the face shield is rotation, the mechanism has only one degree of freedom (DOF). To fulfill this requirement, a parallelogram form of the four-bar linkage was used, as shown in Figure 4(b)). Based on this adaptation, the rotary motion of the driver bar at the driven bar is duplicated, therefore creating a stable parallel relationship.

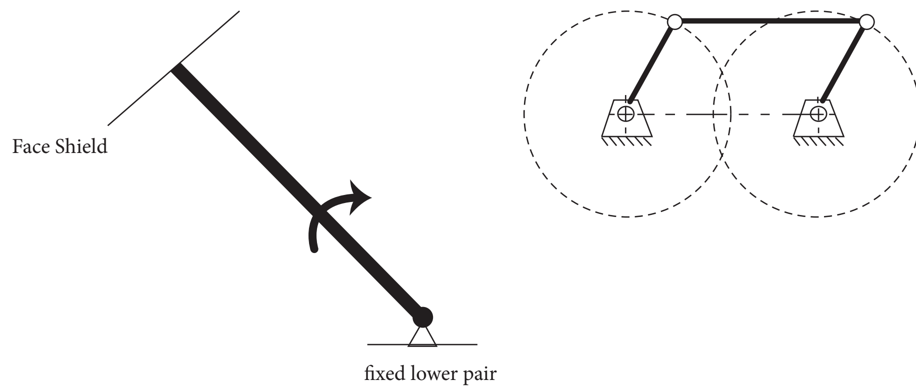
The planar DOF is governed by the following equation:

$$M = 3(L - 1) - 2J_1 - J_2, \quad (1)$$

where M is the DOF, L is the number of links, and J_1 and J_2 are the number of lower and higher pairs, respectively. In the parallelogram linkage, where one bar is already fixed, $L = 4$, $J_1 = 4$, and $J_2 = 0$; therefore, $M = 1$ based on equation (1). This value of DOF indicates that the four-bar linkage of the parallelogram fulfills the requirements of this study.

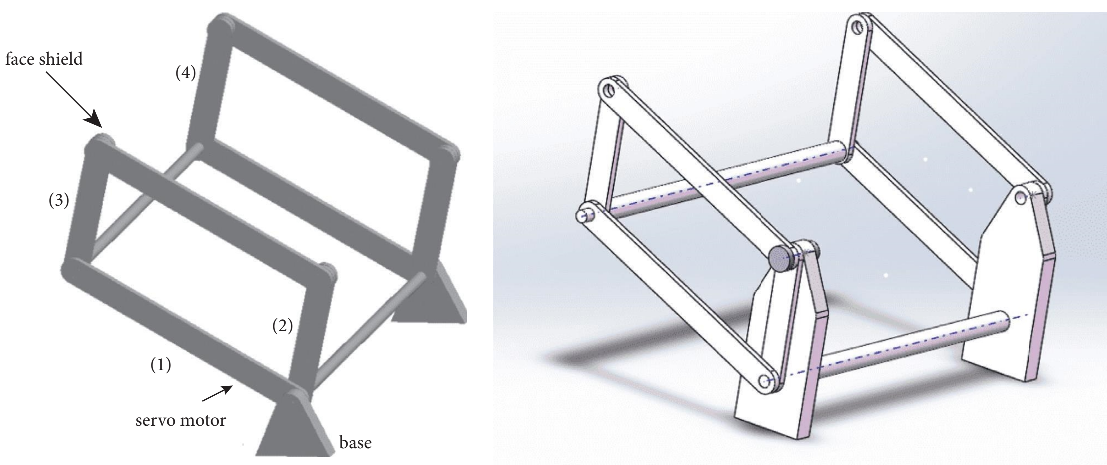
The concept of the planar mechanism was, thereafter, further refined into a 3D mechanism by adding two identical four-bar linkages connected by an axis, therefore completing the structure that could be fixed on the neck of the subject and achieving a rotary motion. The dimensions of the structure were based on the human face and actual movement. Figure 5(a) demonstrates the 3D version of the device constructed through SOLIDWORKS 2020. Two bases were placed on either side of the neck of the subject, and a servo motor was installed to drive rocker1, allowing it to complete the rotary motion. The face shield was placed between connecting rod3 and rod4.

However, according to our requirements, bar2 should be fixed to restrict the DOF to one. Moreover, the joints on which the connectors should be used have not been determined yet. As the stability of the structure must be ensured during operation, the movement of the bars moving along the axle cannot be executed. As a result, based on the



(a) (b)

Figure 4: Simplified model of the device. (a) Simplification of the motion form. (b) Parallelogram configuration of the four-bar linkage.



(a) (b)

Figure 5: Simulations of the device in SOLIDWORKS. (a) 3D mechanism of the face-shielding device, including two equal four-bar linkages, two bases, and two connecting axles. (b) Optimized mechanism containing connectors and new supporting bases.

reliability analysis, the joints were connected by bolts and nuts, a new base was designed to restrict the movement of bar2, and the diameters of the two axles were modified to ensure the axial constraint. The optimized mechanism is shown in Figure 5(b)).

In additive manufacturing (3D printing), simulations can be directly transformed into real objects, resulting in a swift process. The simulation in SOLIDWORKS was already implemented; therefore, due to the principle of economic design, additive manufacturing was selected as our manufacturing method. The material that has been frequently used in this process is resin, as it demonstrates suitable rigidity for the rotation of light objects, such as face shields. The accuracy of this method, however, is not satisfactory yet, which may result in higher dimensional and geometric tolerances in each part.

The proposed mechanism provides, therefore, a relatively effective procedure for taking the face shield on and off without requiring a complex structure. Furthermore, the material selected for the face-shielding device is light and the rigidity against the torque generated by the servo motor is sufficient, resulting in less stress for the subjects when using the device. However, the stability of the entire mechanism is not perfect owing to its simple structure, therefore requiring future improvements. Moreover, the mechanism might wear after a long-term operation due to the lack of protection.

5. Improvement of the Material of the Electrode

5.1. Background. The standard sEMG electrode commonly used in experiments is usually composed of gold (Au), silver (Ag), or silver-silver chloride (Ag/AgCl). Ag/AgCl is the most widely used material, as it has a lower baseline-noise interface than that of the other electrodes. Most Ag/AgCl on the market is present in the form of gel, for better maneuverability. This material can also be used in the surface coating of the electrode to reduce surface impedance and improve signal quality [33].

However, Ag/AgCl electrodes have several problems. The proposed equipment must be designed considering that people can wear it for a long time; however, the long use of an Ag/AgCl electrode can easily stimulate the skin and affect the signal quality after drying [34]. As a frequent replacement of new electrode sheets and stimulation of human skin are not considered in our design, an electrode that can be worn for a long time was developed [35].

Owing to the good dispersibility of carbon nanotubes (CNTs) and the flexibility of polydimethylsiloxane (PDMS), CNT/PDMS composites are considered good flexible conductors. The nanotubes dispersed in the electrode were in good contact with each other, forming a conductive path. Conductivity tests showed that the electrical performance depends on the concentration of carbon nanotubes. Furthermore, electrode materials are safe for biomedical applications, as they are not easily affected by sweat on the surface of the human body [36].

5.2. Materials and Methods

5.2.1. Material Parameters. The CNT used in the electrode was manufactured by Suzhou Tanfeng Tech. Inc., China. The purity and length of the carbon nanotube were over 95 wt% and 3–12 μm, respectively. The multiwall CNT was manufactured through vapor deposition. PDMS was manufactured by Shenzhen Xinwei New Material Co. Ltd. by using 909 potting glue.

5.2.2. Fabrication of Electrodes. The electrode was composed of an insulating layer, conductive film, and button electrode, as indicated in Figure 6.

The CNT was dispersed into the PDMS precursor (viscosity: 4000 ± 500,909-A, Xinwei New Material Co., Ltd.) and mixed through dispersion. A crosslinking agent (viscosity: 100 ± 10,909-B, Xinwei New Material Co., Ltd), whose ratio was 10 : 1, was solidified for 12 h at room temperature. When this agent could not solidify, the button electrode was embedded in the colloid and the solidification process occurred for 24 h. A 10 : 1 ratio of PDMS was used on the periphery, forming an insulating layer to facilitate contact between the electrode and the skin. Table 1.

As shown in Table 2, the specifications of the electrode sheet must be defined to enable the usage of the equipment for a long duration. The diameter of the conductive electrode part of the CNT/PDMS electrode sheet used in the experiment was 10 mm, which is a small part of the entire electrode. The conductive electrode (main body of the electrode), whose length and width were 36.5 mm and 30.2 mm, respectively, was composed of a PDMS solid gel. The overall thickness of the electrode sheet was 2 mm.

5.2.3. Electrical Test and Specification. The impedances of the electrodes were measured using an electric meter. Table 1 shows a test comparison diagram of commercial Ag/AgCl electrodes and CNT/PDMS electrodes considering the same specifications.

The transparent material in Figure 7 is the PDMS patch, and the black component corresponds to the CNT/PDMS electrode. The button electrode was connected on top of the CNT/PDMS to obtain an electrical signal from the device.

6. Electrode Positioning and Muscle Selection

The muscles were selected in this study by mainly two criteria: (1) if they are independent of each other; therefore, they ought not to collaborate to execute the same gesture, to reduce the possibility of accidentally actuating the mechanism; (2) if the selected gesture pattern is easy to achieve. Furthermore, face shielding should not affect the feasibility and regularity of the selected pattern.

The position and orientation of the muscle sensor electrodes significantly affect the strength of the signal. Owing to the differential detection mode of the sensors, two detection points and a reference position should be defined. The electrodes should be placed in the middle of the muscle body and aligned with the muscle fibers [25]. Meanwhile, the reference electrode should be placed on a separate section of the body, such as the bony portion of the elbow or a nonadjacent muscle. Due to the size of the MyoWare™ muscle sensors (AT-04-001), the sensors of the system are closely positioned (C-position). As a result, the differential voltage between the two points in the middle of the muscle body could be detected [37].

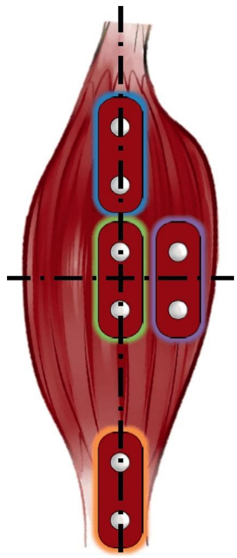

Figure 8: Electrode placement illustration.

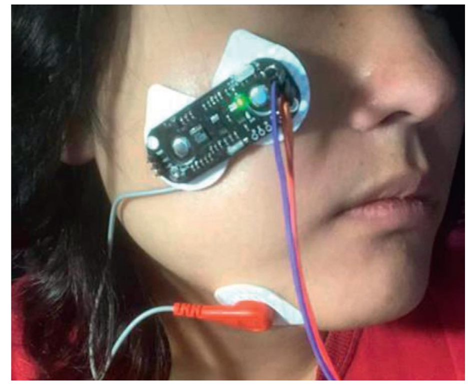
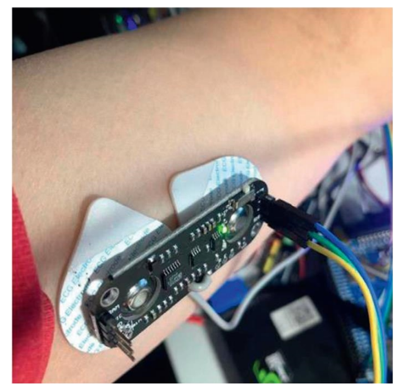


(a)



(b)

Figure 9: Muscle selection and electrodes placement. (a) Positioning of the electrode on zygomaticus. (b) Electrode positioning on the bicipital muscle of the arm.

Figure 8 shows the positions of the electrode placement based on the muscle. The green box indicates the correct positioning of the electrodes (midline of the muscle belly between the innervation zone and myotendinous junction) [24].

After comprehensive consideration of the two major factors affecting the positioning of the electrodes, the gesture pattern was defined based on the zygomaticus and bicipital muscle of the arm. In particular, these muscles were selected as they can be easily contracted and their gestures can be executed by different users, such as patients with upper limb amputation and ordinary people. The gesture pattern was defined as a signal trigger when both muscles simultaneously contracted. The detailed placement of the electrodes is shown in Figure 9. To preserve the accuracy and repeatability of the experiment, the contour of the electrode was marked by using a luminous pen after each test.

After attaching the electrodes to the surface of the muscles, a bichannel ADC function was completed on the MCU utilizing a timer interrupt and setting a sampling rate of 100 Hz. The sampled data were stored in an array for further processing.

7. Preprocessing and Feature Extraction

The preprocessing of the sEMG signal usually involves amplification [29], filtering [26, 27, 29], rectifying [26, 27], and segmentation (or windowing) [28, 38]. An instrumental amplifier, bandpass filter, and rectifying circuits were, therefore, integrated into the MyoWare™ Muscle Sensors (AT-04-001) [24]. As a result, only data segmentation could not be conducted directly by the sensor.

A fixed-length segmentation method [38] was applied in this study. The windowing length was restricted to the performance of the STM32 MCU. The coding process of the MCU was conducted using Keil MDK v5.26 Software. Only 64, 256, and 1024 points of fast Fourier transformation (FFT), which is a method to analyze the power-related characteristics of signals from the aspect of the frequency domain, were allowed on the F1 series of the STM32 [39]. Time-frequency analysis is an important key to EMG signal feature extraction [40, 41]. Due to the selected sampling rate and the requirement for a quick response, the FFT of 64 points was used in this study. To date, a windowing of 64 data points per batch has been set for feature extraction, indicating that the response time for pattern recognition is approximately 80 ms, based on a calculation machine cycle (MC).

The acquired voltage amplitude data of the two inputs and labeling data of the push button were sent from STM32F103ZET6 to the PC using a universal asynchronous receiver/transmitter (UART) and stored in text files (.txt). The files were later processed using MATLAB, as shown in Figure 10, where the vertical and horizontal axis indicates the amplitude and the timeline, respectively. The peaks in the figure are spiky as this dataset was composed of over 15000 points of data, resulting in a contraction in the horizontal display of the graph. The data sent to MATLAB were raw data that were not binned based on 64 batch sizes, as the segmentation of the data was performed via MATLAB2019a in this simulation stage.

During the feature extraction step of this study, the model was first simulated on a PC using MATLAB2019a to

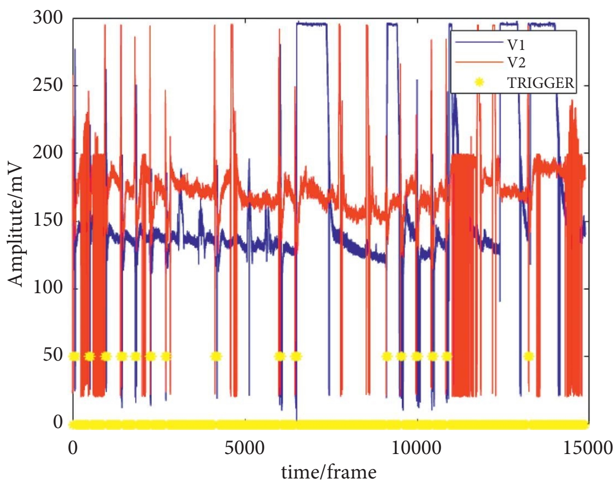


Figure 10: Raw data sent from the MCU to PC.

test the proposed concept. Afterward, the model was coded again using the C language and executed on MCU.

In this study, 16 features, of which 11 were based on the time domain and 5 on the frequency domain, were collected to analyze the binned datasets. The features based on the time domain were the integrated EMG (IEMG), mean absolute value (MAV), modified mean absolute value 1 (MMAV1) and 2 (MMAV2), mean absolute value slope (MAVS), root mean square (RMS), variance (VAR), waveform length (WL), threshold crossing (TC), Willison amplitude (WAMP), and simple square integral (SSI). Meanwhile, the features based on the frequency domain were the frequency median (FMD), frequency mean (FMN), modified frequency median (MFMD), modified frequency mean (MFMN), and frequency ratio (FR).

Equation (2) indicates the IEMG definition [42], where n is the batch size of the segmented data (64) and X_i represents i^{th} data in the dataset. The IEMG is the sum of the absolute value of the EMG signal, which can be treated as a signal power estimator [38].

$$\text{IEMG} = \sum_{i=1}^{n} |X_i|. \tag{2}$$

The MAV, MMAV1, and MMAV2 can be defined by equation (3) [43], equation (4), and equation (5) [44], respectively, where w_i is the i^{th} modified weight of the mean absolute value, which is an important characteristic of the sEMG signals that are based on the time domain.

$$\text{MAV} = \frac{1}{n}\sum_{i=1}^{n} |X_i|, \tag{3}$$

$$\begin{aligned} \text{MMAV1} &= \frac{1}{n}\sum_{i=1}^{n} w_i |X_i|, \\ w_i &= \begin{cases} 1, & 0.25n \le i \le 0.75n, \\ 0.5, & \text{otherwise}, \end{cases} \end{aligned} \tag{4}$$

$$\begin{aligned} \text{MMAV2} &= \frac{1}{n}\sum_{i=1}^{n} w_i |X_i| \\ w_i &= \begin{cases} 1, & 0.25n \le i \le 0.75n, \\ \dfrac{4i}{n}, & i < 0.25n, \\ \dfrac{4(i-n)}{n}, & i > 0.75n. \end{cases} \end{aligned} \tag{5}$$

The MAVS, which indicates the variation between two adjacent batches, can be correctly represented by equation (6) [38], where k represents the k^{th} batch in the dataset.

$$\text{MAVS}_k = \text{MAV}_{k+1} - \text{MAV}_k. \tag{6}$$

The RMS can be described by equation (7) [39]. This quantity is modeled as an amplitude-modulated Gaussian random process whose RMS is related to the constant force and nonfatigue contraction [38].

$$\text{RMS} = \sqrt{\frac{1}{n}\sum_{i=1}^{n} X_i^2}. \tag{7}$$

The VAR can be expressed by equation (8) [42]. This quantity indicates the difference between the signals in the dataset.

$$\text{VAR} = \frac{1}{n}\sum_{i=1}^{n} \left(X_i - \overline{X}\right)^2. \tag{8}$$

The WL is defined by equation (9). This value, which is the cumulative length of the waveform over a segment, is influenced by the waveform amplitude, frequency, and duration [43].

$$WL_k = \sum_{i=1}^{n-1} |X_{i+1} - X_i|. \tag{9}$$

The threshold crossings (TCs) are defined as the instances of the recorded data that crosses a threshold value during one batch.

Equation (10) represents the WAMP [39], which is the cumulative length of the waveform over a segment. This quantity indicates the number of times that the difference of consecutive amplitudes exceeded a predetermined threshold, ℓ.

$$\text{WAMP}_k = \sum_{i=1}^{n-1} f\left(|X_i - X_{i+1}|\right), f(x) = \begin{cases} 1, & x > \ell, \\ 0, & \text{otherwise}. \end{cases} \tag{10}$$

Equation (11) represents the SSI. This quantity is the cumulative length of the waveform over a segment. It also represents the accumulation of the bathed data power [38].

$$\text{SSI}_k = \sum_{i=1}^{n} \left(X_i^2\right). \tag{11}$$

Equations (12) and (13) indicate the FMN [38] and FMD [44], respectively. These quantities use FFT to calculate some properties regarding the power spectrum density (PSD). However, the Pwelch values must be obtained for the calculation of the PSD in MATLAB. This is a difficult task to be executed using an MCU, as similar results are difficult to be obtained. Hence, in this study, we obtained a resemblance [45] between the Pwelch method and the PSD calculated using FFT through equations (14) and (15), respectively. This procedure was added to the MCU using the built-in FFT library from the STM32 DSP.

$$\mathrm{FMN} = \frac{\sum_{i=1}^{n} f_i \mathrm{PSD}_i}{\sum_{i=1}^{n} \mathrm{PSD}_i},\quad f_i = \frac{i * \text{sampling\_rate}}{2 * n}, \tag{12}$$

$$\mathrm{FMD} = \frac{1}{2}\sum_{i=1}^{n} \mathrm{PSD}_i, \tag{13}$$

$$\mathrm{Pwelch} = 2\left(\left|fft\left(X_i\right)\right|\right)^2, \tag{14}$$

$$\mathrm{PSD} = \left(\left|fft\left(X_i\right)\right|\right)^2. \tag{15}$$

The MFMN and MFMD were proposed by Phinyomark et al. [44]. MFMN is calculated as the sum of the product of the amplitude spectrum and frequency divided by the sum of the spectral intensity. MFMD is defined as half of the sum of the amplitude spectrum [38]. As a result, the amplitude spectrum of the signal can result in a volatile FFT.

The frequency ratio (FR) [46] is calculated in equation (16), where $fft_{\max}$ and $fft_{\min}$, respectively, represent the maximum and minimum values of the dataset after the fast Fourier transformation.

$$\mathrm{FR} = \frac{fft_{\min}}{fft_{\max}}. \tag{16}$$

The flag label (FL) shown in equation (17) indicates the decision after evaluating the received data batch. When the dataset includes more than three sampled data points that are labeled, the entire batch is considered for the demand of the decision to trigger the actuator. This feature was omitted in practical scenarios, and it is only available for real-time calibration of the neural network classifier.

$$\mathrm{FL} = \begin{cases} 0, & f < 3, \\ 1, & f \geq 3. \end{cases} \tag{17}$$

The feature extraction was first built using MATLAB2019a considering a raw dataset stored in txt files. Each file contained more than 15000 samples of data. Sixteen feature extractions were applied for each channel of the sEMG signal, resulting in 32 features and one labeling data. These data were stored in csv files and were used, thereafter, in the classification stage.

After the offline data training procedure, the feature extracting model was coded again using the C language and downloaded into the MCU. The FFT was obtained by using the ARM_math and ARM_cFFT_Radix4 libraries [47]. 32 features were extracted from the two input channels. The output of the feature extraction was validated using a COM helper application and a JLINK debugger.

8. Classification

Many classification methods, such as k-nearest neighbours (k-NN) [26, 28], linear discriminant analysis (LDA) [26, 39], quadratic discriminant analysis (QDA) [28], support vector machine (SVM) [27, 28, 41], random tree (RT) [28], random forest (RF) [28, 41], artificial neural networks (ANN) [26, 38, 41], Bayes classifier [26, 38], self-organising map (SOP), and fuzzy classifiers [41], are available in the literature.

The Softmax classifier has outstanding performance when treating a multiclassification problem, as all types of features are normalized according to the number of classes. Furthermore, this classifier can clarify positive features [27]. In the binary classification problem in this study, the device is required to distinguish the triggering signal from the background noise, as the same triggering gesture pattern is used for the masking and unmasking actions. In this case, a Softmax classifier is adequate to solve this problem, as it yields fewer parameters than that of the other classifiers, owing to its simplicity. A large number of parameters would slow the computation speed and consume much flash memory of the MCU. In addition, the increase in complexity of the neural network results in the increase in difficulty to rewrite the model on a portable device.

We constructed the binary Softmax classifier using the 2.3.1 framework backend on TensorFlow 1.13.1. The IDE program on which the algorithm was developed was Pycharm 2020.3–Python version 3.7. No GPU was required, as the network structure and data type were not complicated.

For dataset recording, the person that tested the device was placed in a comfortable position and the electrode was firmly attached to the selected zygomaticus and bicipital muscles. A series of random movements of the limbs and changes in the countenance were performed while periodically executing the triggering pattern (simultaneous contraction of the zygomaticus and bicipital muscles). Whenever the targeting pattern was executed, the subject was requested to press the push button at the same time that he labels the corresponding data batch.

Throughout the offline model training stage, the features were extracted using MATLAB and stored in csv files, which were, thereafter, used in the training of the neural network. However, during the real-time optimization of the model, the features were directly extracted by the portable data processing unit and sent to the PC using UART. These data were again stored in txt files, which were, thereafter, converted into csv files for calibration. As a result, a more realistic dataset was acquired, and the Softmax classifier could be calibrated to achieve its best performance.

The accessed data were shuffled and, thereafter, divided into a training dataset and the test dataset using the K-fold method from the sklearn library. Meanwhile, the label value

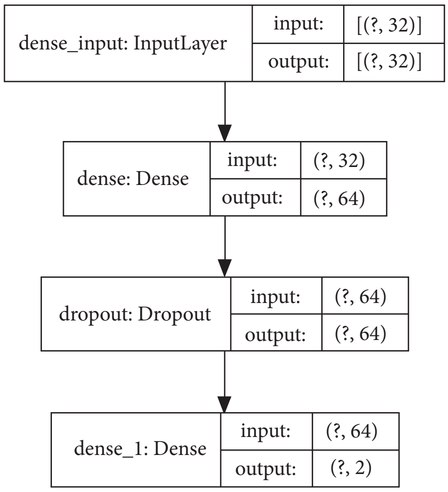

Figure 11: Neural network structure.

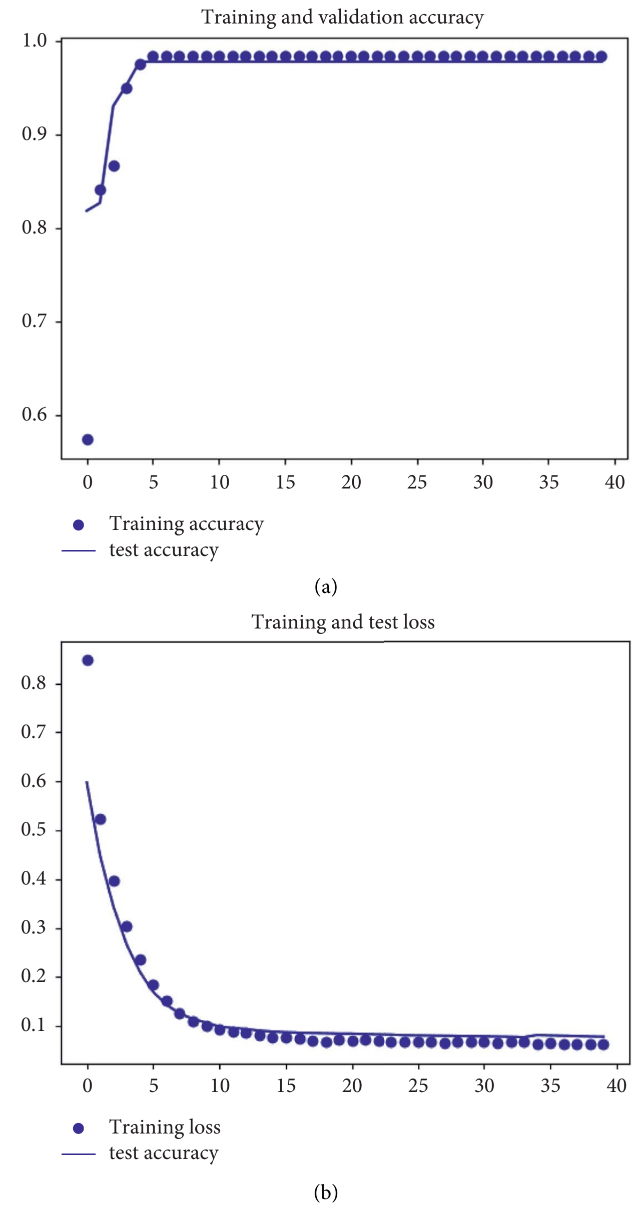

Figure 12: Assessment of the Softmax classifier. (a) Training and validation accuracy of the network. (b) Training and testing loss of the network.

was converted into a one-hot code using the built-in function of Keras.

The structure of the constructed binary Softmax classifier is shown in Figure 11. Overall, the classifier was composed of one input layer, one hidden dense layer, and one output layer. The input layer had a 1×32 input dimension and received a flattened array of 32 features related to the bichannel sEMG input, which could be fed to the network in single frames or catches. The hidden dense layer of the classifier outputted an array of data size 1×64. A drop-out method, whose ratio was 0.02, was introduced to the network to perform a regularization task, preventing the overfitting of the classifier. The output dimension of the network was the same as the class number (2).

For the neural network training process, 40 epochs of 50 batches for each step were implemented. A categorical loss function was used for the loss assessment. The Adam algorithm was implemented for optimization.

The performance analysis of the classifier is shown in Figure 12. Figure 12(a) shows the training and validation accuracy of the network. The average accuracy of 97.7% was achieved, and no significant difference was noticeable between the accuracies of the training and validation models, indicating that no overfitting or owe fitting occurred. Figure 12(b) displays the loss of the network during the training and test stages. Both losses converge to a single value.

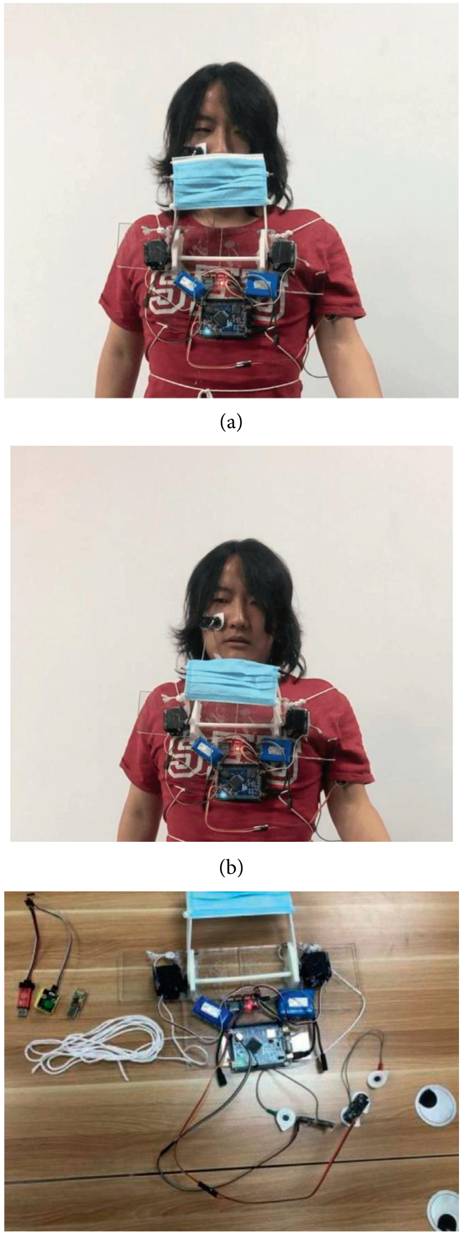
The weights and biases of the trained model were, afterward, converted into array metrics. The copied network of the Softmax classifier was reconstructed using the C language, and the parameters were included. The resulting neural network was repeatedly calibrated considering real-time features sent from the MCU, which were updated to increase the accuracy.

Nevertheless, not all 16 features used in this study should be used during real clinical applications. The FMN shows no significant variation during the test, while the variation of the other features was noticeable. Accordingly, some of the 15 discussed features should be changed in clinical applications.

9. Experiment and Results

Based on the mechanical structure 3D printed and real-time models downloaded, a functioning prototype of the proposed device was built, as indicated in Figure 13.

The mechanism and circuitry of the device were welted on a 5 mm acrylic board using hot-melt adhesives. Actuation of the mechanism was accomplished using a pair of FUTABA S3003 servo motors. Two sets of 5 V batteries were affixed on the board due to the connection plugin shape variance. In the left corner of Figure 13(c), the JLink device, CH340 UART module, and push button were detached using the portable device. The white ropes shown in Figure 13 were used to fasten the device to the subject.



(a)

(b)

(c)

Figure 13: Test pictures of the prototype. (a) Unshielded status of the device. (b) Shielded status of the device. (c) Assembled device prototype.

To test the accuracy of the actual prototype, the accuracy was defined by [26]

$$\mathrm{ACC} = \frac{T_p}{T_p + F_N + F_P} \times 100\%, \quad (18)$$

where T_P, F_P, and F_N denote the number of correct recognitions, incorrect recognitions, and missed gestures. The subject wore the portable device for 1 min. The results are listed in Table 3.

Five tests were conducted considering a recording length of 1 min. Their overall average accuracy was 95.3%. During the test, the subject was asked to perform daily actions, such as drinking or walking, to simulate casual activities. The total number of gestures was not confined; therefore, the experiment could simulate casual activities within a fixed time interval. Based on the test results, therefore, the proposed portable face-shielding device was suitable for further implementation.

Table 3: Test result.

Number	T_P	F_N	F_P	ACC (%)
1	29	0	4	87.9
2	23	0	1	95.8
3	22	0	0	100
4	40	0	0	100
5	38	1	2	92.7

10. Conclusion

A portable face-shielding device utilizing sEMG was proposed, assembled, and proven to be feasible. The purpose of this research was to help disabled and paralyzed patients to independently wear face shields, reducing the risk of contamination due to the direct touch inside the face shield by the hands of ordinary people. Furthermore, new electrode materials using CNT/PDMS were proposed and tested to evaluate their dermotropic properties and electrical conductivity. The proposed device shows promising prospects for future implementation during the COVID-19 pandemic. Further product transitions are encouraged to target wear suitability and audience generalization.

Data Availability

The raw/processed data and program source code required to reproduce these findings are as follows: https://github.com/JasonLvernex/BMI_automatics-faceshielding-device.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

T. Lyu, D. Liu, and C. Shao helped with major contributions to this research, and Z. Zhang was partly involved in the research.

Acknowledgments

This study was supported by the CathayPath Institute of Science (CIS). The authors show their deepest gratitude to Prof. Jan Van Der Spiegel, who offered constructive guidance during this research.

Retracted: Study on Toll-Like Receptor 2-Mediated Inflammation-Induced Familial Hypertension Combined with Hyperlipemia and Its Mechanism

Journal of Healthcare Engineering

Received 11 February 2023; Accepted 11 February 2023; Published 18 February 2023

Journal of Healthcare Engineering has retracted the article titled "Study on Toll-Like Receptor 2-Mediated Inflammation-Induced Familial Hypertension Combined with Hyperlipemia and Its Mechanism" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

The authors disagree with the retraction.

Retracted: Investigation on the Effect of Graded Emergency Nursing Group under the Assistance of Multidisciplinary First Aid Knowledge Internet-Based Approach on the First Aid of Acute Myocardial Infarction

Journal of Healthcare Engineering

Received 12 November 2022; Accepted 12 November 2022; Published 26 January 2023

Journal of Healthcare Engineering has retracted the article titled "Investigation on the Effect of Graded Emergency Nursing Group under the Assistance of Multidisciplinary First Aid Knowledge Internet-Based Approach on the First Aid of Acute Myocardial Infarction" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

Academic Editor: Enas Abdulhay

Diabetes-associated cognitive dysfunction is a major problem of the international community. Dipeptidyl peptidase-4 (DPP-4) inhibitors are drugs with hypoglycemic effect widely used in diabetic treatment in clinic. In this article, we studied the effect of the DPP-4 inhibitor saxagliptin on cognitive function in diabetic rats. Firstly, to observe cognitive dysfunction caused by diabetes, we built the diabetic rat model. Subsequently, the effect of diabetes on cognitive function was evaluated by Morris Water Maze Task. Thirdly, the mechanism of the alleviation effect of DPP-4 inhibitor on cognitive dysfunction was investigated. Specifically, (1) the anti-inflammation mechanism was revealed by quantifying the accumulation of the inflammatory factor interleukin-1β (IL-1β) in the hippocampus area by western blotting and the glial fibrillary acidic protein (GFAP) by immunohistochemistry; (2) the anti-tau phosphorylation mechanism was revealed by quantifying phosphorylated tau by western blotting. This work represents the first study demonstrating the alleviation effect of DPP-4 inhibitor on cognitive dysfunction caused by diabetes. Results obtained here could be useful to seeking for a medical solution with high efficacy to the diabetes-associated cognitive dysfunction.

1. Introduction

Diabetes is one of the most ubiquitous chronic endocrine diseases in the world. According to the statistic, over 387 million people suffer from diabetes globally, and the incidence of diabetes in adults has reached up to 11.6% of the Chinese nation. It is estimated by 2035, the number of the diabetics in the world will exceed 600 million [1]. Diabetes is frequently accompanied by the incidence of cognitive dysfunction. It is due to the pathological changes in the microvessel caused by diabetes, which could lead to cerebrovascular damage and thus damage the central nervous system [2]. Cognitive dysfunction has many manifestations in clinic, including loss of memory, reduced recognition and understanding ability, and even the complete loss of daily activity [3]. Nevertheless, various complications of diabetes could deteriorate the progress of cognitive dysfunction [4]. The cognitive dysfunction makes the diabetics less able to realize they are sick, which could severely lower their compliance to therapy and diet control and result in the extreme fluctuation of the blood glucose level. The instability of the blood glucose level again deteriorates the cognitive dysfunction in return [5]. In such a vicious cycle, there is hardly a guarantee of full recovery from diabetes. Therefore, the prevention and treatment of the cognitive dysfunction caused by diabetes are of great significance. At present, the most widely used drugs in treating cognitive dysfunction include tacrine, rivastigmine, galanthamine, donepezil, memantine, etc. [6]. These drugs function as precursor of acetylcholine, inhibitor of acetylcholine esterase, and activator of cholinergic receptor, and thus only have the efficacy of temporarily alleviating clinical symptoms [7]. Seeking for an effective medical solution to the cognitive dysfunction, especially the diabetes-associated cognitive dysfunction, remains challenging.

Screening from the available antidiabetic drugs provides as the primary option to discover a specific compound with additional efficacy of improving the patient's cognitive function. Furthermore, investigating the mechanism of its pharmacological function will provide some leads in maintaining intact cognitive function of the diabetics in clinical treatment. Recently, researches have confirmed that the glucagon-like peptide 1 (GLP-1) plays an important role in treating degenerative diseases of the central nervous system such as Alzheimer, Parkinson, and vascular dementia, and thus could improve the patients' cognitive function [8].

In addition, hyper-phosphorylated tau has neurotoxicity, which can induce the neuronal necrosis [9]. Abnormal hyper-phosphorylation of tau affects its physiological function, thereby leads to the formation of neurofibrillary tangles, and consequently accelerates the deterioration of degenerative diseases [10]. Studies have shown inhibiting the hyper-phosphorylation of tau can effectively relieve patients' cognitive dysfunction and has therapeutic effects on Alzheimer's disease and other symptoms [11]. The level of dipeptidyl peptidase-4 (DPP-4) in some diabetic patients is elevated, and it is speculated that dipeptidyl peptidase-4 may be related to fat metabolism in diabetic patients [12]. The use of DPP-4 inhibitors can improve glycemic control in patients with type 2 diabetes [13]. The dipeptidyl peptidase-4 (DPP-4) inhibitors are new antidiabetic drugs which are effective in increasing endogenous GLP-1 availability [14, 15]. A variety of DPP-4 inhibitors have been widely used in the treatment of diabetes, among which the effect of saxagliptin on blood glucose control is higher than other oral hypoglycemic drugs [14, 16]. However, it remains unknown whether DPP-4 inhibitors are functional in treating diabetes-associated cognitive dysfunction.

Thus, in this work, we investigated the effect of the DPP-4 inhibitor saxagliptin on improving cognitive function in diabetic rats. Furthermore, we evaluated its efficacy in reducing inflammation and tau hyper-phosphorylation in the hippocampus of diabetic rats. The mechanism of the medical function of saxagliptin was finally discussed. The results obtained here provide information for the discovery and development of highly effective drugs to diabetes-associated cognitive dysfunction.

2. Materials and Methods

2.1. Animals. This study was performed in accordance with regulations for the Care and Use of Laboratory Animals and approved by the Animal Ethics Committee of Nanchang University. Forty-two adult healthy male Sprague-Dawley rats (160–200 g) used in this study were obtained from the Laboratory Animal Center of Nanchang University.

All the rats were bred under standard conditions (20–24°C, 55% ± 5% relative humidity, and 12-h/12-h dark/light cycle) with free access to food and water. All the rats were acclimated to laboratory conditions for 1 week prior to the experiment. At the beginning of the experiment, the rats were randomly divided into normal control group (NC, $n = 14$) and diabetic modeling group ($n = 28$). Rats in the NC group were fed with normal diet, while rats in the diabetic modeling group were fed with high sugar and high fat diet (composition: 67.5% normal feeds, 20% sucrose, 10% pig oil, and 2.5% powder of yolk). After 4 weeks of feeding, rats in the diabetic modeling group were fasted for 12 h but allowed free access to water, then injected with streptozotocin (STZ) intraperitoneally at a dose of 30 mg/kg (currently available, appropriate amount of STZ in the dark, 0.1 mol/L citric acid-sodium citrate in the buffer ice bath, pH = 4.4). 72 h after injection, rats with fasting blood glucose ≥16.7 mmol/L were randomly divided into diabetic model group (DM, $n = 12$) and DPP-4 inhibitor treatment group (DM-S, $n = 12$). Rats in the NC group were weighed and given corresponding dose of citric acid-sodium citrate buffer intraperitoneally instead of STZ. The DM-S group was given saxagliptin by intragastric administration at a dose of 10 mg/Kg/d for 12 weeks, while the NC group and the DM group were given an equal volume of normal saline in the same manner.

2.2. Morris Water Maze Task. 24 h after treatment with DPP-4 inhibitor, rats were subjected to the Morris Water Maze (MWM) test to evaluate the learning and memorizing abilities. A round, black painted pool (diameter, 180 cm; depth, 50 cm) was filled with water to a depth of 30 cm and the water was made opaque by the addition of black nontoxic ink. The water temperature was maintained at 24 ± 1°C. The pool was divided into four quadrants and a platform (diameter, 10 cm) was submerged approximately 2 cm below the water line in the center of one quadrant. Trials were started at 9 a.m. by releasing the rat into the water facing the outer edge of the pool at one of the quadrants (in a random sequence) and letting the rat escape to the submerged platform. Once the rat arrived at the platform, it was allowed to stay on it for 30 s. The rat was allowed to swim for a maximum time of 60 s in a trial. The time it spent in reaching the platform was defined as escape latency. Both the escape latency and the swimming distance were recorded. If the rat failed to get the platform within 60 s, it was manually guided to the platform and allowed to stay on it for 30 s and the escape latency was recorded as 60 s. All the tested rats received four training trials a day for 5 consecutive days, with 10- to 15-min interval between trials. On the sixth day, the platform was removed, and each rat was allowed to swim freely for 60 s. The number of times that the rat crossed over the previous platform site, the swimming distance, and swimming time in the target quadrant were all recorded and analyzed. Each rat's swimming path was tracked by a computerized video system (Electric factory of Anhui, China).

2.3. Measurement of Blood Glucose. Blood samples were collected from rats before and after treatment with DPP-4 inhibitor. The blood glucose level was measured using 3-uL drop of blood obtained by nicking the tail vein and a One Touch Ultra Link Blood Glucose Meter (Life Scan, Shanghai, China).

2.4. Tissue Preparation. After the MWM test, all rats were sacrificed by spinal dislocation. The brains from each group were harvested and the hippocampus was isolated from brain in the ice. The left half of the hippocampus placed in cryopreservation tube was frozen immediately in liquid nitrogen and then stored at −80°C for total protein extraction. Meanwhile, the right hippocampus was fixed in 10% formaldehyde, embedded in paraffin and coronally sectioned (4 μm) for hematoxylin-eosin (HE) staining.

2.5. HE Staining. Before immunostaining, 4-um-thick tissue sections were dewaxed in xylene and fixed on poly-L-lysine-coated slides. The tissue sections were dewaxed by xylene and gradient ethanol and stained with hematoxylin (Beyotime, Shanghai) for 3 min. It was differentiated with 1% ethyl alcohol hydrochloride for 30 s, then dyed with 0.5% eosin for 3 min, then dehydrated with gradient ethanol and xylene successively. After drying in a fume hood, the sheet was sealed with neutral gum. Neuronal damage in the hippocampus was analyzed at 400 × magnification (Nikon, Japan).

2.6. Immunohistochemistry. After MWM experiment and blood glucose measurement, six rats were randomly selected from each group and anesthetized by intraperitoneal injection of 0.5% sodium pentobarbital at a dose of 50 mg/kg. Their hearts were rapidly exposed, and an infusion needle was inserted into the ascending aorta via the left ventricular and infused with 200 ml of heparin saline (12.5 U/ml) rapidly until effluent liquid from the right atrial appendage was colorless and transparent. 4% paraformaldehyde fixative solution was reperfused slowly for about 30 min. Then their brains were rapidly removed and placed in fixation at 4°C for overnight. After dehydration in alcohol and xylene, the slices were embedded in paraffin and sectioned (4 μm thick).

Sections were deparaffinized, rehydrated with decreasing strengths of ethanol (100% to 50%), and then incubated with 3% H_2O_2 for 15 min at 37°C. Thereafter, brain tissue sections were placed in a 0.01 M citrate buffer, boiled at 95°C for 20 min, then cooled down to room temperature. After being sealed with normal goat serum at 37°C for 15 min, sections were probed with the primary antibody, rabbit anti-rat monoclonal antibody to GFAP (1 : 100, CST, Danvers, MA) overnight at 4°C. Then sections were incubated with the secondary antibody, horseradish peroxidase (HRP)-labeled goat anti-rabbit antibody (BL003A, Biosharp Biotech Co., Ltd., Hefei, China), for 30 min at 37°C. Sections were stained with diaminobenzidine (DAB; P0202; Beyotime Biotech Co., Ltd., Shanghai, China) for 5–10 min under microscope observation, counterstained with hematoxylin for 3 min, and then finally sealed. Five random fields from the CA1, CA3, and DG regions were selected respectively at 400 × magnification. The average optical density of GFAP-positive cells can reflect GFAP expression level and was calculated with Image-Pro Plus 6.0 software (Media Cybernetics, US).

2.7. Western Blotting. The hippocampus was harvested, homogenized in RIPA lysis buffer (RIPA: PMSF = 100 : 1) on ice for 15 min, and then centrifuged at 12,000 × g for 15 min at 4°C. The supernatant was collected and stored at -80°C. The total protein concentration was quantified by the BCA Protein Assay kit (Beyotime Institute of Biotechnology, China) following the manufacturer's instructions. 100 μg of protein per line was separated using 10% SDS-PAGE and then transferred to PVDF membranes (Millipore Co., Billerica, MA, USA). After blocking with 5% skim milk for 2 h, the membranes were incubated with primary antibodies overnight at 4°C.

The primary antibodies used in this study were as follows: anti-β-actin (1 : 1000; CST), anti-IL-1β (1 : 1000; CST), anti-tau (1 : 1000; CST), anti-p-tau (s202) (1 : 1000; CST), and anti-p-tau (s396) (1 : 1000; CST). The membranes were then washed with 1 × TBS/0.1% Tween 20 and then incubated with HRP-conjugated anti-rabbit IgG (secondary antibody, 1 : 3000; CST) or HRP-conjugated anti-mouse IgG (secondary antibody, 1 : 3000; CST) at room temperature for 2 h. Subsequently, membranes were washed with 1 × TBS/0.1% Tween 20 three times. Blots were visualized with an ECL detection kit (Beyotime Biotechnology, Shanghai, China) and analyzed using ImageJ software (National Institutes of Health, NIH).

2.8. Statistical Analysis. Results were analyzed using SPSS Statistics 23 software. Significant differences relative to the controls were determined using independent-samples *t*-tests. For multiple group comparisons, one-way ANOVA was used to determine the significant differences. All results were presented as mean ± standard. P values < 0.05 were considered to be statistically significant ($^*P < 0.05$, $\#P < 0.05$). Each experiment was repeated three times.

3. Results

3.1. Diabetes Caused Cognitive Dysfunction in Rats and DPP-4 Inhibitor Alleviated the Symptoms. To observe the effect of diabetes on cognitive function and further investigate the potential effect of DPP-4 inhibitor on diabetic cognitive dysfunction, we built diabetic rat model (see Materials and Methods section) and evaluated the rats' learning and recognition ability by MWM test. Comparative analysis was carried out on rats from three groups: the normal control group (NC), the diabetic model group (DM), and the saxagliptin-treated diabetic model group (DM-S). As shown in Figure 1, within the experimental time of 5 consecutive days, the NC group exhibited clearly patterned swimming path in all trials with an average escape latency of 6.1 s, suggesting conscious activity and unaffected recognition ability. However, rats from the DM group were unable to get to the platform and exhibited abnormal circulated swimming path which tended to be more abnormal with the progressing of the test. It seemed that the more high sugar and high fat diet they had eaten, the more confused they were. The average escape latency of the DM group was 56.5 s, which was 9.3 folds that of the NC group, whereas the daily shuttle times and total distance of the two groups were comparable. Thus, it appeared that DPP-4 treatment caused instant confusion

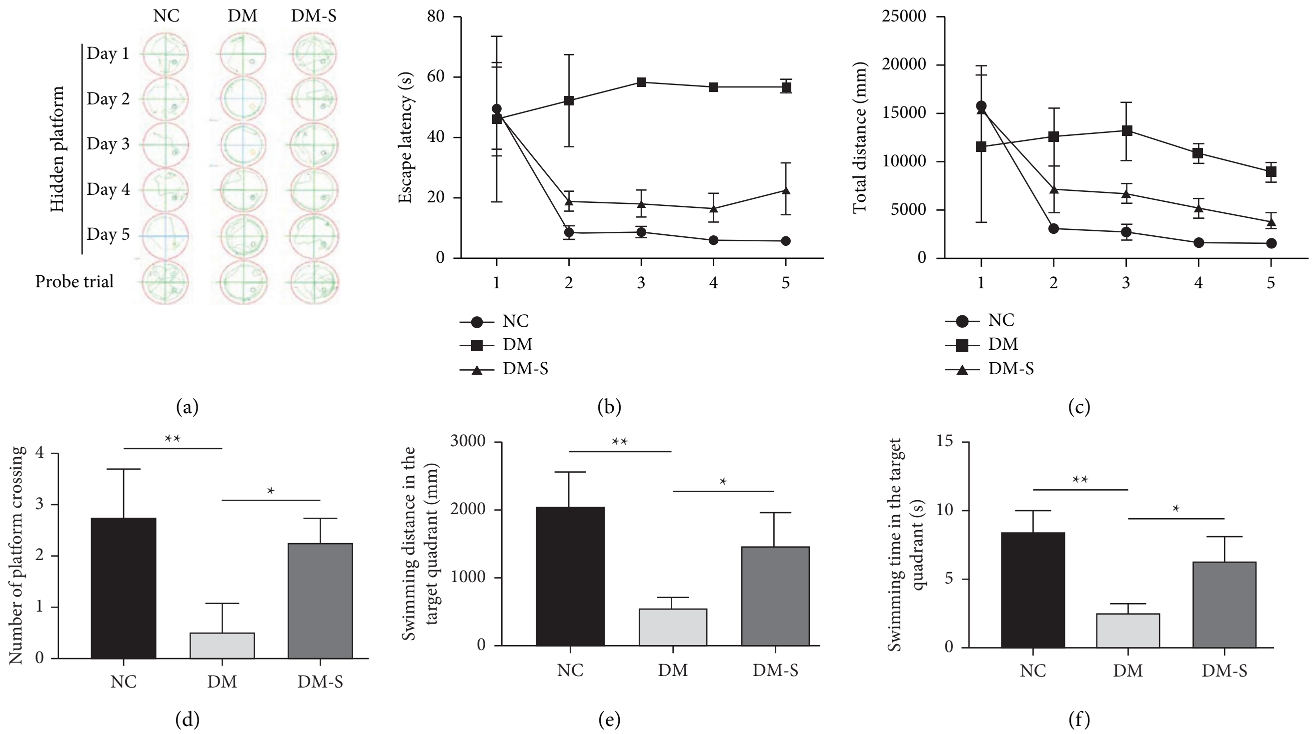

Figure 1: Results of Morris Water Maze Task. (a) The swimming path; (b) the escape latency; (c) the total distance; (d) number of platform crossings; (e) the swimming distance in the target quadrant; and (f) the swimming time in the target quadrant. The shown data represent the average of four parallel physiological replicates. In the experiment for 5 consecutive days, the NC group exhibited clearly patterned swimming path in all trials with an average escape latency of 6.1 s. However, rats from the DM group were unable to get to the platform and exhibited abnormal circulated swimming path. The average escape latency of the DM group was 56.5 s which was 9.3 folds that of the NC group, whereas the daily shuttle times and total distance of the two groups were comparable $^{*}P < 0.05$ $^{**}P < 0.01$.

and slight inactivity in the rats but did not cause the loss of cognitive function. As expected, but still astonishingly, the DM group exhibited disordered swimming path, and neither recovery of cognitive function nor effective physical activity was observed all over the experimental time period. It seemed that the diabetic rats were completely disabled, which was a definite demonstration of cognitive dysfunction. However, rats from the DM-S group exhibited obvious partial recovery of cognitive function along with the advance of time. These results demonstrated that diabetes could cause cognitive dysfunction in rats and DPP-4 inhibitor saxagliptin could alleviate such cognitive dysfunction symptoms caused by diabetes.

We evaluated the efficacy of daily intragastric administration of DPP-4 inhibitor saxagliptin in diabetic rats on blood glucose. The time points included the starting date of week 4 (before treatment) and 16 after intragastric administration of saxagliptin or saline. The fasting blood glucose of the NC group rats was lower than 10 mM before and after treatment. On the other hand, daily intragastric administration of saxagliptin significantly alleviated hyperglycemia of the diabetic rats, controlling the fasting blood glucose to ~7 mM from ~18 mM after 12 weeks of treatment. As a control, the fasting blood glucose increased from ~18 mM to ~24 mM after daily intragastric administration of saline (Figure 2). The preliminary results indicate that DPP-4 inhibitor saxagliptin can ameliorate high blood glucose status.

3.2. DPP-4 Inhibitor Prohibited Neuron Apoptosis in the Hippocampus Area of Diabetic Rats. To reveal the possible mechanism of how DPP-4 inhibitor saxagliptin alleviates cognitive dysfunction in the diabetics, we investigated the neuron apoptosis in the hippocampus area of these rats. We observed the morphology and structure of the hippocampus area of these tested rats under optical microscope after HE staining. As shown in Figure 3, significantly increased number of apoptotic cells was observed in the diabetic group (DM) as compared with the control group (NC), with the morphological change in scattering and decomposing, which demonstrated a severely deteriorated apoptotic process. However, the number of apoptotic cells of rats from the diabetic rats treated with DPP-4 inhibitor saxagliptin was comparable to that of the control group again, demonstrating a rescue from the diabetic status.

3.3. DPP-4 Inhibitor Reduced Inflammation in the Hippocampus in Diabetic Rats. Glial fibrillary acidic protein (GFAP) is the marker of astrocyte activation in the hippocampus, which could indicate the extent of the central inflammation in the hippocampus. Interleukin-1 (IL-1; sub-type IL-1β) is the major inflammatory factor closely related to cognitive function. Since glucagon-like peptide 1 (GLP-1) and its analogs were previously confirmed with an

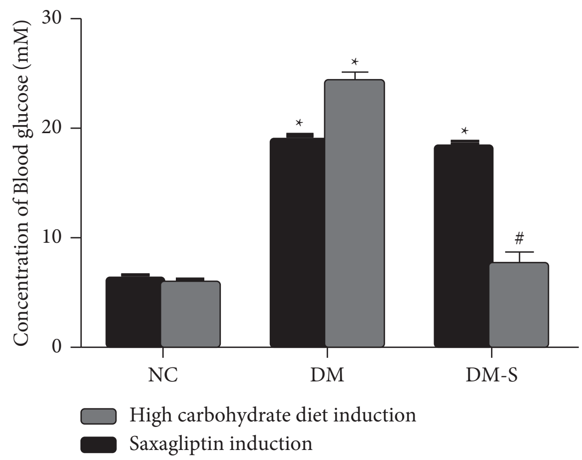

Figure 2: Changes in blood glucose before and after the treatment of rats. The fasting blood glucose of the NC group rats was lower than 10 mM before and after treatment. After daily administration of saxagliptin for 12 weeks in DM-S group, the fasting blood glucose was controlled to ~7 mM from ~18 mM. The fasting blood glucose of the DM group increased from ~18 mM to ~24 mM after daily intragastric administration of saline. $^*P < 0.05$, indicates a significant difference compared with the NC group; $\#P < 0.05$ indicates a significant difference compared with the DM group.

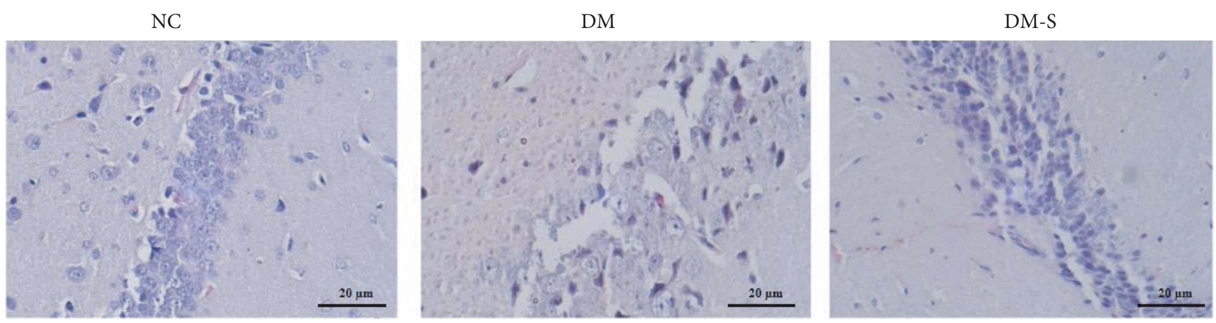

Figure 3: Morphology and structure of the hippocampus area by HE staining (400 × magnification). The significantly increased number of apoptotic cells was observed in the DM group as compared with the NC group, with the morphological change in scattering and decomposing. However, the number of apoptotic cells of rats from the diabetic rats treated with DPP-4 inhibitors was comparable to that of the NC group again.

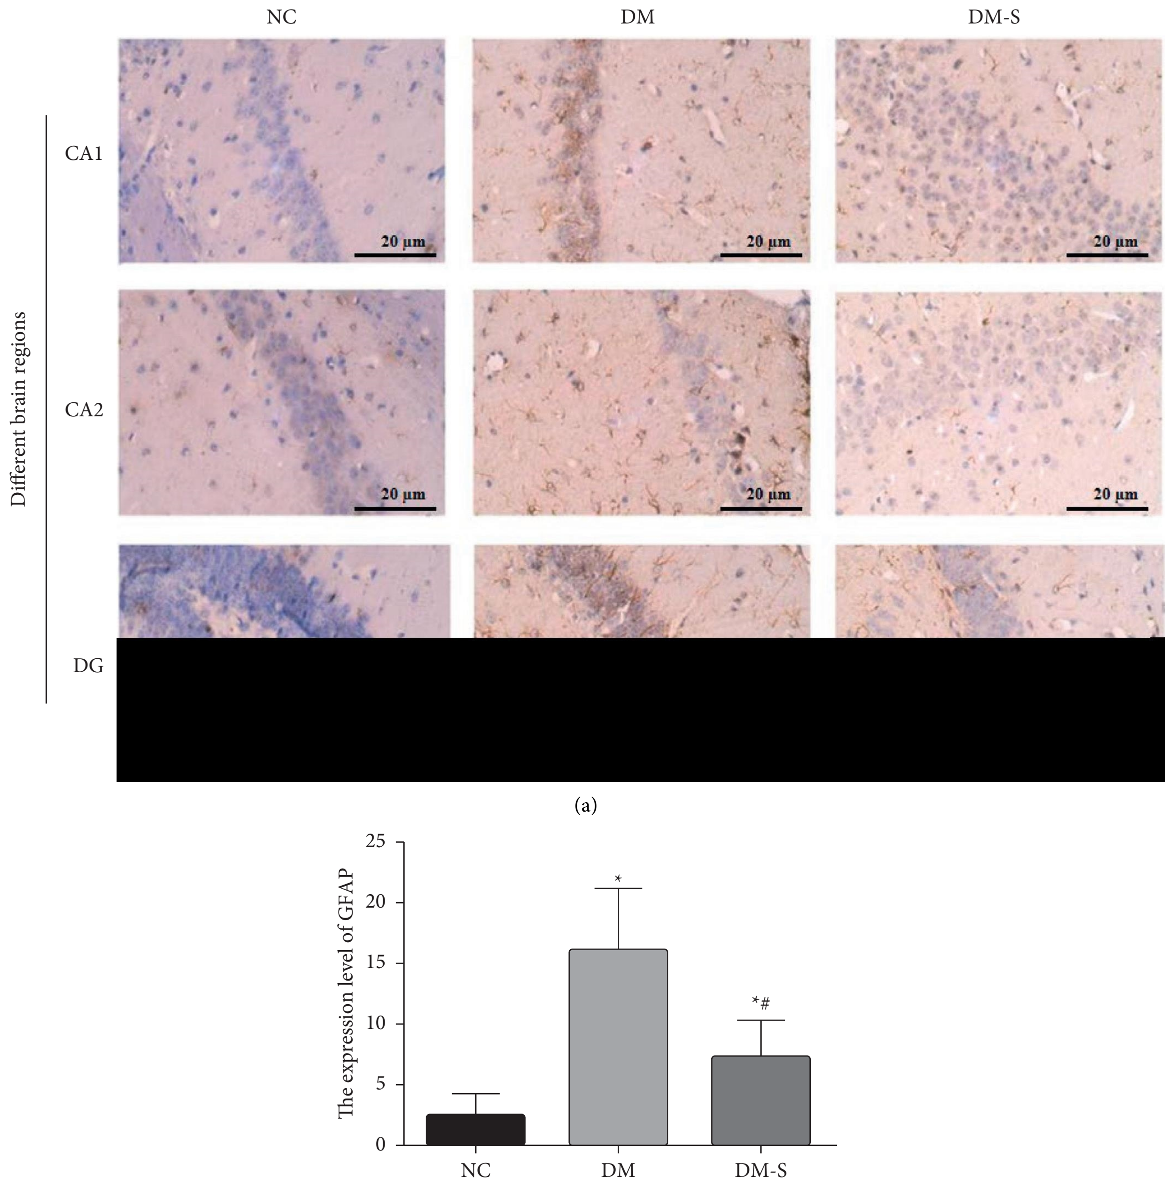
inhibitory effect on the neural inflammation and DPP-4 inhibitor can increase the endogenous GLP-1 availability, we investigated the effect of DPP-4 inhibitor on neural inflammation in diabetic rats to further reveal the mechanism of its protective effect on cognitive function damaged by diabetes. The expression level of GFAP in the CA1, CA2, and DG regions of the brain was detected by immunohistochemistry. The level of inflammatory factor, IL-1β, in the hippocampus area of these rats was tested by the method of western blotting. As shown in Figure 4, a GFAP expression was increased by about 7 folds in rats from the diabetic group than in those from the NC group. However, the GFAP expression sharply decreased by half in the DM-S group compared with the DM group. As for IL-1β (Figure 5), increased IL-1β was detected in the DM group rats relative to the NC group. Whereas an obvious reduction in IL-1β accumulation was observed in rats from the DM-S group as in those from the DM group. These results suggested that diabetes could trigger inflammation and DPP-4 inhibitor could have an anti-inflammation effect on diabetic rats.

3.4. DPP-4 Inhibitor Reduced Tau Hyper-Phosphorylation in the Hippocampus. Hyper-phosphorylated tau has neurotoxicity which can induce the neuronal necrosis. Abnormal hyper-phosphorylation of tau affects its physiological function, thereby leads to the formation of neurofibrillary tangles and consequently accelerates the deterioration of degenerative diseases. We assume hyper-phosphorylation of tau might also be a factor in the incidence of cognitive dysfunction, thus we quantified hyper-phosphorylated tau by western blotting. As shown in Figure 5, the expression of the two forms of phosphorylated tau was abnormally high in rats from the diabetic group. DPP-4 inhibitor treatment has a reducing effect on phosphorylation of tau; however, the level of phosphorylated tau in rats from the DM-S group was still much higher than in those from the NC group.

4. Discussion

According to the WHO data, the number of diabetics worldwide is as high as 4.22 billion. Studies have shown that hyperglycemia, insulin resistance, inflammation, oxidative



(a)

(b)

Figure 4: Effects of DPP-4 inhibitor inflammation in the hippocampus of diabetic rats. (a) Expression of GFAP in CA1, CA2, and DG regions of brain detected by immunohistochemistry (400 × magnification). (b) Quantification of GFAP expression. The GFAP expression was increased by about 7 folds in rats from the DM group than in those from the NC group. However, the GFAP expression sharply decreased by half in the DM-S group compared with the DM group. $^{*}P < 0.05$ indicates a significant difference compared with the NC group; $^{\#}P < 0.05$ indicates a significant difference compared with the DM group.

stress, and other factors all will affect cognitive function, so the probability of developing cognitive dysfunction, dementia, and other central nervous system diseases in patients with diabetes is significantly higher than that in normal people, and diabetes is also an independent risk factor for Alzheimer's disease [17, 18]. The cognitive dysfunction caused by diabetes seriously affects the quality of life of patients and their relatives, and greatly increases the burden of social medical care. Therefore, it is of great significance to study the cognitive dysfunction of diabetes.

It is acknowledged that both diabetes and Alzheimer cause cognitive dysfunction through over-activating the central inflammatory system or imbalancing the pro-inflammatory and anti-inflammatory systems, which could cause damage to the neuron [19]. Peripheral inflammatory mediators could directly enter the central nervous system or stimulate microglia and astrocyte in the hippocampus area to secrete inflammatory factors, causing local inflammation and thereby reducing cognition ability [20]. Since diabetes and Alzheimer's disease share many common physiological characteristics, and there are few breakthroughs in the treatment of Alzheimer's disease, many scholars try to use antidiabetics to treat the cognitive impairment of diabetes patients [21]. Clinical studies have found that among the

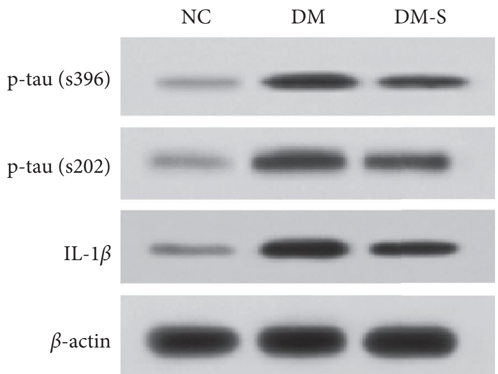


Figure 5: Western blotting of inflammatory factors and phosphorylated tau protein. The expression of the two forms of phosphorylated tau was abnormally high in rats from the DM group. After treatment with DPP-4 inhibitor, tau phosphorylation expression in DM-S group decreased, but it was still much higher than that in the NC group. As for IL-1β, increased IL-1β was detected in the DM group rats relative to the NC group. Compared with the NC group, IL-1β expression was increased in the DM group. The accumulation of IL-1β in DM-S group was significantly lower than that in the DM group.

antidiabetics, metformin, insulin, pioglitazone, sitagliptin, and other drugs can significantly improve the cognitive ability of diabetes patients [22].

Dipeptidyl peptidase-4 (DPP-4) inhibitors are a class of new oral antidiabetics for the treatment of type 2 diabetes mellitus (T2DM), which can not only regulate the metabolism of glucose and lipids in vivo, but also improve endothelial function and reduce the pro-oxidation and pro-inflammatory states of injured cells [23]. The clinical use of DPP-4 inhibitors includes vildagliptin, Alogliptin, etc., which has a significant therapeutic effect on diabetes without increasing the risk of infection [14, 24]. Saxagliptin as monotherapy or in combination with metformin reduces the risk of hypoglycemia in patients with type 2 diabetes. Saxagliptin is generally well tolerated in clinical trials, with relatively mild adverse reactions and high safety and efficacy. Therefore, this study chose saxagliptin as the research object to explore the therapeutic effect of saxagliptin, a DPP-4 inhibitor, on diabetes-related cognitive dysfunction.

In this study, a diabetic mouse model was established and treated with saxagliptin intragastric administration. The experimental results showed that the diabetic mice fed with high sugar and high fat had increased blood glucose, lost cognitive function, and swimming path disorder. The cognitive function of mice treated with saxagliptin was partially recovered and hyperglycemia was relieved. To further study the therapeutic mechanism of DPP-4 inhibitors, we examined the hippocampal area of diabetic rats. The results showed that saxagliptin treatment significantly inhibited neuronal apoptosis and the expression of inflammatory factors in the hippocampal area of diabetic mice, suggesting that DPP-4 inhibitor could effectively inhibit the inflammatory response and neuronal apoptosis induced by elevated blood glucose in diabetic mice. The detection of hyper-phosphorylated tau protein showed that the expression of phosphorylated tau protein in the hippocampal area of diabetic mice was abnormally high, while DPP-4 inhibitor treatment could effectively reduce the content of phosphorylated tau protein in mice. The above experimental results indicate that DPP-4 inhibitor can not only control blood glucose in diabetic mice, but also reduce neuronal apoptosis by inhibiting the expression of inflammatory factors and phosphorylated tau protein in the hippocampus of mice, thus improving the cognitive function of mice.

The limitation of this study is that GLP-1 levels in neuro inflammation have not been determined. However, our previous studies have shown that saxagliptin increases the level of active GLP-1 in the brain [25]. In conclusion, the treatment of diabetic mice with saxagliptin can improve hyperglycemia and partially restore cognitive function. DPP-4 inhibitors have therapeutic effects on diabetes-related cognitive dysfunction. This study provides a new idea for antidiabetics in the treatment of diabetes-related cognitive dysfunction and points out a new research direction for the treatment of Alzheimer's disease.

5. Conclusion

The results of this study suggest that DPP-4 inhibitors can improve the cognitive function of diabetic rats. After treatment with saxagliptin, the cognitive function of mice was partially recovered and the symptoms of hyperglycemia were relieved, so as to control the blood glucose of diabetic mice. Saxagliptin significantly inhibited the expression of phosphorylated tau protein and inflammatory factor IL-1β in hippocampal neurons of diabetic mice and reduced neuronal apoptosis, thus improving the cognitive function of mice.

The tongue coating (TC) microbiota, a crucial component of the tongue coating, illustrates a huge microbial percentage of the body that mostly includes actinobacteria, bacteroides, firmicutes, and fusobacteria. The TC microbiota is closely related to the development of upper gastrointestinal malignancies, such as oral, gastric, and esophageal cancer. Nonetheless, the microbiological characteristics of common TCs in individuals with precancerous lesions of the upper gastrointestinal tract are still unclear. Herein, we designed a case-control study, recruiting 153 PLUGT patients with four different types of TCs, including 47 white-thin, 19 white-thick, 47 yellow-thin, and 40 yellow-thick, as well as 47 volunteers as controls. To analyze microbial characteristics, 16S rRNA microbiome approaches were used. An enzyme-linked immunosorbent assay (ELISA) was employed to assess serum IL-17A and total bile acid (TBA). According to the obtained results, *Leptotrichia* was found to be a promising biomarker for thin as well as thick yellow coatings. In comparison to the control TC microbiota, 39 different genera developed commensal networks in common TCs. *Lachnoanaerobaculum* and *pseudonocardia* were the most striking core bacteria. *Lachnoanaerobaculum* positively correlated with *Leptotrichia* in W-thin and Y-thick coatings, with *actinomyces* and *methylobacterium* in Y-thin coatings, with *Campylobacter* in Y-thick coatings, and with *Bradyrhizobium* in W-thick and Y-thick coatings. Serum IL-17A levels were greater in cases with W-thin coating than in controls, and serum IL-17A was positively linked with *Parvimonas* in patients with W-thick or Y-thin coating. In Y-thin coating, the oral dominating bacteria *Streptococcus* was negatively linked with serum TBA. Taken together, the promoted bacteria were found to be synergistically proliferative in the TCs of PLUGT patients. The diverse TCs had distinct bacterial commensal networks, whereas the common TCs were linked by specific bacteria to serum IL-17A and TBA.

1. Introduction

The upper gastrointestinal tract (GIT) includes the oral cavity, pharynx, esophagus, stomach, and duodenum. Gastric cancer (GC) and esophageal cancer (EC) are two of the most often seen cancers in clinical practice. Globally, GC is the third major reason for deaths related to cancer and the fifth most abundant sort of cancer, whereas EC ranks sixth in mortality and seventh in morbidity [1]. GC has the third greatest incidence and mortality rate of all malignant tumors in China, while EC has the seventh greatest incidence and the rate of mortality [2]. Numerous studies have demonstrated that early recognition and diagnosis of upper GIT cancer are critical strategies for lowering mortality and incidence rates and considerably increasing survival rates up to 5 years [3–5]. Precancerous lesions of the upper gastrointestinal tract (PLUGT) are a crucial stage in the transformation of the normal upper gastrointestinal mucosa into upper gastrointestinal cancer. Atrophy of the gastric glands associated with abnormal hyperplasia and/or intestinal metaplasia of the gastric mucosal epithelium is regarded as a precancerous lesion of gastric cancer (PLGC) [6, 7]. PLGC is the intermediate link in the transformation from gastritis to gastric cancer, and it is essential for reducing GC risk to timely and effective block or reverse the PLGC [8, 9]. Esophageal squamous cell carcinoma (ESCC) accounts for more than 85% of EC globally [10, 11]. ESCC precancerous and cancerous lesions are graded as follows: severe dysplasia/carcinoma, moderate dysplasia, mild dysplasia, and basal cell hyperplasia in situ [12]. Currently, the diagnosis of GC and EC initially depends on endoscopy and pathological biopsy, which has the characteristics of the invasive injury and high cost and leads to fear in patients; therefore, most patients with upper digestive tract cancer are clinically diagnosed at an advanced stage [13–15].

Tongue diagnosis is objective, simple, noninvasive, and rapid in traditional Chinese medicine (TCM) diagnostic methods and has a lengthy background. The holistic view of TCM believes that variable tongue coating (TC) is capable of reflecting the pathophysiological function of the spleen and stomach, which is mainly corresponding to digestive function [16–18]. Tongue diagnosis has great application value in many systemic diseases, systematically summarized in the classical book "*Bianshe Zhinan*" (referred to *Guide to Tongue Diagnosis*). In clinical TCM practices, TC is the key content of tongue diagnosis, and its characteristic (including thickness and color) is an important basis for syndrome differentiation and treatment for many digestive system diseases. The four most common syndromes are exterior cold syndrome, interior cold syndrome, exterior heat syndrome, and interior heat syndrome which are most commonly associated with white-thin (W-thin), white-thick (W-thick), yellow-thin (Y-thin), and yellow-thick (Y-thick) TCs, respectively.

Modern studies believe that TC consists of microorganisms (mainly bacteria and fungi), exfoliated epithelium, blood metabolites, and saliva derived from filamentous papilla [19]. A growing body of research in recent years has revealed a relationship between the TC microbiota and several systemic illnesses, such as malignant tumors and diabetes. The occurrence and progression of systemic disorders, as well as the treatment process, can be dynamically reflected by TC type and its microbiota. The tongue coating microbiota has been established as a possible gastritis biomarker [20] and has been shown to have prognostic significance for pancreatic head cancer [21] and gastric cancer [20]. The changes in the TC microbiota may be related to inflammation and the metabolome, and the bacteria can potentially act as a noninvasive biomarker for GC diagnosis, independent of lifestyle [22]. The tongue coating microbiota changes as halitosis progresses, and assessing tongue coating microbiome biomarkers could help predict the risk of halitosis in children [23]. Ye et al. [24] revealed a genus *Bacillus* that existed exclusively on the yellow tongue coating of cases suffering from chronic erosive gastritis. Both TC type and its microbiota can dynamically reflect the occurrence and development of systemic diseases and the treatment process. Cui et al. [20] found that the prevalence of TC *Campylobacter concisus* was significantly greater in intestinal metaplasia superficial gastritis, and atrophic gastritis compared to normal controls, and that the prevalence of *C. concisus* gradually increased with the progression of gastritis, including the precancerous cascade. Furthermore, TC microbiota has the potential to serve as biomarkers for several different types of systemic diseases, including malignant tumors [18, 25]. Wu et al. [26] found that the GC risk was related to increased *Firmicutes* and decreased *Bacteroidetes*. Xu et al. [22] found that the six TC bacterial genera combinations (*Fusobacterium, Megamonas*, *Rothia, Porphyromonas*, *Peptostreptococcus*, and *Peptococcus*) had a strong diagnostic value for GC risk. These results are further proof of the outstanding ability of tongue diagnosis in many systemic diseases besides malignant tumors. However, the microbial characteristics of the common TCs are still unclear.

Bacteria promote tumor formation by producing carcinogenic metabolites and inhibiting chronic and persistent inflammation, especially in organs exposed to microorganisms for a long time [27, 28]. Numerous studies showed that bile acid promoted intestinal metaplasia and GC [29, 30]. Karstens et al. [31] explored that the IL-17A level was reduced in cases with esophageal adenocarcinomas in comparison to healthy controls. And our previous study found that GC patients demonstrated a high level of serum IL-17A than the controls, and the patients with white coating had substantially lesser serum IL-17A levels compared to those with yellow coatings [32].

Therefore, this study comprehensively analyzed the microbial characteristics and potential biomarkers of common TC (Y-thin, Y-thick, W-thin, and W-thick) in PLUGT patients and explored the relationship between the different TC bacteria and the serum IL-17A and TBA. The results are expected to provide precise methods for the rapid and noninvasive diagnosis of PLUGT and embody the scientific connotation of tongue-diagnosis-assisting TCM syndrome differentiation and treatment.

2. Patients and Methods

2.1. Study Participants. The Clinical Ethics Committee at Yangzhong People's Hospital in Jiangsu Province (No. PHYC2018039) approved this study. From April 2019 to January 2020, the unified questionnaire was utilized for collecting clinical information from the upper gastrointestinal cancer screening of residents aged 40 to 70 in Yangzhong City. Endoscopy and pathologic biopsy were used to diagnose all PLUGT patients, who were histologically confirmed to have pancreatic lesions of gastric cancer (PLGC) and/or precancerous lesions of esophageal squamous cell carcinoma (ESCC). A total of 153 PLUGT patients were included in the case group, whereas 47 white-thin coating volunteers comprised the healthy control group. At the time of enrollment, all participants provided signed informed permission. All participants were excluded on the basis of the following criteria: (1) all participants who got probiotics, antibiotics, or both within the preceding 4 weeks and were diagnosed with periodontitis or another oral disease; (2) had any malignant tumor; (3) had a history of severe systemic diseases (Alzheimer's disease, liver cirrhosis, ulcerative colitis, etc.); and (4) unwillingness to cooperate. Furthermore, participants in the control group with severe digestive diseases, and significant gastrointestinal discomforts, including stomach pain, diarrhea, and abdominal pain, were excluded.

2.2. Sample Collection. All contributors were required to fast during the night hours (≥8 hours) and gargle with normal saline 2 to 3 times in the morning. Two traditional Chinese physicians with a combined clinical experience of >10 years independently diagnosed the TC type, and the TC images were photographed and analyzed using the DS01-B tongue diagnostic information acquisition system (DAOSH Co., Ltd, Shanghai, China). The patients were fit into this study when two physicians' diagnoses and DS01-B analysis were consistent. A sterile one-off toothbrush was used to collect each TC sample along the median groove of the tongue dorsum and suspended it into the sterile normal saline. After centrifugation of 5 min at 3000 r/min, the precipitates were collected as TC samples. All participants' peripheral blood (3–5 mL) was drawn and centrifuged for 10 min at 3000 r/min to achieve the serum. All the specimens were kept at −80°C within 2 h.

2.3. DNA Extraction, Polymerase Chain Reaction (PCR) Amplification, and Sequencing. The extraction of total TC DNA was performed in accordance with the manufacturer's procedure that used QIAamp DNA Mini Kit (Qiagen, Valencia, CA, USA). The V3–V4 region of the 16S (rRNA gene) was amplified employing the forward primer 341F (5′-CCTAYGGGRBGCASCAG-3′) and the reverse primer 806R (5′-GGACTACNNGGGTATCTAAT-3′). The PCR conditions were identical to those used in our previous study [19]. Electrophoresis on a 2% agarose gel was implemented to identify the products of PCR. AxyPrep DNA Gel Extraction Kit (Axygen Biosciences, CA, USA) was used to extract PCR products, and a QuantiFluor^{TM}-ST Assay Kit (Promega, WI, USA) was used to quantify them. The pooled DNA product was utilized for preparing the Illumina pair-end library in the same manner as the Illumina genomic DNA library preparation technique. Following that the library of the amplicon was sequenced paired-end on an Illumina MiSeq platform (Shanghai Biozeron Co., Ltd, Shanghai, China) employing standard guidelines. QIIME version 1.17 was employed to filter and remove low-quality sequencing reads (<200 bp), and UPARSE version 7.1 was implemented to cluster operational taxonomic units (OTUs) with 97% similarity cut-off after removal of chimeric sequences (http://drive5.com/uparse/). Taxonomic assessment was performed using the SILVA database, and each OUT was classified into the following five categories (phylum, class, order, family, and genus).

2.4. Laboratory Detection. Serum interleukin (IL)-17A (Human IL-17A ELISA KIT, ZC-32330) and total bile acid (TBA; Total Bile Acid ELISA Kit, MM-50350H1) levels were determined employing enzyme-linked immunosorbent assay (ELISA). All procedures were performed in metculous compliance with the manufacturer's instructions.

2.5. Bioinformatics and Statistical Analyses. The alpha diversity, community structure, and linear discriminant assessment of the effect size (LEfSe) were executed using the computer program Visual Genomics (Release1, Shanghai Infinity Biotechnology Co., Ltd, Shanghai, China). SPSS software version 26.0 was employed for statistical assessment. The student's t-test was implemented for normal distribution data, which were expressed as the mean ± standard deviation. The chi-square analysis was implemented for the grade data. Non-normal distribution data were assessed applying the Mann–Whitney U nonparametric assessment and represented as the median (interval value). The symbiotic networks were drawn using Spearman's correlation analysis and Cytoscape software (https://cytoscape.org/). GraphPad Prism 8 computer program was employed for drawing the point diagrams. The statistical result was two-sided, and $P < 0.05$ indicated statistically meaningful differences. Potential alterations in the microbiome at the functional level were appraised by implementing PICRUSt computer program and the Kyoto Encyclopedia of Genes and Genomes (KEGG) databank.

3. Results

The following section describes the core findings of the study.

3.1. Characteristics of the Study Population. A total of 153 PLUGT patients were categorized into four categories on the basis of the color and type of their TC (1) The W-thin group ($n = 47$) consisted of women and men (30 and 17), with an average age of 57.3 ± 7.2 years; (2) W-thick group ($n = 19$) included men and women (8 and 11), with an average age of 57.8 ± 8.4 years; (3) Y-thin ($n = 47$) included men and women (17 and 30), with an average age of 57.3 ± 7.7 years; and (4) Y-thick ($n = 40$) consisted of men and women (31 and 9), with an average age of 60.4 ± 5.8 years. The healthy controls ($n = 47$) included men and women (16 and 31), with an average age of 54.7 ± 8.8 years. In terms of age and sex, the W-thin, W-thick, and Y-thin groups have no meaningful differences with the control group ($P > 0.05$); however, the difference is significant in the case of the Y-thick group ($P < 0.05$).

3.2. Diversity of the Bacterial Community. Alpha diversity focuses on the richness and diversity of the microflora. Chao and ACE indices were employed to predict operational taxonomic units (OTUs) richness, whereas Shannon, Simpson, and Observed OTUs indices were implemented to appraise OTUs diversity. The Mann–Whitney U analysis was employed to scrutinize the discrepancy in alpha diversity between the control group and the four PLUGT patient groups (Table S1). Among the total five groups, there are meaningful discrepancies ($P < 0.05$) in Chao, Shannon, and Observed OTUs ($P < 0.05$). Compared with the control group, ACE, Chao, Shannon, and Observed OTUs of microorganisms in PLUGT patients were considerably enhanced ($P < 0.05$), whereas Simpson was considerably diminished ($P < 0.05$). In the W-thin and Y-thick groups, ACE, Chao, Shannon, and Observed OTUs enhanced substantially ($P < 0.05$), whereas Simpson reduced notably ($P < 0.05$). In the Y-thin group, Chao, Shannon, and Observed OTUs increased significantly ($P < 0.05$), whereas Simpson diminished remarkably ($P < 0.05$). The results suggested that the TC type was closely associated with the bacterial richness and diversity in PLUGT cases.

3.3. The Bacterial Community Structure of the Tongue Coating. Across all the TC samples, 13,774 OTUs belonged to 33 phyla, 75 classes, 189 orders, 268 families, and 657 genera. The predominant bacterial phyla and genera (relative abundance >1%) were similar among the five groups (Figure 1). At the phylum level, the cluster analysis found that all samples were categorized into two subgroups: the control group and the PLUGT group, and the bacteria of W-thin and W-thick got together, while the bacteria of Y-thin and Y-thick got together in the PLUGT group (Figure 1(a)). It was suggested that phyla-level bacterial composition was associated with the TC color transformation from white to yellow in PLUGT patients. Eighteen dominant bacterial genera (*Neisseria*, *Prevotella 7*, *Veillonella*, *Streptococcus*, *Haemophilus*, *Prevotella*, *Porphyromonas*, *Fusobacterium*, *Granulicatella*, *Leptotrichia*, *Rothia*, *Actinomyces*, *Alloprevotella*, *Peptostreptococcus*, *Gemella*, *Prevotella 6*, *Capnocytophaga*, and *Campylobacter*) were observed in the five kinds of TCs (Figure 1(b)).

3.4. Linear Discriminant Analysis (LDA) of the Microbiome of Tongue Coating. Based on the microorganisms of the controls, LDA was used to identify potential biomarkers for regular TCs in PLUGT cases. There were 5, 18, 3, and 25 marker bacterial taxa in the Y-thick groups, Y-thin, W-thick, and W-thin, accordingly. At the genus level, there were 10 potential biomarkers in the W-thin group: *Variovorax*, *Bradyrhizobium*, *Stomatobaculum*, *Taonella*, *Lachnoanaerobaculum*, *Prevotella 6*, *Actinomyces*, *Streptococcus*, *Parvimonas*, and *(Eubacterium) yurii group* (Figure 2(a)), *Ruminococcaceae UCG-014,* and *Kingella* were the potential biomarkers in the W-thick group (Figure 2(b)), there were five potential biomarkers in the Y-thin group: *Lachnoanaerobaculum*, *Campylobacter*, *Actinomyces*, *Leptotrichia*, and *Ralstonia* (Figure 2(c)), and *Leptotrichia* was a potential biomarker in the Y-thick group (Figure 2(d)). Therefore, *Leptotrichia* might be a potential biomarker of Y-thin and Y-thick groups in PLUGT cases.

To further study the relationship between coating color and TC microbiota, each group of TC was chosen for comparison with the other three converged groups. The microbial compositions among the four tongue coatings were further analyzed using the LefSe. LefSe analysis analyzed microbial dysbiosis, representing substantial discrepancies in the abundance of bacterial populations between the various groups. As a result of LefSe analysis, 32 bacterial taxa were identified. Among them, the relative abundances of 24 and 8 bacterial taxa were substantially increased and decreased, respectively (Figure 3). The comparative abundances of four bacterial genera (*Psychrobacter*, *Pelomonas*, *Aeromonas*, and *Pseudoramibacter*) were remarkably increased in the W-thin group (Figure 3(a)); the relative abundances of seven bacterial genera (*Clostridium sensu stricto 1*, *Burkholderia_Caballeronia_Paraburkholderia*, *Kingella*, *Parascardovia*, *Flaviflexus*, *Paraclostridium*, and *Thermus*) were significantly increased in the W-thick group (Figure 3(b)); the relative abundances of five bacterial genera (*Parvimonas*, *Prevotellaceae UCG-004*, *Salmonella*, *Dialister*, and *Filifactor*) were significantly increased in the Y-thick group (Figure 3(c)). However, no unique genus was found in the Y-thin group, which might have a similar bacterial community structure as the Y-thick group. The aforementioned results indicated that TC microbiota was closely related to the formation of TC color.

3.5. The Symbiotic Relationship of the TC Microbiome. In a normal circumstance, mixed bacteria have complex symbiotic relationships for maintaining the normal micro ecological balance, but in the disease condition, bacterial dysbiosis results in a distinct symbiotic relationship. Therefore, the symbiotic relationship may present a novel entry point for comprehending the microecological mechanism of disease occurrence. According to the controls' white-thin coating microbiota, Mann–Whitney *U*-test was conducted to screen the distinct bacterial genera in the four pathological TCs (Table S2). Spearman's association assessment was executed on the basis of distinct genera of each group, and the meaningful associations ($P < 0.05$) were presented as symbiotic networks (Figure 4). As shown in Figure 4, each node represents a genus and the genus's average relative abundance is represented by the size of each node. Nodes of the same color represent members of the same phyla. Edges illustrate relationships with values superior to 0.5 and P values lower than 0.05. Generally, most correlations were significantly positive, and only in W-thin coating did the negative correlations appear. As evident from the figure, the W-thick coating manifested the least number of correlations. In the PLUGT patients, the striking *Lachnoanaerobaculum* had the most complex symbiotic relationships. It was found to correlate positively with *Leptotrichia* in W-thin and Y-thick coatings, with *Actinomyces* and *Methylobacterium* in Y-thin coating, with *Campylobacter* in Y-thick coating, and with *Bradyrhizobium* in W-thick and Y-thick coatings. *Pseudonocardia* was the other significant promoted bacterial genus in the four common TCs, it positively correlated with *Methylobacterium* in W-thin coating, and positively correlated with *Variovorax* and *Bradyrhizobium* in Y-thin coating. As

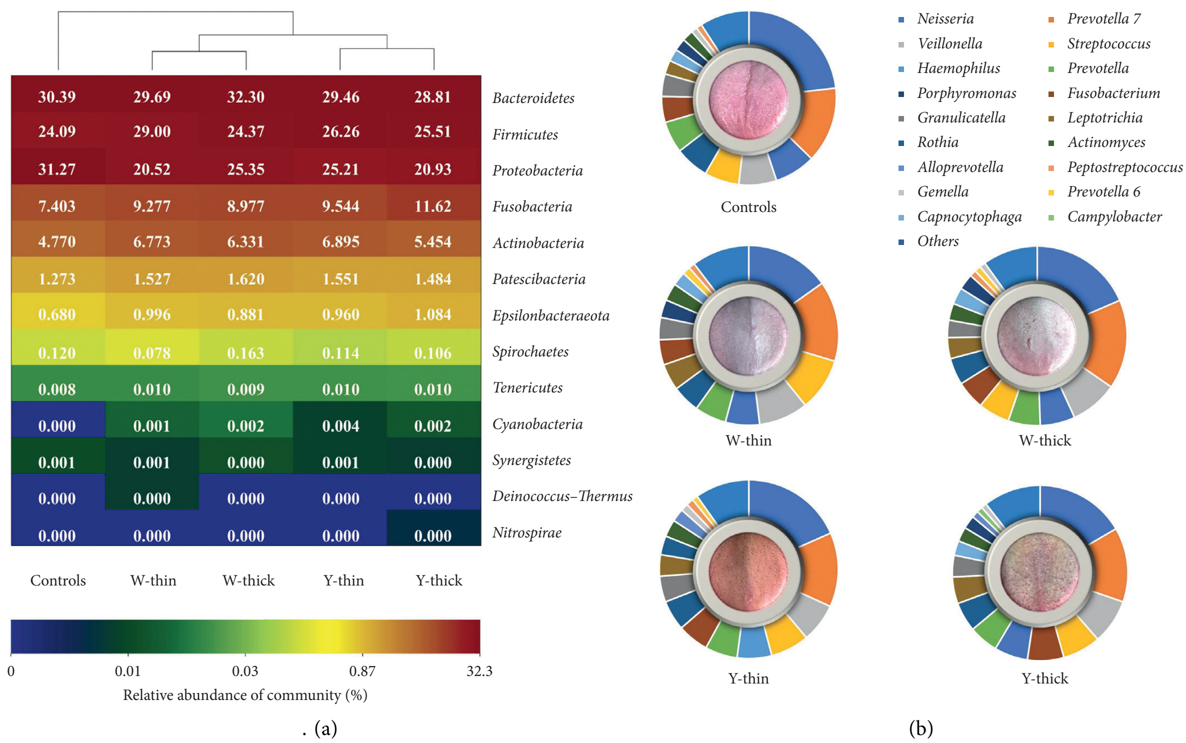

Figure 1: The composition and clustering analysis of TC microbiota in PLUGT patients and the controls. (a) The phylum-level heatmap. Cluster analysis is conducted based on the distance calculation using the Bray–Curtis method, and the results show that the same color TCs have similar microbial structures. (b) The genus-level doughnut chart. The size of bars represents the mean relative abundance of dominant bacterial genera. Each genus is represented by a different color. The image in the center of each doughnut chart is the typical TC.

shown in Figure 4, the *Prevotella* spp was found to have negative associations with *Methylobacterium and Variovorax. Leptotrichia* demonstrated negative correlations with *Streptococcus.* These results suggested that the promoted bacteria were synergistic proliferative.

Each node is related to a distinct genus. The size of each node illustrates the mean relative abundance of each genus. Nodes of the same color come from the same phylum. Relationships with values superior to 0.5 and P values lower than 0.05 are demonstrated as edges. The red edges mean a positive relationship and the blue edges mean a negative relationship.

3.6. Predictive Functional Analysis of the TC Microbiome. Potential biological functions of TC microbiota were evaluated using the KEGG database. Employing the Mann–Whitney U-test, four predictive functions were significantly different between the four PLUGT patients' groups in comparison to the control group ($P < 0.05$). They were betalain biosynthesis, fluorobenzoate degradation, indole alkaloid biosynthesis, and vasopressin-regulated water absorption (Figure S1). Using LDA, we found that changes in the five predictive functions of the Y-thick group also existed in the W-thin and Y-thin groups, including three reduced predictive functions (ABC transporters, phosphotransferase system, and transporters) and two enhanced predictive functions (chaperones and folding catalysts, and chromosome; Figure S2). However, no predictive function was found in the W-thick group, suggesting that a W-thick TC might be the basic pathological TC in PLUGT patients.

To further explore the unique functions of the four common TCs in PLUGT patients, each TC group was chosen for comparison with the other three converged groups. The Mann–Whitney U assessment revealed that the eight predictive functions were significantly different (Figure 5). Among them, the W-thick group manifested six significantly enhanced functions in comparison to the other three converged groups. These included the bacterial invasion of epithelial cells, benzoate degradation, germination, glycerolipid metabolism, *Staphylococcus aureus* infection, and steroid biosynthesis (Figure 5(a)–5(f)). The RIG-I-like receptor (RLR) signaling pathway was significantly enhanced in the W-thin group (Figure 5(g)). Cell motility and secretion were significantly enhanced in the Y-thick group (Figure 5(h)).

3.7. Serum IL-17Aand TBA Correlated with Distinct TC Bacteria. Serum levels of IL-17A and TBA were detected using ELISA. The Mann–Whitney U analysis was employed to ascertain if any two groups (PLUGT groups and controls) are considerably distinct from each other in terms of IL-17A and TBA levels. It was found that IL-17A levels in the W-thin group were substantially higher than

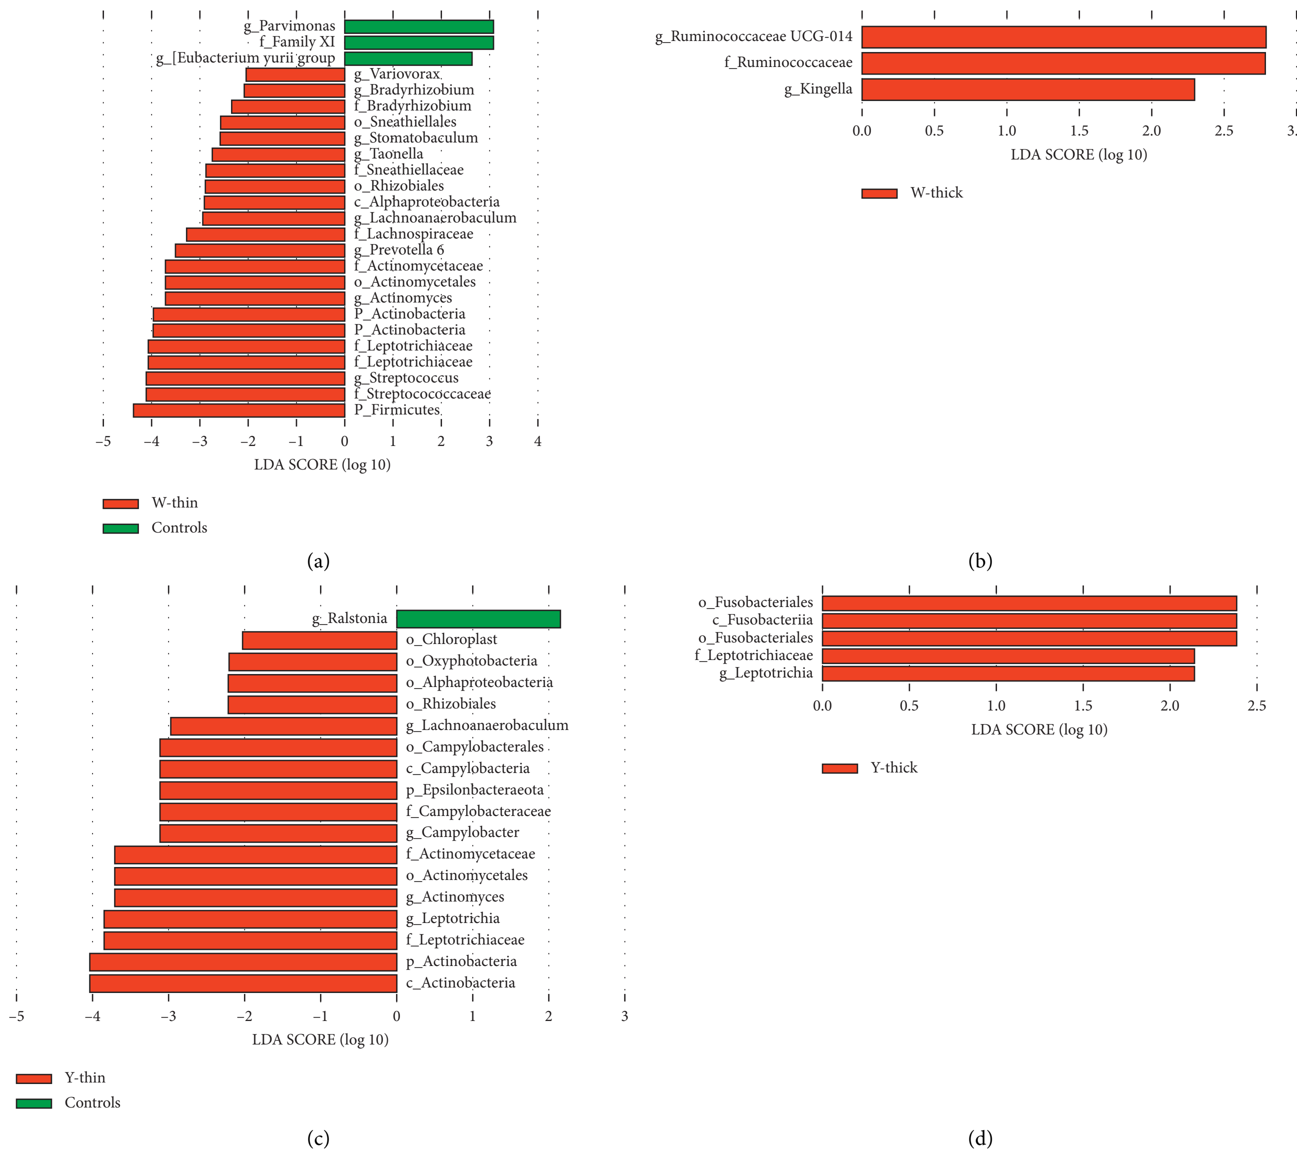

Figure 2: LDA assessment of TC microbiota between PLUGT patients and controls. Based on the controls, LDA analysis is conducted to screen potential biomarkers related to PLUGT with common TCs: (a) Y-thin group, (b) W-thick group, (c) Y-thin group, and (d) Y-thick group. Generally, LDA score means the significance of the microbial taxa. "*p*" refers to phylum, "*c*" refers to a class, "*o*" refers to order, "*f*" refers to family, and "*g*" refers to a genus.

those in the control group ($P < 0.05$), although there existed no remarkable discrepancy in serum TBA levels between the groups ($P > 0.05$; Figure 6(a)). Spearman's correlation analysis was employed for exploring the potential relationship between serum IL-17A, TBA, and the distinct genera (Table S2), and the meaningful relationships ($P < 0.05$) were created into symbiotic networks (Figure 6(b)). The results showed that *Parvimonas* positively associated with serum IL-17A in W-thick and Y-thin coatings. *Dialister* positively associated with serum TBA in W-thin and Y-thick coatings. Significantly, the oral dominant bacteria *Streptococcus* negatively correlated with both serum IL-17A and TBA in the control group, while negatively correlated with only serum TBA in Y-thin coating.

4. Discussion

Tongue diagnosis, or more accurately TC diagnosis, is one of traditional Chinese medicine's most essential diagnostic instruments. On the surface of the tongue, TC appears as a grayish-white deposit. The tongue coating is made up of blood cells, epithelial cells, vascular endothelial cells, bacteria, and a variety of metabolites.

Since the TC microbiota was firstly profiled by Jiang et al. [34], which indicated that different TCs link certain pathological status even in the same disease and occupy unique microbiota and commensal networks. Then, a great deal of literature presented the relationship between TC microbiota and systemic diseases, especially many digestive cancers and precancerous lesions [25]. As everyone knows, TC

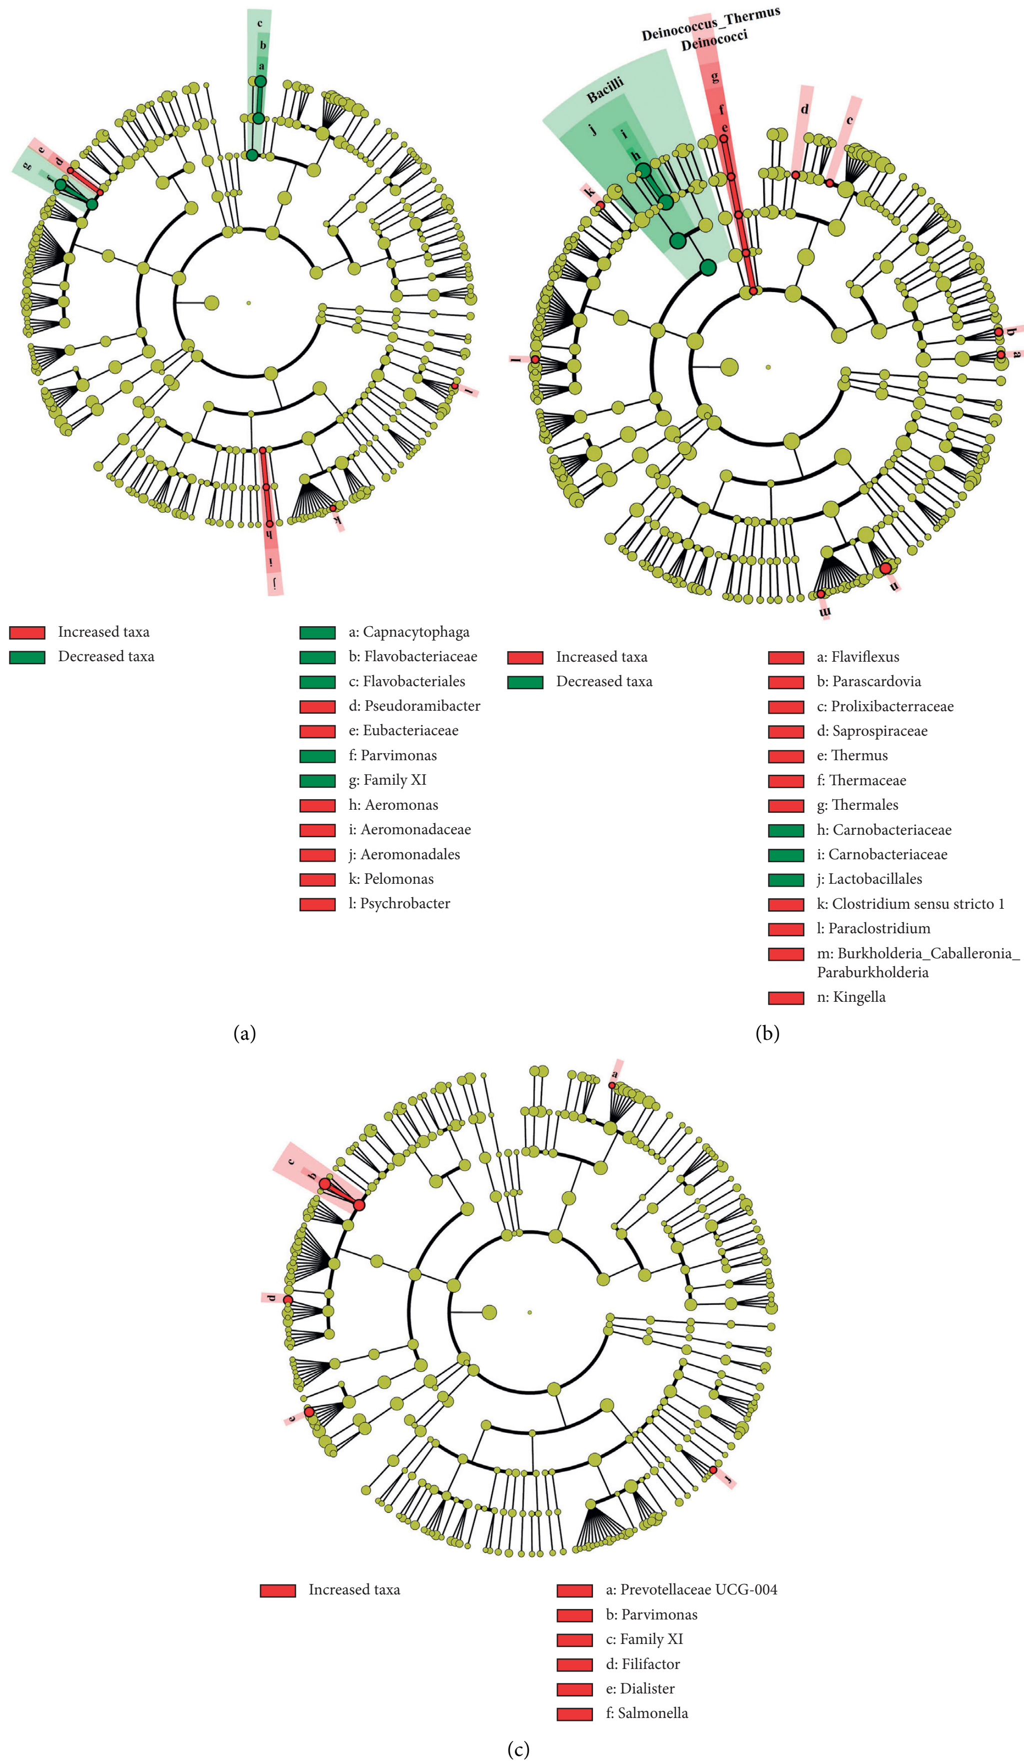

Figure 3: LEfSe analysis of TC microbiota in PLUGT patients. Each TC group is chosen for comparing with the other three converged groups in PLUGT patients. The LEfSe cladogram includes 5 layers of circles, which demonstrate 5 classifications (phylum, class, order, family, and genus) from the center to edge. (a) W-thin TC, (b) W-thick TC, and (c) Y-thick TC.

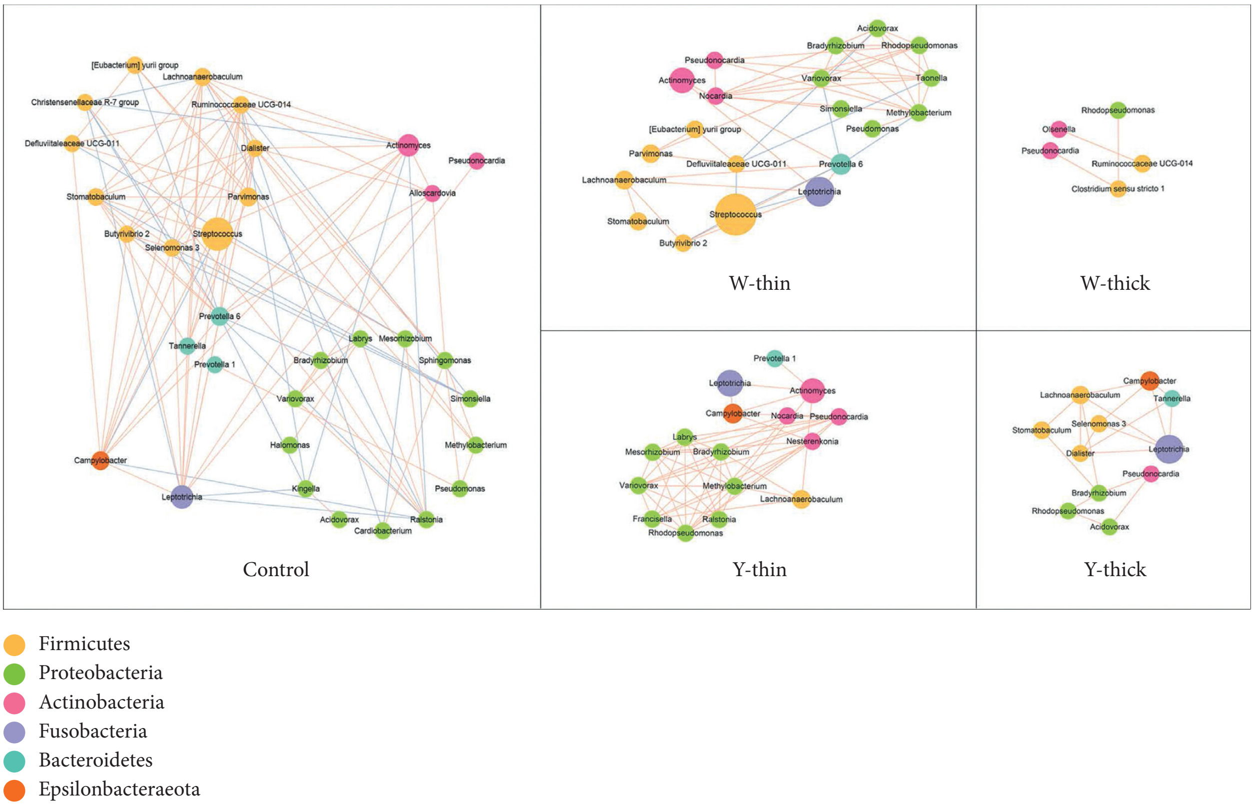

Figure 4: The symbiotic relationship of distinct genera from different TCs.

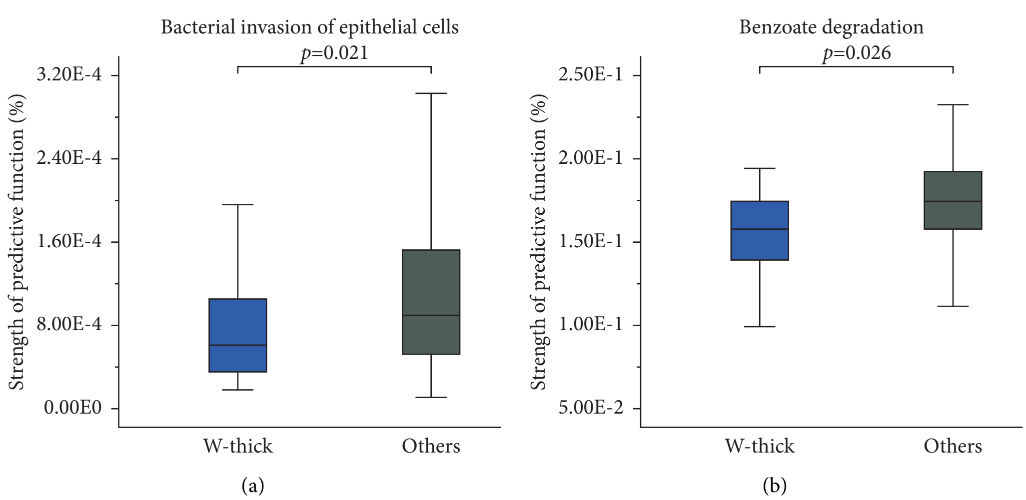

Figure 5: Continued.

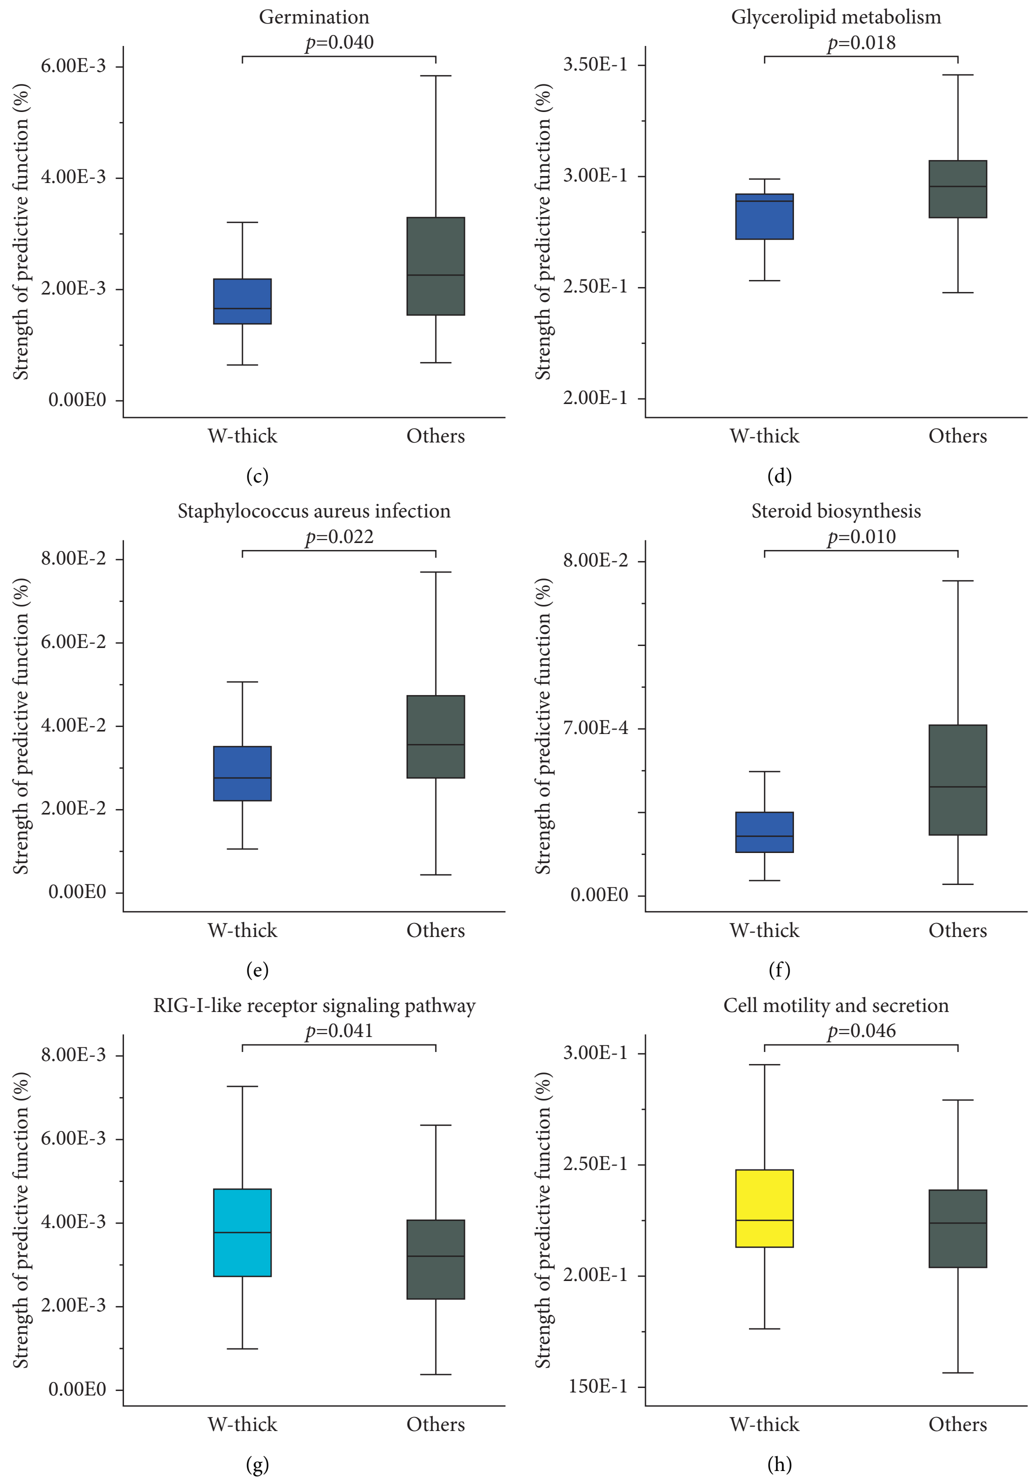

FIGURE 5: Eight predictive functions with significant differences based on TC microbiota in PLUGT patients. Each TC group is chosen for comparing with the other three converged groups in PLUGT patients. Differences between subgroups are evaluated through the Mann–Whitney U-test (only $P < 0.05$ are indicated).

microorganisms can enter the digestive tract with saliva and colonize the mucosal epithelium of the digestive tract. Therefore, here assumes that TC microbiota correlates to PLUGT progression, and analyzed the characteristics of the bacterial community of four common TCs in PLUGT patients to provide new potential biomarkers for accurate PLUGT diagnosis.

This exploration revealed that the bacterial richness and diversity of PLUGT cases were substantially superior to those of the control group. The bacterial richness and diversity in

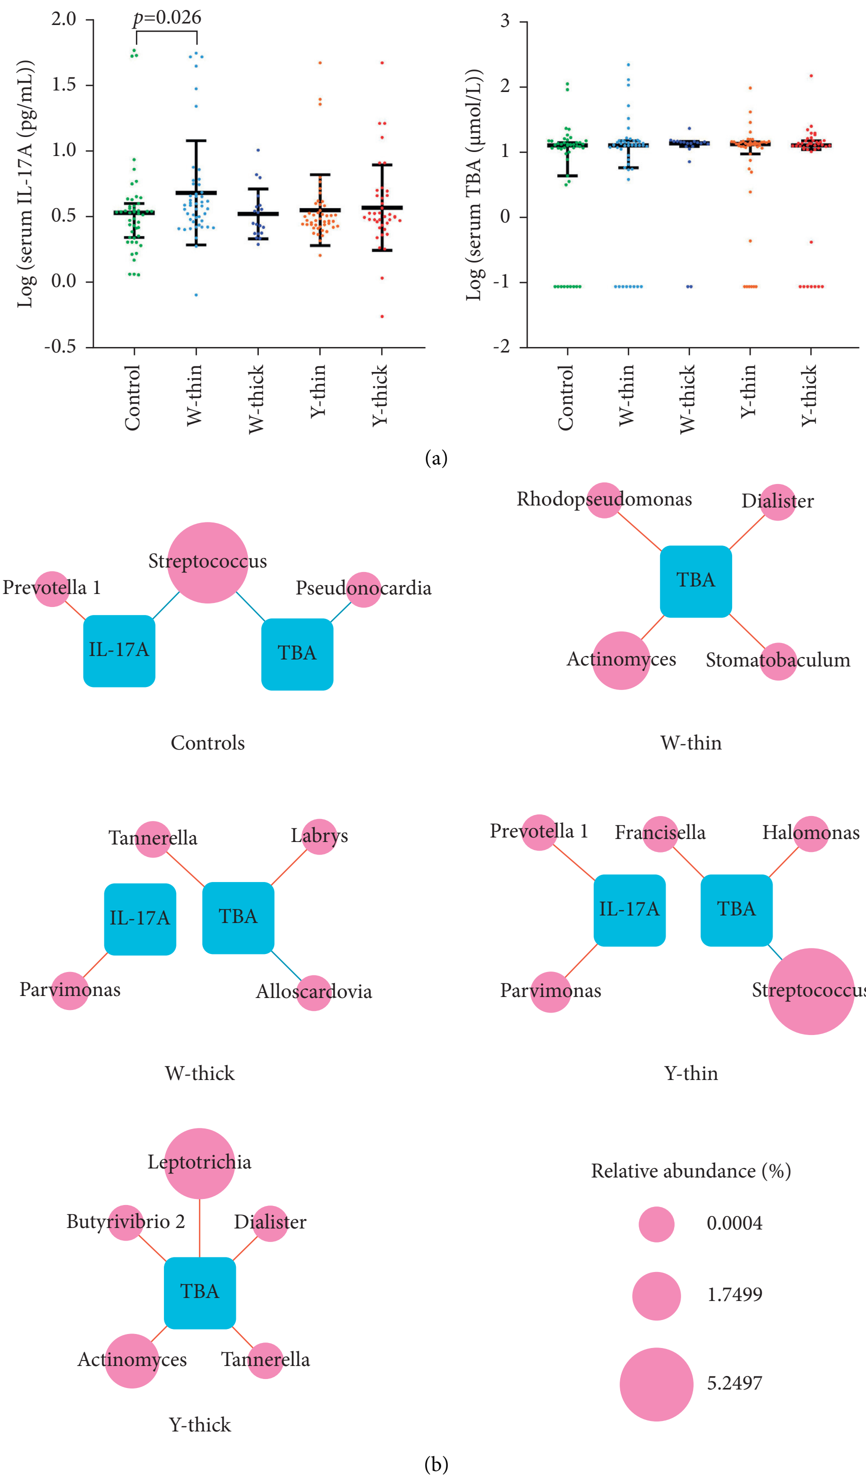

Figure 6: Correlation among serum IL-17A, TBA, and TCs distinct genera. (a) According to the Mann–Whitney U-test, the serum IL-17A was remarkably enhanced in the PLUGT cases with W-thin TC ($P < 0.05$); however, no discrepancies were detected in the serum TBA levels. (b) The commensal networks among serum IL-17A, TBA, and the distinct genera in the five groups. The size of node indicates the relative abundance, the red edges mean positive relationships, and the blue edges mean negative relationships ($P < 0.05$).

the W-thin, Y-thick, and Y-thin groups in PLUGT patients were remarkably superior to those in the control group. However, this result is inconsistent with the results of the already published investigations [19, 22, 35]. For example, Xu et al. [19] discovered that there existed no substantial discrepancy in the alpha diversity of microbiota in common TCs in GC patients, Xu et al. [22] found that GC patients had greater bacterial richness and lower bacterial diversity than those in the control group, Hu et al. [35] divulged that GC cases with thick TC demonstrated lesser bacterial diversity than the patients with thin TC and healthy controls. These inconsistent results may be related to complex factors including sex, age, region, and dietary habits.

In this study, it was found that the microbial community structure of PLUGT patients was similar to that of GC patients in previous studies [19, 35]. This finding suggests that tongue-coating microorganisms have potential diagnostic value for PLUGT. At the phylum level, cluster analysis revealed that the W-thin and W-thick groups were clustered together and the Y-thin and Y-thick groups were clustered together in PLUGT patients. Cheng et al. [36] found that the difference between white and yellow coatings in early gastric cancer patients was greater than that between thin and thick coatings. Jiang et al. [34] found that there were significant differences in the microorganisms of white-greasy and yellow-dense coatings in chronic gastritis (CG) patients. The aforementioned results indicate that the tongue coating color changes were related to the microbial community structure of the tongue coating. The changes in the microbial community in this study were similar to those observed in the esophageal mucosa of esophageal mucosal metaplasia patients [37]. The results suggested that the microbial community of the upper digestive tract, and the tongue coating might have similar changes in the progression of upper gastrointestinal cancer.

TCM believes that white and yellow coating represents cold and hot syndrome, respectively. In this study, *Leptotrichia* was a potential biomarker of Y-thin and Y-thick groups in PLUGT cases, and the relative abundance of *Leptotrichia* was considerably greater in them than in the control group. *Leptotrichia* has extensive genetic diversity. To date, six species belonging to this genus have been validly established [38]. *Leptotrichia* is an opportunistic bacterium that causes opportunistic infections when immune function is compromised by tumor chemotherapy and granulocytopenia disease [38–40]. *Leptotrichia* has strong immunogenicity and can stimulate a mucosal immune response, and anti-*Leptotrichia* antibody can be detected in serum [38]. It is speculated that the immune-inflammatory response resulting from *Leptotrichia* may promote carcinogenesis of the upper digestive mucosa. For instance, the relative abundance of *Leptotrichia* was significantly increased in colon cancer tissue, GC tissue, and mouthwash of pancreatic cancer patients [41–43]. A study showed that *Streptococcus* and *Leptotrichia* in saliva were positively correlated with the risk of pancreatic adenocarcinoma (PDAC), whereas *Veillonella* and *Neisseria* in saliva were negatively correlated with the risk of PDAC [44]. Furthermore, nonparametric test analysis found that the relative abundance of *Campylobacter* in Y-thin and Y-thick groups was significantly increased. Chen and Xie [45] found that rheumatoid arthritis (RA) activity was positively correlated with the degree of yellow tongue coating. Wang et al. [46] believed that RA patients with damp-heat obstruction regularly exhibited high disease activity. Damp and heat are often the causes of yellow-greasy coating formation [47]. Therefore, the tongue-coating type is closely related to RA activity. Previous studies found that the abundance of *Actinomyces* and *Campylobacter* in RA patients was significantly higher than that in healthy controls [48, 49]. The aforementioned results suggest that *Leptotrichia* and *Campylobacter* could be promising biomarkers of yellow coating and are related to the hot syndrome.

TCM regards the image of the tongue as a mirror image of the body's visceral functions. Changes in tongue coating reflect the pathophysiological status of the body. Tongue coating can be used to diagnose diseases and symptoms as a unique diagnostic indicator [25]. In this study, LEfSe analysis was used to analyze the unique biomarkers of regular tongue coatings in PLUGT patients. The unique biomarkers of the W-thin group include *Psychrobacter*, *Pseudoramibacter*, and *Aeromonas*. Kwon et al. [50] discovered that the abundance of *Psychrobacter* diminished in cervical swabs from cervical cancer patients. Gao et al. [51] explored that the abundance of *Psychrobacter* was diminished in cancerous tissues from colorectal cancer patients. Jia et al. [52] revealed that compared with intrahepatic cholangiocarcinoma (ICC) patients with vascular invasion (VI), the abundance of *Pseudoramibacter* in the intestines of ICC patients without VI was significantly higher; *Pseudoramibacter* was negatively correlated with plasma tauroursodeoxycholic acid, which was positively associated with tumor number and negatively associated with survival time. *Aeromonas* is one of the commonly occurring gastrointestinal pathogens associated with infections in animals and humans [53]. Moreover, numerous extracellular proteins, comprising hemolysin, endotoxins, and adhesion factors, are involved in the pathogenesis of *Aeromonas* [54–56]. Gao et al. [57] found that sleep deprivation significantly increased intestinal *Aeromonas* in mice. The unique biomarkers of the W-thick group include *C. sensu stricto 1, Kingella*, and *Thermus*. The relative abundance of intestinal *C. sensu stricto 1*increased in obese patients and was significantly positively correlated with body weight, blood lipid, and uric acid ($P < 0.0 5$) [58]. The increased oral abundance of Kingella is linked to a lower risk of head and neck squamous cell cancer (HNSCC), which could have implications for cancer prevention [59]. The genus *Thermus* is more abundant in tissues from developed lung cancer (IIIB, IV) patients, and it can perform a task in tumor development by means of different microbial functions, such as aldosterone-regulated sodium reabsorption, decreased signal transduction, amino acid metabolism, increased excretory system, and amoebiasis pathways [60].

Using KEGG predictive function analysis to explore the molecular mechanism of common TC formation in PLUGT patients, we found that the RLR signaling pathway in the W-thin group and cell motility and secretion in the Y-thick group were significantly enhanced. RLRs are important initiators of the innate immune response to RNA virus infection [61]. The RLR activates downstream transcription factors, leading to the generation of type-1 interferon and expression of an antiviral gene, eliciting an intracellular immune response capable of controlling viral infection [62]. Zhao et al. [63] found that cell motility (bacterial motility proteins) and membrane transport (secretion system) were enriched in chronic hepatitis B cases with yellow tongue coatings. The results provide clues for further exploration of the biological mechanism of the tongue coating that reflects the body's pathophysiological state and indicate that yellow coating could be substantially susceptible to bacterial colonization.

IL-17A performs a key task in host defense against fungal and bacterial infections, as well as in the development of autoimmunity, inflammation, and tumors. IL-17A greatly enhances protective immune responses in epithelial cells and keratinocytes by inducing the production of G-CSF, CXC chemokines, and antimicrobial peptides [64]. Our last research found that GC patients had an enhanced level of serum IL-17A [32], and here found that the PLUGT patients with W-thin TC had a greater serum IL-17A level than the controls ($P < 0.05$). The commensal networks presented that serum IL-17A positively correlated to *Parvimonas* in the W-thick group and Y-thin group and positively correlated to *Prevotella 1* in Y-thin group. Oral bacterium *Parvimonas* was found to be overexpressed in the gastric mucosa of GC patients and to have high centrality in the GC ecological network, indicating that it might act as a backbone for niche-specific connections and may exert considerable impact on the GC microbial ecology [65]. In addition, Zhao et al. [63] found an enhanced abundance of *Prevotella* in esophagitis or Barrett's oesophagus. Iwakura et al. [64] found salivary *Parvimonas micra* and *Prevotella* sp. were increased in periodontitis patients. A cohort study found that advanced periodontitis was associated with elevated risks of EC [65], and many kinds of research [66, 67] proved that a high level of oral IL-17 promoted the development of periodontitis via its pro-inflammatory and osteoclastogenic properties [68]. These results could assume that W-thick and Y-thin coatings may represent the oral pathogenic trait and inflammation, and simultaneously reflect the progress of upper digestive tract cancer.

Bile acids have a vital role in the development of gastric intestinal metaplasia (IM) and carcinogenesis of the gastric mucosa. Multiple studies have shown that cases with esophageal adenocarcinomas demonstrated lesser levels of IL-17A than healthy controls [29–31]. As our earlier study revealed that GC patients had substantially greater serum IL-17A levels than controls, while those with white coatings had remarkably lesser serum IL-17A levels than those with yellow coatings [32]. The current exploration discovered the association between unique TC bacteria and serum IL-17A and TBA levels, as well as the microbiological characteristics and potential biomarkers of common TC (W-thin, W-thick, Y-thin, and Y-thick) in PLUGT patients. According to the obtained results, the promoted bacteria were found to be synergistically proliferative in the TCs of PLUGT patients. In addition, the different TCs exhibited distinct commensal networks, whereas the common TCs were associated with serum IL-17A and TBA via specific bacteria. The findings are valuable because they can potentially furnish useful solutions to achieve a speedy and noninvasive diagnosis of PLUGT, as well as exemplify the scientific meaning of tongue diagnosis, thereby assisting in the differentiation and treatment of TCM syndromes.

5. Conclusion

This study examined the microbiological properties of four common TCs in PLUGT patients, as well as the relationship between the different TC bacteria and blood IL-17A and TBA, The potential biomarkers of common TC (W-thin, W-thick, Y-thin, and Y-thick) in PLUGT patients were also investigated. The findings add valuable information to our understanding of the biological mechanism of tongue coating development. Nevertheless, validation in a large population is needed due to the heterogeneity in individual habits, which impacts the universality of the study results. The results, however, are significant because they may provide effective ways for obtaining a quick and noninvasive diagnosis of PLUGT. Furthermore, the findings suggested that TC differentiation could provide a more accurate diagnostic for PLUGT clinical administration.

Retracted: The Role of Health Education in Vaccination Nursing

Journal of Healthcare Engineering

Received 25 July 2023; Accepted 25 July 2023; Published 26 July 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The role of health education in vaccination is very important. Through various forms of activities, comprehensive and systematic education of health knowledge for people can promote students and others to be aware of vaccination and actively cooperate with vaccination work. Therefore, this article intends to conduct an in-depth study of the role of health education in prevention and treatment and to enhance people's awareness of vaccination. This article mainly uses questionnaire survey method, interview method, and controlled experiment to explain and analyze the effect of health education. The subjects of this questionnaire are students, parents, and staff. They have mixed reviews for its role in vaccination, but the overall situation is positive. 239 out of 500 people believe that health education can reduce allergic reactions and improve the effectiveness of vaccines. In the control experiment, after health education and publicity training, the parents of the observation group were significantly better than the control group in terms of mastering the relevant knowledge of vaccination, successfully vaccinating unplanned vaccines, etc. This shows that the importance of health education in vaccination care is incomparable.

1. Introduction

Our country's disease prevention work mainly focuses on public health. Factors such as large population, poor sanitation, and unbalanced economic development have affected people's understanding of disease knowledge. Health education is a kind of knowledge dissemination that focuses on prevention and combines prevention and treatment. It achieves the purpose of improving people's ideological awareness and enhancing the role of vaccines by cultivating and educating people in a certain degree of comprehensive physical and psychological qualities.

There are countless research results on the role of health education in vaccination care. For example, Wang et al. emphasized that in view of the problems existing in mass vaccination in schools, if targeted preventive care measures can be taken, the quality of medical care and the safety of vaccination can be greatly improved [1]. Tang pointed out that the scientific development of vaccination nursing work has a good effect on relieving the nervousness of children during vaccination, thereby promoting the success rate and safety of vaccination [2]. Yang and Wu explored the role of parental health education and nursing intervention in reducing the side effects of DPT vaccination among high school students. Parental health education and care intervention can significantly improve the understanding of the DPT vaccine among the parents of students who have received the DPT vaccine, thereby significantly reducing the awareness rate of the DPT vaccine [3]. Therefore, this article also follows the research line of other scholars and conducts in-depth exploration of the role of health education in vaccination care.

This article first studies the relevant theories and knowledge of health education. Then, a brief description of vaccination care is given. Afterwards, the function and performance of the design of the vaccination information management system were analyzed. Finally, through questionnaire surveys and experiments, an in-depth study of the role of health education in vaccination care was carried out, and data results were obtained [4]. The data show that through scientific health education, parents' cognition, the reduction of children's anxiety, and the success rate of vaccination can be significantly improved. The experiment proved the necessity of health education.

2. The Role of Health Education in Vaccination Care

2.1. Health Education. Health education is a scientific education that focuses on prevention and combines treatment. Its purpose is to let the audience have a correct and comprehensive understanding of the disease, improve people's self-protection ability, and enable them to receive effective care in social life. Health education is through the comprehensive and systematic shaping of people's physical and psychological factors so that they can establish a correct, positive, and self-improving ideology. The role of health education in vaccination care is very important [5, 6].

Health education is a systematic project, which requires systematic and planned planning as well as continuity. In terms of health knowledge, it mainly starts from the two perspectives of life care and social hygiene. As people's understanding of diseases continues to deepen, more and more knowledge about vaccination and nursing knowledge, methods, and approaches have begun to spread. The so-called health is a comprehensive good state of physique, psychological quality, and personality quality that combines a good mental state with a good physical shape [7, 8].

Health education can effectively improve people's misunderstanding of diseases, lifestyles, and behaviors, so as to achieve the purpose of vaccination and nursing. In health promotion and education, we must fully consider the individual differences of each patient, family environment, and other factors. Let more people in the whole society understand diabetes knowledge and prevention methods through publicity boards and playing video clips. Regularly organize "sports and fitness" activities to enable the general public to correctly understand the importance and role of sports in improving physical fitness. Actively cooperate with community neighborhood committees or residents' committees to conduct physical examinations for people with diabetes and guide them on how to vaccinate [9, 10].

In daily work, the importance of health education should be strengthened, and comprehensive and systematic publicity should be organized regularly to enable people to fully understand how to properly use and wear disease prevention equipment and related knowledge. At the same time, it can be spread through platforms such as WeChat official account.

Effective antibodies can be produced after vaccination, and such diseases will not occur after future contact, and vaccination is now free [11, 12].

Pay attention to the health education of parents. Parents should observe closely and do not give children antibiotics without authorization [13, 14].

Medical staff should pay attention to giving different nursing care to students' psychological reactions in different periods [15, 16].

2.2. Vaccination Care. Vaccination care refers to regular education of healthy patients so that they understand the disease and how to treat it and cultivate good habits in daily life. Through regular physical examinations, problems are found and solved in time.

Health education plays a very important role in vaccination care. It can help people understand their physical health and take corresponding measures to effectively control diseases. Nurses have a comprehensive knowledge and understanding of health education. In the actual nursing process, implement it to every construction worker, and all participants are required to strictly abide by the relevant regulations and take corresponding measures for different situations.

Regular lectures on vaccination and nursing knowledge: let parents and family members understand what problems need to be paid attention to in daily work and how to better and timely solve the various new situations in the medical history, discover potential risk factors, and control the development trend of the disease.

In health education, we can improve the staff's awareness of disease knowledge and awareness of disease prevention through professional training and qualification examinations. At the same time, it is necessary to strengthen communication with patients and their families.

Strengthen health education and publicity to train people through lectures, playing DVDs, etc., so that everyone can understand the importance of vaccination care and strengthen the relationship between people's disease and vaccination work. At the same time, some simple and easy-to-operate activities should be carried out in the hospital to increase the public's awareness of participation. Organize a regular theme activity with the theme of "Prevention and Treatment of Diseases" and distribute corresponding materials.

2.3. Design of Vaccination Information Management System

2.3.1. Data Mining Technology in the Management System. In the information management of vaccination, special technology is needed to sort and analyze the information and data. Based on the dimensionality of the data involved in the rule, association rules can be divided into single-dimensional and multidimensional. Its definition can be expressed as follows:

$$\begin{aligned}\text{Support}(P \Rightarrow Q) &= P(P \cup Q),\\ \text{Confidence}(P \Rightarrow Q) &= F(P \mid Q).\end{aligned} \tag{1}$$

Among them, the degree of support for association rules $P \Rightarrow Q$ is $F(P \cup Q)$. These data analysis techniques can be directly applied to the vaccination information data warehouse.

2.3.2. Vaccination Management. Vaccination is a welfare policy of the state to ensure the healthy growth of children and avoid contracting diseases. Vaccination information will be entered into the file as a required document for future enrollment. The production, packaging, and distribution of vaccines are also strictly controlled by the relevant departments, and the distribution is agreed.

In order to ensure the accuracy of each link in the vaccination process for children, each link will confirm the information and enter it into the computer, and the vaccine information will also be archived.

As for which vaccines to be vaccinated at different time periods, publicity brochures will also be formulated in advance and distributed to parents, which will also clearly indicate the adverse reactions of some vaccines.

The entire vaccination process plays a vital role in improving children's physical health and reducing the infection rate of group diseases and high-incidence diseases.

3. Experimental Investigation

3.1. Survey Object. This article first interviewed the vaccinated staff of the health center, mainly to explore the attitude and knowledge of the practitioners about the job. There is a total of 80 staff members under investigation. This article designs a relevant questionnaire to conduct a questionnaire survey on them.

Then, select 100 students who need vaccinations as the observation group. Among them, 52 were boys and 48 were girls. The vaccinated students are in good health and normal development. There is no special sensitivity reaction to vaccination. In addition, 90 students who need to receive vaccination were selected as the control group, of which 54 were boys and 46 were girls. There is no significant difference in gender between the two groups of experimental students, and they are comparable.

In addition, this article also invited the parents of the students to conduct surveys and interviews. Among the guardians of the survey subjects, there are up to 120 student mothers, 80 student fathers, and 30 grandparents.

3.2. Health Education Methods. Health education is a step that we all need to focus on throughout the vaccination process. Health education is not only a unilateral propaganda by medical staff but a mode of passive acceptance by parents. This mode can easily lead to parents' irritability and poor results.

Healthcare workers should consider innovative formats, such as educational video clips that encourage parents and children to watch together. In addition, you can also consider printing some storybooks and picture books to promote health education knowledge in the stories. Of course, giving children some small toys printed with health education can also have a good publicity effect.

Of course, the above method will inevitably incur costs, so the relevant part needs to issue funds to the community service station. Through the above methods, children can not only realize the harm of disease and can actively stay away from the source of disease in their daily life but also can enhance parents' awareness of vaccination.

3.3. Questionnaire Survey Method. The survey objects of this paper are parents and the staff of the community service station. The survey site is the community service station. The survey time is selected as weekends, because weekends are the peak time for parents to bring their children to vaccinate. In the form of face-to-face paper questionnaires, parents' real views on vaccination and health education, as well as their satisfaction with the vaccination process, were obtained.

In addition, we also distributed paper questionnaires to the staff of 10 community service workstations, mainly to investigate the difficulties they face during the usual vaccination process so as to propose solutions.

4. Analysis of Survey Results

4.1. Main Difficulties Faced by Vaccination. First of all, this article intends to analyze the main difficulties faced by vaccination. According to the survey data of the staff, we can see that 64 of the 90 staff are concerned about the 5 aspects of vaccination, namely, insufficient assistance, negative reports, noncooperation of the masses, weak team, and lack of salary and labor. There are great opinions on matches, etc. The specific data are shown in Table 1.

As shown in Figure 1, we can judge that the staff attach great importance to the problem of vaccination, and they believe that the two aspects of insufficient aid and the impact of negative reports have a negative impact on the work. This is enough to show that the health education work for vaccination is not yet in place, and the country's management is not perfect. Among them, only 14 people disagreed with these issues, and 12 others did not comment on it.

4.2. Parents' Satisfaction with the Work of Vaccination Clinic. Secondly, this article invites parents to conduct a questionnaire survey and found that the degree of satisfaction with the overall outpatient clinic, the number of consultations, waiting for observation, postevent precautions, sanitary conditions, and service procedures are also different. On average, about 160 people are satisfied with these 6 places, and about 42 people are dissatisfied with these places. The details are shown in Table 2:

As shown in Figure 2, we can clearly see that the parents are most satisfied with the sanitary condition of the vaccinated health center, and then they are satisfied with the service process. The most unsatisfactory thing is the number of visits in the outpatient department. As people are now more and more aware of the importance of vaccination, they attach great importance to vaccination. However, there is a time limit for vaccination, and there are not many consultations, so parents feel distressed about this.

4.3. Comparison of Effects between the Observation Group and the Control Group. Then, this article needs to understand the grouping situation. After conducting health education and publicity training for parents, 97 of the 100 parents of students in the observation group have knowledge of vaccination. 94 cases were successfully vaccinated with unscheduled vaccines, and 95 cases were qualified. Among the 100 parents of students in the control group, 61 parents successfully mastered vaccination-related knowledge. 68 students were successfully vaccinated with unscheduled vaccines, and 72 students passed the vaccine. According to

Table 1: Major difficulties faced in vaccination efforts.

	Agree	Disagree	General
Insufficient superior subsidies	18	4	1
Negative reports impact	19	2	1
The masses do not cooperate	13	3	2
Weak personnel team	6	2	3
Revenue is not linked to the workload	8	3	5

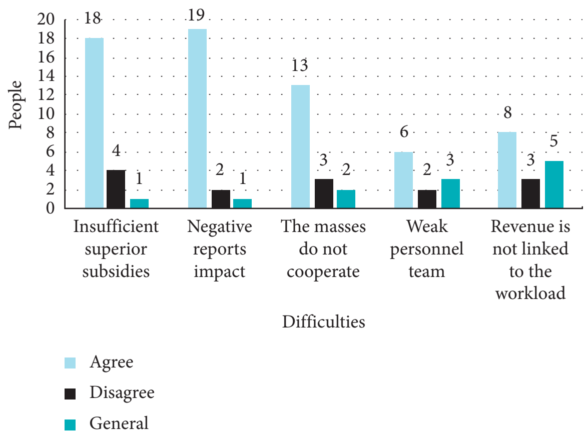

Figure 1: Major difficulties faced in vaccination efforts.

Table 2: Parents' satisfaction with the vaccination clinic work.

	Satisfied	Unsatisfied	General
General outpatient service	161	42	31
Number of opening visits	119	68	39
Waiting for planting to stay	142	61	32
Matters needing attention afterwards	163	36	26
Sanitary conditions	192	22	17
Service process	183	20	22

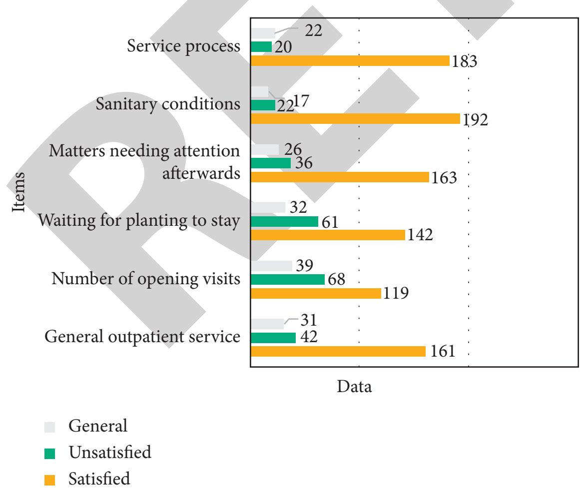

Figure 2: Parents' satisfaction with the vaccination clinic work.

the data comparison, it can be clearly seen that the inoculation effect of the observation group is better than that of the control group. The details are shown in Table 3.

Table 3: Effect comparison between the observed and control groups.

	Observation group	Control group
Number	100	100
Vaccine pass rate	95	68
Out planned qualified rate	94	72
Knowledge mastery rate	97	61

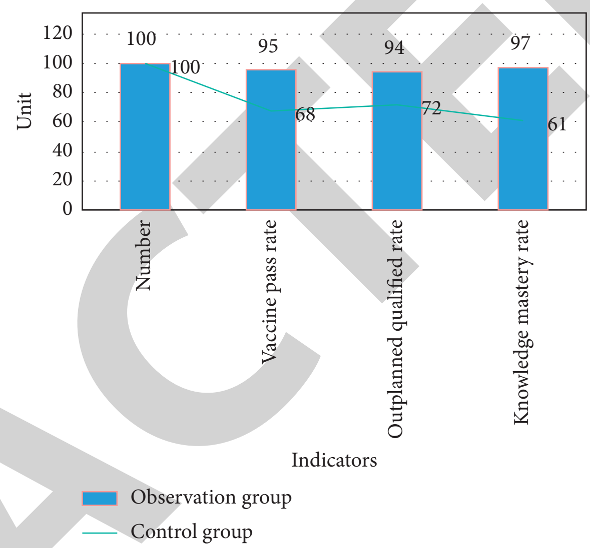

Figure 3: Effect comparison between the observed and control groups.

As shown in Figure 3, we can find that the vaccine qualification rate, unplanned qualification rate, and knowledge mastery rate of the observation group and the control group are better than those of the control group. In terms of vaccine qualification rate, the observation group is 27% larger, and in the unplanned qualification rate, the observation group is 22% larger. In terms of knowledge, the observation group can reach 97%. This shows that health education plays a great role in vaccination and can have an impact on the effectiveness of vaccines.

4.4. The Role of Health Education in Vaccination. Finally, this article conducts research on reducing adverse vaccine reactions, increasing satisfaction, improving vaccine effects, and reducing the occurrence of allergic reactions from the three perspectives of students, parents, and medical staff. From the data collection, it can be found that 142 people think that health education can reduce the occurrence of allergic reactions, 96 people think it can improve the effectiveness of the vaccine, and 153 people say it can increase satisfaction. Another 122 people said that health education would reduce the adverse effects of the vaccine. The details are shown in Table 4.

As shown in Figure 4, we can see that in the student population, most of them believe that health education can reduce the occurrence of allergic reactions. The proportion is 36.8%. In the parent group, most of them think that health education can improve their satisfaction and increase their

Retracted: Low Serum Albumin Is Associated with Poor Prognosis in Patients Receiving Peritoneal Dialysis Treatment

Journal of Healthcare Engineering

Received 15 August 2023; Accepted 15 August 2023; Published 16 August 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Background. The number of patients receiving dialysis treatment is sustainably increasing, especially peritoneal dialysis. *Objectives*. It is necessary to find out potential factors that may indicate the prognosis of patients receiving peritoneal dialysis treatment. *Methods*. This study retrospectively involved 325 patients who received peritoneal dialysis treatment. *Results*.Low serum albumin (HR = 2.254; 95% CI: 1.534–3.311; $P < 0.001$) and high FBG (Fasting blood glucose) (HR = 1.474; 95% CI: 1.025–2.120; $P = 0.037$) were risk factors for death in patients receiving peritoneal dialysis treatment. Serum albumin (AUC = 0.683; $P < 0.001$) and creatinine (AUC = 0.625; $P < 0.001$) exhibited value of prognosis prediction. Both high FBG ($P = 0.005$) and low albumin ($P < 0.001$) were associated with poor prognosis, and low albumin predicted poorer survival. *Conclusions*. Low serum albumin and high fasting blood glucose were risk factors and associated with poor prognosis. Low albumin has a potential in predicting the prognosis of patients receiving peritoneal dialysis treatment.

1. Introduction

Dialysis is a renal replacement therapy (RRT), mainly including hemodialysis and peritoneal dialysis [1, 2]. The principle of peritoneal dialysis is the solutes and fluid exchange between the peritoneal capillary blood and the dialysis solution, in which the flow rate can be adjusted to achieve a maximum removal [2]. It is estimated that more than 272,000 patients are receiving peritoneal dialysis globally, accounting for approximately 11% dialysis patients worldwide (in 2017) [3]. The number of patients receiving dialysis treatment is sustainably increasing, especially peritoneal dialysis [4]. Among different countries, the selection of dialysis modality is dramatically different [3]. Different dialysis modalities bring important consequences for quality of life, patients' survival, financial implications, and logistics for the medical system [1, 5]. In Asia, the application of peritoneal dialysis ranges from 3% to 73%, and China has a fairly high peritoneal dialysis rate [3, 4, 6]. Notably, there is a steep rise in peritoneal dialysis utilization in China in the past decade [7].

Albumin is a single protein species and the most abundant plasma protein representing approximately 3/5 in quantity [8]. Albumin produced in the liver is an anionic, flexible, heart-shaped molecule with a molecular weight of ~65 kDa [9]. Normally, the serum albumin is about 45 g/L in human. Albumin plays an important role in maintaining an oncotic pressure difference between plasma and the interstitial space by regulating fluid exchange [10]. Besides, albumin carries a number of substances including bilirubin, fatty acids, ions, hormones, and drugs [8, 10]. Notably, low albumin in serum is in association with increased mortality [10].

It is necessary to find out potential factors that may indicate the prognosis of patients receiving peritoneal dialysis treatment. Herein, factors associated with the prognosis of patients receiving peritoneal dialysis treatment, such as serum albumin, creatinine, and fasting blood glucose, were evaluated. We also compared their abilities of prognosis prediction by ROC (receiver operating characteristic) analysis and survival analysis.

2. Materials and Methods

2.1. Patients. This study retrospectively involved 325 patients who received peritoneal dialysis treatment. Each patient had a complete record of dialysis during the period. All lab parameters were measured at admission as a baseline. The follow-up duration was 7 years.

Patients who were older than 18 years old and received peritoneal dialysis treatment for more than 3 months were included.

The exclusion criteria were as follows: incubation in other hospitals, hemodialysis to peritoneal dialysis, kidney transplant to peritoneal dialysis, annual follow-up <2, and missing baseline data.

2.2. Clinical Data Collection. After admission, the age of patients was recorded, and systolic pressure, diastolic pressure, and pulse were measured. Moreover, the patients received laboratory examination including total protein (g/L), albumin (g/L), Ca^{2+} (mmol/L), phosphate (mmol/L), K^+ (mmol/L), Na^+ (mmol/L), Cl^- (mmol/L), fasting blood glucose (FBG; mmol/L), blood urea nitrogen (BUN; mmol/L), creatinine (μmoI/L), hemoglobin (g/L), and parathyroid hormone (PTH; pg/mL) test. Normal, low, and high individual parameters were defined according to the clinical standard of the clinical lab of our hospital.

2.3. Statistical Analysis. Software SPSS 22.0 (IBM, USA) was used. Data were exhibited as mean ± SD. Quantitative data are expressed as mean ± standard deviation or median (interquartile range). Qualitative data are expressed as a rate or composition ratio. Differences between groups were analyzed by the *T*-test or analysis of variance. Survival risk analysis was performed using a cox risk regression model. The ROC (receiver operating characteristic) curve was used to predict the risk of death for patients receiving peritoneal dialysis treatment, and the AUC (area under curve) was calculated. $P < 0.05$ was considered statistically significant.

3. Results

3.1. Characteristics of Patients Receiving Peritoneal Dialysis Treatment. The summary of all the characteristics of patients receiving peritoneal dialysis treatment is shown in Table 1. The average age was 62.51 years old. Among the 325 patients, 147 were male and 178 were female. The average survival time was 892.36 days.

3.2. Differences between Survived Patients and Dead Patients. The subsequent comparisons between the survival and the death were further performed (Table 2). No significant differences were found in gender (P = 0.651), systolic pressure (P = 0.198), pulse (P = 0.745), total protein (P = 0.092), Ca^{2+} (P = 533), phosphate (P = 0.467), K^+ (P = 0.322), Na^+ (P = 0.260), Cl^- (P = 0.390), FBG (P = 0.333), BUN (P = 0.251), and PTH (P = 0.882). Survival time (P = 0.049) and diastolic pressure (P = 0.047) showed a little statistical difference. The hemoglobin (P = 0.038) was statistically different.

The age was significantly different (P < 0.001) as the dead patients (66.96 ± 13.89 years old) were much older than the survived patients (28.75 ± 13.13 years old).

The albumin was significantly different (P < 0.001) as the albumin in dead patients (32.98 ± 4.94 mmol/L) was much lower than that in survived patients (36.59 ± 4.85 mmol/L).

The creatinine was significantly different (P < 0.001) as the creatinine in dead patients (564.64 ± 268.80 μmoI/L) was much lower than that in survived patients (684.77 ± 271.00 μmoI/L).

3.3. Risk Factors for Death in Patients Receiving Peritoneal Dialysis Treatment. Based on the results of the comparison between survived patients and dead patients, we further analyzed the risk factors for death in patients receiving peritoneal dialysis treatment. As shown in Table 3, albumin, FBG, and creatinine were found to be significantly different.

However, the HR of creatinine was 0.999, with 95% CI of 0.998–1.000. Therefore, low albumin (HR = 2.254; 95% CI: 1.534–3.311; P < 0.001) and high FBG (HR = 1.474; 95% CI: 1.025–2.120; P = 0.037) were considered to be risk factors.

3.4. Prognosis Prediction in Patients Receiving Peritoneal Dialysis Treatment. To evaluate the prognosis prediction value of the observed risk factors, ROC curves were drawn (Figure 1). FBG did not show the prediction value (P = 0.593). Albumin (P < 0.001) and creatinine (P < 0.001) exhibited a value of prognosis prediction (Table 4). Of note, the albumin (with AUC of 0.683) showed a higher prognosis prediction value than creatinine (with AUC of 0.625).

3.5. Low Albumin and High FBG Were Associated with Poor Prognosis. Finally, the survival of patients receiving peritoneal dialysis treatment was analyzed (Figure 2). Both high FBG (P = 0.005) and low albumin (P < 0.001) were associated with poor prognosis, and low albumin predicted a poorer survival.

4. Discussion

In this study, we found age, albumin, and creatinine were significantly different between dead and survived patients receiving peritoneal dialysis treatment. Albumin and creatinine showed the value of prognosis prediction. Furthermore, low albumin and high fasting blood glucose were risk factors and associated with poor prognosis. Thus, it is suggested that low albumin has a potential in predicting the prognosis of patients receiving peritoneal dialysis treatment.

To some extent, the level of albumin represents nutrition status and infection [11, 12]. Renal handling of albumin can influence renal function by the effects of albumin. Albumin filtration in glomeruli and tubular reabsorption are two major processes in the renal handling of albumin. The dysfunction of them leads to an increased excretion of

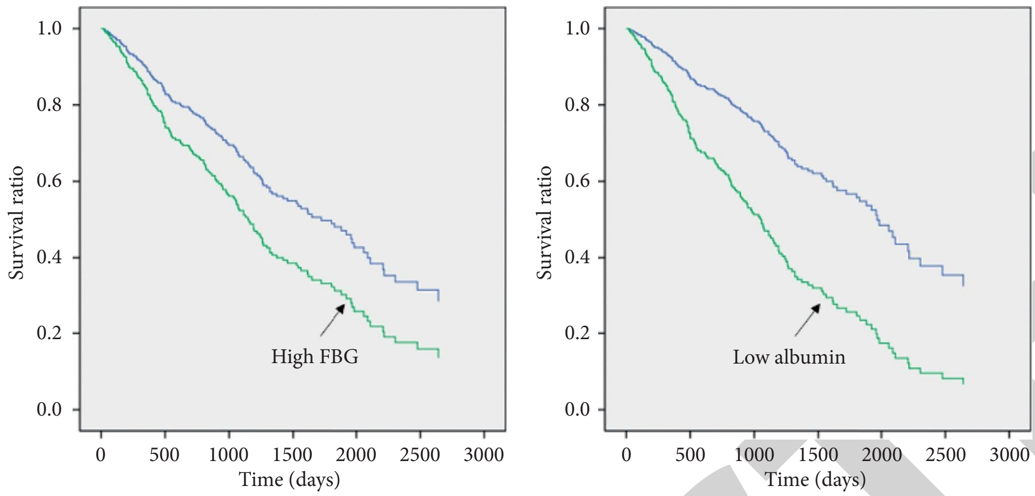
albumin. Recently, Yamada et al. found lower serum albumin level is associated with an increased risk for loss of residual kidney function in patients receiving peritoneal dialysis treatment [13]. The loss of residual kidney function can make the general condition of patients worse and finally lead to the death. Our study goes further in exploring the prognosis prediction value of albumin by involving and considering the survival. Chiu et al. also reported lower serum albumin was associated with poorer survival [14]. Hao et al. used time-averaged albumin level and serum albumin reach rate as predictor variables and found higher serum albumin was associated with a lower all-cause mortality rate in patients undergoing long-term peritoneal dialysis treatment [15]. It is indicated that low serum albumin was a risk factor of both early and late death in incident peritoneal dialysis patients [16]. Interestingly, Singh et al. concluded that peritoneal dialysis is associated with



(a) (b)

Figure 2: (a) Survival of patients with high FBG (green line) and low and normal FBG (blue line). (b) Survival of patients with low albumin (green line) and high and normal FBG (blue line).

lower mortality than hemodialysis in patients with low serum albumin [17]. As for the study of serum creatinine, Inaquma et al. reported the ratio of blood urea nitrogen to serum creatinine is associated with mortality by conducting a multicenter prospective cohort study [18].

By comparison of the age between dead and survived patients receiving peritoneal dialysis treatment, we found the age may influence the clinical outcomes and mortality. Consistent with the study conducted by Sakaci et al., mortality was higher in elderly patients and low albumin levels affected mortality [19]. The treatment of peritoneal dialysis should be cautious and based on accurate assessment, because of a higher incidence of intestinal complications, previous history abdominal surgeries, multiple comorbidities, and other possible contraindications [20, 21]. Our result also revealed that high fasting blood glucose may be associated with poor prognosis. Chen et al. reported the association of impaired fasting glucose and mortality in nondiabetic patients on maintenance peritoneal dialysis [22]. The role of high blood glucose in cardiovascular complications and even mortality of peritoneal dialysis treatment needs to be studied.

A number of researchers focus on the study of risk factors for mortality in patients receiving peritoneal dialysis treatment. Female gender, lower Kt/V (weekly urea clearance), and WCCr (weekly creatinine clearance) were found to be risk factors [23]. Lower hemoglobin levels and the presence of diabetes were shown to be risk factors as well [16].

In this study, common laboratory test indicators were analyzed to predict the prognosis of patients with peritoneal dialysis, which is helpful to advance treatment intervention for patients with possible poor prognosis and improve the prognosis of these patients. For patients with hypoalbuminemia and/or high FBG, which may lead to poor prognosis, dietary modification, intravenous albumin supplementation, and more stringent measures of blood glucose control may be considered. However, further prospective studies are needed to confirm the clinical efficacy of these measures.

This is a retrospective study, which is the major limitation. In the future study, we plan to involve the complications and causes of death. It is known that peritonitis has a notable association with peritoneal dialysis treatment since technique failure of peritoneal dialysis treatment could lead to peritonitis [24, 25]. The cardiovascular complication is another severe risk for peritoneal dialysis treatment [26]. The association of albumin and complication of peritoneal dialysis treatment is not clear and remains to be further studied.

4.1. Implications. Low albumin and high fasting blood glucose were risk factors and associated with poor prognosis. Low albumin has a potential in predicting the prognosis of patients receiving peritoneal dialysis treatment.

Data Availability

The data used to support the findings of this study are included within the article.

Ethical Approval

The clinical study was approved by the Ethics Committee of Beijing Lu-He Hospital and was conducted in accordance with the provisions of the Declaration of Helsinki.

Consent

Written informed consent was obtained from all participants before enrolment.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

Objective. The study aims to analyze the efficacy of rehabilitation nursing interventions on patients with open lower limb fractures. *Methods*. From June 2020, patients who received RNI (observation group) were included and compared with patients who received routine nursing interventions (control group). The efficacy of different nursing modes was compared with several indicators. *Results*. One hundred patients were included in this study, 50 in each group. The baseline characteristics were not significantly different between the groups. Regarding the emotional scores, the Self-Rating Anxiety Scale (SAS) score (26.98 vs 43.47), and Distress Management Screening Measure (DMSM) score (8.01 vs 12.85) in the observation group were significantly lower than those in the control group, both $P < 0.05$. Regarding the postoperative related indexes, the postoperative pain score (10.13 vs 15.53), fracture healing time (6.32 vs 10.86 weeks), and postoperative complications rate (0 vs 12%) in the observation group were all significantly lower than those in the control group, all $P < 0.05$. Regarding the quality of life scores, the WHOQOL-100 score (94.12 vs 83.13) and PSQI score (6.43 vs 10.36) were both significantly better in the observation group, with both $P < 0.05$. *Conclusion*. Patients with open lower limbs who received RNI can help patients reduce postoperative anxiety and stress, promote postoperative rehabilitation and improve their quality of life.

1. Introduction

With the rapid development of China's construction industry and transportation industry, the incidence of open fractures of the lower limbs is also increasing year by year. The trauma caused by the fracture is large. Serious conditions such as tissue defects, bone fracture exposure, and wound infection may occur in these kinds of fractures, resulting in aggravating the pain of patients and delaying their postoperative recovery [1]. Even physical and psychological stress responses will occur in these patients [2].

In order to further reduce the complications and promote the recovery of lower limb function, it is necessary to find scientific measures for patients with open lower limb fractures. Researchers have identified the positive clinical value of rehabilitation nursing interventions (RNI) in patients who underwent general surgeries and orthopedic surgeries [3, 4]. The postoperative RNI may play an important role to ensure the quality of rehabilitation. However, studies about the efficacy of RNI on patients with open lower limb fractures are still rare. Therefore, we conducted a retrospective case-control study to explore the efficacy of RNI compared with routine nursing interventions, and the content is further discussed in this study.

2. Methods

The RNI was adopted in our department since 2020 June. The patients who received RNI after 2020 June were included in our study.

2.1. Case Selection Criteria

2.1.1. Inclusion Criteria. The inclusion criteria were as follows: (1) detailed imaging data can be obtained; (2) age ≥18 years old; (3) meet the standards of surgical operation and anesthesia; (4) has no treatment contraindications and midway withdrawal; (5) normal coagulation function, cardiopulmonary, liver, and kidney functions; and (6) patients or family members were aware of the study and signed the consent [5].

2.1.2. Exclusion Criteria. The exclusion criteria were as follows: (1) minors; (2) women in pregnancy and lactation; (3) with emotional and mental disorders; (4) with other fractures; (5) with blood disease; and (6) patients with malignant tumors [6].

2.2. Nursing Methods. Patients in the control group were given routine nursing and the corresponding nursing and guidance according to the patient's situation. Patients in the observation group provided RNI, the details are further discussed in this study [7].

2.2.1. Evaluation. The postoperative rehabilitation plan was conducted based on the data after a comprehensive examination of the patient's postoperative situation. Communication was strengthened to help patients improve their negative postoperative emotions. Nurses gave targeted nursing interventions for common postoperative complications. The patient's body position was adjusted in time. It is recommended to rest in a rigid bed within 3 weeks after surgery and turn over once every 2 hours. Family members were taught to massage their limbs to effectively prevent pressure sores. Good pain management was carried out for patients to relieve postoperative pain. If the patient took a flat rest, the elbow was extended with a back flexion of 30–40°. When taking the side position, the lower limb's joints were slightly flexed to avoid compression of the upper limbs. Some patients had obvious pain due to their own tolerance, and painkillers were taken under the guidance of the attending doctor to relieve the pain when necessary. When the patient was in pain, the pain pump was used to maximize the pain caregivers' acceptance of the patient. The patient was informed of the attention of the matters in the recovery process. The pain management methods and rehabilitation knowledge were explained, rehabilitation guidance and training were appropriately strengthened, and the patient's immunity was improved [8].

2.2.2. Psychological Nursing Care. Patients with an open fracture of the lower limbs often have severe pain after surgery, leading to a serious bad mood. This kind of bad mood is different from the concerns about surgery preoperatively. Therefore, the psychological counseling strategy adopted by nurses postoperatively is different from that of preoperatively. The proper pain relief guidance and detailed health education were based on timely counseling on patients' physical discomfort and pain condition. Nursing staff should communicate with patients actively to tell them the importance of postoperative medical and nursing cooperation. As a result, the patients' own medical compliance behavior was strengthened [9].

2.2.3. Pain Care. Nursing staff should determine the degree of postoperative pain and analyze the impact of pain symptoms on the quality of sleep.

In order to avoid the use of analgesics, nursing staff should explain how to divert pain attention to patients when the pain can be tolerated. The nursing staff were required to strengthen ward inspection [10] to inquire about the pain degree every day. If the VAS score exceeds 4 points, then report the pain to the doctor in time. After the feedback from the doctors, nursing staff should follow the doctor's advice to provide pain treatment if necessary.

2.2.4. Health Education. Nursing staff should explain the necessity of postoperative rehabilitation care, the high-risk factors that affect postoperative recovery, and the ways of postoperative rehabilitation care. Online consultation was also available for patients to clear up their doubts about the diseases and surgical treatment.

Nursing staff should guide the daily lives of patients to balance bed and activity. Exercise is necessary as soon as possible after the operation to promote blood circulation in the lower limbs. The amount of activity can be gradually increased according to the needs of rehabilitation and the condition of pain. Patients were advised to eat foods with high energy to promote the recovery of wounds. Smoking and drinking were forbidden during the rehabilitation period, and drinking more water was encouraged [11].

2.2.5. Prevention of Postoperative Complications. During the period of an indwelling catheter, nurses should carry out bladder training for the patient to prevent bladder muscle atrophy. After the patient's postoperative condition went well, intermittent catheterization was used to continuously strengthen its own urination function.

Nurses were required to advise patients and their family members of the guidance to avoid wound infection. The prevention methods include disinfecting and cleaning the pressed skin, informing patients not to scratch the wound with their hands, treating timely when the wound was contaminated by blood, and maintaining the skin dry.

There are four aspects to do a good job in the prevention of deep vein thrombosis (DVT). First of all, intravenous care. In order to prevent DVT, lower extremity puncture and infusion are avoided, especially repeated operations at the same location. When infusing drugs, the doctor's advice is followed to choose less irritating drugs for the patient to prevent the liquid from leaking out of the blood vessels. When using a touquet, it is necessary to reduce the binding time to avoid unnecessary damage to the distal and local blood vessels. The puncture site is closely observed, the inflammatory reaction is found and dealt with in time, and the venous channel is reselected. Secondly, lower extremity care. In order to effectively prevent deep venous thrombosis of the lower extremities, nurses instructed patients to raise the affected limb after surgery to facilitate the venous return of the lower extremities and prevent swelling. It should be careful not to compress the deep veins of the patient's legs. The color and temperature of the affected limb were observed, and the pulse of the dorsal foot artery was accurately recorded. On this basis, the cause of the abnormality in time was found and dealt with accordingly. When necessary, an intermittent inflation and compression device were used to perform periodic compression to improve the venous blood flow of the lower extremities and prevent deep vein thrombosis in the lower extremities. At the same time, medication guidance for patients with severe renal insufficiency or patients with thrombosis, unfractionated heparin can be used. The specific dosage depends on individual differences. The patient needs to be continuously monitored for coagulation indicators during the medication process to avoid medication risks. Low-dose heparin has a good effect of preventing thrombosis. It is recommended to use 5000 U subcutaneous injection 2 h before the operation and to monitor the patient's platelet function after the operation to avoid thrombocytopenia. Finally, mechanical prevention. Medical elastic stockings are used to apply external force to restrict venous pressure, promote venous return, and ensure the normal blood circulation function of the veins of the lower extremities, thereby exerting a preventive effect. At the same time, the use of intermittent inflation and compression devices to periodically pressurize patients can also improve the venous blood flow of the patients' lower limbs, increase blood flow, and prevent DVT [12].

2.2.6. Rehabilitation Guidance.

(1) Passive training program. After the operation, a rehabilitation training program was developed for the patient based on the preoperative examination results and the postoperative condition. On the first postoperative day, the patient's affected limb was properly raised and kept in a straightened state to avoid external rotation, and the patient's pain symptoms were evaluated. Patients were encouraged to take the initiative in bed activities. When the patient's pain is mild, their knee joints were passively moved, and ankle back extension exercises and quadriceps isometric exercise training were performed. Patients were instructed to perform ankle pump exercises and quadriceps contraction training to enable patients to master the essentials of movement to accelerate venous return. The patient was instructed to train for muscle tension and contraction. The affected limb was raised by 20~30°. Passive activities should be based on the comfort of the patient. Pillows were not put under the knees, letting the patients raise their entire lower limbs, and placing hard objects under the knees was avoided to avoid hitting the popliteal veins. Oppression was produced. Patients were instructed to press and rub the muscles of the lower limbs at the base of their palms to speed up blood flow, promote venous return, and prevent thrombosis. Patients were instructed to raise their straight legs, exercise their muscles, and prepare themselves for getting out of bed later. The condition of the dorsal artery of the device was closely observed to determine the degree of swelling of the limbs. If there was any abnormality, it was immediately notified to the doctor. On the 3rd day after the operation, the patient's knee joint passive training was carried out with the aid of the joint continuous passive activator. On the 4th to 7th day after the operation, the patient was given quadriceps isometric contraction exercise training, straight leg raising exercise training, and active knee flexion exercise training [13].

(2) Active training program: elastic bandages should be used when the patient goes down to the ground to reduce edema of the lower extremities, speed up the return of venous blood, and avoid thrombosis. According to the patient's postoperative recovery, the patient is guided to restore and contract the quadriceps, ankle joint, and gluteal muscles to avoid complications such as osteoporosis, venous thrombosis, and muscle atrophy. The changes in the recovery of the disease are observed, the patient's hip and knee joint flexion and extension strengths are trained in a timely manner, and the activities of the upper and lower joints of the fracture are carried out. According to the patient's recovery degree, the activity intensity can be appropriately increased to improve joint stiffness. Nursing staff should regularly perform related passive activities for the patient, and then gradually change to active activities, allowing the patient to lie on the bed to perform active leg elevation exercises, and assist them to restore their sitting ability until they can walk slowly and stand up. When the patient can stand autonomously and the affected leg can move forward, walking training is started. Limbs, standing, striding, and other exercises are guided, the patient's gait is observed, a walker is used to assist walking training at an appropriate time, or a small amount of support from family members is provided. Early walking training needs to pay attention to that the amount of activity should be moderate to avoid foot varus, and the patient is required to use the affected side of the lower limb to shift the center of gravity, and the healthy side of the lower limb cannot be used to help walk, to avoid gait instability, and to prevent the occurrence of spasm of the affected side of the lower limb. The range of movement of the uninvolved limb of the patient is controlled, requiring the patient not to move the uninhibited limb at will during training but to use the affected limb subconsciously [14].

2.3. Observation Indicators. The anxiety scores before and after nursing were compared using the Self-Rating Anxiety Scale (SAS). The critical value is 50 points: (1) mild anxiety: 50–59 points; (2) moderate anxiety: 60–69 points; and (3) severe anxiety: >69 score [8]. The psychological pain scores before and after the intervention were compared using the distress management screening measure (DMSM) scale; 0–10 points, 0 points for no psychological pain, and 10 points for extreme psychological pain [9]. The postoperative pain scores, fracture healing times, and times of the two groups of patients postoperative complications were compared. The quality of life scores of the two groups of patients before and after intervention were compared using the World Health Organization Quality of Life Scale (WHO-QOL-100 scale). There are a total of 25 subitems. Each subitem is evaluated according to the 0–4 point method. The total score is 100 points. The higher the score, the higher the quality of life. The comparison of the sleep quality scores of the two groups of patients before and after intervention, using the Pittsburgh Sleep Quality Index (PSQI) scale, 7 evaluation items, 0–3 points scoring method, a total score of 21 points; the lower the score, the better the sleep quality [15].

2.4. Statistics. In this study, SPPS20.0 was used for statistical analysis. The measurement data were described by the mean ± standard deviation ($\overline{x} \pm s$), and student's t test was used; the count data were described by example (%), and the χ^2 test was used. $P < 0.05$ means that the difference is statistically significant.

3. Results

3.1. Baseline Characteristics. In this study, 100 patients were included in this study. In the observation group, 50 patients with open lower limb fractures were included with men: women as 29 : 21. The mean age was 41.89 ± 1.38 years (a range of 25–70 years). The causes of fracture were as follows: 37 traffic accidents, 10 high falls, and 3 other causes. The fracture areas were as follows: 28 femur and 22 tibia. Fracture Gustilo–Anderson classification: 44 A and 6 B. In the control group, there were 32 men and 12 women aged 23–70 years on average (42.71 ± 1.29). Fracture causes were as follows: 34 traffic accidents, 12 falling injuries, and 4 other cases. The fracture areas were as follows: 30 femur and 20 tibia. Fracture Gustilo–Anderson classification: 42 A and 8 B. The two general data comparison results were $P > 0.05$, comparable.

3.2. Effects of RNI on Postoperative Emotional Scores. The comparison of SAS score (64.12 vs 64.30) and DMSM score (17.32 vs 17.46) had no significant difference between the two groups before nursing, with both $P > 0.05$. After the nursing intervention, the scores significantly improved compared with the same group before nursing, $P < 0.05$. Moreover, after the intervention, the abovementioned scores in the observation group decreased significantly more than in the control group (26.98 vs 43.47 and 8.01 vs 12.85), both $P < 0.05$ (Table 1).

3.3. Effects of RNI on Postoperative Related Indexes. The postoperative pain score (10.13 vs 15.53) and fracture healing time (6.32 vs 10.86 weeks) of the observation group were lower than those of the control group, $P < 0.05$; postoperative complications (0) in the observation group were lower than those of the control group (12.0%), $P < 0.05$ (Table 2).

3.4. Effects of RNI on Postoperative Life Quality Scores. The comparison of WHOQOL-100 scores and PSQI scores between the two groups before nursing had no significant difference with $P > 0.05$. After the nursing intervention, the PSQI score of the observation group was lower than that of the control group (94.12 vs 83.13), and the WHOQOL-100 score (6.43 vs 10.36) was higher than that of the control group with both $P < 0.05$ (Table 3) [13].

4. Discussion

Open fracture of the lower limbs is a common type of fracture in clinic practice, which can seriously damage the walking function and affect the daily life of patients. Although aggressive surgical strategies will be adopted, limb dysfunction will still occur in some patients. Moreover, the high risk of infection and strong traumatic stress response of patients was also associated with this kind of fracture [16]. Therefore, it is the common pursuit of orthopedic researchers to take effective measures to promote the prognosis of patients with lower limb fractures.

The concept of rehabilitation nursing focuses on applying multidisciplinary theories to formulate targeted treatment measures to reduce the psychological and physical stress and trauma caused by surgical operations on patients and to promote rehabilitation. [15] The efficacy of RNI has been identified in many fields. However, there is no systematic and authoritative research data about the efficacy of RNI in patients with open low limb fractures. Therefore, we conducted this study because we hypothesized that RNI may be helpful in improving the prognosis of patients with open low limb fractures. Finally, we identified that RNI can help patients reduce postoperative anxiety and stress, promote postoperative rehabilitation, and improve quality of life.

The psychological impact of open fracture surgery on patients is relatively large. Unhealthy emotions such as worry, anxiety, and depression may come from the burden of disease and economic conditions. The unhealthy emotions may decrease compliance and finally worsen the prognosis. Integrating postoperative psychological care into RNI is a supplementary nursing model for humanized nursing intervention. The model aims to help patients overcome their inner conflicts through communication and opinion exchanges. In previous studies, psychological nursing has been identified as playing an important role in the recovery of patients after surgery and in some chronic diseases. [17, 18] In our study, we also found emotional scores significantly improved after psychological nursing intervention in patients with open lower limb fractures.

Postoperative pain is a common phenomenon that often occurs within 3 days after an operation, and the incidence rate is as high as 95%. It is the result of the combined effects of fracture pain, surgical pain, postoperative swelling, and compartment syndrome. Severe pain after fracture is a

Table 1: Comparison of emotional scores between the two groups before and after nursing intervention ($\overline{x} \pm s$).

Group	SAS score (points)		DMSM score (points)	
	Before intervention	After the intervention	Before intervention	After the intervention
Observation group ($n = 50$)	64.12 ± 5.63	26.98 ± 2.12*	17.32 ± 1.25	8.01 ± 0.31*
Control group ($n = 50$)	64.30 ± 5.71	43.47 ± 3.41*	17.46 ± 1.33	12.85 ± 1.68*

Control group ($n = 50$)	15.53 ± 1.13	10.86 ± 0.78	6 (12.0)
t value	9.637	8.561	8.356
P value	0.000	0.000	0.008

Table 3: Comparison of sleep and quality of life scores between the two groups ($\overline{x} \pm s$).

Group	WHOQOL-100 score (points)		PSQI score (points)	
	Before intervention	After the intervention	Before intervention	After the intervention
Observation group ($n = 50$)	78.24 ± 3.63	94.12 ± 2.69*	14.32 ± 1.25	6.43 ± 0.12*
Control group ($n = 50$)	77.92 ± 3.77	83.13 ± 3.24*	14.46 ± 1.33	10.36 ± 0.68*
t value	0.639	13.826	0.639	15.278
P value	0.207	0.000	0.591	0.000

Note: comparison results of before and after interventions within the group, $^*P < 0.05$; WHOQOL-100 = World Health Organization Quality of Life Scale; PSQI = Pittsburgh Sleep Quality Index.

malignant stimulus, which can cause severe pain stress damage and traumatic pathological changes, such as increased systemic oxygen consumption, decreased body immunity, metabolic disorders, rapid loss of nutrients, high blood pressure, and shock response. It will damage the functions of various systems of the human body and affect the postoperative rehabilitation effects [19, 20]. Therefore, improving postoperative pain in patients with open lower limb fractures is of great significance for promoting postoperative recovery. The results of this study showed that RNI can significantly reduce the degree of postoperative pain in patients with open lower limb fractures.

Postoperative DVT is a common complication after surgery for open fractures of the lower limbs. It is generally recognized that early functional exercises and activities can reduce the incidence of postoperative complications [21]. Moreover, DVT can be prevented by many nursing interventions. In the conventional nursing mode, activities are restricted in the early stages after the operation. After the pain is relieved, the patient is encouraged to exercise moderately, but no specific requirements are made to avoid unnecessary trauma, which increases the risk of complications. RNI advocates early activities to avoid DVT caused by blood circulation disorders in the lower limbs. Therefore, DVT can be prevented by RNI [22]. The effects of RNI were identified in our study.

The quality of life and quality of sleep are very important evaluation indicators. Due to the reduced postoperative pain and complications, the WHOQOL-100 score and PSQI score improved significantly. The use of RNI is beneficial to the improvement of the quality of life and quality of sleep of patients with open lower limb fractures.

Our study had several limitations worth discussing. First, its retrospective nature prevented us from making stronger conclusions. The second limitation was the small sample size. Due to RNI being adopted in our hospital less than 2 years, the accumulated cases were not common in our center. Third, a lack of objective indicators may cause bias. More multicenter prospective studies with a large sample size are necessary to better understand the true value of RNI.

5. Conclusion

Based on a retrospective case-control study, we identified that patients with open lower limbs who received RNI can help reduce postoperative anxiety and stress, promote postoperative rehabilitation, and improve quality of life. More multicenter prospective studies with a large sample size are necessary to better understand RNI. More multicenter prospective studies with a large sample size are necessary to better understand the true value of RNI.

Traditional Chinese medicine classifies psoriasis (Ps) according to clinical manifestations, and its different clinical manifestations imply the pathogenesis and material evolution basis of Ps, especially biomarkers that are meaningful to identification of Ps, treatment response, and elucidation of the pathogenesis of the disease. This study aims to screen differential metabolites in plasma of psoriasis vulgaris (PV) of blood heat syndrome based on a widely targeted metabolomic technique and to analyze syndrome metabolic markers and metabolic pathways. Forty-five PV patients were recruited, including 21 cases of the blood heat syndrome group (BH-PPG), 24 cases of the non-blood-heat syndrome group (NBH-PPG), and 30 healthy cases of the normal control group (NPG). The UPLC-MS/MS detection platform, a self-developed database, and multivariate statistical analysis were applied to investigate the plasma metabolic differences. The biomarkers related to blood heat syndrome were screened using the principal component analysis method. A total of 479 metabolites were detected in the three groups of plasma samples; 72 different metabolites were sorted out in the BH-PPG/NPG group, 82 in the NBH-PPG/NPG group, and 8 in the BH-PPG/NBH-PPG group. Differential metabolites mainly consist of metabolites of organic acids, amino acids, carbohydrates, and nucleotides. Multiple metabolites ginkgolic acid, pyrroloquinoline quinone, L-aspartic acid, and citramalic acid were expected to be the potential biomarkers of blood heat syndrome PV. The formation and evolution processes may be associated with disorders and regulation of metabolic pathways, ferroptosis, carbon metabolism, and purine metabolism.

1. Introduction

Psoriasis (Ps) is one of the most common chronic recurrent systemic dermatoses clinically [1], with a mounting incidence every year. The global prevalence rate is 0.51%–11.43% [2], and the recent incidence in China is 0.47% [3]. Because the disease has characteristics such as a long course, high recurrence rate, and low cure rate, it seriously impacts the physical and mental health of patients. Traditional Chinese medicine has unique advantages in the recognition and differentiation of this disease. Based on literature research and expert consensus, the clinical differentiation of psoriasis vulgaris (PV) presents three basic syndromes: blood heat syndrome, blood stasis syndrome, and blood dryness syndrome [4]. Zhao Bingnan was the first to put forward the basic pathogenesis of Ps that "there is long-term accumulated internal heat and stagnation of blood." Blood heat syndrome is the most important syndrome type in the progressive stage. It is not only the beginning of the onset but also essential to the transformation of the disease and syndrome [5]. However, the complexity of its pathogenesis, the internal reality and external deficiency of the syndrome, the multidimensional interface, the nonlinearity, and the formation and evolution of the syndrome need to be further clarified.

As the basic research of traditional Chinese medicine (TCM) syndromes and treatment on clinical metabolomics advances gradually, its advantages of multilevel, multitarget, and overall dynamics and temporal and spatial complexity have provided an effective solution for the investigation of the material basis and biomarker research of TCM syndromes [6]. In recent years, based on the metabolomics technique and bioinformatics methods, certain achievements have been made in research on the basis of Ps TCM syndromes and the efficacy evaluation of prescriptions [7]. However, the techniques of magnetic resonance imaging and nontargeted metabonomics methods, which have been mostly used, provide relatively low sensitivity and quantitative accuracy. Lately, the widely targeted metabolomics integrates the advantages of targeted and nontargeted ones, which is more applicable for the detection of low-to-medium abundant metabolites [8, 9]. Moreover, psoriasis vulgaris of blood-heat syndrome was diagnosed through different symptoms from the non-blood-heat syndrome [10]. It is assumed that differential metabolites are found between psoriasis vulgaris of blood-heat syndrome and non-blood-heat syndrome based on widely targeted metabolomics. The present study applies a widely targeted metabolomics approach and screens out differential metabolites and metabolic pathways in plasma samples of blood heat syndrome PV and intends to explore the material basis and evolution of PV syndrome based on the pathogenesis of blood heat syndrome.

2. Materials and Methods

2.1. Data Collection

2.1.1. Data Source. The 45 Ps volunteers were patients who visited the dermatology department of Chongqing Traditional Chinese Medicine Hospital (Daomenkou Division) from January to June 2019. There were 21 patients in the blood heat syndrome group (BH-PPG), and non-blood heat syndrome groups (NBH-PPG) included 13 for the blood stasis syndrome group (BS-PPG) and 11 for the blood dryness syndrome group (BD-PPG). There were also 30 volunteers in the normal control group (NPG) who were recruited from the physical examination center of this hospital and determined to be healthy during the same period. This project was approved by the Ethics Committee of Chongqing Traditional Chinese Medicine Hospital. All patients and healthy volunteers provided signed informed consent and volunteered to participate in this project.

2.1.2. Diagnostic Criteria. The western medicine diagnostic criteria for psoriasis vulgaris were referred to guidelines as previously published [11, 12]. Diagnosis of TCM syndromes referred to "Clinical Pathways of Traditional Chinese Medicine" diagnosis criteria of TCM clinical pathway syndromes of psoriasis (psoriasis vulgaris) [12]. Western medicine diagnosis and syndrome differentiation of cases were carried out by TCM researchers of attending physicians or above in the Department of Dermatology of this hospital who had been trained and who strictly implemented the previously described diagnostic criteria.

2.1.3. Inclusion Criteria. The inclusion criteria were as follows: ① patients should conform to the diagnostic criteria of western medicine diagnosis of PV and TCM blood heat syndrome, blood stasis syndrome, and blood dryness syndrome diagnosis of PV. ② Patients were of 18–65 years of age. ③ Patients should have no systemic diseases in the circulation, digestion, and endocrine systems, blood, and connective tissue and no other acute or chronic inflammatory or autoimmune dermal diseases except for Ps. ④ During the period from onset to treatment, no systemic or local medications including immunosuppressive agents, glucocorticoid steroid hormones, retinoids, antihistamines, biological agents, and traditional Chinese medicine should be administered, as well as no acceptance of physical therapy; ⑤ Patients should eat a light diet, take rest regularly, avoid bad habits such as smoking or drinking 6 weeks before onset. ⑥ Subjects are those who volunteered for the project and could enjoy the rights and fulfil the obligations as required. ⑦ Patients should have signed the informed consent.

2.1.4. Exclusion Criteria. Subjects with one or more of the previously described inclusion criteria that could not be met were excluded.

2.2. Sample Collection and Treatment. Both patients with PV syndromes and healthy volunteers fasted in the morning before collection of 3 to 5 mL of blood samples, which was carried out using tubes containing an anticoagulant. Immediately after blood collection, the tubes were gently inverted to mix the blood samples evenly 5 to 10 times to ensure the effect of the anticoagulant. The samples, after being collected within 30 min, were centrifuged at 3 000 rpm at 4°C for 10 to 15 min. Subsequently, 100 μL of the supernatant (plasma) was aspirated on ice, transferred to an EP tube, and stored in a refrigerator at −80°C for later use.

2.3. UPLC-MS/MS Analysis Conditions. The liquid phase conditions mainly include ① chromatographic column: Waters ACQUITY UPLC HSS T3 C18 1.8 μm, 2.1 mm $*$ 100 mm; ② mobile phase: phase A used ultrapure water (0.04% acetic acid), and phase B was acetonitrile purchased from Merck (0.04% acetic acid); ③ elution gradient: 0 min water/acetonitrile (95 : 5 V/V), 11.0 min 5 : 95 V/V, 12.0 min 5 : 95 V/V, 12.1 min 95 : 5 V/V, and 14.0 min 95 : 5 V/V; ④ flow rate was at 0.4 ml/min, with a column temperature of 40°C and injection volume of 2 μL. The standard reagent was chromatographically pure grade (China, BioBioPha). The experiment was performed on a shim-pack ultra-performance liquid chromatograph (Japan, SHIMADZU) and a QTRAP® 6500 + tandem mass spectrometer (USA, SCIEX). The mass spectrometry conditions mainly included the following: the temperature of the electrospray ionization source (ESI) is 500°C; the mass spectrum voltage is 5 500 V (positive) and −4 500 V (negative); and the pressure of ion source body I (GS I) is 55 psi, ion source body II (GSII) is 60 psi, and curtain gas (CUR) is 25 psi. The parameter of collision-induced ionization (CAD) was configured is high. Each ion pair of the QTRAP system was scanned based on the optimized declustering potential (DP) and collision energy (CE) [13].

2.4. Data Analysis. The metware database (MWDB), developed by MetWare Biotechnology Co. Ltd., was adopted for qualitative analysis using the retention time of the detected substance, the information of the precursor-product ion pair, and the secondary spectrum data. After obtaining the metabolite spectrum data of different samples, the characteristic ions of each substance were screened out using the QTRAP system. Analyst 1.6.3 and MultiQuant software were also applied to mass spectrometry quantitative analysis. Meanwhile, the construction of a reliable mathematical model adopted multivariate statistical analysis methods. Principal component analysis (PCA) was initially performed on the samples to observe the variability of the differentiated grouping samples. Based on the metabolite content, the range method was used for normalization, and the R software (https://www.r-project.org/) was applied to perform hierarchical cluster analysis (HCA) on the metabolites of different samples. Then, orthogonal partial least squares discriminant analysis (OPLS-DA) was used to distinguish the overall differences in metabolites between groups. Using the obtained multivariate analysis of the variable importance projection (VIP) of the OPLS-DA model, the metabolites of different species or tissues could be initially screened. Meanwhile, the p value or fold change in univariate analysis could be combined to further screen out the metabolites with VIP ≥1, fold change ≥2, or fold change ≤0.5 as significantly different metabolites.

3. Results

3.1. Clinical Baseline Comparison. The general data and disease conditions of the disease group and the normal control group are shown in Table 1. There are no significant differences in gender, age, and BMI between the control group and the disease group. In addition, there are also no significant differences in family history and BMI between BH-PPG and NBH-PPG, whereas significant differences are revealed in gender, age, course of disease, and psoriasis area severity index (PASI) scores.

3.2. Plasma UPLC-MS/MS Inspection Results

3.2.1. Sample Quality Control Analysis. The quality control sample (QC) was prepared by mixing the sample extracts, which was subsequently applied for monitoring the sample repeatability under the same processing method to obtain the trusted Internet connection (TIC) overlay detected by the mass spectrometry (Figure 1). The results indicate that the total ion current curves present a high overlap, detected using the metabolites, and the retention time and peak intensity are consistent, indicating that the signal stability is better when the mass spectrometer detects the same sample at different time points.

3.2.2. PCA and OPLS-DA Results between Groups. Pairwise comparison obtained the three-dimensional PCA structures of BH-PPG v NPG, NBH-PPG v NPG, and BH-PPG v NBH-PPG, and OPLS-DA scores and the S-plot (Figure 2), indicating an apparent trend of separation between groups. The results reveal that there is no crossover and overlap among the groups, with an apparent separation trend, and significant differences in plasma metabolites.

3.2.3. Differential Metabolite Screening Analysis. Based on OPLS-DA results, the metabolites with VIP ≥1, fold change ≥2, or fold change ≤0.5 were selected as significantly differentiated metabolites. Compared with the normal group, BH-PPG has 72 different metabolites, including ginkgolic acid and pyrroloquinoline quinone (Figure 3). They mainly consist of the metabolism of organic acids and their derivatives, followed by the metabolism of amino acids, carbohydrates, nucleotides, and their metabolites. There are 65 overlapped different metabolites with NBH-PPG (Table 2). BH-PPG presents 7 characteristic different metabolites compared with the normal group, including marked upregulation of L-petaminoacetic acid, L-amphetaminoacetic acid, and N-methyl-L-glutamic acid and marked downregulation of acadizine, 2-(methylthio)ethanol, neopterin, benzoic acid, and inositol; There are 17 different metabolites in the NBH-PPG group, including adenosine-3′-phosphate. Comparing the BH-PPG and NBH-PPG groups, four differential metabolites—1-naphthol, cortisol, inosine, and (±) 12-hydroxy-5Z, 8Z, 10E, 14Z-eicosatetraenoic acid—are markedly upregulated, whereas 4 differential metabolites—3,4,5-trimethoxycinnamic acid, 4-pyridoxic acid, mandelic acid, and p-hydroxyphenylacetic acid—are significantly downregulated, as shown in Table 3.

3.2.4. Metabolic Pathway Analysis. The KEGG database [14] was applied to annotate and enrich the selected differential metabolites, which were subsequently classified according to the types of pathways in KEGG (Figures 4 and 5). The results reveal that compared with the normal group, there are 23 entries of metabolic pathways in BH-PPG with differential metabolites ≥4 and 9 entries of metabolic pathways with p value ≤0.05 involve metabolic pathways, ABC transporters, antibiotic biosynthesis, carbon metabolism, ferroptosis, purine metabolism, galactose metabolism, glutathione metabolism, and phosphotransferase system (PTS). Among them, metabolic pathway q-values (corrected p-values), including ferroptosis (Figure 6) and carbon metabolism (Figure 7), are all less than 1, and the enrichment difference is significant.

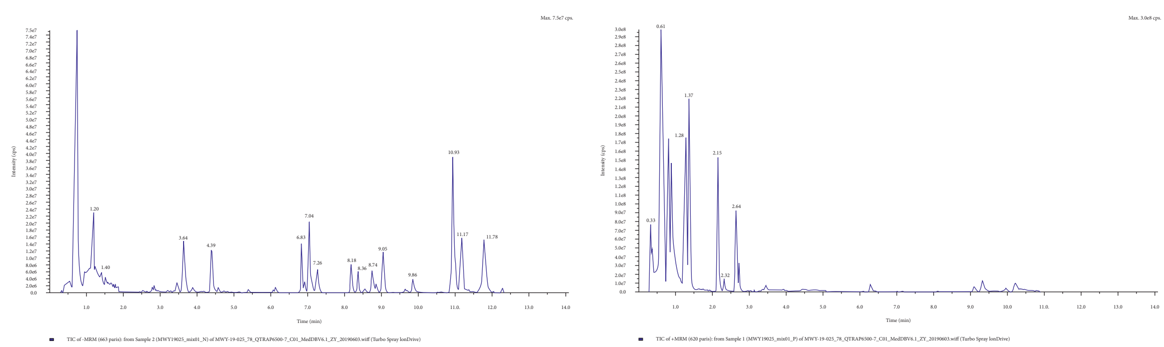
4. Discussion

TCM diagnosis and treatment of psoriasis give priority to symptom differentiation and cause exploration of disease treatment with the corresponding prescriptions and syndromes. Syndrome is the starting point and the core of syndrome differentiation for disease treatment, and it is the bridge and key to the inheritance of principle, prescription, and medication [15]. The recent research on the standardization and material basis of psoriasis syndrome classification is mainly based on macroanalysis such as big data literature research and expert consensus. Despite that, there

Table 1: General data baseline comparison in each group.

Item	Normal control group (30 cases)	Disease group (45 cases)	Blood heat group (21 cases)	Non-blood heat group (24 cases)	Blood stasis group (13 cases)	Blood dryness group (11 cases)
Gender (male/female)	16/14	24/21	14/7**	10/14	4/9	6/5
Age (years)	36.90 [19, 56]	41.51 [18, 65]	35.95 [18, 54]**	46.38 [23, 65]	45.46 [25, 65]	47.45 [23, 65]
BMI index	21.68 [15.68, 25.68]	23.99 [15.57, 32.46]	24.20 [15.57, 32.46]	23.81 [17.96, 28.93]	23.71 [19.52, 28.13]	23.92 [17.96, 28.93]
Family history (yes/no)		18/27	10/11	8/16	3/10	5/6
Course (year)		10.02 [0.3, 30]	7.88 [0.5, 40]*	11.90 [0.5, 40]	11.65 [0.5, 36]	12.18 [4, 40]
PASI scores		13.62 [0.6, 28.8]	15.73 [0.6, 28.8]**	11.78 [1.8, 27.0]	11.41 [1.8, 22.5]	12.21 [2.6, 27.0]

Note. Except for gender and family history, the additional data of each item are represented by the median [minimum, maximum]; $^{*}p < 0.1$ and $^{**}p < 0.05$.



(a) (b)

Figure 1: QC sample TIC overlap detected by mass spectrometry. (a) QC_MS_TIC-N (normal control group) (b) QC_MS_TIC-P (disease group).

is some exploration on the microbiological basis of syndromes, and it is difficult to systematically clarify the formation and evolution mechanism of syndromes under the guidance of reduction theory [16]. Metabonomics starts from the terminal level of the human metabolic network, characterizes the response and regulation of the overall functional state of the body under the influence of pathogenic factors, and reveals essential metabolites closely related to disease and syndrome development. It also explores the formation and evolution of disease and syndrome [17, 18]. Based on a widely targeted metabonomics technique, this study analyzes plasma differential metabolites and screens specific key metabolic biomarkers for the pathogenesis and evolution of PV with blood heat syndrome.

Comparison of general data reveals that the condition is more serious in BH-PPG and the PASI scores are significantly higher than those of the NBH-PPG group. The total course of the disease is slightly short, with more men than women and younger age. These factors indicate that most of the blood-heat syndrome is in a progressive stage, which confirms that blood-heat syndrome is not only the beginning of the onset or recurrence of the disease but also key to the transformation of the disease. Analysis of widely targeted metabolomics shows that there are significant differences in plasma metabolism between BH-PPG, NBH-PPG, and the normal control groups. Comparing the syndrome group with the normal group, 65 overlapped differential metabolites including ginkgolic acid, pyrroloquinoline quinone (PQQ), L-aspartic acid, citramalic acid, and 3-hydroxybutyric acid are identified, and metabolic categories mainly involve organic acids, amino acids, carbohydrates, and nucleotides and its metabolites.

Organic acid is a carboxylic acid in the metabolism of amino acid, lipids, and sugar. It is widely distributed in plants. The human body develops disease due to certain enzyme depletion resulting from the accumulation of related carboxylic acids and their metabolites [19]. In this study, organic acids and their derivatives account for 23.29% of the different metabolite categories. The top 20 organic acids with significant differences include ginkgolic acid, PQQ, argininosuccinic acid, B-hydroxypyruvic acid, methyl isobutyrate, 2-hydroxybutyric acid, and methyl maleic acid. Among them, ginkgolic acid is present mostly in *Ginkgo biloba*. The research on the relationship of ginkgolic acid with diseases is mostly focused on its toxic and side effects such as sensitization, genotoxicity, and hepatorenal cytotoxicity [20, 21]. However, there are few studies on its metabolism in vivo and in vitro, and the apparent increase in plasma ginkgolic acid may be related to some drug oxidative metabolic enzymes. Abnormal expressions of CYP1A1 and CYP2E1, members of the cytochrome P450 (CYP450) family, are closely related to the occurrence and

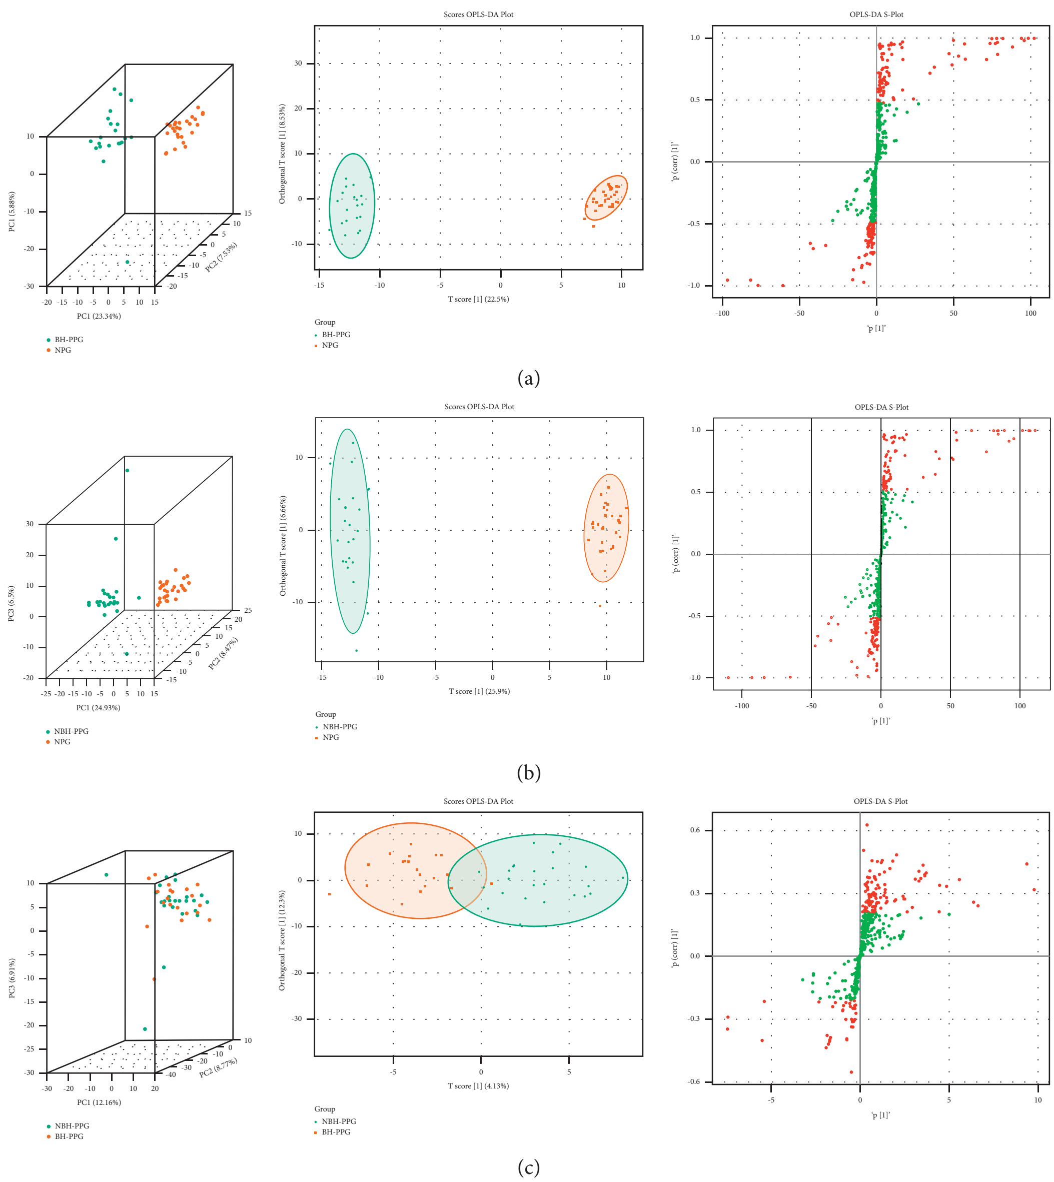


Figure 2: PCA and OPLS-DA plots of plasma samples in each group. *Note.* A1/B1, A2/B2, and A3/B3 represent the PCA three-dimensional structures, OPLS-DA scores, and S-plot of BH-PPG/NBH-PPG and the normal control group, respectively; C1, C2, and C3 represent the PCA three-dimensional structures, OPLS-DA scores, and S-plot of BH-PPG and NBH-PPG groups, respectively.

development of psoriasis [22], which may affect the normal metabolism of ginkgolic acid, thereby leading to a marked elevation in plasma expression levels. PQQ can scavenge intracellular oxygen-free radicals and avoid oxidative damage of tissues and cells, and it can repair mitochondrial dysfunction [23]. The marked increase in plasma PQQ expression may be involved in the inflammatory mechanism of Ps by affecting the function of mitochondria. Argininosuccinic acid ornithine is the intermediate product of circulation. As a precursor of arginine, it can be generated by the condensation of citrulline and aspartic acid under the action of argininosuccinate synthase in the liver and kidney. 3-hydroxybutyric acid is intimately correlated to energy metabolism disorders in organisms and diabetes. It can improve tissue damage, metabolic disorders, and protein metabolism as well as induce tumor cell apoptosis [24, 25]. Meanwhile, the downregulation of expression may be involved in the PV onset. The differential metabolism of some organic acids, namely, ginkgolic acid, selected in this study has not been reported in the previous literature, and its effect mechanism in the pathogenesis of PV or the formation of syndromes needs further exploration.

Second, 13 kinds of amino acids and their derivatives citramalic acid, L-aspartic acid, L-glutamic acid, and glutamate account for 19.18% of the differential metabolite categories. As the main place of amino acid metabolism in the human body, the liver plays an important role in the intake, synthesis, and secretion of amino acids. The level of amino acid metabolism directly reflects the state of liver cell metabolism. Studies have shown that patients with advanced

Note. List of top 10 upregulated and downregulated differential metabolites.

psoriasis have abnormal amino acid metabolism and ratio imbalance [26] and liver and kidney amino acid metabolism disorders, so the abnormal expression of amino acid levels in plasma may be involved in the pathogenesis and progression of Ps [27]. This study reveals that the significant up-regulation of L-aspartic acid, L-glutamic acid, and glutamate is consistent with previous research results. The increased expression of aspartic acid and proline might be involved in the protein biosynthesis of Ps and excessive proliferation of keratinocytes [28, 29]. The expression level of glutamate is positively correlated with the severity of Ps lesions [30]. The expression of citramalic acid is markedly down-regulated. As an important node of the tricarboxylic acid (TCA) cycle, abnormal expression will disrupt the metabolism of the TCA

Note. The upper part of the table presents the significantly differential metabolites of BH-PPG and NBH-PPG compared to the normal control group. The lower part of the table presents the differential metabolites of BH-PPG compared to NBH-PPG.

cycle, thereby affecting the glycolysis process. These metabolic changes enhance the production of mitochondrial reactive oxygen species and the unfolded protein response, which in turn causes an immunoinflammatory response in psoriasis marked by IL-23 and the onset of this disease [31].

In addition, nucleotides, carbohydrates, and their metabolites are in a higher proportion. Nucleotides are mainly involved in a variety of physiological functions, namely, energy metabolism and coenzyme regulation, the metabolism of which consists of three processes—synthesis, decomposition, and regulation. Some research evidence has indicated that abnormal purine nucleotide metabolism can affect the expression of genes and proteins by regulating signal transduction pathways, and a variety of enzymes involved in its metabolism are closely related to tumor cell proliferation, transformation, invasion, metastasis, and drug resistance [32]. Nucleotide metabolites in the BH-PPG group differ greatly from those of the normal group, including 2-hydroxy-6-aminopurine, guanine, guanosine, inosine, and arabinoinosine, suggesting that abnormal purine nucleotide synthesis and catabolism might be involved in Ps progression. Carbohydrates are the main components and major energy supplying substances of living cell structures, which have an important function of regulating cell activities. The metabolic processes contain sugar catabolism and anabolism. The oxidation and decomposition require multiple vitamins and metal ions as coenzymes. It is, therefore, the deficiency of coenzymes that can cause glucose metabolism disorders. Furthermore, the process is also affected by oxygen uptake, metabolic intermediates, hormones, and neurohumour of the body. The expressions of carbohydrate metabolites D-mannose, β-D-glucose, D-sorbitol, and N-acetylglucosamine 1-phosphate are significantly different, suggesting abnormal glucose metabolism in psoriasis with blood-heat syndrome.

Among the nine metabolic pathways with significantly enriched differential metabolites, ferroptosis [33], carbon metabolism [34], and purine metabolism [35] with q value < 1 are closely related to Ps pathogenesis. Among them, the ferroptosis metabolic pathway is mainly enriched with differential metabolites of the amino acid, including L-cystine, L-cysteine, reduced glutathione, glutamate, and L-glutamic acid. The carbon metabolism pathway is mainly enriched with β-D-glucose, L-cysteine, D-xylulose-5-phosphate, leucovorin, B-hydroxypyruvic acid, L-glutamic acid, glutamate, and L-aspartic acid. The purine metabolism pathway is mainly enriched with differential metabolites of the nucleotide, including guanine, hypoxanthine, inosine, guanosine, and adenosine. Metabolic pathway analysis indicated that the formation and evolution of psoriasis with blood-heat syndrome may involve a series of complex metabolic disorders and adjustment processes, namely, liver and kidney amino acid metabolism, energy metabolism, and coenzyme regulation related to nucleotides.

In conclusion, this study analyzes plasma metabonomics of PV with blood heat syndrome and screens multiple differential metabolites of ginkgolic acid, PQQ, L-aspartic acid, and citramalic acid. These metabolites are considered to be potential biomarkers of blood-heat syndrome PV. Specific disease and syndrome metabolic pathways contain carbon metabolism, ferroptosis, and purine metabolism. The exploration of these differential

metabolites and metabolic pathways can provide indicators for diagnosis and treatment of Ps-based blood-heat pathogenesis. Meanwhile, it also offers a new objective basis for revealing the material basis of the occurrence, development, and outcome of the pathogenesis of blood heat disease. Some potential markers for psoriasis have been identified at the genome, transcriptome, proteome, and metabolome level in previous research. This study not only explores the potential metabolic markers of PV based on the widely targeted metabolomic technique but also investigates the metabolic markers and metabolic pathways of two PV syndromes (blood heat syndrome and non-blood-heat syndrome) identified by TCM. Unfortunately, this study still has several limitations. The uncertainty of the dynamic changes during the metabolic process and the characteristics of multifactor interference of metabolites are the causes of difficulty in the reproducibility of metabolic data for subsequent research teams. Several differential metabolites have not been reported in the previous literature, and their effect mechanism in the pathogenesis or syndrome formation of psoriasis has not been further studied. In addition, despite that metabolic pathways and network analysis present some essential biological information, the clinical applicability of relevant evidence remains to be further explored. In subsequent projects, multisample, multilevel, and in-depth research can be performed using serum, urine, feces, saliva, and injured skin tissues to more comprehensively and accurately explore the mechanism of formation and evolution of the pathogenesis of blood heat PV.

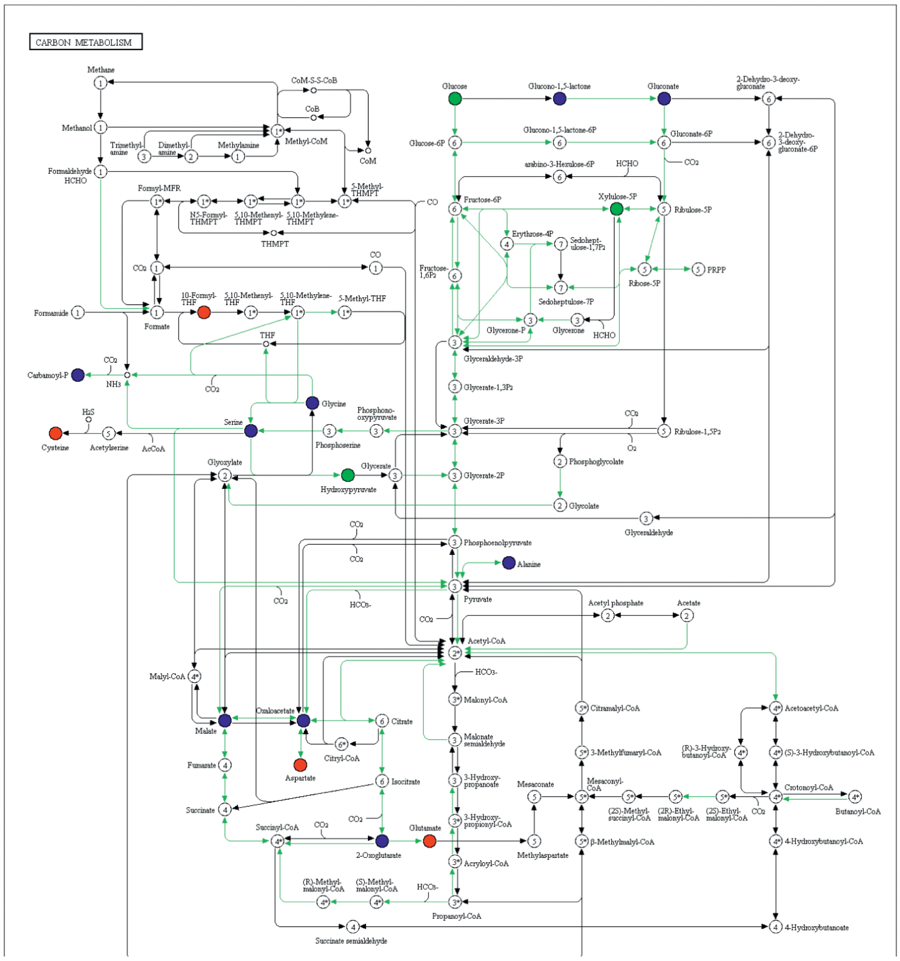

FIGURE 7: Carbon metabolic pathway. *Note.* Red indicated markedly up-regulated content of metabolites in the experimental group. Blue indicated no marked change of the metabolite which had been detected. Green indicated markedly down-regulated content of metabolites in the experimental group. Cause for the phenotypic differences among the research subjects was identified through metabolic pathways.

5. Conclusions

Here, we analyzed plasma metabonomics of PV with blood heat syndrome and found multiple differential metabolites of ginkgolic acid, PQQ, L-aspartic acid, and citramalic acid, which are considered to be potential biomarkers of blood-heat syndrome PV. It is helpful for western medicine to explore the identification of PV syndrome and the mechanism of disease progress, promote the development of western medicine in the identification of PV blood heat syndrome, and facilitate the progress of the PV diagnosis and treatment method.

Coriolus versicolor is a natural drugs which has many pharmacological effects such as antitumor and enhanced immune activity. This paper studies the therapeutic effect of *Coriolus versicolor* fruiting body (CVFB) on streptozotocin (STZ)-induced Institute of Cancer Research (ICR) diabetic mice, the STZ solution was administered intraperitoneally at a dose of 150 mg/kg after fasting the mice, and ICR mice with fasting blood glucose >16.7 mmol/l were selected for research. Metformin was the positive control, and the dose of CVFB powder (1000 mg/kg, 2000 mg/kg, and 4000 mg/kg) for 28 consecutive days by gavage. The serum and liver of mice were collected for relevant index content testing. The results showed that CVFB can control or reduce the fasting blood glucose of mice and accelerate the rate of glucose metabolism, can reduce the levels of total cholesterol (T-CHO), triglyceride (TG), and high-density lipoprotein cholesterol (HDL-C) in mice, and regulate the abnormal symptoms of blood lipid metabolism commonly found in diabetes. It can increase the activity of superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) antioxidant enzymes and enhance the ability of antioxidative stress in diabetic mice. In the H&E staining and apoptosis experiments of pancreatic tissue, CVFB can greatly reduce the inflammatory factors present in islets, increase the islet cells, and reduce the apoptotic rate caused by diabetes. All data confirmed the therapeutic effect of CVFB on diabetic ICR mice. The present study provides a scientific basis for the development of drugs for the prevention and treatment of diabetes, it is of great significance to the in-depth study of *Coriolus versicolor*.

1. Introduction

According to the 9th edition of the Diabetes Map released by the International Diabetes Federation (IDF), diabetes is one of the most common chronic diseases in the world, and the number of adult patients with diabetes of the world is increasing year by year, while the number of adult patients with diabetes in China ranks first in the world, according to the noncommunicable disease.

Current research has not yet found a cure for diabetes drugs or treatment, controlling and treating diabetes are a long-term, ongoing, and slow-moving task, while most diabetes drugs have toxic side effects while treating the symptoms of hyperglycemia, long-term consumption of antidiabetic drugs will aggravate the burden on the liver and kidney, leading to a series of complications. Natural medicine is a kind of natural product with some pharmacological activities, including plants, animals, and minerals, and are easy to be absorbed and utilized by the human body and have stable effects and little toxic side effects on the body. The study found that many natural products have good hypoglycemic components, such as polysaccharides, polyphenols, flavonoids, alkaloids, and other compounds [1]. Therefore, in the prevention and treatment of diabetes, the full use of natural drug adjuvant therapy can improve the efficacy and reduce side effects.

Coriolus versicolor is a natural drug which has many pharmacological effects such as antitumor, ant-atherosclerosis, antiaging, antioxidation, and enhanced immune activity [2–9]. At present, the research on *Coriolus versicolor* is mainly focused on macromolecular compounds such as polysaccharide, glycopeptide, and glycoprotein, but *Coriolus versicolor*'s chemical composition is very complex.

Therefore, this article studies the therapeutic effect of the CVFB on ICR diabetic mice which is caused by streptozotocin (STZ); after the treatment, glucose metabolism, lipid metabolism, and antioxidant indexes of the experimental mice were detected, as well as further pathological analysis of the pancreas. This provides a scientific basis for the development of drugs for the prevention and treatment of diabetes and is of great significance for the in-depth study of CVFB.

2. Materials and Methods

2.1. CVFB Powder and Metformin Hydrochloride Preparation. *Coriolus versicolor* fruiting body powder: origin is Heilongjiang, purchased from Johncan International, Hangzhou, China.

Metformin hydrochloride tablets: Sino-American Shanghai Squibb Pharmaceuticals Ltd.

2.2. Development of Diabetic Mouse Models. A total of 120 four-week-old male ICR mouses ((SPF) grade, SCXK (YUE)-2013-0002) were adaptability to fed about 2 weeks. After 18 h fast (free access to water), mice of $22 + 2$ g were subjected to 150 mg/kg STZ solution intraperitoneally (except the NS group); the control group was injected with citric acid buffer; 2 h after administration, the mice were fed. After 7 days of feeding, fasting without water was done to measure fasting blood glucose. The fasting blood glucose value of mice ≥16.7 mmol/L was determined to be a successful model.

2.3. Drug Treatment Procedure. Diabetic mice were randomly divided into five groups with more than 12 mice in each group (to avoid death in the experiment). Normal mice served as the control group. The duration of drug administration was 28 days. Normal control group (normal saline, NS) and model group (diabetic control, DC) were given sterile normal saline gavage, and positive control group (positive control, PC) was given 200 mg/kg metformin hydrochloride by gavage; the drug group was intragastrically administrated with the CVFB at concentrations of 1000 mg/kg (low dose, LD), 2000 mg/kg (medium dose, MD), and 4000 mg/kg (high dose, HD). Routine diet was fed after administration. Water intake, food intake, weight, and fasting blood glucose were recorded regularly.

2.4. Oral Glucose Tolerance Test (OGTT). Oral glucose tolerance test (OGTT) is a glucose stress test used to determine whether an organism has diabetes to understand the function of pancreatic beta cells in vivo and the body's ability to regulate blood sugar. During the OGTT test, fasting without water for 6 h in the evening of the 26th day of the treatment period and fasting blood glucose values of diabetic mice in each group were measured in the morning of the 27th day. Each group was given 2 g/kg glucose by gavage at one time. Tail venous blood was taken, and blood glucose values of 30 min, 60 min, 90 min, and 120 min after glucose administration were measured by a blood glucose meter and recorded.

2.5. Sample Collection. At the end of the treatment period, the mice were weighed, and then mice were euthanized by ether, the blood was collected by eyeball extirpation, and the organs (liver, kidney, spleen, thymus, pancreas and heart) of the mice were collected and weighing. The pancreas was washed with cold saline and fixed with Carnoy's fluid for tissue sectioning. A small part of liver was washed with cold normal saline, and an appropriate amount of liver fragments were homogenized in cold 0.9% normal saline (liver (g):0.9% normal saline (mL) = 1 : 9). The homogenized mixture was centrifuged at 3000 RPM at 4°C for 10 min, and the supernatant was collected to obtain 10% liver homogenate. The samples were stored at −20°C.

2.6. Serum and Liver Homogenate Sample Index Detection. The contents of glycated serum protein (GSP), insulin (Ins), T-CHO, TG, HDL-C, low-density lipoprotein cholesterol (LDL-C), and blood urea nitrogen (BUN) in the serum and the contents of malondialdehyde (MDA), SOD, and GSH-Px in the serum and liver homogenate were detected by Nanjing Jiechen Kits (Nanjing Jiancheng Institute of Biological Engineering, Nanjing, China).

2.7. Pancreatic Histopathological Tests. Pancreatic tissue was fixed in Carnoy's fluid for 24 h, and the tissue was removed for dehydration, embedding, and sectioning. After the tissue sectioning was completed, some sections were stained with hematoxylin and eosin by H&E to observe the shape of pancreatic cells; the other sections were added with proteinase K and reacted with TUNEL kit (Roche) to observe the apoptosis of pancreatic cells.

2.8. Statistical Analysis. All data are expressed as mean ± standard error (S.EM.). SPSS 20.0 software was used for statistical analysis of the data. A one-way analysis of variance (ANOVA) and multiple comparisons were combined to calculate the significance of the data. In statistics, when $p > 0.05$, it is considered no significant difference, when $p < 0.05$, it is considered significant difference, when $p < 0.01$, it is considered very significant difference, and when $p < 0.001$, it is considered extremely significant difference.

3. Results

3.1. The Effects of the CVFB on Water Intake, Food Intake, Body Weight, and Organ Index of Diabetic Mice. During the treatment period, the water and food intake in the DC group increased significantly compared with the NS group. The body weight of mice in NS group was significantly different from that in 0 days of treatment ($p < 0.001$; Table 1, No. c) and increasing rate on day 28 of the treatment period was 58.0%, while there was no significant difference in the body weight of mice in DC group.

After 28 days of treatment, the water intake in 5 groups of diabetic mice increased significantly compared with 0 days of treatment ($p < 0.001$; Table 1, No. a). The body

$^{*}p < 0.05$, $^{**}p < 0.01$, and$^{***}p < 0.001$ are the comparisons between within the group and day 0; $\#p < 0.05$, $\#\#p < 0.01$, and $\#\#\#p < 0.001$ versus DC group. Growth rate: body weights increment (day 28–day 0)/body weight (day 0)×100%.

weight of mice in the PC group and CVFB treatment group increased significantly compared with 0 days of treatment ($p < 0.01$; Table 1, No. c); compared with the DC group of mice, CVFB dosage group weight increased significantly after 28 days (29.3 ± 0.8; 29.7 ± 0.9, and 30.5 ± 1.4) having significant difference, in which the weight gain was similar to that of the positive control group (29.8 ± 0.9).

Compared with the NS group, the weight of the kidney index was significantly increased ($p < 0.001$; Table 1, No. d), the weight of the spleen, thymus, and heart index was significantly decreased ($p < 0.001$; Table 1, No. d), and the weight of the pancreas index was also decreased in the DC group.

After 28 days of administration of CVFB, it was found that CVFB could inhibit the trend of changing the direction of the organs in the DC group, and the indexes of related organs returned to normal level.

3.2. The Effects of the CVFB on Glucose Metabolism in Diabetic Mice. After 28 days of treatment, the fasting blood glucose concentration of diabetic mice treated with the CVFB decreased to the concentration of 0 days of treatment ($p > 0.05$; Table 2), and the fasting blood glucose concentration of the PC group was significantly different from that at 0 days of treatment ($p < 0.05$; Table 2).

Mice were given 2.0 g/kg glucose solution by gavage for OGTT test. After gavage, the blood glucose of each group increased significantly. After 30 minutes, the blood glucose value of each group showed a different trend to decrease; at 60 minutes, there was a significant difference in blood glucose between the PC group and the DC group ($p < 0.05$; Figure 1), and it was observed that the PC group had a greater tendency to decrease blood sugar than the DC group; at 90 min, the blood glucose levels of the HD group and the PC group were significantly different from those of the DC group ($p < 0.05$, $p < 0.01$; Figure 1).

After 28 days of administration, the CVFB groups and the PC group all decreased the levels of GSP to a certain extent ($p > 0.05$; Figure 2(a)) and had a certain degree of decline in INS content levels and MD and HD groups and PC groups had significant differences in the decline of INS content levels ($P < 0.05$; Figure 2(b)). HOMA-IR was decreased in the HD and PC groups ($P < 0.05$; Figure 2(c)).

3.3. The Effects of the CVFB on Lipid Metabolism in Diabetic Mice. After treatment, the concentrations of T-CHO ($p < 0.05$; Figure 3(a)), TG, and BUN ($p < 0.01$; Figures 3(b) and 3(e)) in diabetic mice were decreased, and the content of HDL-C was significantly increased ($p < 0.05$; Figure 3(c)), indicating that CVFB groups had a certain regulatory effect on lipid metabolism in diabetic mice.

3.4. The Effects of the CVFB on Antioxidant in Diabetic Mice. The serum and liver homogenate of mice were tested. In the serum test, it can be seen that the SOD activities of the MD and HD groups and PC group are all increased ($p < 0.001$; Figure 4(a)). The content of MDA in the LD, MD, and HD groups and the PC group decreased ($p < 0.05$, $p < 0.01$, $p < 0.001$, $p < 0.001$; Figure 4(b)); GSH-Px activity increased in the LD, MD, and HD groups and the PC group ($P < 0.05$, $p < 0.05$, $p < 0.01$, $p < 0.01$; Figure 4(c)).

In liver homogenate, SOD activity increased in the MD and HD groups and PC group ($p < 0.01$, $p < 0.001$, $p < 0.001$; Figure 4(a)). The content of MDA was decreased in the LD, MD, and HD of the CVFB group and the PC group ($p < 0.01$, $p < 0.001$, $p < 0.001$, $p < 0.001$; Figure 4(b)). The GSH-Px activity increased in the LD, MD, and HD groups and the PC group ($p < 0.01$, $p < 0.01$, $p < 0.001$, $p < 0.001$; Figure 4(c)).

The CVFB group and the PC group had certain antioxidant effects on diabetic ICR mice, and the positive drug metformin had better antioxidant properties than the CVFB groups, but there was no significant difference between them.

3.5. The Effects of the CVFB on Histopathology in Diabetic Mice

3.5.1. H&E Staining Results of Pancreatic Tissue Sections. It can be seen from Figure 5 that the number of pancreatic islet cells in the LD group is greatly reduced, and the interior and surrounding of the pancreatic islets are infiltrated by a large number of inflammatory cells, but the borders of the pancreatic islets can still be distinguished.

The pancreatic islets of the mice in the MD group were slightly atrophy, and there were inflammatory cells around the pancreatic islets. Compared with the negative control group, the inflammatory cells were greatly reduced. The structure of pancreatic islets in the HD group is relatively complete, with obvious borders, compared with the DC group, the islet cells are significantly increased, and the inflammatory cells are greatly reduced. However, there are still more inflammatory cells on the side of the islets.

With the concentration of CVFB increased, the number of inflammatory cells gradually decreased.

3.5.2. TUNEL Method to Determine the Results of Cell Apoptosis in Pancreatic Tissue. In the NS group (Figure 6), Normal cells are evenly distributed in mouse pancreatic islets; when there is inflammation, inflammatory cells are produced and pile up together; in the DC group (Figure 6), many inflammatory cell nuclei are distributed inside and outside the pancreatic islets. The *h* diagram shows that diabetes caused by STZ can cause cell apoptosis, and the apoptosis rate is significantly increased.

In the CVFB high-dose group (Figure 6), the inflammatory cells around the pancreatic islets of the mouse were significantly reduced, and the cells in the pancreatic islets were more evenly distributed. The apoptosis rate was significantly reduced (Figure 6).

Table 2: The effect of 28-day CVFB treatment on the fasting blood glucose of STZ-induced ICR diabetic mice ($n = 11$).

28 days	0	7	14	21	28
NS	6.3 ± 0.2	$8.5 \pm 0.3^{**}$	$7.9 \pm 0.5^{*}$	$8.4 \pm 0.5^{**}$	6.2 ± 0.4

4. Discussion

In this experiment, we used the STZ one-time high-dose injection method to build a diabetic ICR mouse model to explore the therapeutic effect of CVFB. Glucose metabolism, lipid metabolism, and antioxidant effects of diabetic ICR mice and the impact on mouse pancreas organs were analyzed by the daily living conditions.

Diabetes is a disease characterized by a relative or absolute lack of insulin, leading to hyperglycemia. Injecting large doses of STZ damages pancreatic β-cells, causing β-cell dysfunction and reducing insulin secretion, and inducing mice to become nonobese diabetic [10]. From the measurement results, we can see that CVFB can effectively control or reduce the fasting blood glucose of diabetic mice to a certain extent and reduce the levels of GSP and INS in the fasting serum. However, the sensitivity of related organs and tissues in diabetic mice to insulin is reduced, and insulin resistance promotes glucose uptake, which causes a variety of biochemical reactions in the body. Therefore, high levels of fasting plasma insulin can reflect insulin resistance [11]. The experimental results show that the HOMA-IR evaluation is reduced, indicating that CVFB can significantly improve insulin resistance and protect pancreatic β cells. At the same time, the OGTT test results show that CVFB can accelerate the decomposition and utilization of blood sugar and finally accelerate the glucose metabolism in diabetic mice.

Diabetes is one of the most common metabolic diseases, in which abnormal lipid metabolism is often an important factor in determining the direction and status of the disease [12]. The experimental results found that CVFB can reduce the content level of T-CHO, TG, BUN, and LDL-C, increase the content level of HDL-C, accelerate the metabolism of blood lipids in diabetic mice, and regulate the disorder of lipid metabolism in the body to reduce the incidence of hyperlipidemia and also reduce the risk of coronary heart disease, atherosclerosis, and diabetes complications.

Many researchers have proved that the oxidative damage associated with diabetes is caused by the production of reactive oxygen species. Therefore, increasing the activity of antioxidant enzymes can increase the body's antioxidant defense system's response to oxidative stress [13]. The experimental results found that CVFB can effectively increase the activity of antioxidant enzymes SOD and GSH-Px in the serum and liver homogenate of diabetic mice and reduce the level of MDA. MDA is the main product of lipid peroxides, which proves that diabetes is related to oxidative stress. The pancreas is an internal organ that produces insulin and glucagon, which regulates the body's blood sugar stability. Observing the H&E staining results and the apoptosis experiment of the pancreas tissue of diabetic mice, it can be seen that compared with the NS group, the CVFB group can reduce the inflammatory factors in the pancreatic islets in the pancreas of diabetic ICR mice and improve the damaged islet structure and increase the islet cells and the apoptosis rate was significantly reduced, indicating that CVFB has a protective effect on the pancreas of diabetic ICR mice.

In this experiment, we studied the therapeutic effect of CVFB on STZ-induced ICR diabetic mice and found that diabetic mice administered with CVFB can control or reduce the blood sugar level of diabetic mice, accelerate the rate of glucose metabolism, regulate the lipid metabolism disorder and abnormal blood lipid metabolism in the body, enhance the antioxidant capacity in mice, reduce oxidative stress damage, protect the pancreas organs, and repair and adjust the function of the pancreas to regulate blood sugar balance. In this experiment, we studied the therapeutic effect of CVFB on STZ-induced ICR diabetic mice and found that diabetic mice administered with CVFB can control or reduce the blood glucose level of diabetic mice and accelerate the rate of glucose metabolism, regulate the lipid metabolism disorder and abnormal blood lipid metabolism in the body, enhance the antioxidant capacity in mice, reduce oxidative stress damage, protect the pancreas organs, and repair and regulate the function of the pancreas to regulate blood sugar balance.

The above aspects show that CVFB has a therapeutic effect on diabetic mice, provides a scientific basis for the development of drugs for the prevention and treatment of diabetes, and is of great significance to the in-depth research of *Coriolus versicolor*.

Purpose. Quantitative scintigraphy to evaluate salivary gland function changes in patients with differentiated thyroid cancer (DTC) after iodine-131 (^{131}I) treatment. *Methods*. A total of 458 patients with DTC grouped by sex and age were included. Salivary gland scintigraphy was performed to evaluate salivary gland function before and after ^{131}I treatment. The uptake fraction (UF), uptake index (UI), and excretion fraction (EF) of two pairs of parotid glands and submandibular glands were measured and compared. The Chi-square test was conducted according to function impairment count. *Results*. Salivary gland function in different age groups and sexes were quite different, especially for women <55 years old, who had decreased UF, UI, and EF of all four glands without basal injury. The secretion or uptake function of some salivary glands with basic function impairment before ^{131}I treatment was increased after iodine treatment. Only a small percentage of males showed reduced functional parameters after several treatments. The most significant difference in the count of impairment for the four salivary glands were the first and third examinations, which was more evident in women. The submandibular gland had the most significant reduction in uptake. *Conclusion*. Changes in salivary gland function are more common in young females being treated for DTC. Impairment of salivary gland function is correlated with the number of treatments and the cumulative dose of ^{131}I. Some salivary gland functions impaired before ^{131}I treatment were enhanced in the early treatment.

1. Introduction

Differentiated thyroid cancer (DTC) is a common endocrine malignancy. According to statistics, 900,590 people were diagnosed with thyroid cancer in the United States. 52,070 people are expected to be diagnosed with thyroid cancer in 2019 [1]. Surgical treatment of thyroid cancer followed by removal of residual thyroid using iodine-131 (^{131}I) is a common treatment approach, but ^{131}I can induce salivary gland damage [2–4]. ^{131}I is absorbed on the membranes of thyroid follicular cells and cancer cells through the reactive sodium iodide transporter (NIS) [5]. Salivary glands expressing NIS can also absorb ^{131}I, and the accumulation of salivary gland ^{131}I is about 30 to 40 times that of plasma levels [6]. The radiation dose of high-concentration ^{131}I is sufficient to cause salivary gland damage and affect their function [7].

Salivary gland dysfunction is mainly reflected in decreased saliva secretion. Saliva is essential for the preservation of oral health. Saliva's functions include buffering, lubricating, mineralizing, and cleaning oral tissues [8]. Saliva also has antibacterial, antiviral, and antifungal properties [9]. Changes in the quantity or quality of saliva can affect the integrity of the oral tissues leading to the appearance of conditions like dental caries, periodontal diseases, and various other oral and pharyngeal disorders [10, 11]. In addition, salivary gland dysfunction is characterized by difficulty swallowing, dental disease, and loss of taste. DTC patients who had one or more ^{131}I treatments may experience the above discomfort [12–14]. Their quality of life was affected. Therefore, determining and protecting salivary gland function in DTC patients should not be ignored. There are many examinations to assess salivary gland function, including salivary gland scintigraphy with ^{99m}Tc-pertechnetate [3, 4, 15], neck ultrasonography [16], salivary flow rate measurement of the whole or individual gland [17]. ^{99m}Tc-pertechnetate is commonly used in hospitals. Because it can quantify the uptake or secretory from individual salivary glands and calculate their function [18–20].

Through salivary gland scintigraphy, we found that some patients had impaired salivary gland function before ^{131}I treatment. We defined it as an impairment of the basic function of the salivary glands. The Impairment of basic function could be associated with different factors, including Sjögren syndrome [21, 22], salivary gland obstructive disease [23], salivary gland infection [24], obesity and diabetes [25, 26], aging [27, 28] and so on. The changes in the salivary gland's function in these patients after ^{131}I treatment are worth discussing.

This study aimed to analyze the changes in salivary gland uptake and excretion function following ^{131}I treatment. And to study the relationships between the function change and different genders, age groups. The results provide clinical guidance for the protection of salivary function in DTC patients undergoing ^{131}I treatment.

2. Materials and Methods

2.1. Patients. A retrospective analysis of the hospital files from the Department of Nuclear Medicine of Tianjin Medical University General Hospital was in this study. The salivary gland scintigraphy parameters and inpatient treatment database of DTC patients from the hospital were used. We reviewed information for DTC patients who received ^{131}I therapy from November 2014 to December 2018. All enrolled patients had two or more pre-hospital scintigraphy of salivary glands. A total of 458 patients with DTC grouped by sex and age were included. Patients with the above information missing were excluded. Total thyroidectomy was performed for all patients by thyroid surgeons, and DTC was diagnosed by postoperative pathology. According to the ATA Guidelines, we selected N1b or M1 DTC patients [2]. All patients received ^{131}I treatment 6 weeks postoperatively. Before treatment with ^{131}I, patients were advised to have a low-iodine diet for 3 weeks. After the first radioiodine treatment, patients in the study received one or more radioiodine treatments. Salivary gland function parameters were recorded by 370 MBq (10 mCi) ^{99m}Tc-Pertechnetate salivary gland scintillation before ^{131}I treatment. The interval between each treatment was ~6 months. The protocol for evaluating salivary gland scintigraphy is shown in Figure 1. Patients with residual thyroid tissue were given 2.96 to 5.55 GBq (30–150 mCi) dosages for each treatment [2, 29].

2.2. Salivary Gland Imaging Protocol. According to our previous reports, pre-ablation salivary gland imaging was performed under thyroid-stimulating hormone (TSH) stimulation in the morning, 4 h before the first ^{131}I intake [3, 4]. Patients were asked to fast before salivary gland imaging. Single-photon emission computed tomography was performed on a Discovery NM/CT 670 (General Electric Medical Systems, Chicago, IL, USA) while subjects laid on their back. A low-energy, parallel hole, high-resolution collimator was used with a peak value of 140 keV and a window width of 20%. Each patient received 370 MBq ^{99m}Tc-pertechnetate intravenously through the cubital vein. After injection, the dynamic images were continuously shot on a 256×256 matrix at minute/frame with zoom 1.5 for 15 minutes. The patients were given 0.2 g oral vitamin C at the 8th minute after injection; they were instructed to chew quickly and then keep the tablet under the tongue for about 1 minute. To accurately calculate the delivered radioactivity dose, we measured the radioactivity count in the syringe before and after the injection. Patients underwent a radionuclide scan as described above before every ^{131}I treatment. Salivary gland imaging was also performed under TSH stimulation.

2.3. Image Analysis. First, circular regions of interest (ROIs) were manually drawn on the parotid and submandibular glands. Parotid glands showed a similar unified background area in the bilateral temporal-orbital region, while submandibular glands appeared as a similar unified background area in the bilateral supraclavicular region. The sizes and positions of these ROIs remained the same for each scanning session. An imaging system was used to generate time-activity curves for ^{99m}Tc-pertechnetate uptake and excretion in counts per minute. Based on these ROIs counts and the

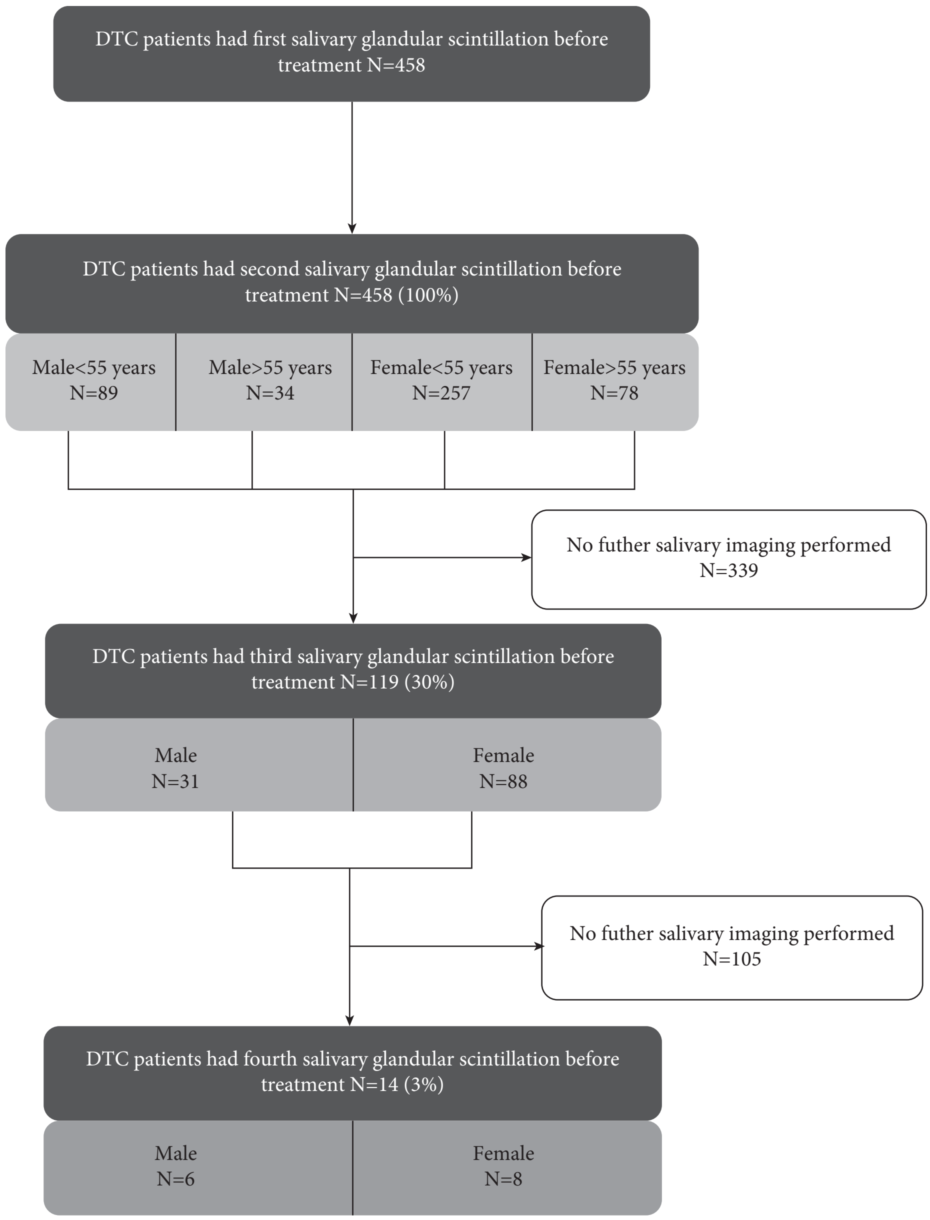

Figure 1: Case follow-up process. Salivary glandular scintillation imaging data were collected from DTC patients before the first, second, third, and fourth ^{131}I treatments. The group was compared according to the number of patients in each treatment course.

subsequent time-activity curves, the salivary gland functional indicators were derived using the following modified formulas [3, 4, 30, 31] (Figure 2):

2.3.1. Uptake Fraction (UF). UF = (salivary gland maximum count minute–salivary gland background count corresponding to maximum count minute)/(count in the syringe before injection–count in the syringe after injection)

2.3.2. Uptake Index (UI). UI = (salivary gland maximum uptake count minute–salivary gland background count corresponding to maximum uptake count minute)/salivary gland background count corresponding to maximum uptake count minute

2.3.3. Excretion Fraction (EF). EF = (salivary gland maximum uptake count minute–salivary gland minimum uptake count minute after vitamin C)/salivary gland background count corresponding to maximum uptake count minute

UI and UF reflect the uptake function of salivary glands, while EF reflects the secretion function.

2.4. Diagnostic Criteria for Salivary Gland Function. Salivary gland function impairment was established based on the diagnostic criteria of the Department of Nuclear Medicine, Tianjin Medical University General Hospital, with reference to previous studies and modified in our institute [18, 19, 32, 33]. Parameters obtained by salivary scintigraphy, the peak uptake (maximum salivary gland uptake count/second count at peak uptake) was set to <50 counts/s

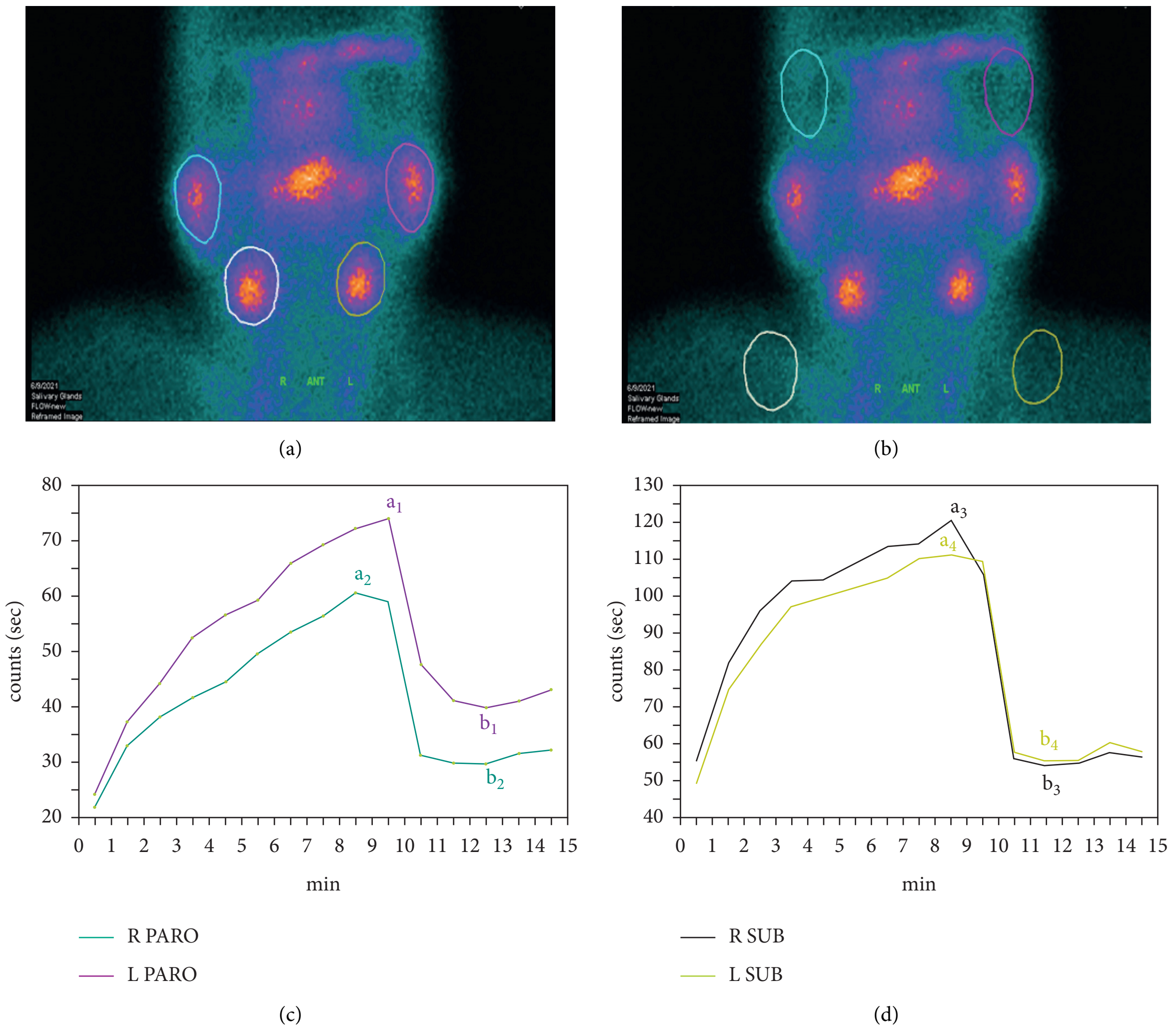

Figure 2: Physiological uptake and excretion of ^{99m}Tc-pertechnetate in parotid and submandibular salivary glands detected by dynamic salivary gland scintigraphy. (a) A clear depiction of the ROIs and ROIs of the salivary and mandibular glands was obtained from all frames. (b) The parotid gland was in the bilateral temporal-orbital region, and the mandibular gland was in the bilateral supraclavicular region to draw similar background areas, and the background ROIs count was recorded. (c-d) Time-activity curve of each salivary gland. The ordinate of a_1-a_4 corresponds to the maximum minute count of each salivary gland. The ordinate of b1- b4 corresponds to the count of each salivary gland at the minimum uptake minute after vitamin C.

with reduced intake function, and EF was set to <30% with reduced secretory function. A reduced diagnosis of either or both of these above salivary glands is dysfunction. The patients with salivary gland dysfunction before the first admission were those with impaired basic salivary gland function.

2.5. Statistical Analysis. All data for males and females were analyzed separately and are presented as either mean ± standard deviation or median (upper quartile, lower quartiles). Statistical analysis was performed by using Statistical Package for Social Sciences (SPSS version 25.0, IBM Corp., Armonk, NY, USA) software. Mann-Whitney U tests were used to compare values of the same patient before and after the first treatment. Kruskal-Wallis tests were performed to evaluate and compare salivary gland function in patients who underwent multiple ^{131}I treatments. After dividing men and women into separate groups, the distribution of salivary gland injuries before the first treatment and before the second to fourth treatments were analyzed by chi-square test.

3. Results

Among the 458 patients, most (72.9%) were female with a mean age of 46 ± 12 years (range 14–76 years). The lowest and highest doses of ^{131}I were 30 and 550 mCi, respectively. Patient demographic data are summarized in Table 1.

From the scintigraphy examinations, the analysis according to age and sex groups evidenced salivary gland function is more sensitive in females than in males. The sensitivity of salivary gland function was ranked from large to small, in order of <55 years female, ≥55 years female, <55 years male, ≥55 years male ($p = 0.05$). After treatment with

Table 1: Clinical characteristics of total patients.

Characteristic	Total	Male	Female	P
Age (years)	46 ± 12/14–76	46 ± 12/22–75	45 ± 12/14–76	0.442
Number/percentage		124/27%	334/73%	
^{131}I activity (mCi)	128 ± 78/30–550	131 ± 68/30–450	126 ± 80/30–550	0.145

Age and ^{131}I activity are stated as median ± standard deviation/range.

^{131}I, the UI, UF, or EF values of patients without impairment of basic salivary gland function tended to decrease. The secretion or uptake function of some salivary glands with basic function impairment before ^{131}I treatment was increased after iodine treatment. Table S1 summarizes the number of patients, age distribution, and cumulative dose before one or more ^{131}I treatments. The UI, UF, and EF of each group were compared before and after ^{131}I treatment (Tables 2–4).

We found that the difference between the first and third injury counts of salivary gland damage on salivary gland scintigraphy tests before hospitalization was the most significant. There were statistically significant differences between the four salivary glands in both the male and female groups. It was more pronounced in the female group (female, $P = 0.001$; male, $P < 0.05$). The percentage of damaged salivary glands increased with the number of treatments in both sexes, while the percentage of normal salivary glands gradually decreased (Table 5, Figure 1S). The cumulative dose of ^{131}I received by patients over several treatments is shown in Figure 2S. Chi-square test was performed to determine the relationship between the number of patients by sex and the impairment of salivary gland function before each ^{131}I treatment (Table S2). There was a statistical difference in the left submandibular gland injury count between sexes before the first treatment ($p < 0.05$).

4. Discussion

Salivary gland damage is a common manifestation of DTC patients after ^{131}I therapy [34]. ^{131}I is mainly concentrated in the duct system of the salivary glands. The radiation causes debris buildup that narrows the lumen, and this obstruction can lead to an injurious process that results in glandular degeneration. Salivary gland scintigraphy examination is necessary for the objective evaluation of the reproducibility of salivary gland function [20]. These measurement parameters mainly assess gland uptake and secretion capacity [15, 35, 36]. We performed salivary gland scintigraphy to identify relevant salivary gland parameters and then analyzed the factors that affect salivary gland function changes in DTC patients after each ^{131}I treatment.

4.1. Sex and Age. By comparing salivary glands without basic functional impairment, we found that functional changes were related to age and sex. The salivary glands of younger patients were more sensitive to ^{131}I treatment than older patients, and female patients were more likely to show decreased function. Other studies have examined age- and sex-dependent differences in salivary gland function changes. Liu et al. assessed iodine dynamics and salivary gland dosimetry after ^{131}I treatment and showed that women's parotid iodine intake was often higher than men's [37]. This suggests that female salivary glands are more susceptible to radiation, leading to decreased function following ^{131}I treatment. Almeida et al. found that patient sex was associated with the uptake phase on salivary glands scintigraphy. Intake of all major salivary gland was decreased in men compared with women. Patient age was the strongest predictor of parotid gland dysfunction as it affects the stage of parotid gland uptake and elimination on salivary gland scintigraphy [38]. Another study revealed the presence of epidermal and nerve growth factors (EGF and NGF) in salivary glands and described their roles in cell growth and differentiation. They are detected at higher levels in the submandibular glands of males than females [39], indicating that male salivary gland cells have stronger repair and regeneration abilities. Animal studies showed sex-attributed differences in wound healing patterns in submandibular glands between male and female mice. In males, the number of convoluted tubules rich in EGF and NGF (involved in cell proliferation and neurogenesis, respectively) was higher than that in females [40, 41]. These sex- differences observed in mice may help explain why the incidence of salivary gland disease tends to be much higher in women than in men (i.e., approximately 9:1) [42].

4.2. Different Basic Functions. Before the first ^{131}I treatment, we selected patients with basic impairment of salivary gland function. After the first ^{131}I treatment, some salivary gland parameters were different in the female group, with most changes in the group younger than 55 years old. After the second ^{131}I treatment, the bilateral submandibular gland EF values were different in females but not males. Interestingly, these altered functional parameters all showed an upward trend rather than the expected decline. We consider that this may be related to the compensatory increase in the function of glandular cells under certain stress states. Poradovskaia et al. showed that after ablating or removing one submandibular salivary gland in rats, the contralateral gland responded by increasing cell proliferation with concomitant increases in the size of the cells and nuclei by 10% and 17%, respectively. Burlage et al. observed that pilocarpine preconditioning induced proliferation of acinar and intercalated duct cells in rats, which could explain the observed enhanced compensatory response in salivary glands [43]. Compensatory proliferation is a mechanism to replace lost cells in rapidly cycling tissues [44]. After an initial singular dose ^{131}I dose of 100 mCi, the salivary glands might increase

uptake to maintain secretory function [4]. Our results are consistent with those of the above-mentioned studies. It is believed that salivary glands with slight damage in the basal state have a certain compensatory function. After the initial radiation injury, the compensatory function of gland cells is activated by stress, manifesting as increased uptake or excretion. With the increase of radiation dose and the passage of time after ^{131}I treatment, this compensatory function gradually decreases or disappears. In this study, we also selected uninjured salivary glands and compared the functional parameters before and after ^{131}I therapy. Notably, these salivary glands were more likely to be affected than those that were already impaired before treatment. Most showed functional reduction without the phenomenon of functional compensatory increase. This provides new ideas for clinical treatment. For example, salivary gland protection should be strengthened during ^{131}I treatment, especially in patients with normal basal function.

4.3. Different Glands. The salivary gland imaging results after the first and second ^{131}I treatments showed that the submandibular glands are more sensitive than the parotid ones, and the most common change was a decreased UF value representing impaired uptake. We analyzed whether this difference was related to salivary gland cell characteristics and salivary gland structure. Damage to the microvascular endothelial cells in salivary glands caused by radiotherapy is one of the causes of impaired gland function [45, 46]. It leads to microvascular dysfunction and the production of ceramide and reactive oxygen species (ROS) that can induce gland dysfunction. ROS scavengers are used to protect salivary gland function in radiotherapy patients [47]. By inhibiting or eliminating aberrant oxidation reactions, it is possible to reduce damage to salivary gland function caused by radiation. One study found that levels of salivary non-enzymatic antioxidants and antioxidant enzymes in the saliva secreted by the parotid gland were higher than those secreted by the submandibular salivary glands [48]. Therefore, salivary gland function changes due to parotid microvascular injury are not as serious as those caused by submandibular microvascular injury. Another group showed that the saliva-to-serum ^{131}I concentration rates in the parotid gland of mice and humans were 0.59 and 4.6, espectively, while those in the submandibular gland were 5.1 and 6.9 [49]. The ^{131}I concentration was higher in the submandibular glands of both species. An investigation showed that murine duct cells in the different salivary glands varied greatly in their ability to concentrate iodide, so it could be shown that ^{131}I was mainly concentrated in the ducts of the submandibular glands in mice, with lower levels in the parotid gland and very little in sublingual gland ducts [50]. Because of their ability to concentrate ^{131}I, the submandibular glands are more susceptible to radiation damage.

After the first ^{131}I treatment, we performed a second scintigraphy scan. We found that the males younger than 55 and females older than 55 showed a tendency of decreased function of the left parotid gland compared to the right parotid gland. The differential changes in the left and right glands after radiation have been reported in several studies and may be due to the asymmetric concentration of radioactive iodine in the salivary glands [3, 15, 31].

4.4. Treatment Frequency and ^{131}I Dose. The Chi-square test showed that the difference between the number of damaged and undamaged salivary glands in males and females increased significantly with the increase of treatment times, and the percentage of damaged glands also increased gradually. The number of treatments was correlated with the ^{131}I cumulative dose. A correlation between radiation dose and salivary gland dysfunction was previously reported [51, 52]. A salivary glandular scintillation imaging study showed that ~30% of salivary parenchymal function was lost following a single ^{131}I dose of 6 GBq (162 mCi), with a cumulative dose of 35 GBq (945 mCi) resulting in complete loss of glandular function [53]. Parthasarathy and Crawford argued that significant side effects were rarely seen at doses <3.7 GBq (100 mCi) [54].

5. Limitations

Our results should be considered in the context of some limitations. First, this was a retrospective study with no survey to assess patient symptoms and signs, so it was not possible to add more conditions (e.g., dry mouth, difficulty swallowing, loss of taste) for case screening. Second, there was a small number of patients, especially among the group treated more than four times, which limited our analysis of salivary gland function in patients with DTC treated for more than 2–3 years. Third, clinical parameters and test data of some patients were missing. Finally, the lack of significant findings in males maybe because they only accounted for 27% of the study cohort.

6. Conclusions

This study quantitatively compared salivary scintigraphy parameters in DTC patients after multiple ^{131}I treatments. Salivary gland function sensitivities are quite variable in different ages and sexes, with the highest sensitivity in women younger than 55. After treatment, the uptake or secretion function of some salivary glands with impaired basic function increased. Decreased salivary gland function is significantly related to the number of ^{131}I treatments and the cumulative dose. The parotid glands have the most significant reduction in uptake.

Supplementary Materials

Table S1 summarizes the number of patients, age distribution, and cumulative dose before one or more ^{131}I treatments. Table S2: Chi-square test was performed to determine the relationship between the number of patients by sex and the impairment of salivary gland function before each ^{131}I treatment. There was a statistical difference in the left submandibular gland injury count between sexes before the first treatment ($p < 0.05$). Figure S1: The percentage of damaged salivary glands increased with the number of treatments in both sexes. Figure S2: The cumulative dose of ^{131}I received by patients over several treatments. PD (Parkinson's Disease) is a severe malady that is painful and incurable, affecting older human beings. Identifying PD early in a precise manner is critical for the lengthened survival of patients, where DMTs (data mining techniques) and MLTs (machine learning techniques) can be advantageous. Studies have examined DMTs for their accuracy using Parkinson's dataset and analyzing feature relevance. Recent studies have used FMBOAs for feature selections and relevance analyses, where the selection of features aims to find the optimal subset of features for classification tasks and combine the learning of FMBOAs. EFSs (ensemble feature selections) are viable solutions for combining the benefits of multiple algorithms while balancing their drawbacks. This work uses OBEFSs (optimization-based ensemble feature selections) to select appropriate features based on agreements. Ensembles have the ability to combine results from multiple feature selection approaches, including FMBOAs, LFCSAs (Lévy flight cuckoo search algorithms), and AFAs (adaptive firefly algorithms). These approaches select optimized feature subsets, resulting in three feature subsets, which are subsequently matched for correlations by ensembles. The optimum features are generated by OBEFSs the trained on FCBi-LSTMs (fuzzy convolution bi-directional long short-term memories) for classifications. This work's suggested model uses the UCI (University of California-Irvine) learning repository, and the methods are evaluated using LOPO-CVs (Leave-One-Person-Out-Cross Validations) in terms of accuracies, F-measure values, and MCCs (Matthews correlation coefficients).

1. Introduction

Parkinson's is a neurologic problem that involves tremors, rigidity, and problems moving, balancing, and coordinating. The signs of the disease normally appear slowly and continue to worsen. PD is a neurological malady classified as a motor system dysfunction. The patient's activities deteriorate with PD as it progresses. Patients are affected in their fundamental bodily systems, including breathing, balance, movements, and heart functioning [1], where, at initial stages, their speech flow gets hindered. The early diagnosis of PD leads to a longer life of patients, and the diagnostics require high precision and robust health informatics tools. Such solutions aim at assisting clinicians [2–4] who detect PD's severity using a range of sensors. This research work uses different speech signal processing methodologies to obtain PD's clinically relevant characteristics, which are then processed using learning algorithms to provide reliable detections of PDs.

The performances of computational algorithms are inextricably linked to the quality of input data. The manual identification of speeches or voices in a complex and intricate task can be executed efficiently by MLTs. Important features from voice signals can be identified by computer-based techniques, which may be one of the three categories, namely supervised, unsupervised, or semisupervised, based on the labeling of data. Filtering, wrapping, and embedding are the examples of supervised feature selection approaches.

Filtering strategies choose features that are unrelated to categorizations, while wrappers use the projected accuracies of previously determined values by algorithms for feature estimations. Embedded approaches like the filter models begin by selecting multiple potential feature subsets with specific cardinalities using statistical criteria, where subgroups with highest classification accuracies are finally selected. Unsupervised feature selections work on unlabeled data, however, evaluating the relevance of features is difficult for them. Using the labeled and unlabeled data and semi-supervised feature selections can evaluate feature relevance.

Computational methods based on biological evolutions provide a stronger basis for solving problems or taking decisions [5, 6]. EFSs boost the stability of feature selections as they take advantage of single approaches while overcoming their flaws. The analysis of features from datasets can be based on individual assessments or by the evaluation of subsets [7, 8]. Individual assessments create a rank of characteristics based on relevance, while alternative approaches employ search strategies to generate a series of feature subsets. These subsets are assessed iteratively using optimality criteria until they arrive at a final subset of selected characteristics [9]. This work's OBEFS framework guides the construction of EFSs that combine the benefits of several feature selection methods, avoid biases, and cover up their drawbacks.

The hierarchical layers of DNNs (deep neural networks), which are DLTs, manage to generate deep abstract representations of input features in applications. DLTs have been exploited in many applications, including speech recognition, image categorization, medication development, and genetic research [10]. Researchers have used DNNs for PD categorizations mainly because of their effectiveness [11, 12]. DNNs are very helpful classifiers in the case of PDs as they simulate complex and nonlinear data linkages. Previous research on PD classifications used single features like EEG data [11] and sensor activities [12] as inputs for CNNs (convolution neural networks), where the usage of unique parallel layers for classifications has not been tried. The study in [13] proliferated voices using more voice recordings of individuals in training and testing procedures with CVs (cross-validations), resulting in biased performance evaluations. Since the data had voice recordings of healthy persons and PD patients, LOPO-CVs were used to assess the performances of the proposed framework. LOPO-CVs removed examples from individuals in iterations in test sets while using other instances in training.

The suggested OBEFSs framework of this work selects features based on agreements. Instead of employing single feature selection approaches, the ensembles of feature selection methods aim to integrate numerous feature selection methods, such as FMBOAs, LFCSAs, and AFAs, whereas in OBEFSs, optimum features are utilized to train FCBi-LSTM classifiers. The proposed technique was trained using datasets from the UCI machine learning repositories, while its performance was validated using LOPO-CVs. This work's suggested model uses UCI learning repositories, and the methods are evaluated using LOPO-CVs in terms of accuracies, F-measure values, and MCCs.

2. Literature Review

In this part, we will outline some current works on PD classification that make use of machine learning techniques and discuss contemporary deep learning methods in PD classification. To evaluate speech recordings for PD classification, Alqahtani et al. [14] proposed classifications based on NNges (non-nested generalized exemplars), which, in spite of their capabilities, were not examined thoroughly. The study's experiments categorized healthy and PD using NNges and the algorithm's optimized parameters. Furthermore, the data was balanced using the synthetic minority oversampling technique (SMOTE) method. Finally, using the balanced data, NNge and ensemble algorithms, notably AdaBoostM1, were developed.

Using the sets of vocal data, Gunduz [15] used the dual frameworks of CNNs for identifying PDs, where different feature sets were generated but merged together. Their first architecture combined several feature sets before feeding them as inputs to 9-layered CNNs, while the second part fed feature set information directly to convolution layers in parallel. Hence, each parallel branch's deep features were obtained before their merger into layers. Their second showed highly promising results in tests as they learned deep features utilizing parallel convolutions. The extracted deep features were efficient in increasing the discriminative powers of classifiers in addition to differentiating patients with PDs from healthy people.

PDs were classified by Li et al. [16] by combining CART and ensemble learning. The study used CART to iteratively identify optimal training speech samples with high levels of differentiation. The study used ensembles, including RFs (random forests), SVMs (support vector machines), and ELMs (extreme learning machines) for learning optimal training data. The study classified test data using trained ensemble-learning systems. The study found that CART and RF combinations were stable when compared to other strategies and also improved PD predictions with speech data categorizations. Caliskan et al. [17] projected the diagnosis of PDs using speech impairments, the first indication of the disease. They used DNNs with stacked autoencoders and the softmax function for classifications. Their simulation results across two databases demonstrated the efficiency of DNN classifiers in comparison with other classification techniques.

For quickly detecting PDs, Cai et al. [18] proposed the usage of enhanced FKNNs (fuzzy K-nearest neighbors) combined with CBFOs (chaotic bacterial foraging optimizations) with Gauss mutations on voices data. Their CBFO-FKNN was an evolutionary instance-based learning methodology, where FKNN's parameters were tuned effectively by CBFOs. The study evaluated their suggested approach exhaustively on PD datasets in terms of classification accuracies, sensitivities, specificities, and AUCs (area under the receiver operating characteristic curves). The study aided physicians in making better clinical diagnostic judgments.

Castro et al. [19] classified PDs on UCI machine learning repository datasets with ANNs using MLPs (multilayer perceptrons). Their collections included voice recordings of patients with PDs along with control groups. The study used several networks and trained 10 to 6000 neurons, which were increased ten folds in the hidden layers. Their analyses of speech-related characteristics by ANNs could be used to assess patients' impacts of PDs. MLTs can identify other neurological disorders when biological data is made available. Disorders were classified by Abdurrahman and Sintawati, [20] where well-known speech characteristics were used in PD research, including jitters, shimmers, basic frequency parameters, and harmonicity parameters, and they assessed PDs using RPDEs (recurrence period density entropies), DFAs (detrended fluctuation analyses), and PPEs (pitch period entropies). PDs were classified using the XGBoost algorithm, which used identified baseline features, followed by feature selections executed from feature importance plots to enhance the model's performance. The resulting locShimmer features were eliminated from the model, and the efficacy of features was improved by XGBoost's assessments of feature importance to increase classification accuracies.

Karabayir et al. [21] examined PD data with multiple MLTs, including LGBs (light gradient boosts), EGBs (extreme gradient boosts), RFs, SVMs, KNNs, least absolute shrinkages, selection operator regressions, and LRs (logistic regressions). The study also conducted variable significance analyses to find important factors in people diagnosed with PDs. The study found that LGBs outperformed other MLTs in benchmarks and could be utilized to screen huge patient groups for PDs at low costs. Patra et al. [22] employed MLTs to assess the voices of patient datasets and identify PDs. The study's base classifiers were DTs (decision trees), LRs, and KNNs, which had their performances compared to ensembles like bagging, RFs, and boosts. Furthermore, the most important traits associated with classifications for PDs were discovered and prioritized, depending on feature importance with the aim of differentiating PD-affected patients by detecting dysphonia.

Parisi et al. [23] proposed the use of hybrid AIs (artificial intelligence) for examining the cases of PDs. The study used UCI's databases, where the dysphonic values of 68 patients' clinical ratings were considered for processing. The study's feature selections were based on MLP weights while ranking input features, where physiological and pathological patterns were given different weight values. This strategy reduced examinable features from 27 to 20, thus effectively reducing the dimensions for the learning of LSVMs (Lagrangian support vector machines). The proposed hybrid MLP-LSVMs performed well in benchmarks against the existing and previously proposed schemes and could be used in clinical environments for the detection of PDs.

Datasets with rich features were examined by Hasan and Hasan [24] using ANOVA (Analysis of Variance) F-score values to extract the top 50 features. Several MLTs were applied, and their results were compared to prior studies. Their experiments found that feeding select characteristics to RFs resulted in the greatest accuracy scores. Their use of ANOVA for feature extraction successfully retrieved important characteristics that distinguish PD patients from healthy persons while improving classification accuracy scores. Qasim et al. [25] suggested hybrid feature selection approaches for processing unbalanced PD datasets. SOMTE approach was used in the study to balance the dataset. Subsequently, RFEs (recursive feature eliminations) and PCAs (principal component analyses) were used to remove contradictions found in the dataset's features and reduce the processing times of PCAs. Their classifiers included bagging, KNNs, MLPs, and SVMs that worked on the acoustic recordings of PDs along with the patient's individual characteristics. Their idea of using SMOLTE with RFEs and PCAs in preprocessing datasets was also compared with other identifiers for PDs and general medical disorders found in people. The study was an asset to healthcare organizations.

Even though the first system integrates distinct selected features [15] prior to feeding them to a 9-layered CNN, the second model feeds feature sets to concurrent input layers that are directly connected to convolution layers. Before integrating deep features from each parallel connection in the merge layer, deep features from each parallel branch are extracted simultaneously. The suggested models are trained using information from UCI machine learning, and their results are verified using Leave-One-Person-Out Cross Validation (LOPO CV). The F-measure and Matthews correlation coefficient measure, as well as correctness, are employed to examine our data because of the imbalanced class distribution. This second model appears to be quite promising, as it is capable of learning feature representations from each set of features via concurrent convolution layers, according to experimental data.

3. Proposed Methodology

This research work proposes a new feature selection and classification framework for identifying PDs. This work uses five major steps, namely, the extraction of features based on voices, dimensionality reductions using KPCAs (kernel-based principal component analyses), the usage of proposed OBEFSs, LFCSAs, AFAs, and FCBi-LSTMs. Subsequently, the assessments are evaluated using LOPO-CVs. Figure 1 depicts the general flowchart of the proposed system.

3.1. PD Dataset. The PD dataset encompassed speech samples used by prior studies to diagnose PDs from UCI's machine learning repositories [13]. The data gathered at Istanbul University's Cerrahpasa Faculty of Medicine's Department of Neurology comprised 188 PD patients (107 men and 81 women) in the age range of [33, 87] and 64 healthy persons (23 men and 41 women) in [41, 82] age ranges. The voices were collected on 44.1 kHz (microphone's frequency), and three copies of the vowels of individuals were collected after doctor's examinations.

3.2. Feature Extractions. The dataset had baseline and temporal frequency features, MFCCs (Mel frequency cepstral coefficients), WTs (wavelet transforms), TQWTs (tunable Q-factor wavelet transforms), and vocal fold features:

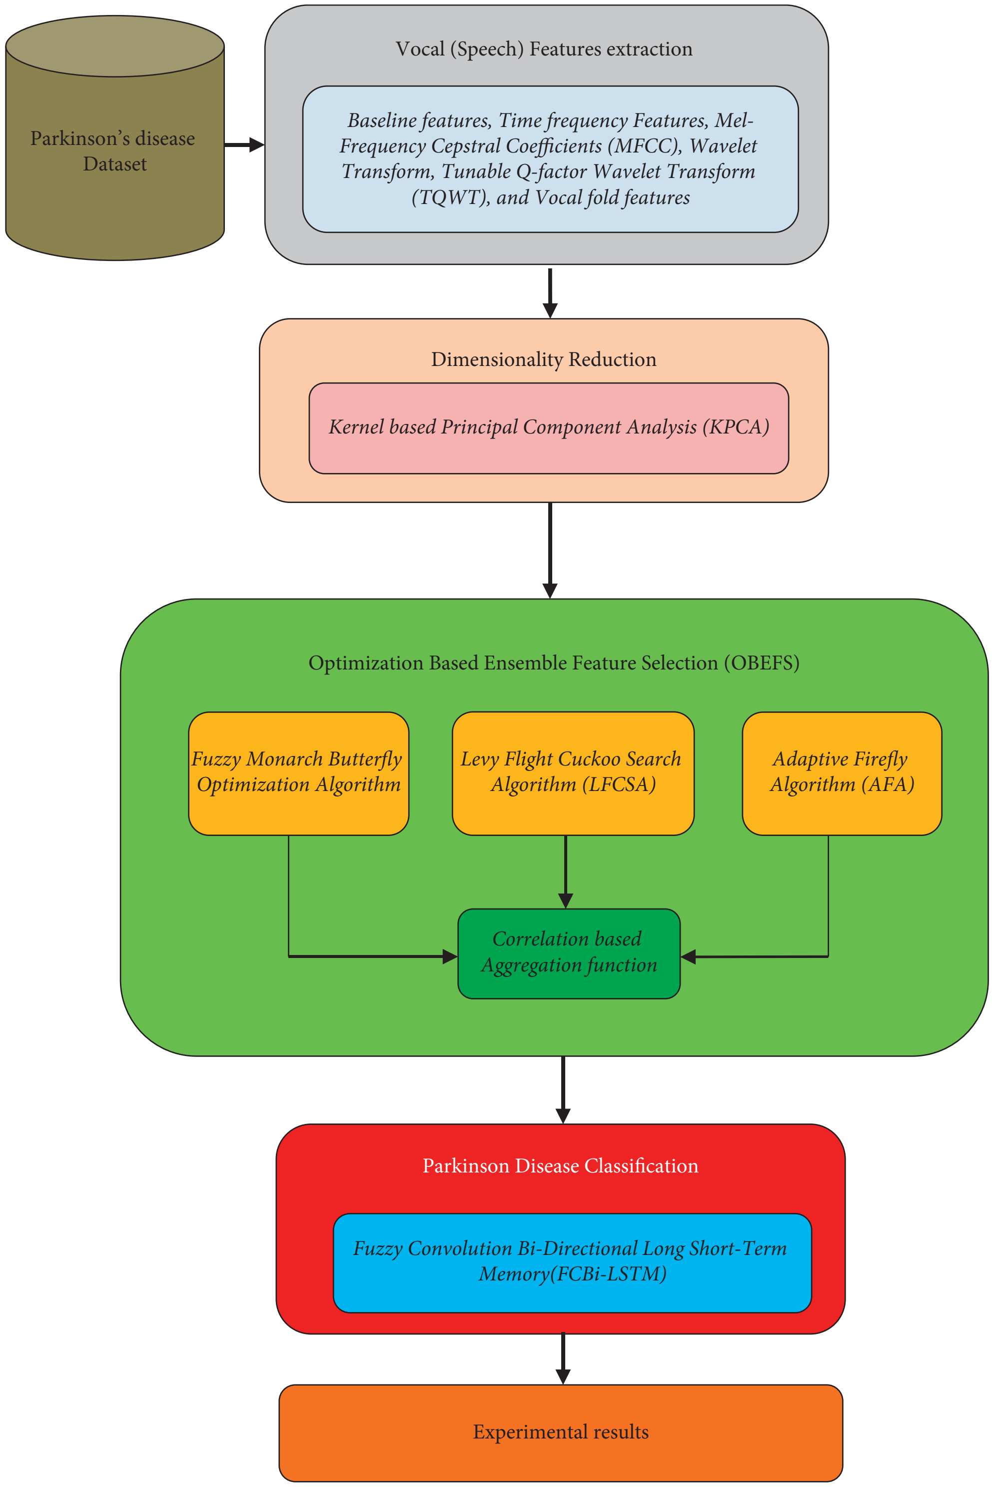

Figure 1: Overall flow of the proposed system.

(i) Baseline features: since PDs impede the speech of patients even in the early stages, speech characteristics were successfully used to evaluate PDs and track the disease's developments following medicinal therapies. The fundamental frequency parameters (#5), harmonicity parameters (#2), RTDEs (recurrence time density entropies) (#1), DFAs (detrended fluctuation analyses) (#1), and PPEs (#1) have been extensively utilized in characterizing speech-based PD researches [24, 26] and form the baseline features [13].

(ii) Time frequency features: intensity parameters (#3), formant frequencies (#4), and bandwidth (#4) are the examples of features.

(iii) MFCCs: MFCC-based extractions use triangular overlapped filter banks to combine cepstral analyses with spectral domain partitions. MFCCs can detect rapid deterioration in the movements of articulators in PDs like the tongues and lips, which are directly affected by the disease. The dataset had 84 characteristics related to MFCCs to identify the PD effects in the vocal tract (#84), and they were generated using the mean and standard deviation of initial 13 MFCCs along with the signal's log energies and $1^{st}/2^{nd}$ order derivatives [13], in addition to vocal folds.

(iv) WTs: generally, WTs are used to make decisions about signals and specifically on signals with minor fluctuations on regional scales. Several studies have utilized WT features obtained from a speech sample's raw fundamental frequencies (F0) to diagnose PD. This work produced 182 WTs characteristics from both approximations and detailed coefficients, including energies, Shannon's and log energy entropies, and Teager-Kaiser energies.

(v) TQWTs: the extraction of features using TQWTs improves signal qualities by adjusting three parameters, namely Q-factors (Q), redundancies (r), and a number of levels (J) based on the signal's behaviors. The oscillations in the time domain signals are proportional to Q-factors, while J stands for decomposed layer counts. On decompositions, J high-pass filters output $J+1$ sub-bands and one final low-pass filtered output. Ringing, controlled by r allows wavelet's localizations with respect to time [27]. This study's tests yielded 432 TQWT-related characteristics from the dataset [13].

(vi) Vocal fold features: the effects of noises on vocal folds were also investigated in this work using features based on vocal fold vibrations. The study extracted the following from the data [13]: glottis quotients (GQs) (#3), glottal-to-noise excitations (GNEs) (#6), vocal fold excitation ratios (VFERs) (#7), and empirical mode decompositions (EMDs).

(vii) Concat features: concat features are the combination of baseline, vocal fold, and time frequency features.

3.3. Dimensionality Reduction Using KPCAs. Approaches based on KPCAs are prominent for dimensionality reductions. KPCAs consider linear subspaces with reduced dimensionalities in the original sound's feature spaces, where new sound recordings of PDs show the greatest variance in features [28]. Assuming $\{a_i\}, i = 1, \ldots N$ is the PD dataset, where a_i represents D-dimensional sound recorded feature vectors, they have to be projected into M-dimensional sound reordered feature subspaces that are lesser than D, and reduced feature vectors of sound recordings are identified. These reduced dimensional feature sets are used by OBEFSs for selecting relevant features.

3.4. Feature Selections Using OBEFSs. The proposed OBEFSs integrate the normalized results of multiple feature selections to arrive at quantitative feature sets with ensemble significances. In the initial phase, the series of feature selectors are created for different outputs, followed by the aggregations of a single model's results. The aggregations of feature selections are accomplished using correlations or consensus on feature ranks or counting most selected features for determining consensus-based feature subsets. The proposed OBEFSs generate final consensus ranks by combining feature ranks supplied by single feature selectors: FMBOAs, LFCSAs, and AFAs.

3.4.1. FMBOAs. This work uses FMBOAs for the selection of feature subsets, where the characteristics for samples are considered based on the effects of feature existences in PDs. Classifiers then use these selected attributes from samples (m denotes the number of voice samples). Classifiers forecast their own class labels, and evaluations are made for ultimate selections. The original characteristics are given feature weights that indicate their significance to classifications, and features with the highest weights are chosen. MBOs are migration-based that are built on migration trends, where fitness and importance of selections are rated. When used without modifications, FMBOAs show good classification accuracy results, indicating that they balance their global and local searches. The global search components of MBOAs were tweaked in this study to provide more precise results and boost effectiveness in locating the right characteristics before resorting to local searches. Individual butterflies analyze attributes that interact with one another on local levels, disseminating information across swarms and resulting in the system's growing capabilities [29–31]. They are carried out with the help of two operations, namely migration operators and adjustments to butterfly operators.

3.4.2. LFCSAs. CSAs (cuckoo search algorithms) are motivated by the unusual habit of cuckoo species, known as obligatory interspecific brood parasitism [32]. These behavioral patterns are based on the fact that certain animals use suitable hosts to optimize the selections of characteristics from datasets to grow their progenies. CSAs avoid parental commitments in rearing their offspring while limiting the dangers of egg loss (irrelevant traits) to other species. The final characteristics are chosen by placing eggs (features) in a variety of nests. The method's purpose is to replace the present solutions with eggs (irrelevant features) previously placed in the nest with these new solutions connected with cuckoo eggs (features). This iterative replacement may undoubtedly increase the quality of the solution over iterations, finally leading to a very good solution of the feature. In particular, CSA is based on three idealized rules [33, 34], which are as follows:

(1) Cuckoos lay the eggs (features) in nests randomly (accuracies).

(2) Nests with the best eggs (quality of features) are considered for subsequent generations for producing better solutions (features).

(3 The host nest counts are set with probability $prb_a \in [0, 1]$. Hosts can find alien eggs (feature), a rule approximated by new nest replacements prb_a of the n available host nests. LFCSA algorithm initially begins with the N host. (1) gives the initial values of the k^{th} component of the j^{th} nest.

$$f_j^k(0) = \mu.\left(\mathrm{up}_j^k - \mathrm{low}_j^k\right) + \mathrm{low}_j^k, \quad (1)$$

where up_j^k is the k^{th} feature's upper bound, low_j^k is the k^{th} feature's lower bound, and μ is the uniform random variable in the range (0, 1). These parameters are adjusted for ensuring the feature values that exist with their feature spaces. The feature (egg), say i, randomly selected in the iteration, results in the solution f_i^{t+1}. The algorithm uses Lévy flights in place of random walks for efficient random searches. These flights, similar to random walks, are characterized by step sizes, following probability distributions with isotropic and random orientations. Lévy flights are depicted by

$$f_i^{t+1} = f_i^t + \alpha \oplus levy(\lambda). \quad (2)$$

The superscript t denotes the current generation, the symbol ⊕ denotes entry-wise multiplication, and $\alpha > 0$ denotes the step size. This step size specifies how far a particle (feature) may move in a certain number of iterations using a random walk. The Lévy distribution modulates the transition probability of the Lévy flights in

$$levy(\lambda) \sim g^{-\lambda}, \quad (1 < \lambda \leq 3), \quad (3)$$

The production of random numbers with Lévy flights has two basic phases from a computational standpoint, which are as follows:

To begin, a random direction based on a uniform distribution is selected.

Then, based on the chosen Lévy distribution, a series of steps is constructed.

For symmetric distributions, Mantegna's approach is employed [34]. This method uses an equation to calculate the factor,

$$\widehat{\phi} = \left(\frac{\Gamma(1+\widehat{\beta}).Sin(\pi.\widehat{\beta}/2)}{\Gamma\left((1+\widehat{\beta}/2).\widehat{\beta}.2^{\widehat{\beta}-1/2}\right)} \right)^{1/\beta}, \quad (4)$$

where the Gamma function is denoted by Γ, and since $\widehat{\beta} = 3/2$ was utilized in a recent study [34], this work used the same ranges here. By (5), this factor is utilized in Mantegna's procedure to compute the step lengths:

$$\varsigma = \frac{u}{|v|^{1/\beta}}, \quad (5)$$

where u and v are the zero mean and deviation normal distributions σ_u^2 and σ_v^2, respectively. $\sigma_v = 1$ and σ_u follow the Lévy distribution given by (4). The step size ζ is then computed using

$$\varsigma = 0.01\varsigma\left(f - f_{best}\right). \quad (6)$$

The obtained ς changes the value of dimension x to: $f \leftarrow f + \zeta.\Psi$, where Ψ stands for the solution's random vector, and the x value lies in the normal distribution in the range (0, 1). LFCSA approaches identify new solutions (feature selections) that are fit (accurate) with existing solutions, where new solutions replace older ones on improvements. Nests with the worst values are discarded for further iterations and replaced with randomized new solutions, where replacement rates are based on probabilities prb_a, which are tuned for optimality. Thus, in iterations, existing solutions (feature selections) are rated based on their fitness values (accuracies), and the best solutions (features) are attained and stored as feature vectors f_{best}. Iterations are continued until the defined stopping criteria are met. LFCSA's pseudocode is depicted as Algorithm 1.

3.4.3. AFAs. The firefly algorithm is based on the idealized behavior of firefly flashing [35]. For the core formulation of FA, the three rules idealized are as follows:

(i) Because all fireflies are unisex, they will attract each other regardless of their gender for the best feature selection from the dataset
(ii) The brightness (accuracy) of a firefly is related to its attractiveness, which decreases as the distance between two fireflies grows
(iii) The brightness of a firefly is controlled by the objective function (accuracy)

The light intensity (In) varies exponentially and monotonically with distance. Equation (7) is used to explain it.

$$\mathrm{In} = \mathrm{In}_0 e^{-\gamma r}, \quad (7)$$

where In_0 is the initial light intensity and γ is the light absorption coefficient. As a firefly's attractiveness is proportional to the light intensity seen by neighbor fireflies (features), define the attractiveness β of a firefly by

$$\beta = \beta_0 e^{-\gamma r^2}, \quad (8)$$

where $\beta_0 = 1$ is the attractiveness at $r = 0$. The movement of a firefly (feature) "i" is attracted to another more attractive firefly(feature) "j", which is determined by

$$x_i = x_i + \beta_0 e^{-\gamma r_{ij}^2}\left(x_i - x_j\right) + \alpha\varepsilon. \quad (9)$$

The third term is the randomization with the step α, being drawn from a Gaussian distribution.

FAs generically use (9) for iterative randomizations, resulting in uniform distributions in the interval [0, 1] range. Their step determinations are static/linear and are defined for unchangeable maximum generations. FAs begin with the same steps, and their values keep decreasing in iterations. As a result, it is possible that it will get stuck at the local optimum, causing premature convergence. Secondly, taking such a large stride may lead the firefly to miss the best option while it is still in the area of the firefly during the early phases of the search. As a result, search performance might be harmed.

Thus, (9) implies the benefits of explorations in FAs, where larger steps result in global optimum convergences.

(1) Begin
(2) Objective function $f(f)$, $f = (f_1, \ldots f_d)^T$ with $d = \dim(\Omega)$
(3) Generate initial population of N host nests $f_i (i = 1, \ldots N)$
(4) While ($t <$ MaxGeneration)
(5) Get a cuckoo (say i) randomly by Lévy flights
(6) Evaluate fitness F_i by the accuracy of the classifier
(7) Choose a nest among N (say j) randomly
(8 **) If** $(F_i > F_j)$
(9) Replace j with the new solution
(10) End
(11) A fraction (prb_a) of worse nest(features in the dataset) are abandoned and new features are built by
(12) Lévy Flights
(13) Keep the best solutions using the accuracy of the feature
(14) End while
(15) Postprocess the results and visualization
(16) End

Algorithm 1: Levy flights cuckoo search algorithm.

For steps with low values, considerable influence occurs on explorations and convergences of algorithms. The values keep declining slowly on more iterations, however, they are faster in reduced iterations. These issues have been overcome in this study by the usage of self-adaptive steps, where the firefly's unique experiences help in selecting the best features from the data.

Step settings should be used to remedy the difficulties listed above. The firefly step should be set to be far away from the ideal solution. Fireflies between the two are utilized to balance the global and local searches for the best feature selection from the dataset. As a result, the firefly's stride must be concerned with both its previous data and current circumstances. This work introduces the firefly's history data, which contains the optimal value of the previous two iterations. Based on the comments mentioned above and many experiments, the step α of each firefly is calculated by (10) and (11), respectively. It is discussed as follows:

$$h_i(t) = \frac{1}{\sqrt{\left(f_{\mathrm{pi}}(t-1) - f_{\mathrm{pi}}(t-2)\right)^2 + 1}}, \quad (10)$$

$$\alpha_i(t+1) = 1 - \frac{1}{\sqrt{\left(f_{\mathrm{best}}(t) - f_i(t)\right)^2 + h_i(t)^2 + 1}}, \quad (11)$$

where $h_i(t)$ is the past two iterations' history data of the i^{th} firefly. f_{pi} is the fitness value of the best solution of the i^{th} firefly. f_{best} is the fitness value of the best solution of population heretofore found, and f_i is the fitness value of the i^{th} firefly, which reflects the current data. The firefly's next iterations are self-adaptive and are decided by the gap between the current fitness values and the population's best fitness values. As a result, the firefly steps might change with repetitions, and each firefly's step is, likewise, changed at the same time.

(1) Begin
(2) Objective function $f(x)$, $x = (x_1, \ldots x_d)^T$
(3) Generate initial population of n fireflies $x_i (i = 1, \ldots n)$
(4) Formulate light intensity In by objective function $f(x)$
(5) While ($t <$ MaxGeneration)
(6) Define absorption coefficient γ
(7) Evaluate fitness F_i by accuracy of the classifier
(8) For $i = 1$ to n(n fireflies)
(9) For $j = 1$ to n(n fireflies)
(10) If $(I_j > I_i)$
(11) Move firefly i towards j
(12) End if
(13) Vary attractiveness with distance r via $\exp(-\gamma r^2)$
(14) Evaluate new selected features solutions and update light intensity
(15) Update the step of each firefly. The step is calculated by (10) and (11).
(16) End for j
(17) End for i
(18) Rank the best features and find the current best features
(19) End *while*
(20) Postprocessing the results and visualization
(21) End

3.4.4. Correlation Function. Correlations between the features are computed by ensemble feature selectors, where high similarities between the features award their eliminations. The features selected using three procedures form ensemble features, where only ideal feature sets are selected by majority votes and based on the outputs of individual feature sets. The correlation coefficient matrices for the features selected in the out-ensemble feature selection outputs are computed using

$$\text{correlation coefficient} = \frac{N\sum xy - (\sum x)(\sum y)}{\sqrt{\left[N\sum x^2 - (\sum x)^2\right]\left[N\sum y^2 - (\sum y)^2\right]}}, \tag{12}$$

where x and y are the attribute values under consideration, and N is the total number of instances. The feature set selected by the correlation-based ensemble feature selector is given as an input to the classification.

3.5. Classification of PDs Using FCBi-LSTMs. This work used FCBi-LSTMs for the classification of PDs. The suggested approach computes fuzzy weight with membership values that are adjusted for extracting the most relevant features with respect to PDs. FCBi-LSTMs and CNNs analyze the selected characteristics from PD datasets [36]. CNNs made of convolution and pooling layers convolute and pool where outputs are fed to subsequent convolution layers. CNNs offer significant advantages in terms of feature extractions as they use partial filters for convolutions based on their understanding of biological vision cells' local perception. The convolution layer is separated into many output matrices using filters to offer a better representation of the selected features from the PD dataset, with each output matrix having a size of $(Nm + 1)$. The pooling layer of CNN is a technique for reducing the dimension of a matrix while keeping the fundamental links between the features. Pooling layers are average pooling layers with inputs from convolution layers. In the Bi-LSTM data analysis technique, the output of the last convolution layer is used as an intermediate variable [37]. As a result, LSTM does more than just add a nonlinear element to the input and loop cell transformation. Fuzzy weights are computed using Gaussian membership functions, where Bi-LSTMs outperform unidirectional LSTMs as they capture more structural information. The final outputs of Bi-LSTMs are processed by CNN's convolution layers for diagnosing PDs. To combine features processed by CNN and features processed by Bi-LSTM, multimodal factorized bilinear pooling (MFB) is utilized.

4. Experimental Results

This section describes the experimental findings achieved by the proposed FCBi-LSTM classifier and compares them to approaches, such as FCLSTM-CNN (fuzzy convolution long short-term memory-based convolution neural networks), CNN, and SVM. Since the samples in the test sets were fewer, LOPO-CVs' performance was evaluated using the training set's remaining individual instances, as each individual had three recordings, and the class labels assigned to these recordings were used to establish the individual's class label. The MIT-BIH arrhythmia database was used to conduct the investigations on arrhythmia recognition and classification systems and MATrix LABoratory R2016a (MATLAB R2016a). The implementation has been done using the following system specifications: Intel (R) Core™i3-4160T CPU@3.10 GHz 3.09 GHz processor, 4.00 GB RAM, Windows 8.1 Pro, 64-bit operating system, and 1 TB hard disk.

4.1. Evaluation Metrics. To test the predictability of the classifiers, evaluation metrics are required. Although accuracy is a widely used statistic, it might produce deceptive findings when data has an imbalanced class distribution. Even when there is a class imbalance, evaluation measures like F-measure and MCCs may be used to assess how effectively a classifier can discriminate between distinct classes. Allow the confusion matrix in Table 1 to represent the numbers of properly and erroneously categorized occurrences per class for binary classification. The letters tp, fp, fn, and tn in the confusion matrix mean true positive (tp), false positive (fp), false negative (fn), and true negative (tn), respectively. Precision, recall, F-measure, accuracy, and error were calculated using the formulae based on these counts.

$$\text{Precision} = \frac{\text{tp}}{\text{tp} + \text{fp}}, \tag{13}$$

$$\text{recall} = \frac{\text{tp}}{\text{tp} + \text{fn}}, \tag{14}$$

$$F - \text{measure} = \frac{2^{*}\text{precision}^{*}\text{recall}}{\text{precision} + \text{recall}}, \tag{15}$$

$$\text{Accuracy} = \frac{\text{tp} + \text{tn}}{\text{tp} + \text{tn} + \text{fp} + \text{fn}}, \tag{16}$$

$$\text{error} = 100 - \text{Accuracy}. \tag{17}$$

MCCs, which take into consideration the tp, fp, fn, and tn counts and are frequently recognized as a balanced measure that may be employed even if the class distribution is uneven, are another statistic for evaluating the validity of binary classifications. MCCs are simply correlation coefficients ranging from −1 to +1 between the actual and predicted occurrences. A score of +1 indicates a perfect prediction, whereas a value of −1 indicates a discrepancy between the forecast and the actual labeling.

4.2. Results Comparison. Experimental evaluations of classifiers were executed with three types of features in terms of accuracy, error, F-measure, and MCC. The combination of MFCCs + Wavelets + Concated features with SVM resulted in the accuracy rate of 88.1294%, although the accuracy rate of MFCCs + Wavelets + Concated combination was 94.1752% for CNN. FCLSTM-CNN had the accuracy results of 93.0470%, 93.0854%, 93.1261%, and 95.1557%, respectively, for TQWT + MFCC + Wavelet, TQWT + Wavelet + Concat, TQWT + MFCC + Concat, and MFCC + Wavelet + Concat. The suggested FCBi-WLSTM classifier with MFCCs + Wavelets + Concated combinations achieved the highest accuracy rates of 98.7720% (F-measure rate of 98.5010% and 71.400% for MCC) (See Table 2).

Figures 2–5 show the F-measures, accuracies, MCCs, and errors of feature set combinations, where the TQWT + MFCC + Wavelet combination of feature sets yielded higher results of 98.3100 percent, 96.6381 percent, 74.300 percent, and 3.3619 percent for f-measures,

Table 1: Confusion matrix for two-class classification.

Actual/predicted as	Positive	Negative
Positive	tp	fn
Negative	fp	tn

Table 2: Results of classifiers with triple feature (KPCA + OBEFS).

Feature combination	F-measure	Accuracy	Error	MCC
SVM classifier (%)				
TQWT + MFCC + Wavelet	82.9150	85.1035	14.8965	56.2000
TQWT + MFCC + Concat	80.7960	83.6640	16.3360	54.6000
TQWT + Wavelet + Concat	86.3590	87.4662	12.5338	58.8000
MFCC + Wavelet + Concat	87.4510	88.1294	11.8706	59.7000
CNN classifier (%)				
TQWT + MFCC + Wavelet	85.8697	87.5696	12.4304	57.2007
TQWT + MFCC + Concat	90.2315	91.9315	8.0684	61.4600
TQWT + Wavelet + Concat	86.3695	88.0694	11.9306	63.3994
MFCC + Wavelet + Concat	92.4752	94.1752	5.8248	64.5384
FCLSTM-CNN classifier (%)				
TQWT + MFCC + Wavelet	94.2258	93.0470	6.9530	67.6669
TQWT + MFCC + Concat	91.5250	93.0854	6.9146	67.7060
TQWT + Wavelet + Concat	93.4200	93.1261	6.8739	65.4457
MFCC + Wavelet + Concat	91.6921	95.1557	4.8443	67.2960
FCBi-LSTM classifier (%)				
TQWT + MFCC + Wavelet	98.3100	96.6381	3.3619	74.300
TQWT + MFCC + Concat	96.5900	98.0244	1.9756	72.300
TQWT + Wavelet + Concat	97.5200	97.3457	2.6543	70.300
MFCC + Wavelet + Concat	98.5010	98.7720	1.2280	71.400

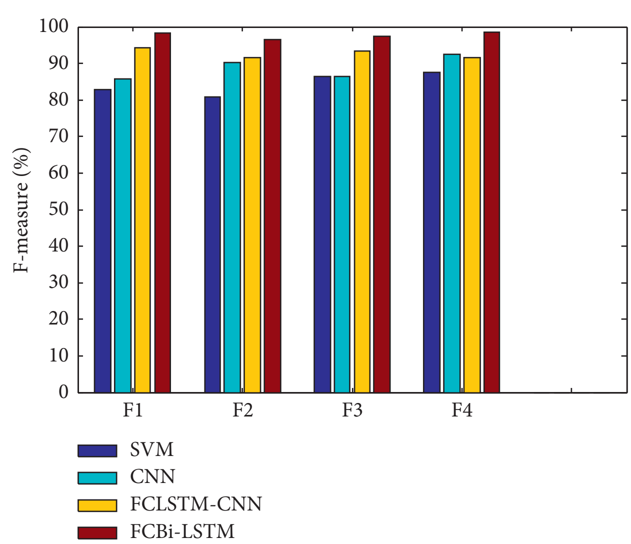

Figure 2: F-measure results of feature level combination vs. classifiers.

accuracies, MCCs, and errors, respectively, when compared to other combinations. Figure 2 compares the F-measure outcomes of four distinct feature level combinations using various classifiers. The proposed FCBi-LSTM with the first feature level combination achieved a higher F-measure value of 98.3100%, which was better than SVM, CNN, and FCLSTM-CNN, which achieved F-measures of 82.9150 percent, 85.8697 percent, and 94.2258 percent, respectively, at the first feature level combination.

Figure 3 depicts accuracies in the x-axis assessed using feature-level combinations on classifiers. FCBi-LSTM achieved 98.772 percent accuracy when compared to SVM, CNN, and FCLSTM-CNN, which achieved 88.1294 percent, 94.1752 percent, and 95.1557 percent accuracy, respectively, at the final feature level combination.

Figure 4 depicts error result comparisons of classifiers with four distinct feature level combinations. According to Figure 4, FCBi-LSTM results on final feature level

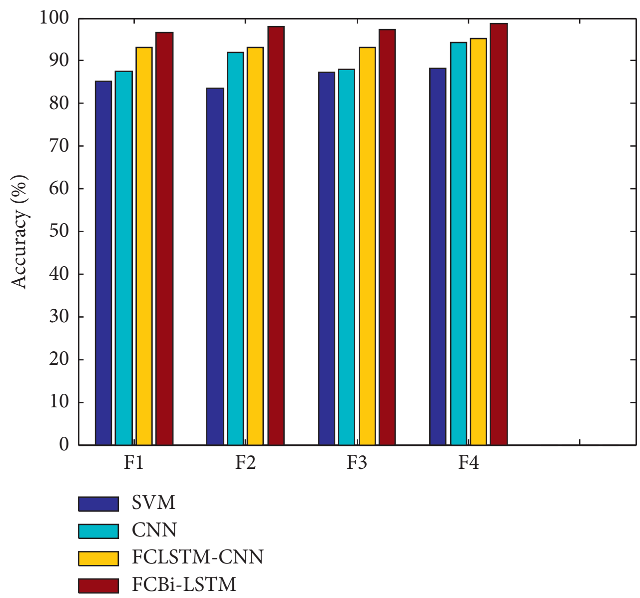

FIGURE 3: Accuracy results of feature level combination vs. classifiers.

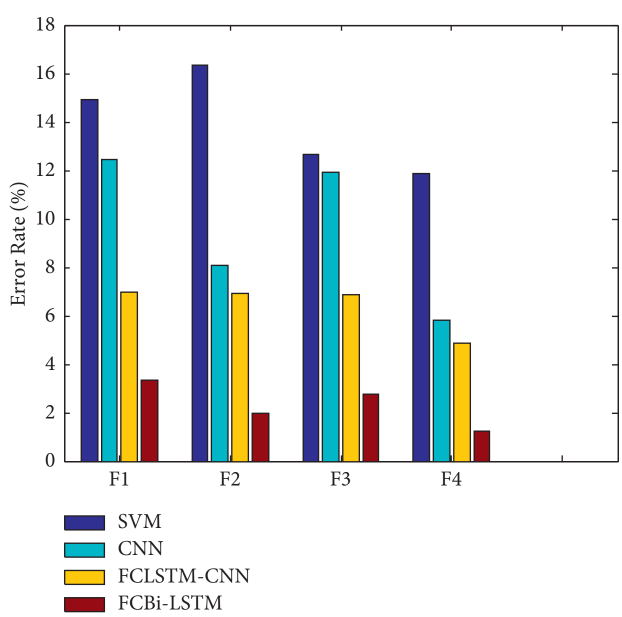

FIGURE 4: Error results of feature level combination vs. classifiers.

combinations produced reduced error values of 1.2280 percent, whereas SVM, CNN, and FCLSTM-CNN had higher error values of 11.8706 percent, 5.8248 percent, and 4.8443 percent, respectively, at the final feature level combination.

Figure 5 compares MCC results of TQWT + MFCC + Concat feature set, which yields a higher result of 74.30 percent for the proposed method, and 56.20 percent, 57.2007 percent, and 67.6669 percent for SVM, CNN, and FCLSTM-CNN classifiers, respectively (1^{st} feature level combination). Because feature selection is accomplished using the proposed approach achieves superior MCC outcomes for all classifiers (OBEFSs).

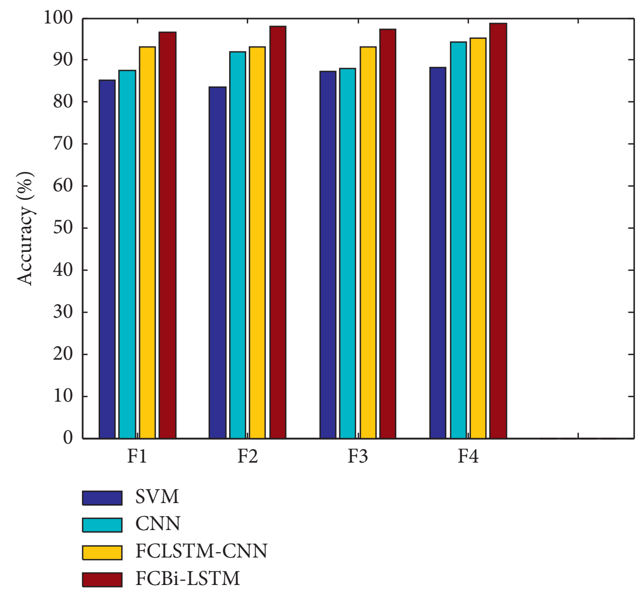

FIGURE 5: MCC results of feature level combination vs. classifiers.

5. Conclusion and Future Work

PD is the second most prevalent neurological ailment, causing considerable impairment, lowering the quality of life, and having no treatment. It is critical to diagnose PD early to use neuroprotective and early treatment techniques. In this research, a feature selection is used to present a multiclass classification challenge for PD analysis. For PD analysis, OBEFS and FCBi-LSTM are presented. The proposed OBEFS method is based on a number of algorithms, including FMBOA, LFCSA, and AFA. To execute OBEFS, the correlation function is utilized to choose optimum features from the three feature subsets. The FCBi-LSTM classifier is then used for PD diagnosis. It is an effective and accurate model for properly diagnosing the condition at an early stage, which might help doctors aid in the cure and recovery of PD patients. Classification algorithms were tested with UCI's machine learning libraries, and their performance is measured using precision, recall, F-measure, accuracy, and MCC. The results were compared to other existing techniques, and the findings show that the suggested model's accuracy is higher than the other current approaches. Deep learning has a bright future in engineering and medicine. In terms of future work, the goal is to extend existing research in novel ways. Different data types can be sent into the network as inputs at the same time using the proposed CNN's parallel convolution layers. It gives us the chance to utilize the multimodal data in PD classification. Also, the authors plan to use different deep learning models in the classification process.

Abbreviations

PD:	Parkinson's Disease
DMTs:	Data mining techniques
MLTs:	Machine learning techniques
EFSs:	Ensemble feature selections

OBEFSs: Optimization-based ensemble feature selections
LFCSAs: Lévy Flight Cuckoo Search Algorithms
AFAs: Adaptive firefly algorithms
FCBi-LSTMs: Fuzzy convolution bidirectional long short-term memories
UCI: University of California-Irvine
LOPO-CVs: Leave-One-Person-Out-Cross Validations
MCCs: Matthews correlation coefficients.

Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

The authors declare no conflicts of interest.

Retracted: Research on the Current Situation of College Students' Physical Health under the Background of the Integration of Sports and Medicine

Journal of Healthcare Engineering

Received 19 November 2022; Accepted 19 November 2022; Published 8 December 2022

Journal of Healthcare Engineering has retracted the article titled "Research on the Current Situation of College Students' Physical Health under the Background of the Integration of Sports and Medicine" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

The authors do not agree to the retraction.

As a health service model promoted by the "Healthy China 2030" plan, the integration of sports and medicine is of great significance to the reformation of college students' health management. Research shows that the general low health literacy, unhealthy lifestyle, significant decline in physical fitness, high incidence of subhealth, and prominent mental health problems are common among college students in China. This article comprehensively utilizes the literature data method, logical analysis method, and questionnaire survey method to analyze the health status of college students, the current status of the health management of college students, and outstanding issues and to focus on analyzing the current status of students' body shape, physical function, and physical fitness indicators. From the perspective of examining, reflecting, and exploring physical and medical integration, it is believed that the construction of students' physical health issues from the perspective of the development of the integration of sports and medicine is manageable and the interaction of medicine, health, and sports can be promoted. This article discusses the enlightenment of "sports–medicine integration" with school physical education, interprets the connotation of "sports–medicine integration", and analyzes the development direction of "sports–medicine integration" and physical education. In order to effectively strengthen school physical education work, we proposed to establish the concept of "sports and medical integration" sports health education, specifically the development strategy of school physical education, including promoting "sports integration," to improve the development of sports education, and establish a teaching service platform, providing ideas and suggestions for the development of national health strategies. In conclusion, colleges and universities should strengthen the construction of sports venues and facilities for physical education, increase students' enthusiasm for participating in physical exercise, and improve students' physical fitness.

1. Introduction

With the improvement in people's health awareness, all levels of the society are deeply aware of the importance of health. Sports and medical care are important pillars of social health, and "the integration of sports and medicine" has become a current research hotspot. Nowadays, people's dietary structure and lifestyle have undergone tremendous changes, and obesity has gradually become a serious problem in the field of public health. The obesity rate of college students continues to increase, and their physical fitness has been declining year by year. Some indicators are even inferior to that of middle school students. Obesity also makes college students low in self-confidence and prone to anxiety, which leads to interpersonal communication disorders. Moreover, the health of college students is also threatened by chronic diseases, and changes in lifestyle have made cardiovascular and cerebrovascular diseases, cancer, diabetes, and other diseases the "killers" that endanger college students; in addition, clinical medicine has little effect on such diseases. This gave birth to "physical medicine fusion" health promotion.

Since 1985, China has conducted four surveys on the health of college students. The results of the survey show that the physique of college students is gradually declining. The decline in college students' physique is not as simple as it seems. Countries are gradually paying attention to physical health. This is because of the poor psychological status of college students and their weak psychological endurance. It is also urgent to update school physical education. "Healthy China 2030" proposes "the integration of physical and medical care". The establishment of the Research Center for Promotion and Innovation of "Sports-Medical Integration" and other policy proposals indicate that the country has elevated health issues affecting the national strategy, which reflects the importance and timeliness of "sports–medical integration". The integration of sports and medicine has pointed out a new direction to our people for good health, and it has also brought new enlightenment to the physical education of our country's colleges and universities. The "Healthy China 2030" planning outline mentioned that health education should be incorporated into the national education system and a diversified health education model should be constructed, with health education as an important part of the education stage [1]. Zhang Jianwei started the concept and connotation of the integration of sports and medicine and put forward strategies based on the analysis of the development of the integration of sports and medicine and local practices: Sports and medical departments should work together, focus on the construction of talent teams, increase publicity and promotion, and explore and develop in accordance with local conditions [2]. Feng Zhenwei tried to use the symbiosis theory to construct a path for the integration of body and medicine. The research found that currently there are disadvantages in emphasizing medicine and neglecting the body, separation of industries, and insufficient laws and policies [3]. However, the current research results on the physical health of college students under the integration of sports and medicine and the research results on the reform of health management in colleges and universities are few. This article analyzes the current status of the physical fitness of college students across the country, analyzes the connotation of the integration of sports and medicine, and analyzes the integration of sports and medicine and physical education. At present, college students also lack the ability of self-decompression and psychological adaptation [4], and the proportion of dropouts due to psychological problems has also been increasing year by year [5]. On the basis of theoretically combing the correlation between the integration of sports and medicine and health management, the thought and feasibility of the reformation of the health management of college students under the integration of sports and medicine are promoted for the development of sports education and improving the physical health of college students. The comprehensive development of college students is promoted, references are provided, and ideas and suggestions are provided for the reformation of physical education.

2. Connotation and Development Status of the Integration of Sports and Medicine

The integration of sports and medicine has not only physical exercise methods but also the concept of medical services. It is a mode of operation that mainly provides nonprofit basic public services and is supplemented by profit-making methods such as the sports industry, that is, sports disciplines and medical disciplines. It is a model of mutual integration, mutual learning, and reference and mutual promotion of concepts, ideas, paths, and models. This model is very suitable for improving the physical health of students in college physical education. It is also one of the most effective ways to improve the physical health of college students. At the same time, it is an important tactical means of the "healthy China" strategy.

The main feature of the integration of sports and medicine is that "there is medicine in the body, and there is body in medicine;" the two are interdependent, permeable, and blended. It has high practical value in the promotion of sports and medical disciplines. "Physicians in sports" are mainly manifested in three aspects: competitive sports, mass sports, and school sports. In competitive sports, for athletes to achieve excellent results, they need not only the support of scientific research knowledge of sports but also the medical and health system to provide athletes with first aid and injury prescriptions; in mass sports, medical interventions are used to conduct physical fitness tests on the public and implement them. Medical supervision promotes scientific fitness for the masses. School physical education provides students with exercise programs with a certain exercise intensity to improve the effect of exercise on the basis of avoiding injuries. "Medicine in the body" is mainly manifested in three aspects: prevention, treatment, and rehabilitation. Prevention cannot rely solely on medical means but must be assisted with appropriate physical exercises and exercise prescriptions; the treatment of chronic diseases requires the use of exercise intervention methods. The effect is far better than that of drug treatment; sports rehabilitation should also be added to rehabilitation, which can accelerate the recovery from the disease and reduce the incidence of cancer.

At present, our school sports and social sports are not in touch with each other. There is a gap in the connection between school sports and social sports, and most students leave sports when they leave school. In the process of physical education, cultivating students' self-health and self-physical abilities is particularly important. The integration of physical and medical strategies and the idea of lifelong physical education influence each other and complement each other. We will take lifelong physical education as the main idea and the integration of physical and medical care as the main means to break the teaching situations that are too weak to deal with errands, deepen the reformation of physical education in an all-round way, and improve the health of students.

Most parents have low awareness of sports. During holidays, students and parents mostly sit quietly and move less. Sitting for a long time and moving less are prone to poor energy metabolism habits, which will also affect muscles and bones, because of which chronic diseases will follow. Studies have shown that the mortality rate of people who sit still and do not move is higher than that of people who exercise. The Institute of Physical Medicine Fusion proposes that reducing sitting and less movement is beneficial to the prevention of chronic diseases. In addition, to urge students to develop exercise habits is also the main task of physical education during holidays. Therefore, through the Internet's big data, the goal of physical education and the viewpoint of integration of sports and medicine are connected in order to achieve the goal of physical education and disseminate the viewpoint of integration of sports and medicine. The integration of sports and medicine has played an important role in improving the health of college students.

3. The Current Status of College Students' Physical Health

Every year, the Ministry of Education organizes health campaigns across the country to detect students' health problems, inputs the test results into a database with dynamic characteristics, and feeds them back to the national educational institutions and colleges and universities; the data indicators become important information to realize health assessment. The physical health of college students has always been an important content of physical education teaching in colleges and universities. In recent years, it has been found that the physical health of students has shown a downward trend through physical tests.

According to the survey, since 1985, the developmental indicators of students have not reached the standard and have been declining, including basic height, weight, vital capacity, and other tests. These declining data reflect that the status quo of students' physical fitness is extremely unoptimistic. A person's lack of self-confidence is largely related to one's appearance, and lack of self-confidence is the cause of many mental illnesses; hence, this also causes students' mental health to become less optimistic, and they lose the vitality that adolescents of the past had such as endurance, coordination, and hard-working spirit. Homework eats up a lot of sports time of young people. They don't have time to exercise, play, and reflect the vitality of young people. Instead, they are bound by scores. They are not released from this kind of major psychological pressure, which can only be accumulated in the bottom of their hearts. This leads to poor mental health. According to a survey, university students suffer from a variety of psychological problems and the rate of students with mental health problems is 12%. In severe cases, they commit suicide. The types of psychological problems of college students are more complicated, and the detection rate of psychological problems is ranked as obsessive-compulsive disorder, interpersonal sensitivity, hostility, depression, paranoia, and anxiety [6]. At the same time, college students are weak in psychological and social adaptability, and the incidence of psychological problems has been increasing year by year; there are also extreme situations in which "small things lead to catastrophes".

At present, about 50% of college students are living with cervical subhealth problems, and some have severe cervical degenerative characteristics [7]. More than 20% of college students suffer from various degrees of mental subhealth symptoms [8]. From a cognitive perspective, the percentage of college students who believe that they are in a subhealthy state is also as high as 52%. Studies have suggested that low sleep quality is the main threat to health, but the incidence of sleep disorders among college students is increasing. About 81.26% of them have sleep disorders, and the detection rate of low sleep quality is as high as 40.2% [9]. At the same time, the "report" pointed out that 30% of college students are dissatisfied with their sleep status, 68% go to bed between 23 : 00 and 24 : 00, and 18% go to bed after 24 : 00. Sleep disorders, low-quality sleep, and late sleep are the effects of these, which speeds up the subhealth state. Scholars have used a variety of theoretical models to conduct in-depth research on the development path of the integration of sports and medicine, enriching the connotation of the top-level design of the integration of sports and medicine and clarifying the development thinking.

The "Outline" proposes that China will carry out an action to popularize health knowledge and by 2030, the health literacy level of residents will not be less than 30%. However, the level of health literacy of college students is low, and there is a serious lack of healthy lifestyle and behavior literacy [10]. Studies have suggested that health literacy is highly positively correlated with autonomous exercise awareness [11], but college students' autonomous exercise awareness is weak, which hinders the improvement of health literacy levels [12]. At this stage, college students have only 9.1% of healthy lifestyle and behaviors, which is far from the national average of 17%. Studies have shown that unhealthy lifestyle is the main threat to health, and the "2020 China University Students Health Survey Report" published by China Youth Daily pointed out that unhealthy lifestyle is common among college students. For example, girls lose weight mainly by diet and meal replacement, but 30% of people do not lose weight but increase. The reason is that they consume too much junk food, eat fewer vegetables and fruits, and eat irregularly. At the same time, insufficient exercise is a risk factor for death. The total mortality rate is 5.5%. While more than 50% of college students in China never exercise or pay attention to their own health management, organ function problems such as abnormal liver function of college students caused by unhealthy lifestyle have also increased slightly in recent years [13]. 86% of college students said they had experienced health problems such as poor skin condition, lack of sleep, and emotional problems; 77% of college students said that a rich social life and various electronic products were the main factors leading to lack of sleep; 67% of college students said they would take action to improve their lifestyle; 64% of college students believe that taking care of the health should start at a young age and one should consciously maintain physical health [14]. These data show that the health problems caused by the irregular work and unhealthy lifestyle of college students have become a barrier to the construction of a healthy campus.

In order to tap sports talents, some colleges and universities blindly increase the intensity of sports training, causing students to feel exhausted and resist; other colleges and universities focus on the students' sports performance, and students perform mechanical exercises in order to obtain sports credits. Training: It is difficult to experience the fun of physical learning when the physical fitness level is not good. Even if the student's physical fitness level reaches the standard, it is difficult to carry out continuous exercise due to lack of exercise awareness and lack of self-discipline ability, resulting in the decline of the students' cardiopulmonary ability and physical fitness indicators in the later period. Analyzed from the perspective of the education system, more college students have suffered a serious decline in their physical health. The main reason is that the current model of exam-oriented education in our country has made physical activities inadequate.

A total of 400 questionnaires were randomly selected from freshmen and sophomore students in a university. A total of 400 questionnaires were distributed, 400 copies were returned, and 396 valid questions were obtained, with an effective rate of 99%.

A survey and analysis of the results of students' physical test results were conducted. From the survey results in Table 1, it can be seen that 19.9% of the students have excellent results in the physical test, 28.5% of the students are good, 31.8% of the students passed, and 19.7% of students failed. From this set of data, it can be seen that the current college students' physical fitness is not high and the students' physical test scores are between pass and good. The results of the physical test can reflect the physical health of the students. Improving the physical fitness of the students and improving the results of the physical test are challenges in the current college physical education teaching setup.

From the survey results in Table 2, it can be seen that 19.9% of students regularly participate in physical exercise, 16.4% of students regularly perform physical exercise, 45.2% of students occasionally perform physical exercise, and 18.4% of students hardly perform physical exercise. From this set of data, it can be seen that the current college students are less involved in exercise. In order to continuously improve the physical health of students, it is necessary to increase the time of students' physical exercise. Students need corresponding sports venues and sports equipment for physical exercise. Although colleges and universities continue to increase their investment in facilities and venue construction, there is still a shortage of supply. Although some colleges and universities have a relatively wide range of sports venues, it is difficult for the construction of facilities to meet the standards. Some colleges and universities have very strict management of facilities and venues due to the fear of loss and the lack of maintenance of sports facilities and rarely open them to students. In addition, some colleges and universities have physical teaching venues. All of the above-mentioned reasons make it difficult for students to meet their daily sport needs, resulting in low levels of physical fitness.

Table 1: Investigation and analysis of students' physical examination ($N = 396$).

Physical test results	Excellent	Good	Pass	Failed
Number of people	79	113	126	78
Percentage	19.9	28.5	31.8	19.7

Table 2: Investigation and analysis of students' extracurricular physical exercises.

Exercise frequency	Regular	Frequently	Occasionally	Almost not
Number of people	79	65	179	73
Percentage	19.9	16.4	45.2	18.4

4. Reformation Strategy of Health Education of "Integration of Sports and Medicine" in Physical Education in Colleges and Universities

The health problems of college students and the problems of health management of students in colleges and universities have seriously hindered the implementation of relevant policies of a healthy China and the progress of school sports and have become a necessary factor in the reformation and development of college students' health management.

The integration of sports and medicine is a new thinking in the development of health management. The "Outline" proposes to promote the formation of a disease management and health service model that integrates sports and medicine and to give full play to the active role of national scientific fitness in health promotion, chronic disease prevention, and rehabilitation. At present, the integration of sports and medicine has become a research hotspot. From the perspective of health elements, Guo and Zheng [15] proposed that the integration of sports and medicine is a model of using sports and medical methods to promote health and other aspects. In the context of the national health strategy and the construction of a healthy China, the integration of sports and medicine has been the health service model that the "Outline" has promoted. Its core is to actively mobilize the health promotion forces and resources of all parties under the integrated thinking and focus on the use of medicine. The scientific health promotion carried out by knowledge and sports science is a new model of health management development promoted by the state and is of great significance to the research on health management of college students.

Only when teachers reflect on teaching and discover and solve problems in time can the quality of college physical education be improved. Diversified teaching can ignite the sports enthusiasm of college students, allowing them to use their spare time for independent training. For example, teachers can use information-based teaching methods to broadcast corresponding sports games videos to cultivate students' sports spirit and promote tactical teaching. Colleges and universities must establish a sound physical and health education curriculum system.

We should promote traditional sports culture, enrich the content of school-based sports courses, and moderately increase burden on students. We also can set up "second classrooms" to meet students with different learning interests and sport needs, help them understand sports culture knowledge, cultivate their sports spirit and character, establish diversified sports clubs, and organize colorful athletic activities. Only by adhering to the educational philosophy of "health first and comprehensive education" can colleges and universities cultivate students' appropriate sports concepts, encourage them to integrate into physical education activities, make them feel the importance of sports to health, and improve their physical endurance, explosive power, and exercise speed.

First, colleges can increase the proportion of health education with the main teaching content of healthy physical fitness, health education, sports nutrition, physical and mental development characteristics of college students, chronic disease characteristics and prevention, etc., to improve the basic theoretical knowledge of sports and health of college students. Second, regular health lectures are to be held to inform college students of the relationship between their physical fitness level and work efficiency, competitiveness, quality of life, and the occurrence of chronic diseases in the form of cases so that college students will pay attention to learn health knowledge and skills from the ideological level and then achieve the goal of health education. Purpose: Third, carrying out various forms of fitness activities, after-school competitions, fun sports activities, etc., actively creates a platform to attract college students to participate in sports activities. The purpose and development target of physical education are all students. The main task of teaching is the acquisition of students' physical education. In teaching, teachers should provide timely and accurate feedback of students' learning changes to them so as to provide them with value for improving their learning status. Please refer to Figure 1 for relevant details.

The "five in one" public physical education curriculum system with equal emphasis on both inside and outside classes and a two-pronged approach between theory and practice [16] is shown in Figure 2. The class focuses on the combination of human science knowledge and special skills and incorporates the concept of integration of sports and medicine into the whole process of syllabus formulation, course goal setting, and teaching design. Based on the principles of fitness, culture, science, and teachability of the course content, the commonality of basic physical disciplines and basic medical disciplines is highlighted; taking the professional interest of medical students as the starting point, the teaching content is matched, and the scientific nature of the movement skills of medical students is improved so that they understand. Extracurricular: Relying on the advantages of the background of medical schools, the content related to sports prescriptions is incorporated into the development goals of the sports courses of medical schools using the student sports medicine club as the carrier; serving the school team, after-school exercise, and various sports events at all levels on the campus are used as the practice platform to strengthen the practical level of students' physical and medical integration skills. On the basis of exploring the relevance of the integration of sports and medicine and health management, combining the spirit of the "Outline" and the thinking of integrating sports and medicine, it is proposed to establish a "health management committee," reorganize the "health management center for integration of sports and medicine," build a "pyramid-style" health management model, build a "five-in-one" data platform, strengthen health education, cultivate healthy lifestyles and other reforms, and develop strategies for college students' health management.

According to the "Healthy China 2030" planning outline," the spirit of "Internet + health care" services is proposed, and the "integration of sports and medicine" construction model for college sports is established to establish an "integration of sports and medicine" smart health information platform for college students. Construction idea: When registering in the educational administration teaching system, each student enters the high-school and school physical examination information, physical fitness test data, personal health status, and physical experience after each exercise; the school hospital's health doctor estimates potential exercise risks. Sports health teachers put forward exercise prescriptions. Students choose appropriate venue facilities and exercise programs for scientific exercise through the suggestions of physical medicine teachers so as to realize the intelligent and convenient consultation and guidance of college teachers and accelerate the process of "Internet + physical medicine integration" in college sports. In order to promote the in-depth implementation of the new teaching reforms of physical education in colleges and universities, the physical fitness of college students should be improved, their physical test scores should be improved, and the failure rate should be reduced; college physical education teachers should promptly change their educational concepts and make up for their teaching shortcomings.

From Figure 3, we can see that the "sports–medical integration" platform service model is a systematic project, which consists of information–resource integration, exercise prescription formulation, fitness effect evaluation, process monitoring, and information feedback. (Health teachers and doctors and) college student groups participate in collaboration; increase publicity and promotion; compound talent training and administrative support; improve educational administration organization and management; and promote the integration and innovation of sports and hospitals so that lifelong sports and health education can be realized, as well as life education, physical fitness, disease prevention, and other educational demands.

5. The Guiding Significance of "Integration of Sports and Medicine" to the Reform of College Physical Education and Health Education

"Integration of sports and medicine" is one of the important means for the implementation of the sports curriculum construction strategy. It integrates scientific sports with the comprehensive sports curriculum construction service system for the trinity of prevention, treatment, and rehabilitation, which is important for the overall improvement of the health of the whole people. The integration of sports and medicine is not only a requirement for cultivating the builders of socialist modernization but also a key task in the implementation of the healthy China construction strategy. It is an all-round exploration of the basic path of the physical health promotion of

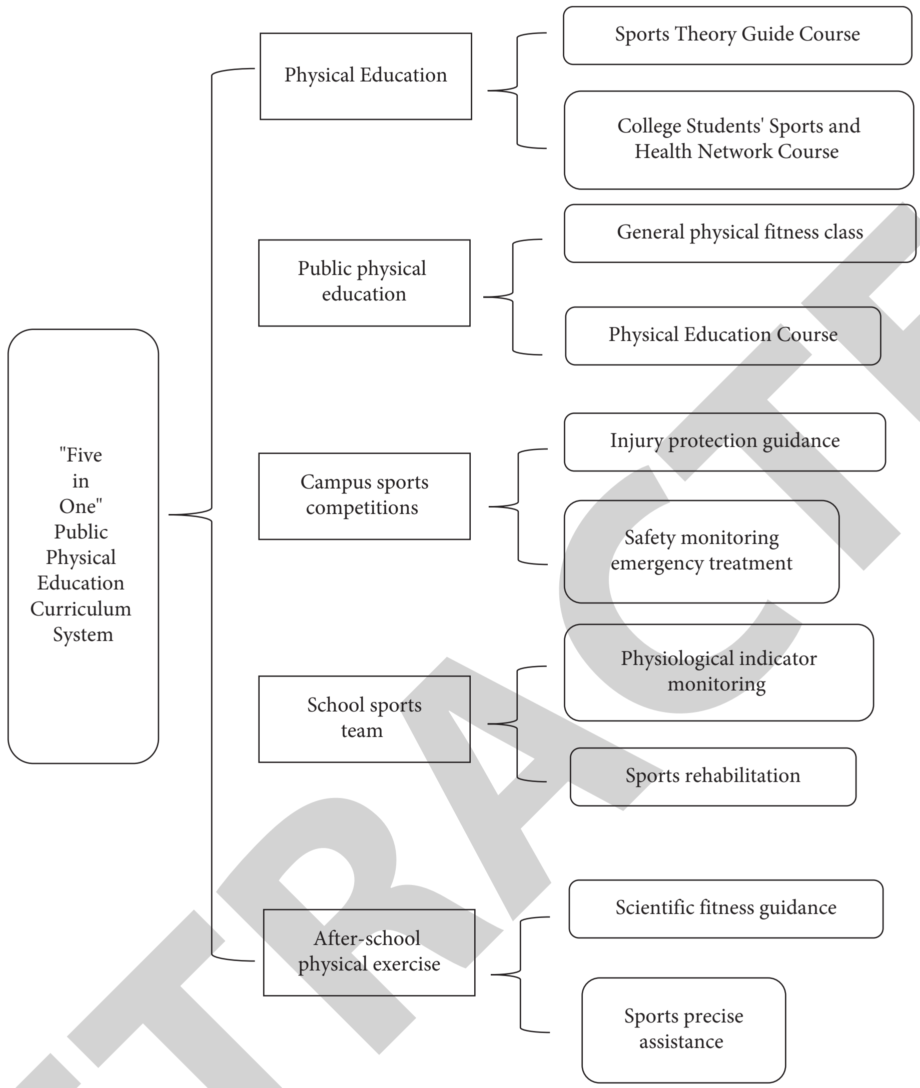

Figure 1: "Sports and medicine integration" sports health education system.

college students in order to promote the integration of sports and medicine.

Academic pressure is another major factor leading to the decline in physical health of college students. Before entering colleges and universities, students experienced three years of hardcore studies in high school and gave up a lot of exercise time in high school. Therefore, even after entering college, most students have lost the habit of exercising, and their physical fitness gradually deteriorated. In addition to the above-mentioned reasons, with the increasingly fierce social competition, more college students use their extracurricular time to study English and prepare for postgraduate entrance examinations and various qualification exams, which hinder students' physical exercise. Many college students approaching graduation, in order to be able to find the ideal job upon graduation, give up all the exercise time.

Nutrition has a basic material effect on the physical health of life and is the energy source for the main life activities of the human body. Balanced material nutrition is a material prerequisite for strengthening the system of college students and improving their health. Most college students live on campus, so it is often difficult to have a healthy life through diet. For this reason, major colleges and universities should strengthen the management of canteens. The scale of canteens should be expanded, attention should be paid to nutritional diet planning, and a healthy and balanced diet should be promoted.

For the effective development of sports activities, the strengths of all walks of life should be made to full use, taking into account the internal and external factors, to form a strong synergy and establish a three-dimensional pattern of physical health promotion of college students and a good environment and to make due contributions to cultivating college students' lifelong sports awareness. On the basis of the investigation of the status quo and analysis of the development trend of the "integration of physical education and medicine" teaching service model in college sports, full play will be given to the scientific and technological service

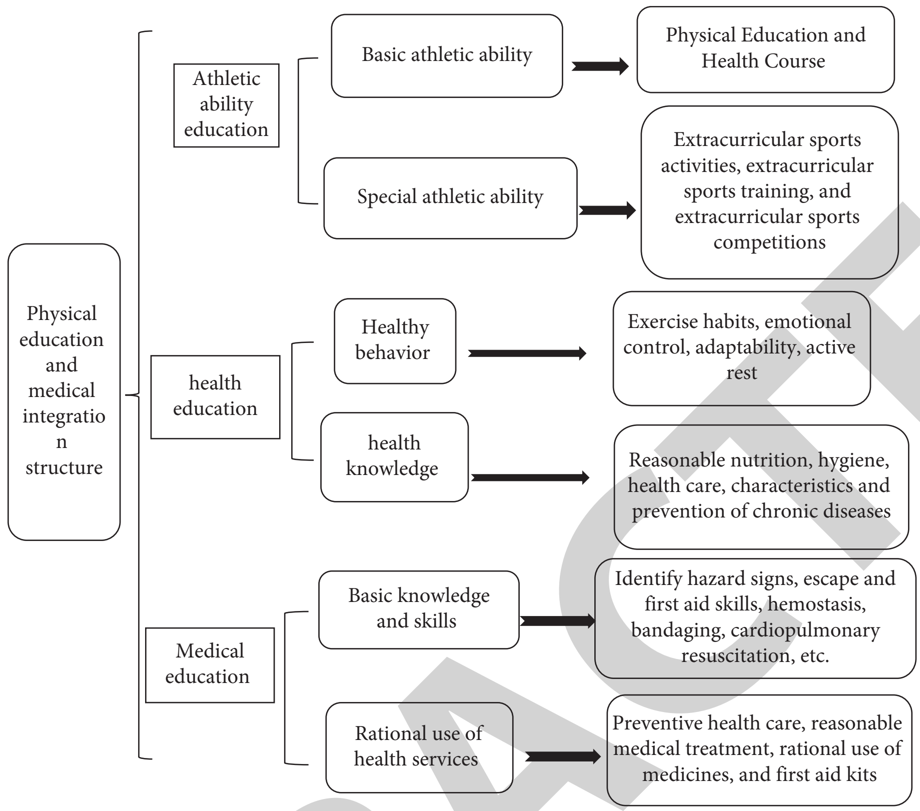

Figure 2: "Five-in-one" public physical education curriculum system.

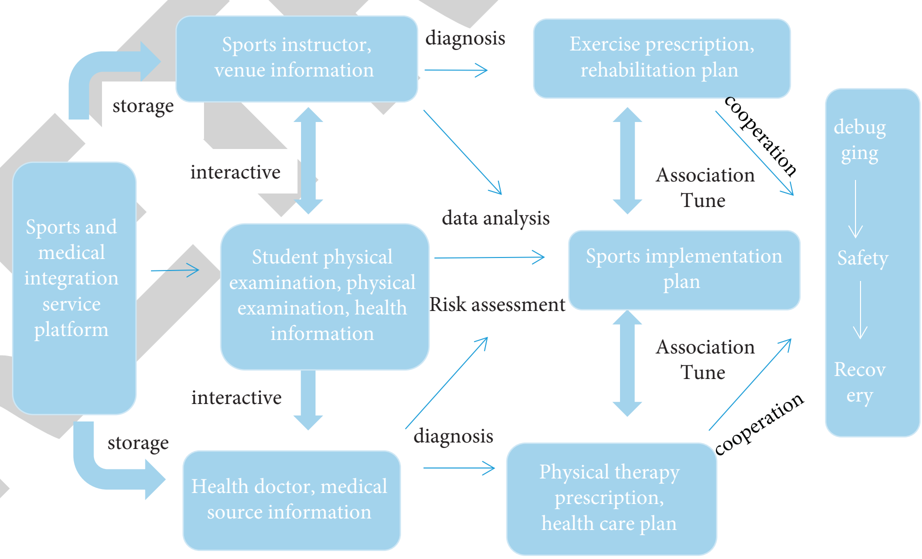

Figure 3: The framework of the teaching platform of "integration of sports and medicine" in colleges and universities.

advantages of the educational administration platform of colleges and universities and the importance of sports risk management and control will be advocated, with sports health programs as the starting point. A "sports–medical integration" teaching service platform that provides services such as exercise ability assessment and exercise prescriptions for students should be created.

6. Conclusion

The integration of physical and medical health promotion is a solution to college students under the new situation. The most obvious and effective method for improving physical fitness can be the fastest and most efficient way to meet the sports and health needs of college students. In order to

CD8+ T cells are required for the establishment of antitumor immunity, and their substantial infiltration is associated with a good prognosis. However, CD8+ T cell subsets in the tumor microenvironment may play distinct roles in tumor progression, prognosis, and immunotherapy. In this study, we used the scRNA-seq data of hepatocellular carcinoma (HCC) to reveal the heterogeneity of different CD8+ T cell subsets. The scRNA-seq data set GSE149614 was obtained from the GEO database, and the transcriptome and sample phenotypic data of TCGA-LIHC were obtained from the TCGA database. CD8+ T cell subtypes and metabolic gene sets were obtained from published reports. The data processing and analysis of CD8+ T cell groups was performed by *R* language. The PPI network was constructed to obtain the hub genes, and the KM survival curve of the hub genes was further plotted to determine the hub genes with differences in survival. CD8+ T cells in HCC were divided into 7 subsets, and the cytotoxic CD8 T cells 4 subset showed considerable differences between the TP53-mutant and nonmutant groups, as well as between different degrees of cirrhosis, HCC grades, stages, ages, and body weights. Cytotoxic CD8 T cells 4 differential genes were analyzed by TCGA-LIHC data and single-cell sequencing data set. 10 hub genes were found: FGA, ApoA1, ApoH, AHSG, FGB, HP, TTR, TF, HPX, and APOC3. Different subsets of CD8+ T cells were found to contribute to heterogeneous prognosis and pathway activity in HCC. Alterations in the cytotoxic and immune checkpoint gene expression during CD8+ T cell differentiation were also identified. We found that cytotoxic CD8 T cells 4 is closely associated with survival and prognosis of HCC and identified four differential genes that can be used as biological markers for survival, prognosis, and clinically relevant characteristics of HCC. Results of this study could help finding targets for immunotherapy of HCC and aid in the accelerated development of immunotherapy for HCC.

1. Introduction

Hepatocellular carcinoma (HCC) is a type of liver cancer that is extremely common [1]. Traditional treatment methods for HCC mainly include surgical treatment (liver resection, liver transplantation), radiofrequency, microwave ablation, embolization (transcatheter hepatic arterial chemoembolization, TACE), and sorafenib [2–6]. In the early stage of hepatocellular carcinoma, the symptoms are hidden without characteristics; hence, most of the patients have developed to the middle and late stage when diagnosed, most of them cannot accept radical treatment, and the prognosis is poor [7]. In recent years, immunotherapy has produced good therapeutic effects in the therapy of various malignant tumors, including melanoma and hematological malignancies, while the therapeutic effects in solid malignant tumors are not satisfactory, especially in HCC [8, 9]. On the one hand, this is related to the complex microenvironment in solid tumors, including low oxygen, high pH, nutritional deficiency, and immunosuppressive cells and factors [10–13]; and on the other hand, the disorder of the functional state of the relevant immune cells in the tumor is also an important factor leading to ineffective or inefficient immunotherapy [14].

Immune imbalance in the microenvironment of the tumor is one of the important characteristics of the tumor.

The adaptive immune response, which is mediated by immune cells, is important in the occurrence and development of tumors [15]. CD8+ T cells are the main antitumor effector cells [16]. The weakened antitumor immunity characterized by CD8+ T cell function disorder plays an essential role in the occurrence and development of hepatocellular carcinoma [17, 18]. CD8+ T cells from the circulation migrate and infiltrate into tumor tissues and are stimulated by contact with tumor antigens to become effective CD8+ T cells with the killing effect of tumor microcytes [19, 20].

In the process of antitumor immune response in normal organisms, antigen-presenting cells present tumor-specific antigen (TSA) as major histocompatibility complex (MHC) and bind to T cell surface TCR (T cell receptor) and then, under the action of various costimulatory signal molecules, activate T cells; activated T cells, mainly cytotoxic CD8+ T cells, bind to tumor cells via recognition of TSA on their surface and kill tumor cells after the costimulatory signal is activated [21, 22]. The activation of costimulatory signal plays an essential role in the killing of tumor by T cells [23]. In tumor microenvironment (TME) T cells, the expressions of costimulatory signal molecules including CD137, CD28, and OX40 are often significantly decreased [24–26], while the expressions of costimulatory signal molecules such as cytotoxic T-lymphocyte-associated protein 4 (CTLA4), programmed cell death protein 1 (PD-1), and T-cell immunoglobulin mucin-3 (TIM-3) are significantly increased [27–29]. These costimulating/inhibiting molecules are known as immune checkpoints, and the treatment of these signaling molecules is also known as immune checkpoint therapy.

Immunocheckpoint therapy has achieved a series of successes in the treatment of solid tumors, breaking through the original view that tumor immunotherapy may only be effective for immunogenic melanoma and kidney cancer [30]. Recent clinical studies have shown that monotherapy has achieved good efficacy in solid tumors such as non-small-cell lung cancer (NSCLC), colorectal cancer, and gastric cancer, and the safety of most immunotherapies has also been recognized [31–33]. The Food and Drug Administration (FDA) and the European Union have approved several immune checkpoint inhibitors and monoclonal antibodies for clinical tumor treatment, such as CTLA4 monoclonal antibody ipilimumab, PD1 monoclonal antibody nivolumab, etc. [34].

Like NSCLC and colorectal cancer, HCC cells also express a large number of co-inhibitory components such as PD-L1 on the surface, but unfortunately, the efficacy of immune checkpoint inhibitors has not been adequately evaluated in early clinical trials [35]. The current scRNA-seq technique is widely used in the study of cell heterogeneity. However, due to the need for preamplification of cDNA before library construction, poor amplification may lead to the loss of some information. To more comprehensively identify the differences among hepatocellular carcinoma cells, Xiao et al. [36] for the first time implemented the Holo-Seq technique to obtain the transcriptome information of mRNAs and small RNAs from a single cell at the same time and combined the information to determine intercellular heterogeneity. In this study, Holo-Seq technology was applied to analyze single cells of human liver cancer, and it was found that mitochondrial activity was downregulated in the early stage of liver cancer [36]. Moreover, tumor suppressor miRNA and tumor-promoting miRNA were upregulated earlier than the activation of classical tumor-promoting signaling pathway [36]. These findings provide important information and references for diagnosing liver cancer. Additionally, they drew a cluster map based on double transcriptional profiles of single-cell mRNAs and miRNAs in HCC [36]. Compared with single scRNA-seq clustering analysis, this approach enables a more complete understanding of the tumor cell heterogeneity in HCC and discover new cell subpopulations.

In this study, we used the scRNA-seq data of hepatocellular carcinoma to reveal the heterogeneity of different CD8+ T cell subsets. The cellular components of the CD8+ T cell subpopulation in liver cancer patients under different states of liver cirrhosis, grade, stage, age, and body weight were determined, and the activity analysis of metabolic pathway and hallmark pathway was carried out based on the pipeline analysis of pathway activity based on single-cell sequencing data. Cell differentiation trajectory and cell-cell interaction network analysis was performed, and the hub genes' expression in different cancers was determined for prognosis/treatment marker identification. Different subsets of CD8+ T cells were found to contribute to heterogeneous prognosis and pathway activity in HCC. Alterations in an immune checkpoint and cytotoxic gene expression during CD8+ T cell differentiation were also identified.

2. Materials and Methods

2.1. scRNA-seq and RNA-seq Data. HCC scRNA-seq was downloaded from the Gene Expression Omnibus (GEO) database (GSE149614), and a total of 34,414 cells from 10 HCC tissue samples were screened. From the TCGA Xena database (https://xenabrowser.net/datapages/), the transcriptome and sample phenotypic data of TCGA-LIHC were downloaded; a total of 424 samples were obtained, of which 374 were tumor tissues (6 of the samples had no survival information and were excluded from subsequent analysis) and 50 were normal tissues. The expressed value from log2 (count +1) were converted to count for subsequent analysis. CD8+ T cell subtypes were obtained from the study by Deng et al. [37]. A total of 85 metabolic gene sets were obtained from Xiao et al. [38], and a total of 50 hallmark gene sets were downloaded from h.all.v7.3.symbols.gmt from MSigDB.

2.2. Identification of CD8+ T Cell Subsets. The R package "Seurat" was used to map the expression profile of CD8A and CD8B (CD8+ T cell markers) and determine the CD8+ T cell population. CD8+ T cells were selected, and UMAP cluster analysis was performed again, and each cell subpopulation was annotated according to the expression distribution of CD8+ T cell subtypes. The proportion of each subtype of CD8+ T cells was counted, and a bar chart was drawn using the R package "ggplot2" for display. Hypervariable genes of each subtype were examined with the help of the Seurat package. To find all markers functions, the min.pct and logfc.threshold parameters set at 0.25 were used. The top 10 highly variable genes of each subtype were selected, and the R package "pheatmap" was used to draw the heatmap of gene expression. Marker genes of previously reported studies were employed to annotate subpopulations of CD8+ T cells including naive/memory CD8+ T cells (CCR7, IL7R, TCF7, SELL, SATB1, GPR183, LTB, LEF1, and S100A10), exhausted CD8+ T cells (CXCL13, HSPB1, IRF4, LAYN, GIMAP6, HSPH1, CXCR6, CTLA4, PDCD1, LAG3, HAVCR2, and TIGIT), and cytotoxic CD8+ T cells (PRF1, GZMA, GZMK, and NKG7).

2.3. The Cellular Components of the CD8+ T Cell Subpopulation. The Seurat package was used to obtain the hypervariable genes of each subtype of CD8+ T cells, and they were screened according to the Bonferroni correction P value <0.05. For screening of gene expression (count), CIBERSORTx (https://cibersortx.stanford.edu/) tools were used following the default parameters of CD8+ T cell subtype of liver cancer signature matrix file. The transcriptome data of TCGA-LIHC were collated, and the count was converted into CPM as the input file of CIBERSORTx to estimate the content of CD8+ T cell subtypes in liver cancer. The surv_cutpoint function was used to analyze the cell content of each subtype, and the cell content of TCGA-LIHC samples was divided into groups of high and low levels, and the survival curve of KM was plotted using Survival packet and survminer packet. The phenotypic data of TCGA-LIHC were sorted. Boxplots were drawn to show the difference in cell content between TP53 mutation and gender, and line plots were drawn to show the content of CD8+ T cell subtypes in liver cancer patients under different states of liver cirrhosis, grade, stage, age, and body weight.

2.4. Pathway Activity Analysis. For scRNA-seq data, the FindMarkers function of the Seurat package was used to obtain the hypervariable genes of each subtype of CD8+ T cells and screen them according to the Bonferroni correction P value <0.05. The ClusterProfiler package was used for Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis, and then using ggplot2, a bubble chart was drawn to display the results. According to the research report of Xiao et al. [38], the activity analysis of metabolic pathway and hallmark pathway was carried out based on the pipeline analysis of pathway activity based on single-cell sequencing data.

2.5. Cell Differentiation Trajectory and Cell-Cell Interaction Network Analysis. Using the package's default parameters, the Slingshot package was utilized to assess the cell differentiation trajectory and the distribution of marker gene expression. The single-cell sequencing data of CD8+ T cells were collated, and the interaction network analysis of CD8+ T cell subtypes was conducted using CellPhoneDB software developed based on Python. The R package SCENIC was used to construct the gene regulation network of CD8+ T cell subtypes.

2.6. Prognosis/Treatment Marker Identification. CD8+ T cell subtypes with significant differences in survival analysis were selected and grouped according to the cell content of the cell subtypes. Differential analysis was performed on the TCGA-LIHC expression data (R package DESeq2), following |log2(-FoldChange)|>1 and corrected the P value <0.05 for differential genes screening. The protein-protein interaction (PPI) network was constructed using the String database (https://www.string-db.org/), and Cytoscape (v3.7.2) and cytoHubba plug-in were used to screen the hub genes. The hub genes were divided into two groups based on their expression levels: high and low according to the median number of hub genes. Kaplan–Meier (KM) survival curves were plotted using the survival package R and Survminer. Hub genes with survival differences were selected and single-gene gene set enrichment analysis (GSEA) was performed using the clusterProfiler package. According to different clinical features, ggstatsplot was used to plot boxplots to show hub gene expression levels with significant differences in survival. The TCGA pan-cancer data was downloaded from the TCGA Xena database, and hub gene expression in various tumors was shown in a bar graph.

2.7. Statistical Analysis. Genes differently expressed in different subsets, KEGG, GO, and GSEA analyses were analyzed statistically using the corresponding software packages or default methods in the software. Random arrangement tests exhibited statistical pathway activity. Student's test was used to assess the frequency of different cell types in normal and tumor samples; statistical analysis was also used to examine the levels of expression in tumors and normal tissue samples. The significance of the KM curves was tested using the log-rank test. The Kruskal–Wallis test was used to determine dynamic changes in cell proportion and levels of gene expression at various stages of pathology.

3. Results

3.1. Data Download and Preprocessing. For liver cancer, the scRNA-seq data set GSE149614 was downloaded from the GEO database (https://www.ncbi.nlm.nih.gov/geo/) and 10 liver cancer tissue samples were screened with a total of 34,414 cells. From the TCGA Xena database (https://xenabrowser.net/datapages/), the transcriptome and sample phenotypic data of the TCGA-LIHC were downloaded; a total of 424 samples were obtained, of which 374 were tumor tissues (6 samples had no survival information and were excluded from subsequent analysis) and 50 were normal tissues.

Single-cell sequencing results showed that the gene number of the samples was mainly distributed between 1000 and 8000, the gene count was mainly distributed between 100 and 50,000, and the mitochondrial proportion was mainly distributed between 0 and 5% (Figure 1). The correlation between the depth of the sequencing and the

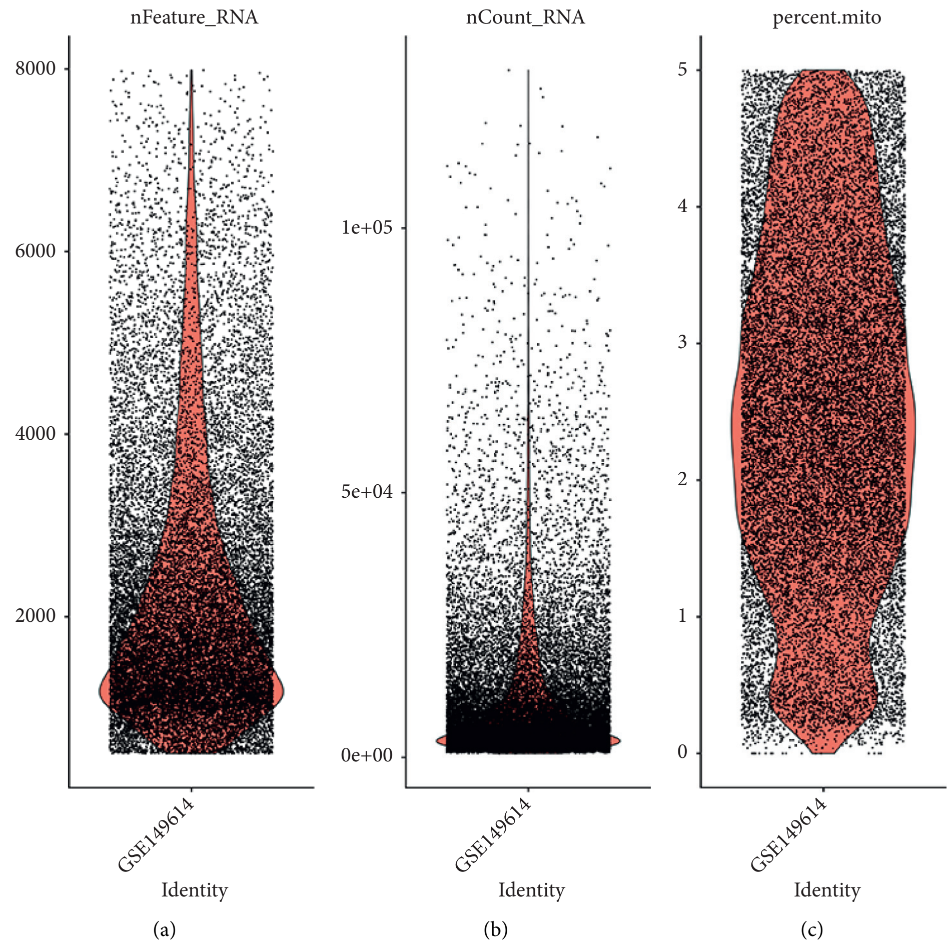

Figure 1: Quality control chart of GSE149614 single-cell data set. (a) The number of genes in a cell. (b) Count distribution of genes. (c) Figure: mitochondria percentage.

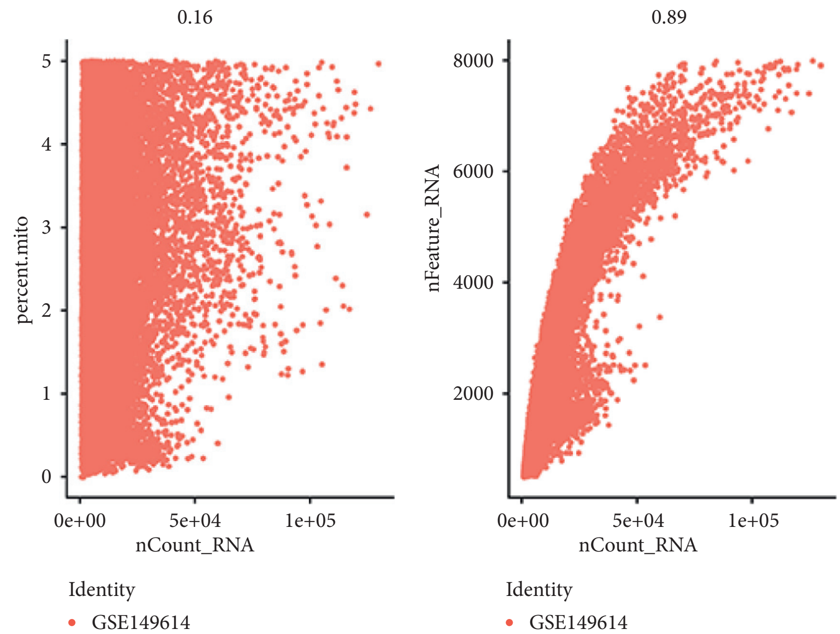
number of genes detected was 0.89, and between the sequencing depth and mitochondria was 0.16, indicating a positive correlation of sequencing depth with the number of measured genes (Figure 2). 2000 differentially expressed genes that are highly expressed were selected for principal component analysis (PCA), and the differences between the first 15 PCs were all highly significant, suggesting a considerable difference between theoretical and actual values, which was used for additional analysis (Figure 3).

3.2. CD8+ T Cell Extraction and Subpopulation Recognition. The UMAP method was used for clustering, and 26 clusters were obtained (Figure 4(b)). Because it was a tumor tissue sample, the heterogeneity was high (Figure 4(a)). CD8A and CD8B were mainly distributed in cluster 0, 6, 9, 16, and 24, with a total of 5062 cells (Figure 5). The cells of these groups were pulled out, and UMAP clustering was performed again to obtain 7 CD8+ T subgroups (Figure 6). CD8+ T cell subtype markers were obtained from the research report of Deng et al. [37], that is, markers of naive/memory CD8 T cells: CCR7, IL7R, TCF7, SELL, SATB1, GPR183, LTB, LEF1, and S100A10; the markers of cytotoxic CD8 T cells: PRF1, GZMA, GZMK, and NKG7; and the markers of exhausted CD8 T cells: CXCL13, HSPB1, IRF4, LAYN, GIMAP6, HSPH1, CXCR6, CTLA4, PDCD1, LAG3, HAVCR2, and TIGIT. Based on the expression of the above markers, 7 cell subgroups were annotated as follows: naive/memory CD8 T cells, exhausted CD8 T cells 1, exhausted CD8 T cells 2, cytotoxic CD8 T cells 1, cytotoxic CD8 T cells 2, cytotoxic CD8 T cells 3, and cytotoxic CD8 T cells 4.

3.3. Cell Proportion and Cell Marker Expression. The proportion of cells in each subpopulation was shown to be naive/memory CD8 T cells in the HCC TME. The proportion of the medium is the highest, followed by exhausted CD8 T cells 1, and the lowest is cytotoxic CD8 T cells 4 (Figure S1A of the supplementary information file). At the same time, the expression of top 10 differentially expressed genes in seven CD8+ T subsets was analyzed (Figure S1B). According to the transcriptome data of TCGA-LIHC, CIBERSORTx calculated that cytotoxic CD8 T cells 4 and exhausted CD8 T cells 2 accounted for the highest proportion (Figure S8, Table S1).



(a) (b)

(a) (b)

Figure 3: PCA analysis. (a) The difference between the theoretical and actual values of the first 20 PCs. (b) Elbow plot.

3.4. Analysis of Prognosis and Clinical Correlation. The survival analysis was performed by log-rank test. The survival difference of the overall immune cell proportion group was statistically significant, and there was a significant survival difference between the groups with a high and low proportion of cytotoxic CD8 T cells 4. The survival difference between the exhausted CD8 T cells 2 and naive/memory CD8 T cells was not statistically significant (Figure S2, Table S2). Cytotoxic CD8 T cells 4 differed significantly between the TP53 mutant and nonmutant groups (nonparametric Wilcox rank-sum test) and between sex (Figures S9A and S9B). Among cirrhosis groups of different degrees, the proportion of cytotoxic CD8 T cells 4 increased first and was the lowest in nodular formation and

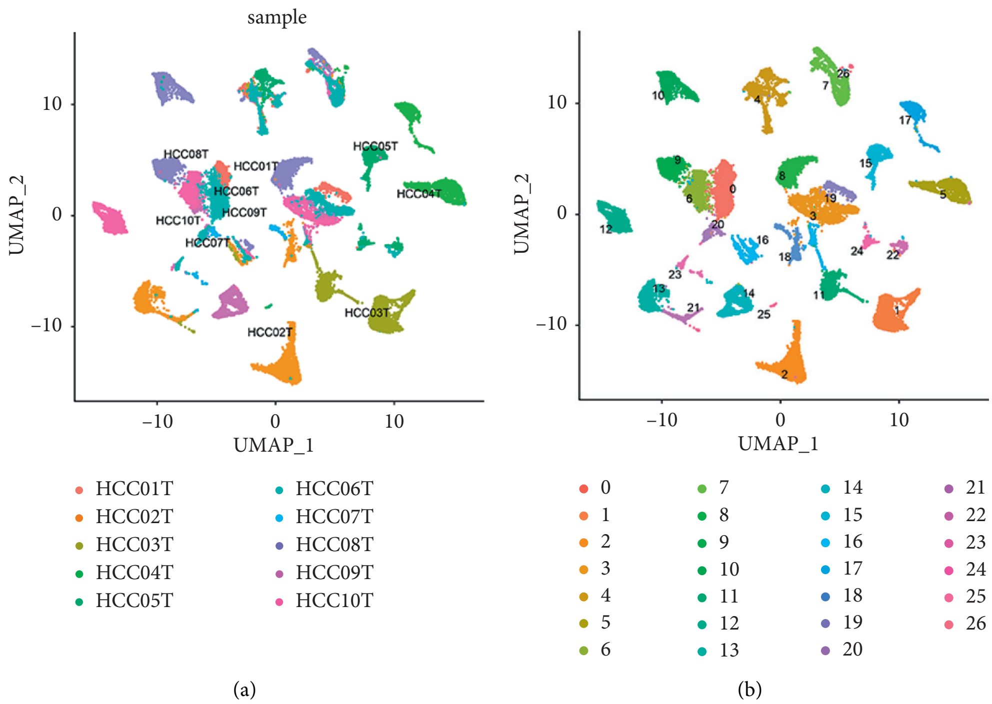

Figure 4: Clustering diagram of cells. (a) Labeled according to the sample name. (b) Labeled according to cluster ID.

incomplete cirrhosis (Figure S9C). In the grading of liver cancer, the ratio of cytotoxic CD8 T cells 4 was highest in G2 and then decreased progressively (Figure S9D). The proportion of cytotoxic CD8 T cells 4 decreased first and then increased in the stage of liver cancer (Figure S9E). The proportion of cytotoxic CD8 T cells 4 was lowest in the 40–60 years age group (Figure S9F). The proportion of cytotoxic CD8 T cells 4 increased with increasing body weight (Figure S9G).

3.5. The Landscape of Heterogeneous Pathway Activity. To investigate the presence of heterogeneous pathways in CD8+ T cell subsets, we used GO and KEGG analysis. GO analysis showed that cytotoxic CD8 T cells 4 had an obvious biological process, cellular component, and molecular function (Figures 7(a)–7(c), Table 1). KEGG results showed that cytotoxic CD8 T cells 4 were related to ribosomes (Figure 7(d), Table 1). To elucidate the heterogeneity of various subgroups further, we also performed the analysis of cell subgroup metabolic pathway activity and hallmark immune checkpoint pathway activity. The analysis of the metabolic pathway activity of cell subsets revealed that exhausted CD8 T cells 1, exhausted CD8 T cells 2, and cytotoxic CD8 T cells 3 had strong metabolic pathway activity, and cytotoxic CD8 T cells 2 had the lowest metabolic pathway activity (Figures S3A and S3B). Oxidative phosphorylation was significantly enriched in 7 CD8+ T cell subgroups (Figure S3C). Hallmark pathway activity analysis revealed that exhausted CD8 T cells 1, exhausted CD8 T cells 2, and cytotoxic CD8 T cells 3 had strong hallmark pathway activity, and cytotoxic CD8 T cells 2 had the lowest hallmark pathway activity (Figures 8(a) and 8(b)). HALLMARK_MYC_TARGETS_V1 was significantly enriched in 7 CD8+ T cell subgroups (Figure 8(c)).

3.6. Analysis of Cell Differentiation Trajectories and Cell Interaction Networks. The initial differentiation group is not specified and a lineage is obtained from exhausted CD8 T cells 1 to cytotoxic CD8 T cells 4, as shown in Figure S4A. The PRF1, GZMA, and NKG7 genes were first downregulated, then upregulated, and finally downregulated during the development of lineage (Figures S4B–S4E).The PDCD1, HAVCR2, LAG3, CD27, CTLA4, TIGIT, and TNFRSF9 genes remained unchanged during the predifferentiation process and significantly differentiated in the mid-term and then remained unchanged (Figures S4F–S4L).

Considering the heterogeneity of CD8+ T cell subsets, we analyzed their communication networks to identify the key ligand-receptor pairs and cell subsets that dominate the interactions. The results showed that cytotoxic CD8 T cells 2, cytotoxic CD8 T cells 1, and cytotoxic CD8 T cells 4 had the highest number of ligand receptors (Figure S5A). The ligand-receptor logarithm between exhausted CD8 T cells 2 and the other 6 subtypes was less (Figure S5B), and the regulatory factors JUND, EGR1, FOSB, IRF1, IRF8, and REL were highly expressed in cytotoxic CD8 T cells 1 (Figure S5C).

3.7. Prognosis/Treatment Marker Identification. Based on the results of significant differences in survival, the differentially expressed genes were calculated first by the TCGA database, and a total of 6813 differentially expressed genes were

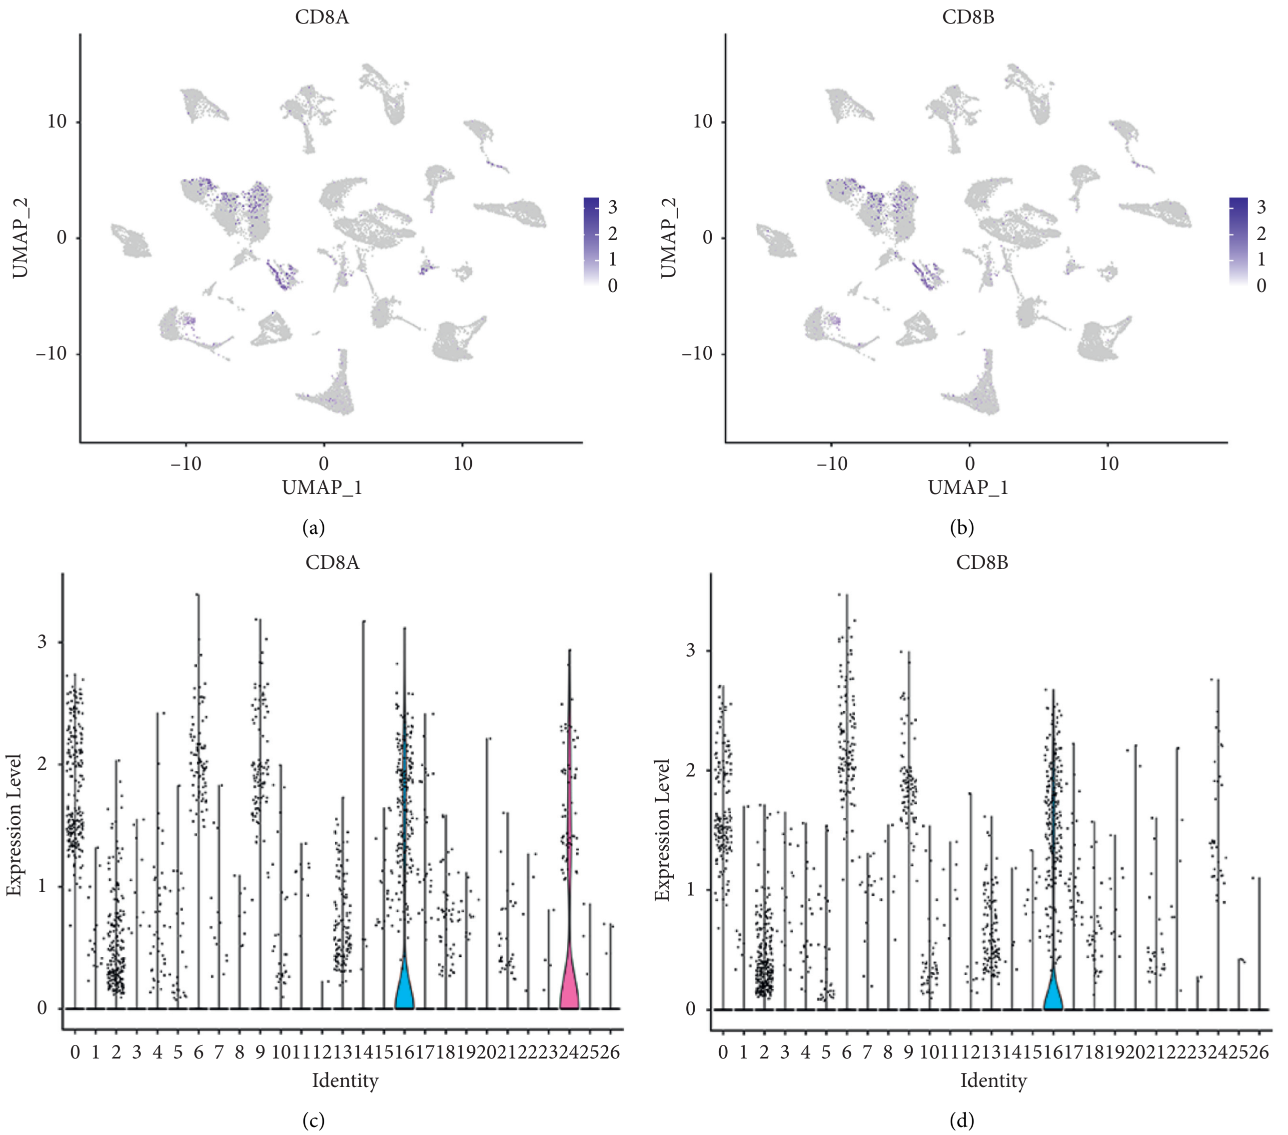

Figure 5: Expression and distribution of CD8+ T cell markers. (a, c) Expression distribution of CD8A. The darker the color, the higher the expression. (b, d) Expression distribution of CD8B.

obtained, of which 2378 were upregulated and 4435 were downregulated (Table S3). The expression of the first 50 differential genes is shown in Figures 9(a) and 9(b). Then, according to the results of significant differences in survival, the corresponding cell subsets and differentially expressed genes were selected, and the ligand receptors and transcription factors among them were given priority. If the subsequent analysis was not supported, only differentially expressed genes were selected, and a total of 168 differentially expressed genes were found. Since the survival analysis of 4 cases of cytotoxic CD8 T cells in the high and low groups showed significant survival differences, the expression of the first 50 differentially expressed genes of cytotoxic CD8 T cells 4 was selected for display (Figure S10). According to the obtained two groups of different genes, the PPI network was constructed and hub genes were identified. cytoHubba found 10 hub genes: FGA, APOA1, APOH, AHSG, FGB, HP, TTR, TF, HPX, and APOC3 (Figure 10). The log-rank test showed that APOC3 among the above 10 hub genes had statistically significant survival differences, while APOH, HPX, and FGB had significant survival differences (Figures 11(a)–11(d)). The Cox test showed that the P-values of APOC3, APOH, HPX, and FGB were 0.02, 0.14, 0.00067, and 0.034, respectively. Genetic GSEA of APOC3, APOH, HPX, and FGB was performed, and the first five enrichment items are shown in Figures 11(a)–11(d) and Table S4 in the supplementary file. Table S4 in the supplementary file shows the analysis results of single-gene GSEA of APOC3, APOH, HPX, and FGB. The expression levels of different genes in different clinical features were further analyzed, and the expression levels of genes APOC3, APOH, HPX, and FGB were significantly different in normal tissues and tumors , and were further analyzed whether TP53 mutation was present or not. There was a significant difference

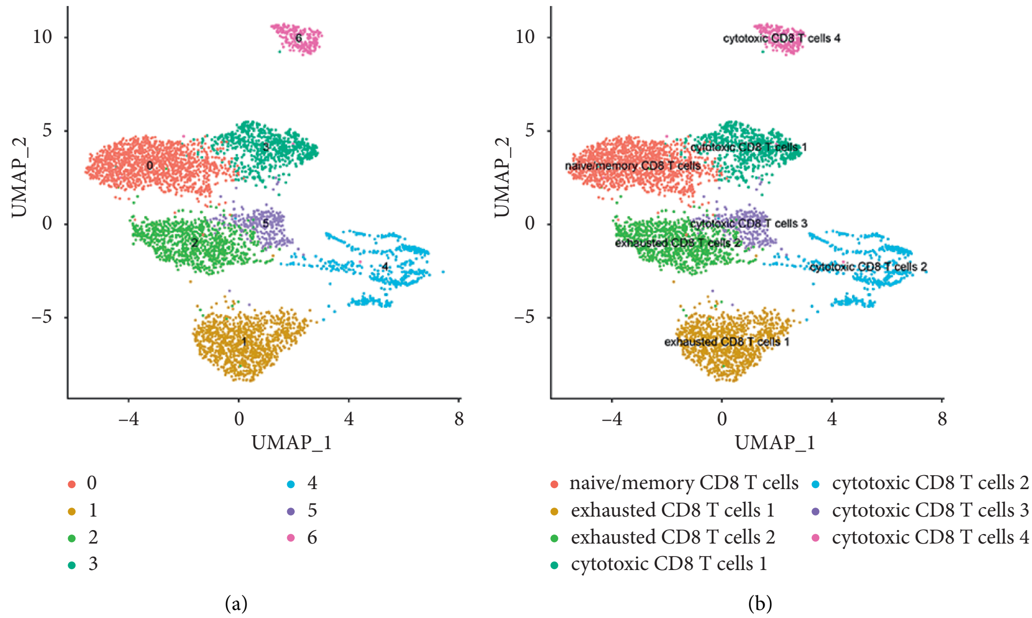

Figure 6: Cluster of CD8+ T cells. (a) An unannotated cluster diagram. (b) A cluster diagram annotated according to CD8+ T subtype markers.

($P = 0.0053$) in the expression of APOH among the sex groups. The expressions of APOC3, APOH, HPX, and FGB were not significantly different in different cirrhosis degrees and different ages ($P > 0.05$). There were significant differences in the grading and staging of liver cancer. The gene APOC3 had no significant difference among different body weights (Figures S6 and S11). Finally, the expression of different genes in different cancers was analyzed, and the results showed that the expression of genes APOC3, APOH, HPX, and FGB was the highest in liver hepatocellular carcinoma (LIHC), and the expression in normal tissues was higher than that in cancer tissues. Genes APOC3, ApoH, HPX, and FGB were also highly expressed in cholangiocarcinoma (CHOL), and their expression levels were higher in normal tissues than in cancer tissues (Figure S12).

4. Discussion

The role of tumor-infiltrating immune cells, particularly T cells, in tumor development has been revolutionized by a deeper understanding that has opened up new avenues for immunotherapeutic strategies. Previous studies have indicated that immune cells infiltrating tumors exhibit various levels of infiltration depending on the type of tumor and stages [39]. Immune-associated cells, including T cells and mast cells, have been shown to be novel prognostic markers in patients with HCC, further suggesting that the combination of immunoinfiltrating cells in tumor tissue can even predict the effects of chemotherapy and immunotherapy [40]. Due to the fact that CD8+ T cells are the most significant effector T cells in current tumor immunotherapy [41], CD8+ T cells detect tumor-associated antigens on the surface of cancer cells as major histocompatibility complex class I molecules [42].

It has been found that four coexpression genes (GZMA, C1QC, CD3D, and PSMB9) have been identified as CD8+ T cell coexpression genes that promote CD8+ T cell infiltration in HCC, and these coexpressed genes are favorably associated with the infiltration of CD8+ T lymphocytes during antigen presentation. This biological process may provide new directions for patients with stem cell cancers that are not sensitive to immunotherapy [43]. Thus, CD8+ T cells are essential for the formation of antitumor immunity, and their increased invasion is related with a favorable prognosis. CD8+ T cell subsets in the microenvironment of the tumor, on the other hand, may play distinct roles in tumor progression, prognosis, and immunotherapy. Cytotoxic CD8+ T cells have been reported to be associated with lymph node metastasis and other prognostic factors in breast cancer [44]. We found that cytotoxic CD8 T cells 4 differed significantly between the TP53-mutated and nonmutated groups, as well as with different degrees of cirrhosis, HCC grade, stage, age, and body weight. Cytotoxic CD8 T cells 4 differential genes were analyzed by the TCGA-LIHC data and single-cell sequencing data set. Finally, 10 hub genes were found: FGA, ApoA1, ApoH, AHSG, FGB, HP, TTR, TF, HPX, and APOC3. There were significant survival differences among APOC3, APOH, HPX, and FGB genes. Further analysis showed that APOC3, APOH, HPX, and FGB were significantly different in normal tissues and tumors irrespective of TP53 mutation, liver cancer grade, and stage. There was a significant difference in the expression of APOH among the sex groups. APOC3, APOH, HPX, and FGB expression levels were highest in HCC and were greater in normal tissues than that in cancer tissues. Additionally, it is significantly expressed in CHOL, and its level of expression is higher in normal tissues than that in cancer tissues. Apoprotein C3 (APOC3) is a key regulator of the

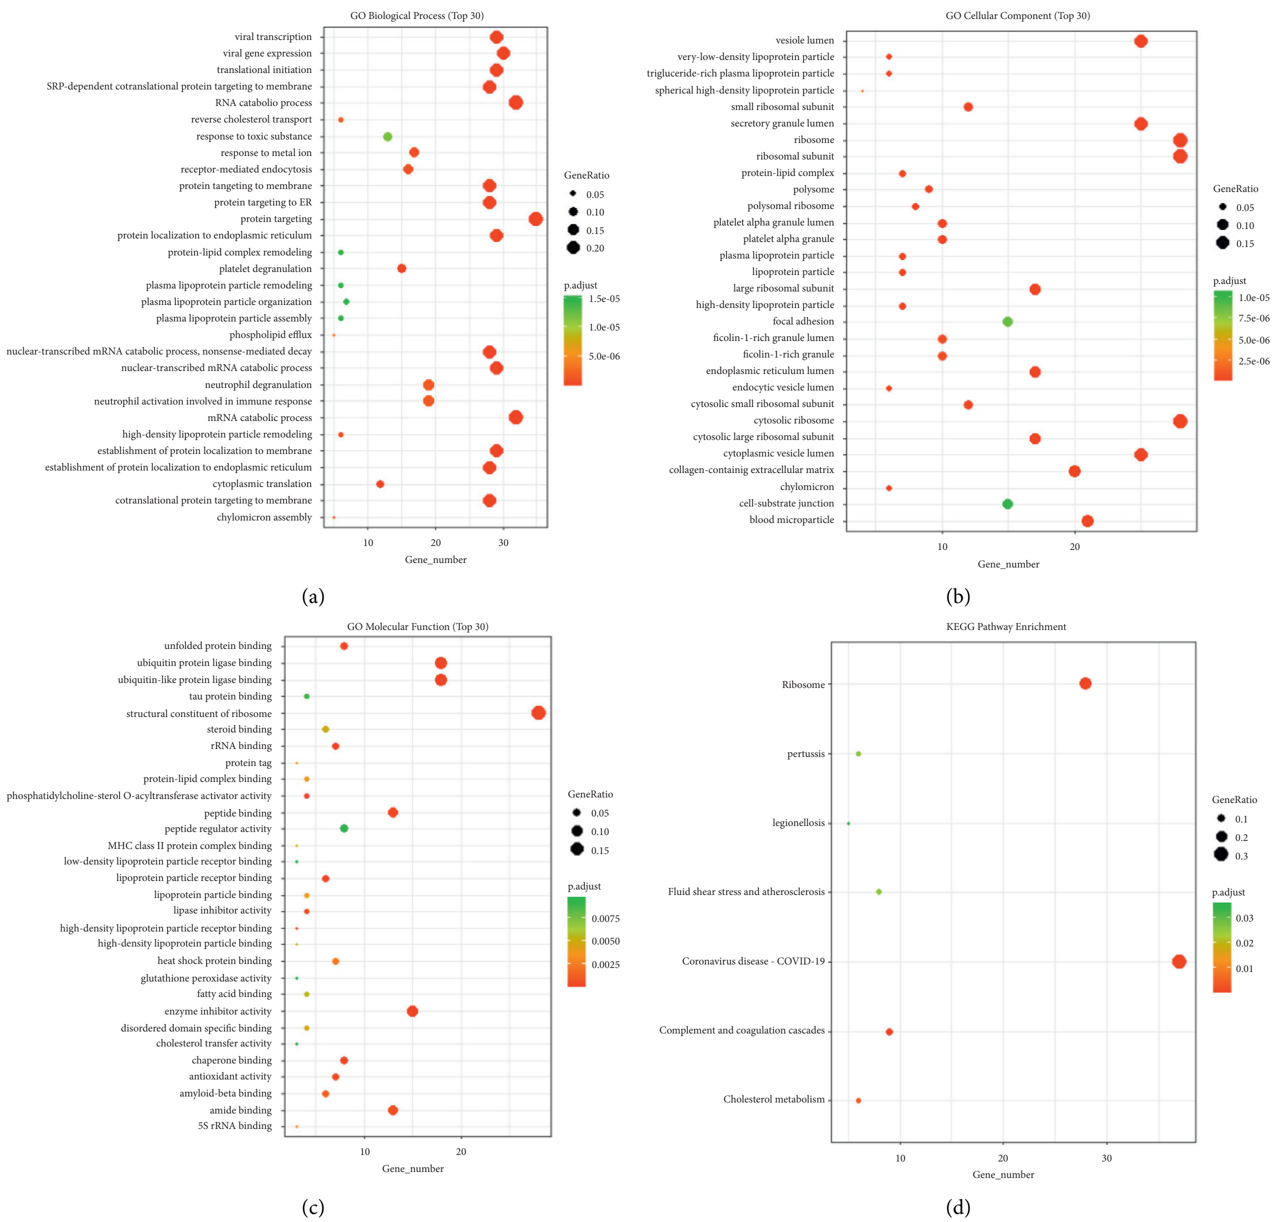

Figure 7: GO and KEGG enrichment analysis of the cytotoxic CD8 T cells 4 subgroup. (a) GO enrichment of biological process. (b) GO enrichment of cellular component. The red color is directly proportional to enrichment.

metabolism of lipoprotein and has been demonstrated to be closely associated with hypertriglyceridemia [45]. β-2-glycoprotein 1 (APOH) has been shown to be associated with liver metastasis from colorectal cancer [46]. Hemopexin (HPX), which acts as a scavenger of toxic plasma heme and a transporter of it to the liver, has been demonstrated to be closely associated to the occurrence and development of breast cancer [47, 48]. Similarly, the fibrinogen β chain (FGB) gene has been revealed to be related with renal cell carcinoma invasion and metastasis [49]. All of these provide strong evidence that APOC3, APOH, HPX, and FGB can be used as biomarkers for hepatocellular carcinoma.

Tumor immunotherapy is a new method to treat cancer in recent years, which has greatly changed the prospect of cancer treatment [50, 51]. Although significant advances can be made in treatments such as immune checkpoint blockade, their efficacy varies greatly among different patients or cancer types [52]. A detailed understanding of the internal immune microenvironment of cancer tissue is of great reference value for the development of new immunotherapy. Single-cell sequencing technology can be used as an effective tool to study the immune microenvironment of liver cancer and plays an essential role in the process of immune cell therapy and antibody drug development of liver cancer.

The incidence and mortality of liver cancer are high [53, 54]. In order to understand the immune microenvironment of liver cancer and to find new targets and effective biomarkers for the immunotherapy of liver cancer, Zheng et al. [17] performed sRNA-seq on 5063 human T cells using the SMART Seq2 technique. Subpopulation classification of T cells based on single-cell transcriptional map showed that there were a large number of dysfunctional lethal CD8+ T cells and inhibitory T cells in tumor tissues. The gene Layilin was found to inhibit the killing function of CD8+ T cells by targeting the genes specifically expressed in these two

types of cells, which may be a new potential target for immunotherapy.

5. Conclusion

Immune-associated cells, including T cells, have been shown to be novel prognostic markers in patients with HCC, suggesting that the combination of immunoinfiltrating cells in tumor tissue can even predict the effects of chemotherapy and immunotherapy. Because CD8+ T cells are the most important effector T cells in the current tumor immunotherapy and they also recognize tumor-associated antigens as major histocompatibility complex class I molecules on the surface of cancer cells, we used scRNA-seq data of hepatocellular carcinoma (HCC) to reveal the heterogeneity of different CD8+ T cell subsets.CD8+ T cells in HCC were divided into 7 subsets, and the subset cytotoxic CD8 T cells 4 showed significant differences between the TP53 mutant group and the nonmutant group, as well as between different degrees of cirrhosis, HCC grades, stages, ages, and body weights. Hub genes were identified by TCGA-LIHC and single-cell sequencing data set analysis, and the genes APOC3, APOH, HPX, and FGB were identified as biological marker genes by the Cox test. The expression of APOC3, APOH, HPX, and FGB in normal tissues and tumors and TP53 mutation were significantly different. There was a significant difference in the expression of APOH among the sex groups. There were significant differences in the grading and staging of liver cancer. The gene APOC3 had no significant difference among different body weights. The expression levels of APOC3, APOH, HPX, and FGB were the highest in HCC and were higher in normal tissues than in cancer tissues. Moreover, it is also highly expressed in CHOL, and the expression level in normal tissues is higher than that in cancer tissues. We found that cytotoxic CD8 T cells 4 is closely associated with survival and prognosis of HCC and identified four differential genes that can be used as biological markers for survival, prognosis, and clinically relevant characteristics of HCC. This study could help to find effective targets for immunotherapy of HCC and accelerate the development of immunotherapy for HCC. At the same time, this work also outlines the map of the tumor-immune environment, which provides a basis for the future study of other tumor-immune microenvironments.

High-intensity sports make tendon injury of professional athletes occur frequently. However, tendon adhesion in the healing process of tendon injury seriously affects the normal functional training of athletes after rehabilitation. Therefore, based on the theory of tendon injury healing, the MRDM image data of tendon injury healing are obtained by using medical image analysis technology, and the useless image data are screened by using the RANSAC algorithm. Through the analysis of filtered MRDM image data, it is found that the application of biomaterials has a positive effect on promoting the stable healing of tendon. A multilevel model was used to evaluate the actual effect of several commonly used biomaterials in repairing tendon injury and adhesion. The results showed that sodium hyaluronate had the best repair effect on tendon injury.

1. Introduction

Sports are good for physical and mental health. After more than 100 years of development, there are many popular sports in the world, many of which have become one of the core events of the Olympic Games (Song) [1]. However, due to the high intensity of exercise itself, it is easy to cause damage to the body during exercise, among which tendon injury is the most prominent [2]. The following is tendon adhesion during tendon healing, which is a very common complication after tendon injury. Tendon adhesion directly affects the subsequent sports and technical competitions [3].

Therefore, how to prevent the healing of tendon injury has been a key research project of related researchers [4]. But so far, no simple and effective method for preventing tendon adhesion has been developed, and a stable healing of the tendon has been developed (Kang) [5]. With the development of modern medical technology, the use of biological materials to prevent the formation of tendon adhesion has made great progress (Zhang) [6].

After years of research, people have a clearer understanding of tendon adhesion (Gross and Hoffmann) [7]. First, the nutrient source required for tendon is that in addition to paratenon, retinaculum tendinum, and tendon bundle vessel, synovial is also a very important source of nutrients (Cheng and Jin) [8]. At the same time, tendon tissue itself can be self-healing. However, after the tendon injury, the tendon sheath is damaged and the synovial is reduced, resulting in insufficient nutrient supply, which slows the healing of the tendon tissue itself, and most of its repair process relies on peritendinous connective tissue for repair (Jia et al.) [9].

As a result, a large amount of scar tissue is produced, eventually forming adhesions (Yang et al.) [10]. Therefore, some scholars have proposed to intervene in the process of tendon healing through biological materials. The current mainstream practice is achieved through drug films (Nouiri et al.) [11]. The properties of this biomaterial are used to form a barrier to prevent the formation of adhesions, while at the same time directly affecting the healing of the tendons by drugs. In turn, a two-pronged approach is achieved to minimize the formation of adhesions (Han et al.) [12].

In this context, the application of biomaterials in the healing and adhesion of sports tendon injury was studied comprehensively. Through multiangle research and analysis, the advantages and disadvantages of current biomaterials for tendon adhesion repair are revealed, which provides the necessary theoretical basis for its future development (Zhang et al.) [13].

2. Related Work

For the repair principle of tendon, there are two different views in the academic world, one is the theory of endogenous healing and the other is the theory of exogenous healing (Lin et al.) [14]. Researchers supporting exogenous healing believe that tendons themselves are not self-healing and that fibroblasts that repair are produced from tendon sheaths and peritendon tissues (Moslehifard and Nokar) [15]. Adhesive bands from the tendon sheath and periorbital tissue are incorporated into the repair cells to achieve tendon repair (Koyanagi) [16]. Researchers believe that adhesions are necessary in the healing process, so it is impossible to completely prevent adhesions (Zhenyu et al.) [17]. Researchers who support the theory of endogenous healing have raised different opinions. During the study of the free tendon placed in the knee joint cavity, they found that the tendon survived on its own and also detected fibroblasts and newly formed collagen. These phenomena all indicate that tendons are self-healing (Guo et al.) [18]. In addition, researchers have found that human flexor tendons can be self-healing during the in vitro culture of human flexor tendons (Geng et al.) [19]. Researchers have also studied the collagen fibers secreted by tendon cells, which are found to be much larger than those produced by the outer membrane cells (Philip et al.) [20]. Moreover, when the newly formed collagen fibers are analyzed, it is found that the collagen fibers produced by the original tendon cells are arranged in the same manner. Therefore, some researchers believe that tendon cells themselves are also self-healing (as shown in Figure 1), can achieve self-proliferation, and self-repair by producing collagen by themselves.

According to research by relevant researchers, tendons can achieve endogenous healing. Therefore, improving the self-repairing efficiency of the tendon cells can effectively reduce the occurrence of adhesions. However, in the actual treatment process, endogenous healing and exogenous healing always exist simultaneously. This is because during the treatment of the tendon injury site, it is necessary to bring the drug into the tendon through the surrounding tissue. After the cut tendon sheath is sutured, there will still be some gaps. It may also be that after the synovial cells have fallen off, they are scattered in the synovial fluid and enter through them through the synovial. In another case, it is located in the tendon sheath. Due to the uneven cutting source and the internal friction of the sheath at the suture, it will cause a certain degree of wear on the inner surface of the sheath and then bring in foreign cells. Even if the tendon can be damaged and subcutaneous tissue, bone surface completely isolated, from the damaged place of the synovial sheath of the exogenous cells can still reach the damaged tendon, so there is no way to completely eliminate the entry of exogenous cells. As for the degree of exogenous healing is the majority or the degree of endogenous healing is the majority, it is judged based on the damage of the tendon, the nutritional status of the repair period, and the external environment. When the degree of exogenous healing is dominant, tendon adhesion will increase and vice versa. Taking into account the current level of medical technology, the best practice is to reduce exogenous healing as much as possible and increase the proportion of endogenous healing. Choosing the right biomaterial for treatment can achieve this goal well.

The properties of the biomaterial are utilized to form a barrier that prevents the formation of adhesions. At the same time, the drug directly affects the healing of the tendon, thereby achieving a two-pronged approach and minimizing the formation of adhesions. Since inflammation is highly likely to occur in areas where the tendon is damaged, inflammation causes the lymphatic vessels to be blocked by cellulose and proteins, resulting in hypoxia in the interior. Biomaterials allow the coverage area to maintain normal blood circulation and provide adequate oxygen supply for tendon repair. Not only that, but when inflammation occurs, it can destroy tissues such as giant cells, resulting in an increase in the concentration of the tissue fluid, an increase in the permeability of the capillaries, and an extravasation of a large amount of fluid, eventually resulting in edema. The use of biological materials here can accelerate blood circulation, resolve the problem of congestion, and eliminate edema. It is also possible to screen and isolate harmful active substances in blood vessels to ensure their recovery progress. In the process of using biological materials, due to its own physical characteristics, it can interfere with the transmission of painful impulses, thereby achieving the effect of relieving pain.

3. Theoretical Model Optimization

At present, the above tendon injury healing theory has been widely used in the medical field and has achieved good medical results. In order to verify the actual effect of biomaterials on the stable tendon healing of athletes, the MRDM image data of tendon injury healing were obtained by using medical image analysis technology to understand the tendon injury healing of patients (as shown in Figure 2). However, the collected data are mixed with a large number of worthless data. Therefore, it is necessary to use the RANSAC algorithm to filter worthless data.

The RANSAC algorithm is a data calculus method that uses an iterative random sampling method to extract and filter abnormal data to obtain a mathematical model. The implementation principle is mainly based on two different data types that exist in the sample data: (1) normal data model and (2) noise and abnormal data model. The algorithm believes that the data that cannot adapt to the mathematical model is mainly because the abnormal data may be caused by wrong assumptions in the process of mathematical model calculation or it is caused by the wrong way of calculation. However, these erroneous data often lack sufficient parameters to restore them. To this end, the algorithm restores its real data through multiple iterative

Figure 2: The healing of tendon injury was obtained by medical image analysis.

screening methods. The RANSAC algorithm is mostly used in image processing in engineering. The basic implementation process is as follows:

It is needed to obtain necessary image data information, such as the edge of the object and the gray scale information. Whether the two information acquisitions are accurate or not will directly affect the accuracy of the detection. In general, when the system acquires graphics, it also needs to perform simple preliminary processing on the image, such as noise reduction. In this way, accurate information about the items to be inspected can be obtained accurately. The means of acquisition are mainly obtained by a CCD camera. Image enhancement is a very important step in image processing and one of the most used methods to improve image quality. There are two directions in this, one is to optimize the visual effect of the image and the other is to strengthen the characteristics of the image. Depending on the field of use, it can be divided into two types, one is airspace processing and the other is frequency domain processing. The former is processed directly on the image itself, while the latter is processed after the image is specially processed. The airspace processing formula is as follows:

$$g(x, y) = EH[f(x, y)], \tag{1}$$

where the image before enhancement is $f(\cdot)$, $g(\cdot)$ is the enhanced image, and EH is the enhanced operation.

The edge information of the image is able to directly reflect the shape of the object, and its importance is obvious. Moreover, it can display most of the information of the item only by the partial image information. But its acquisition has a lot of difficulties. The data obtained by the edge in the system behave as a discontinuous gray value. This requires a special algorithm to calculate its edges. It is usually calculated using the first derivative and the second derivative. The gradient corresponds to the first derivative, and the gradient operator is the first derivative operator. For a continuous function $f(x, y)$, its gradient at position (x, y) can be expressed as

$$\nabla f(x, y) = G(x, y) = \left[G_x G_y\right]^T = \left[\frac{\partial f}{\partial x}\frac{\partial f}{\partial y}\right]^T. \tag{2}$$

A gradient is a vector whose amplitude and direction angle are

$$\begin{aligned} |\nabla f| &= |G(x, y)| = \left[G_x^2 + G_y^2\right]^{\frac{1}{2}}, \\ \phi(x, y) &= \arctan\left(\frac{G_y}{G_x}\right). \end{aligned} \tag{3}$$

The approximate expression of the gradient is

$$\begin{aligned} G_x &= f[i, j+1] - f[i, j], \\ G_y &= f[i+1, j] - f[i, j]. \end{aligned} \tag{4}$$

Usually, in order to reduce the amount of calculation, the absolute value is usually used to approximate the gradient magnitude.

$$|G(x, y)| = \left|G_x\right| + \left|G_y\right|. \tag{5}$$

When analyzing an image, the approximate value is usually calculated using a small area template tape measure. One template is used for each of A and B, which requires two templates. According to the size of different templates, the calculation properties are different. Therefore, there are Robert operators, Prewitt operators, and Sobel operators.

Roberts operator: the Robe operator approximates the magnitude of the continuous gradient of the edge point, and its convolution template is as follows:

$$\begin{aligned} G_x &= \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \\ G_y &= \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}. \end{aligned} \tag{6}$$

The gradient templates in the horizontal and vertical directions of the Sobel operator are as follows:

$$G_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix},$$
$$G_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}. \tag{7}$$

The gradient template in the two directions of the Prewitt operator is as follows:

$$G_x = \begin{bmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix},$$
$$G_y = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{bmatrix}. \tag{8}$$

Then, the image content of the initial processing has been completed to extract corner points. It is assumed that variable I_x and variable I_y are used to represent the first-order partial derivative of image I in two different aspects of Cartesian coordinate x and y axes. Then, the function $w(x, y)$ can be used to represent a two-dimensional Gaussian smoothing function on Cartesian coordinates. The calculation process of this function is shown in the following two formulas:

$$M = \sum_{x,y} w(x, y) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix},$$
$$R = \det M - k \cdot (\operatorname{trace} M)^2, k = 0.04 \sim 0.2. \tag{9}$$

Solving formula (15) can yield a specific number for each corner R on the image. Then, using the normalization idea to match the calculated corner points, the image corner point value can be obtained. The matching calculation equation is as follows:

$$NCC = \frac{\sum_i (I_1(x_i, y_i) - u_1)(I_2(x_i, y_i) - u_2)}{\sqrt{\sum_i (I_1(x_i, y_i) - u_1)^2 \sum_i (I_2(x_i, y_i) - u_2)^2}}. \tag{10}$$

It is worth noting that the results obtained by using the normalized thought tend to be mixed with some singularities. These singularities are the anomalous data belonging to the corner values of the image that are noisy and cannot be normally described by the mathematical model. Therefore, it is necessary to use the RANSAC algorithm to purify the image corner values (as shown in Figure 3). In the process of purification, the images should be considered separately according to the three color channels of red, green, and blue. Then, there is the following linear algebraic equation:

$$\begin{pmatrix} R_2 \\ G_2 \\ B_2 \end{pmatrix} = \begin{pmatrix} c_r & 0 & 0 \\ 0 & c_g & 0 \\ 0 & 0 & c_b \end{pmatrix} \cdot \begin{pmatrix} R_1 \\ G_1 \\ B_1 \end{pmatrix} + \begin{pmatrix} d_r \\ d_g \\ d_b \end{pmatrix}. \tag{11}$$

In the above formula, the variable R_2, the variable G_2, and the variable B_2, respectively, represent three color channels of red, green, and blue of the image. The variable $(R_2, R_1)_{\mathrm{n}}$ is mainly used to represent the transformation parameters of the linear equation (c, d). At this point, the purification is done by iterative summation as follows:

$$E = \sum T\left({d_n}^2\right), \tag{12}$$

In the above formula, when the condition satisfies ${d_n}^2 < \mathrm{Thre}^2$, then $T({d_n}^2) = {d_n}^2$, otherwise $T({d_n}^2) = \mathrm{Thre}^2$. Filter the corner points of the image that meet the conditions and continue the iterative calculation. The entire purification process is completed until the value of E does not change significantly. At this point, all data points belong to the data that can be normally described by the mathematical model. Finally, it is necessary to split the image. The effect of image segmentation is good or not will directly determine whether the analysis of the image is in place or not.

The similarity calculation is performed after the image is segmented, and the predetermined image in the database and the matching are performed according to the calculated result. The matching result of the image is extremely characteristic. The following function is used to measure the similarity between T and f:

$$SE(x, y) = \sum_{i=1}^{N} \sum_{j=1}^{N} [f(x - i, y - j) - T(i, j)]^2, \tag{13}$$

where the size of the image is $N \times N$, the above formula provides a measure of the degree of matching between the image T and the subgraph f at the (x, y) coordinate. Expand the above formula to calculate the matching result:

$$SE(x, y) = \sum_{i=1}^{N} \sum_{j=1}^{N} f^2(x - i, y - j) - 2 \sum_{i=1}^{N} \sum_{j=1}^{N} f(x - i, y - j) T(i, j) + \sum_{i=1}^{N} \sum_{j=1}^{N} T^2(i, j). \tag{14}$$

4. Experimental Results and Analysis

Sports posture is complex, and the amount of exercise is large. Because of the above reasons, professional athletes often have tendon injury in the process of sports. Tendon adhesion is a very common complication after tendon injury in the process of tendon healing and temporarily unable to recover, will affect the athlete's competition and training in varying degrees. Based on the above reasons and based on the theory of tendon injury healing, the MRDM image data of tendon injury healing were obtained by using medical image analysis technology, and the worthless image data were screened by using the RANSAC algorithm. Then, through the analysis of the filtered MRDM image data, it is found that the application of biomaterials can actively promote the stable healing of tendon. Finally, the clinical

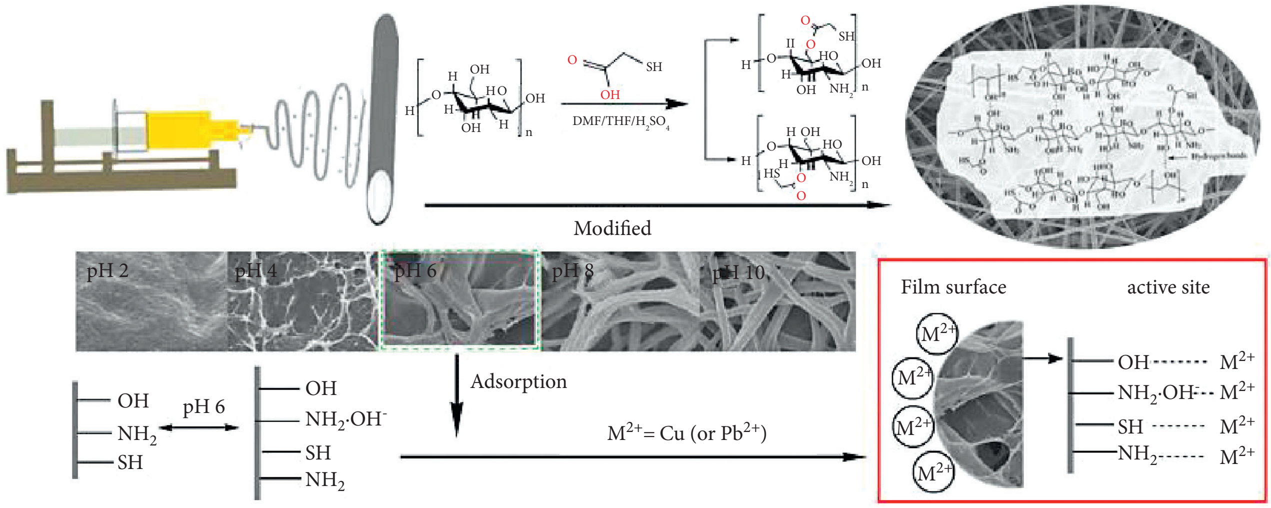

FIGURE 3: In the process of purification, the image should be considered separately according to the red, green, and blue channels.

application of biomaterials is listed, and the actual effect of several commonly used biomaterials to repair tendon injury and adhesion is evaluated by using the multilevel comprehensive evaluation model.

At present, the biological materials commonly used in medical clinics for repairing tendon injury healing adhesions (as shown in Figure 4) are mainly the following: (1) Chitosan: the biomaterial can effectively inactivate the fibroblasts at the site of the damage of the organism and inhibit the growth cycle of the fibroblasts. Furthermore, the proliferation time of endothelial cells is reserved for growth and self-repair of the human body. (2) Absorbable antiadhesion film: the biomaterial can also inactivate fibroblasts at the site of damage to the organism, and it can also act as a barrier to aid in the repair of the tendon. In addition, the absorbable antiadhesion film belongs to a biological material that can be absorbed and degraded by the living body. (3) Sodium hyaluronate: the biomaterial is a liquid material composed of a sodium salt and has high biocompatibility.

In order to more accurately screen out the biomaterials with the best effect on repairing tendon injury, the multilevel fuzzy comprehensive evaluation model is used to evaluate the actual effects of the above three biomaterials for repairing tendon injury healing. The multilevel fuzzy comprehensive evaluation model is an evaluation method based on cognitive science and fuzzy mathematics. The specific form is as follows:

$$\begin{pmatrix} a_{1,1} & a_{1,2} & \cdots & a_{1,n} \\ a_{2,1} & a_{2,2} & \cdots & a_{2,n} \\ \cdot & \cdot & \cdot & \cdot \\ a_{n,1} & a_{n,1} & \cdots & a_{n,n} \end{pmatrix}. \tag{15}$$

In the formula, ai, j represents the relative weight of indicator ai relative to indicator aj.

Calculate the product of each row element of the judgment matrix R,

$$M_i = \prod_{j=1}^{n} B_{ij}, i = 1, 2, \ldots, n. \tag{16}$$

Calculate the root in the times n of M_i,

$$\overline{w_i} = (M_i)^{\frac{1}{n}}, i = 1, 2, \ldots, n. \tag{17}$$

The normalization of $\overline{w_i}$ is as follows:

$$w_i - \frac{\overline{w_i}}{\sum_{i=1}^{n} \overline{w_i}}, i = 1, 2, \ldots, n. \tag{18}$$

Then, the weighting vector is $w = [w_1, w_2, \ldots, w_4]^T$.

The target criterion layer weight vector obtained according to the above method is as follows:

$$W = (w_1, w_2, w_3, \ldots, w_k). \tag{19}$$

w_i is the relative weight of the criterion layer indicator i in the criterion layer.

For the criterion level indicator of number k, the weight of the measure level under each criterion is as follows:

$$W_k = \left(w_{k1}, w_{k2}, w_{k3}, \ldots, w_{kp}\right). \tag{20}$$

In the hierarchical structure, the comprehensive weight calculation operator of the measure indicator j under criterion i is as follows:

$$w_{i,j} = w_i \cdot w_j. \tag{21}$$

After obtaining the weights of the respective indicators, the evaluation score can be finally calculated by multiplying the evaluation values. The calculation operator is as follows:

$$Ea = \left(w_{p,1}, w_{p,2}, \ldots, w_{p,n}\right)\left(v_{p,1}, v_{p,2}, \ldots v_{p,n}\right)^T. \tag{22}$$

$w_{p,i}$ is the comprehensive weight of the lowest level indicator i, and $w_{p,i}$ is its evaluation score.

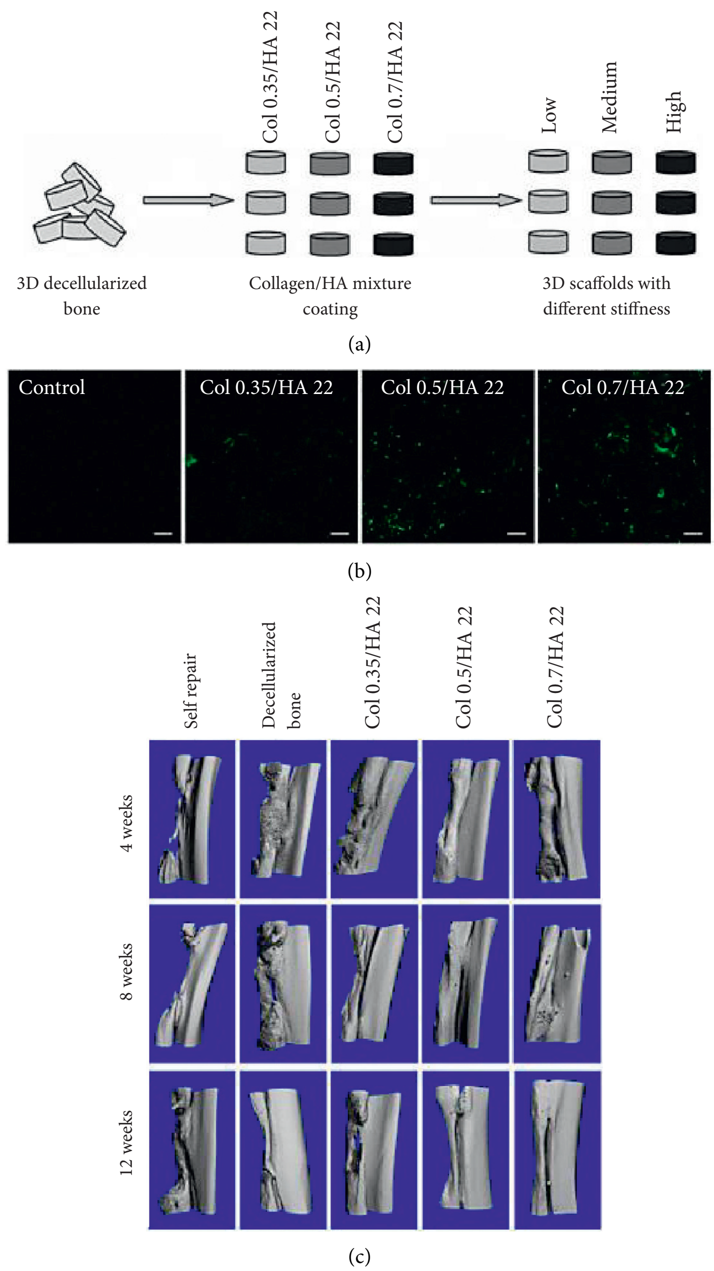

Figure 4: It is a common biological material used in repairing tendon injury and adhesion.

Substituting the data information recorded during the experiment into the above equation can obtain the evaluation result as shown in Figure 5. The data in the figure indicate that the three kinds of sodium hyaluronate in the biomaterials for repairing tendon injury healing have the best tendon damage repair effect.

In order to observe the effect of hyaluronic acid with different molecular weight, Hyalgan and Synvisc were used to evaluate the efficacy of knee osteoarthritis [21]. The rabbit knee osteoarthritis model was made by unilateral anterior cruciate ligament transection. Two weeks after operation, it was randomly divided into group A, group B, and control group (group C). Group A was given Hyalgan 0 2 ml, group B was given Synvisc 0 2 ml, and group C was given 0.2 ml of 0.9% sodium chloride injection. All patients received intra-articular injection once a week for 4 weeks. Three groups of animals were killed 10 weeks after operation, and articular cartilage was taken for gross observation and histological observation under the microscope. Mankin score—the results showed that group A and group B were significantly lighter than group C ($P < 0.05$), while group B was significantly lighter than group A ($P < 0.05$). Synvisc, a hyaluronic acid preparation with high molecular weight, has better short-term therapeutic effect on rabbit knee osteoarthritis than Hyalgan [22].

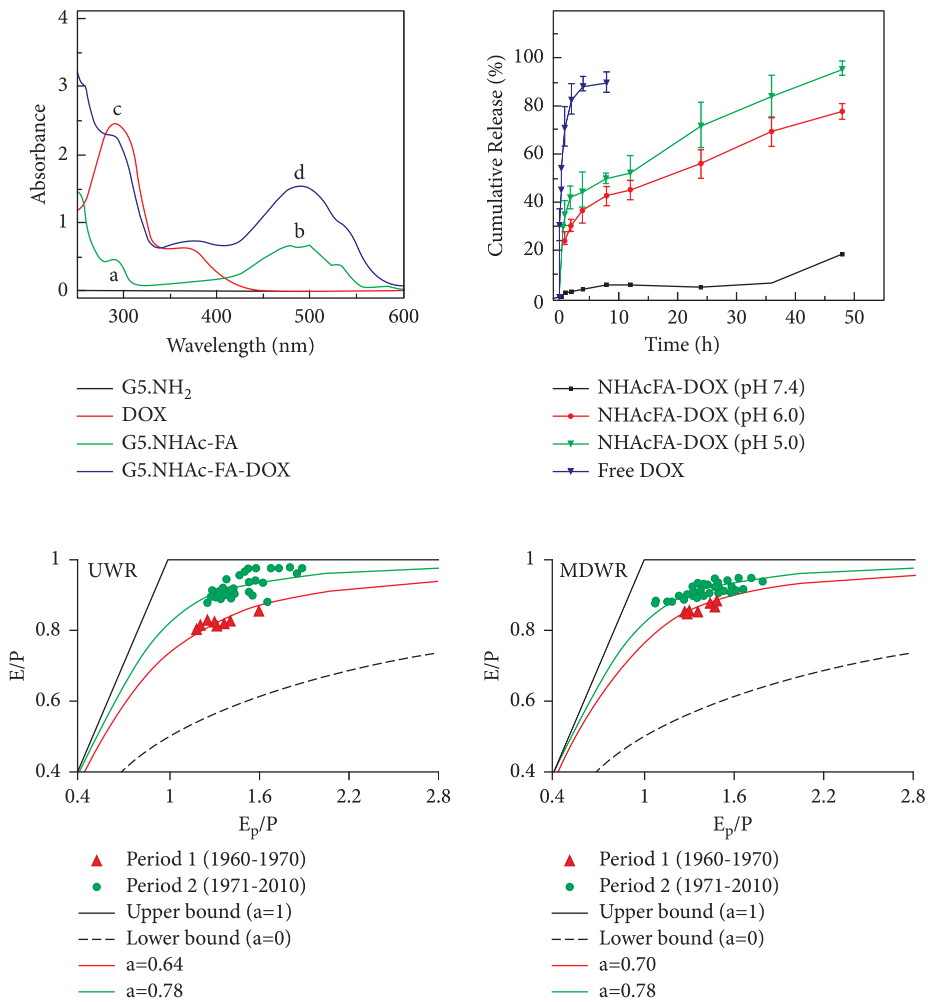

FIGURE 5: Evaluation of growth status of agrobacterium bisporus.

5. Conclusion

Professional athletes often encounter tendon injury in the process of exercise and then tendon adhesion occurs in the process of tendon healing. Tendon injury is a common complication after tendon injury. It is difficult to recover after a period of time, which has different effects on athletes' competition and training. Based on the above reasons, the theory of tendon injury healing has been deeply studied, and it is found that the biological barrier of biomaterials can effectively promote tendon repair and self-healing. In order to verify the actual effect of biomaterials on tendon healing, MRDM image data of tendon injury healing were obtained by medical image analysis technology for research and observation. The acquired MRDM image data contain a lot of useless information. For this reason, the RANSAC algorithm is used to filter the worthless image data and then in-depth analysis is carried out. The application of biomaterials can actively promote the stable healing of tendon. Then, the multilevel model was used to evaluate the actual effect of several biomaterials: (1) chitosan; (2) absorbable antiadhesion membrane; and (3) sodium hyaluronate, which is commonly used in the clinic to repair tendon injury and heal adhesion. The results showed that sodium hyaluronate was the best of the three biomaterials for tendon healing.

Academic Editor: Enas Abdulhay

Patients undergo surgery and anaesthesia on a daily basis across the United States and throughout the world. A major source of worry for these patients continues to be inadvertent hypothermia, once core temperature <36°C (96.8°F). Despite well-documented adverse physiological consequences, anaesthesia nurses continue to have a difficult task in keeping patient warmth pre-/peri-/post-surgical procedure. Thermostasis within postoperative patient necessitates the collaboration of many individuals. In order to provide safe and high-quality treatment, it is essential to use the most up-to-date data to guide therapeutic procedures targeted at achieving balance body temperature in surgical patients. Providing a review of the physiology of perioperative temperature variations and the comorbidities linked with accidental intraoperative hypothermia, this article will also provide preventive and treatment methods.

1. Introduction

Patients undergoing surgery and anaesthesia often experience drops in core-body temperature to <36°C (96.8°F) [1–3]. Hypothermia is characterised by widespread metabolism reduction that affects all bodily systems at the same time. Between 50 and 90 percent of surgery patients suffer from hypothermia at some point throughout their recovery period [4, 5]. The consequence is significant physiological alterations, including changed heart function, fluctuations in state of awareness, shivering and extended plasma half-lives of medicines, which may also enhance oxygen consumption by up to 500 percent [6–8]. Hypothermia is linked with a number of additional negative outcomes, including an increase in the duration of hospital stay, an increase in infection rates, and an increase in cardiac events [9]. According to research, individuals who maintain a normal body temperature during the surgical process are less likely to get infections (64 percent), have 44 percent less cardiac problems, and are 34 percent fewer likely to need perioperative mechanical breathing. Furthermore, patients who got hypothermic were discharged from the hospital 40 percent sooner than those who did not become hypothermic [9, 10]. A solid understanding of the factors that contribute to perioperative hypothermia, as well as the mechanism of heat exchange in operating patients during their perianesthesia and post-surgical time frame, and also the physiologic changes related with this heat loss, are required for the implementation of guiding principles in the perianesthesia context [11]. It is also necessary to be familiar with the risk factors for hypothermia. Perianesthesia nurses continue to play a significant role in maintaining thermal balance in surgical patients. In the postoperative care of operating patients, via treatments targeted at reducing temperature loss, however preserving and/or recovering normothermia differentiates the difficulty faced by perianesthesia nurses from other types of challenges [11–13].

Herein, we first explained the temperature monitoring for patient undergoing anaesthesia and the basic science and temperature regulation physiology of heat lost from a patient to the environment. We explained the various risk factors to improve intraoperative heat control throughout the process.

Next, we highlight the perianesthetic heat loss and the phenomena, balance between thermolysis and thermogenesis and the physiological changes as a result of hypothermia, as well as the various variables for the improvement of perioperative hypothermia. Finally, we highlight the hypothermia and its consequences and provide the concluding remarks. This review will give readers an overview of the implications for perianesthesia nurses in terms of intraoperative changes in temperature and factors associated for unintentional post-operative hypothermia.

2. Temperature Monitoring

"Every patient undergoing anaesthesia should have his or her temperature monitored whenever clinically significant changes in body temperature are intended, expected, or suspected," as described by the American Society of Anesthesiologists' guidelines concerning fundamental anaesthetic observation [14]. Due to the fact that this recommendation does not specify the method of temperature monitoring to be used, when to monitor, or for how long to monitor, variability in patient safety and broad variance in clinical practise will result. The American Society of Perianesthesia Nurses (ASPAN) recommendations offer scientific proof guidelines for monitoring temperature in anaesthesia care settings[15].

Inner abdominal-area / thorax /neural tissue-temperature is defined as CT (CT). This temperature is carefully regulated, and it is typically 2 – 4°C (3.6 – 7.2 degrees Fahrenheit) elevated in comparison to dermal thermo-readings. During general anaesthesia, CTs remain frequently monitored across several sites such as the distal oesophagus, bladder (in instances of excessive urine flow), nasopharynx, and the pulmonary artery, among other places. The CT of people is the single greatest indication of their thermal state, despite the fact that it is not fully representative of their body heat content and distribution [16]. Axillary, rectal, bladder (having low urine flow), and mouth measures of near-CTs are more frequently utilised in regional anaesthetic patients during the perioperative period than other methods of temperature monitoring. This kind of measurement is usually less difficult to acquire, although it is influenced by external factors (such as the surrounding environment's temperature) and internal factors (such as the body's regional cutaneous blood flow). When it comes to axillary and oral temperatures, this concept makes sense, but the differences between bladder and rectal temperatures are less apparent. Temperatures in the rectal area are usually very closely related to CTs [17–19]. In the event of malignant hyperthermia (MH) and heat stroke, however, these precautions are not taken [20–22]. Furthermore, because rectal temperature lags after true CT during cardiac bypass, it is considered a near CT in patients who have been deliberately chilled. As a result, while taking rectal temperature readings, extreme care must be used. When urine flow is high, bladder temperature equals pulmonary artery thermal-reading / CT; however, upon reduced urine output, bladder temperature come close to rectal temperature [23, 24]. Beside this, temperature of bladder is also regarded to be a near-core metric because of its reliance on urine flow. As a result, the capacity of any of these measurements to represent CT is severely restricted. The most appropriate thermoregulatory monitoring location throughout periperative, intra-operative and after operation timeframes remains disputed, with the best source varying depending on the age of the patient. Preoperative temperature measures are most frequently taken by mouth for adults, oral or axillary temperature measurements are taken by mouth for paediatric patients, and axillary measurements are taken by hand for newborns. When feasible, an esophageal probes are employed for intra-surgical patient CT determinations. This technique is relatively safe / inexpensive, offering peak precise evaluation for thermo-readings available on the market. Furthermore, this measurement is the most precise when there are significant fluctuations in temperature. However, measuring the oesophagus is more difficult in patients receiving regional or controlled anaesthesia, as well as in those who are recovering from surgery. Except in the case of severe thermal disturbances, CTs may be calculated with acceptable precision from near-core observations taken near the core [25–27]. The application of a liquid-crystal temperature strip to the forehead is another popular method of thermal monitoring. These gadgets are low-cost, non-invasive, and simple to use, making them an excellent choice. Despite the fact that dermal thermo-reading remain significantly lesser in comparison to CT-readings, with increased vulnerability to environmental temperatures, these strips will offer a good approximation of CTs when regulated with a proper off-set (0.5uC in conscious individuals, 1uC in drowsy/anesthetized individuals) [28]. 19 When temperature fluctuations are more severe, for as during MH, liquid-crystal thermal-strips prove ineffective for noticing temperature rises within porcine models [29]. Such detectors were un-evaluated in people regarding this role, consequently not being recommended for human MH determination [30] . As a result of these considerations, CTs / near-CTs could become employed within the peri-surgical timeframes once risk-benefit analyses are concluded, knowing that clinical-setting situations could necessitate the use of a different technique.

The new AORN "Guideline for prevention of unintended patient hypothermia" gives guidelines in recognizing parameters related to intra-surgical hypothermia and its circumvention, teaching peri-surgical professionals regarding this issue, together with implementing applicable guidelines / protocols (Figure 1) [31].

3. Background Basic Science

There are four different ways through which heat may be lost from a patient to the environment. Radiation and convection are the most significant contributions to global warming [32]. Heat is emitted by any surfaces that are warmer than absolute zero, which is known as radiation (thermal) (infrared radiation). This emitted heat is absorbed by all surfaces in the immediate vicinity. As a result, the patient generates heat that is radiated into the surrounding environment. During surgery, radiation is most likely the most significant heat-loss source.

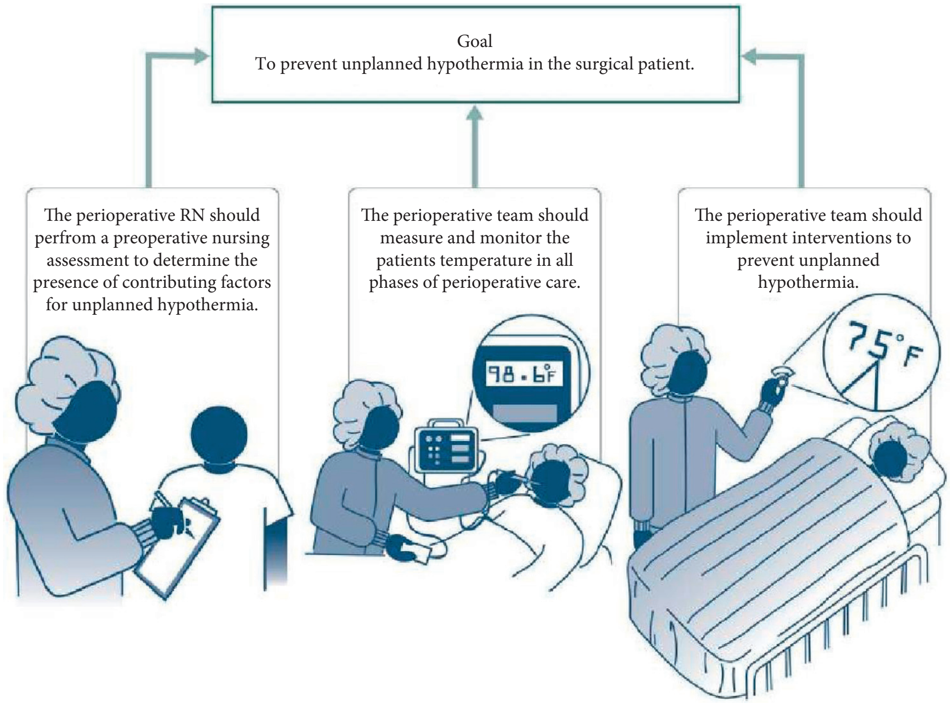

FIGURE 1: AORN Guideline for Prevention of Unplanned Patient Hypothermia. In briefly, peri-surgical registered nurse must conduct pre-surgical nursing assessment for ruling out risk factor manifestations driving unintentional hypothermia. Throughout peri-surgical period, the peri-surgical group must take and track patient thermal readings. The peri-surgical team should take preventative measures to avoid unintentional hypothermia.

3.1. Convection. Usually, minute layers of static-air in proximity to the dermal layer serve as insulation, preventing conduction-based heat from being transmitted through the skin to nearby air molecules. Once air currents pass across it, this layer is disturbed, the insulating qualities of the layer are significantly reduced, resulting in increased heat loss. Convection is the term used to describe this process, which is the foundation for the notion of wind cold factor. When it comes to non-OR hospital settings, room air is usually replaced four times per hour, whereas in distinctive operating room (OR), room air is circulated fifteen times per hour. Because of the little perceptible flow of air throughout the operating room, these rooms are perceived as being cooler. Surgical curtains serve as thermal insulators, reducing convective heat loss to a bare minimum. Contrary to popular belief, convection-based heat-loss forms 2nd paramount cause for thermal-losses within OR.

3.2. Conduction. Conduction can be described as thermal-transference through conductive media deprived of any discernible movement of the medium itself. Because of the temperature differential between two mediums and the material's heat conductivity, heat transfer occurs at a faster pace in certain cases. For the reason that the patient is in close touch with foam protecting sheet on the operating table, conduction contributes only a small portion of the heat loss during surgery.

3.3. Evaporation. This can be described as transformation of liquids into vapors once temperature is below the boiling point. As a result, molecules with the greatest kinetic energy can escape from a liquid's surface, decreasing the kinetic energy (KE) and therefore reduce the temperature. This kind of thermal loss is most often seen when sterile preparation solutions are used in the manufacturing process. It is possible that evaporative losses from surgical wounds will also be a factor [32].

3.4. Temperature regulation physiology. The human thermoregulatory system is capable of maintaining a constant body temperature inside under typical conditions; the usual body temperature is about 37°C. In the operating room, on the other hand, a collection of changed thermoregulatory mechanisms and lower ambient temperatures classically leads a reduction in CT. Hypothermia takes place once CT is less than 36°C, is a reasonably frequent occurrence within operating patients, with a frequency of up to 20% reported. Cases occur when healthy individuals experience CT drops of 0.5 - 1.5°C [33, 34] in the first hour after undergoing a surgical operation.

Physiologic thermoregulation is comprised of a system of afferent temperature sensing, efferent reactions and central regulation that works in concert. Thermosensing cellular populations found within spinal cord, brain, thorax, skin surface together with deep abdominal tissue are responsible for afferent thermal perception in hypothermia [35]. The hypothalamus, with reduced aid by the spinal cord, are responsible for central CT regulation. Endpoints to hypothermia in adults manifests itself mainly via behavioural change, although it may also express itself through vasoconstriction and shivering. Additionally, nonshivering thermogenesis is shown in neonates, and various physiological changes are associated with the with the hypothermia (Figure 2).

3.5. Thermoregulation and aesthetic effects. The body's temperature is well controlled under normal conditions by controlling blood flow using arteriovenous shunts, which have been located on the surface of skin and regulate blood flow. It is possible that this blood flow accounts for as much as 10% of the total cardiac output, and that vasoconstriction might cause an improvement in mean arterial blood pressure of about 15 mmHg [36–38]. Anesthesia has a significant impact on the body's thermoregulatory systems. The use of general anaesthetics may help prevent heat loss-driven vasoconstriction, leading to improvement in patient thermal regulation once they are exposed to a frigid environment. The heat produced by the body is not dispersed evenly. Relatively, heat is often focused within core-regions, namely the head / trunk regions, with peripheral regions remaining lower in temperature. It's important to observe that heat from the core is directed towards the periphery body-stress manifests by decreasing OR temperatures / vasodilation functions through generalized anaesthetic take effect due to a lack of sympathetic tone (Figure 3) [33]. Such change leads into fast CT drop, approximating 0.5-1.5°C (0.9–2.7°F), which may be detected within the first hour after surgery. As a consequence of the vasodilation characteristics of general anaesthetics, this redistribution hypothermia is not a true loss of heat, but instead of a transfer in heat energy from the central to the periphery, which causes the patient to become hypothermic. Following the administration of general anaesthesia, the warmer periphery created by the drug increases the likelihood that the patient may lose CT into external OR area.

Hypothermia under generalized anaesthesia follows distinct profiles, with early-phase fast drop in CT (Phase I), followed by more gradual decrease in CT (Phases II, III, and IV). A plateau-phase (Phase III) take place on process termination, during which CT stabilises (Figure 4). Thermal redistribution may be responsible for the fast heat loss seen during Phase I in the first hour. Phase II (heat transfer from the warmer perimeter to the rest of the environment) is characterised by a gradual linear decrease that occurs over a period of 2-4 hours, during which thermal loss surpasses metabolic heat generation [39–41]. Phase III (thermal homeostasis) starts following 3 - 4 h, once CTs of 33 to 35 degrees Celsius cause peripheral vasoconstriction [42, 43]. Neuraxial anaesthesia, like generalized anaesthesia, interferes with physiologic thermoregulation, but it does so via a different mechanism. The thresholds for tremors / vasoconstriction are lowered (approximately 0.6°C) with epidural 28,29 and spinal anaesthesia, respectively (1.08°F). Leg

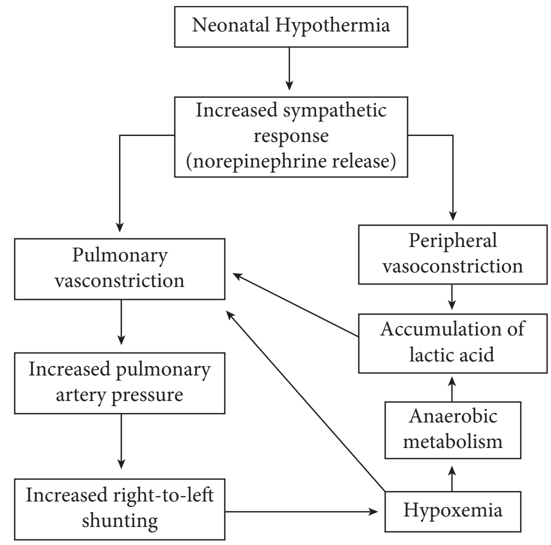

Figure 2: Neonatal physiological dysfunctions linked to hypothermia.

skin sensors provide afferent heat input is responsible for a large portion of the control of the CT. Within conventional ORs, constant cold-signals remain generating from peripheral regions, which are then processed [44]. Thermal input, on the other hand, is stopped across the blocked areas in regional anaesthesia. The lack of cold signals that results as a consequence of this is perceived centrally as relative leg warmth, which eventually lowers the shivering and vasoconstriction thresholds. Consequently, a patient who has been regionally anaesthetized may believe that he feels warm while are actually losing heat. Neuraxial anaesthesia is typically combined with sedatives / analgesics, which further compromise regulation by impairing the ability to regulate body temperature[45–48].

3.6. Risk Factors. Practitioners would, ideally, detect risk parameters leading to UPH before to performing any surgical operation for improving intra-surgical heat control throughout the process. When it came to identifying risk factors, ASPAN used an evidence-based practise approach [49, 50]. Following the evidence evaluation scale developed by colleagues and Stetler, this method evaluated the strength and quality of proof in descending order[51]. The American College of Cardiology/American Heart Association (ACC/AHA) categories were changed to address risk/benefit ratios, with considerable body of proof confirming such guidelines, and the amount of evidence supporting the recommendations. The following are the definitions for these classes[52]:

> Class I: The benefit exceeds the danger in this case, and the suggestion should be followed through on.

A suggestion falls into Class IIa if the profit exceeds the danger, and it is appropriate to carry out or administer the advise in question.

A suggestion falls into Class IIb if the profit outweighs the risk and it is not irrational to follow or implement the advice.

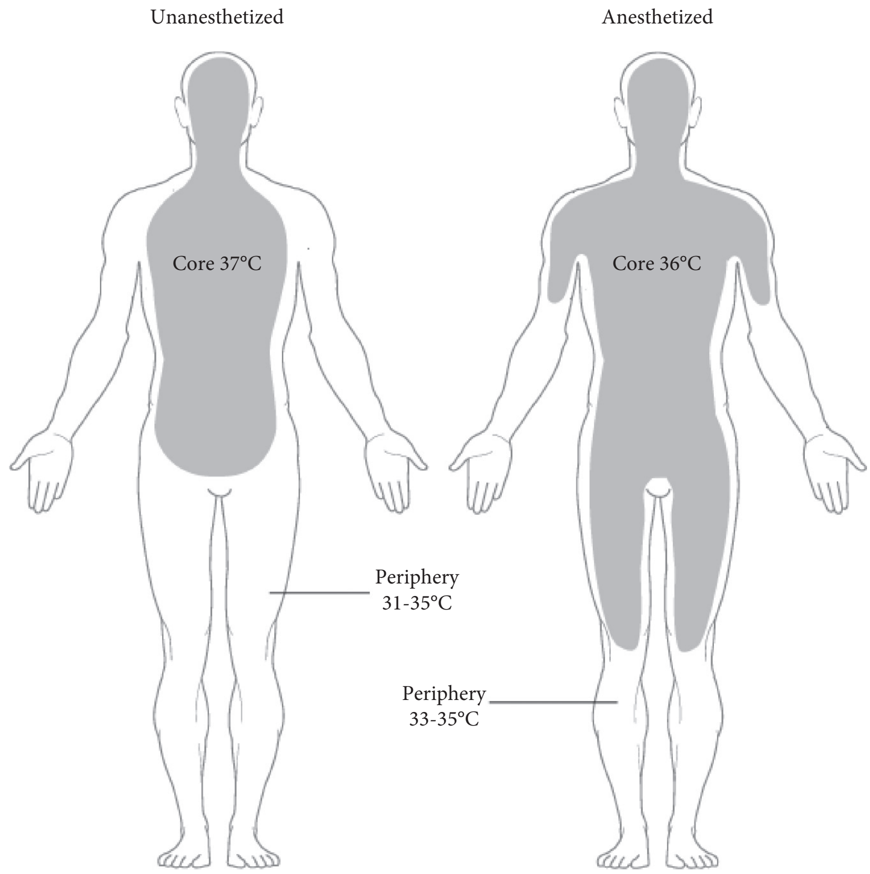

Figure 3: CT/heat re-distribution throughout generalized anaesthesia.

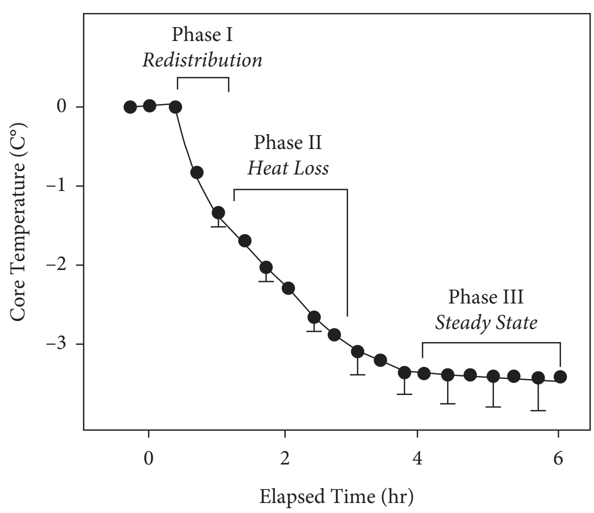

Figure 4: Typical thermal shift profiles observed during generalized anaesthesia. Reproduced with permission from [32].

Classes I, II, and III: The danger exceeds the advantage, therefore the advice would not be carried out or managed.

These suggestions are backed up by three different bodies of proof:

Level-A proof includes proof from several randomised trials / meta-analyses examining various (3–5) populi, having overall reliability in the direction and size of the impact.

A level B proof base would consist of proof from single randomised trials / non-randomized investigations assessing small (2 - 3) population samples.

The proof comes from case-based investigations, treatment quality levels, or skilled opinions containing relatively small (1 - 2) groups.

Unfortunately, neither one of the risk variables found is backed by solid proof, indicating that more study in this area is required. These variables suggest a connection but not necessarily a causal relationship; for example, one patient could carry risk parameters yet not develop hypothermia despite having them. Expectantly, by identifying individuals who are vulnerable to hypothermia during the preoperative evaluation, methods to assist maintain normothermic conditions throughout the peri-surgical phase may be devised.

3.7. Perianesthetic Heat Loss. The hypothalamus is in charge of regulating and maintaining body temperature, which is altered during the duration of perianesthesia [53–55]. The effects of generalized and regional anaesthesia on thermoregulation are similar. Generalized anaesthesia impairs the hypothalamus' capacity to control the small margin of temperature variation within which it operates [56, 57]. In turn, this leads in a suppression of both centrally mediated vasoconstriction and peripheral vasodilatation [58, 59]. Regional anaesthesia, on the other hand, causes a centrally mediated vasodilation that prevents peripheral vasoconstriction, resulting in re-distributing core-heat with consequent thermal losses throughout surgical procedure/s [53, 58]. According to research, the majority of patients have predictable patterns of heat loss due to anesthetic-driven thermoregulatory disruption coupled to body contact with colder OR ambient [60, 61]. During anaesthesia, there is a decrease of body heat that happens in 03 stages. During the first hour following operation, Phase I, or redistribution, occurs and anaesthesia due to fast systemic circulatory redistribution from patient core into peripheral areas throughout initial 60 minutes of surgery / anaesthesia. This is indicated through significant CT decrease (1 – 3°C) [58, 59]. In consequent 2 - 3 hours post-surgery, Phase II (linear phase) thermal losses remain, however, CT drops are less drastic/rapid and follows a linear trend. A decrease in the rate of decrease in the patient CT is caused by thermal losses surpassing the amount of heat produced by metabolic processes [58]. Eventually, within Phase III (the plateau-phase), thermostasis is achieved having the least amount of heat loss. When thermal loss matches metabolic heat generation, the body's CT remains constant [58].

The four main processes of thermal loss for operating patients will define the rate of heat loss throughout the linear phase: evaporation, conduction, convection, and radiation. Evaporation routes predominate thermal losses for operating patients.

Radiation, or the transmission of heat from one surface to another despite the presence of a constant ambient temperature, is the most significant source of thermal loss in patients undergoing surgery and anaesthesia. When it comes to heat loss in this population, convection is the second most frequent culprit. Conduction and convection both use heat transmission mechanisms that are quite similar. During surgery, the evaporation of physiological fluids during breathing offers an additional pathway for the loss of core body temperature (Figure 5).

3.8. Physiological Changes as a Result of Hypothermia. An association linked between hypothermia and the myriad of physiological effects that occur as a consequence of anaesthesia, and this connection is well established (Figure 6). The physiological consequences are characterised by a generalized slowing of metabolism that affects all bodily systems [58, 62, 63]. Apart from the physiological consequences of hypothermia, other possibly harmful consequences include myocardial infarction, impaired wound healing, coagulopathy, improved contagion rates and prolonged advent from anaesthesia due to reduced drug metabolism along with psychological consequences such as stress, pain and changed cognitive functioning [62]. However, while all patients are at increased risk of developing adverse physiological changes as a result of hypothermia, burns and trauma, senior and disabled, infants, mal-nourished patients are among those who are most likely to experience physiological changes as a result of the condition [56]. One study looking at prognostic variables in hypothermia identified patients >70 years had higher risks for adverse consequences linked to improvement of peri-surgical hypothermia [64].

3.9. Peri-surgical Hypothermia and Its Risk Factors. Many variables lead to the improvement of peri-surgical hypothermia, some of which are listed below. In accordance with current study and previous research, aetiology / connection of variables involved with accidental hypothermia are well understood and supported. Temperature and timing of the room natural light are critical. The ambient room temperature continues to be the most important interoperative variable in determining whether or not patients will develop hypothermic during surgery. In three landmark investigations, researchers discovered that all patients who entered operating rooms with external temperatures <70°F (21°C) were hypothermic [65–67]. As part of the research, there were no intra-surgical warming treatments given to the patients in this group. The findings revealed that the largest CT drops occurred within initial 60 minutes of presence inside OR [67]. This body of classic research, dating to 1960s - 1970s, provides substantial proof in support of regulating the ambient temperature aimed at preserving thermostasis across surgery cases. Despite this, present operating rooms remain chilly. Adjusting the operating room thermostat to 70°F (21°C) as soon as the patient enters OR could reduce risk of accidental hypothermia occurring. 18 Additional comfort will be provided by maintaining the patient swaddled as best-possible, as well as by decreasing thermal loss [68].

3.10. Anaesthetic Technique. Local and generalized anaesthesia both lead to the loss of body temperature in surgical patients by redistributing heat away from the body's centre and toward the periphery, respectively [69, 70]. Regional anaesthesia, on the other hand, causes heat loss mostly as a result of peripheral nerve block, rather than the change of the hypothalamus controlling centre for temperature regulation that happens with generalized anaesthesia [58]. Regional anaesthetic impairs the patient's capacity to constrict his or her blood vessels. When it comes to spinal and epidural anaesthesia, the legs are the primary organs responsible for the transfer of body heat. The use of generalized anaesthesia in conjunction with local anaesthetic allows for the maximum degree of heat loss in operating patients [53]. Understanding the kind of anaesthetic, a patient has had will assist the peri-surgical nurse and the perianesthesia team in developing a complete plan of care to maintain normothermia in the patient.

3.11. Hypothermia and Its Consequences. The goal of reducing peri-surgical hypothermia needs a collaborative effort all over the surgical process. When it comes to maintaining proper thermal balance in surgery patients, awareness and training of the whole operating team, containing preoperative, intra-surgical, and post-operative nurses as well as anaesthetic providers, surgeons, and surgery technicians, are essential. The frequency of this

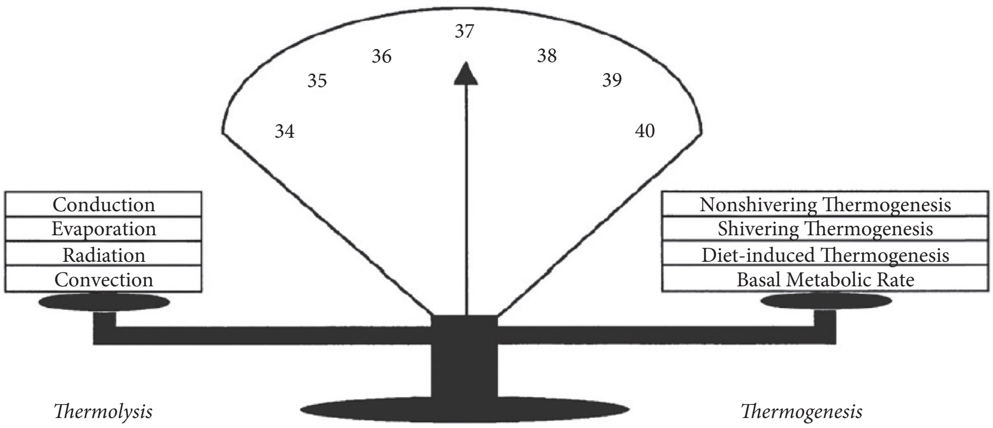

Figure 5: Balance between thermolysis and thermogenesis.

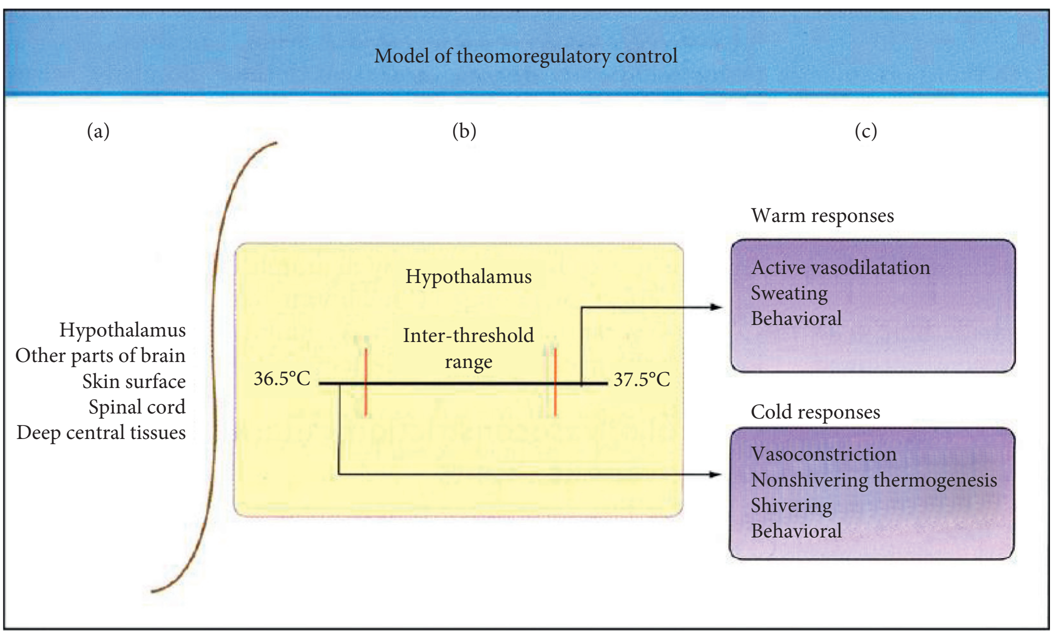

Figure 6: A model of thermoregulatory control.

avoidable illness will continue to rise unless efforts are made to educate all physicians who deal with operating patients before, during, and after surgical treatment about hypothermia and its potentially life-threatening consequences. The American Society of Plastic Surgeons (ASPAN) has well defined guidelines for avoiding hypothermia in surgery patients [71]. but, research aiming at demonstrating a link between these recommendations and a reduction in the prevalence of hypothermia has been difficult to conduct.

Preoperative some patients come in the operating room with hypothermia, but there is no information available on the prevalence of preoperative hypothermia. Showers in the morning, skin preparations, scant-clothing, together with vasodilator impact from pre-medication form variables that lead to a drop in body temperature. Preoperatively, one of the most essential goals should be to get the patient to surgery in a state of normal thermal balance. As a result, maintaining patients warm before entering the operating room highlights the requirement of early nurse involvement targeted at preserving normothermia in the patient [72, 73]. In order to maintain preoperative normothermia, blankets and forced-air warming equipment may be used, which could aid lower prevalence of peri-surgical hypothermia. Moreover, warming patients before they enter the operating room has been shown to have anxiolytic effects and to make the insertion of intravenous catheters easier [74]. In addition to caps and warming lights, which may be beneficial for babies, there is a paucity of research on their effectiveness.

3.12. Intra-surgical. Hypothermia during surgery may be substantially reduced if the operating room temperature is maintained at 70°F throughout the procedure [75, 76].

Although 70°F may appear excessively warm to the operating room personnel, maintain the environment warm until the incision could help to substantially minimise the first Phase I drop in body temperature after the incision. Warming blood products, IV fluids and irrigants may all help to keep the body's thermal balance in normal range. Anesthetic gases that have been heated and humidified also have a role an essential function in maintaining body temperature. Additionally, the use of warming blankets, layered draperies, and head coverings may help to offer extra thermal protection. Forcible warming has been shown to be one of the most efficient treatments for sustaining intra-surgical hypothermia, according to research [77]. The use of forcible heating equipment in the operating room helps to reduce radiant heat loss, which helps to keep the patient's body temperature stable [77].

4. Conclusion

Temperature regulation during the time of anaesthesia and peri-surgical care is affected by a variety of factors, and maintaining control over these factors is frequently challenging. When it comes to patient care, having a strong theoretical foundation is essential. Understanding the temperature physiology regulation and the risk factors linked with accidental hypothermia are important to have. Clearly, the body temperature of all operating patients, particularly those who are at risk of emerging hypothermia, must be closely monitored. The perianesthesia/peri-surgical team is in charge of putting in place preventative measures to keep the patient's body temperature as low as possible. According to the most recent research, rather than relying on a single preventative technique to reduce heat loss in the postoperative patient, it is essential to combine several methods for optimizing endpoints. In order to extend and support current data on treatments regarded most effective for reducing the prevalence of hypothermia all over the perianesthesia/peri-surgical cycle, further research is required. For example, research into preoperative treatments to guarantee that patients enter the operating room in near-normal thermal balance provides a chance to link the gap between research and practise in today's peri-surgical and anaesthetic settings. To use ideal proof to improve heat balance in the surgical patient necessitates the use of current and new investigation results throughout the whole perianesthesia/peri-surgical phase, which includes the full surgical procedure.

Retracted: Analysis of Systolic Blood Pressure Level and Short-Term Variability in Masked Hypertension

Journal of Healthcare Engineering

Received 15 August 2023; Accepted 15 August 2023; Published 16 August 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Background. Patients with masked hypertension are at an elevated risk of cardiovascular events and all-cause death. This risk is close to that of sustained hypertension. The mean value and short-term variability of systolic blood pressure are considered to be risk factors for organ damage in hypertension. *Objective*. To investigate the mean value and short-term variability of systolic blood pressure in patients with masked hypertension. *Methods*. According to the results of in-clinic and ambulatory blood pressure measurement, participants were divided into four groups: normotension group, controlled hypertension group, masked hypertension group, and sustained hypertension group. The mean value and short-term variability of systolic blood pressure of masked hypertension group were evaluated by comparison with the other three groups. *Results*. A total of 250 subjects were enrolled, with an average age of 65.46 ± 8.76 years, and 166 (66.4%) were male, including 62 in the normotension group, 78 in the controlled hypertension group, 69 in the masked hypertension group, and 41 in the sustained hypertension group. Compared with the normotension group and controlled hypertension group, the mean value, blood pressure load, standard deviation, and coefficient of variation of systolic blood pressure over 24 hours and during the day and night, were all higher in the masked hypertension group ($P < 0.05$), while the rate of the nocturnal systolic blood pressure decline was lower ($P < 0.05$). There were no statistically significant differences in the above indexes between the masked hypertension group and sustained hypertension group ($P > 0.05$). *Conclusion*. There are higher mean value of systolic blood pressure and greater short-term variability in masked hypertension patients. Identification of masked hypertension is an important challenge in the clinic.

1. Introduction

Masked hypertension (MH) has recently been identified as a unique hypertension phenotype that occurs in both treated and untreated patients. MH is characterized by an elevated blood pressure when the patient is out of the clinic but a normal blood pressure when the patient is in the clinic. MH accounts for at least 15% of people with apparently normal blood pressure in the clinic [1, 2], but reports suggest that this figure may be an underestimate of its prevalence. Because MH patients can be in a state of elevated blood pressure for long periods of time, the clinical outcomes tend to be different from patients with true normotension. In particular, mounting evidence suggests that MH leads to increased risks of organ damages that are similar to those associated with sustained hypertension (SH) [2–4].

Although the harm of MH has been well recognized, limited research studies on the characteristics of systolic blood pressure (SBP) are available. Notably, multiple studies have shown that the elevated SBP impacts the risks of all-cause mortality, heart failure, stroke, and end-stage renal disease more than diastolic blood pressure does [5–7]. Accordingly, SBP tends to be the key target of blood pressure management in official guidelines [1, 2]. The level and variability of SBP are closely related to the progress of arteriosclerosis, which are the main predictive factors in predicting cardiovascular events and all-cause death [5]. Therefore, both the level of SBP and its variability may represent important factors affecting the prognosis of MH.

There are a few studies analyzing the differences of blood pressure variability among different phenotypes of hypertension [8, 9]. However, few studies have focused on the characteristics of SBP in patients with MH. The purpose of this study is to discuss the reasons for higher target organ damage of MH reported in the past by describing the differences in the average value and short-term variability of SBP over 24 hours and during the day and night among patients with normotension, controlled hypertension, MH, and SH.

2. Materials and Methods

2.1. Study Participants. A cross-sectional study was performed. Information was collected from patients hospitalized in Beijing Tongren Hospital whose vitals were stable from July 2020 to July 2021. This study was approved by Beijing Tongren Hospital Ethics Committee (no. TRECKY2021-192).

2.2. Inclusion and Exclusion Criteria. Details on the inclusion and exclusion of participants are shown in Figure 1. The inclusion criteria were as follows: age ≥45 years old, agreed to participate in the trial, and signed the informed consent form. The diagnostic criteria for hypertension were in line with the 2018 European Society of Cardiology/European Society of Hypertension (ESC/ESH) Guidelines for the Management of Arterial Hypertension [1] (hereinafter referred to as guidelines). The exclusion criteria were as follows: (1) diagnosis of SH; (2) glycosylated hemoglobin HbA1c >7.5%; (3) left ventricular ejection fraction ≤50%; (4) previous diagnosis of myocardial infarction and performing percutaneous intervention or coronary artery bypass grafting; (5) heart failure; (6) cerebrovascular disease, including stroke or transient ischemic attack; (7) carotid or cerebral artery revascularization; (8) hyperthyroidism (TSH <0.1 mU/L) or hypothyroidism (TSH >10 mU/L); (9) liver diseases (jaundice hepatitis, or cirrhosis, or liver failure); (10) chronic kidney disease 4 or above (eGFR <30 mL/min/1.73 m^2); (11) severe infectious diseases or autoimmune diseases; and (12) malignant tumors; mental disorders. Participants were constantly enrolled in the study. A total of 250 participants were eligible. All participants were collected a completed medical history survey and underwent laboratory examination and ambulatory blood pressure monitoring.

2.3. Data Collection

2.3.1. Epidemiological Questionnaire. A questionnaire was completed by participants and then verified by the study physician. The questionnaire items included demographic information, educational background, lifestyle (such as physical activities and use of alcohol or tobacco), types of antihypertension drugs and years medications were used, other complications, and family history. The use of alcohol was defined as having consumed alcohol more than 12 times in the past 12 months [10]. Physical activities were defined as at least 150–300 minutes of moderate-intensity aerobic activity per week; or at least 75–150 minutes of high-intensity aerobic activity [11].

2.3.2. Anthropometric and Biochemical Measurements. Standard instruments were used for all measurements. Anthropometry included height, weight, body mass index (BMI), and blood pressure. Biochemical tests included fasting blood glucose (FBG), HbA1c, triglycerides (TG), total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), and low-density lipoprotein cholesterol (LDL-C). The morning after an overnight fast, blood samples were collected from the forearm vein into vacuum tubes containing EDTA. FBG was measured by the hexokinase method. Determination of cholesterol and triglycerides were performed by enzymatic methods using commercially available kits (Beijing Tongren Hospital Clinical Laboratory).

2.3.3. In-Clinic Blood Pressure Measurements. Participants were instructed to rest in the sitting position for at least 5 minutes prior to measurements. Blood pressure was measured on the same arm throughout the study with a Hem-7051 blood pressure monitor (Omron, Kyoto, Japan). For each measurement, three consecutive blood pressure readings were obtained, and the average of these blood pressure readings was submitted to the clinic.

2.3.4. Twenty-Four-Hour Ambulatory Blood Pressure Monitoring. An ambulatory blood pressure monitor (Vasomedical BIOX Ambulatory Blood Pressure Monitor) was installed on the passive arm of each participant to automatically measure and record blood pressure. In the daytime, it was programmed to perform measurements every 20 minutes between 08:00 and 22:00. In the nighttime, it was programmed to perform measurements every 60 minutes after 22:00. Participants wore the ambulatory blood pressure monitor for 24 hours. If a record contained 70% of the programmed readings, the coverage time was greater than 20 hours and there were at least 20 readings during the day and at least 7 readings during the night, the record was considered effective [2]. Blood pressure values were weighted over the time interval between successive readings.

2.4. Grouping. The participants were divided into four groups according to in-clinic and ambulatory blood pressure values as guided by guidelines [1]. The four groups were assigned as follows. Group 1 was the normotension group: there was no history of hypertension, the blood pressure in the clinic was less than 140/90 mmHg, and the ambulatory blood pressure parameters were not within the range of hypertension. Group

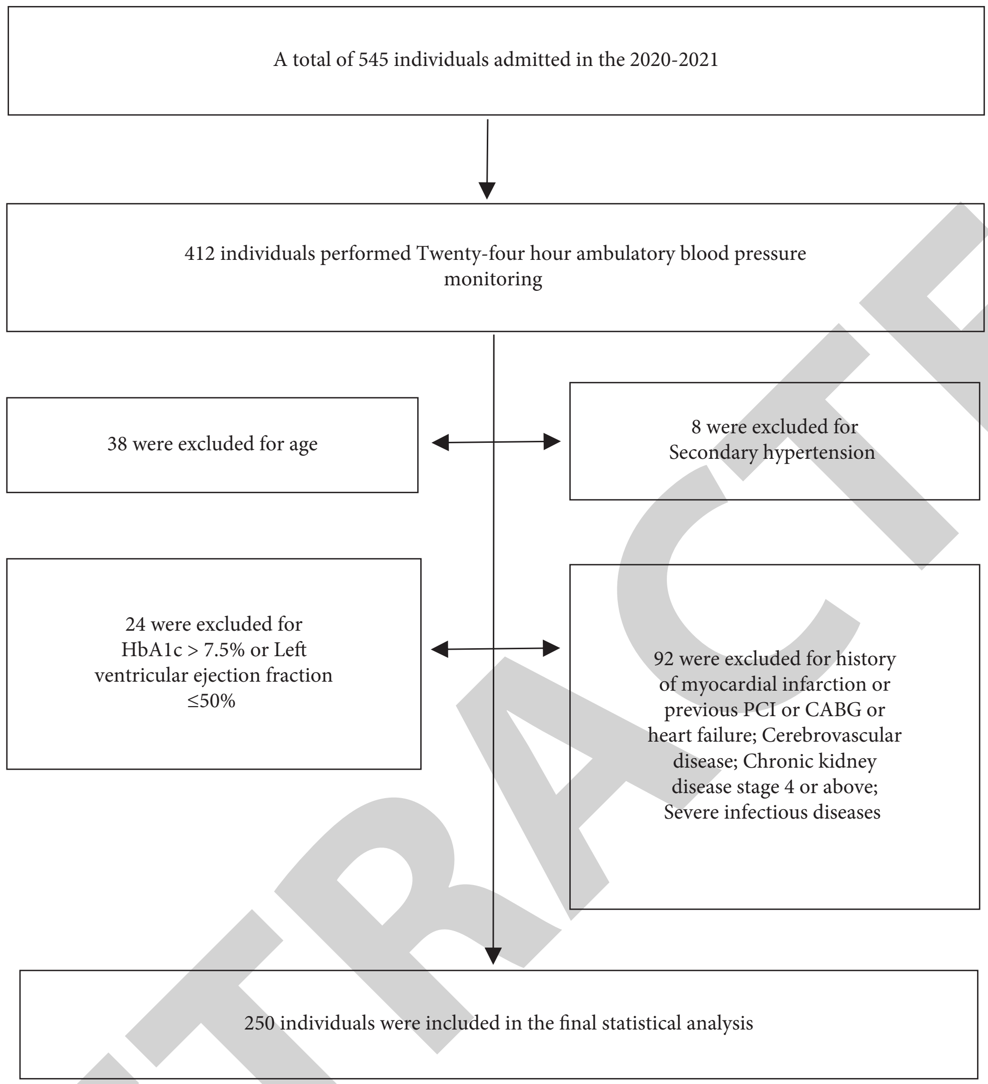

Figure 1: A flow chart of the current study.

2 was the controlled hypertension group: there was a history of hypertension, the blood pressure in the clinic was less than 140/90 mmHg, and the ambulatory blood pressure parameters were not within the range of hypertension. Group 3 was the MH group: the blood pressure in the clinic was less than 140/90 mmHg, and the ambulatory blood pressure parameters were within the range of hypertension. Group 4 was the SH group: the blood pressure in the clinic was greater than 140/90 mmHg, and the ambulatory blood pressure parameters were within the range of hypertension. Specifically, for ambulatory blood pressure parameters to be within the range of hypertension, the 24-hour average blood pressure was at least 130/80 mmHg, or the daytime average blood pressure was at least 135/85 mmHg, or the nighttime average blood pressure was at least 120/70 mmHg.

2.5. Statistical Analysis. The data were recorded by two people and consistency test was carried out. EpiData 3.1 was used to input data. The SPSS 22.0 statistical software was used to process descriptive statistics and difference analyses. Counting data were described by frequency distributions and were analyzed by chi-square tests. After a Kolmogorov–Smirnov normality test, the measurement data conforming to a normal distribution were expressed as $\bar{X} \pm \mathrm{SD}$, and the analysis of variance was used. The data that did not conform to a normal distribution were represented by the M ($Q1$, $Q2$) and were analyzed by the Mann–Whitney U test and the Kruskal–Wallis test. All factors were subjected to bilateral tests. Differences for which $P < 0.05$ were considered to be statistically significant.

3. Results

A total of 250 participants were included in this cross-sectional study. The average age of participants was 65.46 years, and 166 (66.4%) of the participants were male. The normotension group included 62 cases, the controlled hypertension group included 78 cases, the MH group included 69 cases, and the SH group included 41 cases. There were statistically significant differences in age, gender, BMI course of hypertension, number of antihypertension drugs, status of

Bold values represent the significant difference.

diabetes, and hyperlipidemia as well as levels of TG, FBG, and HbA1c among the four groups (Table 1).

The SBP parameters of ambulatory blood pressure monitoring among four groups are summarized in Figure 2. The average value, the standard deviation, and the coefficient of variation of SBP in all three time frames (24 hours, daytime, and nighttime) were significantly higher in the MH group compared with both the normotension group and the controlled hypertension group. The blood pressure load over all three time frames was also significantly higher in the MH group compared with both the normotension group and the controlled hypertension group ($P < 0.05$). The rate of the nocturnal SBP decline was lower in the MH group compared with both the normotension group and the controlled hypertension group. The above indexes regarding SBP in the MH group were not statistically different from those in the SH group ($P > 0.05$).

4. Discussion

In this study, we found that, as compared with participants with normal blood pressure or controlled hypertension, those with MH had a higher average value and blood pressure load and a higher standard deviation and coefficient of variation of SBP over all tested time frames. The rate of the nocturnal SBP decline was lower in participants with MH. These results suggest that the level of SBP and its short-term variability during all time periods (including night) are higher in patients with MH than in those with normal blood pressure. These differences support the idea that the blood pressure of people with MH, are in fact different from those of people with truly normal blood pressure. In addition, these differences in blood pressure suggest that their prognosis must be different. Therefore, it is important that we should pay much attention to identifying patients with MH.

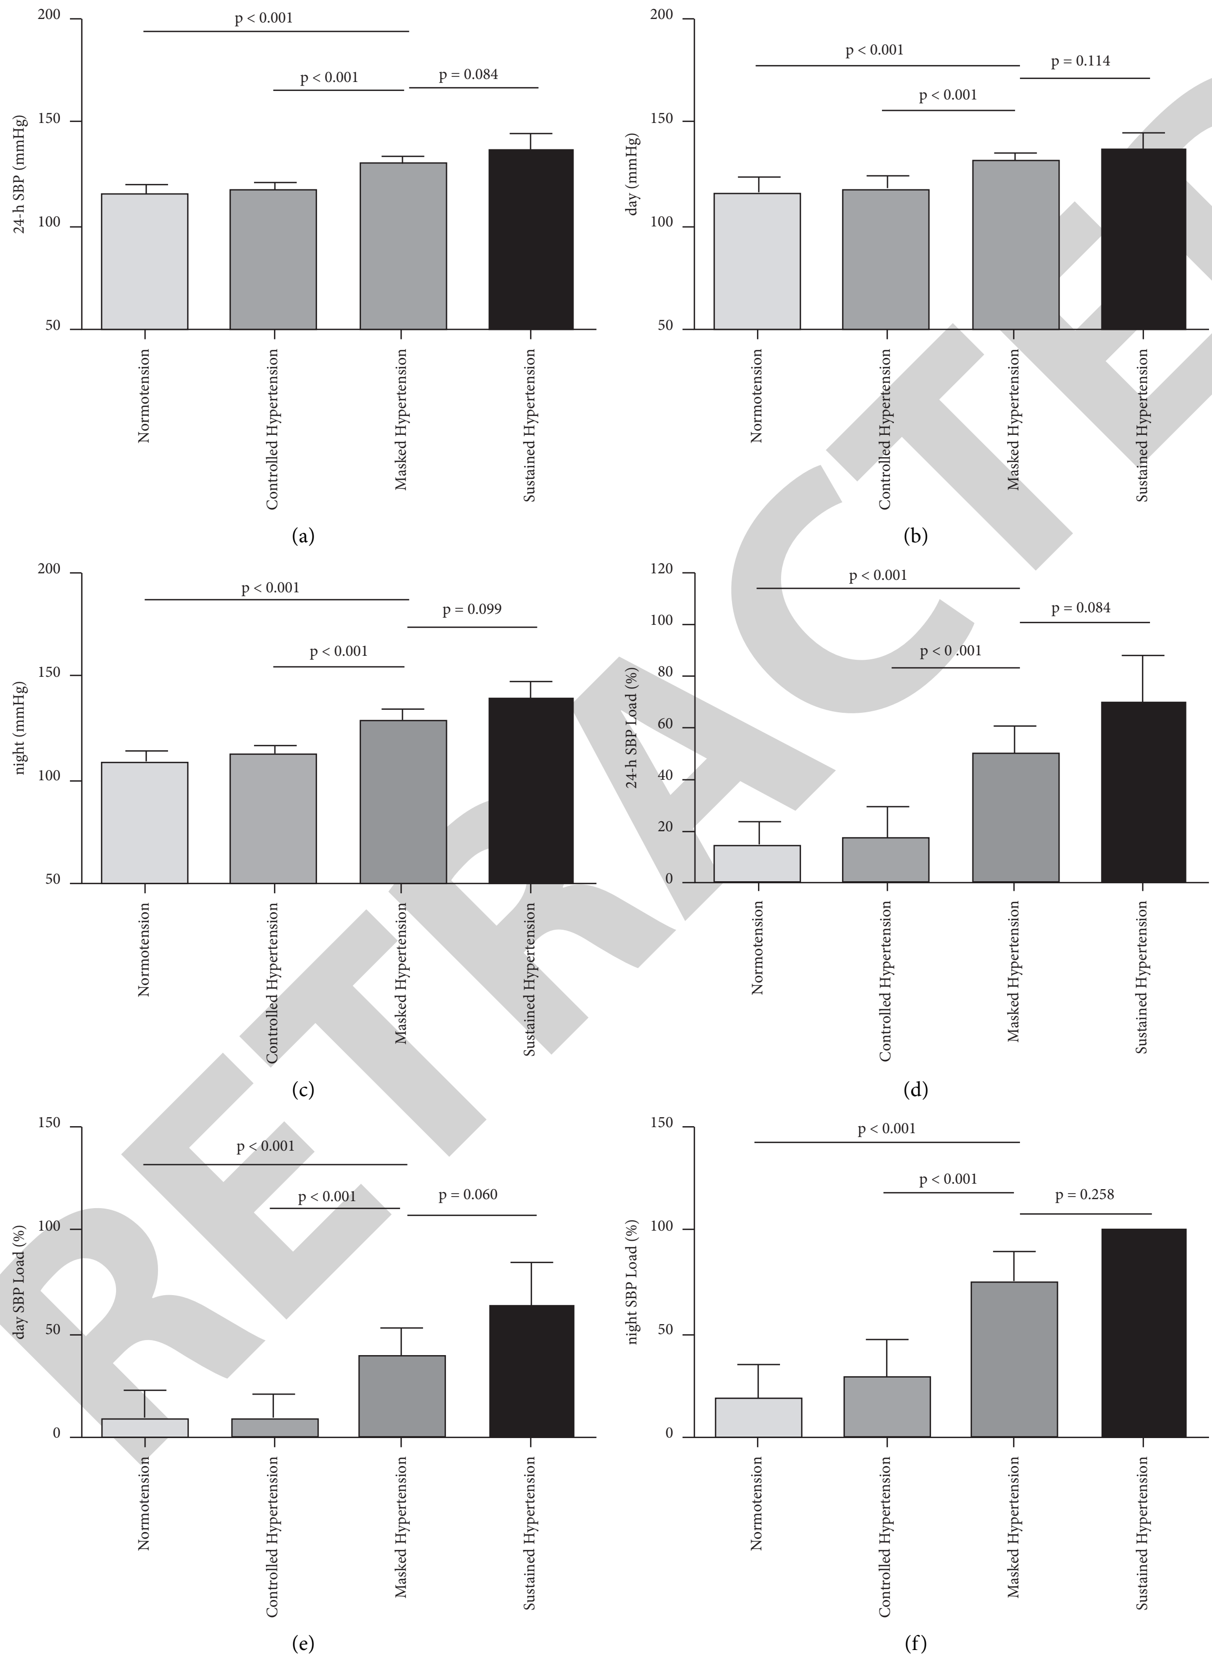

Figure 2: Continued.

(m)

Figure 2: Comparison of systolic blood pressure parameters of ambulatory blood pressure monitoring in the four groups. (a) 24 h systolic blood pressure, (b) daytime systolic blood pressure, (c) nighttime systolic blood pressure, (d) 24 h systolic blood pressure load, (e) daytime systolic blood pressure load, (f) nighttime systolic blood pressure load, (g) 24 h systolic blood pressure standard deviation, (h) daytime systolic blood pressure standard deviation, (i) nighttime systolic blood pressure standard deviation, (j) 24 h systolic blood pressure coefficient of variation, (k) daytime systolic blood pressure coefficient of variation, (l) nighttime systolic blood pressure coefficient of variation, and (m) nocturnal systolic blood pressure decline rate.

In this study, we found that MH patients had generally a high SBP level, which would be expected to negatively impact blood vessels and to result in subsequent damage to multiple organs. High SBP has also been associated with the progression of arteriosclerosis. For example, in a meta-analysis, after adjusting for demographic indicators, a correlation was found between SBP and arteriosclerosis progression. Specifically, after adjusting for age, patients' pulse wave velocity was shown to increase by 1.14 m/s for every 20 mmHg increase in SBP. However, the correlation between mean arterial pressure or diastolic pressure and pulse wave velocity was weak [5]. Arteriosclerosis plays a key role in hypertension-related clinical outcomes and is a powerful predictor of cardiovascular events and all-cause death [12, 13]. Therefore, current hypertension guidelines identify arteriosclerosis as one of the markers of target organ damage. Similarly, these guidelines commonly advise to reduce arteriosclerosis by drastically lowering blood pressure, mainly SBP, to reduce the occurrence of serious organ damage [1, 2]. An important outcome of this study was that SBP tended to be high in patients with MH both during the daytime and nighttime, and the rate of the nocturnal SBP decline was low. These factors are bound to affect the prognosis of MH patients. Studies have shown that high nighttime blood pressure is more closely associated with risks of cardiovascular events and all-cause death than daytime blood pressure [14–16]. Both lifestyle factors, including work stress and lack of sleep, and biological factors, including metabolic syndrome and sleep apnea syndrome, are MH risk factors that all enhance the activities of nocturnal autonomic nerve, resulting in the increase of nighttime SBP. Therefore, controlling nighttime SBP, via the mitigation of risk factors and the appropriate timing of drug administration, will become one of the keys of MH management in the future.

We also found that MH patients have high SBP variability, which also helped to explain the previously reported high cardiovascular risks in MH patients. Multiple studies have demonstrated the links between SBP variability and risks of coronary heart disease, stroke, end-stage renal disease, and all-cause death that are stronger than SBP itself [17–19]. The blood pressure variability may be affected by both sympathetic regulation and arterial elasticity. The results of this study showed that the variabilities of SBP in the MH group and the SH group were similar, which were consistent with the results of previous studies [8]. It may be explained by a similar disturbance of the regulation of sympathetic function. Siddiqui et al. [17] compared the sympathetic nerve activities of patients with controlled hypertension and those with masked uncontrolled hypertension (MUCH) both in the clinic and out of the clinic. They found that blood pressure variability, urinary catecholamine, and urinary norepinephrine levels out of the clinic were significantly higher in patients with MUCH than those with controlled hypertension. It was therefore speculated that the enhancement of sympathetic nerve activities out of the clinic promoted the development of MUCH. Another study found that sympathetic nerve activities in patients with MH was significantly higher than those with normal blood pressure [20]. These studies showed abnormal sympathetic activities in MH patients that resulted in higher blood pressure variability as compared to patients with normal blood pressure.

On the other hand, although the effect of arteriosclerosis on blood pressure variability is not fully understood, the possibility of an alternate direction of causation cannot be ruled out. A major determinant of blood pressure variability depends on baroreceptor sensitivity [21]. When the vascular structure changes significantly, it may reduce the sensitivity of arterial baroreceptors by limiting the extension of baroreceptors, and the lower sensitivity would be expected to lead to increased blood pressure variability [22, 23]. Moreover, atherosclerosis itself may enhance blood pressure fluctuations associated with small changes in cardiac output. Notably, the inverse relationship between blood pressure variability and baroreceptor sensitivity has not been confirmed by prospective studies. However, no matter the reason, the increase of blood pressure variability in MH patients may cause vascular endothelial dysfunction or injury, promote inflammatory responses and immune activation, and lead to atherosclerosis, ischemic myocardial injury, or damage to target organs [24].

5. Limitations

This study had several limitations. First, the sample size of this study was small, and the participants were recruited from a city where inhabitants tended to receive optimal medical care, potentially leading to a certain survey bias. In the future, we plan to recruit participants from different regions of the country to further verify our conclusions. Second, the participants might have some activities during ambulatory blood pressure monitoring, which may affect the accuracy of the results and lead to a certain measurement bias. It is best to repeat ambulatory blood pressure monitoring in the future to ensure the accuracy of the results.

6. Conclusion

MH is a common state of hypertension. We found that the level and variability of SBP over the course of 24 hours and specifically during the daytime and nighttime in people with MH were higher than those in people with normotension or controlled hypertension. In addition, those indexes in people with MH were similar to people with SH. These findings may help to explain why people with MH have target organ damages that are similar to people with SH. However, it is often difficult to identify MH patients because of normal blood pressure in the clinic, which can lead to a relatively poor prognosis when finally diagnosed. Therefore, it is important to pay much attention to developing strategies to increase the clinical detection rate of MH. Screening, diagnostic, and treatment strategies need to be further explored. The results of this study suggest future studies to explore whether reducing the SBP level and variability in MH patients can improve clinical outcomes.

Nitrogen-fixing *Anabaena* and *Chlorella pyrenoidosa* algal biotechnology are known as new agricultural inputs due to their characteristics and are widely used in the field of agricultural planting. This paper discusses the application of algal biotechnology based on nitrogen-fixing *Anabaena* sp. The advantages of algal biotechnology based on nitrogen-fixing *Anabaena* and *Chlorella pyrenoidosa* in terms of yield, sugar content, polyunsaturated fatty acid content, and high-quality yield of hawthorn were compared.

1. Introduction

As for the fruit industry, one of the three major agricultural production industries worldwide [1], its development quality and development level are of great significance to rural revitalization. According to incomplete statistics, the planting area of *Crataegi fructus* has reached 7 million mu in China, accounting for about 10% of the total area of fruit trees planted; the industry scale reached about RMB 20 billion in 2020. *Crataegi fructus*, as a species of edible and medicinal plant, has been widely used in the pharmaceutical industry, food industry and light industry. However, with the continuous expansion of the planting scale, production problems such as the degradation of germplasm resources and increase of group diseases have taken place, especially the significant influence on the quality of *Crataegi fructus* due to the increasing use of fertilizers; therefore, it is urgent to study an ecological, green, efficient, and safe cultivation technology of *Crataegi fructus*, in which, it is quite important to use the new environmentally friendly biotechnology.

Qilipo in Wenxi County and Jiangxian County, Shanxi Province, located in the dominant production area of *Crataegi fructus* in China, have been respectively praised as "The First Village of *Crataegi fructus* Planting in Shanxi" and "The First County of *Crataegi fructus* Planting in China," both of which have planted about 150,000 mu of *Crataegi fructus* [2]. *Crataegi fructus*, as the local specialty product, is also the product protected by geographical indications of agricultural products and the backbone force for the revitalization of rural industries in the new era. In order to further improve the quality and reduce the use of fertilizers and pesticides, the local government has explored the planting technology of algae-rich *Crataegi fructus* based on *Anabaena azotica* and *Chlorella pyrenoidosa* while relying on the Central Geographical Indication Protection Project, following the "Five-Grade Mode" of the high-quality development of characteristic industries, and focusing on the quality [3]. As confirmed, this mode could significantly increase the yield, the content of unsaturated fatty acid, and sugar content, and also reduce the pesticide residue, thus making the quality of *Crataegi fructus* fundamentally different from that of the fruits in other regions. It is of great significance to create a county-specific brand of *Crataegi fructus* and improve the brand value of the product protected by geographical indications of agricultural products and the industrial competitiveness.

2. Selection of Carrier of Biotechnology

Microalgae, a general term for microorganisms, being rich in chlorophyll a and capable of photosynthesis, could absorb heavy metals and inorganic salts from sewage in paddy fields and also degrade organic substances such as pesticides, phenols, and alkanes [4]. The corresponding development and utilization was initiated in the United States, Japan, Germany, Israel, etc. in the 1940s. There are one million species of algae all over the world, over 40,000 of which are known microalgae. At present, the microalgae widely planted or produced with biotechnology mainly include *Chlorella vulgaris*, *Chlorella pyrenoidosa*, nitrogen-fixing blue-green algae, and *Anabaena*. The microalgae could be applied in green production of *Crataegi fructus* based on their own characteristics.

2.1. *Anabaena azotica*

2.1.1. Selection Basis. Strong biological nitrogen fixation of *Anabaena azotica* cells: with the nitrogen-fixing method of ($N_2 + 8e^- + 16MgATP + 8H^+ \longrightarrow 2NH_3 + H_2 + 16\ MgADP + 16Pi$), azotase contained could fix molecular nitrogen in the air and synthesize amino acids and proteins, thus reducing the plant's demand for nitrogen fertilizers by 10%–30% [5]; it could also dissolve the phosphorus fixed in the soil ($Ca_3(PO_4)_2 + CnOnH = H+ + 2PO_4^{3-} + CnOn\ - + 3Ca^{2+}$), and cell secretions can soak into the grid to activate potassium ions for direct absorption by plants so as to prevent the antagonism with other elements in the soil, activate the medium elements and trace elements in the soil, and transport them to the root system, thus promoting the absorption. The rich extracellular polysaccharide colloid EPS and growth stimulating substances could improve soil and improve the fertilizer and water retention capacity of soil.

2.1.2. Mechanism. The reverse carrier system of *Anabaena azotica* cells: The direction of the movement of substances across the membrane is opposite to the direction of ion transfer, namely, when the carrier binds to H+ and then other molecules or ions (such as Na+), they would be transported through the cell membrane in opposite directions. The reverse carrier system could promote the efflux of Na+ and reduce the accumulation of Na+ so as to increase the tolerance of blue-green algae to the salt environment; in addition, it could continuously transfer the extracellular H+ into the cells so as to adjust the balance of the pH value in the cells [6, 7].

2.2. *Chlorella pyrenoidosa*

2.2.1. Selection Basis. Chlorella pyrenoidosa, the microorganism with the largest surface area in the world, has been praised as the "canned sun" by scientists around the world [8]. It could realize photosynthesis under glimmer poor light, and the effect could be over 10 times the photosynthesis of plants. While being able to greatly improve the accumulation of organic matters in plants, provide rich and balanced natural nutrients, and improve the utilization of water by plants, it could also quickly adsorb various heavy metal ions and promote the excretion of harmful substances from plants. The unique active factor (C.G.F.) could repair the damaged cells, activate phagocytes and interferons, induce plant resistance, degrade the residues of pesticides and fertilizers, and convert them into the useable state beneficial to plants [5, 9].

2.2.2. Mechanism. Photosynthesis mechanism of chlorella (see Figure 1): $CO_2 + H_2O = (CH_2O) + O_2$ (conditional enzyme, chlorophyll). At the same time, *Chlorella pyrenoidosa* could make the cellular action of engulf bacteria or viruses active; as the direct user of harmful substances, it could reduce the contents of ammonia nitrogen and nitrite in *Crataegi fructus*. The ability of *Chlorella pyrenoidosa* cells to remove different forms of nitrogen in *Crataegi fructus* can be ordered as follows: ammonia nitrogen > nitrate nitrogen > nitrite nitrogen. The ability to remove different forms of phosphorus can be ordered as follows: orthophosphate > metaphosphate > pyrophosphate > organic phosphate [10].

2.2.3. Kinetic Study. "Severe heavy metal pollution of cultivated land" is one of the practical problems that should be resolved in China at present. The detailed results of the survey on soil pollution of cultivated land indicated that the main pollutants affecting the soil environment and quality of cultivated land were heavy metals, especially cadmium. The study on adsorption kinetics of *Chlorella* indicated that the chemical composition of the cytoderm of *Chlorella pyrenoidosa* had obvious advantages in the adsorption of heavy metals. Cells would continuously release various metabolites into the surrounding environment during growth, such as carbohydrates, amino acids, enzymes, vitamins, organic phosphoric acid, toxins, volatile substances, and inhibitory and promoting factors. As shown in the tracer experiment, at least 5%–10% of the carbon fixed by *Chlorella pyrenoidosa* cells would be released into the waters and soil in the form of DOC, and the value can be up to 10%–25% under better conditions. The adsorption of heavy metals by *Chlorella pyrenoidosa* cells can be ranked as follows: copper > tin > cadmium > nickel > lead > cobalt [11]. By

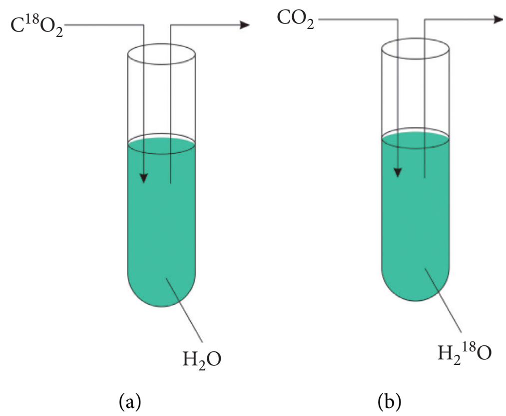

Figure 1: Photosynthesis of *Chlorella*.

means of active adsorption and passive adsorption, the cells can achieve adsorption and passivation of heavy metal ions, thus solving soil pollution of heavy metals.

3. Application Principle of Algae-Rich *Crataegi fructus* Technology Based on *Anabaena azotica* and *Chlorella pyrenoidosa*

3.1. Principle of Cell Fission and Oxygenation. The two kinds of cells would be subject to vegetative propagation and geometric fission after entering the soil. One cell would split into billions of cells in the soil, which would continuously release oxygen; the cell fission and reproduction could increase oxygen and ventilate the soil, thus enabling the original beneficial microorganisms multiply and inhibiting the activity of anaerobic bacteria; and bringing soil back to its original state by vital activity of the cells through increasing the organic matters, which can fundamentally solve the problems such as soil compaction, residual and safety, thus ensuring the natural, organic, nontoxic, and harmless nature of agricultural products.

3.2. Principle of Nutrient Equalization. The planting pattern of algae-rich *Crataegi fructus* based on *Anabaena azotica* and *Chlorella pyrenoidosa* could provide organic nitrogen, dissolve phosphorus, degrade potassium, and activate the medium and trace elements in the soil, thus promoting rapid growth of *Crataegi fructus* and helping to accumulate nutrients. While effectively promoting photosynthesis and providing comprehensive and balanced nutrients for the growth of *Crataegi fructus*, the organic matters generated could effectively adjust the soil acidity and make it neutral [12]. Active cells, with the phototaxis and chemotaxis, would reproduce by fission after entering the soil, thus promoting soil ventilation and water permeability, providing sufficient oxygen and organic nitrogen for soil, dissolving phosphorus and degrading potassium to activate the medium and trace elements in the soil, and help *Crataegi fructus* to accumulate nutrients. While effectively promoting photosynthesis, they could also provide comprehensive and balanced nutrients for the growth of *Crataegi fructus*, thus improving the quality, reduce the use of fertilizer, and realize high yield.

3.3. Principle of Metabolic Promotion. Terpenoids are widely distributed in nature, which could effectively improve the physiological activity of plants in growth metabolism. The planting pattern of algae-rich *Crataegi fructus* based on *Anabaena azotica* and *Chlorella pyrenoidosa* could assist in initiating plant secondary metabolism via the pathway of isoprene pyrophosphate, thus producing terpenoid polymers, which could increase the tolerance of plants to diseases, damage, drought, waterlogging, cold, and continuous cropping, and improve the quality of *Crataegi fructus*. Their application in the planting of *Crataegi fructus* could prolong the shelf life (due to the rich dry matters and increased soluble solids), make the appearance bright, and size uniform.

4. Selection of Manufacturers of Biological Fertilizers and Biotechnology

Yuncheng Biotechnology Development Co., Ltd. is a subsidiary of Microalgae Biological Times (Jilin) Ecological Technology Co., Ltd., a high-tech company integrating R&D, production and sales of algal active cell biological fertilizers. It takes the lead in R&D and application of nitrogen-fixing biological products and has three core technologies, namely metrocyte extraction, culture medium, and cell embedding. The development and application technology of algal active cell compound biofertilizers was evaluated as “domestic leading” by the Science and Technology Development Center of the Ministry of Agriculture, and listed as the main promotion technology by the Ministry of Agriculture in 2015. The production of *Anabaena azotica* and *Chlorella pyrenoidosa*-based biofertilizers adopts the single-cell rapid propagation technology. *Anabaena azotica* and *Chlorella pyrenoidosa* were respectively extracted under the microscope and cytoarchitecture analysis was performed, to select the optimal single-cell chain meeting the requirements as the metrocyte chain. After incubating in test tubes for 5–10 days, the cells were inoculated into a 100 ml flask for cultivating for 5–10 days and then inoculated into an 1-liter triangular flask for cultivating for 5–10 days, a 5-liter triangular flask for cultivating for 5–10 days, a 18-liter barrel for cultivating for 10–20 days, and a 1-ton barrel for cultivating for 20–100 days. The whole process was expanded step by step, with continuous illumination and constant temperature; the water and air should be filtered and purified to the required standard; finally, the amount of *Anabaena azotica* and *Chlorella pyrenoidosa* in biological fertilizers reached 8 million/ML, respectively.

5. Planting Experiment of Algae-Rich *Crataegi fructus* Based on *Anabaena azotica* and *Chlorella pyrenoidosa* in Wenxi County

5.1. Experiment Site and Farmer Information. Site: Duihou Village, Wenxi County, Shanxi Province (*experimental field of Wenxi County Half-mountain Crataegi fructus Planting Cooperative*) (see Figures 2–4).

Name and contact information of the farmer: Li Yuxian, 13834397137.

5.2. Experimental Design. In the treatment group, the soil was treated with *Anabaena azotica* and *Chlorella pyrenoidosa*, and in the control group, the *Crataegi fructus* plants were managed according to the management procedures of *Crataegi fructus* in Wenxi County. After the experiment, the results were compared by soil analysis and quality analysis. In order to ensure the accuracy of experimental results, during the whole growth process, soil tillage, weeding, irrigation, and pest control were carried out normally.

The *Crataegi fructus* experiment set a treatment group and a control group (covering an area of 1 mu), and the experiment was repeated for 3 times. The soil experiment set a treatment group and a control group (covering an area of 1 mu), and the experiment was also repeated for 3 times.

In each treatment and control group, all fruits of the trees in the east, west, south, north, and middle of the field were collected to determine the sugar content, polyunsaturated fatty acids and high-quality fruit rate; and the soil (1,000 cm^3) under these trees was collected for analysis.

5.3. Experimental Materials

5.3.1. Materials. "Dajinxing" *Crataegi fructus* in Duihou Village, Wenxi County, and the soil collected from the field of *Crataegi fructus* in Duihou Village, Wenxi County.

5.3.2. Experimental Materials. Anabaena azotica- and *Chlorella pyrenoidosa*-based biofertilizers were provided by Yuncheng Difulai Biotechnology Co., Ltd., with the single-cell rapid propagation technology, and *Anabaena azotica* and *Chlorella pyrenoidosa* cells reached 8 million/ML, respectively.

5.4. Type of Experimental Treatment.

5.5. Results and Analysis. As shown in Tables 1–3, for *Crataegi fructus* with 200 ml *Anabaena azotica* and *Chlorella pyrenoidosa*, the content of unsaturated fatty acid increased by 0.0041 g/100 g and the sugar content by 1.8% as compared with the control group.

Figure 2: Wenxi experimental field (overall field and performance of Dajinxing treated with biological fertilizers).

Figure 3: Wenxi experimental field (variety performance of Dajinxing treated with biological fertilizers).

Figure 4: Wenxi experimental field (variety performance of Dajinxing without being treated with biological fertilizers).

As shown in Table 4, the content of organic matters was increased by 0.18% in soil treated with 400 ml *Anabaena azotica* and *Chlorella pyrenoidosa*.

6. Experiment Effect of Algae-Rich *Crataegi fructus* Based on *Anabaena azotica* and *Chlorella pyrenoidosa* in Jiangxian County

6.1. Experiment Site and Farmer Information. Site: Zhengchai Village, Jiangxian County, Shanxi Province (see Figures 5–7).

Name and contact information of the farmer: Liu Shanfu 13934396508.

6.2. Experimental Materials

6.2.1. Materials. "Dajinxing" *Crataegi fructus* in Zhengchai Village, Jiangxian County, and the soil collected from the field of *Crataegi fructus* in Zhengchai Village, Jiangxian County.

6.2.2. Experimental materials. Anabaena azotica- and *Chlorella pyrenoidosa*-based biofertilizers were provided by Yuncheng Difulai Biotechnology Co., Ltd., with the single-cell rapid propagation technology, and *Anabaena azotica* and *Chlorella pyrenoidosa* cells reached 8 million/ML, respectively.

Table 1: Treatment of *Crataegi fructus*.

Treatment	Experiment treatment comparison
Treatment	*Anabaena azotica* and *Chlorella pyrenoidosa* + 70% conventional fertilization, once on August 1, 200 ml each of *Anabaena azotica* and *Chlorella pyrenoidosa*
Control	Conventional fertilization

Table 2: Soil treatment.

treatment	Experiment treatment comparison
Treatment	*Anabaena azotica* and *Chlorella pyrenoidosa* + 70% conventional fertilization, once on August 1, 400 ml each of *Anabaena azotica* and *Chlorella pyrenoidosa*
Control	Conventional fertilization

Table 3: *Crataegi fructus* results and analysis.

Item Treatment	Unsaturated fatty acid (g/100 g)	Sugar content (%)	High-quality fruit rate (%)
Treatment	0.0583	17.6	90
Control	0.0542	15.8	85

The detection method of unsaturated fatty acid adopted the first method in GB 5009.168–2016 and that of sugar content adopted the method in GB/T 10786–2006; the fruit greater than 0.15 kg was regarded as a high-quality fruit.

Table 4: Soil results and analysis.

Item Treatment	Sample state	Organic matter (%)
Treatment	Yellowish-brown	1.36
Control	Yellowish-brown	1.18

The detection of organic matters in the soil was performed according to the soil organic matter detection method in NY/T 85–1988 with 50 ml burettes.

Figure 5: Jiangxian experimental field (immature Dajinxing treated with biological fertilizers).

Figure 6: Appearance of "Dajinxing" treated with biological fertilizers.

Figure 7: Appearance of "Dajinxing" without being treated with biological fertilizers (control group).

6.3. Experimental Design. The *Crataegi fructus* experiment set two treatment groups and a control group (covering an area of 1 mu), and the experiment was repeated for 3 times. The soil experiment set two treatment groups and a control group (covering an area of 1 mu), and the experiment was also repeated for 3 times. In order to ensure the accuracy of experimental results, during the whole growth process, soil tillage, weeding, irrigation, and pest control were carried out normally.

In each treatment and control group, all fruits of the trees in the east, west, south, north, and middle of the field were collected to determine the sugar content, polyunsaturated fatty acids, and high-quality fruit rate; and the soil (1,000 cm^3) under these trees was collected for analysis.

Table 5: Treatment of *Crataegi fructus*.

Treatment	Experiment treatment comparison
Treatment 1	*Anabaena azotica* and *Chlorella pyrenoidosa* + 70% conventional fertilization, once on July 6, 200 ml each of *Anabaena azotica* and *Chlorella pyrenoidosa*.
Treatment 2	*Anabaena azotica* and *Chlorella pyrenoidosa* + 70% conventional fertilization, once on July 6, 400 ml each of *Anabaena azotica* and *Chlorella pyrenoidosa*.
Control	Conventional fertilization.

Table 6: Soil treatment.

Treatment	Experiment treatment comparison
Treatment 1	*Anabaena azotica* and *Chlorella pyrenoidosa* + 70% conventional fertilization, once on July 6, 200 ml each of *Anabaena azotica* and *Chlorella pyrenoidosa*.
Treatment 2	*Anabaena azotica* and *Chlorella pyrenoidosa* + 70% conventional fertilization, once on July 6, 600 ml each of *Anabaena azotica* and *Chlorella pyrenoidosa*.
Control	Conventional fertilization.

Table 7: *Crataegi fructus* results and analysis.

Item Treatment	Unsaturated fatty acid (g/100 g)	Diflubenzuron (mg/kg)	Chlordimeform (mg/kg)	Sugar content (%)	High-quality fruit rate (%)
Treatment 1	0.04430	Not detected	Not detected	15.25	91
Treatment 2	0.04735	Not detected	Not detected	15.60	90
Control	0.03890	0.0235	0.00981	14.80	84

Not detected indicated that the value was below the detection limit. The detection method of unsaturated fatty acid adopted the first method in GB 5009.168–2016, which of diflubenzuron and chlordimeform adopted the method in GB/T 20769–2008, and that of sugar content adopted the method in GB/T 10786–2006; the fruit greater than 0.15 kg was regarded as a high-quality fruit.

Table 8: Soil results and analysis.

Item Treatment	Sample state	Organic matter (%)
Treatment 1	Yellowish-brown	1.43
Treatment 2	Yellowish-brown	1.72
Control	Yellowish-brown	1.26

The detection of organic matters in the soil was performed according to the soil organic matter detection method in NY/T 85–1988 with 50 ml burettes.

6.4. Type of Experimental Treatment.

6.5. Results and Analysis. As shown in Tables 5–7, for *Crataegi fructus* with *Anabaena azotica* and *Chlorella pyrenoidosa*, the content of unsaturated fatty acid increased by 0.0054 g/100 g and 0.00845 g/100 g, the contents of diflubenzuron and chlordimeform decreased, and the sugar content increased by 0.45% and 0.80% as compared with the control group.

As shown in Table 8, the contents of organic matters were increased by 0.17% and 0.46% in soil treated with *Anabaena azotica* and *Chlorella pyrenoidosa* as compared with the control group.

7. Conclusion

7.1. Experimental Results. In conclusion, the one-year experiment on 'Dajinxing' treated with *Anabaena azotica* and *Chlorella pyrenoidosa* indicated that the use of *Anabaena azotica* and *Chlorella pyrenoidosa* could significantly reduce the pesticide residue on fruits; improve the appearance and quality of the fruits more significantly as compared with those with the use of chemical fertilizers; increase the content of unsaturated fatty acid, and improve the content of nutrients in the fruits; and obviously increase the content of organic matters in the soil.

7.2. Benefit Estimation. Within the growth cycle of *Crataegi fructus*, fertilization is generally performed twice (base fertilizer + flushing fertilize), with the average fertilizer cost of 500 yuan/mu/year; pesticides are generally sprayed for about 7 times, with the average cost of 350 yuan/mu/year (50 yuan each time); irrigation is generally performed for 4 times, with the average cost of 160 yuan/mu/year (40 yuan each time); therefore, the total cost is 1,100 yuan/mu/year. The cost of algal active cell biological fertilizer is 120 yuan/mu, and as calculated based on the reduction of fertilizers and pesticides by 30% (850×30% = 255), it can help the farmers to reduce the cost of 255–120 = 135 yuan per mu. The experimental results in 2020 and 2021 indicated that after using *Anabaena azotica* and *Chlorella pyrenoidosa*, the *Crataegi fructus* fruits were relatively uniform in size and good in color, and there were much more high-quality fruits. The average yield of 1,500 kg/mu in the experimental area, and the proportion of high-quality fruits without the use of biological fertilizer was about 85%; based on the unit price of high-quality fruits and non-high-quality fruits in the past two years, the benefit of *Crataegi fructus* per mu was 2,685 yuan. After using *Anabaena azotica* and *Chlorella pyrenoidosa*, the proportion of high-quality fruits increased to 90%, and the benefit was 2,790 yuan per mu. Therefore, the application of *Anabaena azotica* and *Chlorella pyrenoidosa* could reduce the cost of 135 yuan and increase the benefit of 105 yuan, with the total cost saving and efficiency increase of about 240 yuan. As calculated based on the area of 150,000 mu in the project area, the direct economic benefit of 36 million yuan could be increased each year. If calculated based on the area of 7 million mu in 2020, the economic benefit of cost saving and efficiency increase would be about 1.68 billion yuan as conservatively estimated; the specific benefits will be further verified and improved in subsequent promotion experiments.

7.3. Recommendations for Future Studies. In future, we will focus on the effects of nitrogen-fixing *Anabaena* and *Chlorella pyrenoidosa* on other fruits such as cherry, apple, and strawberry. If nitrogen-fixing *Anabaena* and *Chlorella pyrenoidosa* do have obvious improvement of content of polyunsaturated fatty acid on other fruits, it will have significant influence on the establishment of Chinese innovative fruit bands.

Objective. At present, there is no special treatment for cirrhotic ascites in modern medicine. Qi Sui Zhu Shui plaster (QSZSP) has been used in ascites. The purpose of this study was to investigate the mechanism of action of QSZSP in the treatment of cirrhotic ascites and its relationship with aquaporin 1 (AQP1). *Methods*. Twenty-four rats were divided into four groups, six rats in each group. Carbon tetrachloride-olive oil is injected into modeling. The control and model groups are treated with blank gel plaster (2 cm × 2 cm), QSZSP low-dose group is treated with Qi Sui Zhu Shui plaster (1 cm × 1 cm), and QSZSP high-dose group is treated with Qi Sui Zhu Shui plaster (2 cm × 2 cm). The changes in body weight and abdominal circumference were measured, the histopathological changes in liver, kidney, and peritoneum were observed in HE staining, the biochemical indexes related to liver function were detected, and the changes in AQP1 expression and the activation of MAPK pathway in the liver, kidney, and peritoneal tissues were evaluated in IHC staining and Western blot. *Results*. After one week of injection of carbon tetrachloride-olive oil, the rats in the model group increased their body weight slowly, the abdominal circumference of the model rats continued to increase with time. After 16 weeks of construction of the cirrhotic ascites model, the liver, kidney, and peritoneum were significantly damaged, and the serum levels of TBiL, AST, ALT, Cr, BUN, K, Na, and Ca in the rats were significantly higher ($P < 0.001$) and ALB levels were significantly lower ($P < 0.001$) than those in the control group. After 4 weeks of treatment, the liver, kidney, and peritoneal injury were improved. TBiL, AST, ALT, Cr, BUN, K, Na, and Ca levels were significantly lower ($P < 0.001$) and ALB levels were significantly higher ($P < 0.001$) than those in the model group. The protein expression of AQP1, p-ERK, p-JNK, and p-p38 was found to be inhibited in the liver, kidney, and peritoneum. *Conclusion*. QSZSP inhibits the protein expression of AQP1 and MAPK signaling pathway in the liver, peritoneum, and kidney to alleviate liver, kidney, and peritoneal injury caused by cirrhotic ascites, thus reducing the abnormal growth of abdominal circumference.

1. Introduction

Cirrhosis is a common clinical disease, which is caused by a series of pathological changes such as degeneration, necrosis, regeneration, and fibrous tissue proliferation of hepatocytes due to the persistent or repeated action of various pathogenic factors on the liver tissues, mainly manifesting as liver function decline [1]. The worldwide prevalence of cirrhosis is unknown. The prevalence of cirrhosis in the United States is about 0.15%–0.27% [2]. 69% of people do not know they have cirrhosis, and diabetes, alcohol abuse, hepatitis C and hepatitis B, being male, and being older are all associated with cirrhosis [3]. Regardless of the etiology, 50% of patients with cirrhosis will develop cirrhotic cardiomyopathy [4]. The 2017 National Vital Statistics Report for the United States reported that approximately 4.5 million adults, or 1.8% of the adult population, have chronic liver disease and cirrhosis. 41,473 people died from chronic liver disease and cirrhosis [5].

Ascites is the most prominent clinical manifestation of cirrhosis. It is the abnormal fluid accumulation in the abdominal cavity. About 60% of patients with compensatory cirrhosis develop abnormal peritoneal fluid accumulation within 10 years of diagnosis high incidence and poor prognosis of cirrhotic ascites, especially refractory ascites, can induce many fatal complications, which seriously affect the quality of life and survival rate of cirrhotic patients [7]. 90% of liver cancer cases are associated with the presence of cirrhosis [8].

Traditional Chinese medicine (TCM) has the effect of blocking or delaying malignancy and has low toxicity [9]. Long-term use of Chinese herbs can reduce the risk of cirrhosis in patients with chronic hepatitis B [10]. Qi Sui Zhu Shui plaster (QSZSP) consists of *Radix Astragali*, *Radix Kansui*, *Radix Aucklandiae*, *Poria*, *Herba Leonuri*, *Radix Salviae miltiorrhizae*, and *Pericarpium Arecae*. A previous clinical study found that QSZSP adjuvant treatment of patients with cirrhotic ascites resulted in improved urine output, 24 h urinary sodium excretion, reduced creatinine and total bilirubin levels, increased albumin content, and improved ascites recurrence rate after 3 months of continuous treatment with QSZSP [11]. There are few studies on QSZSP and cirrhotic ascites. In the history of research on the components in QSZSP and cirrhosis of the liver, Xiaozhang Tie as an adjuvant to primary therapy of cirrhotic ascites is safe [12]. Salviae miltiorrhizae significantly ameliorates cirrhosis and portal hypertension [13]. Further studies are needed on the agents of action of QSZSP in the treatment of cirrhotic ascites.

In 1991, CHIP28 was shown to function as a water channel, and subsequently, CHIP28 was renamed aquaporins [14, 15]. Thirteen aquaporins (AQP0-AQP12) have been identified [16–18]. Aquaporins have three isoforms. The first subtype transports only water molecules, the second subtype transports water molecules, urea, glycerol, etc., and the third subtype transports channels continuously open, without energy consumption or regulation [19–21]. Aquaporin 1 (AQP1) belongs to the first subtype, which exists as a tetramer and allows only water molecules to be transported across the membrane, and it is an independent water channel [22, 23]. The liver, peritoneum, and kidney are the organs in close contact, and AQP1 happens to be distributed in the liver, peritoneum, and kidney [24]. The water content of the human body is 70% of body weight, and abnormal water production-absorption-excretion in the peritoneal cavity is a key factor in the formation of ascites [19]. AQP1 is one of the aquaporins involved only in the transport of water molecules. Ascites in cirrhosis leads to increased accumulation of fluid in the liver, and the excess fluid is transferred to the peritoneum, which does not reabsorb enough water and eventually leads to increased reabsorption of water by the kidney, so AQP1 may be an important intermediate to study the metabolism of ascites.

Initially, cirrhosis leads to decreased liver function and increased fluid accumulation in the abdominal and thoracic cavities, forming ascites [25]. Ascites occurs commonly in cirrhosis [6]. Ascites is the abnormal fluid accumulation in the abdominal cavity [6]. Cirrhotic ascites can lead to kidney dysfunction [26]. In peripheral arterial vasodilation hypothesis, the kidney is involved in all 5 stages of ascites [27]. By linking AQP1 expression in the liver, peritoneum, and kidney, we propose a "liver-peritoneal-kidney" axis in cirrhotic ascites and suggest that it plays a critical role in the formation of cirrhotic ascites. It has been reported that AQP1 is regulated by MEK1/2 inhibitors in glial cells [28]. In prostate cancer cells, AQP1 protein expression levels are regulated by p38MAPK [29]. In human pleural mesothelial cells, peptidoglycan inhibits p38 MAPK regulation of AQP1 protein expression [30]. Therefore, the MAPK pathway would be a direction of AQP1 changes in the "liver-peritoneal-kidney" axis.

The role of QSZSP in the treatment of cirrhotic ascites and its relationship with AQP1 has not been reported yet. We speculate that the "liver-peritoneal-kidney" axis is a functional axis of water metabolism with aquaporins as the common material basis, which is involved in the "production-absorption-excision" of peritoneal fluid and plays a key role in the formation of cirrhotic ascites. The MAPK pathway may mediate QSZSP regulation of AQP1. Therefore, in this study, we treated rats with cirrhotic ascites *in vitro* with QSZSP, observed the histopathological changes in liver, kidney, and peritoneum, and evaluated the changes in AQP1 expression and activation of MAPK pathway in the liver, kidney, and peritoneal tissues to elucidate the effect of QSZSP in treating cirrhotic ascites and its mechanism.

2. Material and Methods

2.1. Regents. The reagents used are as follows: carbon tetrachloride (C805332) from Macklin, olive oil from Yihai Kerry Golden Dragon Fish Cereals, Oils and Foodstuffs Co., Ltd. (China), xylene and absolute ethanol from National Pharmaceutical Group Chemical Reagent Co., Ltd. (China), eosin (E8090) and neutral resin (G8590) from Solarbio (China), and hematoxylin (G1004) from Servicebio.

2.2. Qi Sui Zhu Shui Plaster Process. Qi Sui Zhu Shui plaster consists of Radix Astragali, Radix Kansui, Radix Aucklandiae, Poria, Herba Leonuri, Radix Salviae miltiorrhizae, and Pericarpium Arecae. The above seven Chinese medicines were purchased from the First Affiliated Hospital of Guangxi University of Traditional Chinese Medicine, in accordance with the provisions of the "Chinese Pharmacopoeia" 2010 edition.

12 ml of water is added to each 1 g of Radix Astragali, Poria, and Herba Leonuri and soaked for 30 min, water reflux extraction is repeated 3 times, 1.5 h each time, and the extracts are combined and filtered. 6 ml of 85% ethanol is added to each 1 g of Radix Kansui, Radix Aucklandiae, Radix Salviae miltiorrhizae, and Pericarpium Arecae and soaked for 30 min, water reflux extraction is repeated twice, 1.5 h each time, and the extracts are combined and filtered. The above two extracts were combined and dried under a vacuum to prepare dry powder. The base consists of 60% SodiuM acrylate, 30% carbomer, 10% Aluminium glycinate, and 6 times Glycerine. The penetration enhancer consists of 50% Azone and 50% propylene glycol. The base, penetration enhancer, and dry powder are mixed. Coater (RK-200, Tianjin Ruikang Babu Pharmaceutical Biotechnology Co.,

Ltd.) producing QSZSP is used. The hydrogel paste is prepared by RK-200 hydrogel coating machine (Tianjin Ruikang Babu Pharmaceutical Biotechnology Co.). Each tablet of this product contains Astragalus methyloside ($C_{41}H_{68}O_{14}$) in Radix Astragali, not less than 0.6932 mg, and Euphorbia grandis dienol ($C_{30}H_{50}O$) in Radix Kansui, not less than 1.4766 mg.

2.3. Animal. Animals from three Gorges University, twenty-four rats, male, weighing 200~250 g, were raised under the condition of no specific pathogen (specific pathogen free, SPF). The feeding environment is 22–26°C, 50%–60% of relative humidity. Modeling will begin in two weeks. Carbon tetrachloride-olive oil in 4 : 6 proportion, intraperitoneal injection dose of 3 mL/kg body weight, and injections were given twice a week (the four days and the seven days) for eleven weeks. For the control group, isotonic intraperitoneal injection of an equal amount of olive oil was given. The weight and abdominal circumference are measured before each injection. During the period, distilled water with 75% medical alcohol was used to prepare 10% concentration of drinking water for rats. Finally, four weeks of treatment, the body weight (Table 1), and abdominal circumference (Table 2) of the rats were measured twice a week for 15 weeks.

2.4. Treating and Sampling. Twenty-four rats were divided into four groups, six rats in each group, all rats were dehaired on the abdomen, and the dehairing area was 3 cm × 3 cm. Control group (Con) is treated with blank gel plaster (2 cm × 2 cm); model group (Mod), blank gel plaster (2 cm × 2 cm); QSZSP low-dose group, Qi Sui Zhu Shui plaster (1 cm × 1 cm); and QSZSP high-dose group, Qi Sui Zhu Shui plaster (2 cm × 2 cm). These were applied to the abdominal skin of depilated rats once a day for 6 h for 4 weeks. Carbon tetrachloride-olive oil was injected subcutaneously into the back once a week during treatment to prevent reversal of cirrhosis. After four weeks, the animals were killed by anesthesia and bloodletting. If the animals were not dead, the animals were anesthetized to death with pentobarbital sodium overdose (100 mg/kg). After anesthesia, the animals died without breathing or heartbeat. The filter paper method is used to obtain ascites. The blood from the abdominal aorta is collected and centrifuged, and serum is collected. An appropriate amount of liver tissue, kidney tissue, and peritoneal tissue is cut and fixed with 4% paraformaldehyde. In addition, the tissues of liver, peritoneum, and kidney were stored in an ultra-low-temperature refrigerator at −80°C. The fixed liver, kidney, and peritoneal tissues of rats were dehydrated and embedded in wax. The sections were frozen at −20°C and cut into a thickness of 3 μm, a water bath was used to stretch the sections, the sections were attached to slides, and the sections were stored at 4°C for backup.

2.5. Hematoxylin and Eosin (HE) Staining. The sections were stained in hematoxylin solution for 4 min, followed by rinsing with running tap water for 2 min and 15 s. The sections were then counterstained with eosin solution for 3 min. Cleaning was carried out at 80% and 95% ethanol, respectively, for 30 s each. The sections were then cleared in xylene for 3 s and mounted with neutral balsam. After staining, the sections were observed using a microscope, and Leica Application Suite was used to collect and analyze the relevant parts of the samples.

2.6. Biochemical Analysis. After the serum samples were thawed at 4°C, the serum samples were detected by Shenzhen Mindray BS420 Automatic Biochemical Analyzer, and TBiL, AST, ALT, ALB, Cr, BUN, K, Na, and Ca concentrations were determined with the Shenzhen Mairui (Shenzhen, China) Matching Biochemical Kit.

2.7. Immunohistochemical Staining. The protein expression of AQP1 in the liver, peritoneum, and kidney tissues was examined by immunohistochemistry. The slides were baked at 65°C for 1 h, soaked in xylene for 30 min, and hydrated in gradient alcohol. 1 mM Tris-EDTA buffer solution (G1203, Servicebio) was used for 18 min repair at 125°C and 103 kPa, incubated with 3% H_2O_2 (National Pharmaceutical Group Chemical Reagent Co., Ltd., China) for 10 min, incubated with 10% goat serum (SL038, Solarbio) for 30 min, and titrated with primary antibody AQP1 (PAB45863, Bioswamp), peritoneum dilution 1 : 250, and liver and kidney dilution 1 : 400 at 4°C overnight. The sections were transferred from 4°C to room temperature and left for 45 min. Treated with Max Vision TM HRP-Polymer anti-Rabbit secondary antibody (KIT-5020, MXB) for 60 min at 37°C. Treated with DAB (DA1010, Solarbio) until the sections change color. Soak the sections in turn, hematoxylin 3 min, 75% alcohol 5 min, 85% alcohol 5 min, 95% alcohol 5 min, 100% alcohol 10 min, xylene 10 min. Neutral resins seal sections. Leica Application Suite image system was used to capture the relevant parts of the sample. The nuclei were stained blue with hematoxylin, and the DAB showed positive brownish yellow.

2.8. Western Blot. The protein levels of p38, p-p38, ERK1/2, p-ERK1/2, JNK1/2/3, p-JNK1/2/3, and AQP1 in the liver, peritoneum, and kidney tissues were analyzed by Western blot. Tissue samples were homogenized in RIPA lysate (R0010, Solarbio) containing protease inhibitor at 4°C and centrifuged at 12000 g for 15 min. The concentration of the proteins was measured using the BCA Protein Assay Kit (PC0020, Solarbio). Proteins (20 μg) were separated by 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred onto polyvinylidene fluoride membranes (IPVH00010, Millipore). The membranes were blocked with 5% skim milk for 2 h at room temperature in Tris-buffered saline and incubated with primary antibodies against p-ERK1/2 (ab214036), JNK1/2/3 (ab208035), p-JNK1/2/3 (ab76572), and p-p38 (ab47363) from Abcam (UK), and ERK1/2 (MAB37123), p38 (PAB37381), AQP1 (PAB45863), and GAPDH (PAB36269) from Bioswamp (China), overnight at 4°C. GAPDH antibody (PAB36269, Bioswamp) was

Data presented as mean ± standard deviation.

selected as an internal reference. All of the primary antibody dilution ratio is 1 : 1000. The membranes were then washed with Tris-buffered saline and incubated in goat anti-rabbit IgG secondary antibody (SAB43714, Bioswamp, 1 : 20000) for 2 h at room temperature. Immunoreactivity was visualized by the colorimetric reaction using Immobilon Western HRP (WBKLS0500, Millipore). The membranes were scanned with an Automatic Chemiluminescence Analyzer (Tanon 5200, Tanon).

2.9. Statistical Analyses. Statistical analyses were performed using SPSS 23.0 software. All data were presented as mean ± standard deviation (SD). Comparisons between the two groups were made using the independent-samples *t*-tests. The one-way ANOVA was used to compare differences among three or more groups, and the *post hoc* Fisher's least significant difference (LSD) test was used for the individual group comparisons. The values of $P < 0.05$ were considered statistically significant.

3. Results

3.1. Cirrhotic Ascites Lesions. As shown in Figure 1(a), the nucleus is stained with hematoxylin in a distinct blue color. The components in the cytoplasm and extracellular matrix were stained with eosin in different shades of red. The hepatocytes in the model group all showed steatosis, the pseudolobular structures were obvious in the fourth-week samples, and the sixth-week samples showed sclerotic necrotic features with disorganized hepatocyte arrangement, hepatocyte degeneration and necrosis, obvious proliferation of fibrous connective tissue, and extensive formation of pseudolobular structures. After ten weeks plus three days of carbon tetrachloride-olive oil injection, the rats in the model group increased their body weight slowly, and after the first week, a significant difference in body weight began to appear between the control group and the model group ($P < 0.001$), and the abdominal circumference coefficient (abdominal circumference/body weight) was calculated and found that the rats in the control group increased their abdominal circumference and body weight normally. On the contrary, the abdominal circumference of the model rats continued to increase with time. The increase in abdominal circumference was significantly greater in the model group than that in the control group at week 3 (Figure 1(b)). Thus, cirrhotic ascites can lead to an abnormal increase in abdominal girth and severe damage to the liver in rats.

3.2. QSZSP Alleviates Visceral Damage Caused by Cirrhotic Ascites. As shown in Figure 2, in the cirrhosis model group, the liver structure was disturbed and extensive vacuolar-like degeneration could be seen, and kidney tissue damage, glomerular hypertrophy, increase in the stroma of the thylakoid region, inflammatory cell infiltration, glomerular epithelial cell detachment, and the kidney tubules were dilated; peritoneal mesothelial cells were increased, the submesothelial stroma was thickened, and the peritoneal tissue was thickened. After four weeks of treatment with high-dose QSZSP, the liver tissue structure was basically intact, with centered nuclei and red-stained cytoplasm; most of the glomeruli had normal structure and normal tubules; peritoneal mesothelial cells were shed, and peritoneal tissue thickness was reduced compared with the model group.

3.3. QSZSP Regulates Liver Function-Related Factors in Rats with Cirrhotic Ascites. As shown in Figure 3, the concentrations of TBiL, AST, ALT, Cr, BUN, K, Na, and Ca in the model group were significantly higher ($P < 0.001$) than those in the control group and were significantly reduced after treatment with high doses of QSZSP. The concentrations of ALB in the model group were significantly lower ($P < 0.001$) than those in the control group, and their concentrations were significantly increased ($P < 0.001$) after treatment with a high dose of QSZSP. Combining the above two results, it can be found that QSZSP has the ability to modulate liver function-related factors to alleviate liver, kidney, and peritoneal damage caused by cirrhotic ascites.

3.4. QSZSP Regulates AQP1 Protein Expression in the Liver, Kidney, and Peritoneum. As shown in Figure 4, cirrhotic ascites leads to abnormally high expression of AQP1 protein in the liver, kidney, and peritoneum of rats ($P < 0.001$). Compared with the model group, AQP1 protein expression was reduced after treatment with a low dose of QSZSP and significantly reduced ($P < 0.001$) after treatment with a high dose of QSZSP, but AQP1 protein expression in the liver, kidney, and peritoneum was still higher than that in the control group at this time. QSZSP was able to inhibit AQP1 protein high expression caused by cirrhotic ascites.

3.5. QSZSP Inhibits the MAPK Signaling Pathway. As shown in Figure 5, the activation of p-ERK, p-JNK, and p-p38 in the model group was detected simultaneously in the liver, kidney, and peritoneum. The protein expression of p-ERK, p-JNK, and p-p38 was reduced after QSZSP treatment, and p-ERK, p-JNK, and p-p38 protein expression levels were significantly lower ($P < 0.001$) after a high-dose QSZSP treatment than those in the model group.

3.6. QSZSP Induces Abdomen Circumference in Rats with Cirrhotic Ascites. As shown in Figure 6, after four weeks of treatment, the model group's rat body weight is always lower than the other three groups, and after treatment with QSZSP at high dose, rats with cirrhotic ascites showed a significant increase in body weight, and the body weight of rats in the QSZSP low-dose treatment group was also higher than that of the model group (Figure 6(a)). Interestingly, the rats in the QSZSP high-dose group showed a decreasing trend in abdominal circumference along with an increase in body weight, and after four weeks of treatment, the rats in the QSZSP high-dose group were significantly lower than the model group. Combined with the results of HE staining, it could indicate that QSZSP alleviated the organ damage caused by cirrhotic ascites and reduced the abnormal growth of abdominal circumference.

4. Discussion

Cirrhosis ascites is a pathological phenomenon of fluid accumulation in the abdominal cavity caused by a combination of factors during the decompensated phase of cirrhosis and is the most common first event in the decompensated phase of cirrhosis. It not only brings unbearable pain to patients with liver disease and significantly reduces the quality of life, but also causes water-electrolyte disorders and deterioration of the body's internal environment, which can lead to serious complications such as liver encephalopathy, upper gastrointestinal bleeding, and hepatorenal syndrome, and is one of the main factors leading to death in patients with liver disease [31, 32]. Studies have

shown that patients with cirrhotic ascites have a 3-year morbidity and mortality rate of 50% and a 5-year survival rate of only 5–10% [33]. This study not only found that cirrhotic ascites led to severe liver, peritoneum, and kidney damage, but also found that rats with cirrhotic ascites had slowed weight gain and excessive growth in abdominal circumference (Figure 1). After 4 weeks of treatment, the rats began to gain weight and their abdominal circumference was reduced (Figure 6).

Tie et al. [29] found that in prostate cancer cells, hypoxia induced AQP1 protein upregulation in a p38-dependent manner and that AQP1 was induced by hypoxia at the transcriptional level and that AQP1 regulation in PC-3M was dependent on calcium, PKC, and p38MAPK as well as oxygen tension. AQP1 is widely expressed in lymphatic vessels, capillaries, and endothelial cells of small veins and is distributed in the liver, peritoneum, kidney, pleura, respiratory tract, digestive tract from esophagus to colon, cardiac muscle, smooth muscle, and brain [24]. Huebert et al. [34] found that in the early stages of liver fibrosis, AQP1 expression on liver tissue cell membranes increased accordingly as the degree of liver fibrosis progressed. Liu et al. [30, 35] found that peptidoglycan is an inhibitor of the p38 MAPK transduction pathway and lipopolysaccharide is an inhibitor of the p38/JNK/ERK pathway ultimately acting on the AQP1 gene causing downregulation of AQP1 expression in human pleural mesothelial cells and that the reduction in AQP1 expression is dose-dependent and time-dependent. In this study, QSZSP was able to inhibit AQP1 protein high expression caused by cirrhotic ascites in the "liver-peritoneum-kidney" axis of cirrhotic ascites rats. QSZSP was able to inhibit AQP1 protein high expression caused by cirrhotic ascites, and the MAPK signaling pathway in the "liver-peritoneum-kidney" axis was also inhibited at this time. This demonstrated that the activation of MAPK signaling pathway was involved in organ damage in the "liver-peritoneum-kidney" axis of cirrhotic ascites rats and was associated with AQP1. Finally, it was found that the treated rats had lower Cr and TBiL and significantly higher ALB in serum, which, combined with the increase in body weight after treatment, indicated that QSZSP had some effect on improving the quality of life.

However, for the treatment of patients with cirrhotic ascites, medicine will obviously increase water intake, which contradicts the principle of water restriction in this disease; in particular, for patients with a large amount of ascites, medicine administration will further increase the patient's abdominal distension symptoms, and their compliance is poor. Chinese medicine is an important external treatment method in TCM, which can solve the contradiction between traditional Chinese medicine and the treatment of cirrhotic ascites with water restriction and can act directly on the diseased area. The development of the formulation process, quality standard, and safety of the gel form of QSZSP has been completed in the previous phase [36–39].

Previous studies on the mechanism of ascites formation in cirrhosis have mainly focused on the pathological role of the liver and kidney, such as the alteration of portal hemodynamics by cirrhosis, the water and sodium retention effect of the kidney, or the hormonal changes triggered by both, neglecting the role of the peritoneum and the role of the liver-peritoneum-kidney as an organic whole in the formation of ascites in cirrhosis.

Based on the previous study, this study took the pathological nature of water metabolism disorder in cirrhotic ascites as the starting point and was the first to propose the hypothesis that the "liver-peritoneum-kidney" axis is a functional axis of water metabolism that is involved in the "production-absorption-exhaustion" of peritoneal fluid with aquaporins protein as the common material basis and plays a key role in the formation of cirrhotic ascites. It was proved that QSZSP can inhibit the activation of MAPK signaling pathway and protect liver function in cirrhotic ascites rats, and it was found that AQP1 of "liver-peritoneal-kidney" axis plays a facilitating role in the process of ascites in cirrhosis ascites. The study also demonstrated that QSZSP regulates AQP1 expression in the "liver-peritoneal-kidney" axis, thus achieving the therapeutic effect of blocking ascites. It is clear that QSZSP inhibits AQP1 expression in the liver, peritoneum, and kidney, thus reducing abdominal girth. This process is related to the inhibition of MAPK pathway activation by QSZSP.

Many studies have found that the MAPK signaling pathway is involved in the regulation of ascites in cirrhosis. In this study, we found that the activation of MAPK signaling pathway was inhibited after QSZSP treatment, but whether QSZSP targets the MAPK signaling pathway for the treatment of cirrhotic ascites is unknown in this study. As a limitation of this study, perhaps the targeting relationship of MAPK signaling pathway in QSZSP for the treatment of cirrhotic ascites will be verified *in vitro* in future studies of liver.

5. Conclusion

QSZSP inhibits MAPK activation and AQP1 protein expression in the "liver-peritoneal-kidney" axis to alleviate ascites injury in cirrhosis.

Data Availability

The data used to support the findings of this study are available from the corresponding author upon request.

Additional Points

(i) Qi Sui Zhu Shui plaster inhibits MAPK activation in cirrhotic ascites rat. (ii) Qi Sui Zhu Shui plaster suppressed cirrhotic ascites-induced liver-peritoneum-kidney damage *in vivo*. (iii) Qi Sui Zhu Shui reduced abdominal circumference thickness by inhibiting the overexpression of AQP1.

Ethical Approval

All animal experiments are in line with the relevant provisions of the Ethical Certificate of Experimental Animals of the Animal Administration Commission of Hubei Province. The license number for laboratory animals is as follows: SYXK (E) 2018–0104.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

The aim of the study is to build a tongue image intelligent analysis "end-to-end" deep learning network based on a tongue diagnosis image of traditional Chinese medicine. The tongue target region in the original image was segmented by the UNet tongue segmentation model at the front end of the network. After segmentation, the feature vector of the tongue target region was extracted by the ResNet network, and then the blood pressure on the day of shooting was fused with the feature vector extracted by the ResNet network through the convolution operation method to complete the extraction of two groups of data of tongue feature and fusion feature. Based on analyzing the data of blood pressure, tongue image, and their fusion at the end of the network, four regression analysis methods were used to predict the stage mean value. After training, the model is tested with the test set data, and the test results are evaluated with mean absolute error (MAE). The prediction error of the model based on the fusion data of tongue image and blood pressure on the day of shooting was lower than that of the other two data modes. The UNet tongue segmentation model combined with the ResNet network can realize the automatic extraction of tongue image features. The extracted features combined with machine learning modeling can be used to explore the complex hierarchical mathematical association between tongue image and clinical data. The experimental results show that the multimodal data fusion method is an important way to mine the clinical value of the TCM tongue image.

1. Introduction

Tongue diagnosis is an important part of Chinese medicine diagnosis, and the development of tongue diagnosis in Chinese medicine can be traced back to the Yin and Shang dynasties, after which generations of physicians have attached great importance to the application and research of tongue diagnosis, and it has been inherited as the core content of "diagnosis by looking," which is the first of the four diagnoses in Chinese medicine. A tongue image is the observation object of tongue diagnosis, and its theoretical body is mainly derived from the theory of holistic view of Chinese medicine, which means that the physiological state of the whole body can be detected by localization [1]. Based on the holistic view of Chinese medicine, the expression of the physiological functions of the human body by the tongue can be characterized as phased, comprehensive, and dynamic. Most of the clinical studies on the Chinese medicine tongue are based on the characteristics of the tongue, such as tongue texture, tongue coating, tongue shape, and other characteristics associated with clinical diseases, which to a certain extent limits the value of the tongue to the overall expression of human physiological information. In order to realize the efficient mining of valuable vital information contained in the tongue, this study combines the current information science hotspot "deep learning" technology to explore the intelligent analysis network of tongue image and verify the practicality of the network in tongue image data mining through clinical data.

1.1. "End-to-End" Model of Tongue Image Data Analysis. After decades of development, the modernization of Chinese medicine tongue diagnosis has made many achievements in data acquisition and data feature extraction, but the current research difficulties are mainly focused on the discovery of clinical information of tongue images [2]. Early studies on the objectification of tongue diagnosis mostly used quantitative methods to identify tongue features and thus achieve automated classification of tongue images. In recent years, with the development of machine learning technology, the objectification of tongue diagnosis has become more clinical, and it has become possible to use tongue images to understand the diagnosis and prognosis of diseases intuitively. In 2006, Hinton and Salakhutdinov [3] proposed the concept of layered neural networks, in which there are a large number of hidden layers in these layered networks to enhance the model learning ability. It further stereotyped the neural network by using deep hidden layers to enhance the learning ability of the network for stereoscopic data such as images, speech, and video [4], allowing the network to better handle medical image data such as tongue images. Thanks to the advancement of machine learning modeling, it is possible to mine clinical data of tongue images in an "end-to-end" mode from the input of the original image captured to the output of clinical data. This changes the traditional research paradigm of associating tongue images with clinical data.

1.2. Network Architecture for Intelligent Analysis of Tongue Clinical Information. Intelligent analysis of tongue clinical information refers to the separation of the tongue in the original image, then feature extraction of the target region of the tongue, and modeling analysis with clinical indicators, and finally yielding a prediction model of clinical indicators based on the tongue image. In this study, based on the data characteristics of clinical test indicators, which are mainly continuous variables, an intelligent tongue analysis network is constructed using a "dual-flow" network architecture. The network is composed of four different functional module groups (Figure 1).

One is the Unet tongue segmentation network model developed by our group [5], which is a deep learning network model consisting of 11 "convolution-pooling" layers (Figure 2). The semantic segmentation test results show that the model achieves a mean intersection ratio (MIoU) of 91% and a pixel accuracy (PA) of 93%.

The second is the feature extraction module for ResNet image data. In this module, data feature vector extraction is performed by multilayer residual network (ResNet) using pretrained weight values from ImageNet dataset. The ResNet structure is designed with 8 modules, connecting a convolutional layer from the input layer in turn, and then connecting Bottleneck1-4 modules, with a 1^*1 average pooling at the end of the Bottleneck4 output connection network to retain more coding information (Figure 3).

The third is the convolutional fusion module. To meet the need for further data mining, a convolutional fusion module is set up in the network architecture to integrate the tongue image with the associated data, and the fused data can be output as independent variables for regression modeling analysis. In this module, the collected clinical data are adjusted to 1^*2048 vectors by replication expansion, and then superimposed with the 1^*2048 vectors extracted by the above ResNet network, i.e., each vector channel is D before fusion and 2D after fusion. After completing the connection fusion, a 1^*1 convolutional kernel is used to do the dimensionality reduction in the channel dimension. The data obtained by convolutional fusion for the tongue image can be combined with a certain clinical data parameter to form a multimodal fusion data structure into the end-of-network regression analysis session.

The fourth is the regression modeling analysis part at the end of the network, which uses the tongue data features or the fused data of tongue data features and a certain clinical information as independent variables to carry out the prediction of the target physiological information. The regression analysis can select multiple machine learning models according to the data type, distribution pattern, and other characteristics combined with clinical information.

2. Web Application Experiment of Intelligent Analysis of Tongue Image Based on Deep Learning Technology

The tongue, as a muscular organ, in a healthy state, has a light red color due to the abundance of internal capillaries, i.e., the light red tongue image. In the pathological state, on the other hand, the tongue can take on a dark or light reddish-red, purple-dark, greenish-gray, or pale white color due to factors such as the amount of hemoglobin, impaired vascular circulation, or structural problems [6]. In Su Wen - Yin Yang Ying Xiang Da Lun, "The heart is the master of the tongue …… in the orifice for the tongue"; In Ling Shu - Pulse Degree, "The heart is connected to the tongue, the heart and the tongue can know the five tastes," on the basis of which later medical practitioners further condensed the relationship between the tongue and the heart as "the heart opens the orifice in the tongue, the tongue is the seedling of the heart." In recent years, it has been found that the initial pathological changes of primary hypertensive disease are mostly intermittent spasms of tiny arteries throughout the body [7], which can lead to organ damage after a period of time and the initial damage sites are mainly concentrated in the tiny arteries [8]. Microvascular lesions within the tongue can have an impact on tongue color, and the tongue, as a dense area of microcirculation in the body, has a complex intertwined network of vessels at all levels [9]. It is clear that changes in arterial blood pressure in the human body first affect the microcirculatory system, and the human tongue is the largest dense organ of microcirculation that we can visually and noninvasively observe, suggesting here that

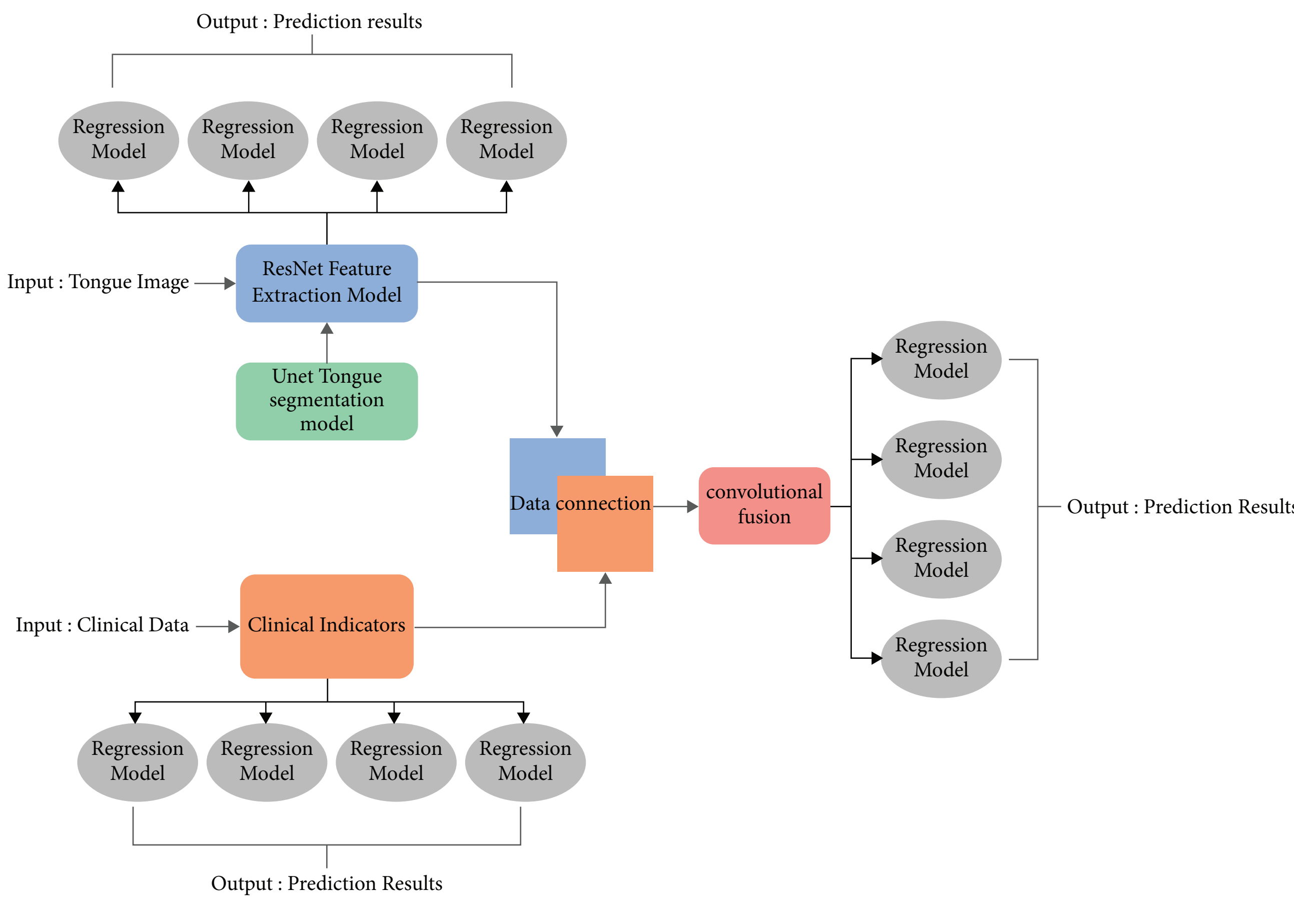

Figure 1: Dual path network architecture diagram.

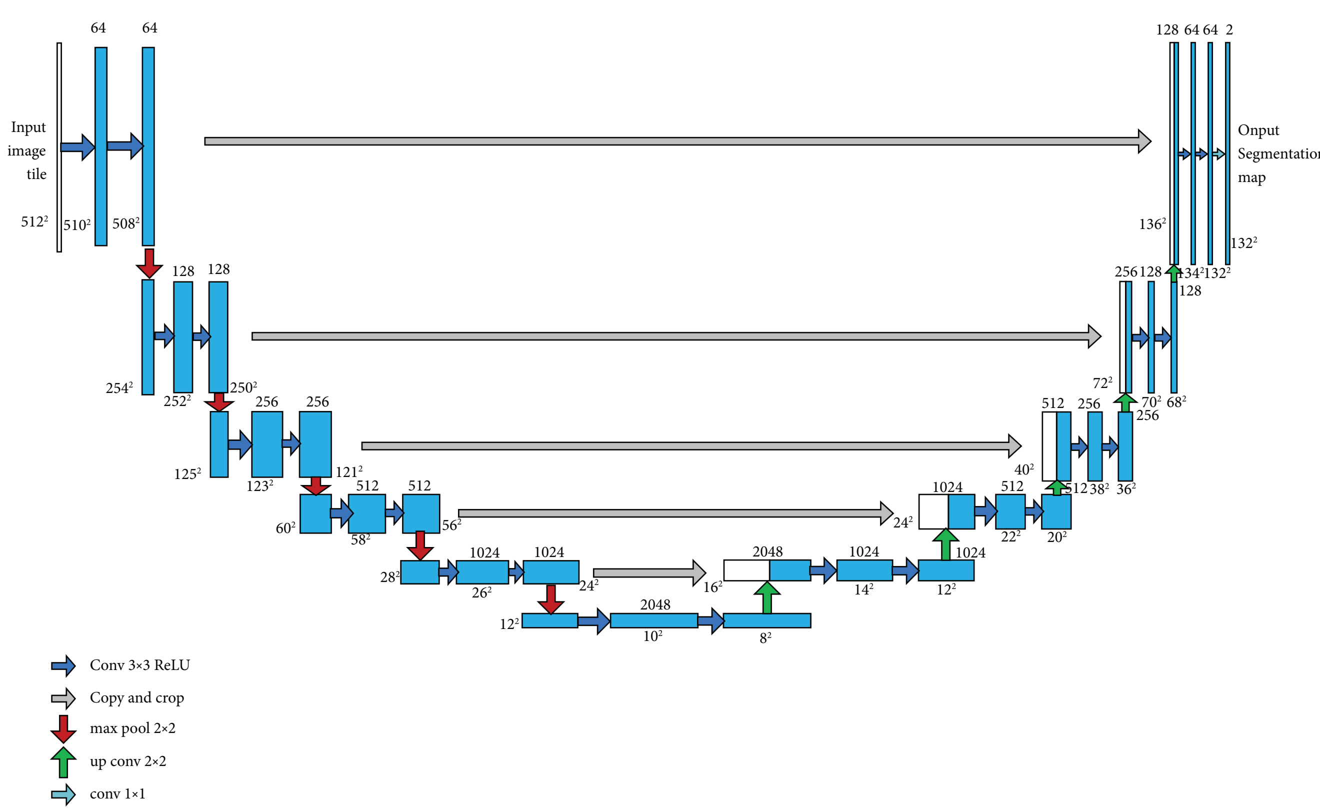

Figure 2: Unet tongue segmentation model.

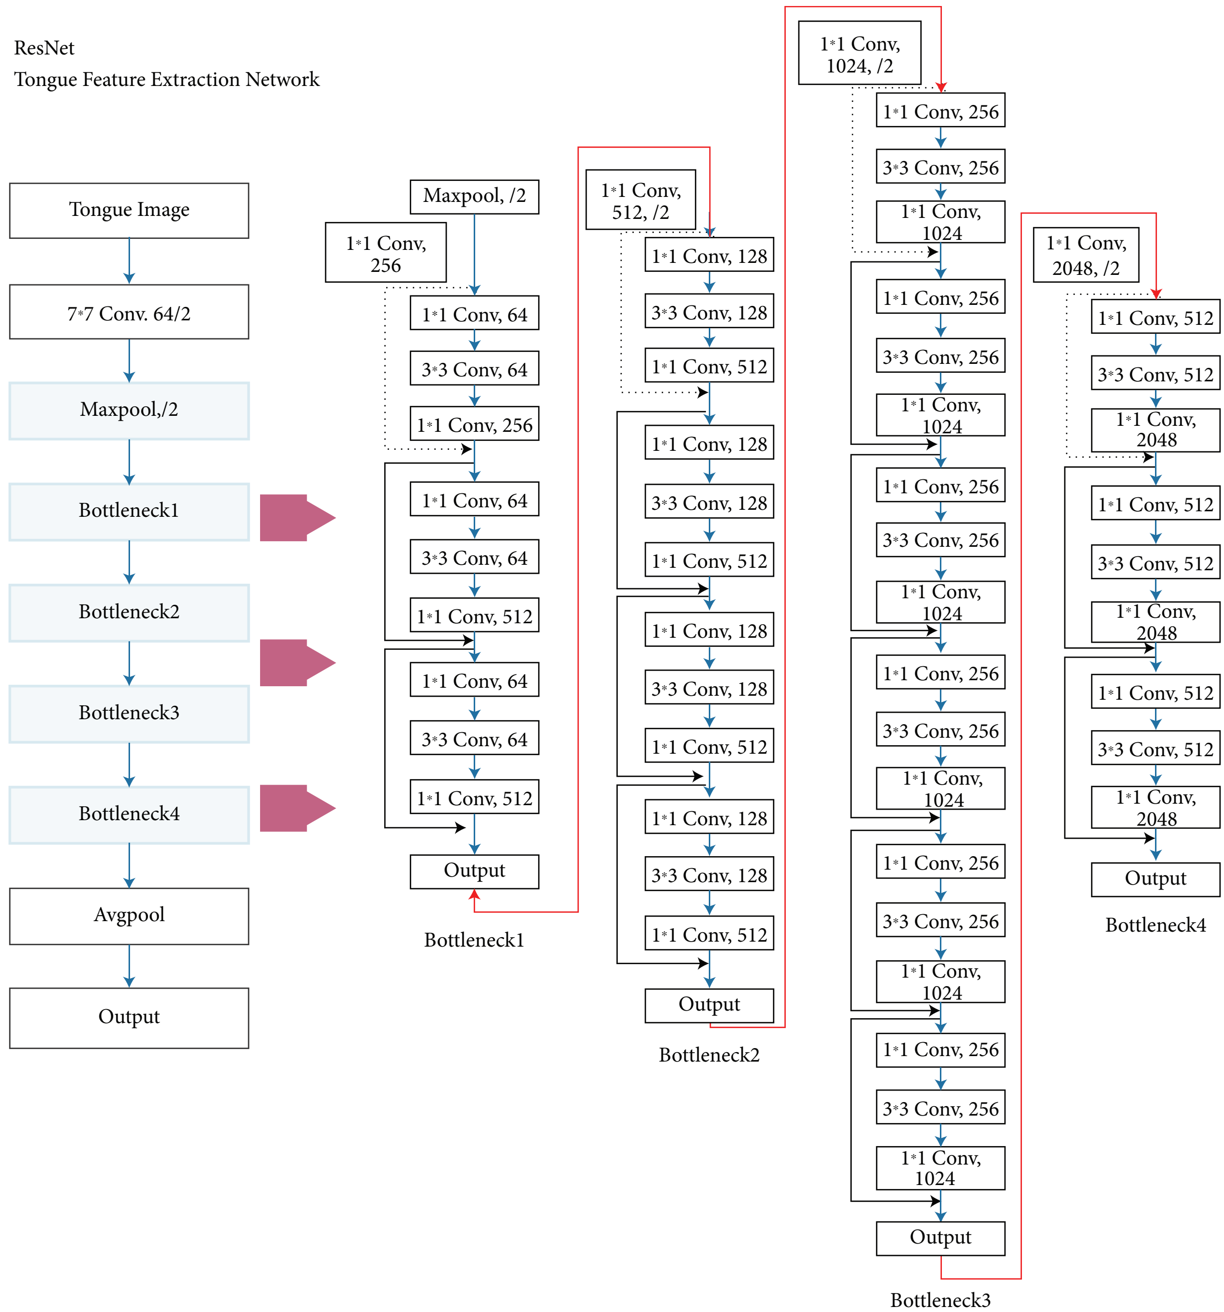

Figure 3: ResNet network structure.

there may be some correlation between tongue image and human blood pressure.

To further explore the application value of the intelligent analysis network of tongue images, a clinical experiment was set up in this study to combine the abovementioned Chinese medicine and modern medical theories for the constructed clinical data analysis network model of tongue images. The experiment was conducted with the mean value of the blood pressure values of the last 6 days of the week with staging diagnostic value as described in the Chinese Guidelines for the Prevention and Treatment of Hypertension 2018 Revision [2] as the target, and the blood pressure values of the day were collected using the tongue image and the tongue image overlay as the independent variables for the prediction experiment. To ensure the reliability and traceability of the experimental data and to reduce some interfering factors, the study population was selected from inpatients with type 2 diabetes mellitus in the Department of Endocrinology of the Affiliated Hospital of Chengdu University of Chinese Medicine. The input data of the dual-stream network were set up with two kinds of data: tongue image and blood pressure on the day of collection, and the network combined the two kinds of data into fused data by a convolutional fusion module. By comparing the prediction results of the three data, the value of tongue image in predicting the target data can be further illustrated, thus reflecting the correlation between the independent variable data and the dependent variable data to a greater extent.

The clinical trial was completed at the China Clinical Trials Registry in August 2018 (registration number: ChiCTR1800018090). The ethical review was approved by the Medical Ethics Committee of the Affiliated Hospital of Chengdu University of Traditional Chinese Medicine in July 2018 (Ethics Committee Approval Document No.: 2018KL-050). Tongue data and clinical data were collected from September 2018 to November 2019.

The tongue photo acquisition equipment used is the TFDA-1 desktop tongue diagnostic instrument developed by Shanghai University of Traditional Chinese Medicine, which consists of a CCD digital camera, LED light source, light shield, base, and curved reflector. The color temperature of the LED light is 5000K and the color rendering index is 97 as shown in Figure 4.

TFDA-1 usage and parameter settings: shooting parameters are M mode, shutter speed is 1/125; aperture value is F6.3; ISO sensitivity is 200; image size is L 5568*3712; central focus metering; automatic white balance. The collected raw tongue data are subject to regular quality control checks.

Clinical data were obtained from the inpatient medical record system of the Affiliated Hospital of Chengdu University of Traditional Chinese Medicine. The raw data were recorded in spreadsheet form using Microsoft Office Excel software and consisted of blood pressure records twice a day, morning and evening, during the patients' hospitalization. After collection, the data were randomly divided into training set (80%) and test set (20%) by inclusion number using Excel software.

2.1. Experimental Environment. The hardware configuration of the experimental computer is: Intel Core I7-9700 processor, Intel Q370 motherboard, NIVDA Geforce GT1080ti graphics card; the operating system is Ubuntu 9.04, the programming language is Python 3.7, and the model network is built through pytorch.

2.2. Regression Analysis. Since the data consisted of three categories, the regression modeling was performed in three groups, with each group modeling diastolic blood pressure and systolic blood pressure separately. The regression models used were identical for all three data categories, and only the input independent variables were changed in the experiment. The regression analysis process of the four models is described in detail in the following section, using "blood pressure on the day" as the independent variable, which is used as a reference for the other two data categories. The sample size of the training set used in this experiment was 260 cases. Since the blood pressure data were divided into diastolic and systolic blood pressure, we modeled the prediction of diastolic blood pressure and systolic blood pressure separately, so the methods used are exactly the same, and we will not describe the methods separately, but use "blood pressure" in the following.

FIGURE 4: TFDA-1 benchtop tongue diagnostic instrument.

2.3. Random Forest (RF). Random forests are reinforced classifiers consisting of multiple decision trees. The basic architecture is to form a model group of multiple decision tree classifiers and to "vote" on the output of these decision trees to determine the most optimal data processing result by the most votes [10]. A random forest of 10 trees was used for the regression experiments. The model training process is as follows:

(1) The value of blood pressure on the first day of the count is taken as the independent variable, x_i, and the mean of the patient's data from the second to the seventh day is taken as the dependent variable, y_i.

(2) For $i = 1,2, \ldots, 260$, the training set is randomly sampled for the ith time and a total of 260 acquisitions are made to obtain a sample set D_i containing 260 blood pressure data samples, and the ith tree model $T_i(x)$ is trained with the sample D_i. When training the tree model nodes, the features of some samples are randomly selected from all the blood pressure sample features on the nodes at the same time, and then an optimal feature is selected from them to be the left and right subtree division feature of the tree.

(3) The abovementioned tree model is averaged out, and the arithmetic average is considered directly here, so that the final output model $L(x) = 1/260\sum_{k=1}^{260} T_k(x)$ is the result.

2.4. Adaptive Enhancement Algorithm (AdaBoost). The adaptive boosting algorithm (AdaBoost) is trained with multiple weak classifiers in the training set and the sample weights are corrected according to the classifier error rate and then given to the next classifier, which forms a strong classification by combining multiple sets of weak classifiers [10] as follows:

(1) Initialize the weight matrix W of the blood pressure data. Each of the 260 data is assigned a weight $w_1 = 1/260$.

(2) Training the regression function f_i. The process is as follows: if a blood pressure sample point is correctly predicted by the regression function f_i, the corresponding weight is reduced for the next blood pressure training, and if it is incorrectly classified, the corresponding weight is increased. The updated blood pressure set is used to train the next classifier,

and so on iteratively. In this case, the error of the regression function f_i is

$$e_t = \sum_{i=1}^{260} w_{ii} I\left(H_t\left(x_i\right) \neq y_i\right), \tag{1}$$

where $I(\cdot)$ is the information function, $H(\cdot)$ is the entropy function, and W_{ii} is the weight of the ith iteration.

(3) The obtained regression function is combined, which is the final regression function:

$$D_{t+1} = \frac{D_t(i)\exp\left(-\alpha_t y_i H_t\left(x_i\right)\right)}{Z_t}, \tag{2}$$

where $Z_t = 2\sqrt{e_t\left(1 - e_t\right)}$ is the normalization constant.

2.5. Iterative Decision Tree (GBRT). GBRT is an integrated model consisting of numerous decision trees of shallow depth combined in a hierarchical connection [11], and the characteristics of GBRT are mainly focused on strong adaptability to various data categories and high accuracy of regression prediction, which is in line with the experimental design of this experiment in which prediction is carried out based on different categories of data. The decision tree model in the model group does not play the role of classification judgment, but carries out regression prediction, and this prediction process is carried out in each regression tree for the input data and more accurate prediction values are obtained through continuous correction. The calculation process in the experiment is as follows:

Input: Blood pressure data set. $D = \{(x_1, y_1), \ldots, (x_{260}, y_{260})\}$

Output: Return to lifting tree. $T_D(x)$

(1) Initialization $T_0(x) = 0$.

(2) For $n = 1, \ldots, 260$, the residual $r_{ni} = y_i - T_{n-1}(x_i)$ is calculated, and the residual is fitted to obtain the regression tree as $T(x; \Theta_m)$, and the update law as $T_m = T_{m-1} + T(x; \Theta_m)$.

(3) Obtaining regression tree $T_D(x) = \sum_{m=1}^{260} T(x; \Theta_m)$.

2.6. Support Vector Regression (SVR). SVR is a regression analysis, so there is only one type of sample points, and the total deviation of all sample points from the hyperplane is found to be the minimum distance in the regression process. For the consideration of linear distribution of blood pressure data, the kernel function is chosen as a linear type in this experiment. Moreover, $C = 1e3$, C represents the importance for outlier points. $\gamma = 0.01$ denotes the coefficient of the kernel function, which is too large to cause overfitting because it is a linear function, and is finally chosen to be 0.01. The blood pressure data are equivalent to solving the following constrained optimization problem in the SVR:

$$\begin{cases} \min\limits_{w,b} \dfrac{1}{2}\|\mathbf{w}\|^2, \\ \text{s.t.} \left|y_i - \left(\mathbf{w}\mathbf{x_i} + b\right)\right| \leq \varepsilon \quad i = 1, 2, \ldots, N, \end{cases} \tag{3}$$

where $\mathbf{w} = w \in R$ is the weight of the regression curve and ε is the maximum value of the distance from the curve to the blood pressure data point.

2.7. Evaluation Methods of Prediction Results. There are two commonly used regression prediction evaluation methods, namely, mean absolute error (MAE) and root mean square error (RMSE). In this experiment, mean absolute error [12] (MAE) was chosen to evaluate the test results, and the mean absolute error is the absolute average of the error between the prediction results and the real data, and the larger the mean absolute error is, the worse the prediction accuracy is proved to be. The use of MAE as a criterion for judging the error can better express the true error of data with 1-dimensional characteristics compared to RMSE [13] and facilitate the comparison between different data categories. The MAE formula is as follows:

$$\text{MAE} = \frac{1}{m}\sum_{i=1}^{m}\left\|y_{\text{test}}^{(i)} - \hat{y}_{\text{test}}^{(i)}\right\|_1. \tag{4}$$

3. Results

3.1. Data Acquisition Results. A total of 429 samples were collected according to the standardized data collection protocol described above, and 325 samples were screened after quality control to meet the study requirements, including 131 female samples and 194 male samples. The general statistics of the patients were as follows Tables 1–4.

3.2. Model Prediction Results. In this experiment, we used three kinds of data: "blood pressure of the day," "blood pressure of the day + tongue," and "tongue," and used four kinds of end-of-data regression models to predict the 6-day average of blood pressure. The prediction accuracy was assessed by the mean absolute error. The results are shown in Tables 5 and 6.

From the prediction trend, it was found that the prediction error performance was higher for the tongue data; the prediction error results were better for the blood pressure on the day of shooting than for the tongue data. The best prediction results were obtained with the fusion data of tongue image overlaid with blood pressure on the day of shooting.

In this study, the value of tongue image in the prediction of blood pressure stage mean was evaluated using the prediction results of the same-day blood pressure data modeling as a baseline. When the mean absolute error (MAE) of the same algorithmic model from the "same-day

Tongue image + blood pressure on the day	6.32	8.54	**4.02**	5.91

blood pressure + tongue" and "tongue" data categories was lower than that of the "same-day blood pressure" model, it represented an improved value. On the contrary, if the MAE is higher than that of the "same-day blood pressure" model, it means that it has no value for blood pressure prediction. The prediction results showed that the MAE of each of the six predictions of systolic and diastolic blood pressure based on the "tongue image" data alone exceeded the prediction of blood pressure on the same day, and there was no significant advantage of using the tongue image alone to predict blood pressure for the next 6 days. The MAE of the model built with the fused tongue and blood pressure data was lower than that of the current day's blood pressure modelin (Figures 5 & 6).

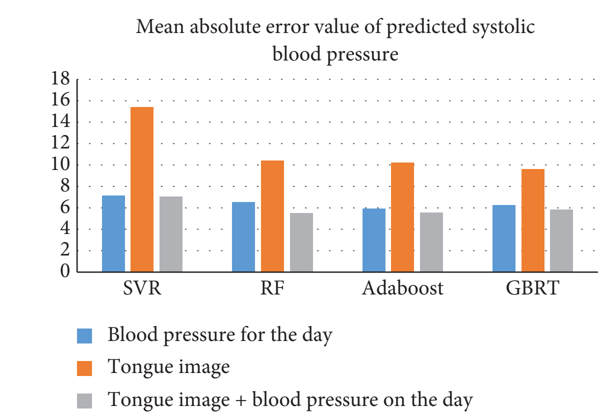

Figure 5: Comparison of mean absolute error in predicting systolic blood pressure prediction.

4. Discussion

In this experiment, we used a dual-input "two-stream network" analysis architecture for the two types of input data to perform blood pressure stage prediction using tongue image, current day blood pressure, and both fused data. The network is designed to use the "blood pressure of the day" prediction results as the baseline, and the cross-sectional comparison of the prediction results can further reflect the contribution of different data categories in prediction

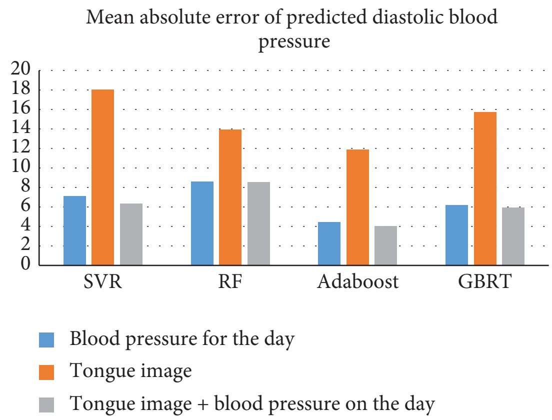

Figure 6: Comparison of mean absolute errors in predicted diastolic blood pressure.

accuracy. The models constructed from the fused data outperformed the models constructed from the same-day blood pressure data in all prediction results. The addition of tongue data contributes to the reduction of the error rate. Since the machine learning technique used is a "black-box" data processing model with uninterpretable complex hierarchical mathematical relationships, it is not possible to know which feature of the tongue data has a positive effect on the prediction of blood pressure. Here, this study argues that data convolution fusion makes the overall linear distribution of the fused data. The tongue image data, on the other hand, makes the amount of information increased by incorporating the information carried by features such as tongue morphology, color, and texture, which enhances the characteristics of the dimensionality of the data to some extent. Thus, the fused data incorporate a lot of lingual information compared to the same-day blood pressure data or the lingual image data only, and the overall data are still linearly distributed, which may be the reason why the fused data model is smaller than the two separate data models in terms of error. Through the above experiments, this study concluded that the multimodal data fusion method of "tongue +" mode can achieve more efficient data mining than the analysis of tongue data only. In the future, with the upgrade of data analysis capability, the tongue diagnosis data can be fused with various clinical data to form a big data matrix, and then the neural network can be used to carry out deep data mining, and its application will cover the auxiliary identification of Chinese medicine, physical determination, and the prognosis assessment of clinical indicators, radiotherapy, chemotherapy, and surgery in modern medicine.

5. Conclusion

Tongue diagnosis is an important part of Chinese medicine diagnosis, and the development of tongue diagnosis in Chinese medicine can be traced back to the Yin and Shang dynasties, after which generations of physicians have attached great importance to the application and research of tongue diagnosis, and it has been inherited as the core content of "diagnosis by looking," which is the first of the four diagnoses in Chinese medicine. The experimental results show that the tongue image overlaying the current day blood pressure can improve the prediction accuracy compared with the current day blood pressure data alone, suggesting the contribution of the tongue image to the improvement of the prediction accuracy and confirming that the data fusion model is an important way to explore the clinical value of the Chinese medicine tongue image.

Data Availability

The numerical dataset used to perform the study presented in the paper are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Retraction

Retracted: Association of Pentachlorophenol with Fetal Risk of Prolonged Bradycardia: A Systematic Review and Meta-Analysis

Journal of Healthcare Engineering

Received 15 August 2023; Accepted 15 August 2023; Published 16 August 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Objective. This study explored the systematic evaluation and meta-analysis of different concentrations of PCP on the risk of long-term bradycardia in fetuses. *Methods*. Cochrane Library, Embase, PubMed, China Biomedical Literature Service, CNCNKI, and Wanfang database were computerized to collect all case-control studies on the association between variety classes and different concentrations of environmental pollutant gas to fetal of prolonged bradycardia. After evaluating the quality of the inclusion study and extracting valid data, meta-analysis was performed using Stata15 software. Relative hazards were calculated using the Mantel-Haenszel method and the random effect model, and P values and I^2 values were used for heterogeneity evaluation. When heterogeneity occurs, subgroup analysis and sensitivity analysis were used to explore the sources. *Results*. A total of 15 studies were included, including 1202 patients with fetal of prolonged bradycardia and 1380 in the control population. Meta-analysis showed that there was no statistical difference in PCP < 0.1 mg/L between the experimental group and control group (OR $= 1.03$, 95% CI (0.62, 1.72), $P = 0.90$, $I^2 = 0\%$, $Z = 0.13$), but there was a statistical difference in PCP > 5 mg/L (OR $= 1.73$, 95% CI (1.15, 2.58), $P = 0.008$, $I^2 = 0\%$, $Z = 2.65$), PCP > 10 mg/L (OR $= 1.75$, 95% CI (1.19, 2.57), $P = 0.004$, $I^2 = 14\%$, $Z = 2.85$), and PCP >15 mg/L (OR $= 2.02$, 95% CI (1.38, 2.95), $P = 0.0003$, $I^2 = 77\%$, $Z = 3.61$). *Conclusion*. In this study, we found that different concentrations of PCP increased the risk of long-term bradycardia in fetuses, and the risk coefficient increased with the increase of PCP concentration.

1. Introduction

Fetal bradycardia was defined as a fetal heart rate below 110 beats/min and with a duration longer than 10 min. The transient decline in fetal heart rate in middle and late pregnancies recovered in a short period of time and had a good prognosis [1]. Pathologic changes, such as sinus bradycardia, atrioventricular block, and long QT syndrome, should be considered when the fetal bradycardia continues. Persistent bradycardia is not common, accounting for about 5% of fetal arrhythmias, and can occur during various periods of the fetus [2]. The main disease accounts for about 14%, including atrioventricular septal defect, left atrial heterogeneous, and large artery abnormalities [3]. Abnormalities of these structures can cause interference with the electrophysiological continuity between the fetal atrium and ventricles, leading to arrhythmias. Fetuses combined with cardiac anatomical abnormalities have a relatively poor prognosis [4, 5].

Pentachlorophenol (PCP) is a white needle crystal, highly volatile, heated when irritant phenol odor, hardly soluble in water, and easy to be soluble in ether, acetone, benzene, and other organic solvents. Pentachlorophenol is widely used as pesticides, antibiotics, and preservatives, covering industrial and commerce, agriculture, water industry, and home life. Due to its high toxicity, long persistence, and difficult degradation, its extensive use and improper treatment lead to the pollution of soil and water resources and has become an environmental pollutant that cannot be ignored [6]. PCP and Na-PCP are slowly degraded in natural environments. It can be enriched in the bottom mud, and the long-term heavy use has caused environmental pollution and biological accumulation. Although many countries, including China, have banned the continued use of PCP, its residual effect will last for years or even decades [7]. A certain level of trichlorophenol can be detected in the water bodies, soil, and plants in the contaminated areas. Pentachlorophenol can have toxic and a series of adverse effects through direct contact (skin and respiratory tract) or food chain enrichment. Pentachlorophenol into the human body can accumulate in the liver, kidney, and adipose tissue for a long time, produce toxicity to the liver and kidney, improve the incidence of tumor, interfere with endocrine, affect immune function, and hinder reproductive development. Pentachlorophenol is not only a direct hazard to the human body, but may be potentially dangerous to electrophysiological function of fetal heart [8].

PCP has a strong uncoupling effect and can cause acute or chronic poisoning in humans and animals. In recent years, numerous studies have shown that PCP contains highly toxic dibenzene dioxin (PcDDs), tetrachloride diphenylfuran (TcBDFs), and other pollutants, especially the highly toxic tetrachlorodibenzene dioxin (TCDD). These substances have strong carcinogenic, teratogenic, mutagenic effects, with a greater impact on the reproductive system. Based on their strong biological stability, they will also be stronger and more durable. In addition, PCP has a strong adsorption to the soil and sediment; PCP water source irrigated crops will affect product quality; fishery will cause pollution to the environment of aquaculture waters, affect the healthy growth of fish, or cause death [9]. In the areas where PCP was used, the produced food PCP content, human daily intake, and urinary PCP concentration were significantly higher than that of the control region. After PCP enters the human body, it circulates to the tissues and organs of the whole body, most of which are discharged from the urine, and about 20% can accumulate in the body. Relevant investigation shows that the content of PCP in residents in polluted areas is significantly increased compared with the control area; therefore, attention should be paid to the potential health harm of food residual PCP to human body [10].

Although the use of PCP has been banned in China, its residual effect will persist for a long time; Na-PCP is still the best and cheapest sterilization effect in China, and this study was to explore the effects of different concentrations of environmental pollutants (PCP) on fetal bradycardia.

2. Materials and Methods

2.1. Search Strategy. Medline, Embase, Cochrane CENTRAL, Chinese Journal Full Text Database (CNKI), Chinese Biomedical Database (CBM), Chinese Science and Technology Journal Full Text Database (VIP), and Wanfang database were searched by computer. Manual retrieval of references is to important literature. Key search terms: “Environmental pollutant,” “Fetal bradycardia,” “Fetal arrhythmia,” and “Fetal prognosis”. All databases were searched from October 2000 to October 2021.

2.2. Literature Selection Criteria

(1) Inclusion criteria: all studies related to fetal bradycardia and environmental pollutants were selected in strict accordance with PRISMA statement, provide data on fetal arrhythmia and concentrations of targeted environmental pollutants, provide sufficient data to calculate OR and 95% CI, case-control study, get full text, duplicate publications from the same population were used, and the largest sample size was selected for inclusion in the study.

(2) Exclusion criteria: incomplete data, studies, case reports, reviews, reviews, summaries, and basic research based on pedigree data.

2.3. Data Extraction and Processing. Two researchers used a unified data extraction table to extract data independently and then cross-checked the data. If necessary, they contacted the authors of the original literature to determine the specific implementation process of the experiment. According to inclusion criteria, the following information was included: first author, year of publication, region, ethnicity, type of arrhythmia (fetal bradycardia and tachycardia), environmental contaminants and concentration detection methods, total number of cases, control group, study quality score, and cases. If two researchers have a dispute during data extraction, a third researcher will help resolve the discussion after referring to the original text.

2.4. Quality Evaluation of the Included Study. There are 3 researchers who independently evaluated the study based on a quality assessment form developed in the prior study quality. The score ranges from 0 to 13, with 0 being the lowest quality and 12 being the highest quality (Figure 1).

2.5. Bias Analysis. Heterogeneity between studies was assessed using I^2 statistics, and 25%, 50%, and 75% representing low, medium, and high heterogeneities, respectively; if I^2 50% and $P > 0.1$ between studies using fixed-effect models and if $I^2 > 50\%$ and $P < 0.1$ from chi-square analysis showed study heterogeneity, meta-analysis is by random effects models and searched for possible heterogeneity by subgroup analysis source. The sensitivity analysis removed the included literature one by one to see whether the pooled effect values were stable and reliable (Figure 2).

2.6. Statistical Analysis. RevMan 5.2 statistical software was used for meta-analysis. Heterogeneity was assessed by the t-test at a significant level $\alpha = 0.10$ ($P < 0.1$ or $I^2 > 50\%$). The results without heterogeneity were combined and analyzed by the fixed-effect model, while those with heterogeneity were analyzed by the random effect model. Mean difference (MD) and its 95% confidence interval (CI) combined effect were used for continuous variables with the same measurement units, and relative risk (RR) and its 95% CI combined effect were used for categorical variables.

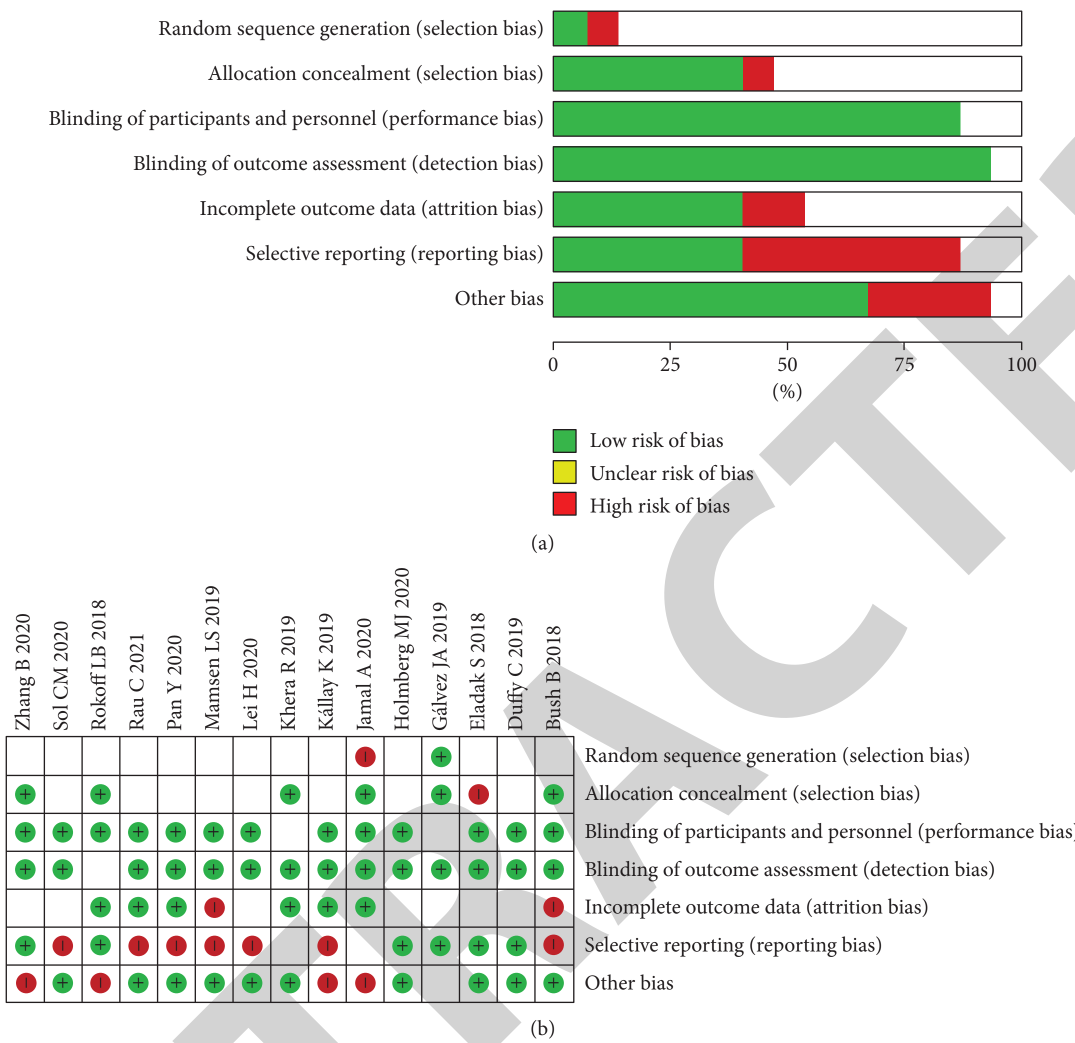

Figure 1: Literature quality evaluation chart. (a) Risk of bias graph. (b) Risk of bias summary.

3. Result

3.1. Retrieving the Results and Incorporating Basic Information in the Study. 359 literatures were obtained according to the retrieval strategy, and the remaining 108 literature entered the screening process after the exclusion of duplicate literature. 15 articles were selected for preliminary screening, among which two English articles were excluded due to lack of reported inclusion outcome indicators. 15 articles were finally included, with a total of 1397 patients [11–25]. There were 864 cases in the experimental group and 533 cases in the control group (Figure 3). Basic information of included studies is given in Table 1.

3.2. PCP < 0.1 mg/L. Among the 4 RCTs literature included in environmental pollutant concentrations with fetal risk of prolonged bradycardia, the heterogeneity test was carried out, and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was no statistical difference in PCP < 0.1 mg/L between the experimental group and control group (OR = 1.03, 95% CI (0.62, 1.72), $P = 0.90$, $I^2 = 0\%$, $Z = 0.13$) (Figure 4).

3.3. PCP > 5 mg/L. Among the 4 RCTs literature included in environmental pollutant concentrations with fetal risk of prolonged bradycardia, the heterogeneity test was carried out, and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was a statistical difference in PCP > 5 mg/L between the experimental group and control group (OR = 1.73, 95% CI (1.15, 2.58), $P = 0.008$, $I^2 = 0\%$, $Z = 2.65$) (Figure 5).

3.4. PCP > 10 mg/L. Among the 4 RCTs literature included in environmental pollutant concentrations with fetal risk of prolonged bradycardia, the heterogeneity test was carried out, and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was a statistical difference in PCP > 10 mg/L between experimental

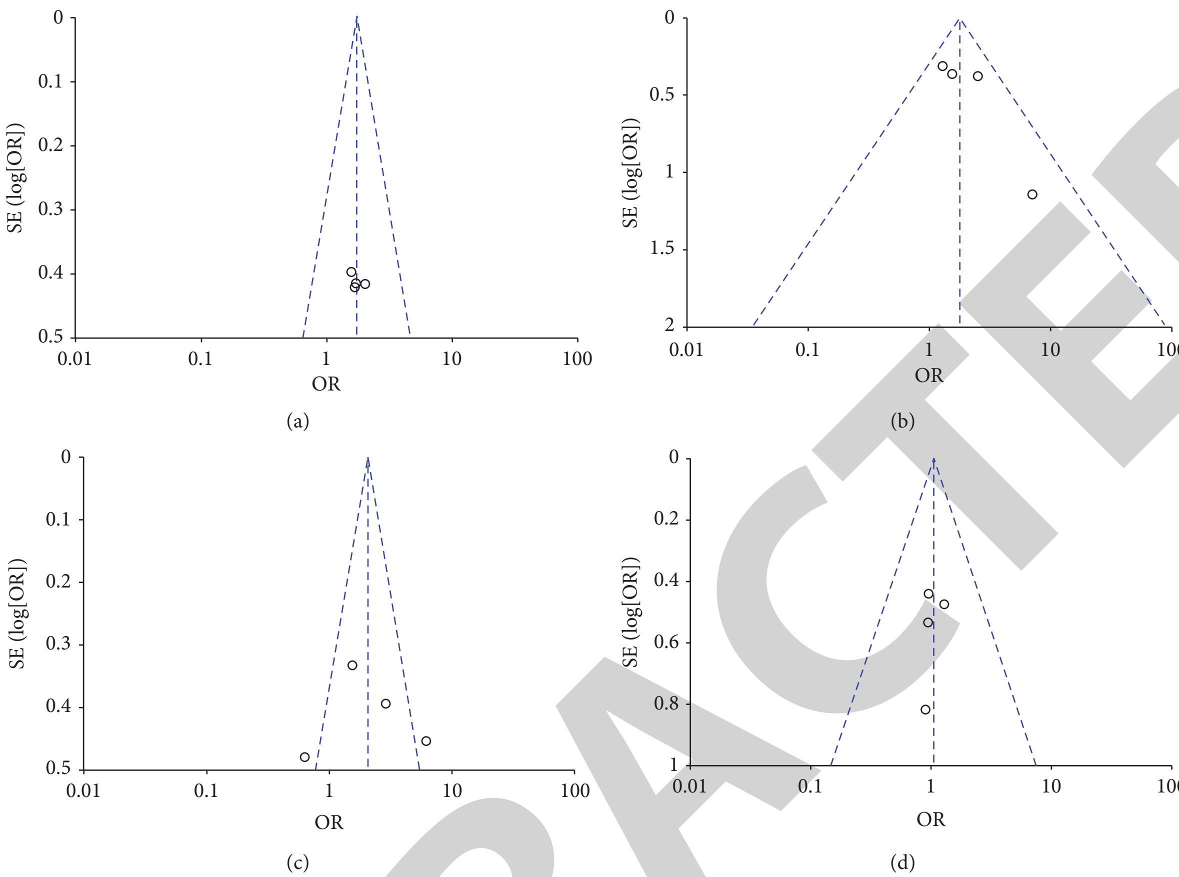

Figure 2: Funnel plot of literature publication bias for PCP < 0.1 mg/L (a), PCP > 5 mg/L (b), PCP > 10 mg/L (c), and PCP > 5 mg/L (d) between two groups.

the group and the control group (OR = 1.75, 95% CI (1.19, 2.57), P = 0.004, $I^2 = 14\%$, $Z = 2.85$) (Figure 6).

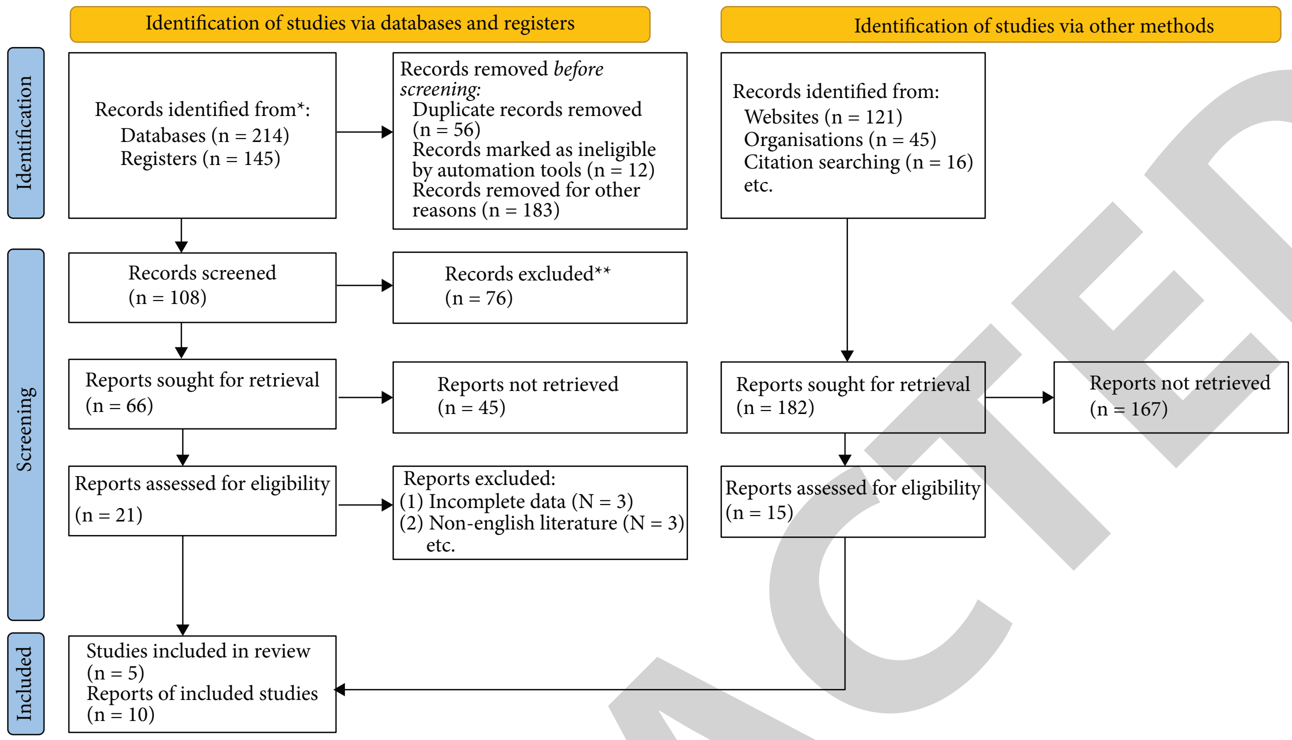
3.5. PCP > 15 mg/L. Among the 4 RCTs literature included in environmental pollutant concentrations with fetal risk of prolonged bradycardia, the heterogeneity test was carried out, and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was a statistical difference in PCP > 15 mg/L between the experimental group and control group (OR = 2.02, 95% CI (1.38, 2.95), P = 0.0003, $I^2 = 77\%$, $Z = 3.61$) (Figure 7).

4. Discussion

PCP in the environment mainly comes from the production and improper processing of the product. It is reported to produce 2,000 tPCP or Na-PCP, and the exhaust gas will contain 18tPCP, 9 t of other phenolic compounds. Na-PCP produces large amounts of PCP and other phenol wastewater; PCP can also be discharged directly into the environment by related industrial wastewater [26]. PCP-treated wood is also being released directly into the environment when used or burning.

Many animal experiments have confirmed that PCP has certain reproductive toxicity to organisms. For example, PCP can inhibit the growth and development of hamster oocytes; cows fed containing PCP found pathological changes such as luteal insufficiency and abnormal oocyte development [27]. After sexual maturation, ranging from 7 to 8 d, both the proportion of female mink receiving the second mating and the rate of lactation was decreased. R raised with feed containing PCP and necrolysis from the beginning of embryonic stage to week 28, the preferential margin of the scrotum increased, and the atrophy of the semen tube increased. The epididymal sperm density was decreased. In 2002, Bemard et al. fed 2 generations of SD rats with PCP, and reproductive toxicity tests showed that high-dose (60 mg/(kg.d)) feeding caused delayed sexual maturation, reduced sperm number, reduced prostate and testes, reduced embryo implantation capacity, and reduced litter production [28].

Similarly, in humans, with the deterioration of environmental quality, many environmental pollutants can pass through the way such as respiratory tract, the digestive tract, the skin into pregnant woman's body, and then through the limited tire barrier into fetal body because the fetus is sensitive to the chemical poison effect than adults; in the process of growth and development, if some poisonous substances contact within the womb, it may produce some effects, and adult contact with the substance is not the same as severe damage or even cancer [29, 30].



*Consider, if feasible to do so, reporting the number of records identified from each database or register searched (rather than the total number across all databases/registers).

**If automation tools were used, indicate how many records were excluded by a human and how many were excluded by automation tools.

PCP is an anticompetitive inhibitor of human placental alkaline phosphatase (PLAP). Toxicology tests show that PCP is a strong mitochondrial unconjugation agent that reduces plasma membrane mobility and also has a strong inhibitory effect in the acetylcholinesterase on the cell membrane [29]. Placental alkaline phosphatase is a metalloglycoprotein located on the membrane of late placental cells; in addition to catalytic function, some substances such as IgG, complement factor B, and cartilage matrix protein are related to fetal growth and development. Changes in the PLAP conformation can not only alter its function but also cause the structure and function of the placental cell membrane change, which must have adverse effects on the normal fetal development. In addition, PCP is a lipid-soluble substance that can enter the fetus through the placenta and have a direct

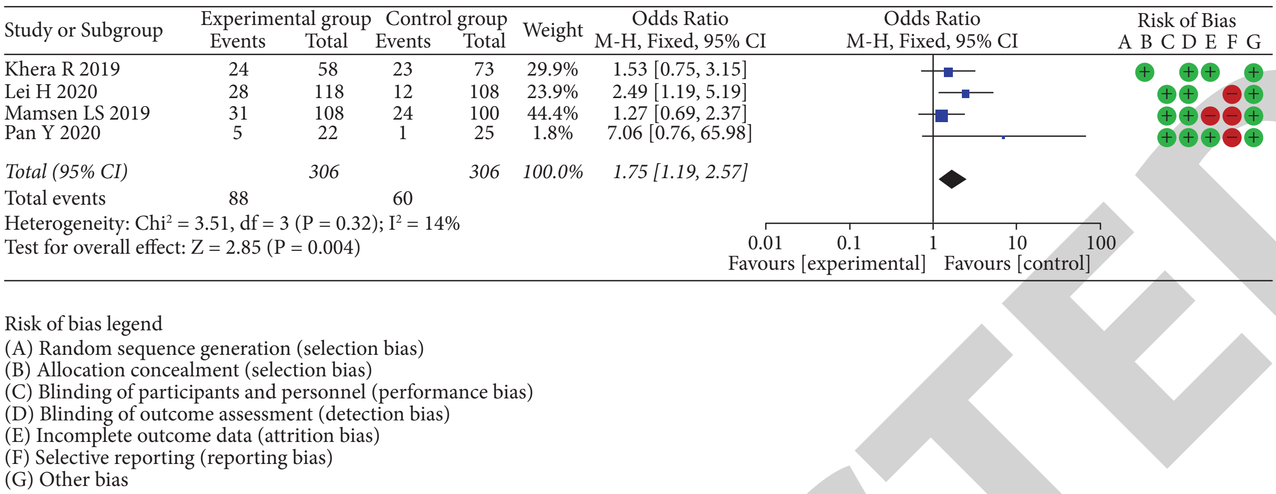

Figure 6: Meta-analysis of PCP > 10 mg/L between two groups.

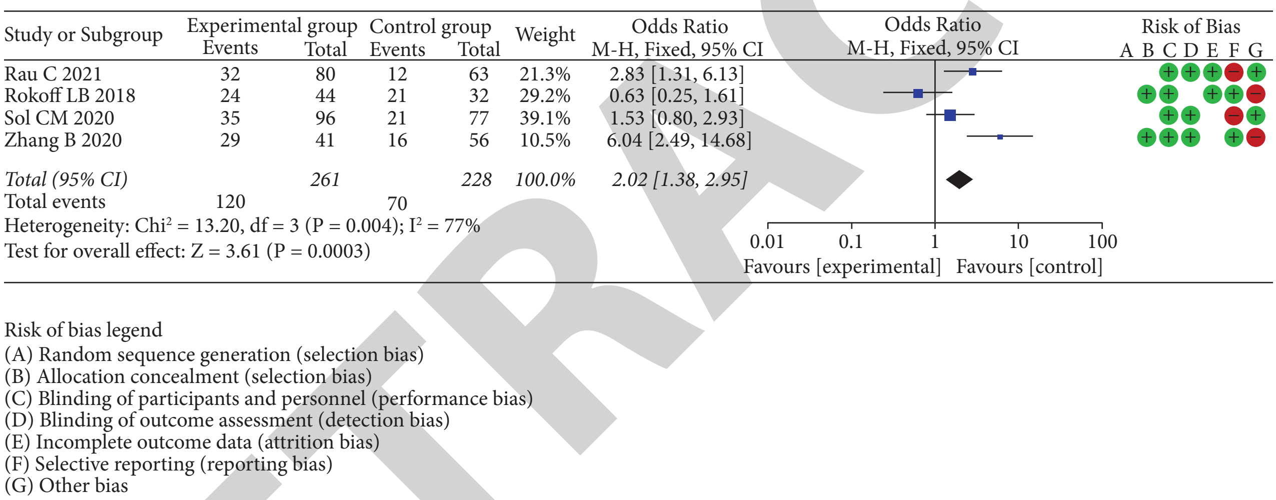

Figure 7: Meta-analysis of PCP > 15 mg/L between two groups.

toxic effect on the fetus [30]. In Heidelberg Hospital, Germany, during a physical examination of 65 women with a long history of PCP exposure, it was found that its serum PCP content was asked above 20 bucket g/L; thus, the exposure history of PCP in pregnant women will also have adverse effects on the fetus.

Fetal arrhythmias caused by the toxic effect of PCP are common in routine prenatal ultrasound screening and can occur throughout any stage of pregnancy, with the incidence reported in foreign literature during pregnancy of up to 1–3%. Fetal JbL, arrhythmias can be divided into three categories: irregular arrhythmias, tachycardia, and bradycardia, among which irregular arrhythmias are the most common, mainly caused by prephase contraction. The most common fetal tachycardia is intraventricular tachycardia and atrial fibrillation. The most common fetal bradycardia is complete atrioventricular block; the mother of children is with normal heart structure. There are high-efficiency anti-SSA antibodies or anti-SSB antibodies staring inside.

The limitations of this study are as follows: incorporating observational studies in the study is limited, the follow-up varies from 3 to 36 months, making the evaluation of long-term complications, the publication bias analysis is only qualitative and large personal factors, and the two techniques described in this study contain multiple surgical procedures, which may increase the bias of the article. Since the assessments were all based on a small number of studies [26–28], the results must be interpreted with caution. As the accumulated evidence grows, our conclusions may either be supported or overturned.

5. Conclusion

In conclusion, environmental pollutant PCP > 0.1 mg/L could increase the risk of fetal bradycardia, and it increased with the increase of PCP concentration. It is of great significance to evaluate the toxic effects of maternal exposure to environmental pollutants in order to reduce the health damage to the next generation.

Retracted: Antitumor Effects of 10058-F4 and Curcumin in Combination Therapy for Pancreatic Cancer In Vitro and In Vivo

Journal of Healthcare Engineering

Received 8 August 2023; Accepted 8 August 2023; Published 9 August 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Objectives of the Study. In vitro and in vivo evaluation of the antipancreatic cancer effects and benefits of the 10058-F4 and curcumin combination therapy. *Background*. Pancreatic cancer (PC) stands out as one of the most lethal cancers. Due to late diagnosis, only a fraction of patients can be resected. Although it still has significant adverse effects and poor results, the treatment is connected with better overall survival than the prior treatment. Thus, new alternative therapy for advanced PC is needed. *Materials/Methods*. The impact of 10058-F4 and curcumin combination therapy on apoptosis and cell growth in SW1990 pancreatic cancer cells were determined in vitro using the CCK-8 assay and flow cytometry of Annexin V-FITC/PI, and the in vivo antitumor effect was determined utilizing SW1990-bearing pancreatic tumor mouse models induced by subcutaneous implantation. *Results*. At concentrations of (10 mol/L+2 mol/L), 10058-F4+curcumin obtained the highest rate of SW1990 cell death, and they had a beneficial effect on SW1990 pancreatic tumor-bearing animals. Furthermore, c-Myc, Akt phosphorylation, and the expression of apoptosis-related molecular were reduced, and the combination therapy modified the expression of apoptosis-related molecular. *Conclusions*. In vitro and in vivo, the combination of 10058-F4 plus curcumin has antipancreatic cancer actions that are substantially effective.

1. Introduction

Pancreatic ductal adenocarcinoma (PDAC), having a 5-year survival rate of only 9%, is one of the fatal human cancers [1]. The only treatment that can potentially offer a cure for pancreatic cancer is surgical resection [2]. Immune checkpoint blockade therapies that are beneficial in other cancers have failed to benefit randomly selected PDAC populations in phase III trials [3]. As a proto-oncogene, c-Myc has been found to be activated in a variety of animal and human malignancies and is required for the metabolism, differentiation, apoptosis, and cell proliferation [4]. Previous research has established that overexpression of c-Myc has an involvement in the development and progression of PDAC [5, 6]. c-Myc downregulation impedes the development of PDAC [7, 8].

A small-molecule inhibitor of c-Myc-Max dimerization, referred to as 10058-F4, has been demonstrated to reduce cellular proliferation, increase apoptosis, and induce chemosensitivity [9–11]. Furthermore, no substantial tumor growth inhibition was observed after intravenous injection of either 20 or 30 mg/kg 10058-F4 into mice. The quick metabolism and low tumor concentration of 10058-F4 may have resulted in its lack of considerable antitumor effect in tumor-bearing mice [12]. The anticancer action of 10058-F4 has been reported in PDAC cell lines, and 10058-F4 therapy sensitizes PANC-1 and SW1990 cells to gemcitabine. In a subcutaneous xenograft model, 10058-F4 did not affect pancreatic carcinogenesis; however, when paired with 10058-F4, the anticancer impact of gemcitabine is more substantial [13].

Curcumin is a pure crystalline yellow pigment derived from the turmeric plant [14]. Curcumin possesses antitumor, antiangiogenesis, antiproliferative, and anti-inflammatory activities without causing cytotoxicity in normal cells [15, 16]. Curcumin has the potential to cause apoptosis in cancer cells [17]. Apoptotic proteins, inflammatory cytokines, transcription factors, and growth factors have all been shown to be modulated by curcumin. It can be an effective cancer therapy agent when used alone or in combination with other drugs [18]. Two reports indicate that curcumin regulates c-Myc [19, 20]. Curcumin inhibits gastric cancer cell proliferation by inhibiting the c-Myc/H19 pathway [19]. It can also have a strong inhibitory effect in three prostate cancer cell lines by upregulating miR-34a and downregulating β-catenin and c-Myc levels [20]. Curcumin has been found to have anticancer properties in PDAC cell lines. Interacting with the miR-340/XIAP signaling pathway has been demonstrated to promote apoptosis in pancreatic cancer cells in vitro [21].

Curcumin can also block EGF-induced pancreatic cancer cell invasion and migration by inhibiting the EGF/EGFR signaling pathway and downstream signaling molecules, for instance, ERK and Akt [22]. Curcumin inhibits the PI3K/Akt/NF-κB signaling pathway, preventing SOD-driven H_2O_2-induced pancreatic cancer metastasis [23]. Curcumin is shown to sensitize gemcitabine-resistant PDAC cell lines via an inhibitory effect on the PRC2-PVT1-c-Myc axis [24]. Such studies suggest that using curcumin in combination with chemotherapy to overcome chemoresistance in PDAC has therapeutic efficacy. Curcumin may inhibit c-Myc and improve the clinical therapeutic potential of the c-Myc inhibitor 10058-F4 in pancreatic cancer cells. This study used curcumin or 10058-F4 alone or in combination to treat SW1990 cells in vitro and in vivo. Curcumin therapy sensitized SW1990 cells to 10058-F4 for the first time.

2. Materials and Methods

2.1. Chemicals and Cell Culture. The Chinese Academy of Sciences (CAS) Cell Bank provided the pancreatic cancer cell lines PANC-1, SW1990, BxPC3, Capan-1, and Capan-2 (Shanghai, China). In a 5% CO_2 cell culture incubator at 37°C, cells were grown in high-glucose DMEMR or PMI-1640 media supplemented with 10% fetal bovine serum (FBS; Gibco) and 1% penicillin or streptomycin. In dimethylsulfoxide (DMSO) (Sigma), 100 mM stock solutions of curcumin and 100 mM stock solutions of 10058-F4 (Selleck) were produced.

2.2. Cell Proliferation Assay. 5,000 SW1990 cells were planted in individual wells of a 96-well plate, in 100 μl completed DMEM medium. Cells were monotreated with either 10058-F4 (10 μM) or curcumin (5 μM) for 48 hours before cotreatment with both 10058-F4 and curcumin. The Cell Counting Kit-8 (CCK-8, Dojindo) was employed to analyze cell proliferation, following the protocol elaborated by the manufacturer. Each well was filled with 10 μl CCK-8 solution and 90 μl DMEM. After oscillating for 15 seconds, the cell absorbance was measured at a wavelength of 450 nm (OD450) 2 hours later.

2.3. Colony Formation Assay. Different groups of people took part in the colony formation test. SW1990 cells were trypsinized and grown in 6-well plates at a density of 1,000 cells per well. Four groups of cells were created. The cells were monotreated with 10058-F4 (10 μM) or curcumin (5 μM) for 24 or 72 hours, later cotreated with 10058-F4 and curcumin twice. After 2 weeks, the colonies were fixed for 15 minutes with 4% (*w/v*) formaldehyde and stained for 15 minutes with 0.1% (*w/v*) crystal violet. Chemiluminescent image analysis photographs the colonies (Bio-Rad, ChemiDoc Touch, USA).

2.4. Flow Cytometry. SW1990 cells were trypsinized and grown in 6-well plates at a density of 2×10^5 cells per well. The cells were separated into four groups and treated with either 10058-F4 (10 μM) or curcumin (5 μM) alone or in combination for 48 hours. Trypsinization was used to harvest cells from four groups, and the cell density was maintained at 5×10^5 cells per ml. Centrifugation at 1200 rpm was used to wash the cell samples with phosphate-buffered saline (PBS). Following that, the Annexin V-FITC/PI Apoptosis Detection Kit (BD Pharmingen, CA, USA) was used to stain the cell samples as mentioned in the instructions provided by the manufacturer. After 30 minutes at 37°C in the dark, the stained cells were counted by making use of a FACS Calibur (BD Biosciences, San Jose, CA, USA) and analyzed through FlowJo software v.7.6.5 (Tree Star, OR, USA).

2.5. Xenograft Models of SW1990 Cells in Nude Mice. 12 male BALB/c nu/nu mice (5 weeks old and weighing around 18–22 g) were acquired from Shanghai Beijing Vital River Laboratory Animal Technology and kept within 12/12 h light/dark cycles with unrestricted supply of water and rat chow. The Medical Experimental Animal Care Commission approved the experimental methodology of Chengdu Medical College's First Affiliated Hospital. For producing the subcutaneous tumors, SW1990 cells (1×10^7 cells) in 0.2 ml PBS were injected into the right flank of test mice. Following one week, the mice were divided into four groups: the control group (with intraperitoneal and intravenous injections of equivalent solvent), the 10058-F4 group (with intravenous injections of 20 mg/kg 10058-F4 every other day), the curcumin group (with intraperitoneal injections of 25 mg/kg curcumin every other day), and the combination group (with intravenous injections of 20 mg/kg 10058-F4 and 25 mg/kg curcumin. Curcumin (25 mg/kg) was dissolved in 80% ddH_2O, 10% PEG300, 5% Tween 80, and 5% DMSO following the manufacturer's protocol. Dissolution of 10058-F4 (20 mg/kg) in a mixture of ethanol, Cremophor EL, and saline (1 : 1:8

v/v/v) to a final concentration of 2 mg/ml yielded the dosing solutions. Three mice from each group were slain three weeks later to obtain the implanted tumors.

2.5.1. Immunohistochemistry and Terminal Deoxynucleotidyl Transferase d-UTP Nick End Labeling (TUNEL) Staining. To eliminate endogenous peroxidase activity, the xenograft tumor tissues were cut into 4 μm thick slides after being embedded in paraffin and then treated with xylene to remove paraffin and rehydrate. The slides were incubated for 30 minutes at room temperature with 5% goat serum. A rabbit anti-PCNA antibody was used to treat the slides after being washed (1 : 100, Abcam, Cambridge, UK). As a final step, the Thermo Fisher Scientific HRP DAB (UltraVision Quanto Detection System) was employed for the detection of PCNA expression. Mayer's hematoxylin (Sigma-Aldrich, St. Louis, MO) was employed for counterstaining the slides, and neutral resins (Thermo Fisher Scientific, Pittsburgh, PA, USA) were used to attach coverslips. This study used the TdT-mediated d-UTP labeling approach to assess TUNEL staining, which was conducted in accordance with the manufacturer's instructions (Roche, Applied Biosystems). Apoptotic cell DNA fragments were tagged at free 3′-OH DNA ends and strand breaks, respectively. An antifluorescein antibody coupled with alkaline phosphatase was used to detect fluorescein. Light microscopy was used to examine the stained cells after the reaction with the substrate had taken place.

2.6. Western Blot. Using RIPA lysis buffer and protease/phosphatase inhibitor cocktail (MedChemExpress, NJ, USA) with 1 mM phenylmethyl sulphonyl fluoride PMSF (Beyotime Biotech, Shanghai, China), the whole protein in each cell sample was extracted and quantified with a BCA protein assay (Beyotime Biotech, Shanghai, China). After blocking the protein with the primary antibodies against c-Myc, SOX2, p-Akt (Ser473), Akt, MCL-1, Bcl-2, FAS, and cleaved-caspase 3 beta-actin (1 : 1000, Cell Signaling Technology, Danvers, MA USA), the incubation period was extended overnight at 4°C. Secondary antibody conjugated to HRP (Beyotime Biotech, Shanghai, China, 1 : 4000) was incubated for 2 hours at room temperature with protein. The eECL Western blot kit (Beyotime Biotech, Shanghai, China) was utilized to detect the protein.

3. Results

3.1. High Expression of c-Myc in Pancreatic Cancer. In prior research, the c-Myc gene is substantially expressed in pancreatic cancer cells [7, 8, 13]. It was shown that human pancreatic cancer cells overexpress c-Myc, as were normal pancreatic epithelial cell hTERT-HPNE in our investigation of 5 human pancreatic cancer cell lines (PANC-1, SW1990, BxPC3, Capan-1, and Capan-2 cells), as shown in Figure 1(a).

3.2. Curcumin Sensitized the Anticancer Influence of 10058-F4 in Pancreatic Cancer Cells. 10058-F4 is a c-Myc inhibitor [9, 10]. Curcumin also inhibits c-Myc [19, 20]. To further confirm the therapeutic value of targeting c-Myc, we attempted to sensitize the anticancer influence of 10058-F4 using curcumin and investigated the degree of inhibition of c-Myc using 10058-F4, curcumin, or a combination of both. First, we checked cell viability in 10058-F4 curcumin and combined treating SW1990 cells by detecting OD450 with CCK-8 reagent. Cell viability was gradually inhibited in the combination group (Figure 1(b)). The clonogenic assay results also confirmed the potent anticancer effect of the combination (Figure 2(a)). Since 10058-F4 and curcumin can induce apoptosis [9, 17], we postulated that the combination of 10058-F4 and curcumin might induce server apoptotic death in SW1990 cells. We used flow cytometry to directly examine the effects of 10058-F4 or curcumin treatment on early (Annexin V+/PI-) and late (Annexin V+/PI+) apoptosis on SW1990 cells. According to our findings, curcumin improved the sensitivity of 10058-F4 to SW1990 cells (Figure 2(b)).

3.3. In Vivo, Curcumin Increased the Therapeutic Efficacy of 10058-F4 in Pancreatic Cancer Cells. To further explore the effect of cotreatment with curcumin and 10058-F4 in vivo, SW1990 cells were implanted subcutaneously in Balb/c nu/nu mice ($n = 3$ for each group); one week later, the mice were treated with 10058-F4 by vein injection or curcumin alone by intraperitoneal injection or both 10058-F4 and curcumin every 3 days. After continuously treating the indicated drugs for 3 weeks, the combined group's average tumor weight was significantly lighter than in the monotherapy groups (Figure 3).

Additionally, PCNA and TUNEL labeling were used to detect cells in growth or death, respectively. Compared to the control group, the 10058-F4 and curcumin-treated groups have reduced the number of PCNA-positive cells and increased TUNEL-positive cells, but not the 10058-F4-treated group (Figure 4). As a result, our data established that the combination of 10058-F4 and curcumin had significant anticancer activity in vivo.

3.4. Curcumin Increased the Susceptibility of Pancreatic Cancer Cells to 10058-F4 by Inhibiting the Akt-Mediated Apoptotic Pathway. Accumulating evidence has shown that the Akt expression and phosphorylation are reduced by curcumin [22, 23] and upregulated by c-Myc [25]; we evaluated the expression levels of c-Myc, p-Akt, and Akt. As a result, we examined the expression levels of the apoptosis-related proteins Mcl-1, Bcl-2, Fas, and cleaved-caspase 3. Our findings showed that c-Myc and Akt phosphorylated protein levels were lower in SW1990 cells undergoing treatment with a combination of medicines than in cells treated with 10058-F4 alone (Figure 5(a)). Furthermore, the protein levels of Mcl-1 and Bcl-2 were dramatically reduced, whereas Fas and cleaved-caspase 3 were significantly enhanced in the combo treatment group (Figure 5(b)).

4. Discussion

The oncogene c-Myc is involved in cell proliferation, death, differentiation, and the sensitivity of cancer cells to

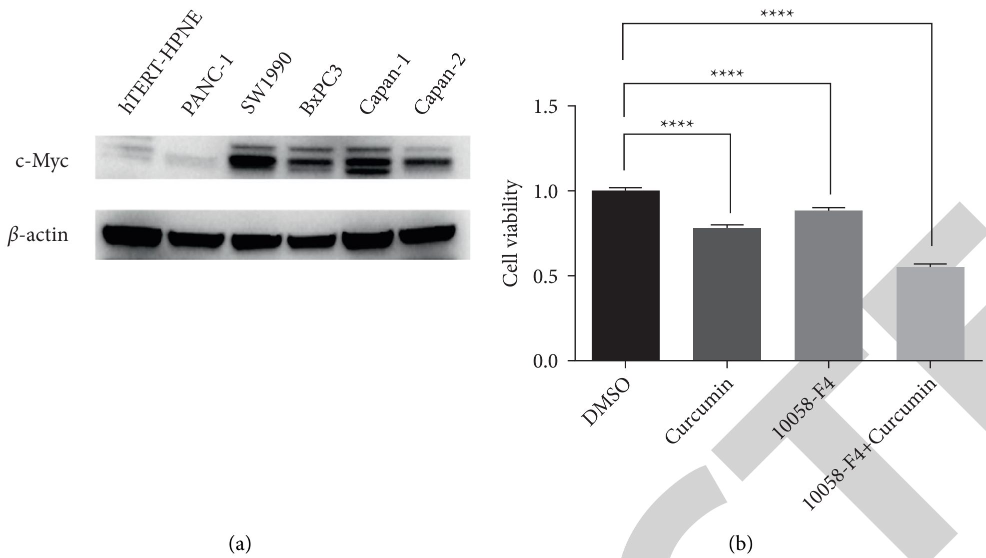

Figure 1: c-Myc highly expressed in pancreatic cancer (a) examined the expression of c-Myc in 5 human pancreatic cancer cell lines (PANC-1, SW1990, BxPC3, Capan-1, and Capan-2 cells) and normal pancreatic epithelial cell hTERT-HPNE. (b) Cell viability was inhibited in the combination group.

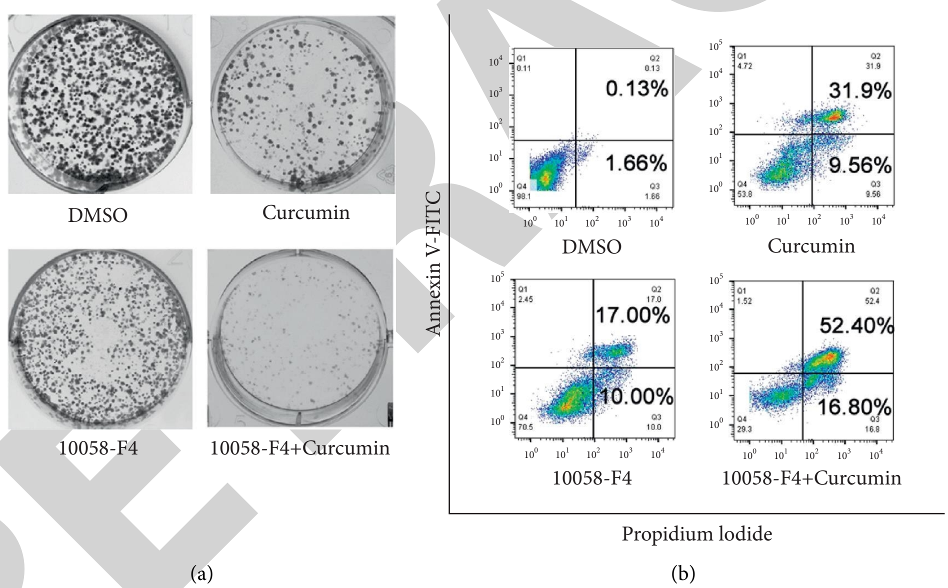

Figure 2: Curcumin sensitized the anticancer influence of 10058-F4 in pancreatic cancer cells. (a) Colonogenic assay for the potent anticancer effect of combination. (b) Curcumin enhanced the sensitization the sensitization effect of 10058-F4 on SW1990 cells.

chemotherapy [26]. 10058-F4 inhibits c-Myc, regressing human acute myeloid leukemia, hepatocellular carcinoma, and ovarian cancer cells [9, 10, 27]. In pre-B acute lymphoblastic leukemia cells, 10058-F4 can also intensify the antileukemic effect of vincristine [11].

However, on account of its quick metabolism and low concentration within tumors, no substantial anticancer effect is observed in vivo following exposure of mice to either 20 or 30 mg/kg 10058-F4 [12]. Curcumin has been used to treat numerous types of cancer, including colorectal cancer, either alone or in conjunction with other treatments [28, 29], breast cancer [30, 31], lung cancer [32], prostate cancer [33], and liver cancer [34]. The potent antineoplastic properties of curcumin against different cancers are due to proapoptotic, antiproliferative, proapoptotic, and anti-inflammatory mechanisms [15, 16, 35]. Emerging preclinical research suggests that curcumin-based combination treatments improve anticancer activity without increasing toxicity. Banerjee et al. [36] observed that treating prostate cancer (PC3) (DU145 and PC3) cells with a combination of curcumin (20 mM) and docetaxel (10 mM) for 48 hours substantially decreased proliferation and promoted apoptosis in comparison to docetaxel and curcumin alone. A study based on HepG2 and PLC/PRF/5 cells found that a

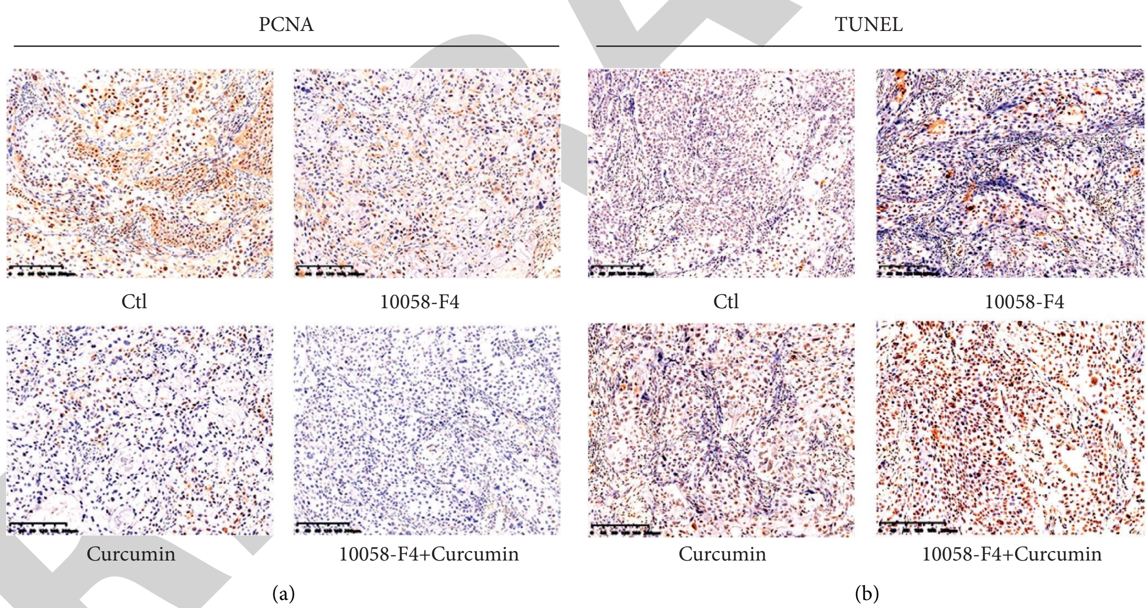

Figure 4: Detection of cells in proliferation or apoptosis by PCNA and TUNEL staining.

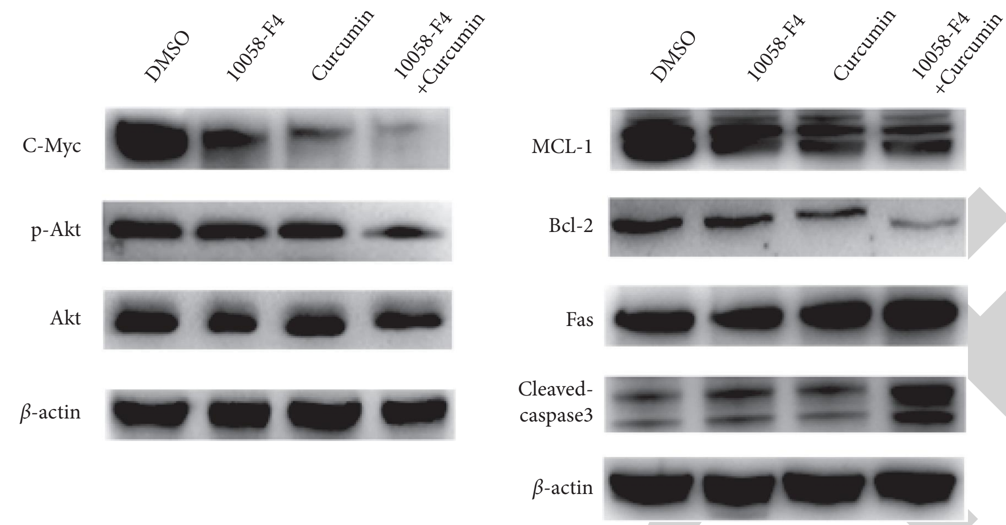
combination of curcumin (5 and 10 mM) and metformin (10 mM) can cause apoptosis and impede metastasis and invasion. Reduction of the epidermal growth factor receptor (EGFR)/STAT3 and NF–B/mTOR/Akt/PI3K inhibition of MMP2/9, vascular endothelial growth factor (VEGF), and vascular endothelial growth factor receptor 2 (VEGFR-2) and p53 and PTEN activation could all be contributors towards the anticancer effects.

Curcumin inhibits the expression of c-Myc in nonsmall cell lung cancer cells [36] and pancreatic cancer cells [24], in vitro and in vivo. In this work, we attempted to look into the impact of 10058-F4 combined with curcumin in PDAC, based on encouraging results obtained with c-Myc targeting techniques.

Consistent with previous reports [7, 8, 13], in most PDAC cell lines, c-Myc is amplified (Figure 1(a)). In vitro, 10058-F4 or curcumin alone reduced cell growth and induced apoptosis. Additionally, the combination-treated group's proliferation and apoptosis abilities were considerably altered (Figures 1(b) and 2). However, the 10058-F4



(a) (b)

Figure 5: Curcumin sensitized pancreatic cancer cells to 10058-F4 via inhibition of the Akt-modulated apoptosis pathway. (a) Protein levels of c-Myc and Akt phosphorylation in SW1990 cells treated with combination drugs and 10058-F4 alone. (b) Protein levels of Mcl-1 and Bcl-2 and the protein levels Fas and cleaved-caspase 3 in the combination treating group.

therapy had no discernible effect on the tumor burden. Compared to the control and 10058-F4 groups, combined curcumin plus 10058-F4 therapy substantially inhibited tumor growth (Figure 3). In the combination treatment group, the PCNA-positive cells were notably decreased, while the TUNEL-positive cells were considerably increased (Figure 4). This study also found that the combination of curcumin with 10058-F4 downregulated c-Myc and phosphorylation of Akt weakened Bcl-2 and Mcl-1 expression and increased Fas and cleaved-caspase 3 levels in SW1990 cells (Figure 5). Our findings show that curcumin induces tumor cell death and increases PDAC chemosensitivity to 10058-F4 through altering p-Akt and apoptosis-associated molecules. Importantly, our work furnishes sufficient in vivo evidence of the therapeutic potential of combined curcumin and 10058-F4 treatment in pancreatic cancer and shows cases a simple and convenient method for curcumin and 10058-F4 combinatorial therapy as a viable anticancer strategy in PDAC adjuvant therapy.

5. Conclusion

In conclusion, employing in vitro tests, we demonstrated the pharmacologic reduction of proliferation and induction of apoptotic effects of curcumin and 10058-F4, either alone or in combination. In vivo tests revealed that curcumin-induced tumor growth arrest boosted the anticancer efficacy of 10058-F4. However, additional tests, either in vivo or clinical trials, are a must to assess the effectiveness of the curcumin-10058-F4 combination and the safety of this technique in PDAC patients.

The purpose of this study was to explore the deep learning radiomics (DLR) nomogram to predict the overall 3-year survival after chemoradiotherapy in patients with esophageal cancer. The 154 patients' data were used in this study, which was randomly split into training (116) and validation (38) data. Deep learning and handcrafted features were obtained via the preprocessing diagnostic computed tomography images. The selected features were used to construct radiomics signatures through the least absolute shrinkage and selection operator (LASSO) regression, maximizing relevance while minimizing redundancy. The DLR signature, handcrafted features' radiomics (HCR) signature, and clinical factors were incorporated to develop a DLR nomogram. The DLR nomogram was evaluated in terms of discrimination and calibration with comparison to the HCR signature-based radiomics model. The experimental results showed the outperforming discrimination ability of the proposed DLR over the HCR model in terms of Harrel's concordance index, 0.76 and 0.784, for training and validation sets, respectively. Also, the proposed DLR nomogram calibrates and classifies better than the HCR model in terms of AUC, 0.984 (vs. 0.797) and 0.942 (vs. 0.665) for training and validation sets, respectively. Furthermore, the nomogram-predicted Kaplan–Meier survival (KMS) curves differed significantly from the nonsurvival groups in the log-rank test (p value <0.05). The proposed DLR model based on conventional CT images showed the outperforming performance over the HCR signature model in noninvasively individualized prediction of the 3-year survival rate in esophageal cancer patients. The proposed model can potentially provide prognostic information that guides and helps the clinical decisions between observation and treatment.

1. Introduction

Esophageal cancer (EC) is the eighth most common malignancy and the sixth most common disease-related cause of death worldwide [1, 2]. The incidence of esophageal cancer is notably high in Asia and Iceland, as well as the United Kingdom and the United States [3–5]. In order to systemically control the disease, radiotherapy and neoadjuvant chemotherapy are commonly combined with surgery [6–8]. Regardless of its benefit for severe patients with a low survival rate, an aggressive treatment plan, including multiple cycles of treatment and adjuvant chemotherapy, is not suitable for the other patients with esophageal cancer [9]. Pre-identification for such patients having a low survival rate before surgery can help provide other suitable treatment regimens for these patients [10]. Therefore, identification of patients having a lower survival rate is vital to take benefit from additional treatment.

Radiomics features [11, 12] have been widely used as an extremely useful tool in quantitative analysis of medical imaging and in medical diagnosis [13, 14]. The traditional radiomics utilized handcrafted features, such as tumor shape and texture, obtained from medical images [11]. However, such handcrafted low-order features are not suitable to define intrinsic characteristics of intratumor imaging heterogeneity, limiting the applicability of the radiomics model [11–13]. Furthermore, the construction of handcrafted features is limited within the known knowledge of medical imaging.

Deep learning, especially CNN, has recently achieved promising results in medical image analysis [15–18]. Deep networks consist of multiple layers that can be learned from data [19, 20]. For example, prognostic tumor features can be extracted through hierarchical convolution operation on the medical images [21–24]. Compared with handcrafted features, DLR features contain more important tumor information that may help diagnose [25–27].

However, unlike handcrafted radiomics studied widely for radiological diagnosis and prediction [28], the application of deep learning in predicting overall survival in esophageal cancer has not been thoroughly explored yet. Hence, this study aims to develop and validate the deep survival prediction model based on a radiomics nomogram for individualized prediction of three years' overall survival in patients with esophageal cancer.

It is worthwhile to highlight three aspects of the contributions here. (1) This study investigated DLR features in the survival prediction of patients with esophageal cancer. Unlike the traditional handcrafted features, clinical target-oriented DLR features can be automatically learned from data. (2) Both HCR features and DLR features are considered in the prediction model to characterize the esophageal lesions thoroughly. The main reason is that the DLR and HCR can describe imaging heterogeneity of esophageal lesions in different levels. In particular, HCR comprise shape features, first-order statistics, and texture features; DLR contains the "real-world" textures, which are extracted from the pretrained DenseNet-169 network via transfer learning strategy. (3) This study develops a noninvasive predictive model that combines deep learning-based radiomics features, handcrafted features, and clinical factors to predict survival rates within three years at diagnosis of esophageal cancer. The DLR nomogram survival prediction of esophageal cancer patients can allow more proper treatment. The experimental results showed that the DLR nomogram outperforms the HCR model and the clinical model.

2. Materials and Methods

2.1. Patients. Esophageal cancer patients at Shanxi Cancer Hospital were the subject of our retrospective study. The patients were included according to the inclusion criteria: (a) patients who had pathologically confirmed esophageal cancer, (b) a standard CT scan performed before any treatment, and (c) clinical characteristics available. The patients were excluded with the following criteria: (a) too poor CT image quality, which may affect the diagnosis of the patient, (b) patients who had chemotherapy treatment at another institution, and (c) patients who are also suffering from other cancers.

The survival group includes patients who survived more than three years since the treatment, whereas the non-survival group includes patients who died within three years. A total of 154 esophageal cancer patients diagnosed from November 2012 to February 2015 participated in our retrospective study. Those data were grouped into two sets: training (116) and validation (38) data at a ratio of 3 : 1.

Baseline clinical data were collected via the electronic medical record system (EMRS) [29], including gender, BMI, age, M-stage, N-stage, T-stage, overall stage, and planning target volume (PTV). The picture archiving and communication system (PACS) was used to obtain CT images. The dataset was constructed and evaluated in April 2019, and all enrolled patients were followed for at least 3 years. The Institutional Review Board approved the study.

2.2. CT Image and Region of Interest (ROI) Acquisition. General Electric Light Speed RT16 was used for scanning, with a CT thickness of 5 mm. The primary tumor volumes for radiotherapy planning were set as the ROI to quantitatively analyze the images. Two skilled radiologists manually selected the three-dimensional tumor ROI using the software package 3D Slicer [30].

Training CT images were preprocessed to avoid accuracy degradation of DL models caused by noises introduced with the interval change, which include resampling, rescaling, and voxel normalization. Those CT images were reconstructed with a matrix of 512×512 and $0.5 \times 0.5\,\text{mm}^2$ pixel size, and the resampling with cubic interpolation to $1 \times 1 \times 1\,\text{mm}^3$ pixels was conducted, minimizing CT images variabilities [31].

The tumor area was located with a rectangle bounding box that covers the primary tumor area. The ROI for each patient was obtained with three cropped consecutive slices to avoid the bias of manual segmentation that affects the location of a bounding box. Lastly, the tumor image was resized to $224 \times 224 \times 3$ voxels.

2.3. Radiomics Feature Extraction. Phenotypic differences between tumors can be captured by a large number of quantitative radiomics features. In this study, deep learning features and handcrafted features were extracted to quantify tumor phenotype to enhance the learning efficiency of the radiomics model. Those two feature sets have complementary advantages that can be combined to improve the model. Also, expert knowledge on the esophageal cancer lesion can be reflected with shape and texture features. On the contrary, the high-level DLR features can significantly represent complex spatial features in both global and local perspectives.

The handcrafted feature extraction algorithm was standardized by referring to the Image Biomarker Standardization Initiative (IBSI) [32–34] and Radiomics Ontology [35]. For each CT ROI, 1,670 handcrafted features were extracted using Python implementation, including 18 first-order statistics, 16 geometric, and 1,564 texture features. The textural features include 14 gray-level dependence [36], 23 gray-level co-occurrence [37], 16 gray-level run-length [38], 16 gray-level size-zone [39], and 5 neighborhood gray-tone difference [40] matrices. Refer to the supplementary appendix of Lambing [41], for mathematical definitions of those features.

The DenseNet-169, designed for the image classification task, was adopted to extract DLR features. In the training cohort, data augmentation approaches including random rotation, random shear, and random zoom were employed before the training procedure. The deep learning model was pretrained on the ImageNet dataset, one of the largest image datasets, and then fine-tuned in a transfer learning strategy to avoid the overfitting problem [42]. The network was trained with cross-entropy loss function and Adam optimizer with a learning rate of 0.0001, a batch size of 16, and a regularization weight of 0.0001. The network was implemented on Keras (https://keras.io/) with the TensorFlow library as the backend (https://www.tensorflow.org/). As depicted in Figure 1, the tumor ROI was fed into the DenseNet-169, and the outputs of hidden layers were collected to obtain 1,664 features in total.

2.4. DLR Signature Building. In order to obtain the most effective feature, three stages of feature selection were carried out. First, features ($p < 0.05$) were obtained through the Mann–Whitney U (MWU) test. Then, the features were sorted based on the mutual information (MI) between features and the survival status using the minimum redundancy maximum correlation (mRMR) scheme [43]. It should be noted that, in this study, only the top 50 features in mRMR were retained. Lastly, the dimension of features is reduced by the LASSO to obtain optimal features [44]. The survival-related features were retained while the other features were removed by LASSO regression. The 10-fold cross validation was conducted with 100 iterations in LASSO regression. The obtained features are used to construct the DLR signature, and the HCR signature was constructed in a similar way for comparison.

2.5. DLR Nomogram Construction. A DLR nomogram was built by integrating DLR signature, HCR signature, and clinical features with a multivariable logistic regression model. Backward stepping selection was used with information criterion of Akaike as the stopping rule [45]. The variable multicollinearity in the multiple logistic regression model was checked by the variance inflation factor (VIF), where $VIF > 10$ indicates high multicollinearity [46]. A DLR nomogram was then built based on the multivariate logistic analysis, predicting the individual probability of survival in the training dataset.

2.6. Evaluation of the DLR Nomogram. Harrel's C -index was employed to evaluate the discrimination ability of the DLR nomogram in both training and testing datasets. The bootstrap method was used to resampling 1,000 times, and the C index in both cohorts was calculated with 95% confidence intervals. The AUC, accuracy, specificity, and sensitivity were calculated on the plotted ROC curves. The calibration ability of the DLR nomogram was evaluated using the calibration curve that depicts the consistency between predicted and actual survival probabilities. Hosmer–Lemeshow (HL) test [47] and decision curve analysis (DCA) [48] were utilized to evaluate the fitting accuracy and robustness of the DLR nomogram, respectively. Furthermore, KMS curves were constructed to predict survival status. Accordingly, the patients were predicted as survival or nonsurvival, and then, the difference in survival curves between the two groups was evaluated using the log-rank test.

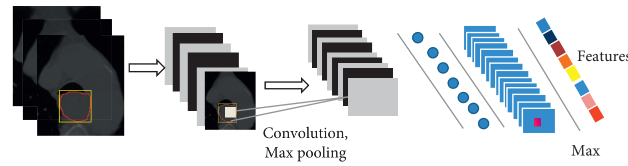

Figure 1: DLR feature extraction process.

2.7. Statistical Analysis. All the statistical analyses were conducted with R software (version 4.0.3; http://www.Rproject.org). MWU and Chi-square tests were adopted for univariate analysis, and Spearman's correlation rank was employed for correlation. The penalty parameter (λ) was tuned by LASSO logistic regression model. This study used the following packages for each analysis. "glomnet" package: LASSO logistic regression, "rms" package: nomograms and calibration plots, "ResourceSelection" package: HL test, "car" package: VIFs calculation, "survivalROC" package: AUC analysis, "survminer" package: KMS analysis, and "dca.R" function: DCA performance. This study utilized a bilateral statistical significance level p value <0.05.

3. Results

Figure 2 depicts the schematic diagram of the study.

3.1. Clinical Characteristics. Table 1 summarizes the clinical characteristics of the training and validation cohorts, where the Chi-square test (p value is 0.572) for two data shows no significant observable difference in the survival rate, 30.2% and 36.8%, for training and validation, respectively.

3.2. DLR Signature. Fifty features were obtained for each patient after survival-unrelated and redundant feature removal from 1,664 DLR features. Then, based on the training cohort, 33 potential predictors were selected by LASSO regression. Parameter (λ) selection and coefficients of LASSO are given in Supplementary Material (II). The DLR signature was constructed using the selected features.

The results show that scores of the survival group were higher than the nonsurvival group with a significant difference in terms of DLR signatures (1.10 ± 0.75 vs. -2.22 ± 0.75) in the training cohort and (0.15 ± 1.11 vs. -1.90 ± 1.12) in the validation cohort. MWU test was used with a p value <.001. Also, a significant correlation between DLR signature and survival status was found (C index: 0.729, $p = 0.035$ in the training data, and C index: 0.766, all $p < 0.001$ in the validation data).

The LASSO algorithm selected 18 handcrafted features to build HCR signatures. HCR signatures were also significantly different between survival and nonsurvival groups. In the training data, 0.68 ± 1.12 vs. -0.50 ± 1.03, p value <.001,

PTV	379.62 ± 158.34	335.22 ± 179.33	0.186	382.56 ± 134.39	362.53 ± 166.27	0.687
HCR_signature	−0.50 ± 1.03	0.68 ± 1.12	<0.001	−0.23 ± 1.48	0.80 ± 1.26	0.035
DLR_signature	−2.22 ± 0.75	1.10 ± 0.75	<0.001	−1.90 ± 1.12	0.15 ± 1.11	<0.001

MWU test, and in the validation data, 0.80 ± 1.26 vs. -0.23 ± 1.48, p value = 0.035, MWU test. HCR feature selection by LASSO regression is described in detail in Supplementary Material (I).

3.3. DLR Nomogram. The DLR signature, HCR signature, and BMI were combined to construct a DLR nomogram, as shown in Figure 3. The VIFs of DLR signature, HCR signature, and BMI were 1.45, 1.41, and 1.07, respectively, indicating no severe collinearity in the regression model.

Figure 4 depicts ROC curves of the DLR nomogram for the DLR signature model and HCR signature model. The AUC was 0.984, 0.955, and 0.797 for the DLR nomogram, DLR signature model, and HCR signatures' model, respectively, in the training data. In the validation data, the

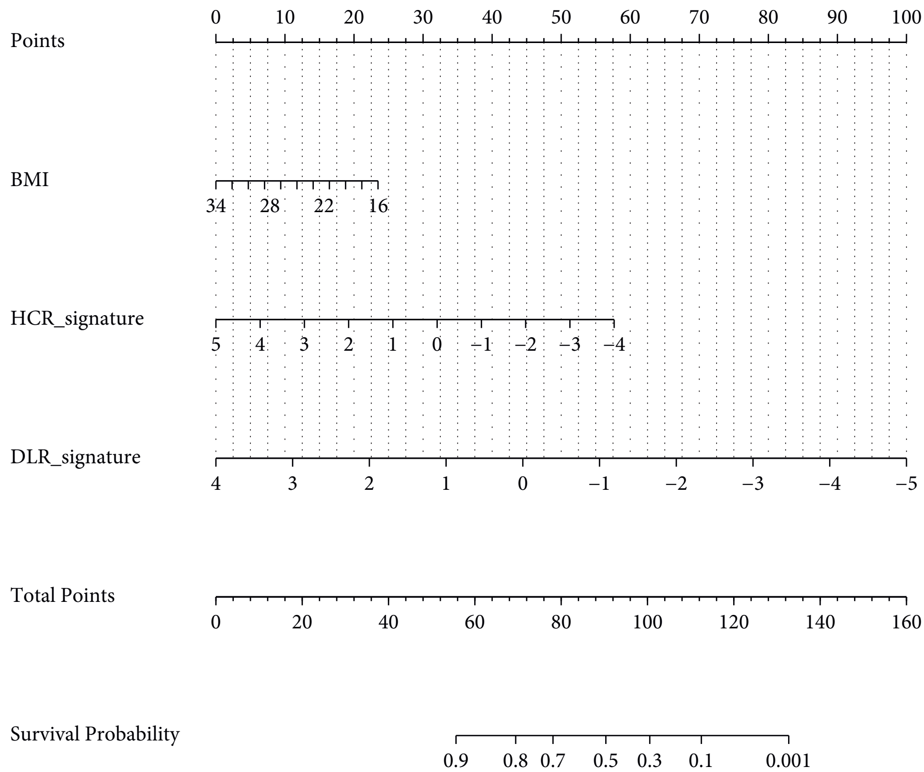

FIGURE 3: The construction of the DLR nomogram.

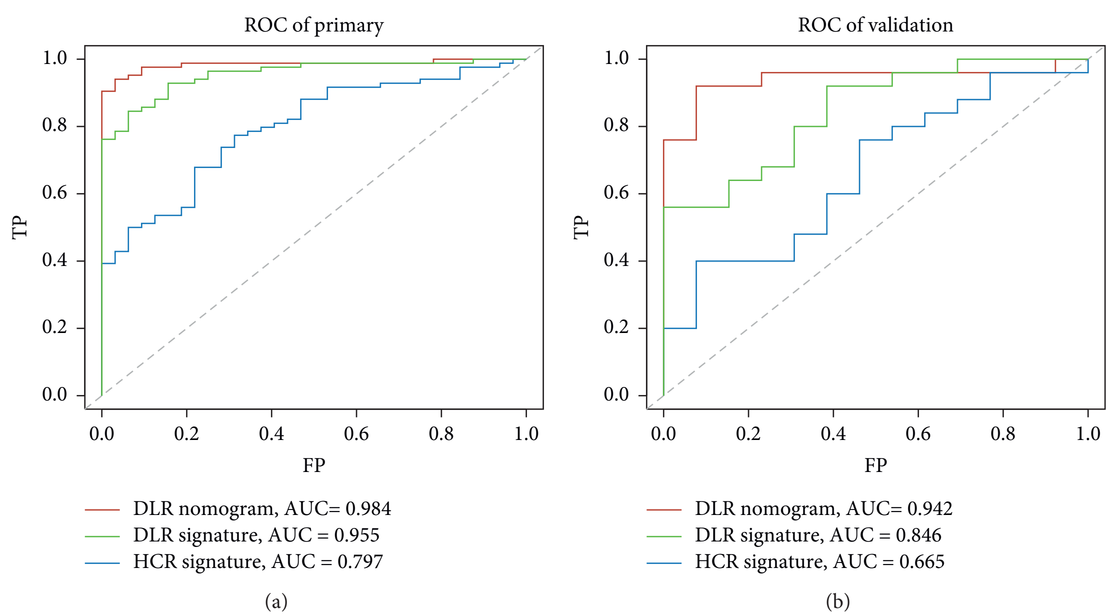

FIGURE 4: ROC curves for the DLR and HCR signatures for (a) training data and (b) validation data.

AUC was 0.942, 0.846, and 0.665 for the DLR nomogram, DLR signature model, and HCR signatures' model, respectively. The results indicate that the DLR nomogram model provides better discrimination ability (Harrel's concordance index, 0.76 and 0.784, for the training and validation data, respectively).

Figure 5 depicts the calibration curves, showing the consistency between predicted and actual survival rates. A nonsignificant statistic of the training cohort (p value = .563, HL test) showed no deviation from the ideal fit. In the validation cohort, the 3-year survival rate was also well-calibrated (p value = .648, HL test).

The DCA examined the clinical outcomes based on threshold probability at which a net benefit could be derived. Figure 6 depicts the DCA of the DLR nomogram, showing that the DLR nomogram obtained outstanding net benefits

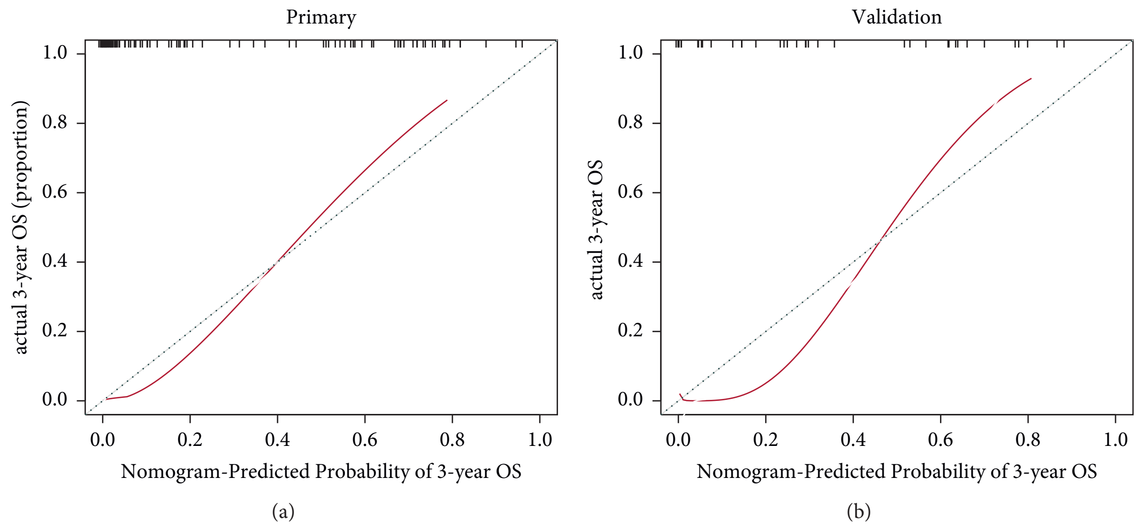

Figure 5: Calibration curves for the DLR nomogram for (a) training data and (b) validation data, where the x-axis and y-axis represent the predicted and actual rates. The solid red line is the performance of the DLR nomogram, and the dashed blue line is the ideal prediction. Closer the solid red line is to the dashed blue line, more accurate the prediction of the model.

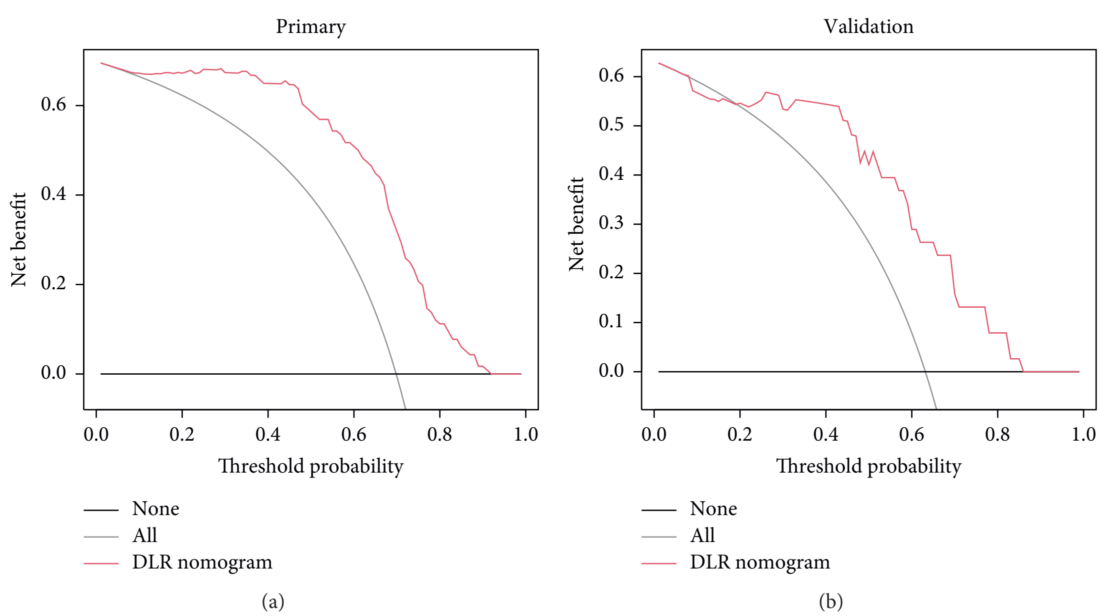

Figure 6: DCA for the DLR nomogram in (a) training and (b) validation data. The black and gray lines represent the hypothesis that all patients die and that no patient dies within three years, respectively. The red line represents the net benefit of the DLR nomogram.

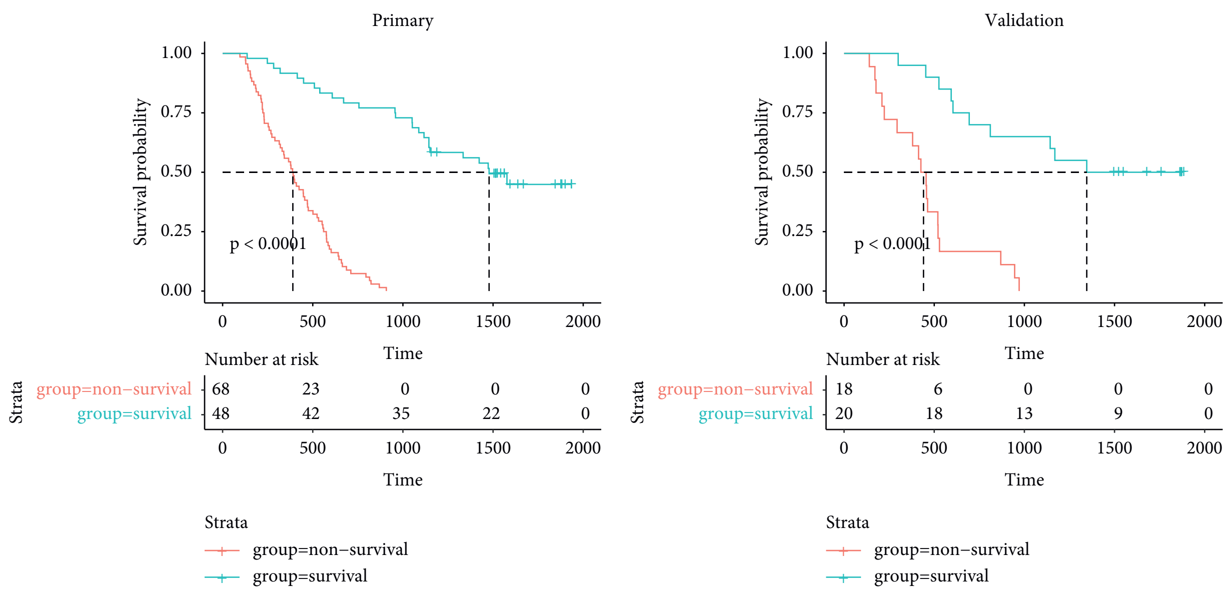
over the other strategies: treat-all-patients and treat-none strategies. A significant difference (p value <.05, log-rank test) between prediction survival and nonsurvival groups was found in KMS curves (Figure 7).

4. Discussion

Treatment planning can be further individualized via preoperative prediction of three-year survival. In previous studies, handcrafted features were analyzed to predict survival rates. However, due to the limited feature extraction ability, the prediction accuracy was not high enough. In order to overcome such a limitation, this study investigated DLR features in the survival prediction of patients with esophageal cancer. Unlike the traditional handcrafted features, clinical target-oriented DLR features can be automatically learned from data [49].

Intratumor heterogeneity has been considered a potential prognosis factor. The DRL feature extraction can robustly characterize the intratumor heterogeneity noninvasively from the medical images [26]. The experimental results showed that the use of DLR features contributed to the performance of the model, which is also supported by recent studies that high-dimensional features can preserve more detailed cancer information, making them more sensitive when assessing survival status [24]. Therefore, by



(a) (b)

Figure 7: KMS curves of the predicted survival and nonsurvival groups in (a) training and (b) validation data.

combining these DLR features, a DLR nomogram survival prediction of esophageal cancer patients can allow more proper treatment. The experimental results showed that the DLR nomogram outperforms the HCR model and the clinical model.

This study has several limitations, described as follows. First, only 154 patients were available for a three-year follow-up analysis. A larger amount of data is required to improve the performance of the model. Second, all the patients were collected to form a single-center, thereby limiting the generalizability of the DLR model. A more diverse dataset is required to validate the robustness and reproducibility of the DLR model. Third, our study did not consider genetic markers. Multiple factors should be considered for more personalized treatment, including biology, pathology, genomics [24, 26, 42–52], and imaging biomarkers [53]. In addition, this study was limited to CT images despite the essentiality of MIR images in surgical planning due to their excellent resolution for soft tissues. The focus should, therefore, be given towards developing an additional model combining CT and MRI image features. Finally, the primary tumor volumes were manually delineated for feature extraction. Even though the delineations are commonly used with confirmation by another radiation oncologist in radiotherapy planning, previous studies showed that semi-automatic tumor segmentation could reduce interobserver variability and therefore is more suitable for radiomics studies [54].

5. Conclusions

This study details the development of a noninvasive predictive model that combines deep learning-based radiomics features, handcrafted features, and clinical factors to predict survival rates within three years at diagnosis of esophageal cancer. The performance of the proposed DLR nomogram is superior to the traditional radiomics model in terms of Harrel's concordance index and AUC. The calibration curves show the good prediction performance of the nomogram. The nomogram-predicted Kaplan–Meier survival (KMS) curves differed significantly from the nonsurvival groups in the log-rank test (p value <0.05). The proposed model can present the basis for clinicians to make better treatment decisions and personalized diagnoses. Future works will include the model improvement based on larger data and complementary clinical factors.

Supplementary Materials

(I) HCR feature selection using the least absolute shrinkage and selection operator (LASSO) logistic regression model. Figure S1. HCR feature selection using the LASSO logistic regression algorithm. (a) The penalization coefficient λ in the LASSO model was tuned by the binomial deviance minimization criteria. The binomial deviance metrics (the y-axis) were plotted against $\log(\lambda)$ (the bottom x-axis). The top x-axis indicates the number of predictors with the given $\log(\lambda)$. Red dots indicate average binomial deviance for each model at the given λ. Vertical bars through the red dots show the upper and lower values of the binomial deviance. The vertical black lines represent the optimal λ, where the model provides the best fit to the data. As a result, the optimal λ of 0.02373184 was selected. (b) LASSO coefficient profiles of the 50 radiomics features. For the optimal λ, eighteen features with nonzero coefficient were selected. (II) DLR feature selection using the least absolute shrinkage and selection operator (LASSO) logistic regression model. Figure S2. DLR feature selection using the LASSO logistic regression algorithm. (a) The penalization coefficient λ in the LASSO model was tuned by the binomial deviance minimization criteria. As a result, the optimal λ of 0.0445107 was selected. (b) LASSO coefficient profiles of the 50 radiomics features. For the optimal λ, thirty three features with nonzero coefficient were selected. (*Supplementary Materials*)

In the intensive care unit, the monitored variables collected from sensors may have different behaviors among patients with different clinical basic information. Giving prior information of the monitored variables based on their specific basic information as soon as the patient is admitted will support the clinicians with better decisions during the surgery. Instead of black box models, the explainable hidden Markov model is proposed, which can estimate the possible distribution parameters of the monitored variables under different clinical basic information. A Student's *t*-test or correlation test is conducted further to test whether the parameters have a significant relationship with the basic variables. The specific relationship is explored by using a conditional inference tree, which is an explainable model giving deciding rules. Instead of point estimation, interval forecast is chosen as the performance metrics including coverage rate and relative interval width, which provide more reliable results. By applying the methods to an intensive care unit data set with more than 20 thousand patients, the model has good performance with an area under the ROC Curve value of 0.75, which means the hidden states can generally be correctly labelled. The significant test shows that only a few combinations of the basic and monitored variables are not significant under the 0.01 significant level. The tree model based on different quantile intervals provides different coverage and width combination choices. A coverage rate around 0.8 is suggested, which has a relative interval width of 0.77.

1. Introduction

In the intensive care unit (ICU), patients suffer from complications like sepsis and circulatory failure during surgery. Such complications will incur serious conditions out of medical control [1, 2]. Without fast and accurate disease diagnosis, patients face a high death rate due to lack of proper treatment. To improve the diagnosis efficiency, a prior information extraction method was developed in this research. As soon as the patients are admitted into the ICU, their basic clinical data can be checked from the medical information system. By giving the prior probability calculated from the basic clinical data, it can improve the posterior probability either diagnosed by the surgeons or by models like Bayesian.

The model developed during the training process in this research utilizes the basic clinical data before the surgery and the monitored data during the surgery. The data include two parts (1) the basic clinical data $B_{n,\cdot}$ for patient n including variables such as sex, age, weight, and height.

$$B_{n,\cdot} = \left[B_{n,1}, B_{n,2}, \ldots, B_{n,k}, \ldots\right], \quad (1)$$

where $n = 1, 2, \ldots, N$ and $k = 1, 2, \ldots, K$. (2) The monitored data during the surgery for patient n, including variables such as heart rate and cardiac output.

$$A_{n,\cdot,\cdot} = \begin{bmatrix} A_{n,1,1} & \cdots & A_{n,K,1} \\ A_{n,1,2} & \cdots & A_{n,K,2} \\ \vdots & \ddots & \vdots \\ A_{n,1,T_n} & \cdots & A_{n,K,T_n} \end{bmatrix}, \qquad (2)$$

where A_n refers to the matrix for the n^{th} individual containing all variables at all times. As the time length for patients differ, T_n is used to measure the time length for patient n. Without any extra information, the data for patient n are $\{B_{n,\cdot}, A_{n,\cdot,\cdot}\}$.

For diseases such as circulatory failure and sepsis during surgery, there are typical methods to diagnose their onset. For example, systemic inflammatory response syndrome (SIRS) and sequential organ failure asses (SOFA) are designed for sepsis detection. These are simple decision rules by including criteria like that the temperature is higher than 38 or lower than 36. These criteria are the general diagnosis standard when patients show obvious symptoms. In the early diagnosis of neonatal sepsis, the semiquantitative PCT test kit helps to exclude negative results [3]. Cheadle et al. [4] have surveyed a number of host defense parameters that pertain to an adequate immune response and developed an outcome predictive score, which can identify patients within hours of hospitalization who are at risk of subsequently developing overt clinical infection and sepsis. For observations $A_{n,\cdot,t}$ at time t, a response can be given according to the diagnosis standard as $y_{n,t}$. Until now, the data for patient n are $\{B_{n,\cdot}, A_{n,\cdot,\cdot}, y_{n,\cdot}\}$.

The current research for disease analysis by using the abovementioned data can be divided into three aspects, which are as follows:

(1) The relationship analysis of basic clinical data B and response variables such as survival rate. The models can be traditional biostatistics tests and machine learning methods [5]. For example, Chicco and Jurman [6] predict the survival rate of patients with sepsis from age, sex, and septic episode number alone.

(2) From the static aspect, the data A is regarded as a static multivariate time series, which assumes the data follow the same distribution without changing with time, thus a stationary process. Methods such as neural networks or ensemble learning technics such as the random forest or AdaBoost are used in the modeling process [7].

(3) From the dynamic aspect, the time series are regarded as dynamic multivariate variables, thus a nonstationary process [8]. Dynamic models are designed by giving model updating or retraining criteria. For example, Zhao et al. [9] use wavelet transform and decision tree-based methods to do interval forecasting for monitored data A. The input variables involved include A and sometimes B. For example, Esteban et al. [10] predict clinical events by combining static and dynamic information using recurrent neural networks. The data B is involved as an input layer in the neural network, resulting in an improvement in the performance. Bernhardt [11] proposes a two-part regression model composed of logistic regression and a truncated accelerated failure time model, which helps to use all of the available survival information. Instead of involving the data B in the existing model, Lin et al. [12] built a separate model to train B and combined it with the convolutional long short-term memory neural networks trained for A. In addition to the data A and B, pharmacy data are also used in the modeling process, as demonstrated by Hyland et al. [13].

Current research mainly concentrate on one specific disease with two states being safe or onset. But the reality is that multiple states may occur during the surgery process. Prediction of one specific state may reduce the data information utility and ignoring other states may bring more uncertainty to the health condition of the patients. In addition, the criteria of disease onset detection like SIRS may not cover all possible hidden conditions. The states can be regarded as hidden states that are not seen or cannot be measured directly while the monitored variables like A or basic information B are not hidden. One of the main hidden states model is the hidden Markov model. Christopher et al. give the initial probability distribution calculation method of the multi-Markov model for such data. Their following research can be seen from Christopher, Ieva et al. [14]. In this case, hidden state models are proposed in this research to label the state for each observation of each patient.

The distribution of data A is rarely studied among the researches, as most of the methods are nonparametric methods which have no parameter assumptions like some of the machine learning methods. But if the distributions can be estimated, the correlation of the basic clinical data B and the distributions of different state labels can be established. In that case, by giving the prior information of B, the clinicians can have the estimated posterior distribution of A of different disease states. For example, if females have an average higher heart rate than males, a heart rate value normal for females may be alerted for males. If the heart rate is not distinguished by sex, male patients may be delayed in medical treatment. So, in this research, the distributions of monitored data A are studied under different states' labels. The correlation between distribution parameters and basic clinical data is tested to distinguish their differences among different basic information.

The innovative aspects in this paper include the following: (1) the multivariable hidden Markov model is selected to discover the hidden states that may not be measured by the general standard rules. (2) The variables' distribution of A labelled with different states is estimated by the hidden Markov model under the Gaussian assumption. (3) The variables' distributions are compared under different prior basic clinic conditions to give a posterior information for clinical decision.

We introduce our basic model in Section 2, and apply it to the real data in Section 3. Some concluding comments appear in Section 4. All calculations were carried out using R

Core Team [15]; "depmmixS4" [16] was used for the hidden Markov model and "ctree" by Hothorn et al. [17] for the Ctree.

2. Methods

The hidden Markov model (HMM) origins from the research [18] for discrete observations and is further developed for time series; detailed study was carried out in [19]. The HMM has observations which are observable, such as the monitored variable heart rate which can be collected by sensors. The observations are generated by the corresponding states which are not observable, like the status of the patient as sick or healthy, as circulatory failure or normal. The HMM has three typical questions: likelihood, decoding, and learning. What is used in this research are decoding and learning, which are finding the most likely hidden status and learning the parameters of the model.

If the distribution of the observations are assumed to be Gaussian distribution, for patient n and monitored variable k at status s, by giving the parameters of initial distribution as π_s, Gaussian distribution as $\mu_{n,\cdot,s}$, $\Sigma_{n,\cdot,s}$, the conditional joint distribution is

$$f\left(A_{n,\cdot,\cdot}, y_{n,\cdot} | \pi_s, \mu_{n,k,s}, \sigma_{n,k,s}\right) = \prod_{t=1}^{T_n} \prod_{k=1}^{K} \pi_s^{I\left(y_{n,t}=s\right)} \mathcal{N}\left(A_{n,k,t} | \mu_{n,\cdot,s}, \Sigma_{n,\cdot,s}\right)^{I\left(y_{n,t}=s\right)}, \tag{3}$$

where $I(y_{n,t} = s)$ is the indicator variable showing whether the status of patient n at time t is s or not. If the variables are further assumed to be independent mutually, then the distribution is

$$f\left(A_{n,\cdot,\cdot}, y_{n,\cdot} | \pi_s, \mu_{n,k,s}, \sigma_{n,k,s}\right) = \prod_{t=1}^{T_n} \prod_{k=1}^{K} \pi_s^{I\left(y_{n,t}=s\right)} \left\{ \prod_{k=1}^{K} \mathcal{N}\left(A_{n,k,t} | \mu_{n,k,s}, \sigma_{n,k,s}\right) \right\}^{I\left(y_{n,t}=s\right)}. \tag{4}$$

By using the Baum–Welch algorithm (expectation maximization algorithm) and assuming the initial distribution is equally distributed, the Gaussian distribution parameters can be estimated for patient n, variable k, and state s as follows:

$$\left\{\widehat{\mu}_{n,k,s}, \widehat{\sigma}_{n,k,s}\right\}. \tag{5}$$

By applying the forward-backward algorithm, the best hidden states $\widehat{y}_{n,t}$ and its corresponding probability $p(y_{n,t} = s)$ can be estimated.

Since the hidden states are discrete, the metric AUC (area under the ROC curve) is chosen to measure the similarity between the real and estimated hidden states. A ROC curve (receiver operating characteristic curve) is a graph showing the performance of a classification model at all classification thresholds. AUC provides an aggregate measure of performance across all possible classification thresholds, which ranges in value from 0 to 1. A model whose predictions are 100 % wrong has an AUC of 0.0; one whose predictions are 100 % correct has an AUC of 1.0, while random guessing has an AUC of 0.5.

If the AUC results are acceptable, the estimated parameters $\left\{\widehat{\mu}_{n,k,s}, \widehat{\sigma}_{n,k,s}\right\}$ can be reliable. After that, the parameters are compared under different basic clinical data B. For example, the data $\widehat{\mu}_{\cdot,k,s}$ of variable k and state s are compared under different sex to test whether it has significant difference between female and male patients. The comparing methods include Student's t-test for discrete variables such as sex and the correlation test for continuous variables such as age, weight, and height. If the test shows significant results, the model decision tree is further conducted to find how the basic clinical variable influences the monitored variables' distribution, namely, the estimated parameters.

The model decision tree is a model of tree-like decision rules, which splits the sample space into subspaces by choosing the best split each time. Specifically, the model used in this research is a conditional inference tree (Ctree [17]). Ctree estimates a regression relationship by binary recursive partitioning in a conditional inference framework. The predictor variable, like the clinical basic variables, with the lowest p value is selected for splitting the response variable, for example, $\widehat{\mu}_{\cdot,k,s}$ of variable k and state s. The p value belongs to a split criterion which can be Spearman's correlation test, the Wilcoxon–Mann–Whitney test, the Kruskal–Wallis test, permutation tests, and so on. The stoping criteria are not constrained to the p value, but also include the max tree depth allowance. For example, a max tree depth of 5 means the tree can be no bigger than 5 in depth. Other stopping criteria may also be applied. A regression tree is formed by iteratively splitting nodes so as to maximize the decreased p value at each step.

For each observation, it will be split into one single terminal node. The observations in the same terminal node can be regarded as a set. By ranging the Y values in that set,

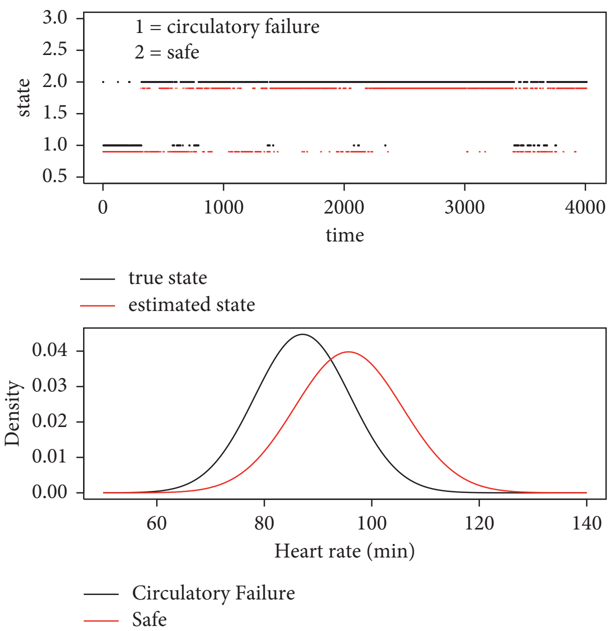

Figure 1: The hidden Markov model (HMM) result for one patient with multiple states. In the first figure, the HMM estimated red (below the black line) points are generally consistent with the black points (above the red line). Its corresponding AUC value is 0.8962. In the second figure, the right red Gaussian curve has the parameters $\mu = 95.675$ and $\sigma = 10.027$, and the left black curve has the parameters $\mu = 87.123$ and $\sigma = 8.918$. The observations of state circulatory failure have a relatively lower μ.

the quantile values can be selected as the forecast interval. For example, an 80 % interval has an upper value of 0.9 quantiles and a lower value of 0.1 quantiles. The width of the quantile interval is further standard adjusted to remove the influence of the different variable units by dividing their 0.9 quantile difference of the variable.

$$\text{Relative interval width} = \frac{\text{original interval width}}{0.95\ \text{quantile} - 0.05\ \text{quantile}}. \tag{6}$$

The coverage of the interval is as follows:

$$\text{coverage rate} = \frac{\text{number of observations in the interval}}{\text{total number of observations}}. \tag{7}$$

A wider interval has a high coverage when a new observation comes into the same terminal node, but at the cost of a higher width. An interval with good coverage and suitable width is suggested.

3. Real Data Analysis and Results

In the real data analysis, the circulatory failure data from Hyland et al. [13] are used. After deleting patients who have missing values, the data contains 22290 patients. The data include monitored variables A such as heart rate, systolic blood pressure (BP), diastolic BP, mean arterial pressure (MAP), and basic clinical data B such as sex, age, weight, height, and body mass index (BMI). Sepsis is a systemic inflammatory response syndrome caused by the invasion of

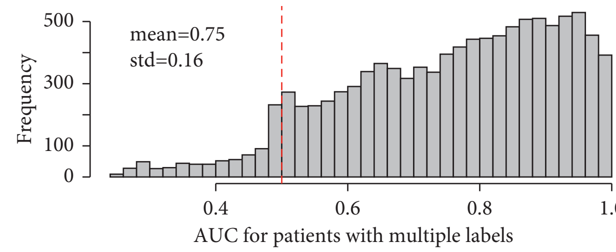

Figure 2: The area under the ROC curve (AUC) results for patients with multiple states. The AUC value of 0.5 means the model has a performance of random guessing. A value higher than that means the model has better performance.

pathogenic microorganisms such as bacteria into the body. Associated dysregulation of the inflammatory response has been thought to be directly associated with cardiomyocyte dysfunction. And heart rate reflects the frequency with which cardiomyocytes move. Systolic BP, diastolic BP, and MAP are related to blood volume, elasticity and tension of blood vessel walls, and cardiac output. They can all reflect well the ability of cardiomyocytes and can serve as an indicator of sepsis. For the state variable y, it is labelled generally according to the rule from [13]: $y_{n,t}$ is labelled as circulatory failure if MAP is ≤ 65 mmHg or (not exclusive) vasoactive/inotropic drugs are present and lactate is bigger than $2\ \mathrm{mmol\ l^{-1}}$. Under the other circumstances, $y_{n,t}$ is labelled as safe.

For the data $A_{n,\cdot,\cdot}$ of patient n, we train them with the model HMM under the Gaussian distribution assumption. The estimated states and the estimated parameters for the variable heart rate of one patient example are shown in Figure 1.

$$\hat{y}_{n,t} = f\left(A_{n,\cdot,\cdot}\right). \tag{8}$$

One thing that needs to be noticed is that the hidden state of not being safe is not constrained to circulatory failure but may also include others. The reason $y_{n,t}$ is labelled as circulatory failure is because circulatory failure is the main disease during the process. If it can be correctly labelled, the HMM results can be reliable. After the HMM processing, the AUC value is calculated for patients who have multiple states in $y_{n,\cdot}$. The patients with only circulatory failure or safe state, namely, $y_{n,}$ with only one label, are not involved in the AUC measurement. After that, the number of patients is 10406. The histogram of the results is shown in Figure 2.

The result shows that, the HMM model can efficiently recognize the patterns of the data, thus most of the states are labelled with the right tag. Since the AUC results are acceptable, the estimated parameters $\{\hat{\mu}_{n,k,s}, \hat{\sigma}_{n,k,s}\}$ can be reliable. After that, the t-test or correlation test is conducted to test whether the estimated $\hat{\mu}_{n,\cdot,s}$, $\hat{\Sigma}_{n,\cdot,s}$ have significant difference among different basic clinical settings. The results are shown in Table 1.

The results show that most of the parameters have a significant correlation with the clinical basic variables. By giving the clinical basic information, the parameters can have their values estimated, which can be regarded as the prior values for the monitored variables. Instead of

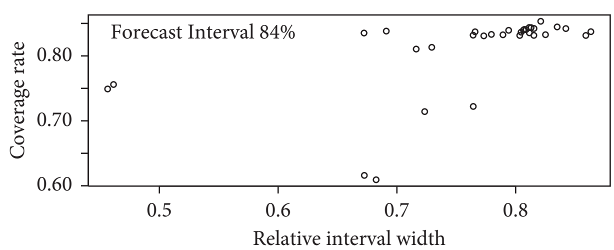

Figure 3: The coverage rate and relative interval width of the 32 monitored variables under the 84% forecast interval. The averaged relative interval width is 0.77, and the averaged coverage rate is 0.81.

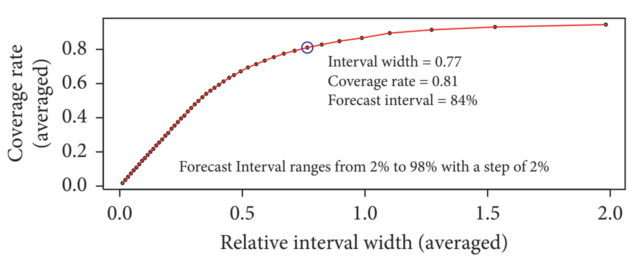

Figure 4: The averaged coverage rate and relative interval width of the 32 monitored variables under different forecast intervals.

point estimation, interval estimation is suggested to give more reliable support for clinicians. The model Ctree is applied, with the threshold chosen as 0.1 and the tree max depth as 5, which balances the performance and complexity of the model. For example, when the forecast interval is set as 84 %, the coverage rate and relative width across the 32 monitored variables are shown in Figure 3.

Since the correlation significant results differ across the monitored variables, the coverage rate and relative interval width have different performances. But the results are relatively acceptable as they are generally around 0.84, the preset forecast interval.

When the forecast interval changes, the averaged coverage rate and averaged relative interval width can be estimated. The results are shown in Figure 4. It can be shown that when the interval width increases, the coverage rate also increases, but at a decreasing speed. An increase of 0.1 may cost the width of 0.5 when coverage has reached 0.8. A result of around 0.8 is proposed, which has relatively high coverage but not that wider width. It should be noted that this study involves one disease, sepsis, but includes different stages of sepsis and has a large sample size to support the data, so the model is stable and can be generalized.

4. Conclusion

In order to calculate the prior distribution parameters of the monitored variables of different hidden states, this research gives a method by using the explainable HMM and Ctree models. The HMM finds the most possible hidden states, and the estimated states are compared with the true circulatory failure states, which results in an AUC of 0.75 in the real data analysis. Thus, the distribution parameters of the monitored variables learned by the HMM can be reliable. The t-test or correlation test is applied to test the significant relationship between the basic clinical variable and the distribution parameters of the monitored variables. Results show that most relationships are significant, which means the distribution of the monitored variables truly has some kind of dependence on the clinical basic information. To further explore the specific relationship, the model Ctree is conducted. Instead of point estimation, interval forecast is applied, along with the coverage rate and relative interval width as the performance metrics. Results show that, with a wider width, the coverage increases. But the increase decays when the coverage reaches a high level. A good coverage of 0.8 with a suitable width is suggested.

In further research, in terms of the method, the parameters of the monitored variables can be assumed to follow different distributions without being constrained to follow a Gaussian distribution. This can help extend the method for more general conditions. In terms of the variable relationship exploration part, the relationship test can be applied to a mixture of variables instead of one at a time. This helps explore more potential relationships among different variables. In the interval forecast method, point estimation can be conducted by including other input variables so as to get a good performance. In terms of sepsis, as it is a threat to the public health with high morbidity and mortality, further research can be extended from diagnosis assistance to also include prevention and treatment support. More machine learning methods can be developed to solve the potential problems incurred by the rapid development of medical technology.

The results of the research can not only be used for clinician support but also provide prior distribution for the models of state prediction during the monitoring process. This can improve the prediction accuracy at the beginning of the prediction process. If further pharmacy information is added, the research can also be used for exploring the influence of clinical basic information in the usage of drugs. Suitable and timely drug dosage provides the possibility of precision medicine. By combining machine learning technologies with medical demand, medical problems can be solved more automatically by modern algorithms, and less human resources are required. The method developed in this research can be also applied in other areas such as financial and economical areas, environmental regulation, and so on.

Objective. The objective of the study is to develop a nomogram for estimating three- and five-year survival rates in mucinous breast cancer patients. *Methods*. Between 2010 and 2016, the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) were searched as a data source for patients associated with mucinous breast cancer (MBC). A total of 3964 patients were recruited after screening. The multivariate Cox model and the univariate Kaplan-Meier (KM) approach were employed to evaluate the independent prognostic markers, followed by developing a nomogram for estimating three- and five-year survival rates in MBC patients. Consequently, the consistency index (C-index) was employed to assess the predictive accuracy of the generated nomogram. *Results*. Age, race, T stage, M stage, surgery, and radiotherapy were all independent predictive biomarkers for the MBC patients ($P < 0.05$). The nomogram was finally developed based on the underlined factors. Furthermore, the C-index of 0.803 and reliable calibration curves were obtained in the nomogram's assessment. *Conclusions*. In patients with mucinous breast cancer, the proposed nomogram provides a viable tool for accurate prognostic prediction. In clinical practice, it could serve as a personalized diagnosis tool, estimate prognosis, and help in suggesting treatment plans for patients with MBC.

1. Introduction

Mucinous breast cancer (MBC) is a rare and unusual type of breast cancer that manifests itself primarily by a huge percentage of extracellular mucins [1, 2]. It accounts for around 1%–6% of all primary breast cancers. MBC is more frequent in postmenopausal women and has a better survival [3]. MBC was shown to have elevated hormone receptor expression and decreased human epidermal growth factor receptor 2 expressions in prior research [4–6]. Because of the low incidence of MBC, it has different clinical, histopathological, and biological characteristics from common breast cancers in general [7], and there is a lack of reports of large sample studies on MBC, which predisposes to undertreatment or overtreatment. The prognosis of MBC is influenced by many factors at the same time. It is difficult to predict the actual situation of patients by one or several prognostic factors alone. The lack of a particular prognosis evaluation system for MBC has resulted in a uniform treatment for MBC, without any consideration of individual patient needs.

Nomograms have been developed as the new standard for predicting the occurrence and prognosis of certain cancers, and most cancer types have established prognostic nomograms [8, 9]. Such nomograms are considered a reliable tool that can help clinicians make accurate individualized predictions [10]. However, no satisfactory nomogram has yet been developed to predict survival in MBC. To solve the problem, this study attempts to establish a new nomogram-based prediction model for MBC that incorporates more than one clinical parameter in an attempt to individualize the estimation of prognosis for patients. It involves retrospective analysis of the data of MBC from 2010 to 2016 in the SEER database, screening independent prognostic factors, and, subsequently, constructing a nomogram prognostic model to provide a reference for clinicians to assess patient prognosis and develop individualized treatment plans.

2. Material and Methods

2.1. Source of Data. The data for the current study were attained from the SEER database of the US National Cancer Institute (NCI), and the data were obtained by SEER Stat 8.3.8 software.

2.2. Patient Inclusion and Information Extraction

2.2.1. Patient Inclusion and Exclusion Criteria. The data of MBC patients in the SEER database from 2010 to 2016 were collected. Inclusion criteria were as follows: (1) ICD-O-3 Hist/behave, malignant = "8480/3: mucinous adenocarcinoma"; (2) patients newly diagnosed with MBC; (3) patients with breast cancer as the only primary tumor; (4) patients with complete general clinicopathological information; (5) patients with complete follow-up (follow-up up to December 31, 2016). The exclusion criteria were given as follows: (1) male MBC patients; (2) confirmed patients of postmortem examination and death report; (3) patients with missing information and survival time less than 1 month (Figure 1).

2.2.2. Information Extraction. Extract the patient's age, race, marital status, tumor location (left breast, right breast), histological grade, TNM stage (7th edition AJCC-TNM staging system), ER status, PR status, HER-2 status, surgery, radiotherapy, chemotherapy, survival data, and other information.

2.3. Statistical Methods. Patients were randomly split into modeling and validation groups using *R* software. First, univariate analysis was conducted to evaluate the factors affecting the survival prognosis of patients in the modeling group, and variables that showed statistical significance on univariate analysis were also involved in the multivariate Cox proportional hazards regression (CPHR) model to determine the final independent prognostic factors, the effect of independent prognostic factors on the survival rate of MBC patients was shown by the KM method, and then, the nomogram was constructed using *R* software, and the consistency index was calculated, and the correction curve was drawn. The Bootstrap method was used to conduct internal and external validation for the modeling group and the validation group, respectively. In the calibration curve, the closer the curve is to the ideal 45° reference line, the closer the predicted value is to the actual observed value. *R* software (version 4.0.2) (http://www.r-project.org/) was employed to conduct the statistical evaluations.

3. Results

3.1. Clinicopathological Features of Included Patients. From 2010 to 2016, the SEER database yielded 3,964 eligible female MBC patients (2,776 in the modeling group and 1,188 in the validation group). It summarizes the sociodemographic and clinicopathological features of the two groups in Table 1. The 3,964 patients were followed up for a period of 1 to 83 months, with a mean follow-up of 39 months. Approximately three-quarters of patients were white ($n = 2{,}992$, 75.4%), more than one-half were Grade I ($n = 2{,}354$, 59.3%), and more than 90% were N0, M0, ER (+), PR (+), HER-2 (−). Other clinicopathological features are shown in Table 1.

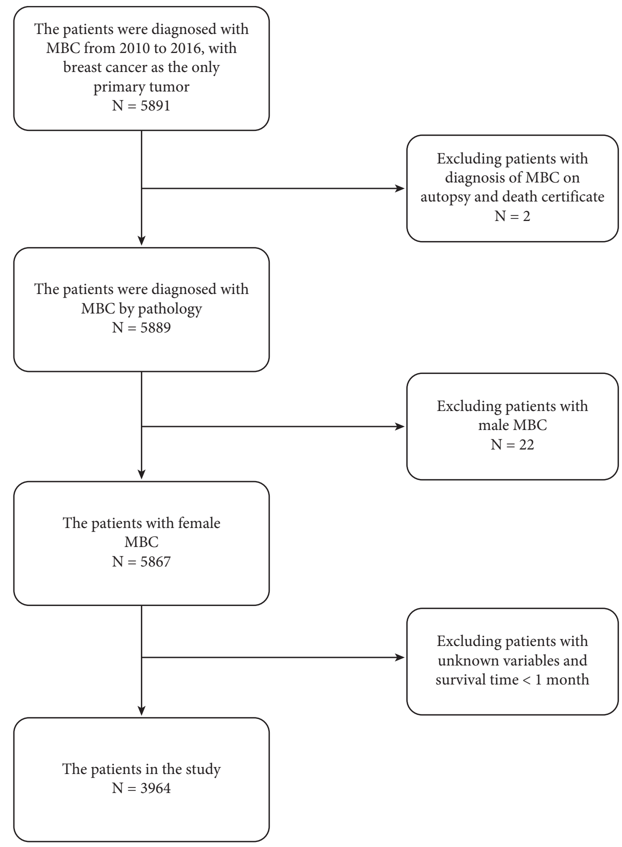

Figure 1: Flow chart of patient screening in SEER database.

3.2. Analysis of Influencing Factors of Survival Prognosis

3.2.1. Univariate Analysis Results. Univariate analysis of the survival of 2,776 MBC patients in the modeling group revealed that the 3- and 5-year survival rates of patients were linked to their age, ethnicity, marital status, T stage, N stage, M stage, surgery, radiotherapy, and chemotherapy ($P < 0.05$) but not to histological grade, lesion location, PR status, ER status, or HER-2 status ($P > 0.05$), as indicated in Table 2.

3.2.2. Results of Multivariate CPHR Analysis. Table 2 shows the results of multivariate CPHR analysis, which were based on the findings of univariate analysis. In this study, age, ethnicity, T stage, M stage, surgery, and radiotherapy were all found to be independent risk factors for MBC patients' prognosis ($P < 0.05$). The KM curve was used to demonstrate the impact of independent prognostic factors on MBC patient survival rates, as indicated in Figures 2(a)–2(f). In

each of the graphical representations, the horizontal axis (x-axis) represents time in months, and the vertical axis (y-axis) shows the probability of survival or the proportion of people surviving. A vertical drop in the curves indicates an event.

3.3. The Development of a Nomogram to Assess MBC Patients' 3- and 5-Year Overall Survival (OS) Rates. Age, ethnicity, T stage, M stage, radiation, and surgery were among the statistically significant prognostic factors in the multivariate CPHR model. A nomogram was constructed using *R* software. The predictive nomogram for the 3- and 5-year OS rates of MBC patients is shown in Figure 3. The nomogram is used by totaling the points identified on the top scale for each independent covariate. The score of each item of an individual can be obtained by projecting each clinicopathologic feature upwards to the score, and the total score is obtained by adding the scores of each item. There is a total points line at the bottom of the nomogram. The total points projected to the bottom scale indicate the % probability of 3-, 5-year ***overall survival (OS).***

The higher the total score, the worse the survival prognosis. The nomogram in Figure 3 shows that age at diagnosis is the greatest contributor to the prognosis, followed, respectively, by M stage, TNM stage, ethnicity, surgery status, and radiotherapy status. The nomogram shows that the use of radiotherapy is beneficial for patients with MBC.

3.4. Verification of Nomograms. We established a nomogram model integrating independent predictors of OS (e.g., age, tumor site, tumor size, tumor extension, and radiotherapy) to provide a visual statistical predictive tool for the survival of patients with MGCTB. We established a nomogram model integrating independent predictors of OS (e.g., age, tumor site, tumor size, tumor extension, and radiotherapy) to provide a visual statistical predictive tool for the survival of patients with MGCTB. We established a nomogram model integrating independent predictors of OS (e.g., age, tumor site, tumor size, tumor extension, and radiotherapy) to provide a visual statistical predictive tool for the survival of patients with MGCTB. We established a monogram model integrating independent predictors of OS (age, ethnicity, T stage, M stage, radiotherapy, and surgery) to provide a visual statistical predictive tool for the survival of patients with MBC. A calibration curve of the nomograph was drawn to evaluate the consistency between the observed and estimated survivals. The C-index calculated by *R* software was 0.803 (95% CI: 0.772–0.834) for the modeling group and 0.817 (95% CI: 0.768–0.866) for the validation group, suggesting that both had good predictive values and good discriminative ability. The bootstrap method was used for internal verification and external verification of nomogram. The self-sampling number $B = 1{,}000$. Figure 4 shows the calibration plots of the nomogram for predicting the probability of OS at 3 and 5 years. The calibration curves of 3- and 5-year survival rates in the modeling group and validation group were close to the ideal 45° reference line (Figure 4), suggesting that there was good consistency between the predicted value and the actual 3 and 5 years OS. Thus, the monogram has been internally and externally verified for both the modeling and validation group, respectively, showing good accuracy and clinical applicability. It can effectively predict OS in MBC patients, which may

help clinicians personalize prognostic assessments and clinical decisions.

4. Discussions

MBC is a kind of breast cancer that is quite uncommon. It affects 1%–6% of all initial breast tumors. [1, 11] Relative to other kinds of breast cancer, MBC has a few distinct clinical characteristics. MBC is more common in postmenopausal and elderly women and has a satisfactory rate of survival. The positive rates of estrogen and progesterone receptors in MBC are substantial and demonstrate greater differentiation and a decreased rate of lymph node metastasis [6, 12, 13]. The underlined data showed consistency with the findings of

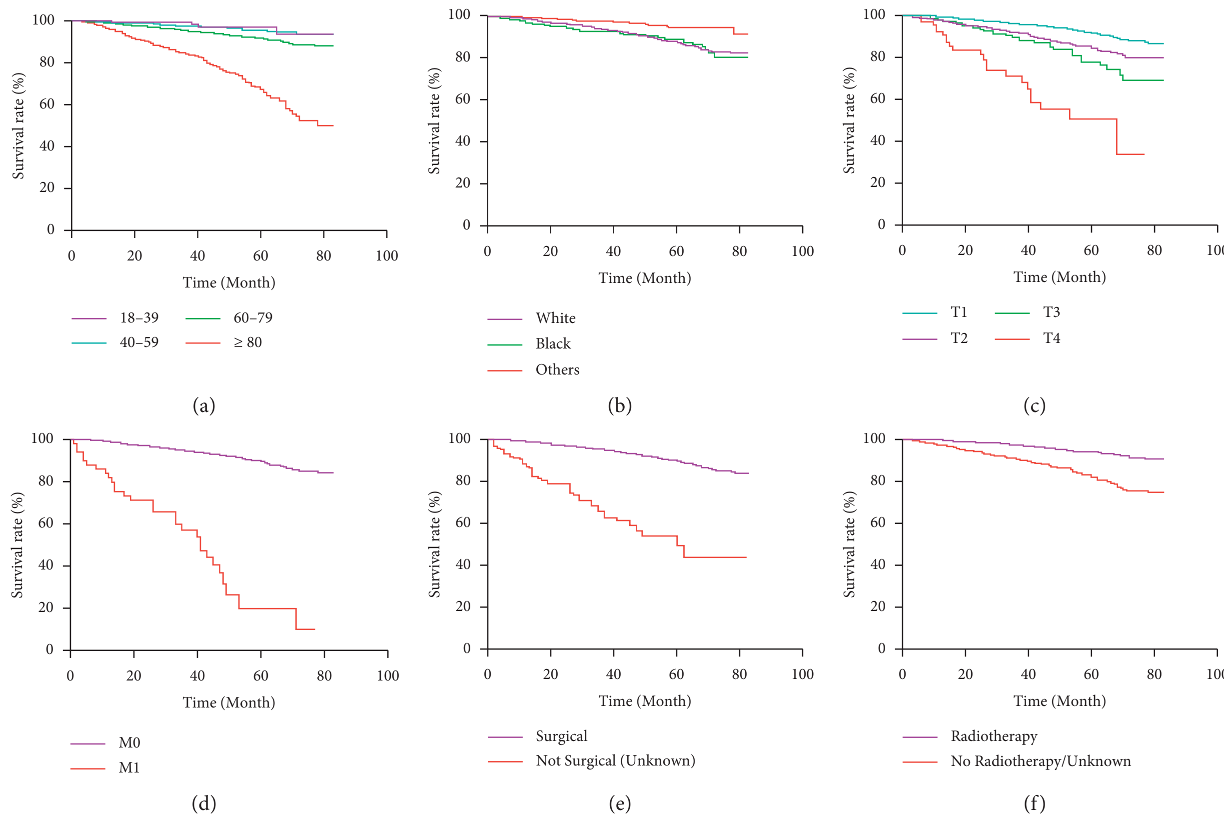

Figure 2: Kaplan-Meier curve of the effect of each independent risk factor on the prognosis of MBC. (a) Age; (b) ethnicity; (c) T stage; (d) M stage; (e) with or without surgery; (f) with or without radiotherapy.

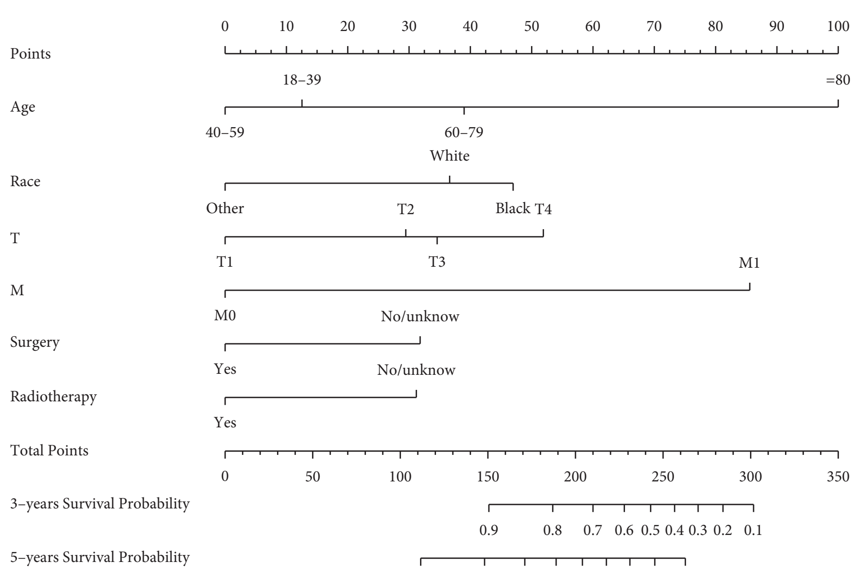

Figure 3: Prognostic nomogram models for 3- and 5-year OS rates of MBC patients. The nomogram is used by totaling the points identified on the top scale for each independent covariate. The total points projected to the bottom scale indicate the % probability of 3- and 5-year OS.

this study. Because of its rarity in the clinic, most studies on MBC have small sample sizes, relatively short follow-up times, and insufficient evidence on the clinical influencing factors and survival of MBC patients. Currently, data from invasive ductal carcinoma are used to generate guideline recommendations for both local and systemic adjuvant treatment of MBC, and the accuracy of survival prognostic information is influenced by physician experience, so a more accurate survival prediction model is lacking. In this study, an objective nomogram was constructed based on the SEER

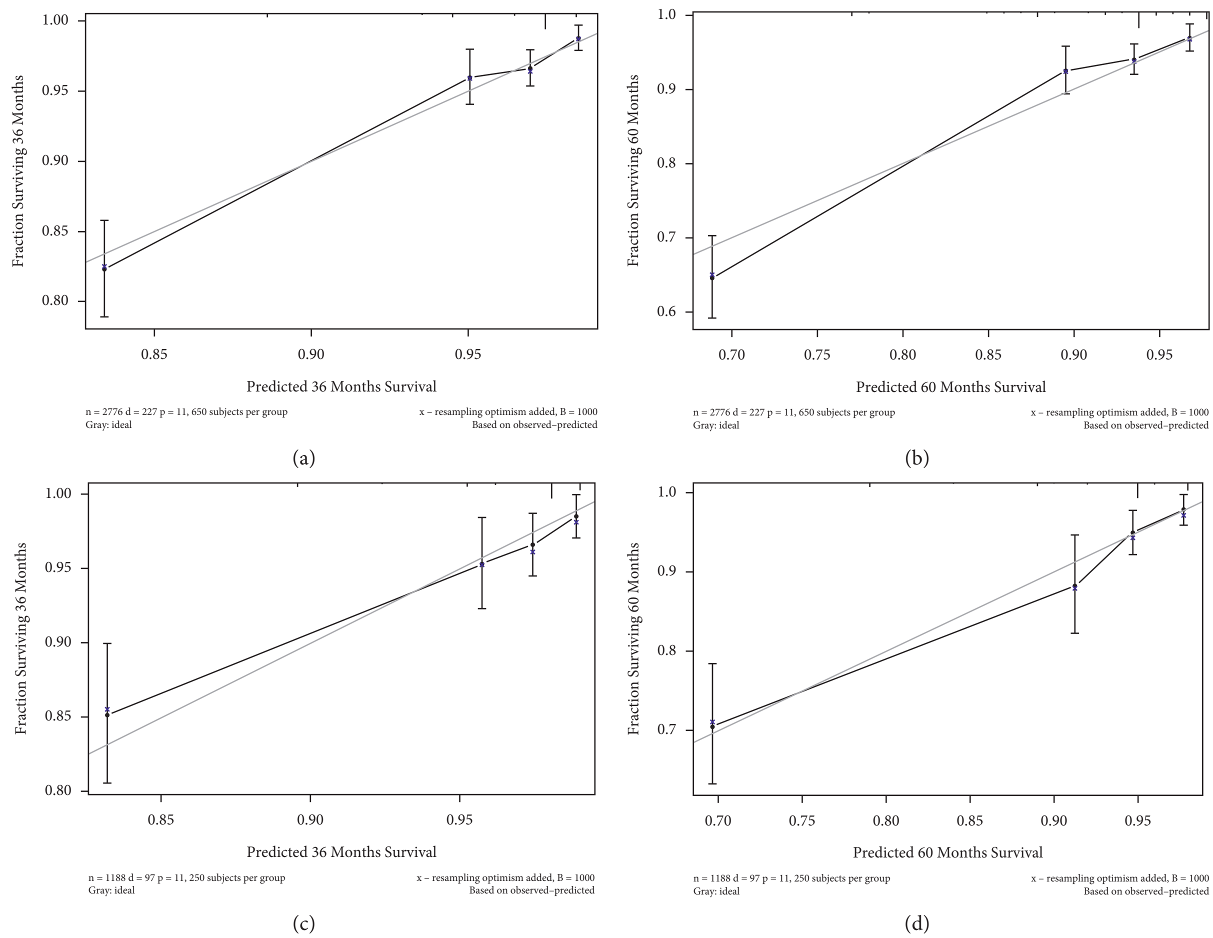

Figure 4: Calibration curve of the nomogram for predicting the probability of OS at 3 and 5 years. (a, b) modeling group; (c, d) validation group.

database to make a more accurate estimate of the 3- and 5-year survival rates of patients suffering from MBC, which improved the rationality of both doctors and patients for disease management and was important for clinical decision-making.

In this study, we analyzed multiple possible prognostic factors in MBC patients, and the results showed that age, ethnicity, T stage, M stage, surgery, and radiotherapy were all independent factors for patient survival prognosis. In our study, 68.1% of patients were over 60 years of age, and the prognosis was best for people aged 40–59 years, and previous studies have shown that MBC is common in older patients, and its incidence generally peaks after menopause [6, 14]. Patients with MBC had high ER or PR positivity (98.8% and 92.0% of ER and PR positivity, accordingly), low histological score (59.3% Grade I), and less lymph node metastasis (90.1% without lymph node metastasis). The findings of this study were consistent with the findings of previous research [2, 5, 15–17], which demonstrated that MBC patients had a substantial chance of surviving.

The predictive importance of tumor size in MBC patients is a point of contention. Patients with tumors greater than 2 cm were previously advised to take adjuvant chemotherapy, according to NCCN recommendations. However, the recommendations have been modified so that only lymph node involvement is considered chemotherapeutic, regardless of the T stage. While tumor size has been linked to the diagnosis of less aggressive tumors, its predictive value has been questioned due to the inclusion of extensive extracellular mucins in tumor size measurement [18]. As a result, tumor size measurements may not accurately reflect actual tumor size, making tumor size prediction problematic [19]. Furthermore, lymph node involvement was found to be unrelated to tumor size in one investigation [20]. T3 and T4 tumors had a worse prognosis than T1 and T2 tumors in our study, according to the nomogram. As a result, a tumor with a diameter of more than 5 cm may be associated with a bad prognosis.

At present, the treatment modalities for MBC patients are mainly surgery, chemotherapy, radiotherapy, and endocrine therapy. The choice of surgical approach also has a considerable influence on the subsequent treatment options of patients and the survival prognosis of patients. In this study, 3,817 patients (96.2%) received surgical treatment, and the nomogram showed that the prognosis of patients who received surgical treatment was better than that of patients who did not receive surgery. It has been shown that patients treated with breast-conserving surgery in stage T1-2

MBC have a better prognosis than those who undergo mastectomy, particularly in patients aged 50–79 years; [21] however, this study did not compare the specific modalities of surgery, and in the subsequent study, we will consider this aspect of the influencing factors. As a considerable adjuvant therapy, radiotherapy is commonly used in patients with high-risk factors post breast-conserving therapy or mastectomy for breast cancer [22]. However, there is a lack of clarity regarding the clinical value of radiotherapy in MBC. In the current study, a total of 2,043 (51.5%) patients received radiotherapy and 1,921 (48.4%) did not. The nomogram shows that the use of radiotherapy is beneficial for patients with MBC. It has been reported in the literature that [23, 24] the reason for the low efficacy of chemotherapy is that mucus accounts for most of the total volume in MBC cells, forming a large pool of mucin, resulting in inconsistency between clinical or imaging assessment of chemotherapy efficacy and mucinous carcinoma pathology. Despite the effective elimination of malignant cells by chemotherapy, the mucin pool remains [25].

However, this study has several limitations. First, important details such as treatment information (e.g., radiation dose, chemotherapy dose, targeted therapy, endocrine therapy, or immunotherapy) are missing in the SEER database because most patients with MBC are hormone receptor-positive. Patients who complete local therapy are likely to receive standard endocrine therapy, and the SEER database cannot provide data on endocrine therapy and is difficult to guide physicians in the treatment of patients of the same category. Second, the lack of information in the SEER database may affect the data of the CPHR model (such as Ki-67, tumor markers, and other related factors), and these important variables should be considered in future studies. Finally, the database does not perform specific pathological classification of MBC, such as pure mucinous breast carcinoma (PMBC) as well as mixed mucinous breast carcinoma (MMBC) [26], because MBC of different pathological types may have different prognoses. The nomograms in this study were internally and externally validated for the population of the SEER database. It is validated in the same population, and the validation of model performance can be biased. Hence, other multicenter data are needed for external validation to further test the predictive effect of nomograms.

5. Conclusion

Routine clinical data obtained from the SEER database were used to develop a useful clinical nomogram that could help clinicians treat MBC in their daily practice. The nomogram incorporates various clinicopathological indicators and can render great help in clinical decision-making thereby enabling individualized therapy and management of MCB patients.

The future directions of this work will potentially involve a larger sample size, including more related factors to further screen the independent influencing factors of the prognosis of MBC patients. In addition, we plan to carry out a multicenter prospective randomized controlled study to verify its predictive effect, improve the nomogram prognostic model, and provide a reference for the evaluation of the prognosis of MBC patients as well as the selection of personalized treatment plan.

Objective. To investigate the clinical efficacy and possible mechanism of electroacupuncture in the treatment of premature ejaculation. *Methods*. 50 cases of premature ejaculation patients who met the diagnostic criteria were randomly divided into 2 groups with 25 cases in each group. The observation group was treated with electroacupuncture, and the control group was treated with Longdan Xiegan decoction. The treatment period was 4 weeks. Ejaculation latency (IELT), sexual satisfaction score of patients, sexual satisfaction score of partners, testosterone test, and drug safety assessment were performed in all 4 groups before and after treatment. *Results*. IELT was prolonged in all groups after treatment, the difference was statistically significant ($P < 0.05$). At the same time, the IELT of the observation group was significantly higher than that of the control group after treatment. Life satisfaction scores of patients and spouses in 2 groups were improved after treatment compared with before treatment, the difference was statistically significant ($P < 0.05$). After treatment, the satisfaction scores of patients and spouses in the observation group were higher than those in the control group, and the difference was statistically significant ($P < 0.05$). Before treatment, there was no significant difference in serum testosterone levels among all groups ($P > 0.05$). Serum testosterone levels in all groups were decreased after treatment compared with before treatment, with statistical significance ($P < 0.05$). After treatment, the serum testosterone level of the observation group was lower than that of the control group, and the difference was statistically significant ($P < 0.05$). During the treatment, the adverse reactions in each group disappeared after treatment, and no obvious abnormality was observed in the safety indicators. *Conclusion*. Electroacupuncture can improve the symptoms of premature ejaculation, which may be related to the regulation of serum testosterone by acupuncture.

1. Introduction

Premature ejaculation (PE) is a common disease in male sexual dysfunction, and its incidence rate is very high. PE refers to conditions in which the penis has not been inserted into the vagina, the parties have not contacted or have just been exposed to ejaculation, or ejaculation in less than 1 minute after insertion, resulting in an inability to perform normal sexual intercourse for more than 1 month. This disease is a common sexual dysfunction disease in adult men, and data show that about 75% of men will have premature ejaculation in their lifetime [1]. Among adult males, the incidence rate is 35%–50% [2]. Under the pressure of modern stressful life pace, the incidence rate of male premature ejaculation is on the rise every year, which greatly reduced the happiness in family.

At present, the treatment methods of Western medicine include psychotherapy and behavioral intervention, the application of antidepressants, the use of drug local anesthesia, and surgical treatment. Traditional Chinese medicine has a long history of treating the disease, accumulated rich clinical experience, and achieved good clinical efficacy. In traditional Chinese medicine, there are mainly traditional Chinese medicine, acupuncture, moxibustion, massage, umbilical therapy, acupoint application, acupoint embedding, and other relatively conservative treatment methods [3].

With the modern tense pace of life, physical overdraft, life pressure, air, food, and water pollution, and other factors, the incidence of male premature ejaculation has been increasing year by year, greatly affecting the quality of life of the couple and family happiness and stability. Now, there are many methods to treat premature ejaculation, and the application of antidepressants easily increases the misunderstanding of patients and increases the psychological burden. The curative effect of surgical therapy is not exact, and the harm is great. Psychological or behavioral treatment is difficult to operate clinically, long-term use of local anesthetics may cause erectile dysfunction, and to a certain extent, the internal environment of the woman has certain damage, affecting life. The operation of acupuncture and moxibustion is simple, and the deputy general use is small. Therefore, this study explores the efficacy of electroacupuncture in the treatment of premature ejaculation.

The etiology of premature ejaculation is complex, and the treatment is mainly based on serotonin reabsorption inhibitors. Studies have shown that low doses of testosterone combined with doxazosin in the treatment of premature ejaculation can achieve satisfactory results [4]. This study investigated 50 patients with premature ejaculation and observed the changes of IETE and spouse satisfaction and testosterone level in the two groups after treatment, which will provide more effective treatment methods for clinical application.

2. Methods

2.1. Ethical Statements. The included cases were from the outpatient department of acupuncture and moxibustion in our hospital from January 2019 to June 2021. The 50 patients who met the criteria for case selection were numbered from 1 to 50 according to the order of medical treatment. The odd and even numbers were divided into electroacupuncture group (hereinafter referred to as the observation group) and control group, with 25 patients in each group. All patients wrote the informed consent, and these studies were approved by the ethics boards of the hospital.

2.2. Diagnostic Criteria. “Chinese traditional medicine new medicine clinical research guiding principle” for premature ejaculation in Chinese medicine diagnosis standard was referred: during sexual intercourse, ejaculation when the penis has not been inserted into the vagina, or when both sides have not been contacted or just contacted, or ejaculation in less than 1 minute after inserting, as a result cannot have normal sexual intercourse, and lasting for more than 1 month are the diagnostic criteria for this disease. Inclusion criteria are as follows: (1) the patients meet the above diagnostic criteria for premature ejaculation; (2) age ≥24 years and ≤48 years and course of disease >3 months and <10 years; (3) married or with a regular sexual partner and sexual life for more than half a year; (4) no surgical treatment was performed; (5) patients who have not taken drugs or received other treatments recently (within 1 month before the treatment); and (6) voluntarily participate in the clinical study and signed informed consent.

Exclusion criteria are as follows: (1) ejaculation latency >1 min; (2) persons aged <24 or >48; course of disease ≤1 month or ≥10 years; (3) the penis and testicles have organic lesions, including phimosis, foreskin too long, foreskin frenulum too short, and cryptorchidism; (4) inflammation of the genitourinary system, such as prostatitis, seminal vesiculitis, vermontanetis, epididymitis, spermatic cord quietly varicose, and urethritis; (5) hyperthyroidism; (6) schizophrenics; (7) erectile dysfunction; (8) patients with abnormal blood lipid, blood glucose, and blood pressure; (9) patients with other diseases of brain, heart, liver, and kidney that affect the effectiveness evaluation of this treatment; (10) patients with neurological diseases (brain tumor, cerebrovascular disease, and spinal cord injury); (11) patients who have taken drugs or received other treatments recently (within 1 month before the treatment); (12) irregular sexual life; (13) the patient had undergone surgical treatment; and (14) needle sickness.

2.3. Treatment. The observation group was treated in the acupuncture points: Zhongji point (−) and Sanyinjiao point (+). The frequency was 2–100 Hz, the current intensity was 0.1 mA–1.0 mA, and the intensity was tolerated by patients with slight local beating. The needle was left for 30 min. Once a day, 6 times in a row, then rest for 1 day, 6 times in a course of treatment, a total of 4 courses. The control group was given one dose of Longdan Xiegan decoction every day, 300 ml of decoction, twice in the morning, and 1 hour after dinner.

2.4. Observation of Curative Effect Index. The changes of IELT before and after treatment were observed, and the average value of three sexual lives before and after treatment was taken as the value. The changes of sexual satisfaction scores of the patients and their spouses were observed before and after treatment. The sexual satisfaction scores of the patients were evaluated by 6, 7, and 8 points of the International Erectile Function Index (IIEF), with a total score of 0–15 points. The scores of 10, 13, and 14 in the IIEF table were used to evaluate the spouse’s sexual satisfaction with a total score of 0 to 15 points.

2.5. Sexual Satisfaction of Spouse. The observation form of spouse satisfaction was filled in. It was recorded once before the treatment, once at the end of the treatment, and follow-up was performed once 3 months after the treatment.

2.6. Determination of Serum Testosterone. The serum testosterone level of the selected subjects was measured by ELISA at 8–10 a.m., and the unit was nmol/*L*.

2.7. Safety Test. (1) The general physical examination items were checked (once before and after treatment). (2) Possible adverse reactions, such as diarrhea, abdominal pain, and abnormal discomfort of penile skin, were observed, and at the same time, whether women have abnormal discomfort of vagina, etc. was also observed.

2.8. Statistical Analysis. All data were analyzed with the SPSS18.0 statistical software. The counting data were analyzed by the chi square test. The measurement data were expressed in ($x \pm s$), and the difference was statistically significant ($P < 0.05$).

3. Results

3.1. General Information Comparison. There was no significant difference in the general information between the two groups, which was comparable ($P > 0.05$) (Table 1).

3.2. Comparison of IELT and Sexual Life Satisfaction Scores of Patients and Spouses between the Two Groups before and after Treatment. IELT was prolonged in both groups after treatment. At the same time, the IELT of the observation group was 3.28 ± 0.59, which was significantly higher than that of the control group (3.09 ± 0.62) after treatment. The sexual life satisfaction scores of patients and spouses in each group were 10.06 ± 1.28, which was significantly higher than those (6.85 ± 1.02) before treatment ($P < 0.05$). After treatment, the sexual life satisfaction score of patients and spouses in the observation group was 10.86 ± 1.49, which was higher than that (10.57 ± 1.75) in the control group ($P < 0.05$) (Table 2).

3.3. Comparison of Serum Testosterone Changes between the Two Groups before and after Treatment. Before treatment, there was no significant difference in serum testosterone levels among all groups ($P > 0.05$). The serum testosterone level after treatment in all groups (13.28 ± 3.15, 15.88 ± 4.71) was decreased compared with that before treatment (26.16 ± 5.26, 25.97 ± 5.58), with statistical significance ($P < 0.05$). After treatment, the level of serum testosterone in the observation group was 13.28 ± 3.15, which decreased significantly compared with the control group 915.88 ± 4.71) (Table 3).

3.4. Adverse Reactions. In the observation group, 5 cases had adverse reactions, including 2 cases of dizziness and 3 cases of subcutaneous hematoma. In the control group, there were 6 cases of malady, 4 cases of stomach discomfort, 1 case of mild diarrhea, and 1 case of dizziness.

3.5. Security Testing. Before and after treatment, no abnormality was found in blood, urine and stool routine tests, electrocardiogram, and liver and kidney functions in the two groups. After treatment, there were no serious adverse reactions in the two groups, and no patients were terminated due to adverse reactions.

4. Discussion

Traditional Chinese medicine believes that the etiology of premature ejaculation is caused by many aspects, which is most closely related to the center of the five Zang organs, liver, and kidney [5]. Its mechanism is in the heart, its movement is in the liver, and it is hidden in the kidney. If the functions of the heart, liver, and kidney are abnormal, such as pouring damp heat into the liver, uncomfortable liver Qi, and liver depression and fire; heart-kidney disharmony and hyperactivity of heart fire; and kidney deficiency, can lead to adverse catharsis, dereliction of duty in sealing and hiding, failure of God, resulting in no right to restrict Jingguan and premature ejaculation due to easy opening of Jingguan. Western medicine believes that the etiology and pathogenesis of this disease are complex, and the specific pathogenesis is inconclusive at present. There are various methods to treat the disease, but no curative effect has been widely recognized. Sertraline hydrochloride, as a highly selective serotonin reuptake inhibitor, can inhibit the reuptake of serotonin in ejaculatory central neurons so as to reduce the excitability of ejaculatory central neurons. On the other hand, sertraline has weak affinity for dopamine receptor, cholinergic receptor, histamine receptor, and adrenergic receptor and will not enhance the activity of catechol neurotransmitters so as to achieve the effect of treating premature ejaculation [6, 7]. However, the drug takes effect 1–2 weeks after taking, often including drowsiness, dry mouth, dizziness, nausea, diarrhea, decreased sexual desire, and nonejaculation [8, 9].

IELT and patient and spouse satisfaction score are commonly used to evaluate the efficacy of premature ejaculation. In this study, the IELT of each group was prolonged after treatment compared with that before treatment, and the difference was statistically significant, indicating that both traditional Chinese medicine and acupuncture had good therapeutic effects in the treatment of premature ejaculation, while electroacupuncture group had better efficacy compared between groups. The results showed that electroacupuncture treatment of premature ejaculation was better than traditional Chinese medicine in IELT and satisfaction score of patient and spouse. The adverse reactions of acupuncture were not significant. Erection is a prerequisite for sexual intercourse, and testosterone plays an important role in erection. Testosterone plays a central and peripheral regulatory role in penile erection response, and a certain level of testosterone is a necessary condition for maintaining sexual desire and penile erection [10]. Corona et al. [11] showed that high serum testosterone level is related to the occurrence of premature ejaculation, and delayed ejaculation is more likely to occur in patients with low serum testosterone. Sakamoto et al. [12] also found that the serum free testosterone level and serum FSH level of patients with premature ejaculation were significantly higher than those of patients without premature ejaculation, but there was no significant difference in the total serum testosterone level between them. In this study, serum testosterone in each group was lower after treatment than before, and the difference was statistically significant. After treatment, the decrease of serum testosterone in the electroacupuncture group was more obvious than that in the traditional Chinese medicine group. It is suggested that electroacupuncture may improve the symptoms of premature ejaculation by reducing the serum testosterone level to some extent. The mechanism of acupuncture in the treatment of premature ejaculation will be further studied in the future.

Table 1: General information comparison.

Group	No. of patients (n)	Age	Course of disease	No. of cases with different severity before treatment (n)		
				Light	Moderate	Severe
Observation group	25	32.68 ± 4.76	39.82 ± 7.95	18	6	1
Control group	25	33.57 ± 5.02	40.07 ± 8.75	17	7	1

Table 2: Comparison of IELT and sexual life satisfaction scores of patients and spouses between the two groups before and after treatment.

Item	Time	Observation group	Control group	P value
IELT	Before the treatment	1.08 ± 0.36	1.06 ± 0.44	$P < 0.05$
	After the treatment	3.28 ± 0.59	3.09 ± 0.62	
Patient satisfaction score of sexual life	Before the treatment	6.85 ± 1.02	6.91 ± 1.14	$P < 0.05$
	After the treatment	10.06 ± 1.28	9.86 ± 1.67	
Spouse's sexual satisfaction score	Before the treatment	4.85 ± 0.98	4.90 ± 1.04	$P < 0.05$
	After the treatment	10.86 ± 1.49	10.57 ± 1.75	

Table 3: Comparison of serum testosterone changes between the two groups before and after treatment.

Item	Time	Observation group	Control group	P value
Testosterone level	Before the treatment	26.16 ± 5.26	25.97 ± 5.58	$P < 0.05$
	After the treatment	13.28 ± 3.15	15.88 ± 4.71	

However, there are also limits in this study. The number of patients is small, which is not so scientific. Besides, the mechanism under this treatment was not clarified, which need further studies to explain it.

5. Conclusion

In conclusion, acupuncture therapy based on meridian points has definite curative effect in the treatment of premature ejaculation. Besides, acupuncture is relatively simple, convenient, and easy to implement, with minimal trauma and almost no side effects. Therefore, it is recommended to be popularized and applied in clinical practice. However, due to the small number of patients included in the current study, the overall level of the study is not high, and because there is no unified diagnostic standard and efficacy evaluation standard is inconsistent, the efficacy of each study is prone to bias, resulting in authenticity. Therefore, more researchers and patients need to join the clinical study for further verification.

The polycystic ovary syndrome (PCOS) is the disease featured by elevated levels of androgens, ovulatory dysfunction, and morphological abnormalities. At reproductive stage of women, the rate of PCOS occurrence is measured as 6–10% and the prevalence rate may be double. There are different pathophysiological factors involved in PCOS, and they play a major role in various abnormalities in individual patient. It is clear that there is noteworthy elevation of androgen in PCOS, causing substantial misery and infertility problems. The overexposure of androgen is directly linked with insulin resistance and hyperinsulinaemia. It has been reported previously that PCOS is related to cardiac metabolic miseries and potently increases the risk of heart diseases. Endometrial cancer is also a serious concern which is reported with exceedingly high incidence in women with PCOS. However, the overexposure of androgen has direct and specific influence on the development of insulin resistance. Although many factors are involved, resistance to the insulin and enhanced level of androgen are considered the major causes of PCOS. In the present review, we have focused on the pathophysiology and major revolutions of insulin resistance and excessive levels of androgen in females with PCOS.

1. Introduction

The polycystic ovary syndrome (PCOS) is the disease featured by elevated levels of androgens, ovulatory dysfunction, and morphological abnormalities. According to NIH (National Institutes of Health), it can be defined as "hyperandrogenism with ovulatory dysfunction." At reproductive stage of women, the rate of PCOS occurrence is measured as 6–10% and the prevalence rate may be double [1–4]. It is clear that there is noteworthy elevation of androgen in PCOS, causing substantial misery and infertility problems. Somehow, PCOS has also some environmental influences like obesity, as well as factors contributing to obesity. Most of the previous reports concluded that deformities associated steroidogenesis and follicular development are crucially involved in PCOS progression [4, 5]. PCOS generally exhibits constantly secreted levels of the gonadotropin-releasing hormone (GnRH), increased levels of the luteinizing hormone (LH), and insufficient follicle-stimulating hormone (FSH) secretion contributing to elevated secretions of the androgens and ovulatory dysfunction. Moreover, majority of the PCOS-suffering population develops insulin resistance, which in turn leads to the amplified secretion levels of the androgen, thereby decreasing the sex hormone-binding globulin secretions [6–11]. Genome research has been discovered numerous genes linked investigations such genes for the beta subunit of FSH, gonadotropin receptors, insulin receptor, neoplastic cells domain-containing protein

1A (DENND1A), differentially expressed in normal, and thyroid adenoma-associated protein (THADA). "Developmental programming" by environmental or hormonal influences may also add to the development of the PCOS. There are different pathophysiological factors involved in PCOS and they play a major role in various abnormalities in individual patient. It has been found that PCOS is related to cardiac metabolic miseries and potently increases the risk of heart diseases [11–16]. The mechanism of androgen biosynthesis in ovaries and adrenal gland is explained in Figure 1.

PCOS is found to be the major concern of women health and puts serious life-threatening conditions. Among the ratio of women suffering from PCOS, 50–80% are the obese women, 30–35% are those reported with impaired glucose tolerance, and 8–10% are found to be diabetic or having family diabetes history. The risk of PCOS is related to the history and severity of these influences [5, 16–20]. Generally, women with PCOS exhibit reduced levels of high-density lipoprotein (HDL) and amplified concentrations of triglycerides and low-density lipoproteins (LDL) cholesterols compared with normal women. LDL cholesterol differences appeared to play a significant role in PCOS, and it remains a major concern in most of women. However, sometimes LDL levels in normal range may lead to misconception as the activities of the LDL and HDL in PCOS women are sparse [21, 22]. The elevation of coronary artery calcium scores has been also described in PCOS women and high incidence is reported for the postmenopausal women with PCOS. Many reports provide evidence on the cardiovascular abnormalities in patients with history of PCOS. Endometrial cancer is also a serious concern which is reported with exceedingly high incidence in females with PCOS [21, 22]. The risk factors of the endometrial cancer in menopausal PCOS women include anovulation, heavy fats, and insulin resistance. The fear of chronic anovulation results in prolonged estrogen-mediated mitogenic activation of the endometrium with inadequate progesterone access to cause endometrial differentiation. Females with PCOS also face severe problems in pregnancy like risk of gestational diabetes mellitus, obstructive sleep apnea, and emotional distress [23–29]. Although many factors are involved, resistance to the insulin and high androgen are considered the major causes of PCOS. In the present review, we focus on the pathophysiology and major revolutions of insulin resistance and excessive levels of androgen in females with PCOS. The discussions are focused on insulin resistance, mechanism of insulin resistance, hyperandrogenism in PCOS, PCOS phenotypes, impacts of PCOS on physiological functions of the PCOS woman, and various treatments approaches for the treatment of PCOS, insulin resistance, and high secretions of androgens.

2. Insulin Resistance in PCOS

The actual understanding of insulin resistance can be explained by the requirement of excessive insulin for the metabolic activities, while, besides metabolic activities, insulin is also required for mitogenic and reproductive actions [24]. The rapid and fast glucose analysis make the researchers able to analyse insulin resistance. For this purpose, homeostatic model evaluation, quantitative insulin sensitivity check index, and fasting glucose and insulin levels have been established and utilized in clinical research and also metabolic investigations in PCOS [24–27].

In general, the obesity of abdomen in PCOS is the reason of insulin resistance possibly induced via subclinical swelling but whether the metabolically active intra-abdominal adipose tissues are augmented or not is unclear. However, it was previously investigated that the lower circulating adiponectin detection in PCOS justified subcutaneous adipose tissue as a dysfunctional adipose tissue compartment and having correlation with insulin resistance. Although different methods have been used for prevalence of insulin resistance, where it was found to be varied in PCOS women with respect to the detection method [28–31], more recent findings concluded that obesity is the main risk factor of insulin resistance in individuals suffering from PCOS. The investigations revealed that diagnostic criteria of insulin resistance have limited impact on the insulin resistance detection in PCOS women. Insulin resistance in PCOS patients is the main concern, and its prevalence and mechanism need to be investigated. In previous reports, it was found that large population of PCOS women is suffering from compromised glucose tolerance and type 2 diabetes mellitus (T2DM) [28, 29]. The statistically higher prevalence rate of the compromised glucose tolerance and T2DM serious threatening bell for healthy life. Few clinical studies have reported the glucose tolerance in PCOS women and T2DM risk in PCOS individuals. According to the findings of various studies, it was found that all those PCOS females who are obese and overweight are at greater risk of the disturbances in glucose metabolism and they required to check their glucose regularly with proper metabolic profiling [29–35].

3. Pathways of Insulin Resistivity in Patients with PCOS

Insulin is receptor binding hormone that binds to its membrane glycoprotein. This consists of two subunits α and β, associated with disulphide bonds. Subunit α is extracellular region responsible for the binding site, while subunit β is the intracellular region responsible for provoking intrinsic tyrosine kinase activity [36]. Ligand bindings lead to generating intrinsic tyrosine kinase activity in subunit β and initiate tyrosine phosphorylation. That further leads to the metabolic activities of insulin upon substrate binding, for example, glucose transport and glycogen synthesis [36, 37]. PCOS is a health issue for women and insulin resistance is one of the crucial issues that need to be emphasized. Insulin is an essential hormone for glucose metabolism and its sensitization is necessary for proper glucose uptake and metabolism [8, 38]. The cell surface receptor is homologous with the insulin-like growth factor 1 (IGF-1) receptor, so there is specific interaction for the binding of insulin to surface. The uptake of glucose is stimulated [19, 28, 39, 40]. The MAPK-ERK pathway initiation takes place, which

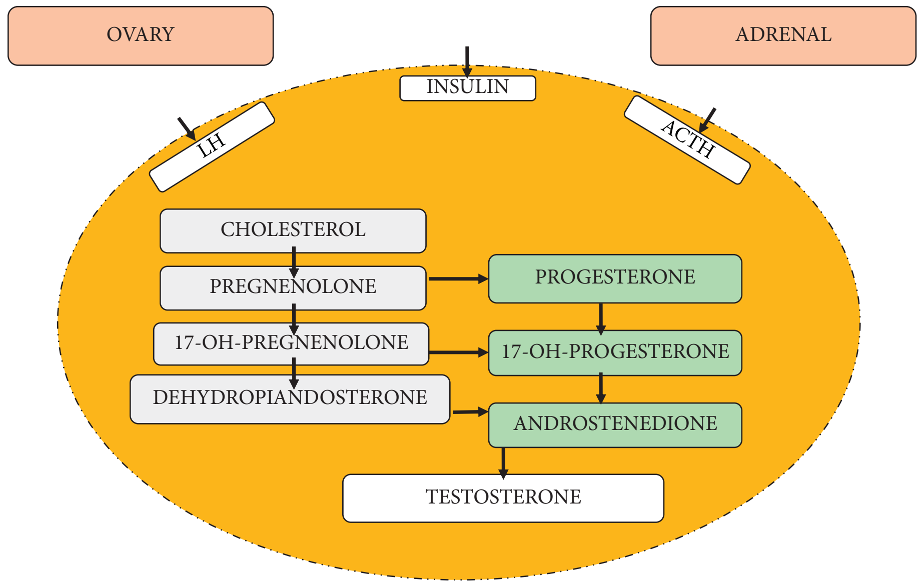

Figure 1: Production of androgen in ovaries and adrenal gland. Biosynthesis of the androgens associated with the ovary and the adrenal gland.

initiates stimulation of a series of enzymes cascades. In previous studies on PCOS women, cellular and molecular mechanism of insulin was highlighted and glucose uptake in insulin target tissues like adipose and skeletal muscles was evaluated in both lean and obese women [20, 25]. When observed in PCOS patients, it was concluded that although the receptors affinities of insulin are similar in both PCOS women and normal females, decreased insulin binding was recorded at pancreatic β-cell in adipose tissues resulting in low glucose uptake and insulin sensitivity in PCOSs females compared to normal females. The fact might be due the reduced abundance of GLUT4 in subcutaneous adipose tissues in PCOS patients, which leads to insulin insensitivity [19, 20, 25, 28, 41, 42]. Besides the reduction in sensitivity of insulin, β-cell dysfunction is also one of the reasons for low disposition. However, still it is unclear whether the subunit β defected function is the primary cause of insulin resistance or it is secondarily involved in insulin resistance [43, 44]. To analyse insulin resistance in PCOS patients, proinsulin and insulin ratio can be a marker. In PCOS women, the ratio of proinsulin and insulin can explain the insulin resistance and activity of β-cell. It was found that, in obese and overweight PCOS patients, there was increased secretion of insulin followed by the excessive levels of proinsulin, which results in insulin resistance and hyperinsulinaemia [19, 20, 25, 28, 39, 40]. These studies explained the dysfunction of β-cell in PCOS women and insulin resistance mechanism. PCOS is a genetically contributed disorder in its pathogenesis and considered a hereditary condition. It has been shown that first relatives of PCOS history will have reproductive and metabolic issues and more investigations revealed that hyperinsulineaemia will be developed in the early stages of life and remain persistent throughout the puberty of girls with hereditary history of PCOS. In such cases, the subjects are at high risk for hyperinsulinaemia and insulin resistance, even if they are not diagnosed with PCOS. The follow-up study of peripubertal adolescent girls whose mothers were suffering from PCOS presented reduced disposition index persistently which proposes the dysfunction of pancreatic β-cell and this might be one of the genetic causes in first-degree relatives of the PCOS population. Another probable hereditary reason for insulin resistance in PCOS is a significant rate of SH2 domain-containing adaptor protein (Lnk) activity in PCOS female's ovarian cell lines, which suppresses the MAPK-ERK and phosphatidylinositol 3-kinase-AKT signaling responses to insulin. Previously, skin fibroblasts were for the intrinsic problems in in insulin function in PCOS because both hyperandrogenism and hyperinsulinaemia affect insulin sensitivity. When PCOS fibroblasts were assessed for insulin stimulated receptors autophosphorylation, there was reduced receptors stimulation as well as minimal insulin sensitivity. More importantly, immunopurification studies revealed that there was no mutation in receptor gene of insulin in PCOS patients [19, 36, 38, 40, 41].

4. Hyperandrogenism and PCOS

The genetically determined excessive secretions of androgens from ovary are the major concern in clinical evaluation of PCOS [45, 46]. The secretions of androgen at early stages are generally considered premature in PCOS and though to develop insulin resistance in prior stages. In visceral adipocytes, the disturbances in lipid metabolism result in insulin resistance. Nevertheless, the overexposure of androgen has direct and specific influence on onset of insulin resistance [47–52]. The increased secretion of androgen is associated with malfunctioning of islets of Langerhans, thereby compromising the pancreatic metabolic functions and causing hyperinsulinaemia. In preclinical studies, in PCOS women, it was found to be a major cause of T2DM. These facts revealed the direct relationship of overexposure of androgens with hyperinsulinaemia, insulin resistance, and T2DM in PCOS population [45–59]. The impact of insulin on hypersecretion of LH and androgen and its correlation with ovary, pituitary gland, and adrenal gland are illustrated in Figure 2.

Androgens belong to the family of steroid hormones and oversecretion of androgens is considered the main clinical manifesto of the PCOS. So, how androgens are biologically manufactured and regulated should be understood. Since androgens are very important for women's reproductive hormonal system, their normal synthesis and secretion are of prime importance. Androgens are critical female reproductive endocrine system hormones. Androgens include androstenedione (A4), dihydrotestosterone (DHT), dehydroepiandrosterone (DHEA), testosterone (T), and dehydroepiandrosterone sulfate (DHEAS). A4, DHEA, and DHEAS are regarded as precursors of T and DHT. Among these, only DHT and T have a direction with androgenic receptors. Androgens are majorly prepared ovaries and adrenal glands, while steroidogenic enzymes regulate their synthesis [60–64].

Besides this, in PCOS gonadotropin releasing was seen to have much more secretions of luteinizing hormone (LH) with normal abundance of the follicle-stimulating hormone (FSH). The increase in LH secretions in PCOS women may be due to pulsatile increase in the secretions of gonadotropin-releasing hormone (GnRH). Previous analysis raises the point that the change in GRH secretion might be due to defects in hypothalamus in PCOS populations. However, these complications are not only concerned with PCOS, but such changes have been also observed with hyperandrogenism in other cases like ovarian cancer, where there are increased secretions of androgens. The discussion based on previous literature declares that GRH releasing behaviour in correlation with hyperandrogenism in PCOS may be the secondary issue not involved primarily [65, 66]. Women suffering from PCOS generally exhibit hyperandrogenism with increased ovarian androgen as illustrated in Figure 3. The theca cells are the cells of ovary which are responsible for the production of androgens; these cells secrete amplified levels of androgen (androstenedione) and 17-hydroxyprogesterone. 17-Hydroxyprogesterone is a steroidal intermediate for the biosynthesis steps of androgens and glucocorticoids to retort the LH. The questions arise that such abnormalities originate from the theca cells from the ovary of PCOS patients and chronic anovulation-PCOS or from theca cells of the normal ovaries [67–69]. Insulin can have mimicking influences on the LH in women with PCOS. When theca cells from women with PCOS were passaged in tissue culture, they demonstrated elevated activity of numerous steroidogenic enzymes: 3-hydroxysteroid dehydrogenase, 17-hydroxylase/17-20 lyase, and 17-hydroxysteroid hydrogenase. The previously published reports revealed the fact that the amplification of the steroidogenic activity is intrinsic and presumably genetic and leads to blemishes in PCOS. The PCOS might be a morphological associate of these steroidogenic abnormalities [56–62, 70].

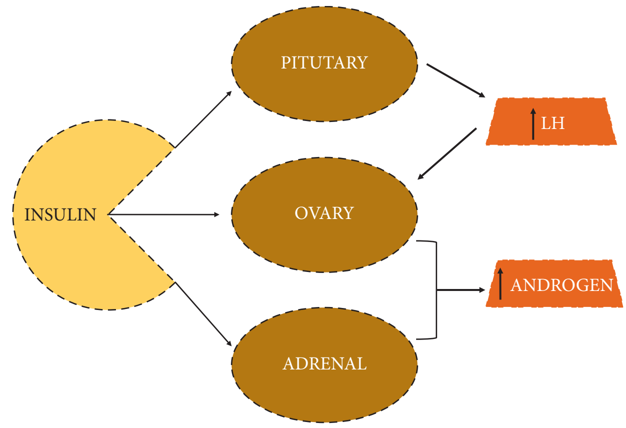

Figure 2: Impact of insulin on hypersecretion of LH and androgen.

5. PCOS Phenotypes

There are 4 various phenotypes of the PCOS identified up till now which are as follows: Type A: polycystic ovaries [PCO], chronic anovulation [CA], and Hyperandrogenism [H]; Type B: chronic anovulation [CA] and hyperandrogenism [H]; Type C: polycystic ovaries [PCO] and hyperandrogenism [H]; and Type D: polycystic ovaries [PCO] and chronic anovulation [CA] [70, 71]. The type of PCOS is related to metabolism and cardiovascular health, as it has been observed that most of the PCOS women are obese with severe or mild metabolic deformities [19, 70, 71] and often face problems of dyslipidaemia, hyperinsulinaemia, insulin resistance, and other metabolic disorders [20]. The major discussion is on fabricating how PCOS phenotypes can be related to aging. Patients with phenotype A are investigated to have high insulin resistance and overexposure of androgens as compared to phenotype B. Phenotype D is generally characterized by the insulin resistance in obese condition even if there is no overexposure of androgens. Meanwhile, in case of type C, the scenario is different where cardiovascular risk is high which may be due to lack of insulin resistance in PCOS. Dyslipidaemia is a serious metabolic issue in PCOS correlated with the HDL and LDL cholesterol levels. According to a research on the PCOS population, both lean and obese PCOS women exhibit aberrant phosphatidylcholine and polyunsaturated fatty acids (PUFAs) levels as well as free fatty acids [71–73].

6. Impact of PCOS on Physiologic Functions

PCOS is a heterogeneous disease of endocrine system which is followed by various clinical and physiological abnormalities. It exerts harmful and pervasive effects on physiological as well as metabolic system, and these characteristics categorise PCOS as a disorder associated with metabolism. Various dysfunctions like insulin resistance, hyperinsulinaemia, obesity, dyslipidaemia, hypertension, elevating risk of developing T2DM, endometrial hyperplasia, and coronary artery diseases. Here, we discussed the impact of the PCOS on various physiological functions of the body.

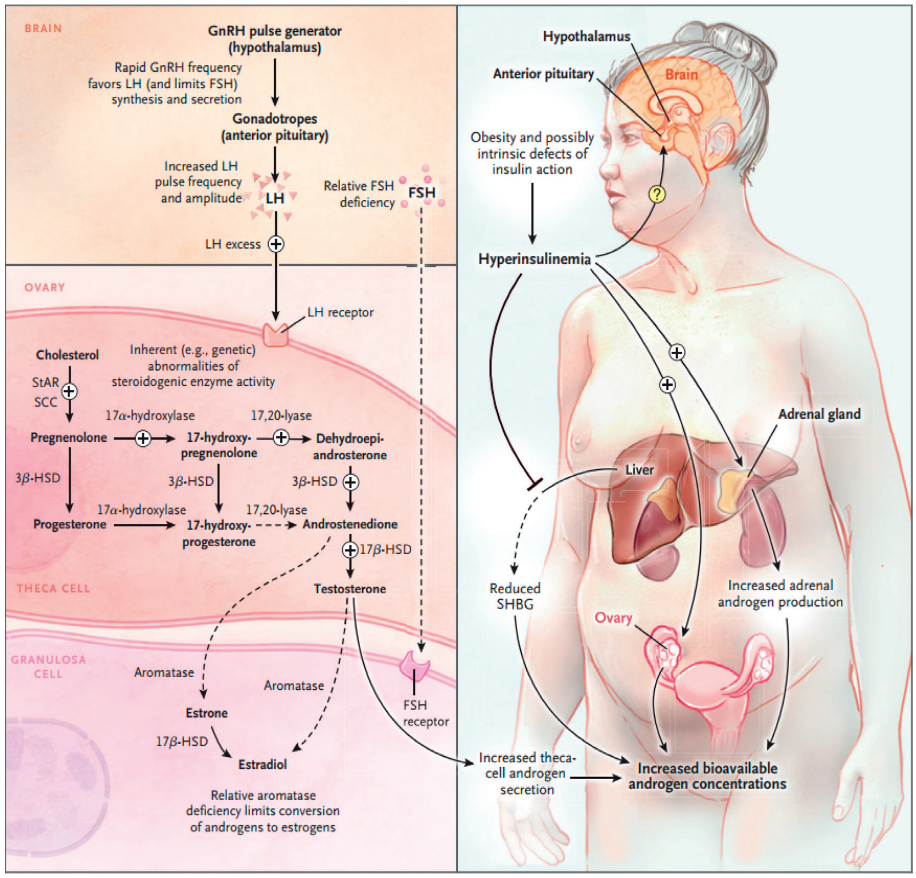

FIGURE 3: The basic mechanism of androgen overexposure in PCOS women [69]. The figure is cited with permission granted.

6.1. Liver Function. The excessive aggregation of fats in liver is called nonalcoholic fatty liver disease (NAFLD) and presents high risk of T2DM and CVS in PCOS. NAFLD is characterized by the presentation of insulin resistance and obesity. These issues are specifically related to abnormalities in liver metabolism. In PCOS population, there is always a high risk of NAFLD because PCOS women usually have insulin resistance with metabolic dysfunctions and unconditional obesity. So, PCOS consequences are found to be associated with NAFLD [74, 75].

6.2. Cardiac Functions. It was concluded that all the PCOS phenotypes have serious cardiovascular risks in PCOS patients. Phenotypes, insulin resistance, hyperinsulinaemia, overexposure of androgens, and ovaries function are reported to display increased cardiovascular health risk for PCOS women [76–78]. The insulin resistance is associated with the inactivation of NO after release from endothelial cells and decreased production of nitric oxide (NO) and synthesis of vasoconstricting agents in excessive amounts; all these defects lead to impaired vasodilatation and cardiac muscles stiffness [79, 80]. Insulin resistance and hyperinsulinaemia also display hypertrophic effect directly and proceed with the endothelial dysfunction. Clinical reports revealed increased risk of cardiac dysfunctions in PCOS population [77–81].

6.3. Reproductive Functions. PCOS is a primary disorder of the ovaries and will directly affect the reproductive system and functions. The excessive secretions of insulin have been observed to cause amplified levels of estrogens and progesterone secretions in women with PCOS. Insulin receptors are responsible for mediating these effects. It was reported that the insulin activity in in vitro granulosa cells can be treated with troglitazone, where IGF-1 mitogenic pathways are increased with the therapy. Besides this, there was an amplification in the IGF-1 receptor in the follicle cells of PCOS patient. This occurred in all stages of development in PCOS women [82]. In the recently reported data, it was concluded that the activity of cortisol is defective in follicular fluid and granulosa cells in PCOS population, where insulin resistance can further lead to tissue-specific insulin resistance. Endometrium cancer is a health-depriving deadly disorder and PCOS women are at high risk to develop endometrium cancer because of the high incidence of insulin resistance and hyperinsulinaemia together with overexposure of androgens. In PCOS, there is always increased upregulation of insulin receptors that have the direct implication of insulin signaling, thereby leading to cardiogenesis and development of endometrium cancer [83]. It might be due to metabolic defects, proteins expression in endometrium with insulin activity, and faulty glucose metabolism. Furthermore, the insulin receptor expression and IGF-1 signaling synergistically contribute to the development of endometrium cancer in PCOS population. So, PCOS is one of the major reasons for establishing endometrium cancer [82–84]. In Figure 4, the mechanism of PCOS associated infertility is illustrated, which displays the reproductive defects in PCOS women. The PCOS leads to increased production of androgens and decreased sensitivity of the follicle-stimulating hormone receptors (FSHR) as illustrated in Figure 4. The increased production of the androgens leads to failure in dominant follicles development and corpus luteum. It is responsible for decreased production of aromatase and progesterone. On the other hand, decreased sensitivity of the FSHR also leads to decreased aromatase production that further decreases the production of estrogens. So, overall, the syndrome leads to decreased production of the estrogens and progesterone followed by infertility.

6.4. PCOS and Hypertension. Hypertension is a persistently elevated blood pressure that affects a large human population and leads to serious health issues [84]. In PCOS population, the existence of systemic arterial hypertension (SAH) is more usual and has high incidence. A survey conducted on SAH in PCOS women demonstrated that there are 40% more chances of SAH occurrence in PCOS women than in the normal women. SAH has specific and central contribution in the development of PCOS and secondary cardiovascular disorders [84–88]. According to clinical investigational studies, there is a major and specific relationship between hypertension and endocrine system, so any abnormality in endocrine system will be definitely associated with the hypertension. In PCOS, the defective endocrine system is commonly observed leading to hypertension [85]. Besides this, insulin resistance and metabolic defects have also more commonly occurring issues in PCOS women, resulting in increased incidence of hypertension [84, 85]. The insulin resistance results in hyperinsulinaemia and increased production of LH, consequently increasing the androgen secretions causing persistently high blood pressure in PCOS women [89, 90]. The critical clinical studies show that there is a high occurrence of hypertension in females with PCOS. Moreover, it should be clearly understood that women suffering from PCOS should always monitor their blood pressure regularly in order to avoid delayed management [89–91].

6.5. Inflammation in PCOS. PCOS also promotes basis for chronic low-grade inflammation and inflammation pathways including interleukin-6 (IL-6), TNF-a, and type 2 TNF receptors. The circulating C-reactive protein (CRP) observation also leads to the point that PCOS is concerned with low-grade chronic inflammation [81, 91]. The basis can also be displayed from excessive adipose tissues which is direct producer of the CRP [92, 93]. Additionally, CRP has a physiological purpose by increasing lipid absorption into foamy macrophages inside atherosclerotic plaques. CRP is a direct and specific biomarker of abnormally low inflammation, according to a study [94, 95]. In general, PCOS patients have mild risk of chronic inflammation but it is not reflective at molecular levels.

7. Treatment Options for Hyperandrogenism, Insulin Resistance, and PCOS

7.1. Exercise and Weight Loss. Exercise is the best treatment modality for all the embolic manifestations and is recognized as necessary as food for human health. In PCOS, exercise and weight losing activities have supreme importance because they will help in lowering the adipose tissues having a major contribution to insulin resistance and androgenism [89, 96, 97]. The fats deposits are the key factors for insulin resistance, hyperinsulinaemia, hyperglycemia, T2DM, and oversecretion of androgen, so losing fats, specifically abdomen fats, has a direct and positive impact on all the major issues in PCOS women. It is also investigated that exercise not only diminishes fats but also promotes the normal endocrine and adrenal functions [97]. Physical exercises and weight losing activities can result in complete recovery from the clinical characteristics of PCOS.

7.2. Pharmacological Mediation. Drug therapy is always considered prime requirement for PCOS, where drugs like pioglitazone, inositol, and metformin isoforms have been recognized as therapeutic regimens for reproductive abnormalities and metabolic disorders in PCOS. Metformin is an insulin-sensitizing hormone that is used in PCOS even without diabetes and exerts actions on adipose tissue, skeletal muscles, ovary, and endothelium, impacted by insulin resistance. Prolonged use of metformin in PCOS treatment can augment ovulation rate, regulate menstrual cycle, and decrease the androgens secretions [87, 98–100]. The combinatorial regimen of clomiphene and metformin is considered more beneficial than single therapy of clomiphene or metformin for ovulation and pregnancy in PCOS women [101]. Metformin had no impact on fasting glucose, serum lipids, or anthropometric characteristics in women with PCOS, although it may postpone the advancement of glucose intolerance. Other insulin-sensitizing agents have also been shown to be effective in the treatment of PCOS [102]. Pioglitazone and rosiglitazone are also considered effective in eliminating insulin resistance, abnormal glucose tolerance, hyperandrogenaemia, ovulation rate, and menstrual regularity in PCOS patients. The combination of metformin and pioglitazone is also reported to have synergistic clinical profile in PCOS women's treatment; however, it should be avoided if pregnancy is desired due to teratogenic effects [103]. Inositol is another novel insulin-sensitizing agent that withholds superb insulin-sensitizing efficiency in PCOS women. Insulin resistance is troublesome along with hyperinsulinaemia for PCOS population and needs further research for the radical treatments. Hypersecretion of androgen in PCOS is considered fatal and hereditary. Therefore, there is an unmet need to evaluate the pathogenic and molecular network of this syndrome, insulin resistance, and excessive secretion of androgen [102, 103]. The metabolic irregularities and malfunctioning lead to complications like obesity, excessive lipids

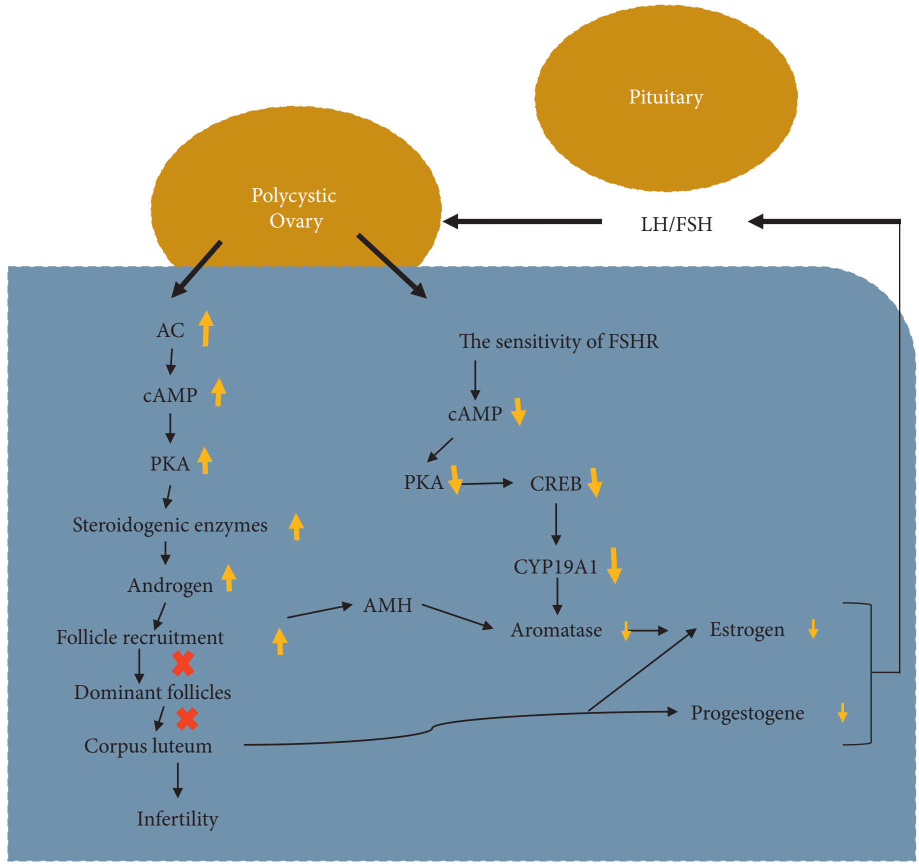

Figure 4: Schematic representation of PCOS associated infertility. The increased production of the androgens leads to failure in dominant follicles development and corpus luteum that is responsible for decreased production of aromatase and progesterone. Decreased sensitivity of the FSHR also leads to decreased aromatase production that further decreases the production of estrogens. So, overall the syndrome leads to decreased production of the estrogens and progesterone leading to infertility. H: anti-Mullerian hormone; PKA: protein kinase A; AC: adenylate cyclase; cAMP-response element binding protein:CREB.

aggregations, impaired glucose tolerance, hypertension, endometrium cancer, and hyperinsulinaemia [104, 105]. There is intended need for randomised clinical control trials for effective therapeutic approach in order to treat PCOS and its related complications.

7.3. Assisted Reproductive Technology (ART). Women infertility is also a major concern in PCOS, where assisted reproductive technology (ART) is employed for the fertility purposes. In ART, ovary is hyperstimulated in order to regulate the growth of multiple follicles, but it is ineffective in most cases due to augmented response to gonadotropins [106, 107]. In vitro maturation (IVM) methods have been employed for the fertilization of women with PCOS. IVF and IVM-IVF methods are also used for the embryo implantation to PCOS women [106–108]. However, further clinical research is aimed at yielding specified model for the success of ART in PCOS women to get fertilized.

7.4. Laparoscopic Ovarian Drilling (LOD). In 1984, laparoscopic ovarian drilling (LOD) was established to replace the invasive ovarian wedge resection surgery [109]. Currently, this technique is highly recommended and is developing pregnancy in 84% of the PCOS women who are facing infertility problems. LOD also augments insulin resistance and androgen production from ovaries. The improvements achieved with LOD have been observed to remain for a long time in 54% of the PCOS population. LOD is also a beneficial approach, as it results in low incidence of miscarriages in PCOS patients. LOD is also thought to be the first-line treatment when the CC treatment fails [26, 110–116]. These findings should be further evaluated for the confined use of LOD and its clinical benefits.

7.5. Oral Contraceptive Pills (OCPs). Oral contraceptives pills (OCPs) are regarded first-line therapy for people with PCOS who are not pursuing pregnancy. Not only are OCPs helpful in regulating the menstrual cycle, but also they reduce the secretion of androgens and regulate other physical activities [117]. OCPs have been reported which can significantly decrease the risk of endometrium cancer. OCPs are a combination of estrogen and progestogen, where estrogen is intended to decrease the levels of LH and FSH; the reduction in LH and FSH levels leads to suppression of T secretions and reduces the secretion of androgens.

Progestogen is generally recommended for low androgenic activity in women with PCOS [118, 119]. Three commonly used progestogens are desogestrel, cyproterone acetate, and drospirenone. As discussed earlier in this review, the PCOS population has high risk to develop disorders like insulin resistance, T2DM, hyperglycemia, abnormal glucose tolerance, enhanced levels of HDL and LDL cholesterols, hyperinsulinaemia, and so forth. Investigations in clinics revealed that OCPs can cause serious cardiac disorders like thrombosis, hypertension, insulin resistance, and myocardial infarction. These anomalies are thought to be having high risk in PCOS women compared to normal women and those who are on OCPs therapy. However, up till now, no clinical examination has been reported, to the best of our knowledge, regarding the metabolic effects of OCPs in PCOS population [118–122]. So, there is a great demand of clinical research in this area of interest because OCPs are the first-line treatment modality in females with PCOS. The recent interventions declared a new regimen with OCPs by adding metformin along with OCP, and the results found were satisfactory in reducing insulin resistance as well as decreasing the androgen production in PCOS population.

7.6. Dietary Therapy. Dietary therapy to reduce the weight of women with PCOS has a significant impact on metabolic conditions and is recognized to improve many PCOS issues like regulating androgen secretions, reducing insulin resistance, regularity of endocrine secretions, and menstrual cycle regulation [123, 124]. Weight loss can surely meet the goals of obtaining improved symptoms of PCOS and metabolic issues can intently resolve without medications. Moreover, the reproductive consequences in PCOS women can be improved with weight loss for those PCOS women who are interested in getting pregnant [123]. The weight loss results in high rates of pregnancy as well as decrease of the chances of miscarriages, suggesting weight loss significance for PCOS population. Dietary plan for weight loss is important and should be considered as first clinical regimen in order to live a healthy life with PCOS [125–128]. There is a need for clinical research and trials on the significance and effectiveness of dietary therapy for PCOS women.

8. Conclusion

Polycystic ovarian syndrome (PCOS) is considered as a major health issue. Women with PCOS face insulin resistance and overexposure of androgen, leading to a number of metabolic and reproductive abnormalities. These are considered the major causes of PCOS and other PCOS related manifestations. Herein, we have discussed the mechanism and treatment modalities of PCOS based on hypersecretion of androgen and insulin resistance. The current study gives concise and comprehensive outlook for the understanding of insulin resistance and androgen overexposure. We for the first time reported detailed review on the mechanism, pathophysiology, and treatment interventions for the insulin resistance and hypersecretion of insulin. The current study provides better understanding of the PCOS and provides a base for further exploration.

Objective. lncRNA H19 (H19) elevation is related to the risk of coronary artery disease. DIANA-lncBase database analysis suggested that microRNA-152 (miR-152) and H19 have binding sites. Here, the effect and mechanism of H19 and miR-152 in the oxidized low-density lipoprotein (ox-LDL)-induced human aortic endothelial cells (HAECs) were explored. *Methods*. The expression of H19, miR-152, and vascular endothelial growth factor (VEGF)-A in the HAECs treated with 5 μg/mL ox-LDL was detected by qRT-PCR. MTT, wound-healing assay, and tube formation assay were analyzed to evaluate the angiogenic activity of H19 and miR-152 in the HAECs cells knocked down H19. Dual-luciferase assay was performed to verify the targeting relationship of miR-152 to either H19 or VEGFA, respectively. Western blot was used to detect the expression of epithelial-mesenchymal transition (EMT)-related proteins (E-cadherin and vimentin) and VEGFA protein in the cells. *Results*. After ox-LDL treatment, the expression of H19 and VEGFA was significantly increased, miR-152 expression was remarkably decreased. H19 was mainly expressed in the cytoplasm of HAECs. Knocking down H19 or overexpression of miR-152 significantly inhibited the cellular proliferation, migration, tube formation, and EMT trend of the HAECs. On the contrary, miR-152 interference reversed H19 silencing-mediated effects in the ox-LDL-induced HAECs. The dual-luciferase assay showed that miR-152 had a targeting relationship with H19 and VEGFA. MiR-152 was negatively corrected with the VEGFA expression. *Conclusion*. Ox-LDL negatively regulates miR-152 via H19, promotes the expression of VEGFA, and induces the dysfunction of HAECs.

1. Introduction

Cardiovascular diseases (CVDs) are characterized by high morbidity and mortality, which seriously threaten global adults and constitute a major socioeconomic burden on global economic growth [1]. Atherosclerosis is the major underlying cause of CVDs. Atherosclerosis is a widespread chronic inflammatory disease of the arterial wall, which usually leads to disability or even death [2]. Previous studies have shown that the main mechanism of atherosclerosis is lipid accumulation and chronic inflammation in the arterial wall, while atherosclerosis is usually associated with altered lipid metabolism and hypercholesterolemia [3]. Oxidized low-density lipoprotein (ox-LDL) is a known risk factor for CVDs, which expresses the heterogeneous oxidative changes of the lipid portion of LDL and apolipoprotein B (ApoB) [4]. Studies have pointed out that plasma levels of ox-LDL in patients with atherosclerotic CVDs are elevated. Moreover, clinically, the level of the ox-LDL or anti-ox-LDL antibody is selected as a biomarker for predicting cardiovascular events [5]. Overproduction of ox-LDL leads to abnormal proliferation, apoptosis, migration, angiogenesis, and inflammatory responses, all of which are responsible for endothelial cell dysregulation [6]. It is suggested that ox-LDL can be used as a new therapeutic target for the treatment of atherosclerosis and cardiovascular diseases.

Epithelial-mesenchymal transition (EMT) plays a crucial role in progress and destabilizing atherosclerotic plaques via infiltration of fibroblasts and upregulation of matrix metalloproteinase [7, 8]. Downregulation of E-cadherin is a hallmark of EMT [9]. Abnormality of E-cadherin in foam cells during the process of atherosclerosis suggests that lipid accumulation may relate to the reorganization of cellular interactions in atherogenesis [10]. In the EMT process, vimentin maintains intracellular homeostasis via regulation of cytoskeleton architecture and cellular force generation [11]. Gong et al. [12] recently showed that vimentin promotes atherogenesis in $ApoE^{-/-}$ mice. These data indicate that both E-cadherin and vimentin are important factors of EMT and have pathological activities in atherosclerosis.

lncRNA is a type of long-chain non-coding RNA larger than 200 nt. Early studies have confirmed that lncRNA can be used as a signal molecule to participate in cellular growth and development, as well as the occurrence and development of diseases [13]. Some studies have pointed out that lncRNA is an important information transmission mediator between cells and tissues, which can transmit information efficiently and accurately [14]. Studies have shown that lncRNA can promote tumor growth and metastasis. lncRNA MALAT1 can promote tumorigenesis through the Wnt/β-catenin pathway, EMT, phosphatidylinositol kinase (PI3K)/protein kinase B (AKT) pathway, extracellular regulatory protein kinase (ERK)/mitogen-activated protein kinase (MAPK) pathway, and angiogenesis [15]. lncRNA PCGEM1 is a specific lncRNA for prostate cancer, which can promote cell proliferation and reduce apoptosis induced by anticancer drugs [16]. A number of research have shown that the expression of lncRNA H19 (H19) in cancer cell lines and samples of patients with cancer is significantly upregulated [17]. After knocking down the H19, the viability, invasion, and migration ability of cancer cell lines were significantly reduced [18]. It shows that H19 has a great relationship with the biological activity of cells. Some studies reveal that increase of H19 is related to the risk of coronary artery disease [19]. Further, other scholars found that H19 is involved in the process of atherosclerosis. Sun et al. reported that knocking down the H19 can prevent atherosclerosis deterioration by increasing p53-mediated apoptosis in vascular smooth muscle cells [20]. Zhang et al. [21] revealed that knocking down H19 could regulate the proliferation and apoptosis of vascular smooth muscle cells induced by ox-LDL through the miR-148b/Wnt/β-catenin pathway. Thus, H19 is closely related to the formation of atherosclerosis and is an important mediator of the ox-LDL damaged vascular cells. At the same time, studies have found that H19 regulates the apoptosis of vascular endothelial cells in occlusive arteriosclerosis through the NF-κB pathway [22]. However, no research has revealed the role of H19 in the process of ox-LDL inducing vascular endothelial cells. Therefore, in order to explore the effect of H19 on atherosclerosis, this study aims to elucidate the pathological mechanism of ox-LDL-induced vascular endothelial cell lesions *in vitro*, which would provide new therapeutic targets for atherosclerosis.

2. Materials and Methods

2.1. Cell Culture and Grouping. Human aortic endothelial cells (HAECs) were purchased from the American Type Culture Collection (ATCC; Manassas, VA, USA). The cells were cultured in complete Dulbecco's modified Eagle's medium (DMEM) (Gibco, Waltham, MA, USA) containing 10% fetal bovine serum (FBS) (Gibco), 100 mg/mL penicillin, and 100 mg/mL streptomycin (Gibco) at 37°C and 5% CO_2 in an incubator (ThermoFisher Scientific, Waltham, MA, USA). Wild-type HAECs were used as negative controls (Control group). HAECs treated with 5 μg/mL of ox-LDL [23] (Feather biology, Shanghai, China) for 24 h were used as the ox-LDL group. H19 siRNA (si-H19) and siRNA scramble (si-NC), miR-152 inhibitor and NC inhibitor, miR-152 mimics and mimics NC, vascular endothelial growth factor (VEGF)-A overexpression plasmids (VEGFA) were all designed and synthesized by Guangzhou Ruibo Biotech (Guangdong, China) and transfected with Lipofectamine 3000 (ThermoFisher) by following the manufacture instructions in the ox-LDL-treated HAECs.

2.2. Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR). The nucleus and cytoplasm of HAECs were isolated by a Subcellular Protein Fractionation Kit for Cultured Cells (ThermoFisher). Total RNA of the cells in each treatment group was extracted by TRIzol reagent (ThermoFisher) according to the instruction. The extracted RNA was detected by a NanoDrop microspectrophotometer (ThermoFisher), and cDNA was prepared according to the High-Capacity cDNA Reverse Transcription Kits (ThermoFisher). QRT-PCR analysis was performed according to the instructions of the SYBR GREEN kit (TaKaRa, Tokyo, Japan) to detect the expression levels of H19, miR-152, VEGFA mRNA, and other genes. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an internal reference control. Each experiment was set with 6 replicates. The experimental data obtained by qRT-PCR were calculated using the $2^{-\Delta\Delta Ct}$ method to calculate the relative expression of the target gene. The primer sequence is shown in Table 1.

2.3. Detection of Cellular Growth by Thiazolyl Blue (MTT) Staining. After treatment, each group of cells in the logarithmic growth phase was seeded in a 96-well plate at a density of 5000 cells/well, cultured in complete DMEM for 24, 48, and 72 h. 20 μL of 5 mg/mL MTT (Sigma-Aldrich, St. Louis, MO, USA) solution was added into each well of the cells and incubated in a 37°C incubator for 4 h. Following this, the supernatant was discarded, 150 μL of DMSO was added, and shaken for 15 minutes. The absorbance value of each well was measured with a wavelength of 570 nm in a microplate reader.

2.4. Wound-Healing Assay. Cells from each group were seeded into a 6-well plate, cultured to confluence. A 10 μL sterile pipette tip was used to scratch the diameter vertical to the horizontal plane of a single well. Cell debris and detached cells were removed by washing with PBS. Fresh serum-free medium was added, cultured for 24 h, and photographs were taken with an inverted microscope to record the experimental results. ImageJ software was used to calculate the

Table 1: qRT-PCR primers.

cellular migrated area on the scratched space. Each assay was repeated thrice.

2.5. Tube Formation Assay. 100 μL of Matrigel (HD Biosciences, San Diego, CA, USA) was added to each well of a 24-well plate and incubated at 37°C for 30 min. Cells treated with different conditions were resuspended in FBS-free DMEM and seeded at a concentration of 1×10^5 cells/well. After 6 h, the formation of capillary structures was counted under a light microscope, and scanning and quantification were performed. Each assay was repeated thrice.

2.6. Double-Luciferase Reporter Gene Assay. The sequence of H19, miR-152, and VEGFA binding site and their mutant sequences were inserted into the downstream of the firefly luciferase gene to construct an expression vector (Promega, Madison, Wisconsin, USA). MiR-152 mimics/mimics NC and mammalian cell miRNA reporter plasmid pmirGLO (Qincheng Biotechnology, Shanghai, China)-H19-WT/MUT recombinant plasmid, miR-152 mimics/mimics NC and pmirGLO-VEGFA-WT/MUT, and recombinant plasmid and Lipo2000 liposomes were mixed, respectively, and transfected into 293T cells (ATCC). After transfection 48 h, luciferase activity was detected according to the instructions of the Dual Luciferase Reporter Gene Assay kit (Promega).

2.7. Western Blot. Detecting cells were lysed by an RIPA reagent (Beyotime Biotechnology, Shanghai, China) to extract total protein. The protein concentration of the lysates was detected with a BCA kit (Abcam, Cambridge, British). Each 20 μg of the lysate protein was mixed with 4 x Protein Loading Buffer and boiled for denaturation, separated by SDS-PAGE, and was transferred on PVDF membranes. 5% skimmed milk was used to block the nonspecific proteins for 1 h. The primary antibody was reacted with the membrane overnight at 4°C. After washing, the membrane reacted with the secondary antibody for 1 h at room temperature. After washing, a chemiluminescence reagent (Haoxin-Biotech, Hanzhou, China) was applied to visualize the probed protein. The image was analyzed in an imaging system. Densitometry of the target protein bands was evaluated using ImageJ software, and the relative protein expression was calculated using β-actin as an internal reference.

2.8. Statistical Analysis. The tested results were analyzed by one-way ANOVA and independent samples *t-test* analysis with SPSS 26.0 (IBM-SPSS, Chicago, IL, USA). Results were expressed as mean ± standard deviation (SD). The correlation between miR-152 and H19/VEGFA was analyzed by the Pearson correlation analysis. $P < 0.05$ was used as the criterion for judging the significance of the difference.

3. Results

3.1. Ox-LDL Induced Upregulation of H19 Expression and Downregulation of miR-152 Expression in HAECs. DIANA-lncBase database (https://diana.e-ce.uth.gr/lncbasev3/interactions) predicted that miR-152 and H19 have binding sites (Figure 1(a)). QRT-PCR was performed to evaluate the H19 and miR-152 levels in the ox-LDL-treated HAECs. The results showed that compared with the control group, the expression of H19 in the ox-LDL group was significantly increased, but the expression of miR-152 was remarkably decreased (Figures 1(b) and 1(c), $P < 0.05$). This result indicates that H19 and miR-152 may involve the pathogenesis of the ox-LDL-induced atherosclerosis.

3.2. H19 Inhibited Cell Proliferation, Tube Formation, and Migration of the Ox-LDL-Induced HAECs. To further investigate the biological functions of H19 in the ox-LDL treated HAECs. We prepared H19 knockdown HAECs by H19 siRNA transfection. QRT-PCR analysis (Figure 2(a)) showed that compared with the siRNA scramble (si-NC) group, the expression of H19 in the H19 siRNA transfected (si-H19 group) HAECs were significantly downregulated. Further, compared with the siNC group, H19 knockdown significantly reduced cellular proliferation rate (Figure 2(b)), tube formation (Figure 2(c)), and cellular migration (Figure 2(d)) of the ox-LDL treated HAECs. E-cadherin and vimentin are reported to participate in the pathogenesis of atherosclerosis. Western blot detection indicated (Figure 2(e)) that compared with the siNC group, the E-cadherin protein expression in the si-H19 group cells was significantly increased, while vimentin expression was significantly reduced, indicating that knocking down H19 would reduce the epithelial-mesenchymal transformation (EMT) trend of the ox-LDL treated HAECs.

3.3. Expression of H19 Was Negatively Correlated to miR-152 in the Ox-LDL-HAECs. In order to study the molecular mechanism of H19, we determined whether H19 was expressed in the cytoplasm or the nucleus by qRT-PCR. The result showed that H19 was mainly expressed in the cytoplasm in the ox-LDL-HAECs (Figure 3(a)). Dual-luciferase experiment indicated that co-transfection of miR-152 mimics significantly inhibited the luciferase activity of the H19 vector (lncRNA H19-WT) but did not inhibit the luciferase activity of the lncRNA H19-MUT vector. Thus, the targeting relationship between H19 and miR-152 was confirmed (Figure 3(b)). In addition, compared with the siNC group, H19 knockdown significantly upregulated the expression of miR-152 (Figure 3(c)). The expression of H19

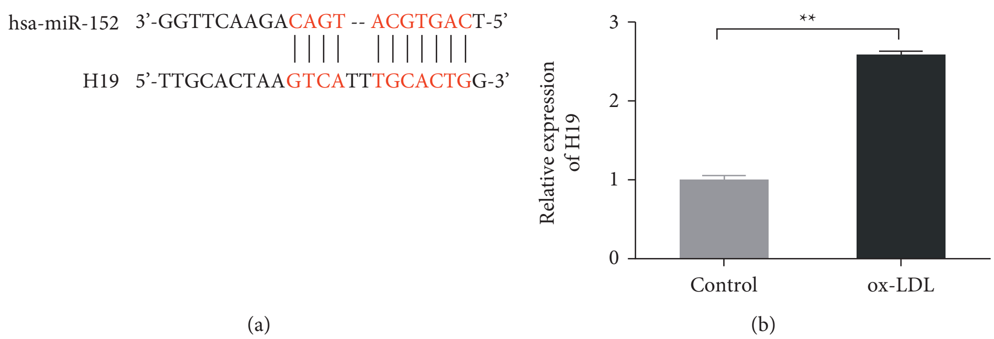

Figure 1: Ox-LDL induced upregulation of H19 expression and downregulation of miR-152 expression in ox-LDL-treated HAECs. A. Potential binding sites between miR-152 and lncRNA H19 (H19) were analyzed by DIANA-lncBase database. B. Expression of H19 was detected by qRT-PCR in the wild type HAECs (Control) and ox-LDL-treated HAECs. C. The expression of miR-152 was analyzed in the control and ox-LDL groups in HAECs. Each data were obtained from three different independent test results. $^{**}P < 0.01$.

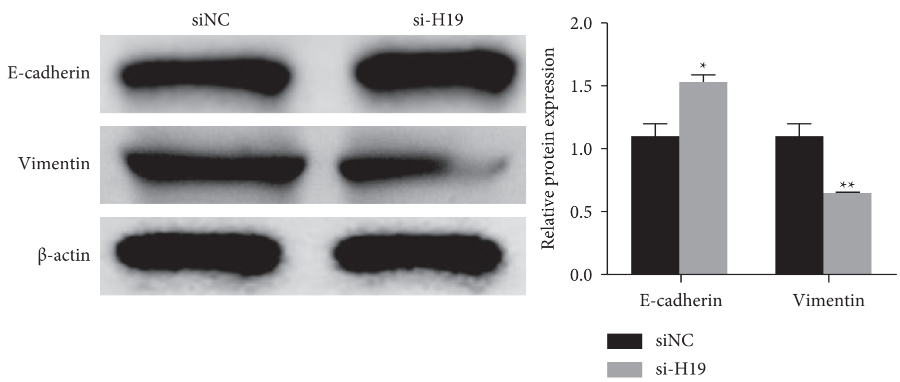
(d)



(e)

Figure 2: Knockdown of H19 inhibited the ox-LDL-induced proangiogenic activities of HAECs. (a). Efficiency of the si-lncRNA H19 (si-H19) was evaluated by qRT-PCR in the ox-LDL-HAECs. (b). Cellular proliferation was detected by MTT in the indicated cells. (c) Tube formation was performed to detect the angiogenesis ability in the indicated cells. (d) Cellular migration was evaluated by Wound-healing assay in the indicated cells. (e) Protein expression of E-cadherin and vimentin was analyzed by Western blot. $^{*}P < 0.05$ and $^{**}P < 0.01$ *vs.* siNC group.

was negatively correlated to the miR-152 in the ox-LDL-HAECs (Figure 3(d)).

3.4. Knockdown of miR-152 Attenuated the si-H19 Induced Antiangiogenic Activities in the Ox-LDL-HAECs. Compared with the siNC + NC inhibitor group, the proangiogenic activity (including cellular proliferation rate, migration ability, tube formation ability, and EMT trend) of the si-H19 + NC inhibitor group cells was significantly reduced. On the contrary, the cellular proliferation rate, migration ability, tube formation ability, and EMT trend of the ox-LDL-HAECs increased significantly after interference with miR-152. Interestingly, miR-152 inhibitor transfection attenuated the antiangiogenic activity induced by si-H19 in the ox-LDL-HAECs (Figures 4(a)–4(d)).

3.5. VEGFA Is the Target Gene of miR-152, Which Is Regulated by H19 via miR-152. TargetScan database (http://www.targetscan.org/vert_72/) was applied to predict the target genes of miR-152. The prediction results show that there is a binding site between VEGFA and miR-152 (Figure 5(a)). Dual-luciferase assay was then applied to verify this prediction, which showed that miR-152 mimics significantly inhibited the luciferase activity of the VEGFA-WT carrier but did not inhibit the luciferase activity of the VEGFA-mutation (VEGFA-MUT) carrier (Figure 5(a)). These results confirmed the targeting relationship between miR-152 and VEGFA. To further verify this relationship, qRT-PCR and Western blot were performed and showed that compared with the NC mimics group, miR-152 mimics transfection significantly inhibited the expression of VEGFA mRNA and protein in the ox-LDL-HAECs (Figures 5(b)–5(c)). Correlation analysis revealed that miR-152 was negatively correlated with VEGFA (Figure 5(d)). In addition, compared with the siNC group, the expression of VEGFA in the ox-LDL-HAECs was significantly reduced after interference with si-H19, and the expression of H19 and VEGFA was positively correlated (Figures 5(e)–5(f)). At the same time, after interfering with the miR-152, the expression of VEGFA in the cells increased significantly. However, compared with the si-H19NC inhibitor group, miR-152 inhibitor can reverse the expression of VEGFA (Figures 5(g) and 5(h)).

3.6. Antiangiogenic Activity of miR-152 Inhibits via Downregulating VEGFA in the Ox-LDL-HAECs. The angiogenic assay was further applied to determine whether miR-152

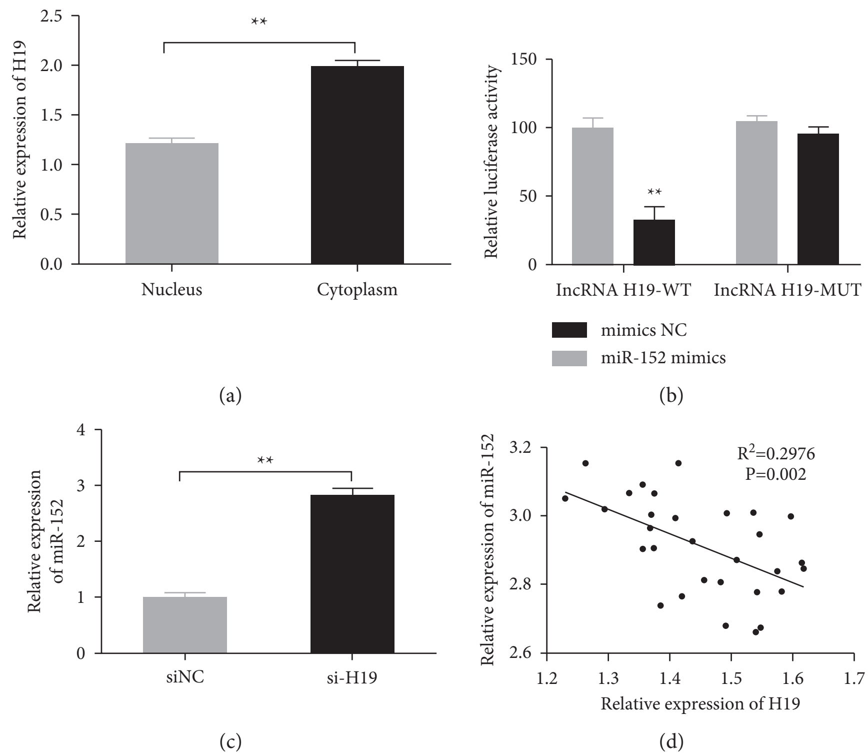


Figure 3: Expression of H19 was negatively correlated to the miR-152 in the ox-LDL-HAECs. (a) qRT-PCR detected the expression of H19 in the isolated cytoplasm and nucleus of the ox-LDL-HAECs. $^{**}P < 0.01$. (b) Binding relationship of the H19 and miR-152 were analyzed by Dual-luciferase assays. $^{**}P < 0.01$ *vs* mimics NC group. (c) qRT-PCR was used to detect the expression of miR-152 in the siNC group and si-H19 group in the ox-LDL-HAECs, $^{**}P < 0.01$. (d) Correlation between the expression of H19 and miR-152 was analysis by Pearson analyzes.

could regulate HAECs by targeting VEGFA. Compared with the NC mimics + vector group, the proliferation rate (Figure 6(a)), migration ability (Figure 6(b)), tube formation ability (Figure 6(c)), and EMT trend (Figure 6(d)) of the ox-LDL-HAECs were significantly reduced after miR-152 mimic transfection. While these activities and EMT trend were significantly higher in the VEGFA overexpressed ox-LDL-HAECs. At the same time, overexpression of VEGFA can reverse the effect of miR-152 upregulation on the angiogenic activity of the ox-LDL-HACEs.

4. Discussion

Atherosclerosis is a chronic multifactorial vascular disease and the root cause of cardiovascular disease. It is characterized by lipid accumulation and the formation of fatty plaques in blood vessels [24]. Despite advances in treatment, the morbidity and mortality of atherosclerosis are still at a high level. Therefore, there is an urgent need to reveal detailed mechanism of atherosclerosis and find effective treatment targets and methods for atherosclerosis.

Studies have shown that ox-LDL has a bidirectional effect on angiogenesis [25]. Low concentrations of ox-LDL (less than 5 μg/ml) stimulate VEGF expression, endothelial cell migration, and neocapillary formation [25, 26]. Therefore, in this study, 5 μg/ml was used to induce HAECs into an atherosclerosis cell model. Previous studies have shown that expression of H19 is upregulated in cardiovascular diseases, including vascular smooth muscle cells [27]. This study also found that H19 was significantly upregulated in HAECs induced by 5 μg/ml ox-LDL. Moreover, after knocking down the expression of H19, the proliferation, migration, and tube formation of ox-LDL-induced HAECs were significantly inhibited, which is similar to the role of the H19 in many cancer cells. For example, Zhao et al. found that knocking down H19 can significantly inhibit the proliferation and metastasis ability of lung cancer cell lines [28]. It is suggested that H19 has the potential to be a biomarker for diagnosing changes in the state of vascular endothelial cells, and H19 is related to the biological functions of cells.

According to previous research reports, lncRNA exhibits its activities in a variety of ways. It can participate in the regulation of protein before and after transcription to directly control the protein activity. It mainly includes direct binding to target protein to affect its function, or binding to miRNA or circRNA to participate in signal transduction and other ways [29]. Among them, miRNA is a type of short noncoding RNA with a length of about 22 nt [30]. Due to the high efficiency and specificity of miRNA, it is often used as a biomarker of disease [31]. Many studies have found that the expression of miR-152 is often downregulated in different solid tumors [32], suggesting that miR-152 can inhibit the biological activity of cancer, acting as a tumor suppressor.

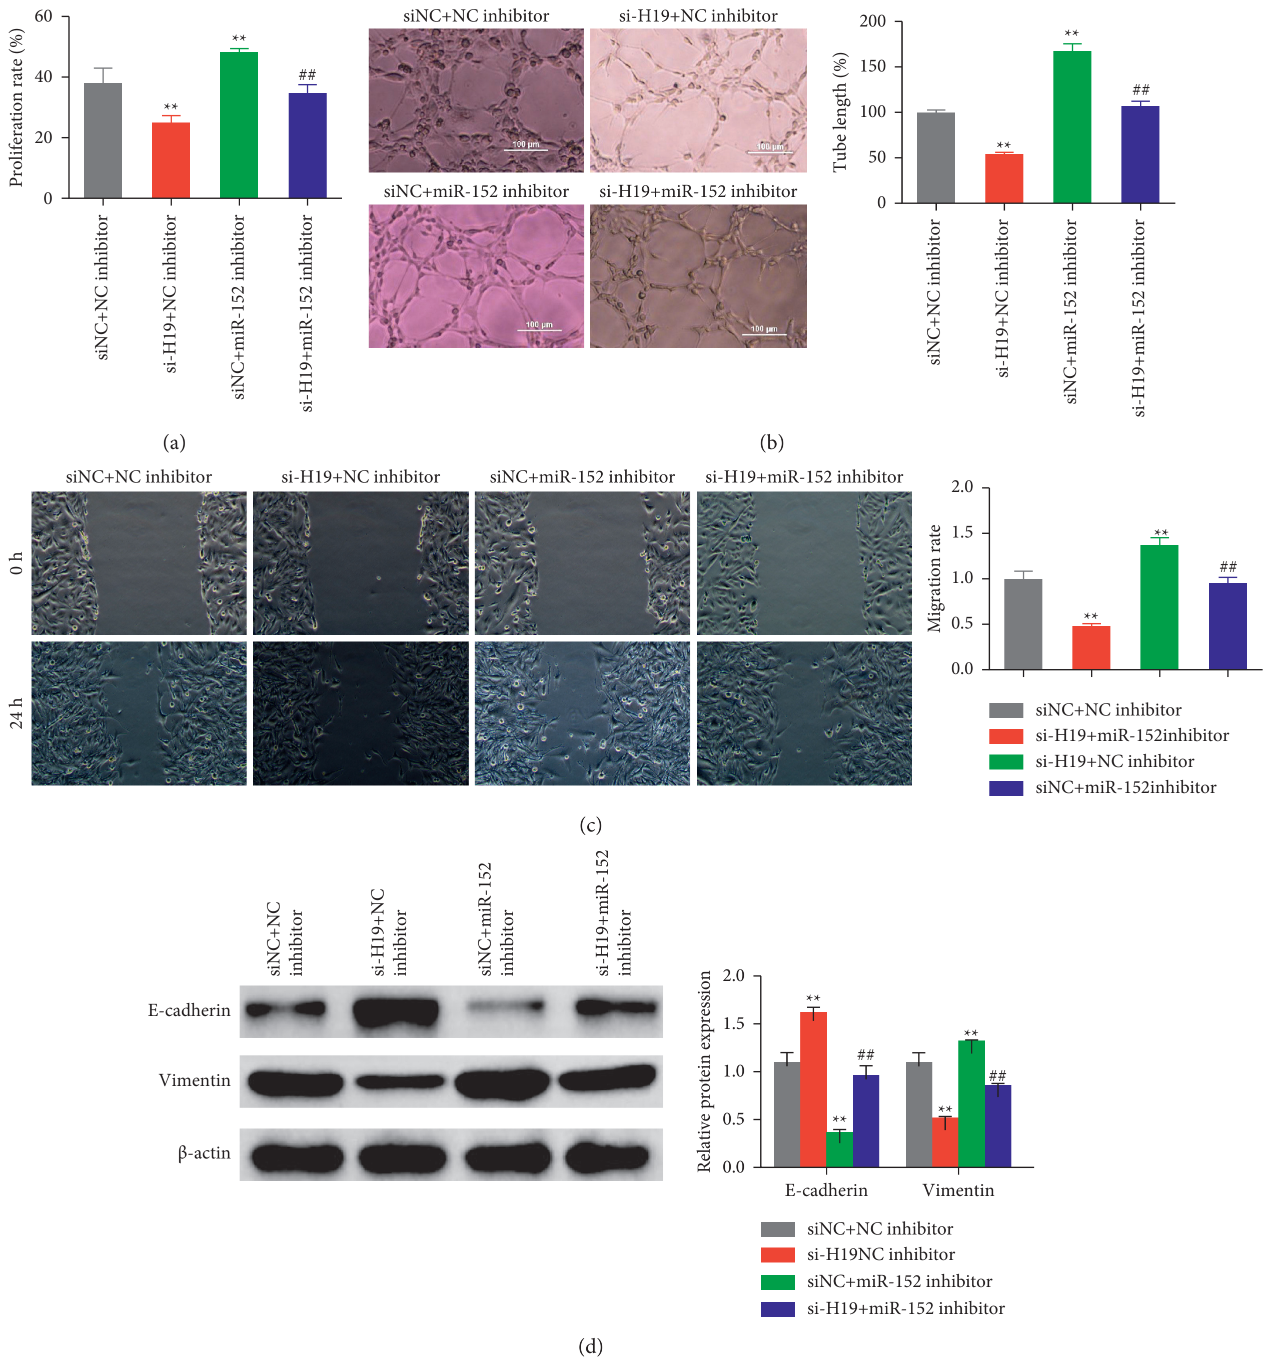

Figure 4: Low expression of miR-152 attenuated the si-H19-induced antiangiogenic activity in the ox-LDL-HAECs. Cellular proliferation, tube formation, migration, and protein expression of E-cadherin and vimentin were analyzed by MTT (a), Matrigel tuber formation (b), Wound-healing assay (c), and Western blot (d) in the ox-LDL-HAECs. $^{**}P < 0.01$ *vs* siNC + NC inhibitor group; ## $P < 0.01$ *vs* si-H19 + NC inhibitor group.

There have been some reports on the pathological regulation of the H19/miR-152 axis, which mostly involves cell proliferation, invasion, angiogenesis, and apoptosis. Li et al. [33] showed that in the study of diabetic foot ulcer repair, H19 inhibited the apoptosis and inflammation of fibroblasts by reducing the activity of miR-152-3p-mediated tensin protein homolog activity, thereby promoting wound healing of diabetic foot ulcers. In human glioma cells, the level of H19 increases, while the level of miR-152 decreases. Lowering H19 or increasing miR-152 can inhibit the proliferation and invasion of glioma cells to inhibit the growth of glioma cells [34]. The results of this study found that the expression of miR-152 was significantly downregulated in cardiovascular ox-LDL–treated HAECs. Dual-luciferase assay showed that H19 could bind miR-152. Knocking down H19 significantly upregulated miR-152 expression accompanied with

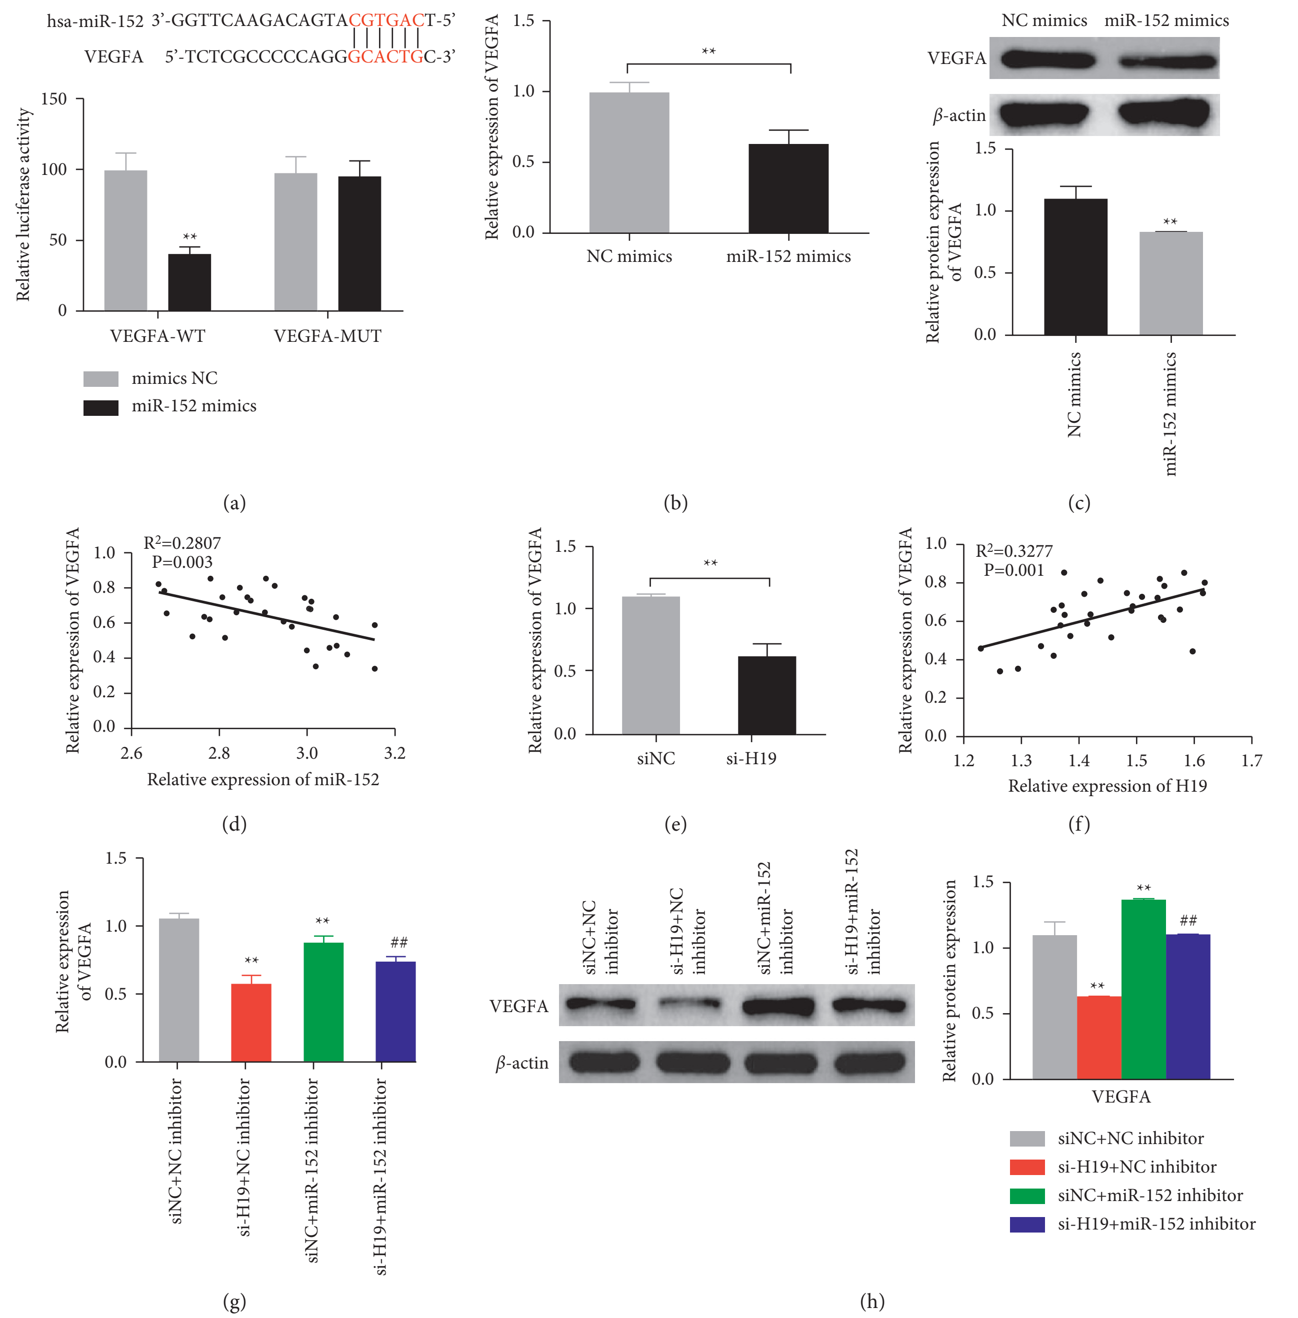

Figure 5: VEGFA is the target gene of miR-152, through which H19 can regulate the VEGFA expression. (a) Binding site between the miR-152 and VEGFA was predicated by TargetScan database analysis (up panel). Dual-luciferase analysis of miR-152 to VEGFA. $^{**}P < 0.01$ *vs* mimics NC. B–C. The expression of VEGFA mRNA and protein were analyzed by qRT-PCR (b) and Western blot (c) in the miR-152 mimics or mimics NC transfected ox-LDL-HAECs; $^{**}P < 0.01$. (d) Pearson analysis of the correlation between miR-152 and VEGFA expression. (e) VEGFA gene expression was detected by qRT-PCR in the si-H19 transfected ox-LDL-HAECs, $^{**}P < 0.01$. (f) Correlation of the expression of H19 and VEGFA was analyzed by Pearson analysis. **G-H**. VEGFA mRNA and protein expression were detected by qRT-PCR (g) and Western blot (h) in the indicated groups of the ox-LDL-HAECs. $^{**}P < 0.01$ *vs* siNC + NC inhibitor group, ## $P < 0.01$ *vs* si-H19 + NC inhibitor group.

antiangiogenic activity. Li et al. [35] showed that H19 can upregulate the expression of DNMT1 through sponge miR-152, thereby promoting the proliferation and invasion of breast cancer, suggesting that miR-152 is a key mediator for H19 to exert its biological functions. These data show that H19 has a negative regulatory effect on miR152. H19 is involved in the regulation of cell proliferation (vascular endothelial or tumor) through the negative regulation of miR152 to involve angiogenesis or tumor pathogenesis.

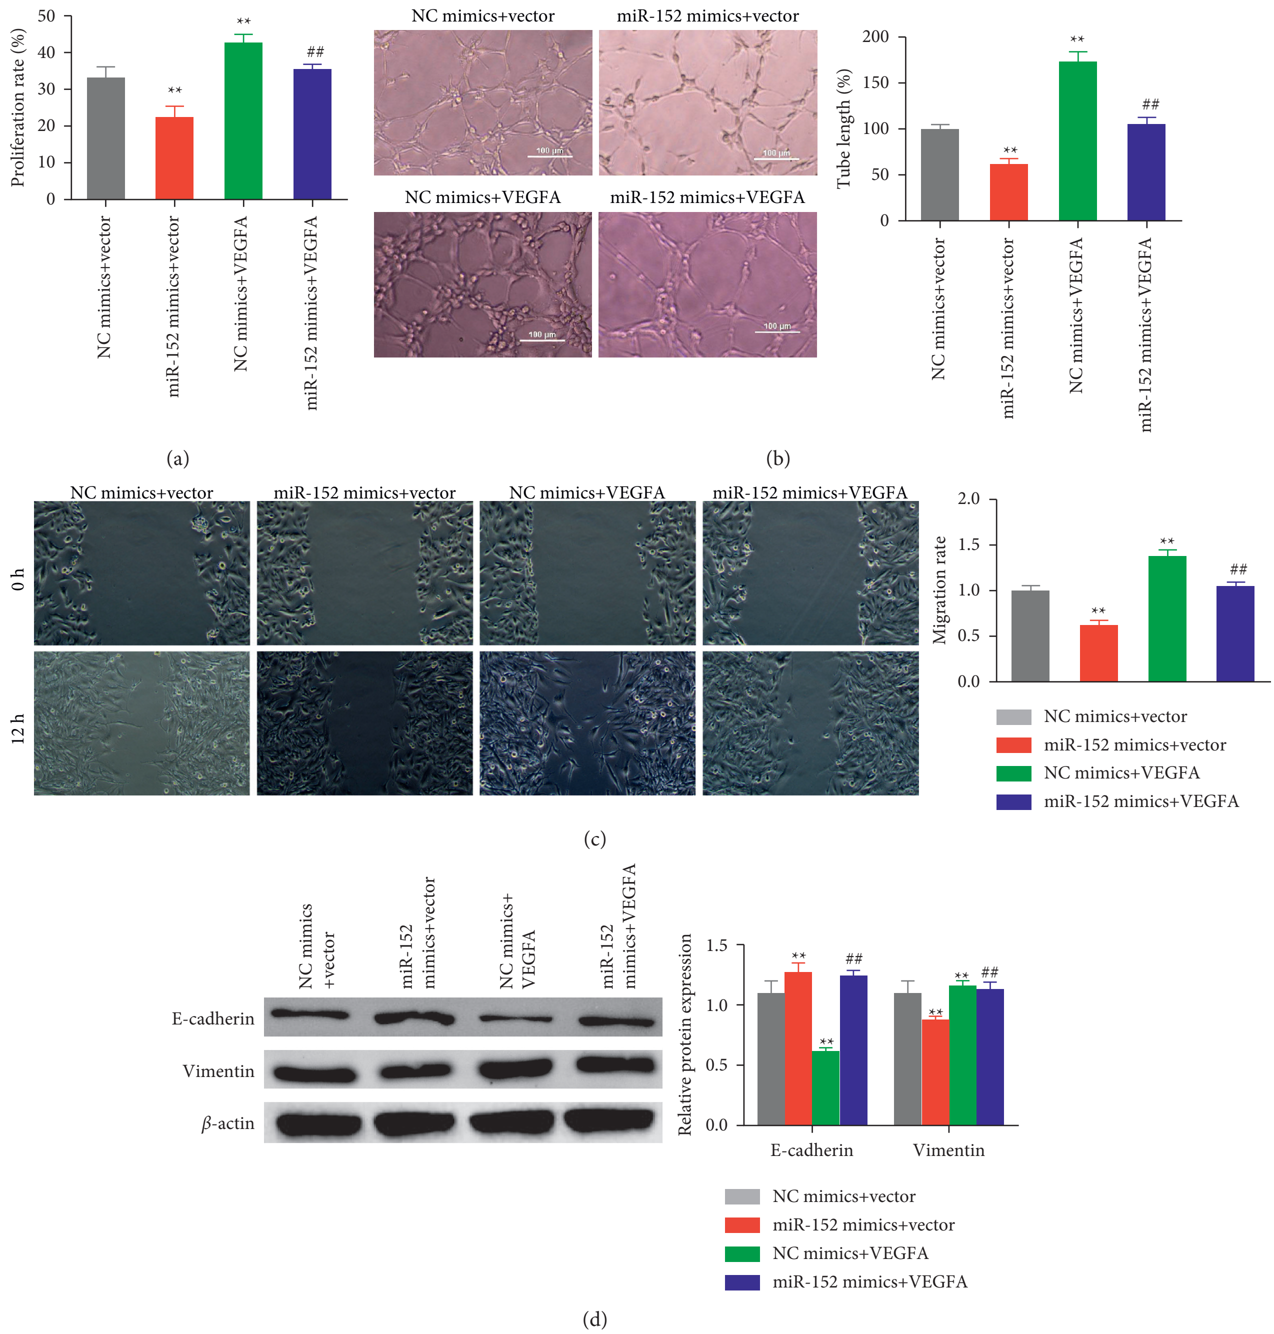

FIGURE 6: Antiangiogenic activity of miR-152 by downregulating VEGFA in the ox-LDL-HAECs. Cellular proliferation (a), tube formation (b), wound-healing assay (c) were detected in the indicated groups. (d) E-cadherin and Vimentin protein levels were analyzed by Western blot. $^{**}P < 0.01$ *vs.* NC mimics + vector group, ## $P < 0.01$ *vs.* miR-152 mimics + vector group.

According to previous research reports, miRNA can bind to the 3′-UTR of a specific mRNA through its seed sequence to inhibit the translation of the mRNA and participate in the regulation of cell life activities [36]. This study also showed that miR-152 has a target relationship with VEGFA that is an important signal molecule leading to atherosclerosis. Balance of VEGFA is crucial to maintaining the physiological vascular homeostasis of cells and tissues [37]. High expression of VEGFA is the direct cause activating vascular endothelial cells. Haque et al. found that overexpression of miR-152 can significantly inhibit the expression of VEGF and TGFβ1 in retinal endothelial cells [38]. Fu et al. [39] reported that overexpression of miR-152 can inhibit high glucose-induced angiogenesis in human retinal endothelium cells and retinal microvascular endothelial cell lines by targeting inhibition of VEGF signaling. All the data suggest that VEGF signal is the main target of miR-152 to inhibit angiogenesis.

5. Conclusion

In conclusion, H19 promotes cellular proliferation, migration, and angiogenesis through the miR-152/VEGFA axis in the ox-LDL-induced HAECs. These findings also suggested that H19 could be a target to regulate the biological activity of vascular endothelial cells. However, in order to reveal the relationship between ox-LDL and H19, further investigations are needed to more comprehensively elaborate the mechanism of ox-LDL causing changes in the activity of vascular endothelial cells.

Background. Lumbopelvic kinematics has been observed to include different parameters and directly relate to the movement of the hip spine. In the current scenario, more than 65 million people have been suffering from spinal pain, and 18% of adults experience chronic spinal pain. *Methods*. This systematic review and meta-analysis selected 9 studies for analysis via electronic databases like EMBASE, MEDLINE, Web of Science, Scopus, CINAHL, and Cochrane (CENTRAL). After collecting the data, the dataset has been systematically analyzed through statistical methodologies using RevMan and Stata. *Results*. Out of 116 studies initially scrutinized, nine were finally selected for the meta-analysis. When range of motion was studied via meta-analysis, it was noted that a considerable reduced movement was noted in the lumbar region of the spine when people were suffering from lower back pain in comparison to control group people. Hence, reduced lumbar range of motion, no difference in the angle of lordosis, and no significant difference in extension and rotation in people with lower back pain were found. However, variability was noted in people suffering from lower back pain for flexion and lateral flexion. A significant heterogeneity was found between the studies which lacked some details and standardization of the criteria which were used for defining patients with lower back pain or without them (control group). Results show that spinal pain is the main reason behind the limitation of lumbar range of motion. It is clear from the data set of mean and standard deviation, and this is clear to establish the relationship between the causes of pelvic and spinal pain. In flexion-based ROM, the mean difference was found to be −9.77 (95% CI: −21.86, 2.32). Similarly, for lateral flexion, the mean difference was found to be −5.58 (with 95% CI: −10.38, −0.79). *Conclusion*. It can be concluded that spinal disease is too influential for people; thereby, it affects day-to-day life activities by creating painful and restricted movements. It is concluded that people suffering from lower back pain have reduced proprioception and range of movement in the lumbar region when compared to control groups with no lower back pain, which mainly focus on flexion and lateral flexion.

1. Introduction

Lumbopelvic kinematics have been observed to include a wide range of parameters, such as lumbar and pelvic ROM, regional movement timing, and muscle activation. In addition to that, the duration of movement and postural position associated with the coordination of movement are also linked with lumbopelvic kinematics. The lumbopelvic rhythm for the coordination of the hip-spine can be described as the movement of the lumbar spine combined with the movement of the pelvis. The lower back muscle, called the erector spinae, contracts and relaxes to control the body's movement against gravity [1].

It has also been observed that the nerves in the pelvic region come from the lower back portion, and issues with the lumbar spine can contribute to the development of pelvic pain or spine pain. In addition to that, the other potential causes of lower back disorders associated with spine pain can be triggered by disc herniation, spinal stenosis, and pinched nerves [2]. This study will systematically review and provide a meta-analysis on the comparative kinematics in the pelvic region for patients who are suffering from spinal pain. In addition to that, this study will also shed light on the finding of possible solutions to mitigate the issues related to spinal pain [3].

This study aims to systematically review and produce a meta-analysis on the comparative research regarding kinematics in the lumbopelvic region for patients suffering from spinal pain. The key objectives of the study are as follows: (i) to analyze the current scenario of developing lumbopelvic disorders among patients suffering from spinal pain; (ii) to investigate the importance of kinematics in the lumbopelvic region; and (iii) to examine the possible ways of improving strategies to mitigate the issues associated with the lumbopelvic region.

Spinal pain has been observed to be a common disorder among adults from the age group of 40 to above 60. In the current scenario, more than 65 million people have been suffering from spinal pain. At the same time, 18% of adults have been found to experience chronic or persistent spinal pain because of certain daily activities [4].

Therefore, this has become a potential issue nowadays and needs to be controlled. In this regard, this study will systematically review and provide a meta-analysis on the comparative kinematics for the lumbopelvic region among patients suffering from spinal pain. This study will analyze different perspectives of other researchers through conducting a secondary systematic review that can contribute to finding something new in the process of creating this kind of spinal pain. Therefore, this study will also contribute to the development of strategies and procedures that can effectively reduce the number of individuals suffering from spinal pain through conducting a systematic review and meta-analysis.

2. Methodology

The methodology can be defined as conducting research, describing each step selected and completed in research. This study has been conducted with a systematic review of secondary sources that has presented a meta-analysis regarding the research topic [5].

2.1. Study Selection: Inclusion and Exclusion Criteria. The inclusion-exclusion criteria have been chosen to identify the selected population in this study as a reliable, consistent, uniform, and objective manager. At the same time, the selected source of data has also been passed through these inclusion and exclusion criteria. It has lowered the size of the population by removing the ineligible samples from the study. Databases such as EMBASE, MEDLINE, Web of Science, Scopus, CINAHL, and Cochrane (CENTRAL) were used for data extraction.

A PRISMA flow chart has been implemented to systematically include and exclude studies from this review work and meta-analysis. Records identified through electronic database searching have collected 113 studies from different sources. After that, three additional articles have also been included in this study from other sources.

Out of these 116 studies, 76 duplicate types of research were discarded. Following the inclusion criteria and eligibility standards, 40 studies were found applicable as per the aim of the current study. Articles were rejected as per their exclusion criteria, which were as follows: insufficient patient data, nonclinical studies, studies with no conclusions, review papers, abstracts, letters, or editorials were found to be 31 studies; therefore, nine studies were shortlisted for analysis (Table 1). The PRISMA statement flow chart shows this process (Figure 1).

In this systematic review and meta-analysis study, four major electronic databases have been searched systematically since November 2021. Electronic databases including PubMed, Google Scholar, ProQuest, and MEDLINE have been searched with specific combinations of keywords. The selection of articles from the data sources has been conducted with relieving the abstracts and titles of the journals.

Online data sources have contributed to this research and have helped the researchers conduct these meta-analyses and systematic reviews. During the data search, researchers selected only the journals related to this topic and used a bulletin table to search the most relevant journals [14]. In this secondary data collection, the researchers have also considered the relevance and eligibility of each online source that has been reviewed in this study. During the selection of online sources, the researchers chose different clinical studies, individual participant data, regulatory information, and other types of secondary data that are relevant to the review topic.

2.2. Data Extraction and Quality Assessment of the Study. Researchers have developed based on the checklist used in different articles and published the quality assessment tools to extract data from the collected sample. Data extraction and quality assessment have been necessary to reduce risk factors and bias in the systematic review while synthesizing the key findings. The characteristics included in the data extraction were the age of participants and the characteristics of the source. The other factors that have been included in the checklist for the text fraction include inclusion-exclusion criteria, along with the methods used in the studies [15]. The quality assessment has been conducted with the aim of reducing bias from the study based on the study population, LBP among the participants, measurement procedures, and assessor bindings to the presence of spine pain (yes/no) [16]. The analysis of studies has been conducted via RevMan and Stata where forest and funnel plots were drawn and interpreted [15]. However, the key focus of this meta-analysis and systematic review has been on the statistical data. Still, the thematic analysis has also allowed the researchers to establish a common link between different variables [17].

3. Results

3.1. Characteristics of Movement. A total of 1887 participants were divided into LBP groups ($n = 643$) and NoLBP groups ($n = 596$). The sample size ranged from 29 to 840.

A meta-analysis was performed for six studies where the angle of lumbar lordosis was compared in people with or

Youdas [10]	55.5	10.4	30	52.7	15.3	45

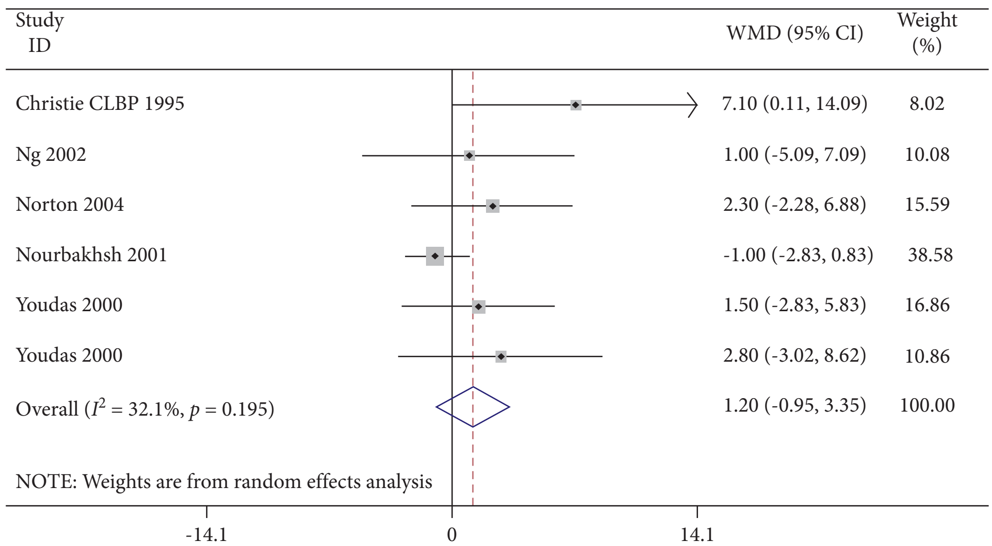

Figure 2: Forest plot analysis of lumbar lordosis in the LBP group to NoLBP on lumbar lordosis.

even without lower back pain, as shown in Table 2 and Figures 2 and 3. Most studies have reported small insignificant differences amongst groups.

3.2. Range of Motion. A meta-analysis of four studies was performed and it was found that there was a consistently reduced movement range in the lumbar spine region with people suffering from lower back pain. A meta-analysis has been performed in Table 3 with the findings listed in Figure 4 with forest and funnel plots. In some of the studies included the groups with chronic or acute lower back pain were compared with other groups showing no back pain signs. Variability was noted in people suffering from lower back pain during flexion. The meta-analysis showed that the flexion in the LBP group was significantly lower (WMD: −0.77; 95% CI: −21.86–2.32; $P \leq 0.001$, $I_2 = 95.2\%$) than that in the NoLBP group.

Studies which measured bilateral movement were meta-analyzed for extension (Table 4 and Figures 5 and 6), for lateral flexion (Table 5 and Figures 7 and 8), and for rotation (Table 6 and Figures 9 and 10). Meta-analysis showed that the lateral flexion in the LBP group was significantly lower (WMD: −5.58; 95% CI: −10.38 to −0.79; $P = 0.006$; $I_2 = 75.7\%$) than that in the NoLBP group. The studies selected were measured for their bilateral movement, that is, in both left and right rotations, and a mean difference was calculated. A significant relationship exists between lower back pain and movement restrictions along with dependent variables that not only efficiently but also effectively cause the same [18].

4. Discussion

4.1. Analysis of the Current Scenario for Growing of Lumbo-pelvic Disorder. In most cases, it has been seen that low back pain has contributed to pelvic disorders. The pelvic floor disorder has been noticed to be originating from the displacement of lumbar spines, which hardly has vivid symptoms in most human bodies. However, without or with the symptoms, this disorder reaches an extreme condition to some humans. It has been spotted from many discussions and scientific magazines and journals that the connection between the "low back pain" (LBP) or "spinal pain" and "pelvic floor dysfunction" (PFD) has been evident in the case of women's bodies [19]. The highest number of responses indicated the link between spinal pain and PFD, such as a considerable positive correlation.

4.2. Investigation on the Essence of Kinematics. Observing different studies, it has come to light that when the pelvic region muscles are unable to contract, it immediately causes a failure in the urinary tract contraction that results in

urinary inconsistency. In the opinion of Aitken et al. [20], adding to it, it has been noticed that the pelvic organ starts prolapsing due to the same reason and gives rise to other abnormalities in the human body. It has been transparent that this phenomenon also disturbs the kinematics of the human body functions and causes PFD.

4.3. Analysis of Causes that Develop Further Issues in the Pelvic Region. Low back pain can be derived due to soft-tissue as well as mechanical issues, and these injuries can lead to more pain in their pelvic region. This has been the reason for coming up with more severity, which can lead to more suffering. Furthermore, they have been going through infections, and because of that, they have been facing more casualties.

Due to this reason, more complex problems have been coming up, which can lead to no proper movement of their lives [21]. Hence, it is clear from the discussion that issues developing due to derived spinal pain are related to the

pelvic region. This may increase the severity of pain leading to suffering and infections, which might be the reason to other diseases.

4.4. Examination of Mitigation Strategies. Here, they should develop proper mitigation strategies at the beginning stage of the pelvic derivation of pelvic. Furthermore, they should

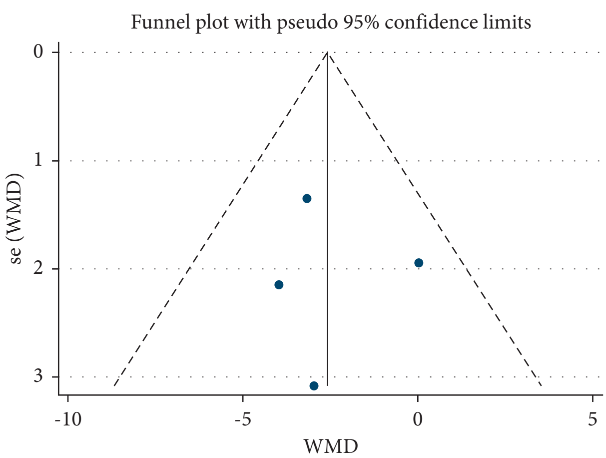

Figure 10: Funnel plot analysis of lumbar lordosis in the LBP group to NoLBP on rotation.

easily take physicians' appointments to solve their issues [22]. It is not possible to identify pelvic at their initial stage, but they should pay heed that they should not face any damage so that no issue or further complexity can be generated.

5. Conclusion

It can be concluded that lumbopelvic has been derived, so it is too problematic for people to lead their normal lives [23]. There are too many causes behind deriving pelvic disorders such as spinal stenosis, pinched nerves, and herniation. Here, proper analysis of the development of this disorder has been paid heed, and in this regard, it has been identified that spinal pain is the most significant cause [24]. Kinematics has become too vivid a reason for deriving this issue as well, and in this case, all of the explanation has been provided with giving analysis [25]. Possible strategies have been given heed to so that patients can get relieved from this kind of situation to a further extent. Here, for vivid results, primary data has been utilized and the data set given insight into mean and standard deviation values. The analysis of movement in the lumbopelvic region is based on the examination of kinematics such as posture, range of movement like flexion, and extension. This also includes a higher range of movements such as sequential and temporal patterns in case of proprioception, complex functions, physiological movements, or case of complex functions such as walking or lifting. Thus, analysis of all causes for developing various issues in the pelvic region among the patient is very effective, which is generated from spinal pain. It is concluded that people suffering from lower back pain have reduced proprioception and range of movement in the lumbar region when compared to control groups with no lower back pain, which mainly focus on flexion and lateral flexion [26].

Hence, it was concluded from the studies that people with lower back pain have a reduced range and speed of movement, but it is not significant for other characteristics of movement. But people suffering from lower back pain move slowly with low proprioception when compared to control group people. For patients with limited lumbar spine mobility, especially in forward flexion and lateral flexion, early intervention should be performed to reduce pain. For patients who already have low back pain, reducing forward flexion and lateral flexion activities may reduce the pain to a certain extent.

Academic Editor: Enas Abdulhay

A common consequence of acute ischemic stroke (AIS), stroke-associated pneumonia (SAP), might result in a poor prognosis after stroke. Based on the critical position of inflammation in SAP, this study aimed to explore the correlation between platelet-to-lymphocyte ratio (PLR) and the occurrence of SAP. We included 295 patients with acute ischemic stroke, 40 with SAP, and 255 without SAP. The area under the receiver operating characteristic curve was used to determine the diagnostic value of SAP risk factors using binary logistic regression analysis. The comparison between the two groups showed that age, the baseline National Institutes of Health Stroke Scale (NIHSS) score, and the proportion of dysphagia, atrial fibrillation, and total anterior circulation infarct were higher, and the proportion of lacunar circulation infarct was lower in the SAP group ($P < 0.001$). In terms of laboratory data, the SAP group had considerably greater neutrophil counts and PLR, while the non-SAP group ($P < 0.001$) had significantly lower lymphocyte counts and triglycerides. Binary logistic regression analysis revealed that older age (aOR = 1.062, 95% CI: 1.023–1.102, $P = 0.002$), atrial fibrillation (aOR = 3.585, 95% CI: 1.605–8.007, $P = 0.019$), and PLR (aOR = 1.003, 95% CI: 1.001–1.006, $P = 0.020$) were independent risk factors associated with SAP after adjusting for potential confounders. The sensitivity and specificity of PLR with a cutoff value of 152.22 (AUC: 0.663, 95% CI: 0.606–0.717, $P = 0.0006$) were 57.5% and 70.6%, respectively. This study showed that high PLR is an associated factor for SAP in AIS patients. Increased systemic inflammation is linked to SAP in ischemic stroke. Inflammatory biomarkers that are easily accessible may aid in the diagnosis of high-risk SAP patients.

1. Introduction

Stroke is a common and leading cause of death and disability worldwide, imposing a heavy burden on society and the economy [1, 2]. Stroke-associated pneumonia (SAP) often occurs after a stroke; approximately 7%–38% [3–8] of stroke patients are diagnosed with SAP during hospitalization. Once a patient develops SAP, it leads to a poor prognosis and a prolonged hospital duration [9–12].Early diagnosis and preventive treatment are necessary for patients at high risk of SAP. Therefore, an effective biomarker is needed for risk assessment and early detection of SAP. Neurogenic immunosuppression is one of the critical mechanisms of increased susceptibility to postinfection [13, 14].

Platelet-to-lymphocyte ratio (PLR) is a novel and inexpensive biomarker that reflects systemic inflammation response [15, 16], which is affected by changes in lymphocytes and platelets after acute stroke. PLR is a sensitive marker to predict the occurrence and prognosis of cardiovascular events [16, 17], cerebrovascular diseases [18], poststroke depression [19],and pneumonia [20]. However, the association of PLR with SAP is uncertain. In light of this, we investigated the relationship of PLR with SAP in AIS patients.

In the proposed investigation, we discovered that high PLR is linked to SAP in AIS patients. PLR could be a useful tool for identifying high-risk SAP patients. It is more beneficial to improve results if SAP is detected early and well prevented. PLR was found to be considerably greater in the SAP group than in the non-SAP group in this study.

In the following section, we discuss the section-wise study. Section 2 discusses the materials and methods and also discusses the study subjects, clinical variables collection, laboratory parameters and clinical features, statistical analysis, and results. Section 3 defines the conclusion of the study. Finally, the research work is concluded in Section 4.

2. Materials and Methods

The overall quality of any research dissemination output is evaluated in this section and it reveals to readers what techniques, methodologies, designs, and treatments are used in the research, allowing us to repeat the results.

2.1. Study Subjects. Acute ischemic stroke patients in the Department of Neurology, Beijing Shijitan Hospital, were included in this study between March 1, 2018, and July 31, 2019. The study protocol was approved by the Scientific Research Ethics Committee of Beijing Shijitan Hospital Affiliated with Capital Medical University.

The inclusion criteria for enrolled patients are as follows:

(1) Hospitalization within 72 h after the onset of symptoms
(2) Patients diagnosed as new acute ischemic stroke by imaging examination (cranial magnetic resonance imaging or computed tomography) at the time of admission
(3) Modified Rankin scale (mRS) score<2 before admission
(4) Patients who were not discharged within 3 days before hospitalization

The exclusion criteria are as follows:

(1) The acute infections (vacuities, urinary, and infection of the upper or lower respiratory tract) within 2 weeks before the onset of the stroke
(2) Medical history of cancer, hematologic disease, severe liver and kidney dysfunction, and autoimmune disease

2.2. Clinical Variables Collection. Demographic data obtained at admission include age, sex, and the length of hospitalization. Premorbid history relevant risk factors contain current smoking, coronary heart disease, hypertension, diabetes, previous stroke, and atrial fibrillation.

2.3. Laboratory Parameters and Clinical Features. Within 24 h after admission, peripheral venous blood was collected from the participants and used for immediate biomarker detection. Laboratory data consisted of neutrophils, lymphocytes, platelets, total cholesterol (TC), triglycerides (TG), and low-density lipoprotein cholesterol (LDL-C). The PLR (defined as platelet/lymphocyte) was calculated. The clinical features of patients included dysphagia, the Oxfordshire Community Stroke Project (OCSP), and baseline National Institutes of Health Stroke Scale (NIHSS) score on admission.

According to clinical and laboratory examinations and chest X-ray or CT scan results retrospectively gathered from medical records, SAP was defined as a lower respiratory tract infection within the first 7 days of hospitalization after a stroke [21, 22].

2.4. Statistical Analysis. Normally distributed continuous variables were expressed as the mean ± standard deviation, while nonnormally distributed variables were expressed as the median (interquartile range). The Mann–Whitney *U* test was used to compare the clinical characteristics of continuous variables between groups. The chi-square test was used for categorical variables. Variables with $P < 0.05$ from the results of the univariate analyses were considered confounders in the multivariable logistic regression analysis. The association between different PLR and SAP risks was estimated using univariate analysis and binary logistic regression analysis. All patients were classified into two groups according to their median PLR (126.67), and the potential confounders of PLR were identified. We adjusted all potential confounding factors (parameters with $P < 0.05$ in univariate analysis). The results are presented in the form of an adjusted odds ratio (aOR) and 95% confidence interval (CI).

We conducted the receiver operative curve (ROC) and the area under the curve (AUC) to measure the specificity and sensitivity of PLR and obtained the optimal cutoff value of PLR. Results were considered significant at $P < 0.05$. The analysis of ROC was performed with MedCalc 15.6 (MedCalc Software, Belgium). Other statistical analyses were carried out using SPSS v23 (SPSS Inc., Chicago, IL).

3. Results

A total of 295 consecutive AIS patients were retrospectively included from March 1, 2018, and July 31, 2019, according to the inclusion and exclusion criteria, 40 (13.6%) of whom were diagnosed with SAP in the final analysis (Figure 1). The average age of patients was 69.5 ± 12.0 years, and 196 (66.4%) were male. The median length of hospitalization was 14.0 (11.0, 17.0) days. The comparison of demographic, clinical, and laboratory characteristics is given in Table 1. There were significant differences in age ($P < 0.001$) and baseline NIHSS score ($P < 0.001$) between the SAP group and the non-SAP group. The presence of dysphagia ($P < 0.001$), atrial fibrillation ($P < 0.001$), total anterior circulation infarction (TACI) ($P < 0.001$), and lacunar circulation infarction (LACI) ($P < 0.001$) were significantly different between the two groups. Neutrophil counts and PLR were significantly increased ($P \leq 0.001$; Figure 2), whereas lymphocyte counts and TG were significantly decreased in the SAP group ($P < 0.001$). The number of platelets in the patients with SAP was decreased, although not statistically significant.

The demographic and clinical characteristics (parameters with $P < 0.05$ in univariate analysis) in the high and low PLR groups are given in Table 2. We found that patients with the high PLR had high baseline NIHSS scores ($P = 0.047$) and low TG ($P = 0.004$). The prevalence of dysphagia ($P = 0.020$) was significantly higher in the high PLR group than in the low PLR group.

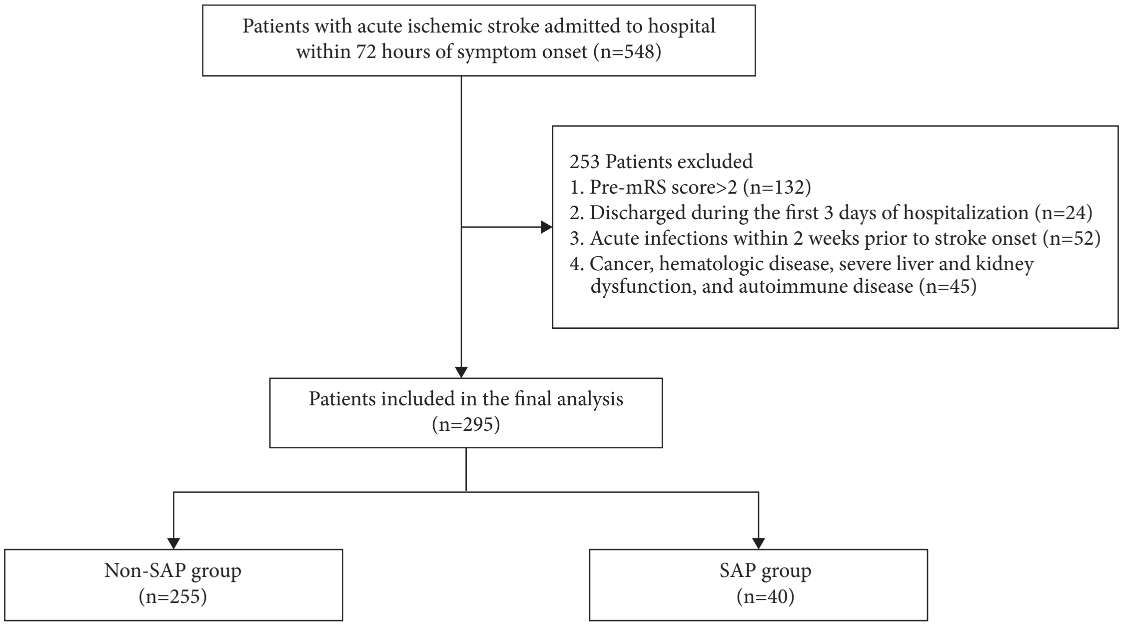

Figure 1: Flow diagram of the patient selection process.

PLR, median (IQR)	126.7 (99.6, 175.3)	123.2 (98.0, 163.8)	161.2 (114.1, 209.2)	0.001 *

NIHSS, National Institute of Health Stroke Scale; OCSP, Oxfordshire Community Stroke Project; TACI, total anterior circulation infarct; PACI, partial anterior circulation infarct; POCI, posterior circulation infarct; LACI, lacunar circulation infarct; TC, total cholesterol; TG, triglycerides; LDL-C, low-density lipoprotein cholesterol; PLT, platelet; PLR, platelet-to-lymphocyte ratio; SD, standard deviation; IQR, interquartile range; SAP, stroke-associated pneumonia. * P values less than 0.05 were considered statistically significant.

In the univariate analysis, the variables with $P < 0.05$ were used as covariates, and SAP was used as a dependent variable. As given in Table 3, after adjusting for the confounders of PLR, multivariate logistic regression analysis showed that PLR (aOR = 1.003, 95% CI: 1.001–1.006, $P = 0.020$), age (aOR = 1.062, 95% CI: 1.023–1.102, $P = 0.002$), and atrial fibrillation (aOR = 3.585, 95% CI: 1.605–8.007, $P = 0.019$) remained associated with SAP. In the ROC analysis, the best cutoff level of PLR was 152.22 ($P = 0.0006$), with 0.575 sensitivity and 0.706 specificity. The area under the ROC curve was 0.663 (95% CI: 0.606–0.717) (Figure 3).

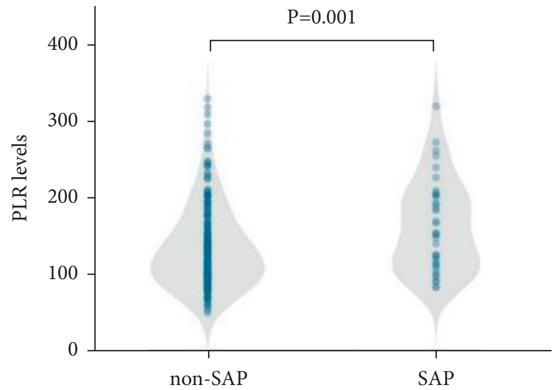

Figure 2: PLR levels and SAP. Violin plot of PLR distribution in patients with SAP and without SAP.

Table 2: Comparison of the characteristics between subgroups based on the median PLR.

Characteristics	Low PLR $N = 147$ (PLR<126.67)	High PLR $N = 148$ (PLR≥126.67)	P value
Age, years, mean ± SD	68.8 ± 12.2	70.0 ± 11.7	0.346
Baseline NIHSS, median (IQR)	3 (1, 5)	4 (2, 8)	0.047*
Dysphagia	17 (11.6)	32 (21.6)	0.020*
Atrial fibrillation, n (%)	17 (11.6)	29 (19.6)	0.057
TG, mmol/L, median (IQR)	1.2 (1.0, 1.8)	1.1 (0.8, 1.6)	0.004*

NIHSS, National Institute of Health Stroke Scale; TG, triglycerides; PLR, platelet-to-lymphocyte ratio; SD, standard deviation; IQR, interquartile range. *P values less than 0.05 were considered statistically significant.

Table 3: Multivariate logistic regression analysis of the associations between PLR and SAP.

Risk factors	B	SE	Wald	P value	aOR	aOR (95% CI)
Age	0.060	0.019	9.819	0.002*	1.062	1.023–1.102
Atrial fibrillation	1.277	0.410	9.699	0.019*	3.585	1.605–8.007
PLR	0.003	0.002	5.393	0.020*	1.003	1.001–1.006

PLR, platelet-to-lymphocyte ratio; SAP, stroke-associated pneumonia; SE, standard error; aOR, adjusted odds ratio. *P values less than 0.05 were considered statistically significant.

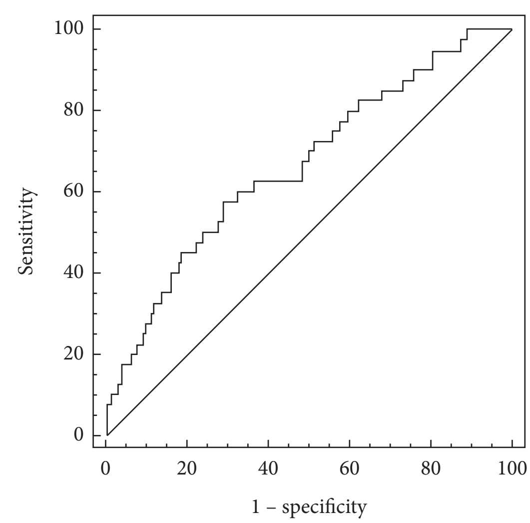

Figure 3: The receiver operating characteristic (ROC) curve analysis of platelet-to-lymphocyte ratio for predicting SAP.

4. Discussion

Based on increasing evidence, researchers reported the predictive effectiveness of PLR in the prognosis of artery diseases [16–18] and inflammation diseases. With reference to the studies by Turkmen et al. and Uslu et al. [23, 24] in the present study, we found that high PLR is associated with SAP in AIS patients. The results of multivariate analysis showed that PLR, a marker of systemic inflammation, is an independent risk factor for SAP, which further confirmed high PLR may be used as an effective indicator of inflammatory diseases.

Platelets have the function of regulating inflammation and immune responses, which play an important role in the formation of thrombosis in the arterial circulation. When AIS occurs, abnormal platelets are overactivated and accumulated [25], which may lead to thrombosis and vascular blockage and then vascular events [26]. Changes in circulating platelet counts are uncertain in diverse diseases. Platelets can increase in many inflammations with an acute phase. In the case of sepsis, the platelet count will increase due to the accelerated expression of platelets after the increase in their breakdown [27]. However, we found the platelet counts were decreased in AIS patients with SAP. There could be three reasons for this observation. The first reason is the particularities of AIS patients. When arterial platelet-fibrin thrombi are formed in AIS patients, a reduction of the circulation platelet counts occurs due to their increased consumption in the infarction area [28]. The second reason is that platelet count in AIS patients may correlate with disease severity. Ming Yang et al. showed that AIS patients in the lowest platelet count quintile had a higher risk of poor functional outcome [29]. In this study, SAP patients were severe, with high admission NIHSS scores, which lead to the reduction of platelet count. The third reason may be the effect of antithrombotic therapy of acute AIS on platelets. IVT using rt-PA influences peripheral blood platelet counts and lymphocyte concentrations, resulting in enhancing infection risk [30].

The lymphocytes belong to the adaptive immune cells, which influence the regulation of the inflammatory response. Lymphocytes were suggested to be a pivotal subtype that determined the severity of neuroinflammation in acute brain injuries. Urra et al. [31] suggested that lymphopenia in the early stages of stroke is a sign of persistent brain damage, stress response, and a greater possibility of infection. In addition, it has been reported that lymphopenia after reperfusion in vascular events can effectively predict the existence of microvascular occlusion in the early stage [32]. Konstantin et al. [33] reported apoptosis of lymphocytes after stroke, and catecholamine-mediated lymphocyte defect played an important role in stroke-associated infection. Recent studies in rodent models have shown that T cells accumulate early in the damaged area within the first 24 hours after the onset of a stroke, which causes lymphopenia in peripheral blood [34]. The stroke-induced lymphocyte apoptosis results in immune system suppression and inflammation [35, 36], shifting from a proinflammatory Th1 type response to an anti-inflammatory Th2 type response. Therefore, stroke causes local inflammation and leads to stroke-induced immunosuppressive syndrome (SIDS) [14]. SIDS then leads to the systemic inflammatory response through endocrine pathways involving the hypothalamic-pituitary-adrenal axis or activation of the sympathetic nervous system [33, 37, 38]. Meanwhile, SIDS results in decreased peripheral blood lymphocyte counts and functional T cell inactivation [39]. The results of this study further supported that lymphopenia caused by immunosuppression after stroke has a potential effect on SAP susceptibility.

PLR is a systemic inflammation index, which is calculated by dividing the platelet count by lymphocyte count. PLR represents the burden of systemic inflammation and combines platelet counts and lymphocytes counts to predict the prognosis of cardiovascular diseases [40] and ischemic stroke [41]. Altintas et al. found that high PLR values could reflect the infarcted size and poor recanalization rate in patients with thrombectomy therapy, supporting the view that PLR represents a prothrombotic inflammatory state [40]. In addition, PLR may provide important information for pulmonary diseases. Kumar et al. [42] showed that PLR could predict the 90-day mortality in patients with acute exacerbations of COPD. The PLR value can guide in diagnosing hypersensitivity pneumonia [43]. Kartal et al. showed that utilization of PLR may differentiate patients with community-acquired pneumonia [44]. Moreover, Jong-Han Lee et al. detected PLR might have diagnostic utilities such as CRP in the evaluation of the severity of pneumonia patients [45]. CRP has been reported to have a significant prognostic value and a useful adjunctive test as well as being a marker of treatment response in inflammation disease. The ability of PLR to predict infectious diseases is further proved by this indirect evidence. PLR was found to be considerably greater in the SAP group than in the non-SAP group in this study. However, Ahmet Adiguzel et al. found no correlation between the PLR level and SAP [46]. The possible reason for the different results is the difference in the severity of the stroke patients included. They included stroke patients with NIHSS >10 who were sicker than the patients in our study. Based on the discussion above, we speculated that there may be a correlation between high PLR and the occurrence of SAP, helping clinicians assess high-risk SAP in clinical works. The followings could be viewed as potential limitations to the study. First, selection bias is a concern because we undertook a single-center retrospective study. This study would have been more convincing if our sample size was enlarged. Second, as a retrospective study, some acute inflammation biomarkers were not incorporated for analysis. This could have a certain impact on the result. We will conduct prospective studies in the future to further prove this conclusion. Third, PLR was only measured at admission. Given the limitations related to the retrospective design, no data evaluating the dynamic change of PLR were available. In future studies, the hematologic markers during hospitalization should be dynamically measured to evaluate the predictive value of PLR for SAP. Fourth, we cannot rule out residual confounding or the effect of unmeasured confounders. Further studies need to record more potential risk factors for SAP.

5. Conclusion

In conclusion, our study showed that high PLR is associated with SAP in AIS patients. PLR may be a promising indicator to identify high-risk SAP patients. High PLR was found to be a risk factor for SAP in AIS patients in this investigation. In ischemic stroke, increased systemic inflammation is connected to SAP. Easy-to-find inflammatory biomarkers could aid in the diagnosis of high-risk SAP patients. It is more beneficial to improve results if SAP is detected early and well prevented.

Objective. To study the effect of Narcotrend monitoring on the incidence of early postoperative cognitive dysfunction (POCD) under different bispectral index (BIS) conditions and the effect of different depths of anesthesia on the incidence of POCD. *Methods*. We performed a literature search of PubMed, Embase, OVID (database system made by Ovid Technologies, USA), CBM (Chinese Biomedical Literature database), CNKI (China National Knowledge Infrastructure), Wanfang, and VIP databases (full-text database of Chinese sci-tech journals), etc., from the date of the establishment of the database until December 31, 2020. Our meta-analysis was focused on the collection and study of Narcotrend monitoring of different depths of anesthesia. We carefully read the abstracts and full texts of randomized controlled trials on the incidence of POCD in the early postoperative period, and their references were tracked. Data extraction and quality evaluation of the included literature were also performed, and RevMan 5.3 software was used for analysis. *Results*. In the end, eight articles were included, with a total of 714 patients. The meta-analysis results showed that four articles (255 patients) compared the state of deep anesthesia (BIS 30–40) with conventional anesthesia (BIS 40–60 earlier) after POCD. Also, the incidence of POCD on the first day after deep anesthesia (Narcotrend stage (NTS): negative correlation is currently the most appropriate EEG description; Nd can subdivide the original EEG into six stages and 15 levels (Nd Sg, NTS), namely, A (state of wakefulness) state, B0 B2 (sedated state), C0 C2 (light anesthetic state), D0 D2 (general anesthesia), and E0–E1) was significantly lower than that of conventional anesthesia (NTS DO–D1) (odds ratio (OR) = 0.21, 95% confidence interval (CI): 0.13–0.35, $P < 0.00001$). Moreover, the incidence of POCD in deep anesthesia (NTS E1) at 7 days after surgery was significantly lower than that of conventional anesthesia (NTS D0) (OR (odds ratio) = 0.45, 95% CI: 0.23–0.91, $P = 0.03$), while the incidence of POCD 7 days after NTS D2 in conventional anesthesia was significantly lower than that of NTS D0 (OR = 0.42, 95% CI: 0.24–0.71, $P = 0.001$). *Discussion*. Deep anesthesia can reduce the incidence of POCD (OR = 0.40, 95% CI: 0.22–0.73, $P = 0.002$). This meta-analysis included three studies (216 patients) that compared the early postoperative POCD incidence of BIS 40–50 under conventional anesthesia and BIS 50–60; the BIS 40–50 did not significantly reduce the incidence of POCD (OR = 1.11, 95% CI: 0.24–5.24, $P = 0.9$). The incidence of POCD under deep anesthesia with Narcotrend monitoring was lower than that under conventional anesthesia.

1. Introduction

Postoperative cognitive dysfunction (POCD) is a postoperative complication of the central nervous system [1]. It is mainly manifested as differing degrees of obstacles such as memory, judgment, thinking, intelligence, orientation, etc., accompanied by a decline in social activity ability, and patients often experience anxiety, confusion, personality changes, and memory loss within 1 to 3 days after surgery. According to reports, the incidence of POCD within 1 week after major noncardiac surgery in elderly patients is as high as 25.8% [2]. Thus, POCD prevention has become a research hotspot, and there is currently no unified view on the impact of the depth of anesthesia on POCD.

This complication not only affects the patient's ability to take care of themselves, but also imposes a great burden on the family and society. As our society enters the aging stage of the population, the number of operations for elderly patients is gradually increasing. Thus, POCD prevention has become a research hotspot. Narcotrend monitoring is a novel anesthesia depth monitoring method that can subdivide the general anesthesia state into six stages and 15 sublevels of EEG (electroencephalogram) (Narcotrend stage, NTS). Among them, NTS D0–D2 (normal anesthesia state) and NTS E0–E2 (deep anesthesia state) are suitable for general anesthesia. The appropriate anesthesia depth can have the least impact on the postoperative cognitive function of the patient.

This study aims to systematically evaluate the effects of Narcotrend monitoring of different depths of anesthesia on POCD in order to provide a reference for clinical applications and further research. Studies have shown that maintaining an intraoperative bispectral index (BIS) value of 30–40 is more conducive to the recovery of early postoperative cognitive function. In this study, a meta-analysis was conducted to systematically evaluate the impact of different BIS values on POCD in order to provide a clinical reference [3].

2. Methods

2.1. Included Data. We performed a literature search for studies comparing Narcotrend monitoring under different BIS conditions in order to compare the incidence of early POCD in different patients. The treatment group received deep anesthesia surgery, while the control group received light anesthesia surgery.

The inclusion criteria were as follows: (I) patients aged >18 years old, without serious heart, liver, lung, nephropathy, or endocrine disease and no history of neuropsychiatry or anesthetic allergy; (II) patients with normal cognitive function before surgery who were planning to undergo elective surgery; and (III) postoperative patients with an incidence of early POCD ranging from 1 to 7 days. The exclusion criteria were as follows: (I) studies that did not provide a specific number of cases of cognitive dysfunction; and (II) studies that involved significant differences in the baseline data between the groups [4].

2.2. Detection Methods. We performed literature searches of the PubMed, Embase, OVID, CBM, CNKI, Wanfang, and VIP databases from the date of establishment of the database to December 2020. The English search terms included depth of anesthesia, postoperative cognitive dysfunction, cognitive function, cognitive dysfunction, cognitive impairments, mental disorders, and cognitive performance. The Chinese search terms included depth of anesthesia and postoperative cognition. There was no language restriction. The references of the retrieved documents were tracked, and the documents that met the inclusion criteria were included [5, 6].

2.3. Data Extraction. Two reviewers independently extracted data and evaluated the quality of the obtained literature. Differences of opinion were resolved by a third party ruling. The following data were extracted: (I) general information of the study, such as first author and year of publication; (II) research methods (such as retrospective research); (III) general information of the research subjects, such as age, gender, and ASA (American Society of Anesthesiologists) classification of the patient; (IV) treatment of the research object, such as the specific anesthesia methods; and (V) research results (such as the evaluation method of the research outcome and the research results (four-grid table data)).

The Jadad scale was used to evaluate the quality of the included literature. The scoring standards are as follows: randomization (0–2 points: 0 points for nondescription, 1 point for random descriptions only, and 2 points for random descriptions of normal methods); blinding method (0–2 points: 0 points for not stated, 1 point for blinding only, and 2 points for double-blind description); and loss to follow-up (including reasons, 0 or 1 point: 0 points for not stated and 1 point for narration). Literature with a score of 7 and a total score of 24 was considered high-quality research [7].

2.4. Statistical Analysis. Statistical analysis was performed using RevMan 5.3 statistical software provided by the Cochrane Collaboration. Measurement data were expressed in terms of the weighted mean difference (WMD) and its 95% confidence interval (CI), and count data were expressed in terms of odds ratio (OR) and its 95% CI. Subgroup and statistical homogeneity analyses were also performed, with $P > 1$ as the homogeneity test level. When the Q statistic of the heterogeneity test was $P > 0.1$, it was considered that there was no obvious heterogeneity between the studies, and the fixed-effects model was used for analysis. However, if the heterogeneity test statistic $P > 0.1$, it was considered that there was heterogeneity between the studies. In these cases, the sources of heterogeneity were divided into subgroups, and a random effects model was used.

3. Results

3.1. Retrieval Results and Quality Evaluation. A total of 551 documents were obtained from the initial search, including 114 from PubMed, 35 from OVID, 117 from CNKI, 97 from CBM, 137 from Wanfang, and 51 from VIP (Figure 1). After carefully reading the abstracts and full texts, a total of eight studies with a total of 714 patients met the inclusion criteria. The basic data of the included studies are shown in Table 1.

3.2. Meta-Analysis Results. A total of three studies compared the incidence of POCD on the first day after deep anesthesia (NTS E0–E1) and conventional anesthesia (NTS D0–D1). There was no significant heterogeneity between the studies

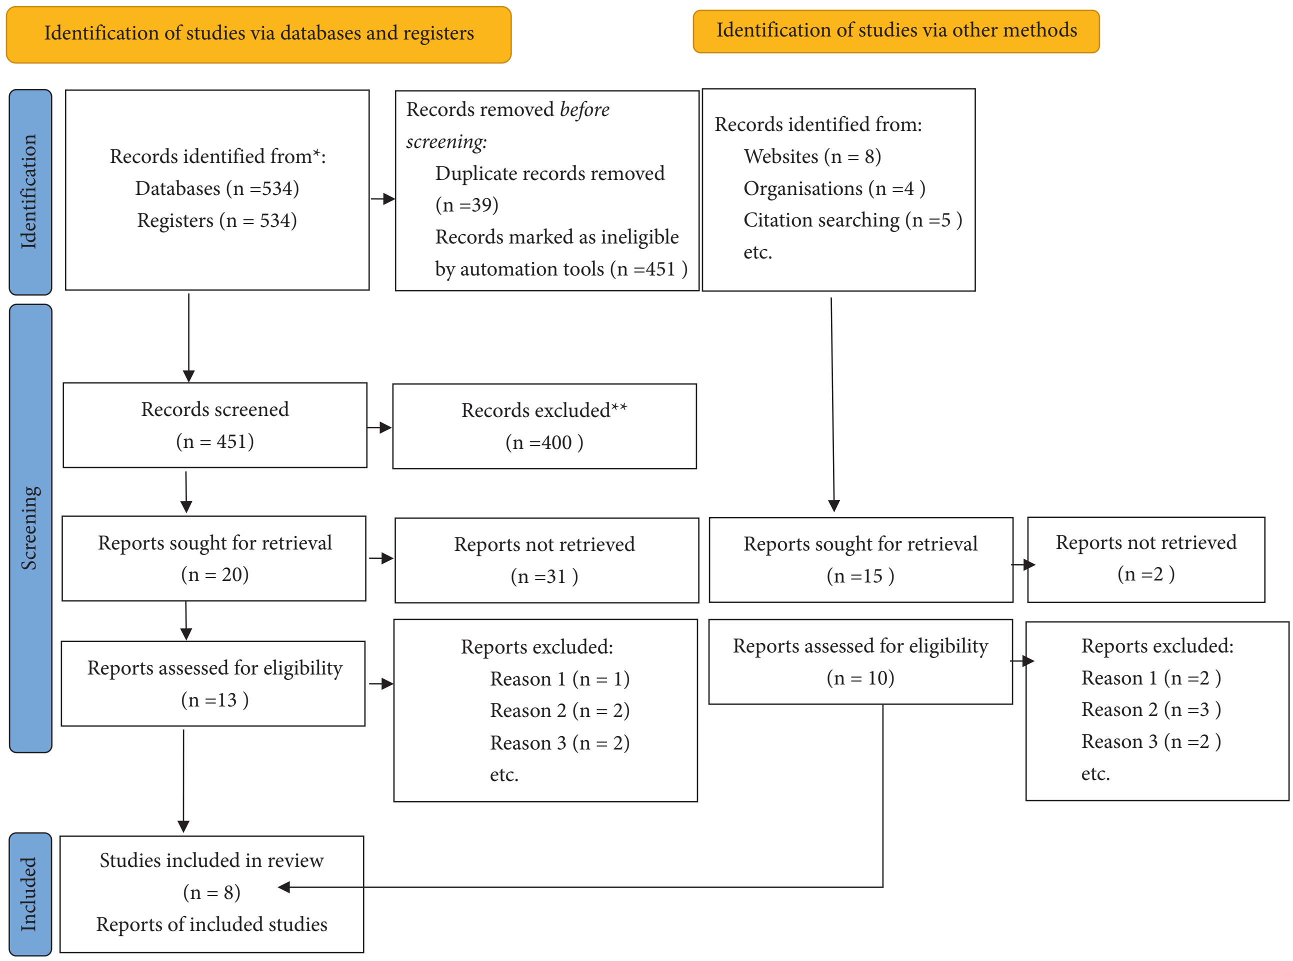

Figure 1: PRISMA flowchart. *Consider, if feasible to do so, reporting the number of records identified from each database or register searched (rather than the total number across all databases/registers). **If automation tools were used, indicate how many records were excluded by a human and how many were excluded by automation tools.

Table 1: Basic characteristics of the included studies.

Study	Age (years)	ASA rating (level)	Type of surgery	Research design	Detection indicator (ASA classification standard for anesthesia)	Detection time
Chengjin Le, 2019	>60	N–M	General anesthesia abdominal surgery	Random number table	(I)	Preoperative 1 day, after 1 day
Tao Feng, 2020	>70	I–M	Laparoscopic radical resection of bowel cancer	Random (unknown method) double-blind	(I), (II), (III), (IV), (V)	7 days before and after operation
Nian Liu, 2019	>60	I–M	Laparoscopic radical resection of bowel cancer	Random number table	(I), (II), (III), (IV), (V)	1 day before operation, 7 days after operation
Dongqing Wu, 2020	≥60	N–M	General anesthesia abdominal surgery	Random number table	(I)	Before operation and 1 day after operation
Yin Kang, 2018	60–92	I–M	Laparoscopic radical resection of bowel cancer	Computer random number method	(I), (II), (III), (IV), (V)	1 day before operation, 7 days after operation
Lingling Li, 2020	60–74	N–M	General anesthesia abdominal surgery	Random number table	(I)	Preoperative 1 day, after 1 day
Jia Deng, 2020	>65	I–N	Abdominal surgery	Random (method unknown)	(I), (VI)	1 day before operation, 7 days after operation
Shan Gao, 2019	3–65	I–N	Upper abdominal general surgery	Random (method unknown)	(I), (VI)	1 day before operation, 7 days after operation

Note: a total of three studies compared the state of deep anesthesia (NTSE1).

(P = 0.94, $I^2 = 0\%$), so a fixed-effects model was used for meta-analysis [8, 9]. The results showed that the incidence of POCD on the first day after deep anesthesia was significantly lower than that of conventional anesthesia (OR = 0.21, 95% CI: 0.13–0.35, $P < 0.00001$) (Figure 2).

Compared with conventional anesthesia (NTS D0), the incidence of POCD at 7 days postoperatively, there was no heterogeneity among the studies (P = 0.94, $I^2 = 0\%$), and the fixed-effects model was used for meta-analysis. The results showed that the incidence of POCD 7 days after deep anesthesia was significantly lower than that of conventional anesthesia (OR = 0.45, 95% CI: 0.23–0.91, P = 0.03) (Figure 3).

A total of five studies compared the incidence of POCD 7 days after surgery of NTS D2 and NTS D0 in conventional anesthesia. There was no heterogeneity among the studies (P = 0.87, $I^2 = 0\%$), and thus the fixed effects model was used for the meta-analysis. The results showed that the NTS POCD incidence of the postoperative NTS D2 group was significantly lower than the NTS D0 group (OR = 0.42, 95% CI: 0.24–0.71, P = 0.001) (Figure 4).

3.3. Sensitivity Analysis. A sensitivity analysis was carried out by changing the model, removing the maximum weight, and removing the minimum weight literature. The results showed that after three changes, the result has little change from the original OR value. Therefore, it can be considered that the sensitivity was low and the results of this study were relatively stable and reliable [10].

In the end, six studies met the inclusion criteria, including five Chinese studies and one English article, with a total of 521 patients. Four studies did not describe the method of random sequence generation, five studies did not describe the hiding of randomized sequences, and none of the studies described whether blinding was used; however, the subjects were blinded (i.e., single-blind) (Table 2). Furthermore, all of the included studies described the reasons for loss to follow-up as well as the treatment of these cases, and it could be considered that there is no incomplete data bias. The methodological quality evaluation of the included studies was detailed in four studies comparing the incidence of POCD on the first day after deep anesthesia (BIS 30–40) and conventional anesthesia (BIS 40–60). There was no heterogeneity among the studies, and the fixed effects model was used for the analysis. The results showed that under deep anesthesia, the incidence of POCD was significantly lower than that under conventional anesthesia (OR = 0.40, 95% CI: 0.22–0.73, P = 0.002) (Figure 5) [11–13].

The incidence of early postoperative POCD was compared between BIS 40–50 and BIS 50–60 in conventional anesthesia. There was heterogeneity among the research results, and thus, the random-effects model was used for analysis (Kant et al.) [14]. The results showed that there were no statistically significant differences in the incidence of early postoperative POCD between BIS 40–50 and BIS 50–60 (OR = 1.11, 95% CI: 0.24–5.24, P = 0.90) (Figure 6).

The deep anesthesia state (BIS 30–40) and the conventional anesthesia state (BIS 40–60) were compared on the third day after surgery, the incidence of POCD. There was no obvious heterogeneity between the studies, and the fixed-effects model was used for analysis. The results showed that after the first three deep anesthesias in anaesthetic-day conventional POCD, the difference in the incidence was not statistical significance (OR = 0.47, 95% CI: 0.13–1.71, P = 0.25) (Figure 7).

4. Discussion

At present, the pathogenesis of POCD is not clear. It may be based on the ageing of the nervous system, which is induced or aggravated by adverse stresses such as anesthesia and surgical trauma. Although the depth of anesthesia may have a certain relationship with the occurrence of POCD, there is currently no unified view. The intervention measures of this article are to perform anesthesia and surgical operations on patients, so it is difficult to double-blind the study subjects [14].

In this study, six articles with different BIS values were systematically evaluated, and the effects of different BIS values on the incidence of early postoperative POCD were compared. Four studies compared deep anesthesia (BIS 30–40) and general anesthesia (BIS 40–60) after the first day. At 1 day postoperatively, the incidence of POCD was significantly lower under general anesthesia than under deep anesthesia.

Systematic analysis of conventional anesthesia states such as BIS 40–50 and 50–60 showed that there was heterogeneity between the included studies. After analyzing and processing the existing heterogeneity, the results showed that there was no significant difference in the incidence of POCD under conventional anesthesia. This may be due to different studies using different surgical methods and anesthesia protocols. In addition, the sample size of this study is too small, which leads to deviations in the results.

This study further compared the incidence of POCD on the 3rd day after surgery under deep anesthesia (BIS 30–40) and conventional anesthesia (BIS 40–60), and the results showed that there was no significant difference between the two methods. This result may be compared with the literature method included in the study; poor learning quality is related to factors such as small sample size. Therefore, it is necessary to design more large-sample and high-quality randomized controlled trials for further systematic analysis.

In addition, this study found that under deep anesthesia, such as when BIS was 30–40, the incidence of POCD in the early postoperative period was lower than that of conventional anesthesia, which is consistent with the research conclusions. Previous studies have shown that deep anesthesia can significantly reduce the cerebral oxygen metabolism rate, thereby reducing the incidence of POCD in patients. Other studies have shown that deep anesthesia can inhibit the levels of cortisol, epinephrine, norepinephrine, etc., and reduce the body's stress response [15–17].

In summary, deep anesthesia has a certain effect on reducing POCD in the early postoperative period. However,

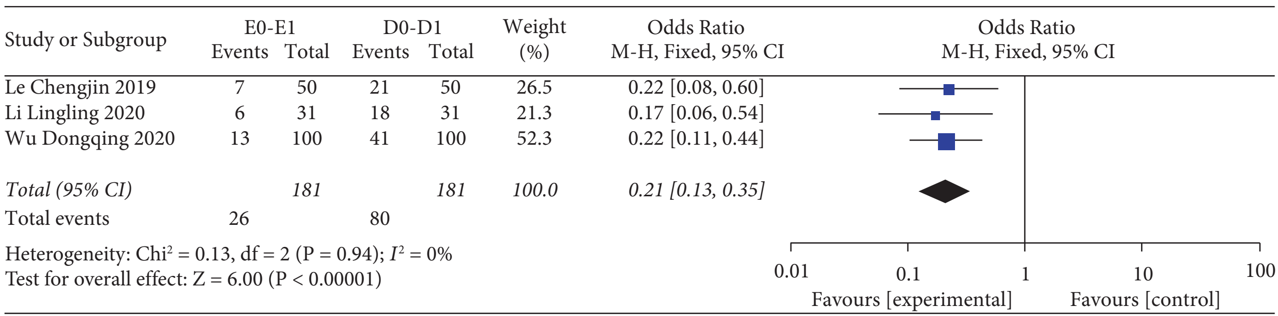

Figure 2: Forest plot of POCD incidence on day 1 after deep anesthesia and conventional anesthesia. POCD, postoperative cognitive dysfunction.

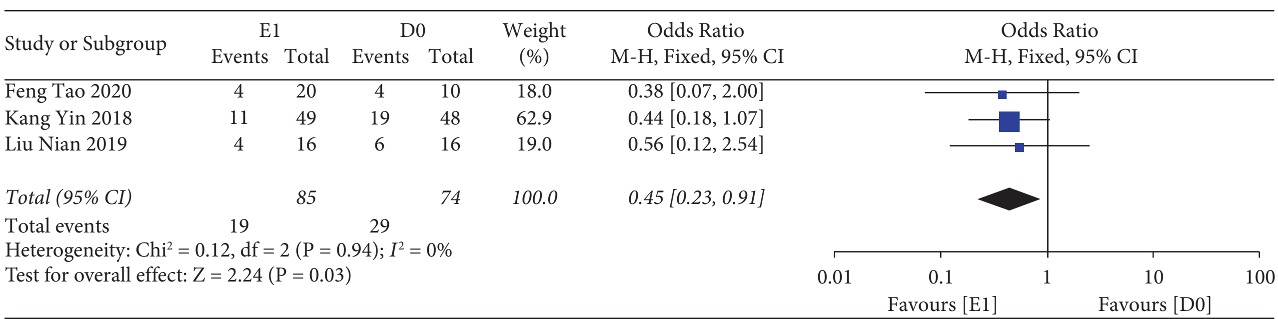

Figure 3: Forest plot of the incidence of POCD at 7 days after deep anesthesia and conventional anesthesia. POCD, postoperative cognitive dysfunction.

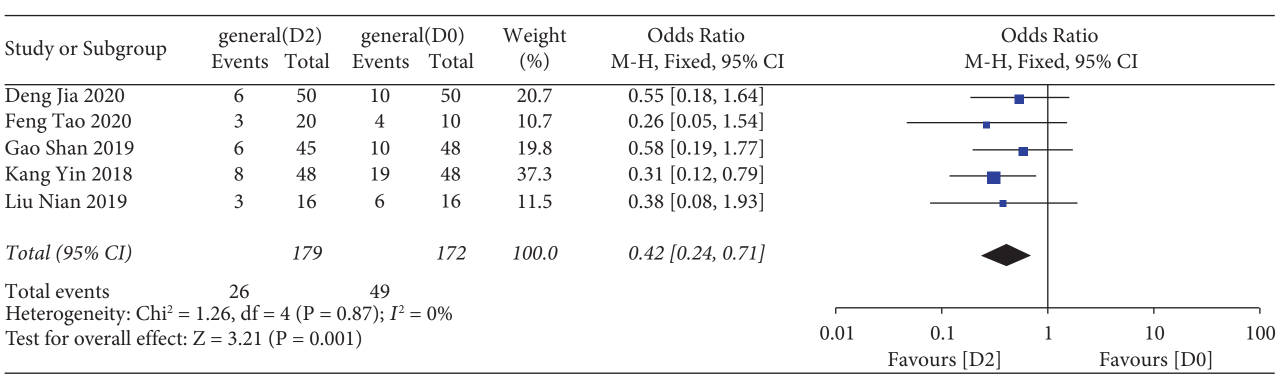

Figure 4: Forest plot of POCD incidence at 7 days after NTS D2 and NTS D0. POCD, postoperative cognitive dysfunction; NTS, XXXXX. NTS: negative correlation is currently the most appropriate EEG description; Nd can subdivide the original EEG into six stages and 15 levels (Nd Sg, NTS), or A (state of wakefulness) state, B0 B2 (sedated state), C0 C2 (light anesthetic state), and D0 D2 (general anesthesia).

Bo Hong, 2020	Not sure	Not sure	Not sure	Without	3

due to the lack of multicenter studies in the literature included in this study, as well as the insufficient number and quality of randomized controlled trials, it was impossible to compare the incidence on the third or even the seventh day after surgery. Therefore, it is necessary to further develop rigorously designed and high-quality randomized controlled trials [18, 19].

POCD is the result of a combination of multiple factors, including the preoperative application of anticholinergic drugs, the patient's age, the preoperative underlying disease,

the type of operation, the method and duration of anesthesia, the depth of anesthesia, as well as intraoperative hypotension and hypoxia. Older age is a definite influencing factor for the occurrence of POCD; the older the age, the higher the incidence of POCD and the longer the duration. The application of Narcotrend to select an appropriate depth of anesthesia is more conducive to reducing the incidence of various adverse reactions. Therefore, more attention should be paid to the influence of different depths of anesthesia on POCD [20, 21].

Narcotrend anesthesia trend is a new type of EEG/consciousness depth monitoring system with a professional EEG signal collection amplifier, which can accurately collect, monitor, and analyze real-time EEG signals at any position of the brain through ordinary ECG electrodes. Studies in China and abroad have found that Narcotrend can accurately reflect the changes in the depth of anesthesia during intravenous and inhalation anesthesia, and the depth of anesthesia is negatively correlated with NTS, which is currently the most suitable description for EEG [22, 23].

Narcotrend can subdivide the original EEG into six stages and 15 levels (NTS), namely, A (awake state), B0–B2 (sedation state), C0–C2 (light anesthesia state), D0–D2 (conventional anesthesia state), E0–E2 (deep anesthesia state), and F0–F2 (burst suppression state), and use the 0–100 dimensionless anesthesia depth index (Narcotrend index (NI)) to reflect the whole process from awake to deep anesthesia. Compared with BIS, Narcotrend not only distinguishes the state of consciousness over a large span but also provides the advantage of monitoring sudden changes in the depth of anesthesia [24, 25].

This study included eight articles and compared the effects of Narcotrend monitoring of different depths of anesthesia on POCD. The results showed that the incidence of early postoperative POCD under Narcotrend monitoring of deep anesthesia (E0–E1) was significantly lower than that of conventional anesthesia (D0–D1). The depth of anesthesia was maintained at the level of NTS D2 under conventional anesthesia. Compared with NTS D0, the incidence of postoperative POCD was significantly reduced.

Whether anesthesia has adverse effects on cognitive function is an area of particular interest for clinical anesthesiologists. The mechanism of deep anesthesia to protect cognitive function remains unclear. It may be that deep anesthesia reduces brain metabolism and produces neuroprotective effects, which further reduces the incidence of POCD in patients. In addition, surgery to stimulate the body's release of inflammatory factors and activation of glial cells can cause POCD cold. Studies such as FIDALGO have shown that an appropriate depth of anesthesia can also inhibit the inflammatory stress response and help protect the brain. However, in recent years, there have been limitations and controversies in the monitoring of the depth of anesthesia, and there are still reports of the awakening of patients under deep anesthesia. Therefore, this requires further study.

This systematic review has certain limitations that should be noted. At present, there are few studies on Narcotrend monitoring the influence of different depths of anesthesia on POCD in China and abroad. Due to the high literature requirements for meta-analysis, only eight articles met the final inclusion criteria. The sample sizes and the numbers of studies are insufficient, and thus, more large-sample and high-quality multicenter studies and randomized controlled trials need to be designed for further systematic analysis. In addition, due to the particularity of the anesthesia and surgeries to be performed on patients, it was difficult to implement rigorous blinding of the study subjects. The inclusion criteria did not report the allocation concealment, so the results of this study should be cautiously interpreted and applied [26].

In conclusion, deep anesthesia under Narcotrend monitoring can reduce the occurrence of early postoperative POCD, which can provide certain evidence-based medical assistance for the clinical work of anesthesiologists. Thus, deep anesthesia has a certain mitigating effect on POCD in the early postoperative period. However, the literature included in this study lacks multicenter research as well as a comparison of the incidences on postoperative days 3 or even 7, and therefore, more well-designed, high-quality controlled trials are needed to validate our findings.

Objective. To explore the intracytoplasmic sperm injection (ICSI) and *in vitro* fertilization (IVF) method on the clinical outcomes of infertile women with ≤3 eggs retrieved. *Study Design*. We retrospectively analyzed a cohort of female patients who received IVF/ICSI to assist pregnancy with retrieved eggs ≤3. The general conditions, i.e., two pronuclei (2PN) fertilization rate, abnormal fertilization rate, high-quality embryo rate, cycle cancellation rate, pregnancy rate of fresh embryo transfer, cumulative pregnancy rate, and miscarriage were compared between the two groups. *Results*. When the number of retrieved eggs was one, the fertilization rate of 2PN was higher and the cycle cancellation rate was lower in the ICSI group than in the IVF group ($P < 0.05$). The pregnancy rates of fresh embryo transfer, frozen-thawed embryo transfer, and the cumulative pregnancy rate were all higher in the ICSI group than in the IVF group ($P < 0.05$). When the number of retrieved eggs was two, the pregnancy rate of frozen-thawed embryo transfer and cumulative pregnancy rate in the ICSI group were higher than those in the IVF group ($P < 0.05$). When the number of retrieved eggs was three, the fertilization rate of 2PN and the pregnancy rate of frozen-thawed embryo transfer were higher in the ICSI group than those in the IVF group (all ($P < 0.05$)). *Conclusions*. For patients with one egg retrieved, ICSI fertilization can reduce abnormal fertilization rate and cycle cancellation rate and improve cumulative pregnancy rate significantly enhancing patients' benefits. However, increasing the number of eggs retrieved decreases the advantages of ICSI fertilization.

1. Introduction

With the development of assisted reproductive technology (ART), the clinical pregnancy rate has gradually increased. Studies have shown that the clinical pregnancy rate increases with the number of retrieved eggs [1, 2]. However, patients with decreased ovarian reserve function and low ovarian response have fewer eggs retrieved in a single operation, which is often less than or equal to 3. In these patients, fewer embryos can be transferred and the pregnancy rate is low [3]. Multiple egg retrieval operations are needed to achieve a successful pregnancy ultimately increasing the trauma of patients [4]. At present, the problem that needs to be solved is to improve the effective utilization of eggs when the number of eggs retrieved is low. An effective approach is to reduce the occurrence of abnormal fertilization, such as the occurrence of fertilization failure (zero pronucleus, 0PN) and multiple pronuclei (multi-PN, MPN) [5].

Intracytoplasmic sperm injection (ICSI) technology has been applied to non-male-derived infertility in the world, such as preimplantation genetic testing, failure of more than two ART assisted pregnancies, less than 5 eggs retrieved, patients ≥38 years old, and unexplained infertility [6]. The National Assisted Reproductive Technology Surveillance System (NASS) reported that the utilization rate of ICSI for male infertility had increased from 76.3% to 93.93% between 1996 and 2012. The utilization rate of ICSI in nonmale factor caused infertility had increased from 15.4% to 66.9% [7]. However, since ICSI is an invasive procedure, experts have different opinions on whether ICSI should be applied to patients with fewer eggs retrieved [8, 9]. In China, ICSI indications are relatively strictly controlled, and the increase of ICSI application rate is not as significant as that in Western countries. Scientists have discussed for many years whether ICSI indications should be extended to low retrieved egg number, poor fertilization history, and unexplained infertility. However, the conclusions remain controversial [10]. For the pregnancy outcome of patients with retrieved eggs ≤3, some studies suggest that ICSI can reduce the abnormal fertilization rate and cycle cancellation rate and improve the number of transferrable embryos and pregnancy rate [11, 12]. Other studies suggest that ICSI and IVF have no difference in pregnancy outcomes [13, 14]. Therefore, we retrospectively analyzed patients with retrieved egg number ≤3 and divided them into an ICSI group and an IVF group according to different fertilization methods they received. We matched the patients in the two groups based on age and ovulation induction scheme to reduce selection bias. By comparing the mature egg (MII) rate, 2PN fertilization rate, abnormal fertilization rate, high-quality embryo rate, cycle cancellation rate, pregnancy rate of fresh embryo transfer, miscarriage rate, cumulative pregnancy rate, and cumulative miscarriage rate, we investigated the effects of ICSI and IVF on the pregnancy outcomes of patients with retrieved eggs ≤3.

2. Materials and Methods

2.1. Research Subjects. This study was approved by the Ethics Committee of Qingdao University-affiliated Yantai Yuhuangding Hospital. All patients signed IVF or ICSI informed consent forms. Infertility patients who received IVF/ICSI in the Department of Reproductive Medicine, Qingdao University-affiliated Yantai Yuhuangding Hospital between January 2017 and June 2020 were selected for this study. Patients' inclusion was based on the following: (1) ≤3 retrieved eggs; (2) no abnormality in uterus and hysteroscopy showed that the endometrium was normal; (3) pituitary prolactin (PRL) was within normal range (6.0 ng/ml 29.9 ng/ml); and (4) normal thyroid function. Patients with (1) 42 years of age or above; (2) suffering from diabetes, hypertension, or other uncontrolled medical complications; and (3) received preimplantation genetic testing (PGT) were excluded from this study.

3. Research Methods

3.1. Grouping. The patients were divided into an ICSI group and an IVF group according to the different fertilization methods they received. After screening by inclusion and exclusion criteria, 326 cycles were included in the ICSI group, and 2,086 cycles that had ≤3 retrieved eggs were included in the IVF group.

3.2. Ovulation Induction Process. Ovulation induction treatment included microstimulation treatment, antagonist treatment, and natural cycle IVF.

(i) Microstimulation treatment: on the second day of the menstrual cycle, letrozole (0.5 mg/tablet, Furui, Hengrui Medicine, China) was given orally at 5 mg/d for 5 days After five days of letrozole treatment, urinary follicle stimulating hormone (75 IU/package, Lishenbao, Lizhu Medicine, China) for injection was initiated. The initial dose was 150–300 IU/d and continued until the day of HCG.

(ii) Antagonist treatment: on the second day of menstrual cycle, recombinant human follicle stimulating hormone (rFSH, 600 IU/package, Puregon, Organon, the Netherlands) was injected daily. The initial dose was 150–300 IU/d, and the dosage was adjusted according to the patient's condition until the maximum follicle diameter was 12 mm or E_2 level was higher than 1,468 pmol/L. Subsequently, GnRH antagonist (Ganirelix, 0.25 mg/package, MSD, USA) 0.25 mg/d was added to the treatment schedule until the day of HCG.

Follicular development was monitored by transvaginal ultrasound. When the diameter of at least one or two follicles was ≥1.8 cm, human chorionic gonadotrophin (hCG, 2,000 IU/package, Lizhu, Zhuhai, China) at 6,000 IU was injected subcutaneously to the patient. After 36 h, ultrasound-guided transvaginal egg retrieval was performed.

3.3. Fertilization and Embryo Transfer. IVF or ICSI was used according to the quality of semen. In IVF, 50 ul microdrop insemination technique was used. Sperm at the insemination concentration of 10,000 sperm/50 ul was added into the microdrop in insemination dish using a Pasteur pipette, and one oocyte was added to each microdrop. Before ICSI insemination, oocytes were degranulated. MII-stage oocytes were selected for ICSI insemination. After immobilization, the sperm was aspirated into an injection needle so that the sperm head was located at the tip of the injection needle. The tip of the needle was moved into the droplet containing an oocyte. The oocyte was fixed with the fix needle so that the first polar body was located at 11–12 o'clock position or 6 o'clock position. Next, the injection needle passed through the zona pellucida and entered the cytoplasm of the oocyte. After the oocyte membrane was broken, the sperm was slowly injected into the central area of the oocyte, and then, the injection needle was slowly withdrawn.

On the third day after oocyte retrieval, one or two embryos were transferred to the uterine cavity of the patient and the remaining embryos were cryopreserved. After embryo transfer, progesterone soft capsule (Utrogestan, 100 mg/capsule, Laboratoires Besins International, France) at 200 mg was given intravaginally, once every 8 h for luteal support. On the 14th day following embryo transfer, hCG levels of the patients were determined. The level of hCG >5.0 IU/L was considered biochemical pregnancy. On the 35th day after the embryo transfer, patients received ultrasonography, the appearance of the gestational sac confirmed clinical pregnancy. For frozen-thawed embryo transfer (FET), patients with regular menstrual cycle were treated with natural cycle plan for endometrial preparation, while patients with irregular menstrual cycles were treated with hormone replacement plan for endometrial preparation. The embryo transfer criterium was based on that the endometrium should be ≥8 mm with homogeneous echo.

3.4. Observation Index. The general conditions of the patients, including age, duration of infertility, type of infertility (primary/secondary), basic FSH, basic E_2, BMI, AMH, ovulation induction scheme, and abnormal semen of the male were observed. Laboratory and clinical outcomes were recorded, including MII rate (number of mature eggs/number of retrieved eggs), 2PN fertilization rate (2PN fertilized eggs/number of mature eggs), fertilization failure rate (number of mature eggs−number of 2PN fertilized eggs/number of mature eggs), high-quality embryo rate (number of high-quality embryos/number of 2PN cleaved embryos), cycle cancellation rate, pregnancy rate and miscarriage rate of fresh embryo transfer, pregnancy rate and miscarriage rate of frozen-thawed embryo transfer, miscarriage rate, and cumulative pregnancy rate. In this study, normal fertilization was defined as zygotes with 2PN following ICSI or IVF. Fertilization failure was defined as zero oocytes reaching the zygote stage with 2PN. The cycle cancellation rate only referred to the cycle cancelled due to the absence of transferrable embryos because of the failure of fertilization. The cumulative pregnancy rate referred to the total number of pregnancies achieved in all egg retrieval cycles analyzed in this study with normally fertilized embryos following fresh embryo transfer and frozen-thawed embryo transfer.

3.5. Statistical Analysis. The statistical software package (SPSS 20.0) was employed for statistical processing and analysis. Mean ± standard deviation ($\overline{x} \pm s$) was used for expressing measurement data, while percentage (%) was used for expressing count data. The analysis of the measurement data was carried out using independent sample *t*-test, while Fisher exact test and chi-square test were employed for the analysis of count data. ($P < 0.05$) was considered statistically significant.

4. Results

4.1. Comparison of General Data between the ICSI Group and IVF Group. After screening using inclusion and exclusion criteria, there were 326 cycles in the ICSI group and 2,086 cycles in the IVF group. There were no significant differences in age, infertility duration, body mass index (BMI), basic E_2, AMH, and ovulation induction scheme between the two groups with ($P > 0.05$) suggesting that the two groups were similar in terms of basic characteristics. However, the proportion of primary infertility was higher in the ICSI group than that in the IVF group ($P < 0.05$). The basic FSH value was higher in the ICSI group than that in the IVF group ($P < 0.05$). The proportion of abnormal semen of males in the ICSI group was also higher than that in the IVF group ($P < 0.05$). The details of patients' demographics and other characteristics are shown in Table 1.

4.2. Comparison of the Clinical Outcomes between the ICSI Group and IVF Group When ≤3 Eggs Were Retrieved. The fertilization rate of 2PN was higher in the ICSI group than that in the IVF group ($P < 0.05$). The cycle cancellation rate was markedly higher in the IVF group than that in the ICSI group ($P < 0.05$). The pregnancy rate and cumulative pregnancy rate were both higher in the ICSI group than that in the IVF group (($P < 0.05$), Table 2).

4.3. Comparison between the ICSI Group and IVF Group When the Number of Retrieved Eggs Were One, Two, and Three, Respectively. When the number of retrieved eggs was one, the fertilization rate of 2PN was higher in the ICSI group than that in the IVF group ($P < 0.05$). The cycle cancellation rate was higher in the IVF group than that in the ICSI group ($P < 0.05$). The pregnancy rates of fresh embryo transfer and frozen-thawed embryo transfer as well as cumulative pregnancy rate were all significantly higher in the ICSI group than that in the IVF group ($P < 0.05$).

When the number of retrieved eggs was two, the pregnancy rate of frozen-thawed embryo transfer and cumulative pregnancy rate were higher in the ICSI group than that in the IVF group ($P < 0.05$).

When the number of retrieved eggs was three, the fertilization rate of 2PN was significantly higher in the ICSI group than that in the IVF group ($P < 0.05$). The pregnancy rate of frozen-thawed embryo transfer was higher in the ICSI group than in the IVF group ($P < 0.05$). Detailed comparison between the groups is shown in Table 3.

5. Discussion

In the IVF cycle, if all or most of the eggs are not fertilized or fertilized abnormally and there is no transferrable embryo, it will bring a double blow to the patient economically and mentally [15]. The key to successful pregnancy for patients with ≤3 eggs retrieved is to obtain as many transferrable embryos as possible. The premise of obtaining transferrable embryo is to obtain normally fertilized embryo. Most of the patients whose number of retrieved eggs is ≤3 have poor ovarian function and low ovarian response. Studies have shown that the live birth rate in patients with poor ovarian function decreases. However, with the increase of the number of retrieved eggs, the cumulative live birth rate increases. At the same time, the proportion of cycles cancellation due to the lack of transferrable embryos decreases significantly [1]. Patients with ovarian dysfunction and low ovarian response often need multiple egg retrieval to achieve pregnancy. Multiple egg retrieval operations can cause enormous physical and psychological trauma and economic burden to the patients. How to improve the effective utilization of retrieved eggs and increase the pregnancy rate of patients with ≤3 retrieved eggs was the focus of this study.

According to the statistics of 2,414 cycles, the proportion of primary infertility was higher in the ICSI group than that

Table 1: Comparison of the general data between the ICSI group and IVF group.

Index	ICSI group $n = 326$	IVF group $n = 2086$	F/x^2	P value
Age (years, $\overline{x} \pm s$)	34.88 ± 3.82	35.11 ± 4.03	1.248	0.348

*(0PN + 1PN + multi-PN) fertilization. **Cancellation of cycles due to abnormal fertilization (multi-PN fertilization in the IVF group and 0PN + 1PN + multi-PN fertilization in the ICSI group).

in the IVF group. This is because the proportion of poor semen quality in the ICSI group was higher than that in the IVF group, and the proportion of infertility caused by male factors was also higher in the ICSI group. The basic FSH value in ICSI group was higher than that in the IVF group (11.49 ± 5.89 vs 10.55 ± 76) ($P < 0.05$). However, the number of eggs retrieved in enrolled patients was fixed, and there was no statistical difference in ovulation induction treatment and AMH value. Therefore, the basic FSH value had no impact on this study. The basic FSH values of the two groups were both higher than 10 IU/L, and the AMH values were both less than 1 ng/ml, suggesting that the ovarian reserve function was decreased in both groups.

In this study, in patients with ≤3 eggs retrieved, the 2PN fertilization rate was higher in the ICSI group than that in the IVF group ($P < 0.05$), while the cycle cancellation rate was higher in the IVF group than in the ICSI group ($P < 0.05$). The pregnancy rate of frozen-thawed embryo transfer and cumulative pregnancy rate were both higher in the ICSI group than in the IVF group ($P < 0.05$). However, after further grouping patients according to the number of retrieved eggs (one, two, and three), we found when the number of retrieved eggs was one that the pregnancy rates of fresh embryo transfer and frozen-thawed embryo transfer, and the cumulative pregnancy rate were all higher in the ICSI group than that in the IVF group ($P < 0.05$). When the number of retrieved eggs was two, the pregnancy rate of frozen-thawed embryo transfer and cumulative pregnancy rate of the ICSI group were higher than those of the IVF group ($P < 0.05$). When the number of retrieved eggs was three, the pregnancy rate of frozen-thawed embryo transfer in the ICSI group was higher than that of the IVF group ($P < 0.05$). Cycle cancellation can be caused by many reasons, including luteal phase ovulation induction, thin endometrium, and abnormal fertilization. Therefore, abnormal fertilization-caused cycle cancellation should be analyzed separately to reflect the difference of clinical outcomes caused by different fertilization methods. In this study, in

$P < 0.05$ was considered that the difference was statistically significant. *(0PN+ 1PN + multi-PN) fertilization. **Cancellation of cycles due to abnormal fertilization (multi-PN fertilization in the IVF group and 0PN + 1PN + multi-PN fertilization in the ICSI group).

patients with one egg retrieved, 22.87% (177 cycles) of IVF group patients and 14.29% (17 cycles) of the ICSI group patients were cancelled due to abnormal fertilization. The patients who had no transferrable embryos due to abnormal fertilization needed to receive another ovulation induction and egg retrieval operation. The patients who have less transferrable embryos due to abnormal fertilization will lose the chance of frozen-thawed embryo transfer, which will reduce the cumulative pregnancy rate. It suggested that ICSI is a better fertilization method for patients with one egg retrieved.

In general, ICSI is more beneficial than IVF in patients with one egg retrieved when compared with patients with two or three eggs retrieved. It not only can improve the cumulative pregnancy rate and reduce the cycle cancellation rate but also can reduce the potential risk and trauma of multiple egg retrieval operations. In previous studies, whether ICSI can improve the pregnancy outcome of patients with ≤3 eggs retrieved remains controversial. Some researchers believe that ICSI can improve the number of transferrable embryos and the pregnancy rate [11, 12]. Some others consider that compared with IVF, ICSI has no significant impact on pregnancy outcome [13, 14]. In previous studies, it may be because the number of cycles with one, two, and three eggs retrieved was not consistent, e.g., there were more patients in the group with one egg retrieved. ICSI can provide more transferrable embryos and improve the cumulative pregnancy rate. ICSI can improve pregnancy outcome. In contrast, when most patients had 2 or ≥3 eggs retrieved, ICSI-provided improvement of pregnancy outcome was limited, which may be the reason for inconsistent statistical outcomes.

According to literature reports, in women with advanced age and nonmale factor infertility, ICSI does not significantly improve the embryo quality and clinical outcomes [16, 17]. Our study indicated that in patients with nonmale infertility, advanced age is not a criterion for whether choose ICSI as *in vitro* fertilization method. Patients with advanced ages can also obtain more than three embryos. Low number of retrieved eggs is the criterion for ICSI fertilization.

The damage of ICSI to oocytes remains controversial, and there is no clear evidence to show that ICSI can affect the health of offspring [18, 19]. In our study, when patients with ≤3 eggs retrieved, high-quality embryo rate was 56.70% in the ICSI group and 56.74% in the IVF group. There was no significant difference between the two groups. This result suggests that ICSI does not damage the quality of embryo. The miscarriage rate of fresh embryo transfer was 13.33% in the ICSI group and 15.17% in the IVF group, with no significant difference between the two groups. Regarding frozen-thawed embryo transfer, the miscarriage rate in the ICSI group and IVF group was 14.61% and 10.16%, respectively, with no significant difference between the two groups. The cumulative miscarriage rates were also similar between the two groups (14.29% in the ICSI group vs. 13.07% in the IVF group). These data suggest that ICSI does not increase the miscarriage rate. We will continue to track the impact of ICSI on the health of offspring.

The limitations of this study are as follows: (1) The difference between groups was not completely eliminated, especially the semen quality of the male, which is also a factor affecting the quality of pregnancy. Our next study is to use the randomized controlled trial (RCT) method to group patients to eliminate selection bias. (2) The dataset analyzed in this study was from a single center. Thus, the data are of limitation. The analytic results cannot represent the overall situation. However, our findings still provide a reference for clinical practice.

6. Conclusion

Patients with ovarian dysfunction and low ovarian response often need multiple egg retrieval to achieve pregnancy causing enormous physical and psychological trauma and economic burden to the patients. This study focused on the comparison of ICSI and IVF as effective utilization of retrieved eggs and increasing the pregnancy rate of patients with ≤3 retrieved eggs. Results of this study results show that for infertility patients with ≤3 eggs retrieved, ICSI can improve the normal fertilization rate and reduce the cycle cancellation rate caused by fertilization failure. In particular, for patients with one egg retrieved, the benefits of one egg retrieval cycle can be maximized so as to reduce the trauma and complications caused by multiple egg retrieval operations. However, with increased number of eggs retrieved, the advantages of ICSI fertilization decrease.

Data Availability

All the data generated or analyzed during this study are available from the corresponding author upon reasonable request.

Ethical Approval

The Ethics Committee of Qingdao University-affiliated Yantai Yuhuangding Hospital approved the current study.

Consent

All patients signed the IVF or ICSI informed consent form.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

All authors designed the study, evaluated the results, reviewed the manuscript, and approved the draft of the final manuscript. Shuang Wang played a major role in the manuscript's writing and carrying out the statistical analysis. Shuang Wang and Xiaoyan Zhang contributed equally to this work.

Retraction

Retracted: Clinical Efficacy and Safety of Percutaneous Spinal Endoscopy versus Traditional Open Surgery for Lumbar Disc Herniation: Systematic Review and Meta-Analysis

Journal of Healthcare Engineering

Received 27 January 2023; Accepted 27 January 2023; Published 2 February 2023

Journal of Healthcare Engineering has retracted the article titled "Clinical Efficacy and Safety of Percutaneous Spinal Endoscopy versus Traditional Open Surgery for Lumbar Disc Herniation: Systematic Review and Meta-Analysis" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

The authors do not agree to the retraction.

Objective. Systematic analysis of the incidence of percutaneous spinal endoscopic technique and traditional open surgery for lumbar disc herniation. *Methods*. A randomized controlled trial (RCT) and cohort study on complications related to traditional open surgery was searched on the MEDLINE, Cochrane Library, PubMed, Web of Science, Chinese journal full-text database (CNKI), Wanfang, and Embase database. Language is not limited. The quality of each study was evaluated, various complications were compiled into electronic baseline tables, and the data from these studies were available. Meta-analysis and synthesis were performed with the RevMan 5.3 software to evaluate the statistical significance of both surgical techniques in terms of various complications. *Results*. 12 studies were eventually included, and a total of 2,797 patients were included in the analysis. Meta-analysis results showed that there was no statistical difference in postoperative paresthesia between percutaneous spinal endoscopy and traditional open surgery (OR = 1.17, 95% CI (0.82, 1.66), $P = 0.38$, $I^2 = 0\%$, $Z = 0.88$), direct nerve root damage (OR = 0.79, 95% CI (0.58, 1.07), $P = 0.13$, $I^2 = 73\%$, $Z = 1.52$), and intraoperative hemorrhage and hematoma formation (OR = 1.00, 95% CI (0.67, 1.48), $P = 0.99$, $I^2 = 0\%$, $Z = 0.02$), but there was a statistical difference in disc recurrence (OR = 2.24, 95% CI (1.56, 3.21), $P < 0.0001$, $I^2 = 81\%$, $Z = 4.39$). *Conclusion*. Compared with the traditional open surgical treatment of lumbar disc herniation, percutaneous spinal endoscopic technology has obvious advantages in reducing nerve root injury, dural injury, and surgical area wound complications, but it is limited to preventing the technical characteristics of the surgical site, which is worse than that of open surgery.

1. Introduction

With the development of the time, the continuous promotion of the concept of minimally invasive surgery and the rapid development of surgical instruments, the increasingly mature minimally invasive spine technology has begun to attract attention [1]. Xin et al. [2] has treated the lumbar disc herniation (percutaneous endoscopic lumbar decompression, PELD, with the use of a combined percutaneous spinal endoscopic system with wide-angle visual decompression in the disc with the help of arthroscopy). It has become one of the important means to treat lumbar disc herniation and lumbar degenerative diseases [3]. However, most previous surgeons remain more focused on technological reform and innovations, surgical techniques, and clinical efficacy. There are few studies on complications of surgery, and previous reports have only studied the treatment of the procedure for lumbar disc herniation alone [4]. With the continuous development of percutaneous spinal endoscopic technology and the continuous expansion of the treatment scope, the indirect decompression from endoscopic disc resection to the direct expansion of the spinal canal, lateral crypt, and nerve root canal is also changing accordingly. For each clinical surgeon, the complications of surgery are a great challenge, so it is only fully and systematically important to know and grasp the surgical complications. The common complications of PELD are summarized to provide a reference for clinical surgeons [5].

Postoperative sensory abnormalities are a specific and common complication of PELD, which is generally considered to be associated with the stimulation of the dorsal root ganglion (DRG) during surgery. Some scholars have also referred to it as the "solar burning syndrome," with the incidence of about 2% to 17%. Kim et al. reported that with 93 laminina methods and 385 lamininal methods for lumbar disc disease, the incidences of postoperative sensory abnormalities were 16.13% and 7.53%, respectively. The reason may be caused by prolonged pulling stimulation of nerve roots during surgical operation [6]. Repeated positioning puncture, the use of microscopic abrasive, the use of ring saw and bone drilling for lamina and vertebral plate expansion, radiofrequency electrocoagulation, and rotation adjustment working casing to block the surrounding soft tissue may indirectly or directly stimulate the compression of nerve roots to make their ischemia and hypoxia and the corresponding symptoms. Anatomical changes in the lumbosacral nerve, lumbar trauma, and surgical history as well as foraminal size can also cause postoperative sensory abnormalities [7].

Most are because of direct damage to nerve roots during surgery and are one of the serious complications of PELD surgery. Cheng et al. [8] reported that the incidence of nerve root injury in 923 patients undergoing PELD for lumbar disc herniation was approximately 0.5%. Guo et al. [9] reported that the incidence of nerve root injury in 276 patients undergoing PELD for lumbar spinal stenosis was 1.1% [10]. The main reasons for its occurrence are summarized in the following points: anatomical structure factors, mainly including the anatomical variation in some patients and external physicians have an unclear understanding of the local anatomy, especially in the early stages of the technology, which eventually leads to nerve damage.

2. Materials and Methods

2.1. Search Strategy. This study was conducted according to the PRISMA systematic evaluation guidelines. Relevant meta-analysis and original literature were retrieved from the Medline, Cochrane Library, PubMed, Web of Science, Chinese journal full-text database (China National Knowledge Infrastructure, CNKI), Wanfang database, and Embase database. The time range is the library construction until November 2018. English retrieval keywords are Lumbar Discectomy Complication (s), Lumbar Discectomy Complication (s) and Outcome (s), and Lumbar and Discectomy or Percutaneous endoscopic lumbar discectomy and Complications (Figure 1).

2.2. Inclusion and Exclusion Criteria

(1) Inclusion criteria: randomized controlled trial (RCT) and cohort studies on percutaneous endoscopic discectomy and traditional open discectomy for the treatment of lumbar disc herniation (LDH) which are not limited in language. Subjects: unlimited gender, age older than 18 years, diagnosed with single segment lumbar disc herniation by physical examination and imaging examination (CT and MRI) and ineffective after 3 months of conservative treatment. Intervention group (the percutaneous spinal endoscopic technical group): discectomy with the following characteristics was defined as the meridian: the cutaneous spinal endoscopic discectomy places the working sleeve directly into the disc or canal, combined with the percutaneous puncture technique and then uses the suction, grasping, electrocoagulation, and other techniques to remove the diseased part of the disc. The control group (the traditional open surgery group): traditional open laminectomy, lamenestration, hemilaminectomy, and translaminectomy discectomy.

(2) Exclusion criteria: (1) randomized controlled trials (RCT) and cohort studies not related to the topic; (2) multisegment lumbar disc herniation, cauda equina syndrome, malignancy, spinal deformity, intervertebral hole injury, vertebral fusion, minimally invasive transabdominal and lumbar discectomy, and laminectomy; (3) preoperative studies with uncontrollable factors such as neurological injury, infection, or rheumatism; and (4) animal, in vitro, biomechanical studies were also excluded.

2.3. Evaluation of Literature Quality. The included literature was read in full and evaluated, and the disagreement is decided by discussion or by a third-party expert arbitration. Quality evaluation included in the RCT study was conducted according to the quality evaluation criteria recommended by the Cochrane system: (1) whether the randomization method is correct (selection bias); (2) adequate randomization concealment (selection bias); (3) whether the blinding method between participants and subjects is in place (implementation bias); (4) whether the blinding method of efficacy assessors is feasible (measurement bias); and (5) loss of visit. For the included observational studies and cohort studies, NOS can be used to evaluate the included studies. NOS adopts the semiquantitative principle of star system to make quantitative evaluation on the selection of research quality, comparability, and results (Figure 2).

2.4. Data Extraction and Analysis. Data were extracted and finally summarized and checked. Main observation indicators are total complications, postoperative sensory abnormalities (nerve root pain and burning nerve root pain), direct nerve root injury (any nerve root puncture or direct nerve root injury and nerve root displacement), dural injury (for perioperative dural damage and cerebrospinal fluid leakage), surgical area wound complications (including cellulitis, discitis, spondylitis, skin infection, superficial wound infection, suture granuloma, crack and hematoma),

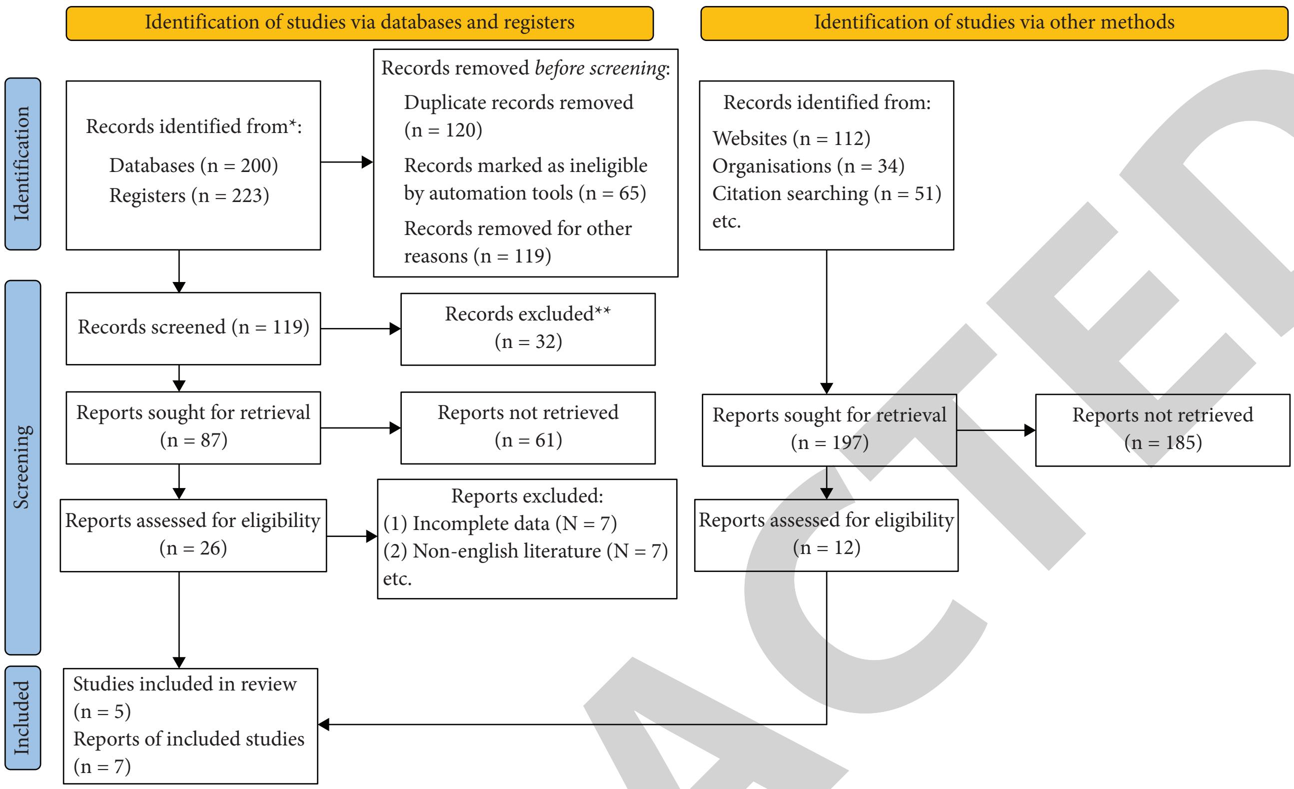

Figure 1: Flow chart of the literature screening.

intervertebral disc recurrence (complete remission of nucleus removal after the same space ipsilateral or contralateral lumbar disc herniation, with radiographic confirmation), residual nucleus pulposus (no remission or incomplete postoperative symptoms, confirmed by review MRI as residual compression of the nerve root), additional surgery of related complications (secondary surgery due to disc recurrence, nucleus pulposus residual, or other related complications). Among them, it is difficult to analyze and obtain the small sample size and low incidence of events, which is difficult to obtain reference data, so it will be integrated into other complications for analysis and discussion. Using the Cochran database, the extracted data were analyzed by using the RevMan 5.3.0 software. A chi-square test was first used to determine the heterogeneity of each study result. There was significant interstudy heterogeneity when included at $P < 0.1$ or $I^2 > 50\%$. For those with heterogeneity, the causes of heterogeneity were first analyzed, and subgroup analysis and sensitivity treatment were conducted. If it has clinical consistency, the analysis was combined with a random effect model. Fixed-effect models were used for the study data without heterogeneity.

2.5. Bias Analysis. The data in this study were all dichotomous variables, and odds ratio (OR) and 95% confidence interval (CI) were calculated. If the analysis showed statistically significant differences in complications among studies, a funnel plot was used to analyze whether publication bias existed. Sensitivity analysis was performed on the effects of studies of low quality, particularly high weight or results that differed from other studies (Figure 3).

3. Result

3.1. Characteristics and Quality Evaluation of the Included Literature. The initial examination obtained 423 documents by reading text questions, abstract, and full text and finally included 24 relevant research articles, 12 randomized controlled trials and 12 cohort studies [11–22]. A total of 2,797 patients were included in this study. Basic characteristics of the included study are as follows: there were no significant baseline differences in gender or age of the patients included in the literature (Table 1). For the 12 cohort studies included, the NOS score was 5–9. For the 12 included randomized controlled studies, the Cochrane Risk of Bias tool was used for risk assessment.

3.2. Postoperative Paresthesia. Among the 4 RCT literatures included in percutaneous spinal endoscopy versus traditional open surgery for lumbar disc herniation, the heterogeneity test was carried out and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was no statistical difference in postoperative paresthesia between percutaneous spinal endoscopy and traditional open surgery (OR = 1.17, 95% CI (0.82, 1.66), $P = 0.38$, $I^2 = 0\%$, $Z = 0.88$) (Figure 4).

Figure 2: Literature quality evaluation chart. (a) Risk of bias graph. (b) Risk of bias summary.

3.3. Direct Nerve Root Damage. Among the 4 RCT literatures included in percutaneous spinal endoscopy versus traditional open surgery for lumbar disc herniation, the heterogeneity test was carried out and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was no statistical difference in direct nerve root damage between percutaneous spinal endoscopy and traditional open surgery ($OR = 0.79$, 95% CI (0.58, 1.07), $P = 0.13$, $I^2 = 73\%$, $Z = 1.52$) (Figure 5).

3.4. Disc Recurrence. Among the 4 RCT literatures included in percutaneous spinal endoscopy versus traditional open surgery for lumbar disc herniation, the heterogeneity test was carried out and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was statistical difference in disc recurrence between percutaneous spinal endoscopy and traditional open surgery ($OR = 2.24$, 95% CI (1.56, 3.21), $P < 0.0001$, $I^2 = 81\%$, $Z = 4.39$) (Figure 6).

3.5. Intraoperative Hemorrhage and Hematoma Formation. Among the 4 RCT literatures included in percutaneous spinal endoscopy versus traditional open surgery for lumbar disc herniation, the heterogeneity test was carried out and it was found that the heterogeneity of the selected studies was small, so meta-analysis with fixed models could be performed. Meta-analysis results showed that there was no statistical difference in intraoperative hemorrhage and hematoma formation between percutaneous spinal endoscopy

4. Discussion

Surgical treatment of lumbar intervertebral disc herniation with the social development and scientific and technological progress has experienced from traditional to minimally invasive changes, and laminofenestration lumbar intervertebral disc resection is one of the classic traditional surgical treatments of LDH. Its clinical effect is satisfactory, but it causes lumbar rear muscle and bone structure damage, prone to lumbar instability and residual back pain [23]. At the same period, the technology was introduced into China, which favorably laid the foundation for the development of minimally invasive spine surgery technology in China. Wang et al. [24] invented the spinal endoscopic system (Thomas Hoogland Endoscopy Spine Systems, THESYS), which further developed as TESSYS. To enable the surgeon to reach the imaging and operating apparatus directly into the vertebral canal through the foramen to remove the protruding compressor, the technique is aided by a special multilayer drill hole which expands the foramen and the postoperative satisfaction rate can reach more than 80%

[25]. However, in the process of TESSYS application in clinical practice, various complications such as inaccurate puncture positioning, medical personnel damage due to too long perspective time, damage to nerve roots and dura, long channel establishment time, and other problems often occur. However, with the continuous development of percutaneous spinal endoscopic technology and the improvement of instruments, the efficacy and safety in the treatment of lumbar disc herniation are continuously improved [26].

Transcutaneous spinal endoscopic technology for lumbar disc herniation compared with traditional open surgical technology: its advantages are recognized by scholars, but its surgical complications are controversial. This study analyzed the percutaneous spinal endoscopic technology and traditional open surgery treatment of the LDH trial and cohort study [27], and the results show that the former in the total complications, direct nerve root injury, dural sac injury, and surgical wound complications were significantly better than the latter and in the myeloid residue inferior to the latter [28]. The results also showed no significant differences among the two technical methods in postoperative sensory abnormalities, disc recurrence, or other complications. Some scholars [29] believe that percutaneous spinal endoscopic technology after percutaneous puncture positioning casing and endoscopy directly by the foraminal area into the spinal canal and in the circulating water environment avoid large incision exposure, and timely debris, intraoperative bleeding point in the intraoperative area clearly visible, plasma bipolar radiofrequency hemostasis, and various conditions reduce the surgical area wound complications [30].

The total incidence of complications varied between the two surgical techniques in this study; however, due to the high heterogeneity, a subgroup analysis was performed and the results showed that percutaneous spinal endoscopic techniques outperform traditional open surgery in total complications. Also, it has statistical significance. However, percutaneous cohort endoscopy and traditional open surgery did not show significant advantages and disadvantages in the cohort study. The reason may be the large reporting bias in observational studies, leading to greater heterogeneity in the study. Due to the great controversy between the two techniques in postoperative disc recurrence, this study is hereby conducted according to the follow-up time subgroup analysis, and the results indicated no statistically significant complication incidence of postoperative disc recurrence between the two techniques.

The limitations of this study are as follows: (1) incorporating observational studies in the study is limited; (2) the follow-up varies from 3 to 36 months, making the evaluation of long-term complications; (3) the publication bias analysis is only qualitative and large personal factors; and (4) the two techniques described in this paper contain multiple surgical procedures, which may increase the bias of the study. Since the assessments were all based on a small number of studies, the results must be interpreted with caution. As the accumulated evidence grows, our conclusions may either be supported or overturned.

Compared with the traditional open surgical treatment of lumbar disc herniation, percutaneous spinal endoscopic technology has obvious advantages in reducing nerve root injury, dural injury, and surgical area wound complications, but it is limited to preventing the technical characteristics of the surgical site, which is worse than that of open surgery.

Academic Editor: Enas Abdulhay

Objective. To evaluate the efficacy of recombinant human endostatin combined with gemcitabine and cisplatin in the treatment of non-small-cell lung cancer (NSCLC). *Methods*. The databases of Cochrane Library, Embase, ClinicalTrials, PubMed, HowNet, Wanfang, and VIP were searched to collect randomized controlled trials (RCTs) of recombinant human endostatin combined with gemcitabine and cisplatin (experimental group) and gemcitabine combined with cisplatin (control group) for comparative study. The quality of literature was evaluated by bias risk assessment tools and related scales, and then meta-analysis was performed. *Results*. A total of 27 RCTs (1646 patients) were included. The results of meta-analysis showed that the effective rate ($P < 0.000\,01$) and benefit rate ($P < 0.000\,01$) of the experimental group were significantly higher than those of the control group, the incidence of leucopenia ($P = 0.79$), thrombocytopenia ($P = 0.39$), and gastrointestinal reaction ($P = 0.85$) were not statistically significant. *Conclusion*. The combination of recombinant human endostatin, gemcitabine, and cisplatin can increase the efficacy and safety of NSCLC patients.

1. Introduction

Nowadays, the prevalence trend and death status of lung cancer are not optimistic. Non-small-cell lung cancer (NSCLC) accounts for about 4/5 of all lung cancer patients, which is a cancer with high mortality in the world. The first-line chemotherapy of NSCLC is vinorelbine, gemcitabine, and cisplatin, which is widely used [1]. However, chemotherapy drugs are generally cytotoxic. Although they have a destructive effect on lung cancer cells, they also limit human immunity. In the process of lung cancer chemotherapy, it is a difficult problem for NSCLC to ensure the curative effect and reduce the adverse reactions as much as possible. Chemotherapy is the main treatment for advanced NSCLC patients. The standard treatment is 4–6 cycles of platinum combined with the third generation of cytotoxic drugs. The effective rate is 20.00%–30.00% [2]. The median survival time is 8–10 months, and the time of disease progression is 3–5 months. To some extent, the survival time of NSCLC patients can be prolonged, but the curative effect has reached the plateau [3, 4]. Therefore, in order to improve the survival and efficiency of patients with advanced NSCLC, we need to try new drugs and new chemotherapy regimens that are different from the existing treatment mechanisms. It is against this background that antitumor angiogenesis therapy is produced. Since the role of angiogenesis in tumor growth and progression was identified in the 1970s, the exploration of antiangiogenic drugs has not been interrupted [5]. With the progress of science and technology, many antiangiogenic drugs have been developed and applied in clinic. A large number of clinical studies have confirmed that the combination of molecular targeted drugs and chemotherapy can achieve the above therapeutic purposes, and some reports have shown that these drugs have a certain effect on tumor vascular normalization and can increase the sensitivity to chemotherapy and radiotherapy; when combined with chemotherapy, it has a positive synergistic effect. Recombinant human endostatin, also known as endostatin, is an angiogenesis inhibitor, which can inhibit angiogenesis and limit tumor angiogenesis. Nowadays, recombinant human endostatin can be used to intervene in NSCLC, gastric cancer, and so on [6]. Studies have shown that recombinant human endostatin and chemotherapy drugs can play a synergistic effect, making the efficacy increase. Although targeted therapy combined with chemotherapy has achieved a positive therapeutic effect in clinic, antiangiogenesis therapy has not achieved the obvious antitumor effect as in the animal experiment stage. There are many factors related to its possibility, but the difference in drug use is one of the most important factors [7]. Conventional drugs are treated by intravenous route. After the combination of drugs with plasma protein, the concentration of drugs distributed to the local tumor is significantly reduced, and the therapeutic effect of the tumor is not good. Interventional targeted therapy of tumor blood supply artery is a mature method of local perfusion chemotherapy [8]. This method is through superselective intubation to the target artery of tumor blood supply, a high concentration of therapeutic drugs is infused into the tumor area. Through the first-pass effect of drugs, the concentration of drugs in the tumor is increased; the action time is prolonged; the clinical side effects are reduced; and the tolerance of patients is increased. It is believed that endostatin combined with chemotherapeutic drugs can significantly increase the clinical therapeutic effect of NSCLC. In this study, we systematically reviewed the efficacy of recombinant human endostatin, gemcitabine, and cisplatin combined therapy and gemcitabine and cisplatin combined therapy in the treatment of NSCLC.

2. Information and Methods

2.1. Inclusion Criteria and Exclusion Criteria

2.1.1. Inclusion Criteria. The inclusion criteria are as follows: (1) randomized controlled trials (RCTs) were published in Chinese and English; (2) cytological or histopathological diagnosis of NSCLC was made, regardless of gender, age, course of disease, and so on; (3) the blood routine, heart, liver, kidney, and brain function were basically normal, and there were no structural or functional abnormalities of important organs; and (4) the period of treatment is no less than 2 cycles (1 cycle is 2 weeks).

2.1.2. Exclusion Criteria. The exclusion criteria are as follows: (1) the score of the Jadad scale was 0 or non-RCT literature, (2) repetitive literature, (3) descriptive research, (4) impossible to extract literature, and (5) animal experiments.

2.1.3. Method. The control group was treated with gemcitabine and cisplatin; patients in the experimental group were treated with gemcitabine, cisplatin, and recombinant human endostatin.

2.1.4. Outcome Measures. (1) Total effective rate, (2) benefit rate, (3) the incidence of leukopenia, (4) the incidence of thrombocytopenia, and (5) the incidence of gastrointestinal reactions are calculated. According to the new criteria for evaluation of solid tumor efficacy, the efficacy criteria were divided into complete remission (CR), partial remission (PR), steady (SD), and advanced (PD). Effective rate = (Cr + PR)/total cases × 100.00%; benefit rate = (Cr + PR + SD)/total cases × 100.00%; the incidence of leukopenia = 1–4 cases/total cases × 100.00%; and incidence of thrombocytopenia = cases of grade 1–4/total cases × 100.00%.

2.2. Literature Retrieval. A total of 501 databases of Cochrane Library, Embase, ClinicalTrials, PubMed, HowNet, Wanfang, and VIP are searched. Of these, 404 were included, and 97 were excluded. The Chinese keywords are "recombinant human angiostatin," "non-small cell lung cancer," "gemcitabine," "cisplatin," "meta-analysis," and so on. The English keywords are "recombinant human endostatin," "non-small cell lung cancer," "gemcitabine," "cisplatin," and "meta-analysis." The retrieval time period is from the establishment of each database to October 2020.

2.3. Screening of the Literature and Data. A total of three reviewers screened and checked the literature; two of them independently screened the literature according to the inclusion criteria and exclusion criteria; and two of them checked the literature. The third reviewer assisted in the case of different opinions. The extracted information included the year of publication, first author, sample size, age range, intervention method, disease stage, intervention course, outcome index, and so on.

2.4. Literature Quality Assessment. The Cochrane system version 5.1.0 was used to assess the risk of bias, whether the distribution was hidden, whether blinding was used (blinding of investigators and subjects and blinded assessment of the final results of the study), whether the results from the data were complete, whether the results of the study were selectively reported, and whether there were other sources of bias. Each item has a low risk of bias, ambiguity, and high risk of bias. Jadad scale was used to evaluate the quality of the study, including random sequence generation (appropriate 2 points, uncertain 1 points, and inappropriate 0 points), randomized concealment (appropriate 2 points, uncertain 1 points, and inappropriate 0 points), blind method (appropriate 2 points, uncertain 1 points, and inappropriate 0 points), withdrawal and withdrawal (description 1 points, no description, and 0 points). The score of low-quality research is less than 3, and that of high-quality research is 4–7.

2.5. Statistical Methods. Revman 5.3 software was used to analyze the data. The relative risk (RR) or odds ratio (or) and 95% confidence interval (CI) were used as the combined effect quantity if the included indexes were binary variables;

if the included research indicators were continuous variables, they were expressed by weight mean difference (MD) or standard mean difference (SMD) and 95% CI. For the heterogeneity analysis of the included studies, when the heterogeneity among the studies was low ($I^2 \leq 50\%$), the fixed-effect model was used for meta-analysis; when the heterogeneity among the studies was relatively high ($I^2 > 50\%$), the random-effects model was used for meta-analysis, and the incomplete data were used for descriptive analysis. The bias was analyzed qualitatively by funnel plot and quantitatively by state 12.0.

3. Results

3.1. Results of Literature Search. A total of 360 literature were collected, including 317 in Chinese and 43 in English. After reading the title and abstract, 81 related articles were obtained. After careful study of the full text, 27 articles were finally included, including 1,646 subjects, 830 patients in the experimental group, and 816 patients in the control group (Figure 1). The basic information of the study is shown in Table 1.

3.2. Assessment of the Quality of Included Studies. All studies were RCTs; among them, six studies involved randomized methods, and none of them involved allocation concealment, blind method, or other sources of bias. See Figures 2 and 3 for details.

3.3. Results of Meta-Analysis

3.3.1. Efficiency. Among them, 27 studies related to the effective rate, which had no statistical heterogeneity ($P = 0.99$, $I^2 = 0$). The fixed-effect model was used for the meta-analysis, as shown in Table 2. The results of meta-analysis showed that the effective rate of the experimental group was significantly higher than that of the control group, with statistical significance (RR = 1.67, 95% CI (1.48, 1.89), $P < 0.00001$).

3.3.2. Clinical Benefit Rate. Among them, 27 studies related to the benefit rate, which had no statistical heterogeneity ($P = 0.49$, $I^2 = 0$). The fixed-effect model was used for the meta-analysis, as shown in Table 3. The results of meta-analysis showed that the benefit rate of the experimental group was significantly higher than that of the control group (RR = 1.26, 95% CI (1.20, 1.33), $P < 0.00001$).

3.3.3. Incidence of Leukopenia. Among them, 19 studies related to the incidence of leukopenia, which was not statistically heterogeneous ($P = 1.00$, $I^2 = 0$). The fixed effect model was used for meta-analysis. Meta-analysis showed that the incidence of leukopenia among the groups was not statistically significant (RR = 0.98, 95% CI (0.88, 1.11), $P = 0.79$).

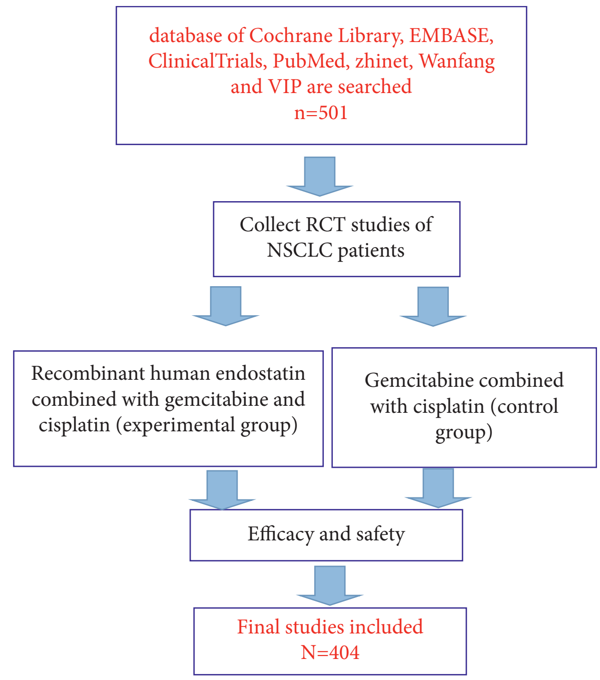

Figure 1: Flow chart.

3.4. Bias Analysis. Take the effective rate as an index and use the inverted funnel plot and Begg's test to analyze the bias, as shown in Figures 4 and 5. It can be seen from Figure 5 that all the scattered points in the study are within the scope of the inverted funnel diagram, and the distribution is basically symmetrical, indicating that there is a small possibility of bias in this study. Figure 5 shows that the P value of Begg's test is $0.084 > 0.05$, indicating that there is no obvious bias in this study.

4. Discussion

Lung cancer is the most malignant tumor in China and has the highest incidence rate in the world [9]. Most patients have an advanced tumor at the time of diagnosis, and NSCLC accounts for 80.00% of lung cancer in the late stage. Because the prognosis of NSCLC is not ideal, its treatment is very challenging [10]. Treatment of advanced NSCLC has also experienced a process. In 1980s, there were serious side effects of the first-generation chemotherapy drugs (cyclophosphamide, etc.); a clinical study showed that the prognosis after the first-generation chemotherapy drug treatment was not significantly improved compared with the patients with the best support treatment [11]. Therefore, it was generally considered that support therapy was the best treatment method for advanced NSCLC. The idea lasted until 1995; a meta-analysis published in the British Journal of medicine confirmed for the first time that platinum-containing chemotherapy significantly improved the survival time of patients with advanced NSCLC than the best support therapy [12]. This meta-analysis was selected into 52 randomized controlled studies, including 9,387 NSCLC patients. The results showed that the death risk and 1-year survival rate were improved by 10.00% ($P < 0.0001$) after

chemotherapy with platinum in patients with advanced NSCLC. The results of the analysis of the effects of chemotherapy on the survival of 2,714 patients with advanced NSCLC in 16 randomized controlled studies showed that chemotherapy combined with support therapy reduced the risk of death by 23.00% ($P < 0.0001$); the total survival time was prolonged by 1.50 months, and the 1-year survival rate was improved by 9.00% [13]. The results fully show that

chemotherapy based on platinum drugs can reduce the risk of death and bring obvious survival benefits to patients, thus promoting NSCLC treatment into platinum-containing chemotherapy era. Among the above chemotherapy schemes, gemcitabine + cisplatin (GP) has some advantages. In 2005, Le Chavalier et al. conducted a meta-analysis of a single study of gemcitabine plus platinum-based chemotherapy and other platinum-containing chemotherapy options to assess whether there is a treatment that is more advantageous in advanced NSCLC [14]. The meta-analysis was selected into 13 studies (4,500 cases), except for two phase II studies, all of which were phase III studies. Five studies were cisplatin single drug or first and second generation combined platinum-containing programs (1,900 cases), and 8 were third generation combined platinum (2,600 cases). The results showed that GP could significantly reduce the disease progression and death risk by 12.00% and 10.00%, respectively, compared with other chemotherapy schemes; compared with the first and second generation combined platinum-containing regimen, GP could significantly prolong the total survival period of patients ($P < 0.001$); and compared with other third-generation platinum-containing regimen without gemcitabine, gemcitabine significantly prolonged the progression-free survival period ($P < 0.001$). The results of this analysis fully confirm that gemcitabine plus platinum combined regimen can significantly prolong the total and progression-free survival of patients with advanced NSCLC compared with other platinum-containing schemes. In 2007, Grossi et al.'s meta-analysis compared the activity of gemcitabine with three other third-generation platinum-containing chemotherapy programs [15]. The meta-analysis included 48 studies, with 6,671 patients. The results showed that gemcitabine could significantly reduce the risk of disease progression by 14.00% compared with other third-generation platinum-containing chemotherapy. This meta-analysis study not only laid the foundation position of platinum-containing chemotherapy in advanced NSCLC treatment but also highlighted the treatment advantages of GP. Patients with advanced NSCLC received gemcitabine plus platinum first-line treatment, which can achieve a higher quality of life and longer life [16]. Therefore, GP with small side effects and good tolerance was used as chemotherapy. But there is no essential difference in efficacy between the third-generation chemotherapy drugs and platinum. The randomized controlled study ECoG 1594, published in the New England Journal of medicine in 2002, showed that there was no significant difference in the median OS between the four third-generation platinum-containing chemotherapy regimens (gemcitabine, paclitaxel, docetaxel, and vinorelbine combined with platinum) [17]. The treatment cycle of the first-line chemotherapy program and the combination of three chemotherapy drugs were also confirmed by the phase II clinical study of MPCRN cancer research network in the United States [18]. Therefore, if we want to further improve the chemotherapy effect of lung cancer, we must take new ideas.

The growth and diffusion of cancer cells depend on angiogenesis and tumor neogenesis, which is the most important antitumor method of vascular targeted therapy [19, 20]. In some studies, NSCLC patients were divided into 34 cases of platinum chemotherapy and 54 cases of platinum plus recombinant human endostatin [21–23]. It was found that the progression-free survival rate and overall survival rate of patients treated with combination therapy were significantly improved. Other related studies have pointed out that the efficacy of combined therapy is controversial and needs further study [24]. Gemcitabine is a substitute for inhibitory enzymes, which can inhibit the DNA replication of tumor cells in the process of DNA synthesis and repair. In order to study the curative effect of recombinant human endostatin in patients with NSCLC, this study summarized the randomized controlled trials of chemotherapy regimens in patients with NSCLC. The results showed that recombinant human endostatin combined with gemcitabine and cisplatin could significantly improve the total effective rate and benefit rate, and the bias analysis of funnel plot and Egger's test showed that the results were more reliable. The incidence of leucopenia, thrombocytopenia, and gastrointestinal reactions between the two groups were not statistically significant, indicating that the combination of recombinant human endostatin, gemcitabine, and cisplatin is safe [25].

Ouyang Lihui et al. conducted a meta-analysis in 2012 to compare the efficacy of gemcitabine + cisplatin + recombinant human endostatin (GPE) regimen and gemcitabine + cisplatin (GP) regimen in patients with NSCLC; GPE is superior to GP in total effective rate and disease control rate. Ma et al. included 9 studies and 839 patients with NSCLC [26]. The results showed that the GPE regimen did not increase the incidence of adverse reactions compared with the GP regimen. The combined results of 4 studies found that compared with the GP scheme, the GPE scheme led to increased arrhythmia, and the difference was statistically significant. This suggests that clinicians should pay close attention to the ECG of patients with NSCLC when using a GPE regimen to prevent serious adverse reactions of arrhythmia. At the same time, the log-rank test was used to compare the disease progression and overall survival of the two groups. It was found that recombinant human endostatin combined with GP regimen did not improve the overall survival of patients with advanced NSCLC, but it did not exclude the bias caused by the small sample size of this study, and it was also affected by the later treatment effect of patients. The main adverse reactions of recombinant human endostatin combined with GP regimen to patients with advanced NSCLC were myelosuppression and gastrointestinal reactions. A few patients had liver function damage and ECG changes, but there was no significant difference compared with patients treated with GP regimen alone.

The curative effect of recombinant human endostatin, gemcitabine, and cisplatin in the treatment of patients with NSCLC has been improved, without obvious adverse reactions. The disadvantages are as follows: firstly, the unpublished literature are not included; secondly, the comprehensive quality evaluation of the included literature is low; thirdly, the included literature are all Chinese literature, which are not suitable for foreign patients; and fourthly, the quality of life evaluation of patients is not involved.

5. Conclusion

The combination of recombinant human endostatin, gemcitabine, and cisplatin can increase the efficacy and safety of NSCLC patients.

Retracted: The Effect of Acupuncture Combined with Aerobic Exercise for Coronary Heart Disease as Cardiac Rehabilitation

Journal of Healthcare Engineering

Received 12 January 2023; Accepted 12 January 2023; Published 21 January 2023

Journal of Healthcare Engineering has retracted the article titled "The Effect of Acupuncture Combined with Aerobic Exercise for Coronary Heart Disease as Cardiac Rehabilitation" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

Background. The mortality of coronary heart disease continues to rise. Cardiac rehabilitation intervenes the risk factors of cardiovascular disease, improves cardiopulmonary function, maintains healthy psychology, improves the quality of life of patients, and reduces cardiovascular mortality. *Objective*. To explore the effect of acupuncture combined with aerobic exercise on cardiopulmonary exercise ability, blood lipid, fatty acid oxidation, and psychology in patients with coronary heart disease. *Methods*. Sixty patients with coronary heart disease from February 2018 to October 2020 were randomly divided into two groups: the control group and experimental group. The control group was given an exercise prescription, and the experimental group was given acupuncture combined with an exercise prescription. Before and after the intervention, the cardiopulmonary exercise test, blood lipid, carnitine acyltransferase (CACT), the Self-Rating Somatic Symptom Scale (SSS), the Generalized Anxiety Disorder-7 (GAD-7), and the Patient Health Questionnaire-9 (PHQ-9) of the two groups were compared. *Results*. The PHQ-9 score was better in the experimental group than in the control group. In both groups, after the intervention, the peak oxygen uptake and anaerobic threshold were increased, and blood lipid and PHQ-9 scores were decreased. In the experimental group, the carbon dioxide metabolic equivalent was decreased, CACT was increased, and SSS and GAD-7 scores were decreased, with statistical difference ($P < 0.05$). *Conclusion*. Acupuncture combined with aerobic exercise can improve the cardiopulmonary exercise ability, increase fatty acid oxidation, decrease blood lipid, and ameliorate anxiety and depression symptoms of patients with coronary heart disease as cardiac rehabilitation.

1. Introduction

Cardiovascular disease is the leading cause of disability and death in Chinese residents [1]. There are more than 11 million people suffering from Coronary Artery Atherosclerotic Heart Disease (CHD) in China [2]. Despite the continuous development of drugs and interventional therapy, the mortality of coronary heart disease in China continues to rise [3]. The substantial decline in mortality of coronary heart disease in developed countries is due to coronary heart disease rehabilitation and secondary prevention [4]. China urgently needs to strengthen the prevention and rehabilitation of cardiovascular diseases. Cardiac rehabilitation applied drugs, exercise, nutrition, and psychological and behavioural intervention to comprehensively intervene the risk factors of cardiovascular disease, improve cardiopulmonary function, maintain healthy psychology, improve the quality of life of patients, and reduce cardiovascular mortality [5–7].

Acupuncture, having bidirectional regulatory ability and a much lower incidence of side effects, can treat a variety of diseases. It can intervene hypertension and psychological stress-induced cardiovascular reactivity to prevent cardiovascular disease and cardiovascular death [8]. It has been used as adjuvant therapy for chronic stable angina pectoris, which can reduce the frequency of angina attacks [9]. This study observed the effect of acupuncture treatment on cardiopulmonary exercise ability, blood lipid metabolism, and psychology of patients with coronary heart disease and explored rehabilitation strategy suitable for China's national conditions.

2. Subjects and Methods

2.1. Subjects. This study included sixty patients with stable coronary heart disease who were admitted to the Department of Cardiology, Punan Hospital, Pudong New District, Shanghai, from February 2018 to October 2020. Inclusion criteria: age >18 years and <85 years, stability of symptoms and dose for at least 2 weeks; coronary angiography showed at least one major coronary artery stenosis >50%; and obtained consent and sign informed consent. Exclusion criteria: those who are unwilling or unable to exercise or acupuncture treatment; there has been acupuncture treatment in the recent 6 months; bone and joint diseases affecting movement; aortic dissection; acute coronary syndrome; uncontrolled heart failure; and severe liver and renal dysfunction. Using random numbers, 60 cases were divided into the control group and experimental group.

2.2. Methods

2.2.1. Intervention Methods. All patients were treated with cardiac rehabilitation under the guidance of cardiac rehabilitation doctors. Exercise prescriptions were issued according to cardiopulmonary exercise test (CPXT). The control group received exercise rehabilitation, and the experimental group received acupuncture treatment and exercise rehabilitation. Exercise prescription: exercise intensity set anaerobic threshold heart rate as target heart rate; exercise frequency for 3–5 times a week, 20–30 minutes aerobic exercise, a total of 8 weeks; the form of exercise is mainly jogging and power cycling. Acupuncture acupoints were selected by acupuncture doctors according to the clinical symptoms of patients, and the selected acupoints were the following acupoint combinations. Chest discomfort acupoints: Nei guan, Ju Que, Shen men, Guan Yuan, Qi hai, and Da ling; insomnia acupoints: Bai hui, Zhao hai, and Tai Chong; shoulder pain acupoint: Jian yu, Jian Liao, Jian Zhen, Qu chi, and Wai guan; lower limb pain acupoint: Yin ling Quan, Chen shan, Tiao Kou, Zu san li, San yin jiao, Fu Tu, and Feng shi; and knee Joint pain acupoints: Nei Wai Xi Yan, Xue Hai, He Ding, Yang Ling Quan, etc. Acupuncture treatment was performed for 30 minutes each time, 1-2 times a week, for a total of 12 times.

2.2.2. Cardiopulmonary Exercise Test (CPXT). The Italian COSMED Cardiopulmonary exercise test system, exercise equipment for power cycling, with an increasing power (10–20 Watt Ramp) scheme for the symptom-limited maximum exercise load test, the V-slop method was used to calculate the anaerobic threshold (see Table 1).

2.2.3. Biochemical Indicators. All patients were taken fasting venous blood, Abbott C16000 automatic biochemical analyzer for blood lipid testing, triglycerides with the GPO-PAP method, total cholesterol with the enzyme method, low-density lipoprotein with the direct method-surfactant clearance method, high-density lipoprotein with the direct method-selective inhibition method, free fatty acids with the ACS-ACOD method, blood glucose with the glucose oxidase method, serum creatinine with the enzyme method, the uric acid kinase method, and homocysteine with the double-reagent circulation enzyme method. Glycosylated haemoglobin was measured by using the Arkray 8180 instrument and high-performance liquid chromatography. Serum CACT was determined by using the ELISA kit. The kit was provided by Shanghai Kamishu Biotechnology Co., Ltd.

2.3. Observation Indicators

2.3.1. CPXT Indicators. The CPXT indicators were peak oxygen uptake per kg body weight (VO2/kg), anaerobic threshold (AT) oxygen uptake, respiratory reserve, oxygen pulse, one-minute heart rate recovery, anaerobic threshold carbon dioxide ventilation equivalent (VE/VCO2 @ AT), and others.

2.3.2. Biochemical Indicators. The biochemical indicators were serum creatinine, uric acid, triglyceride, cholesterol, low-density lipoprotein, high-density lipoprotein, free fatty acids, serum carnitine acyltransferase, blood glucose, glycosylated haemoglobin, blood homocysteine, etc.

2.3.3. Psychological Assessment. Before and after the intervention, patients were asked to fill out the Self-Rating Somatic Symptom Scale (SSS), PHQ-9 health questionnaire (depression screening scale), and GAD-7 generalized anxiety disorder scale for psychological assessment.

2.4. Statistical Method. SPSS22.0 software was used. The measurement data were expressed as mean ± standard deviation, which was in line with normal distribution. A paired t-test was used for intragroup comparison, and an independent-sample t-test was used for intergroup comparison. Enumeration data were expressed as frequency and percentage. The Chi-square test was used for comparison between groups. $P < 0.05$ indicated statistical difference.

3. Results

3.1. Comparison of Baseline Basic Data between the Two Groups of Patients. There was no significant difference in gender, age, body mass index, history of hypertension, history of diabetes, homocysteine, creatinine, uric acid, triglyceride, cholesterol, low-density lipoprotein, high-density lipoprotein, free fatty acid, blood glucose, glycosylated haemoglobin (HbA1c), and other biochemical indicators between the two groups ($P > 0.05$), as shown in Table 2.

3.2. Comparison of the Cardiopulmonary Exercise Test. There was no significant difference between the two groups before and after intervention ($P > 0.05$). The peak oxygen

uptake per kilogram (VO2/kg peak) and anaerobic threshold (VO2/kg @ AT) in the two groups were increased after intervention. The carbon dioxide ventilation equivalent (VE/VCO2 @ AT) in the experimental group decreased after intervention, with statistical significance ($P < 0.05$).

3.3. Comparison of Biochemical Indicators. There was no significant difference between the two groups in serum creatinine, uric acid, triglyceride, high-density lipoprotein, free fatty acid, blood glucose, glycosylated haemoglobin, and other biochemical indicators before and after intervention ($P > 0.05$). Compared within the group, the low-density lipoprotein and cholesterol in the two groups decreased after the intervention, and the serum carnitine acyltransferase in the experimental group increased after intervention, with a statistical difference ($P < 0.05$) (Table 3).

3.4. Comparison of Psychological Scales between the Two Groups. There was no significant difference between the two groups before intervention. After intervention, the acupuncture group improved PHQ-9 compared with the control group ($P < 0.05$). Compared within the group before and after intervention, the acupuncture group improved the Chinese somatization symptom checklist, PHQ-9 and CAD-7, and aerobic exercise improved PHQ-9 ($P < 0.05$), see Table 4.

4. Discussion

This study shows that aerobic exercise can improve peak oxygen uptake and anaerobic threshold in patients with coronary heart disease and reduce blood lipids. Aerobic exercise increases ventricular end-diastolic volume, myocardial contractility, and cardiac output through the sympathetic nerve and improves coronary artery circulation by increasing nitric oxide production and vasodilation; exercise can also reduce blood lipids and inflammation indicators [10]. Therefore, exercise is good medicine for heart rehabilitation. Based on a large number of clinical studies and systematic evaluation results in China, Europe, the United States, and other countries, guidelines for the prevention and rehabilitation of cardiovascular diseases based on exercise are introduced [11, 12].

This study found that acupuncture in the rehabilitation of patients with coronary heart disease can also bring three other benefits.

Fatty acid is an important source of muscle contraction energy, acetyl-CoA fatty acid is tranfered by the carnitine palmitoyl transferase system into mitochondrial oxidation. This study suggests that acupuncture can increase the concentration of serum carnitine acyltransferase, infer acupuncture promote fatty acid oxidation, and enhance myocardial and skeletal muscle energy supplement. Glucose is the main energy source during embryogenesis, and fatty acid oxidation is the main energy source after birth. The

selection and change of myocardial energy substrates are the objects of myocardial metabolise in patients with ischemic heart disease and heart failure. Energy utilization efficiency and myocardial efficiency is a potential target for the treatment of heart failure and ischemia [13]. Animal experiments have found that the lack of carnitine palmitoyltransferase can lead to cardiac hypertrophy due to excessive pressure load caused by lipotoxicity [14]. Acupuncture treatment can regulate heart energy metabolism by affecting the key enzymes of fatty acid metabolism, with fewer adverse reactions and high safety.

Carbon dioxide ventilation equivalent (VE/VCO2) is the most widely studied ventilation efficiency parameter. The increase in VE/VCO2 is significantly associated with the mortality of patients, which is a reliable indicator for the prognosis of heart failure [15]. In this study, it was found that acupuncture treatment could reduce the anaerobic threshold carbon dioxide ventilation equivalent (VE/VCO2 @ AT), which was similar to the previous research results of acupuncture treatment for patients with heart failure in Germany [16]. The increase of VE/VCO2 was due to the increase of invalid ventilation residual cavity, mismatch of blood flow and ventilation, a decrease of skeletal muscle oxidation ability, and an increase of exercise lactic acid to stimulate breathing. Previous studies have found that acupuncture can reduce the production of lactic acid during exercise [17]. This study found that acupuncture can enhance fatty acid oxidation, so it is speculated that these two factors are the reasons why acupuncture can reduce VE/VCO2. Lowering VE/VCO2 may benefit, especially, cardiovascular patients who cannot exercise and have a poor response to treatment, suggesting that acupuncture can be used as a choice for rehabilitation.

Psychological anxiety, depression, and other emotional factors are not only risk factors for coronary heart disease but also closely related to the development of coronary heart disease. A systematic review [18] shows that exercise therapy may reduce depressive symptoms, while anxiety symptoms may be reduced in the short term (less than 12 weeks) and long-term outcomes are uncertain. By literature analysis [19] from 2011 to 2020, more and more studies have shown that acupuncture can be used as a potentially effective treatment for depression and improve depressive symptoms. Acupuncture treatment has positive results in the treatment of anxiety [20]. Metabonomics technology is used to analyze the body metabolism by acupuncture and moxibustion, which shows that acupuncture and moxibustion canchange plasma tryptophan and glutamate, regulate neurotransmitter, improve function, and promote health [21].

Acupuncture is based on the meridian theory, a guide for TCM dorctors to treat diseases, but the mechanism of acupunture is still unclarified; animal experiments have found that acupuncture activates the peripheral sensory nerve fibres of dorsal root ganglion and transmits the signals to the spinal cord and brain, thereby activating the peripheral autonomic nerve. Stimulating the acupoints of hind limbs (Zusanli) in mice can activate the vagal-adrenal anti-inflammatory pathway [22, 23]. Acupuncture and moxibustion activate the vagus nerve, reduce visceral immune cell production factors, reduce inflammatory factors, inhibit sympathetic nerve, and regulate neurohumoral factors, which can theoretically play more roles in cardiovascular diseases.

Therefore, acupuncture can improve the efficiency of exercise ventilation,promote fatty acid oxidation, improve anxiety and depression symptoms, and treat somatization symptoms in patients with coronary heart disease; combined with aerobic exercise can improve the cardiopulmonary exercise ability of patients and reduce blood lipids, which can be applied as cardiac rehabilitation technology.

The shortcomings of this study: (1) failure to set up a sham acupuncture control group because it was difficult to select acupoints in the sham acupuncture group during the preexperiment; (2) also, because there is no effect, patient compliance is not high in the sham acupuncture group after completing 1-2 times; and (3) the number of cases enrolled in this study is small; subsequent studies can expand the sample size and improve follow-up time to assess the long-term efficacy of acupuncture.

The first reported case of coronavirus disease 2019 (COVID-19) occurred in Wuhan, Hubei, China. Thereafter, it spread through China and worldwide in only a few months, reaching a pandemic level. It can cause severe respiratory illnesses such as pneumonia and lung failure. Since the onset of the disease, the rapid response and intervention of traditional Chinese medicine (TCM) have played a significant role in the effective control of the epidemic. Yinqiaosan (YQS) was used to treat COVID-19 pneumonia, with good curative effects. However, a systematic overview of its active compounds and the therapeutic mechanisms underlying its action has yet to be performed. The purpose of the current study is to explore the compounds and mechanism of YQS in treating COVID-19 pneumonia using system pharmacology. A system pharmacology method involving drug-likeness assessment, oral bioavailability forecasting, virtual docking, and network analysis was applied to estimate the active compounds, hub targets, and key pathways of YQS in the treatment of COVID-19 pneumonia. With this method, 117 active compounds were successfully identified in YQS, and 77 potential targets were obtained from the targets of 95 compounds and COVID-19 pneumonia. The results show that YQS may act in treating COVID-19 pneumonia and its complications (atherosclerosis and nephropathy) through Kaposi sarcoma-related herpesvirus infection and the AGE-RAGE signaling pathway in diabetic complications and pathways in cancer. We distinguished the hub molecular targets within pathways such as TNF, GAPDH, MAPK3, MAPK1, EGFR, CASP3, MAPK8, mTOR, IL-2, and MAPK14. Five of the more highly active compounds (acacetin, kaempferol, luteolin, naringenin, and quercetin) have anti-inflammatory and antioxidative properties. In summary, by introducing a systematic network pharmacology method, our research perfectly forecasts the active compounds, potential targets, and key pathways of YQS applied to COVID-19 and helps to comprehensively clarify its mechanism of action.

1. Introduction

Coronavirus infectious disease 2019 (COVID-19) is caused by 2019-nCoV virus and it seriously endangers human health. On January 12, 2020, the World Health Organization (WHO) confirmed and named its pathogen 2019-nCoV [1], which belongs to the novel coronavirus pneumonia of genus β. On January 31, 2020, it was designated a Public Health Emergency of International Concern (PHEIC). According to the latest statistics of the World Health Organization, as of October 28, 2021, there were approximately 244385444 confirmed cases and more than 4961489 deaths worldwide, including over 7053806 confirmed cases and over 108334 deaths in the United States.

The main clinical features of these cases are a high body temperature, cough without mucous, breathing difficulties (dyspnea), headache, and pneumonia. Disease attack may lead to progressive respiratory failure due to alveolar damage (which has been observed by transverse chest computerized tomography images) and cytokine storm syndrome and it could also develop a severe form with sometimes fatal outcomes [2, 3]. The cause of the disease was identified by clinicians as virus-induced pneumonia in line with the clinical signs and other standards, including increased body temperature, decreased lymphocytes and white blood cells (although the levels of the latter seemed normal sometimes), new pulmonary infiltrates on chest radiography, and no evident improvement after treatment with antibiotics for three days [4].

In traditional Chinese medicine (TCM), COVID-19 falls under the category of "pestilences," which occur because of direct or indirect contact with epidemic pathogens. Since the onset of the disease, the rapid response and intervention of TCM have played a vital role in effectively controlling the epidemic, and the classic prescription has become one of the highlights in preventing and controlling the epidemic [5, 6]. Yinqiaosan (YQS) is a traditional prescription for treating the influenza virus from the "Wen Bing Tiao Bian." YQS is a herbal formula comprised of 10 medicinal herbs (Jinyinhua (JYH, *Lonicera japonica* Thunb.), Lianqiao (LQ, *Forsythia suspensa* (Thunb.)), Jiegeng (JG, *Platycodon grandiflorum* (Jacq.) A. DC), Bohe (BH, *Mentha haplocalyx* Briq.), Dantouchi (DDC, *Glycine* max (L.) Merr.), Danzhuye (DZY, *Lophatherum gracile* Brongn.), Niubangzi (NBZ, *Arctium lappa* L.), Jingjie (JJ, *Schizonepeta tenuifolia* Eriq.), Lugen (LG, *Phragmites communis* Trin.), and Gancao (GC, *Glycyrrhiza uralensis* Fisch., *Glycyrrhiza inflata* Bat., or *Glycyrrhiza glabra* L.). The National Health Commission of the People's Republic of China and the National Administration of TCM issued the "Diagnosis and Treatment Program for COVID-19 (Trial Version 3)." They began to recommend TCM therapy, among which the recommended prescriptions are Maxing Shigan decoction and YQS.

Tang et al. [7], based on the TCMATCOV platform, analyzed the potential effects of commonly used traditional formulations for treating COVID-19 and discovered that YQS is a frequently used therapy for pneumonia. For the past few years, systems pharmacology [8, 9] means have been widely introduced in the prescription and mechanism of TCM. System pharmacology is an emerging systematic methodology and is guided by the "multicomponent multitarget network" theory, which conforms to the integrity and systematicity of TCM prescriptions. In addition, it combines oral bioavailability screening and multiple drug target prediction, providing an overall method for exploring the targets and potential mechanisms of TCM, and it can be used as an alternative strategy to analyze the therapeutic effects of the active ingredients [10, 11]. Wang et al. [12] discussed the targets and signaling pathways of Maxing Shigan decoction for treating pneumonia through systems pharmacology and found that the possible targets were IL-6, TNF, MAPK8, etc. Xia et al. found that Akt1 was a potential target of Lianhua Qingwen to treat and prevent COVID-19 using network pharmacology and molecular docking analyses [13].

Aiming to explore the possibility and mechanism of YQS in treating COVID-19, this paper uses systems pharmacology techniques and approaches to forecast the possible targets and signaling pathways of YQS and provides data for subsequent experimental research.

2. Materials and Methods

2.1. Finding Potential Targets of YQS. Taking the herbs (Jinyinhua, Lianqiao, Jiegeng, Bohe, Dantouchi, Danzhuye, Niubangzi, Jingjie, Lugen, and Gancao) in YQS as keywords, the TCMSP database (http://tcmspw.com/tcmsp.php) was used to retrieve their relevant chemical compositions, and oral bioavailability (OB) ≥ 30%, drug-likeness (DL) ≥ 0.18, and drug half-life (HL) ≥ 4 h were adopted as screening conditions to obtain active ingredients that meet the conditions [14–16]. Among them, the active ingredients of Danzhuye were obtained through a combination of a literature search [17] and the TCMSP database.

Through the TCMSP database and the PubChem database (https://pubchem.ncbi.nlm.nih.gov/) combined with the Swiss Target Prediction database, the targets of the active ingredients were obtained. UniProt KB (http://www.UniProt.org/), which prevents, for example, overannotation of semblable proteins such as paralogs and putative products of pseudogenes, was utilized to normalize gene names and organisms. Through the UniProt database (https://www.UniProt.org/), the species was set as "*Homo sapiens* (Human)" to standardize the obtained drug targets.

2.2. Screening of COVID-19-Associated Genes. Through the GeneCards database (http://www.genecards.org/) and OMIM (https://www.omim.org/) database, using "novel coronavirus pneumonia" as the keyword, COVID-19-related disease targets were retrieved and obtained. Only "*Homo sapiens*" proteins linked to COVID-19 were selected. The UniProt database was applied to standardize the obtained disease targets in *Homo sapiens*.

2.3. Screening of Candidate Targets. The acting targets of the active ingredients of YQS and the disease targets of COVID-19 were processed through Venny2.1 software (http://bioinfogp.cnb.csic.es/tools/venny/index.html) to acquire their common targets, which were taken as alternative targets of YQS for treating COVID-19, and its Venny map was also acquired.

2.4. Protein-Protein Interaction (PPI). The retrieved YQS active ingredient targets were linked to COVID-19 targets by the STRING (https://string-db.org/, ver.11.0) database [18]. The requirement was restrained to "*Homo sapiens*." In this paper, a high confidence score with a correlation degree ≥0.400 [19] as the cutoff value was set to obtain the network.

2.5. GO and KEGG Pathway Enrichment Analysis. Gene Ontology (GO) enrichment analysis was conducted using the OmicShare tools (http://www.omicshare.com/tools). The KOBAS 3.0 database was applied to analyze the KEGG pathway enrichment of the candidate targets, and the

RStudio 3.6.3 and ggplot2 packages were applied to illustrate the results.

2.6. Networks Construction and Analysis. Cytoscape 3.5.1, an open-source software platform to visualize complex networks, was employed to illustrate the networks. With this software, the network building was handled as follows: (1) compound-COVID19 PPI network, (2) compound-targets network, and (3) YQS (Yinqiaosan)-compound-targets-pathway network. In addition, four topological features of the hub network, such as "Degree" and "Betweenness Centrality," were determined to choose YQS alternative targets with topological significance [20, 21]. To determine the relationship between network clusters and to identify high-connectivity hub genes, "Cytohubba" (a plug-in of Cytoscape) was introduced to check the node element. The top 10 nodes were ranked by EPC [22].

2.7. Molecular Docking. For the sake of validation of the drug-targeted correlations, the molecular docking simulation further proceeded on every drug docking with their targets. Each drug molecule, such as luteolin, naringenin, acacetin, kaempferol, and quercetin, was downloaded from the TCMSP database and converted to a PDBQT file by Chimera (version 1.10.2).

The structures of the proteins in each alternative target were downloaded from the RCBS Protein Data Bank (http://www.rcsb.org/pdb), and every protein file was opened with ADT (version 1.5.6), a free GUI for AutoDock. In every file, the water molecules were canceled, the polar hydrogen atoms were increased, and then they were written to a PDBQT file.

The intersection of possible alternative targets and drug targets of PCOS was chosen for in-depth investigations. To validate the interaction and observe the docking sites between drugs and targets, molecular docking was performed by an open-source program called Autodock vina 1.1.2. The docking results were observed with ADT.

The foundation for developing medications for the clinical therapy of COVID-19 is shown in Figure 1.

3. Results

3.1. Active Components and Target Proteins of Yinqiaosan. By a systematic search of the public databases, 141 components were retrieved in JYH (17), LQ (11), JG (7), BH (10), DDC (2), DZY (4), NBZ (4), JG (9), LG (1), and GC (76), and the specific information of these components can be found in Table 1. After deleting the duplicate values, 117 active ingredients were acquired. Refer to the results in Figure S1. Through observation, it was discovered that some special compounds in this network interacted with multiple targets and took part in the regulation of multiple targets, such as luteolin, naringenin, acacetin, kaempferol, and quercetin.

A total of 810 targets were obtained from public databases, but not all information on all 810 targets is shown. The YQS compounds may jointly affect all of these targets, producing pharmacological impacts on COVID-19.

3.2. Screening Results of COVID-19-Related Disease Targets. The GeneCards database, as an online catalog of human genes and genetic illness, can enable effective navigation of gene-disease linkages [23]. The OMIM database deals with over 15,500 gene entries and concentrates on elaborating gene-phenotype correlations [24]. Through the two databases, we obtained 435 genes in total (not all shown).

3.3. Screening Results of Candidate Targets. Altogether, 77 overlapping genes were acquired by searching the overlaps of the aforementioned compound targets with the 435 COVID-19 gene targets. These genes included PIK3CD, PLA2G5, and ECE1 (Table S1, Figure 2(a)).

By importing compound-disease cotarget information into STRING, a compound-COVID-19 target PPI network was obtained. Taking a score ≥ 0.4 as the limiting condition [19], the interaction relationship of 77 targets obtained from the String network database was screened. Then, a network diagram of 77 targets protein interactions was obtained. Combined with Cytoscape 3.5.1 software, we obtained an interaction network graph of alternative targets of YQS for treating COVID-19, including 77 nodes and 719 edges. The node colors are illustrated from red to yellow in descending order of degree values (Figure 2(b)). Among the targets of YQS for treating COVID-19, the 5 targets with the highest degree were TNF, GAPDH, MAPK1, MAPK3, and EGFR.

3.4. Results of the Construction of the Compound-Target Network. The data of the active ingredients of YQS as well as its targets for treating COVID-19 were input into Cytoscape 3.5.1 software to obtain the network chart of active ingredient-acting targets. The active ingredients of YQS were represented by their Mol IDs. There were 173 nodes and 831 edges forming the compound-target network. The diamonds represent 95 active ingredients, and the ellipse indicates 77 targets of active ingredients (Figure 3).

3.5. Enrichment Analysis Results of Biological Processes and Pathways. To carry out an in-depth recognition of the biological functions of the above 77 potential targets in biological networks, a GO enrichment analysis was implemented with the OmicShare tools, a free online platform for data analysis (http://www.omicshare.com/tools) [25]. As shown in Figure 4, the results fell into three strata: biological processes (BP), cellular components (CC), and molecular functions (MF). The limiting condition was $P < 0.01$, where the smaller the P value is, the closer the relationship with YQS will be in treating pneumonia. The results show that the BP analysis mainly includes the response to organic substances, the cellular response to organic substances, and the cellular response to chemical stimulus (Figure 4(a)). The CC analysis mainly included membrane microdomains, membrane rafts, and membrane regions (Figure 4(b)). The MF analysis was mainly related to enzyme binding, phosphotransferase activities, alcohol groups as acceptors, and kinase activities (Figure 4(c)).

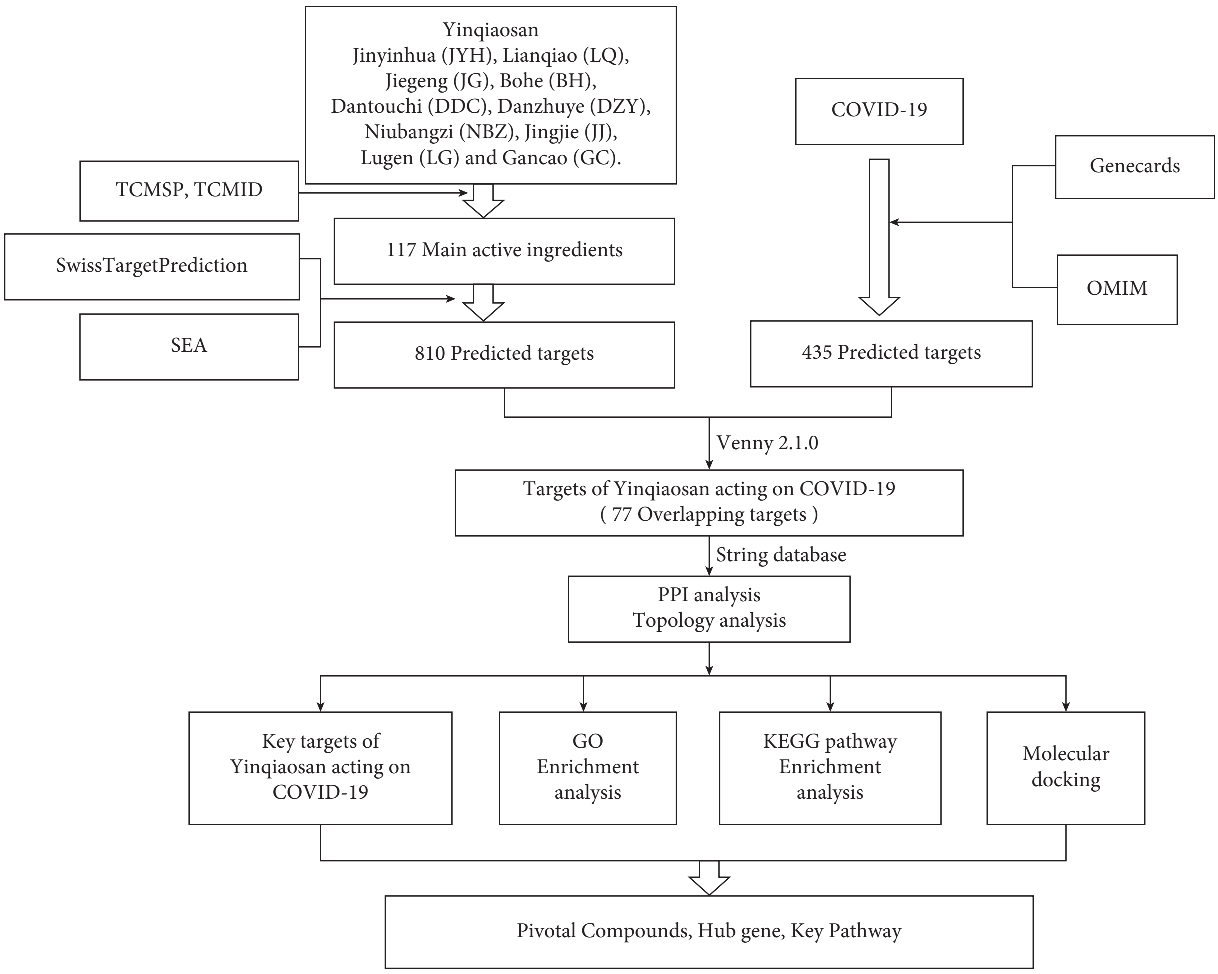

Figure 1: Process overview. To understand the active ingredients of each single drug in Yinqiaosan (YQS) through the TCMSP (Traditional Chinese Medicine Systems Pharmacology Database and Analysis Platform) and TCMID (Traditional Chinese Medicine Integrated Database), the targets of the active ingredients were identified by Swiss TargetPrediction and SEA (similarity ensemble approach). Similarly, COVID-19 targets were obtained through the GeneCards and OMIM (Online Mendelian Inheritance in Man) databases. Intersecting targets were then assessed by molecular docking and GO and KEGG enrichment analysis. GO (Gene Ontology) enrichment analysis was carried out with the OmicShare tools. The KOBAS 3.0 database was used for KEGG enrichment analysis, and RStudio was used to visualize the results. Molecular docking was conducted by an open-source program named Autodock vina 1.1.2. Networks were constructed to provide a visual view by Cytoscape 3.5.1 software.

(a)

(b)

Figure 2: Overlapping targets (a) and the protein-protein network (b). Node colors change gradually from red to yellow, and node sizes are in proportion to their degree.

Utilizing the online platform KOBAS 3.0, 190 important KEGG pathways ($P < 0.01$) were found on the basis of differentially expressed coding transcripts. The most important pathways included Kaposi sarcoma-related herpesvirus infection, AGE-RAGE signaling pathways in diabetic complications, and pathways in cancer. The result was constructed by KOBAS 3.0, and the top 20 enrichment pathways were visualized by RStudio (Figure 5). This indicated that YQS might be a candidate for treating COVID-19 through these pathways.

3.6. Construction of "YQS-Compounds-Targets-Pathway" Network. The top ten channels in the enrichment analysis of the KEGG pathway and the compound and compound targets were imported into Cytoscape 3.5.1 software to build a "YQS-compounds-targets-pathway" network (Figure 6). The figure includes 194 nodes and 1185 edges. The red diamonds denote YQS, yellow hexagons represent the traditional Chinese herbs in YQS, green rectangles represent the potential active ingredients, blue ellipses represent YQS candidate treatment targets for COVID-19, and purple triangles represent the possible signaling pathways for the active ingredients to function. It can be seen from the figure that YQS includes 10 herbs and 95 active ingredients. It mainly acts on TNF, GAPDH, MAPK3, MAPK1, EGFR, CASP3, MAPK8, MTOR, IL-2, and MAPK14 and uses Kaposi sarcoma-related herpesvirus infection, AGE-RAGE signaling pathways in diabetic complications, pathways in cancer, apoptosis, hepatitis B, human cytomegalovirus signaling pathways such as infection, measles, and hepatitis C to treat pneumonia.

3.7. Molecular Docking. Molecular docking was further utilized in our research to estimate the interaction between components and targets to reduce the complexity and increase the precision of the constituent target network [26].

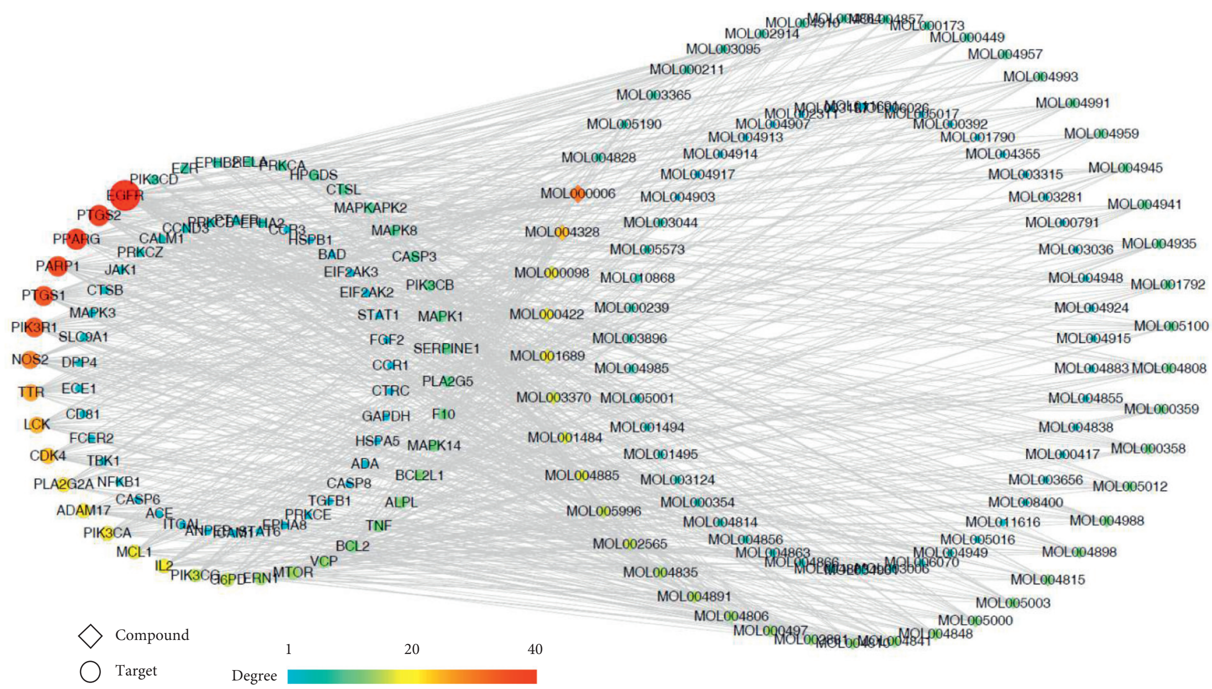

FIGURE 3: The compound-target networks of Yinqiaosan (YQS). The diamond nodes denote ingredients, and the circular nodes denote targets. The node colors from red to blue and node size are proportional to its degree.

The cytoHubba control panel is a useful tool to retrieve subnetworks from the whole large PPI set [27]. Hub gene recognition was processed by the cytoHubba plug-in in Cytoscape software. All active ingredients in the top 5 online pharmacology degrees of freedom were taken as the research object. To determine the valid connecting effects between YQS-main active ingredients and their predicted targets, molecular docking was assessed using the YQS-hub genes connecting the energy. Molecular docking analyzed 10 hub genes (CASP3, EGFR, GAPDH, IL-2, MAPK1, MAPK14, MAPK3, MAPK8, mTOR, and TNF) and 5 compounds (acacetin, kaempferol, luteolin, naringenin, and quercetin).

Zhou et al. [3] ascertained that 2019-nCoV makes use of the same cell entry receptor, angiotensin transforming enzyme II (ACE2), as SARS-CoV. 3CL hydrolase is the core protease of single-stranded RNA virus precursor polyproteolysis and it plays a vital role when replicating the single-stranded RNA virus [28]. Therefore, in this study, the 5 compounds were also molecularly docked with SARS-CoV-2 3CL hydrolase (Mpro) and ACE2 to provide references for treating COVID-19 by TCM.

The lower the binding energy, the more stable the conformation of the ligand-receptor binding [29]. When the binding energy is less than −5.0 kcal/mol, this suggests that the compound can bind to the target. When the binding energy is less than -7.0 kcal/mol, this suggests that the compound has a good ability to bind to the target. We selected the conformation with the lowest binding energy to analyze the docking binding mode and used Discovery Studio for mapping.

Molecular docking results showed that all five active ingredients could be combined with 10 hub genes (Table S2), Mpro or ACE2 (Table 2, Figure 7). Therefore, the 5 compounds could efficiently act on the 10 targets, especially TNF, MAPK14, MAPK3, and MAPK8. Kaempferol (Figures 7(a) and 7(b)) and Mpro have a better binding capacity, which is consistent with the docking results of the molecules discovered by Ling [30]. Acacetin (Figures 7(c) and 7(d)), luteolin (Figures 7(e) and 7(f)), and ACE2 have a better combining ability.

4. Discussion

At present, COVID-19 has expanded to over 200 countries and areas, and the lives and health of people around the world are under serious threat. Special drugs against COVID-19 are still under development. TCM adopts the principle of dialectical treatment with the characteristics of multiple targets and multiple pathways, and it plays a vital role in antiepidemic treatment [31–33]. The "COVID-19 Diagnosis and Treatment Program (Trial Ver. 3)" issued by the National Health Commission of the People's Republic of China pointed out that COVID-19 is categorized as a "pestile" in TCM, which happens under direct or indirect contact with epidemic pathogens. The main features are "damp, heat, poisonous, stasis." COVID-19 is divided into four types of TCM syndromes: cold-dampness stagnating in the lung, damp-heat accumulating in the lung, damp toxin stagnating in the lung, and internal blocking causing external collapse. The clinical symptoms of "damp-heat accumulating in the lung" are low body temperature or no fever, mild aversion to cold, fatigue, a heavy sensation in the head and body, dry coughs with scanty phlegm, sore throat, and a dry mouth with no wish to drink water. Alternatively, chest tightness, epigastric fullness, absence of sweating or

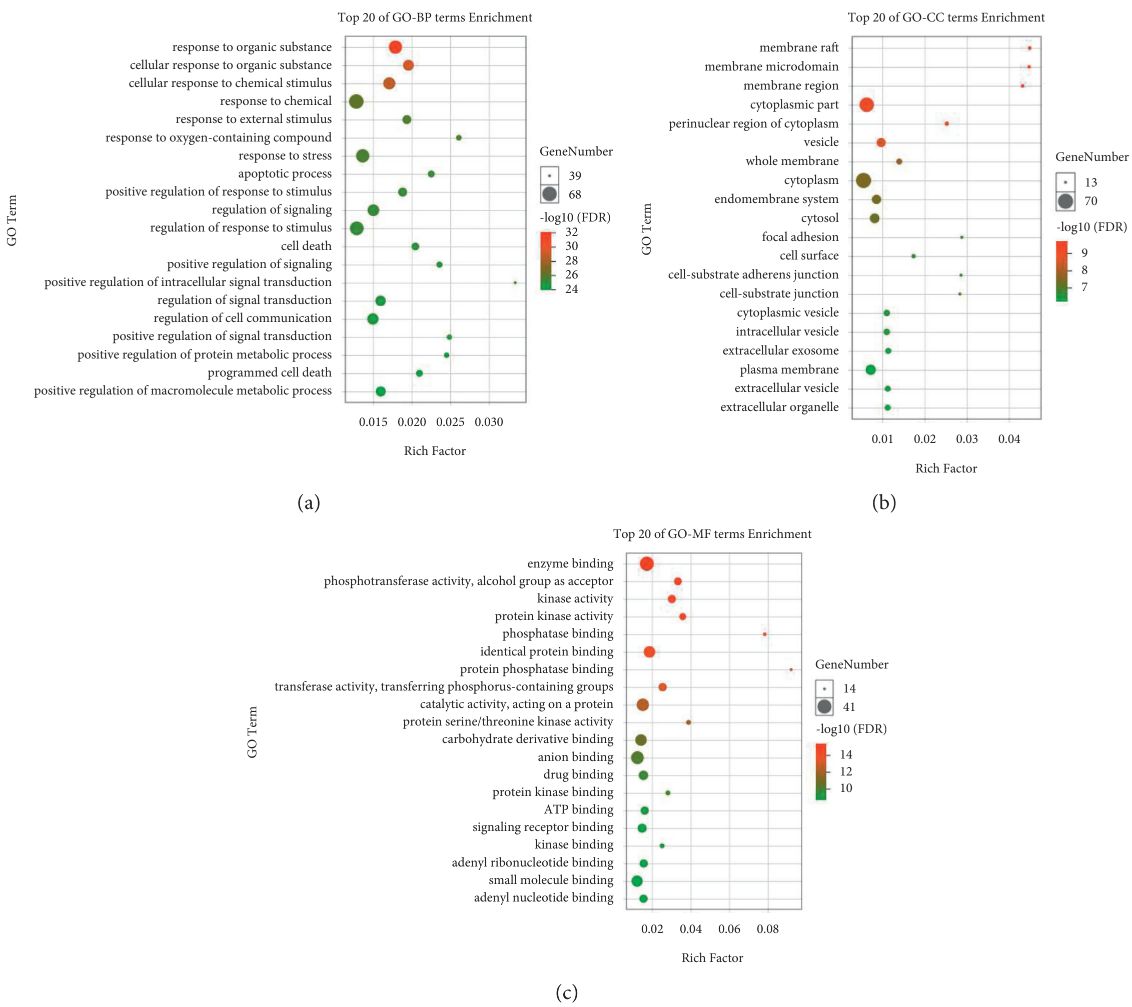

Figure 4: GO enrichment analysis of Yinqiaosan (YQS) targets. The three strata were biological processes (BP) (a), cellular components (CC) (b), and molecular functions (MF) (c). *Y*-axis: top 20 biological processes associated with the enriched targets. *X*-axis: enrichment factors (rich factors). Rich factors are proportional to the degree of enrichment. The node size shows the number of genes, and the larger the node is, the more the genes enriched in the term are. The color depth of the node demonstrates the significance level, and the redder the node is, the higher the significance will be to the term.

inhibited sweating, vomiting, a poor appetite, and loose stools or sticky stools with a feeling of incomplete bowel movement may also be present. The tongue is pale red with a white, thick, and greasy or thin, yellow coating. The pulse is soft or slippery and rapid. The recommended prescriptions are Maxing shigantang and YQS.

YQS was described by Wu in "Wen Bing Tiao Bian." He is a famous infectious febrile disease specialist. Part of the composition of the Lianhua Qingwen capsule comes from YQS, which is particularly effective in treating pneumonia. YQS is comprised of ten Chinese herbs, JYH, LQ, JG, BH, DDC, DZY, NBZ, JJ, LG, and GC, and mainly treats the manifestations caused by diseases such as damp-heat accumulation in the lung. Bohe and Niubangzi have flavor and cool properties and can help sore throats. Jingjie and Dandouchi can help the main medicine drive away damp heat. Dan Zhuye and Lugen can clear the heat, and Jiegeng and Gancao can relieve cough. YQS is commonly used in the clinic against influenza A virus infection [34–36].

This study uses network pharmacology to forecast the main active components and potential molecular mechanism of YQS against COVID-19. Through the TCMSP database, 141 active ingredients of each single medicine in Yinqiao powder were obtained, of which the five most powerful components were acacetin, kaempferol, luteolin, naringenin, and quercetin. Studies have shown that luteolin may suppress the infection of respiratory epithelial cells by *Escherichia coli* through immunomodulation [37]. Wu et al. established a mouse model of *Staphylococcus aureus* pneumonia and found that naringenin could significantly alleviate the disease [38]. Acacia has antibacterial, antioxidant, anti-inflammatory, antiviral, antipyretic, and analgesic effects [39]. It can protect against atherosclerosis by antagonizing the LysoPC-induced apoptosis of vascular smooth muscle cells and stimulating the antioxidant regulatory factor Nrf2 [40]. Kaempferol has an extensive scope of pharmacological activities, including antioxidant, anti-inflammatory, antimicrobial, etc. [41], and its derivatives are

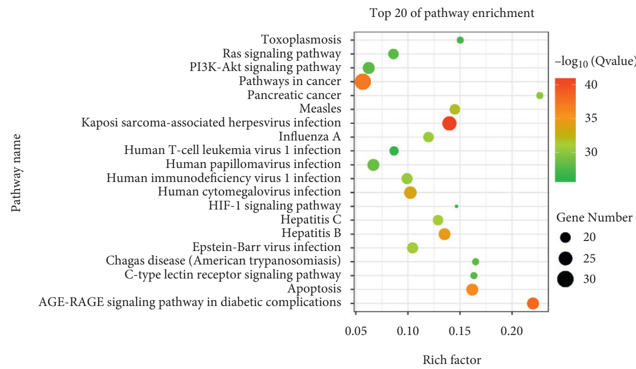

Figure 5: Analysis of the 20 most enriched KEGG pathways of candidate targets of Yinqiaosan (YQS) for COVID-19. The node size denotes the number of target genes that belong to the pathway. The X-axis denotes the enrichment factor (rich factor), that is, the number of genes in the pathway in the target gene/the number of genes contained in the pathway in the background gene set. The Y-axis denotes the pathway. The color depth of the node demonstrates the significance level, and the redder the node is, the higher the significance will be to the pathway.

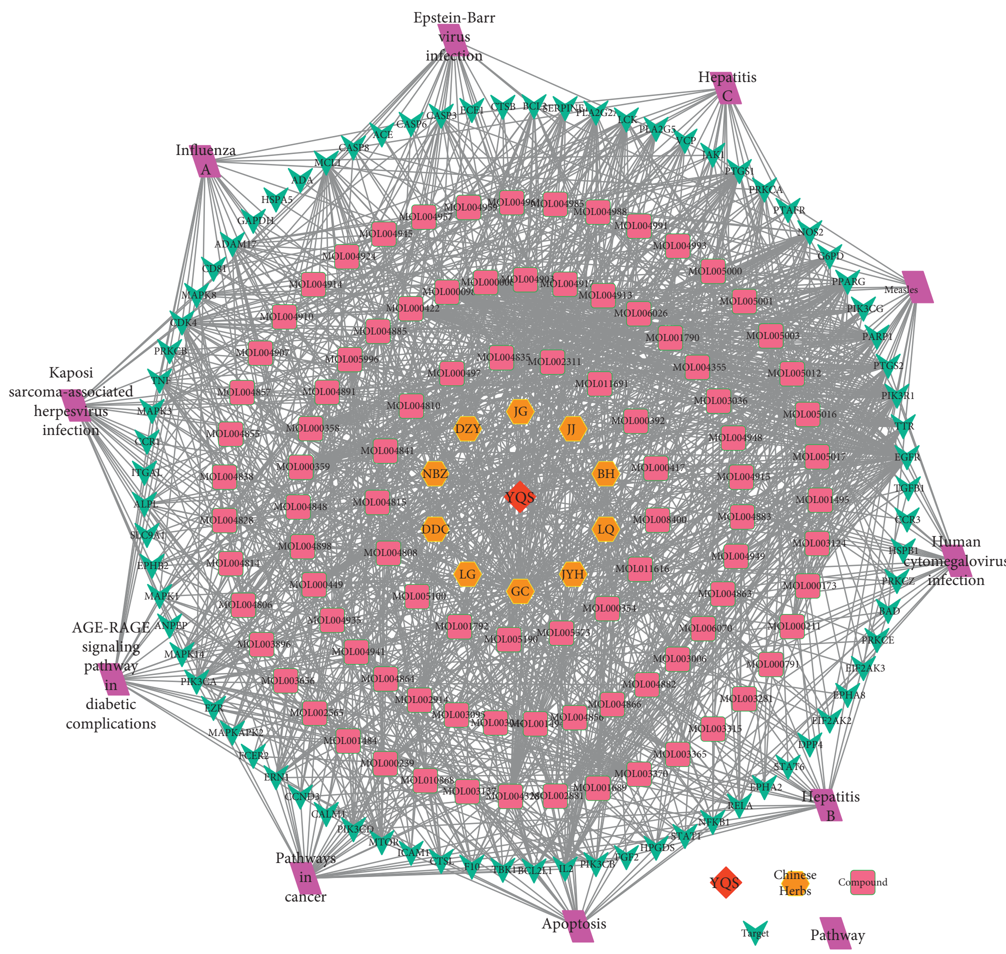

Figure 6: Yinqiaosan (YQS)-compound-target-pathway network. The red bubbles denote YQS (Yinqiaosan), the yellow bubbles denote Chinese herbs, the pink bubbles denote compounds, and the violet bubbles denote pathways.

used as antiviral drugs against coronavirus 3a channel protein [42]. Quercetin and its derivatives also have strong anti-inflammatory and analgesic pharmacological activities [43]. Wang et al. [12] found that active compounds such as quercetin, kaempferol, naringenin, and luteolin also played a pivotal role when treating COVID-19 using Maxing Shigan decoction. Kong et al. [44] discovered through molecular docking that kaempferol, quercetin, luteolin, and new coronavirus (SARS-CoV-2) 3CL hydrolase have good affinity.

There are 77 candidate targets for YQS in COVID-19 treatment. TNF, GAPDH, MAPK3, MAPK1, EGFR, CASP3,

MAPK8, mTOR, IL-2, and MAPK14 are important targets for YQS in COVID-19 treatment. COVID-19 is similar to other viral pneumonia conditions. Some scholars have found that cytokine storms (CSs) may affect the progression of COVID-19 illness [45]. The cytokines involved in CS mainly include six categories: tumor necrosis factor (TNF), interleukin (IL), interferon (IFN), colony stimulating factor (CSF), and growth factor (GF). The cytokine storm induced by SARS-CoV-2 includes the cytokine IL-2, and the TNF-α- and H7N9-induced cytokine storms include cytokines, including IL-2 [46]. Studies have shown that, in throat swabs and sputum specimens of 4 cases of COVID-19, the housekeeping gene GAPDH of human cells showed a typical amplification signal curve [47]. *Staphylococcus aureus* pneumonia and virulence factor A can stimulate the AMPK signaling pathway and inhibit the mTOR pathway to induce autophagy in alveolar epithelial cells, an important mechanism during early infection of *S. pneumoniae* [48]. Liu et al. [49] predicted MAPK1, MAPK3, and MAPK14 through network pharmacology as important targets for Dayuanyin to treat COVID-19. Huang et al. [4] predicted that MAPK1 and MAPK14 were important targets for Huanglian Jiedu decoction to treat COVID-19. Other studies have shown that EGFR may be a key factor in the inflammation caused by *Klebsiella pneumoniae* infection [50].

Furthermore, molecular docking results showed that the 5 compounds could efficiently act on the 10 targets, especially TNF, MAPK14, MAPK3, and MAPK8. Kaempferol and Mpro have a better binding capacity. Acacetin, luteolin, and ACE2 have a better combining ability. Whether they are docked with molecules of hub genes or docked with the proven targets of pneumonia, this shows the feasibility of using these five compounds to treat pneumonia. Reportedly, AGEs modulate COVID-19 pathogenesis and related comorbidities through their interactions with RAGE, among other molecules [51]. Interestingly, Yalcin Kehribar et al. [52] found that the RAGE pathway plays an important role in the aggravation of COVID-19. These reports provide strong evidence for our data.

To clarify the role of YQS in COVID-19 treatment based on gene functions and signaling pathways, this study performed GO functional enrichment and pathway enrichment analysis of the candidate targets. The GO enrichment analysis showed that the biological procedure of YQS against COVID-19 was mainly reflected in the positive regulation of the adhesion of white blood cells and vascular endothelial cells and the negative regulation of the apoptosis process of cholangiocarcinoma cells. The cellular components were mainly reflected in cytoplasmic vesicles, membrane rafts, and organelle membranes. The molecular functions were mainly reflected in phosphotransferase activity, alcohol receptor, and cytokine receptor binding. The results of KEGG pathway enrichment analysis show that YQS may comprehensively play a role in preventing and treating pneumonia by way of PTGS2, MAPK14, CCR1, CCR3, MAPKAPK2, MAPK3, MAPK1, ICAM1, JAK1, NFKB1, MAPK8, PIK3R1, MTOR, RELA, CASP3, FGF2, TBK1, EIF2AK2, CASP8, and CDK4 targets that are related to the Kaposi sarcoma-associated herpesvirus infection signaling pathway; TGFB1, MAPK14, SERPINE1, STAT1, PIK3CA, PIK3CB, PIK3CD, MAPK3, MAPK1, PIK3R1, NFKB1, RELA, ICAM1, PRKCA, PRKCB, PRKCE, PRKCZ, MAPK8, CASP3, TNF, CDK4, and BCL2 targets that are related to the AGE-RAGE signaling pathway; and TGFB1, MAPK14, SERPINE1, STAT1, PIK3CA, PIK3CB, PIK3CD, MAPK3, MAPK1, PIK3R1, NFKB1, RELA, ICAM1, PRKCA, PRKCB, PRKCE, PRKCZ, MAPK8, CASP3, TNF, CDK4, and BCL2 targets that are related to the pathways in cancer signaling pathways.

5. Summary

In summary, our study found that active ingredients such as luteolin, naringenin, farnesin, kaempferol, and quercetin can act on targets such as TNF, GAPDH, MAPK3, MAPK1, EGFR, CASP3, MAPK8, MTOR, IL-2, and MAPK14 to regulate signaling pathways such as Kaposi sarcoma-associated herpesvirus infection and AGE-RAGE, finally achieving the effect of curing COVID-19.

In the next step, further in vitro and in vivo experimental validation will be carried out to advance our research. The follow-up plan of our research group is to carry out more in-depth experimental research on YQS and to fully explore the mechanism of its efficacy.

With the development of intelligent sports in China and the rapid improvement of the strength of colleges and universities, the reform of traditional football players' header shooting training methods is becoming more and more urgent in order to solve some problems in the development of sports and speed up the intelligent training of Chinese football players. Based on this, this paper studies the biomechanical analysis and training method based on the integration of header strength data of football players. A dynamic header tracking model of football players based on a local search algorithm is designed. The data collection is realized from the aspects of athletes' header shooting training, skill improvement, physical consumption, and trajectory. The biological data of header shooting power is comprehensively analyzed and evaluated by using a local search algorithm. The results show that the training system based on a local search algorithm has the advantages of high feasibility, high data accuracy, and fast response speed. It can effectively conduct accurate guidance and improve the shooting accuracy according to the biological characteristics of header shooting intensity. This paper studies the biological analysis and training method of header strength of football players based on a local search algorithm. This has certain reference significance for accelerating the construction of intelligent training of Chinese football players.

1. Introduction

Up to now, the teaching process of College Physical Education in China is mainly based on the traditional collective and group teaching, supplemented by the independent teaching of the main team members [1]. Since the reform and opening up, the rapid development of various information technologies in China has also led to the reform of China's football system and training methods. The emergence of modern football teaching methods such as team cooperation provides an opportunity for the large-scale development of new football courses in colleges and universities. Intelligence has become an important feature of China's current football training system [2]. At present, although the existing football training system provides a large number of football training methods, it is difficult for players to choose targeted football header shooting training methods according to their own strength structure and biological characteristics in the training process of header shooting and can not achieve the optimal football actual combat effect [3]. In this context, this paper studies the strength characteristics and biological characteristics of the headshot process of government and enterprise players and proposes a dynamic tracking training method of headshot based on the integration of football players' strength information.

The innovation of this paper is to propose a local search algorithm. On this basis, it can make full use of each player's strength training and biological energy characteristic information. Through real-time dynamic tracking, it can achieve the overall approach and quantitatively describe the degree of similarity between the comparison column and the reference column and the degree of agreement between the expected indicators with local correlation factors. By using quantitative indicators to complete the influence degree ranking of training system indicators, it can efficiently carry out customized analysis on the factors affecting players' skill level.

This paper studies the biological analysis of the headshot strength of football players and the construction of training methods, which is mainly divided into three parts. The first part introduces the research status of football training factors at home and abroad. In the second part, the dynamic tracking training model of football player's header shooting based on a local search algorithm is constructed, and the Laplace factor method is used to construct the evaluation index system of header shooting accuracy. The third part tests the evaluation index of the dynamic tracking training system of football players' heading and shooting strength and draws a conclusion.

2. Related Work

Since entering the twenty-first century, the training of sports players has encountered difficulties, especially in the construction of football teaching and training systems [4]. Columbia University scholars found that most football training still follows the traditional football training ideas, ignoring the cultivation of practical skills and comprehensive ability. Football training is mainly divided by basic football knowledge, basic football skills and professional knowledge, and broad football skills. Players are not interested in traditional football training. Scholars from Tokyo University of Japan teach according to the rules of football playing and put forward that we should pay attention to the development of classroom-based explanation or teaching video playback, strengthen the development and construction of professional football knowledge courses, and enhance the cognition and attention to football teaching, and the cultivation of football teachers' ability should be improved [5]. According to the multifactor relationship theory and local cooperation theory, a new multirelationship recommendation algorithm is proposed by scholars of Harvard University in the United States, The local weak relation recommendation algorithm has better heterogeneous information acquisition ability than the classical recommendation algorithm [6]. Scholars from Beijing Sport University of China adopted the local search algorithm based on multilocal high weight correlation factors, selected three characteristic parameters related to football players and training system influence indicators, and proposed a dynamic tracking training system for football players' heading and shooting based on local search algorithm for athletes' training characteristic parameters. Football training and other related theories improve the particle swarm optimization algorithm, construct the particle swarm optimization algorithm based on the traditional football training system, and explain the theoretical basis and practical significance of these changes in the algorithm performance with the theory of game theory. Experiments show that the improved algorithm has good local optimization performance [7]. Based on the kinematic theory, scholars from the University of London proposed a hierarchical football header shooting training method. Through the research and analysis of the dynamic differences of weight, height, body fat, and running speed of different football members, it is found that the algorithm can realize the personalized training improvement of hierarchical football players [8]. In order to improve the training efficiency and overall team coordination of football players, scholars from the University of Melbourne in Australia proposed a new team fusion intensive training system based on hyperchaotic mapping through the research of daily training, heading posture analysis and detection, and physical consumption, It is suitable for the analysis of football training and looking for the problems existing in training [9]. Scholars from the University of Toronto in Canada scramble the original football training method by using the transformed chaotic sequence. The results show that the innovative training system has a good overall coordination effect and can resist attack and defense. It can be used in the construction of a football training system [10]. Scholars from Waseda University in Japan proposed a new hyperchaotic cellular neural network football training algorithm to generate the keystream in the team defense stage of football training. The results show that, compared with other related algorithms, this algorithm has the advantages of key sensitivity and strong antiattack and is suitable for football training [11]. Based on the traditional football training fusion strategy technology, scholars from the University of California proposed a panoramic video football cross-border folding search algorithm, which clearly defined the hierarchical framework and index relationship of the whole football training system. This paper evaluates the system from multiple perspectives and provides a comprehensive index sample for the evaluation of the training system of intelligent Chinese football players. Then, it uses the local search algorithm to analyze the characteristics of the players' training results. The results show that the algorithm can effectively reduce the error of football search matching blocks and improve the training efficiency. It is conducive to improving the training skills of heading and shooting in football [12]. Scholars from the Northwestern University of the United States put forward the Fourier function algorithm, and the results show that the algorithm can effectively remove the inefficient cooperation events in the football training system [13]. In order to solve the problem of efficiency and tactical effectiveness of group training, scholars from Shanghai Jiaotong University of China proposed a football competition tactical method based on genetic algorithm and particle swarm optimization algorithm. Experiments show that the algorithm can effectively improve the practicability of football tactics [14]. Scholars from the Hong Kong Polytechnic University of China have realized the tactical evaluation basis in football training by simulating the "modeling structure diagram" in the process of football modeling and improved the flexible transformation from traditional football tactics to modern tactics [15].

To sum up, it can be seen that most of the current football training modes do not involve intelligent depth mining analysis and local search algorithms based on the dynamic training data of football players' heading and shooting. On the other hand, although China has done a lot of basic research, the specific quantitative dynamic evaluation of football intelligent training system and the improvement of football training effect research results are relatively less, and there is no research and related model construction on the intelligence of Chinese football players' heading and shooting training system.

3. Methodology

3.1. Application Principle of Local Search Algorithm in the Biomechanical Analysis Model of Heading Shot. In order to more intelligently and accurately analyze the specific effect of the signal processing link in the football header shooting, this paper uses the local search algorithm to detect and analyze the head dynamic signal of the football group in the daily football training process. The basic principle of the common local search algorithm is shown in Figure 1, in which DC is the search center.

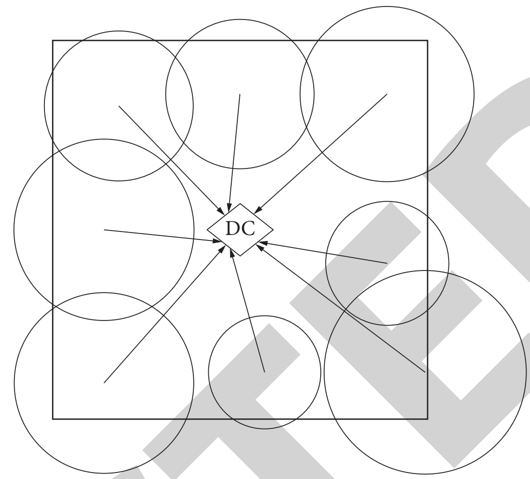

Figure 1: The basic principle of the local search algorithm.

In this study, the local search algorithm is to find the groups with high similarity of force signals in the process of header shooting from each football player and cluster them. Therefore, the probability of the standard motion data being selected for secondary or multiple detection and analysis is high. On the contrary, if the signal form with a low correlation of dynamic strength structure of football players is selected for secondary or multiple analysis, the probability will be very low. After many times of comparative analyses, the new generation of people with overlapping head ball posture features not only inherits the dynamic head data information of the previous round of intelligent screening but also has a better optimization degree than the information set of the previous generation of eliminated football signals. In this way, after several interactive cycles of two-way heading posture information, the specific information that meets the heading posture requirement conditions corresponding to the lowest normal football skills is finally generated; that is, the analysis value of the normal boundary of a certain football heading posture signal approximates the normal requirement value of the actual heading posture signal. In this way, we can analyze and record the unique heading posture information under the condition of "optimized local search algorithm," and the mode can also realize the function of self-storage and prediction. The more the process of accumulating the dynamic data of football players' heads, the stronger the self-learning ability and self-evaluation of the system. In addition, in the process of establishing this model, we found that, in the current Chinese long-term football and power sports groups, the analysis of most of the shooting posture of the head ball is based on the traditional detection equipment, and the detection process is mainly direct contact detection. However, noncontact real-time head ball attitude signal detection is rare. Therefore, in this model, a standard structure data evaluation model of football header shooting posture is set in advance (in order to determine the key detection nodes). Therefore, this paper studies the processing object based on the head ball poses randomly selected from the local multigroup head ball pose set of multiple targets to be detected. By comparing with the big data system of the real-time heading posture analysis model of football players, it is very easy to know through simulation that in the two groups with low similarity in the structure of heading posture, it is found that there is a great difference in the skill of shooting between them. And engaged in the football game, the difference in the way of attack will be relatively large.

The above is the basic principle of the local search algorithm used in the research of dynamic signal tracking and data processing of football players' headshots. Through the above optimized local search algorithm, the analysis process is shown in Figure 2, where BN is the connection center, and the rest (*a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *k*) are the classification subcenters. Compared with the common head posture analysis method of football players, it can achieve more accurate analysis and strength correction, which plays a more effective role in the training process of football players' heading and shooting.

3.2. Implementation Steps of the Dynamic Tracking Training Model for Football Players' Heading and Shooting. In order to reduce the error analysis of the dynamic signal processing in the training process, we use the local search algorithm with adaptive characteristics. Aiming at the head ball posture signal analysis model of football players in the daily training process, firstly, we will use the big data information and intelligent analysis and processing of the heading posture corresponding to the existing skillful football movements to obtain the initial weight and the minimum threshold value of the heading posture requirement of normal football movement required in the optimized local search algorithm. Then, the local search algorithm is used to analyze and trace the demand degree of heading posture in accordance with the standard with secondary subdivision in the category group of a specific football player's heading posture information. Finally, the optimal solution is searched, and then the real-time dynamic range of heading posture data in the training process is screened out. The three simulation analysis results of the local search algorithm (TSBN, TSFA, and GCSA) are shown in Figure 3, where the horizontal axis

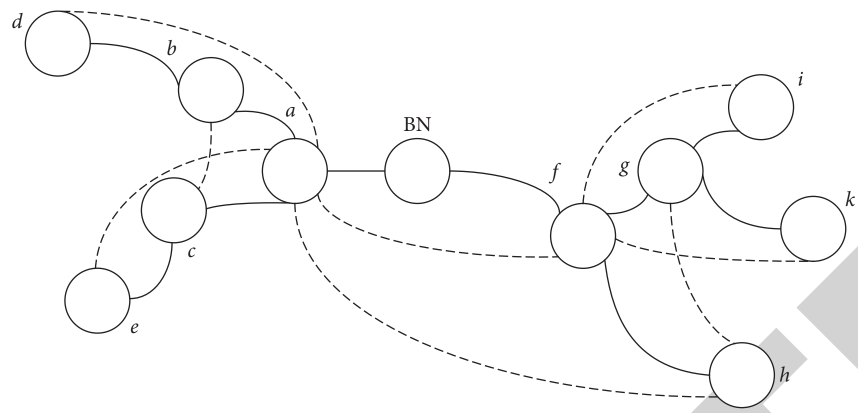

Figure 2: Analysis process of the local search algorithm.

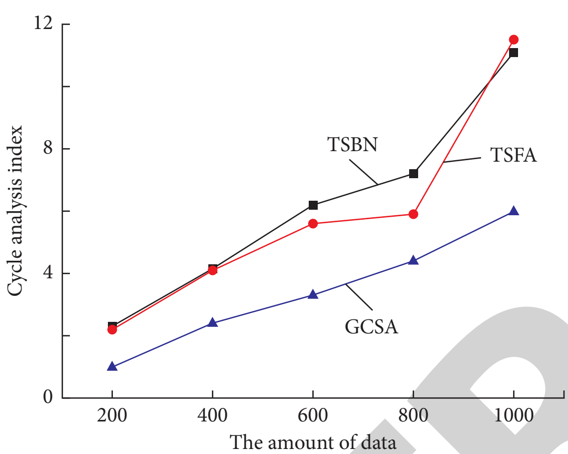

Figure 3: Three kinds of simulation analysis results of the local search algorithm.

is the amount of data and the vertical axis is the cycle index factor.

In the later simulation analysis process, we found that the effect of the traditional local search algorithm is not particularly good. Therefore, in order to improve the detection and intelligent analysis of the head dynamic signal in the football group through the local search algorithm, we need to optimize the local search algorithm, so we use the partial implementation process. In this process, the local search algorithm aims at the dynamic structure of the head ball and the realization process characteristics of the football movement analysis, which is based on the head ball posture information characteristics of the whole crowd target to carry out fuzzy random selection. The purpose of this fuzzy random selection process is to make the signal detection of the common heading posture of different football players more effective because the well-known local search algorithm is not based on a single target in a certain type of feature detection node of the overall target. But through the whole local group of football head ball posture of joint node structure type group to find and get the type of football head dynamic data detection and analysis, the value of the processing conforms to the standard value of the optimal data target. In the process of simulation, the headshot of a random group is taken as the control simulation object. At the beginning of the simulation, the competitive level of one group is lower than the average (the accuracy of the headshot is low), and the other group is lower than the average (the accuracy of the headshot is high). Through nearly 1000 times of simulation experiments and data training under the dynamic tracking model of football players' header shots based on a local search algorithm, it is found that the two groups of data have a great improvement in the comprehensive performance of the new football header shot strength analysis. Therefore, according to the simulation results, the head movement state and strength biological analysis model of the football player has a high accuracy when he is heading, which also shows that the model has good reliability.

Next, the implementation steps and results of the head dynamic signal processing model of football players in the process of training are shown in Figure 4 (under the three methods of TSBN, TSFA and GCSA, the horizontal axis is the amount of data, and the vertical axis is the cycle index factor).

3.3. Mathematical Algorithm of the Dynamic Tracking Training Model for Football Player's Headshot. The mathematical operation process is as follows when the dynamic tracking training model of a football player's headshot is realized. First, we need to initialize the parameters. First, let the initial parameter $x = 0$ set its judgment function as

$$F_{ij}(x) = \cos\frac{Nx}{x+1}, \tag{1}$$

where N is a constant, and $F_{00}(x) = 0$.

Next, the mathematical operation judgment process is verified, and the verification function is

$$H(x) = \sqrt{\left|\cos\frac{Nx}{x+1} - \sin\frac{Nx}{x+1}\right|}, \tag{2}$$

where N is a constant and x is the amount of information.

We also need to judge the constraints [16]. After the completion of the header shooting data information update, if the end condition is met, the constraint judgment and process update are carried out, and the judgment function is

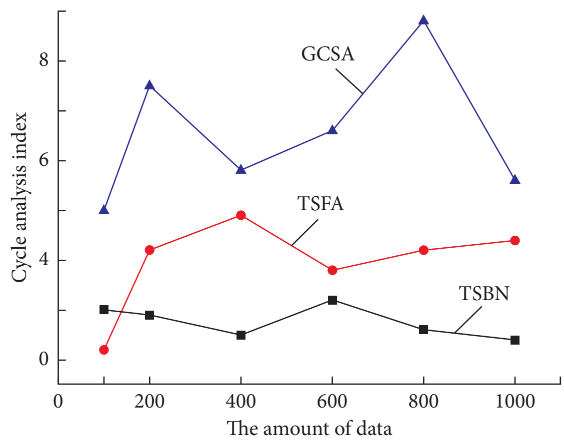

Figure 4: The process flow chart of the ant system algorithm.

$$Q(x) = \left| \frac{s - H(x)}{(s + 1)H(x)} \right|, \quad (3)$$

where s is determined by

$$s = (1 - \rho) * H(x) + \Delta\tau_{ij}. \quad (4)$$

Among them, $\Delta\tau_{ij} = \sum_{k=1}^{m} \Delta\tau_{ij}^{k}$, where τ_{ij} is the length of the current global optimal solution.

Finally, after the pheromone update is completed, the pheromone concentration on each side is limited between $[\tau_{ij\,\min}, \tau_{ij\,\max}]$, to avoid the pheromone on some sides being too large and reduce the pheromone gap on each side of the graph, so as to expand the search space of the solution, so as to complete the biological analysis of the header shot [17].

4. Results of Analysis and Discussion

4.1. Design Confirmatory Experiment. Based on the analysis of the above local search algorithms, the system compares the head ball attitude information data of the analyzed target in the process of processing the header shot signal of different players according to the optimized local search algorithm and the intelligent analysis mode of big data of real-time header shooting attitude information based on football players, so the multilevel comparative analysis can be realized. Under this model, there are different ways of heading posture of different football players and we need to know how to analyze whether the tested players' head posture conforms to the best degree of relevant football movements. Through the dynamic analysis model of football head posture after optimization based on multiple comparative analyses and screening, first, the signal similarity of the same football player in the dynamic training process is received, the data processing is carried out, and the relevant unique vector group is obtained. Then, the head ball attitude signal evaluation sample data of different football players are obtained. The data of the unique vector group of the specific single soccer head posture are processed uniformly and orthogonalized. Then, through the automatic comparison and analysis system of the head ball posture of normal football sport based on big data level and the intelligent combination mode of automatic two-way information interaction, and then through the detection and fuzzy processing of various header posture data of local football players, the minimum threshold of initialization weight and the prediction of head ball attitude signal data required by the optimized local search algorithm is realized. The parameter indexes are shown in Table 1.

In this verification experiment, in order to find the relationship between the headshot strength signal processing of football players and the spatial position of intelligent head ball posture, so that the analysis of football head ball posture can bring effective influence on the daily training of football players, this study calls on the local search algorithm, through the first screening and multilevel horizontal and vertical analysis and processing. The initialization weight and the actual threshold of the whole sample are optimized. The optimal vector obtained by the local search algorithm is transformed back as the optimal weight of the local search algorithm and the output average of the ball attitude structure data of football. Through the above process, the head ball posture analysis and the prediction of the future heading posture trend of football can be realized. According to the experimental results, we can find that the model can avoid some complicated links and achieve the same analysis effect or better processing effect in the process of real-time header attitude signal processing of football players. In the process of the research and establishment of the analysis model of the soccer players' real-time head gesture signal processing method, this paper establishes a unique fuzzy detection analysis and processing model from the aspect of the construction of the local search algorithm model.

4.2. Experimental Results and Analysis of the Analysis Model of Header Shooting Power. The experimental data of the key node signal under the local search algorithm is shown in Table 2.

The experimental results are shown in Figure 5. The horizontal axis is the number of experiments, and the vertical axis is the positive factor.

According to the results of Table 2 and Figure 5, when analyzing the movement process of different header shots in this football header shooting strength analysis model, we can accurately classify them according to the accuracy of shooting and update them according to the way of high shooting success rate, so as to analyze and summarize their internal verification relationship and continuity. Therefore, according to the experimental results, the dynamic signal detection analysis and processing model based on a local search algorithm can have good accuracy and reliability.

The accuracy results of the experimental results of the signals of key nodes under the local search algorithm are shown in Table 2.

The results of this experiment show that the model can compare and analyze the present state of the header shooting attitude of a specific target (football player) according to the information of key detection nodes, and then, we can know whether the skill of a target in football players is affected by the head ball posture. Therefore, the new method of dynamic

signal processing of football players' headshots based on a local search algorithm can be applied to detect and process the real-time head ball attitude signal of professional football players and can complete the monitoring and data analysis of the athletes' posture and strength with high accuracy.

5. Conclusion

In this paper, the local search algorithm based on multiple related factors is used to analyze the header strength of football players. Three characteristic parameters related to header shooting and training system are selected, and a dynamic header shooting tracking training system for football players based on a local search algorithm is proposed. Through the research on the improvement of header shooting posture, header technology, and body consumption of football players, this paper expounds on the hierarchical structure and index relationship of the real-time header posture training system of football players. The local search algorithm and ant colony algorithm are used to analyze the characteristics of the screening results. Compared with the existing training search algorithm system, the training system can make full use of each player's football training and game characteristic information, realize the close combination of players, effectively analyze the factors affecting the player's technical level, and improve the player's football training level. However, this paper only focuses on the construction of a dynamic tracking training system for header shooting of football players, without considering the potential impact and overall cooperation of foreign header shooting. Therefore, the comprehensive analysis and evaluation of the index system need to be further studied.

Data Availability

The data used to support the findings of this study are included within the article.

Academic Editor: Enas Abdulhay

Background. As a special occupation of human beings, teachers have an important responsibility for society and students. As preachers, all their actions will affect the students. Teachers can be said to be the indicator of students' happy life. According to a survey by educational institutions, more than 90% of teachers believe that work pressure is increasing. 64.2% of teachers have experienced job burnout, and the status quo of teachers' professional well-being is worrying. So we must pay attention to teachers' happiness research. However, based on ergonomics, piano education is a kind of piano education to relieve fatigue and an important way to improve teachers' happiness. *Objective*. Using the self-designed questionnaire related to teachers' professional happiness, we investigated piano teachers in universities to understand the status quo of piano teachers' professional happiness, reduce the fatigue of piano teaching, explore the relationship between work fatigue and college piano teachers' professional happiness. *Methods*. This study combines qualitative and quantitative survey methods to make a qualitative analysis of the collected literature and survey and, at the same time, to make a quantitative survey of the collected data so as to get more scientific and accurate survey results. *Results*. According to the above analysis, this paper puts forward effective suggestions in order to reduce the fatigue of piano teaching and ultimately greatly improve the enthusiasm and efficiency of piano teaching, improve the professional happiness of piano teachers, and promote the effective progress of education. *Conclusions*. Through this study, the overall situation of piano teachers' professional happiness in H University is general and the evaluation of piano teachers' professional happiness in H University is mostly at the ordinary level. However, more than half of the teachers do not feel happy and excited at work, and some of them are tired and bored.

1. Introduction

Occupation refers to the exertion of individual personality and refers to the realization of human activities in life and sustainable life. The so-called professional happiness means that when human experimenters engage in specific professional activities, they have a sense of psychological satisfaction and joy, which is necessary for life and work. Their psychological activities not only show psychological satisfaction but also reflect their personal ability and give full play to their ability to get a higher sense of experience. At the same time, it is a kind of continuous happy life experience. From the perspective of subjective well-being, individuals are satisfied with the present working life and working state. From the perspective of satisfaction, it is a subjective experience of the working state.

1.1. Teachers' Professional Happiness. So far, there is no clear concept of teachers' professional happiness. For teachers, their professional happiness mainly comes from students' evaluation, satisfaction, and achievement in the teaching process, and recognition from colleagues and leaders in the school. Teachers also have their own career plans and goals. If they achieve them, it is also a source of their career happiness [1]. In fact, teachers' career happiness is closely related to students. Teachers, in the process of promoting the development of students, on the one hand, will make their own ability to develop, on the other hand, will also promote the development of students.

So far, there is no clear concept of teachers' professional happiness. For teachers, their professional happiness mainly comes from students' evaluation, satisfaction, and achievement in the process of education, as well as the understanding of school colleagues and leaders [2]. Every teacher has his own career plan and goal. If achieved, it is also a source of professional happiness. In fact, teachers' professional happiness is closely related to students. In the process of promoting the growth of students, on the one hand, teachers improve their ability. On the other hand, they also promote the development of students.

In general, it is a kind of spiritual happiness and satisfaction. It used to be thought that teachers' happiness is teachers' state. In other words, teachers have achieved certain results in life and work, so they often narrow the gap between their goals and understanding. But Durand et al. believe that when he feels happy as a teacher, his contribution is precious [3]. This is a model that benefits both sides. Mastering this sense of happiness is helpful for teachers and students to promote each other. As for the definition of teachers' professional happiness, Appannah and Biggs pointed out that this is their inner satisfaction in their work and life, and they have been realizing their ideals and goals [4], and, in this process, continue to play the greatest enthusiasm, to improve ability, and professional level of themselves [4]. They have been recognized and evaluated by all sides and received more joy and thanks. In this paper, this study adopts the definition of Mr. Wang.

1.2. Theoretical Basis of Teachers' Professional Well-Being. Subjective well-being is often defined in the field of western psychology. The focus of this definition is mainly related to the interaction between the internal environment and the external environment. The purpose is to investigate the influence of human personality factors on the social environment and the relationship between subjective well-being and some things in objective reality [5]. How people treat all kinds of personalities, reactions to things, and attitudes in all kinds of environments will affect their subjective well-being. This is the key research content in the field of western psychology. Through the study of subjective well-being, we can know the main source of happiness by studying people's various experiences of happiness. From the existing research results in the field of psychology at home and abroad, many different theories in the field of subjective well-being have been developed [6]. Based on these, many theoretical branches have been expanded. These theories discuss and analyze subjective well-being from different angles and draw some corresponding conclusions. It lays a specific foundation for the subjective well-being theory of University piano teachers, provides a lot of useful theoretical basis and information, and points out the direction for the follow-up research.

1.2.1. The Impact of Career Goals on Well-Being. As we all know, people's subjective well-being is closely related to a variety of people's personality, quality, environment, emotional state, and career goals. Therefore, the supporters of goal theory believe that personal career goals will have a great impact on career happiness, but also related to the personal environment, development direction, future, feelings, and other factors [7]. When each career goal is achieved, these factors are closely related. Then, in order to obtain personal subjective happiness, we must look forward. On the contrary, if an individual fails to achieve his or her goals, it will lead to a more negative emotional experience. Because different goals have different effects, the reasons for subjective well-being vary from person to person.

1.2.2. Theoretical Basis of Pedagogy. Life education theory is a good theoretical method. Its supporters believe that education is to cultivate people who can enjoy happiness, obtain happiness, understand happiness, and inherit happiness. Therefore, for teachers, students usually need to feel the happiness of learning. Happy student learning and happy teacher education are important channels and information sources for teachers to obtain professional happiness [8]. In a sense, teachers' happiness is the premise and foundation. Of course, different teachers have different levels of happiness because of their different morality and wisdom. Therefore, to make every teacher have a professional sense of happiness, we must constantly train and educate teachers to form a good moral character and realize the cultivation of wisdom [9]. Of course, all of these need to constantly pay attention to and improve the happiness level and professional level of teachers so that piano teachers can harvest the happiness of being a teacher.

Life education theory is used to criticize the neglect of life in modern education. Therefore, it is gradually formed and based on this continuous development. The theory of life education pays special attention to respecting life and pursuing life happiness. Life theory has the function of foresight. It may become a procedural theory, guiding teachers and students to pursue happiness has good traction [10]. The goal of this theory is to let teachers and students understand that the pursuit of happiness education is the common ideal and topic of teachers and students. At the same time, it also tells us that the pursuit of happiness, whether teachers or students, is the result of human nature. However, the premise of realizing teachers' professional happiness is the process of life education. Because people's life is the most important, so all this is based on cherishing life and promoting the good growth of personality. Otherwise, it is difficult for teachers and students to get happiness [11]. And it does not make sense. Therefore, for University piano teachers who want to achieve professional happiness, our teachers must adhere to the pursuit of happiness, and the pursuit process is based on the concern for life.

1.3. Overview of Ergonomics. Ergonomics includes human physiology, anthropometry, physiological anatomy, biomechanics, medicine, psychology, environmental science, management science, humanities, engineering science, etc., not only in the industrial sector but also in the research of work space, posture, seat, pedal work, operation method, workload, safety, working environment, work schedule, information operator, etc. In addition, it can also provide the design of management mode, the size parameters of "human" in industrial design, the reasonable scientific basis of "object," and the design guide of "environmental factors" [12]. The main research content can be summarized as the research of humans, including the physiological and psychological characteristics of humans, through the research of humans to solve the relationship between human and machine adaptation problem, to make workers healthy, comfortable, safe, and efficient in operation. Information communication design of the man-machine system, information exchange between man and machine, and reasonable consideration of environment are very important, which is very important in industrial design [13]. Therefore, in the design of the man-machine system, in order to meet the needs of man-machine, the functions of man and machine should be allocated reasonably. Workplace design includes the improvement of the workplace environment and the overall design of the workplace. Appropriate jobs can not only alleviate people's fatigue but also greatly improve work efficiency. In order to ensure the security and reliability of the system, the system security design not only greatly reduces the error rate but also meets the needs of society [14]. The overall efficiency of the system is designed by improving the operation method, optimizing the production or service process, and comprehensively improving the overall efficiency of the man-machine system. The main research methods are observation and investigation (including systematic observation and analysis, investigation, measurement, and recording), experimental method, graphic model method, and simulation method.

1.4. Research on Work Fatigue. Work fatigue is a physiological phenomenon that can be recovered through proper rest and adjustment. Due to the work itself, people's sports ability is temporarily reduced. A thorough exercise is a special form of burnout. That is to say, when you are tired, keep exercising until you cannot maintain the normal operation of your body [15]. The causes of work fatigue vary with the degree and place of occurrence. Generally speaking, the symptoms are weakness, hand tremor, waist pain, lower limb pain, yawning, carelessness, loss of memory, lack of thinking agility, etc. Bakker analyzed the executive control ability of piano staff before and after exercise fatigue and compared it with college students who did not receive professional training [16]. The results show that the executive control function of piano instructors and nonprofessional piano education and training students has been improved after work fatigue, and professionals show better executive control function. Yu Shuang's animal experiments show that job burnout may lead to poor learning ability and memory. In order to explore the mechanism of the brain regulating job burnout, Petrou et al. studied the brain function activities of seven healthy male college students before and after a thorough exercise of power bicycle and observed the active exercise in the brain field in the random running stage [17]. Through the use of whole-brain functional magnetic resonance imaging (fMRI) technology, it was found that there was no significant difference in the active parts of the brain before and after work fatigue in the execution stage of random movement, but the number of lines and thalamus in the active nucleus of the brain decreased, and gradually weakened. Tims's research is aimed at 800 m piano teachers [18]. Compared with quiet time, the connections between the primary motor area and cerebellum, somatosensory motor area and cerebellum, hippocampus/parahippocampal gyrus, and cerebellum became weaker after increasing exercise fatigue. At rest, the brain of the subjects formed a stable network system centered on the cerebellum, and the connection function decreased due to burnout and boredom. In short, there are differences in the effects of physical fatigue caused by piano teaching on psychological cognition, which may be related to exercise program, observation place, and detection method.

2. Methods

2.1. Participants. Based on the principle of research convenience, the piano teachers in H County colleges and universities are selected as the investigation object.

2.2. Process. In this study, 190 questionnaires were issued and 190 were recovered by random sampling. The recovery rate is 100%. Among them, 180 effective questionnaires were used, and the effective rate was 94.7%.

2.3. Research Design. Master the basic information of teachers such as gender, position, school type, school year, region, and income. There are 10 questions in this questionnaire, and there are several alternative answers after each question. Choose the answer that is consistent with the actual situation and the answer consistent with the situation of yourself. This paper uses the questionnaire of Andrews and wig from foreign countries to measure the overall occupational happiness of teachers [19]. The questionnaire has been evaluated highly internationally, and its reliability and appropriateness reach about 0.7. In this paper, the use of this intuitive graphic option avoids text deviation and improves the accuracy of the survey.

In order to promote the correctness of the investigation, this questionnaire specifically raises 30 specific questions and provides some answers to certain factors so as to better investigate the factors affecting the career happiness of university music teachers [20]. That is, it is divided into complete consistency, more consistent, unclear, no complete consistency, and complete inconsistency. The questioner uses the interview method to ask the teacher's occupational happiness question. In order to supplement the investigation of the influencing factors of the teacher's occupational happiness, let the teacher talk about his own ideas and suggestions so as to obtain a more accurate analysis.

2.4. Data Analysis. In this survey, the collected question list will be counted and processed scientifically through Excel and SPSS11.0 and analyzed and discussed by the analysis and processing of the collected data. Finally, based on ergonomics, the paper explores the relationship between alleviating the burnout of piano guidance and the happiness of teachers and makes a deep analysis.

3. Results

3.1. Analysis of Teachers' Subjective Occupational Happiness. Table 1 shows the statistical results of teachers' subjective occupational well-being towards their current work attitude. On the surface, 4.6% of teachers feel very happy. 34.6% of the teachers were happy, accounting for 39.2% of the total. 13.1% of the teachers were not very happy; 7.3% were unhappy; these two accounted for 20.4% of the total; the remaining 40.4% felt very ordinary.

The image description of teachers' subjective professional well-being survey is shown in Figure 1.

3.2. Subjective Factor Analysis. Table 2 shows the statistical results of teachers' response to whether they are satisfied in the workplace. 52.7% of the teachers are dissatisfied and basically dissatisfied in the workplace. In the process of work, 47.3% of teachers are always happy.

As shown in Table 3, the qualifications of music education managers based on ergonomics are not unified. Only three of them are high, and the moderate talents are the main ones, which has a certain impact on the popularization of music culture.

3.3. Objective Factor Analysis. In Table 4, "1" refers to teachers under 30 years old, "2" refers to teachers over 45 years old, and "3" refers to teachers over 46 years old. According to the table data, teachers under the age of 30 have the lowest professional well-being, with an average score of 2.286, while teachers over the age of 46 have an average score of 4.571. Second, the occupational well-being of 45-year-old teachers is also very high, with an average of 3.774 years old, but slightly lower than that of teachers over 46 years old.

The image description of the age difference of teachers' professional well-being is shown in Figure 2.

The average score and standard deviation of 180 effective question tables are investigated and analyzed, and a preliminary understanding of the status and characteristics of teachers' working fatigue is obtained. The specific results are shown in Table 5. When answering the questionnaire, use 5 grades of the scoring system. In this system, 1 is absolutely not, 2 is less than once a month, 3 is at least once a month, and 4 is at least once a week at least once a day. From Table 5, we can see that the overall situation of teachers' burnout is more than once a month, which shows that the teachers' burnout is in the middle and high level.

It can be seen from Table 6 that there is an obvious relationship between job burnout, job happiness, and turnover intention. In other words, there is a significant negative relationship between job burnout and job happiness and a significant positive correlation between job burnout and turnover intention. There is a significant negative relationship between job happiness and turnover intention.

Table 1: Questionnaire of teachers' subjective occupational happiness.

Your evaluation of your current job	Frequency	Percentage
Very happy	12	4.60
Relatively happy	90	34.60
General	105	40.40
Less happy	34	13.10
Very unhappy	19	7.30
Total	260	100.00

Table 5: Status quo of piano teaching fatigue based on ergonomics.

	Standard deviation (SD)	Average (M)	Number of items (n)	Average score of each question (m)
Physical work fatigue	3.463	20.22	6	3.370
Psychological work fatigue	3.585	19.34	6	3.224
Emotional work fatigue	2.932	18.57	6	3.092
General questionnaire	5.004	58.01	18	3.223

Table 6: Analysis of the relationship between piano teaching fatigue and teachers' happiness.

	Physical work fatigue	Psychological work fatigue	Emotional work fatigue	Total score	Turnover intention
Work value	−0.109	−0.213	−0.202	−0.167	−0.297
Welfare	−0.157	−0.243	−0.217	−0.190	−0.352
Prospects	−0.156	−0.17	−0.214	−0.186	−0.217
Environmental control	−0.309	−0.215	−0.296	−0.221	−0.186
Self-acceptance	−0.068	−0.024	−0.232	−0.177	−0.277
Interpersonal relationship	−0.245	−0.212	−0.317	−0.243	−0.408
Autonomy	−0.054	−0.258	−0.061	−0.167	−0.238
Total score for job well-being	−0.321	−0.225	−0.212	−0.245	−0.099
Turnover intention	0.277	0.138	0.355	0.237	

Table 6 shows the relationship between job burnout and job happiness. Seven aspects of job happiness (job value, welfare, development prospects, environmental control, self-acceptance, interpersonal relationship, and self-discipline), teachers' scores and the total scores of job happiness and job burnout (physical job burnout, mental job burnout, and emotional job burnout) [21], excluding self-discipline and physical job burnout, teachers' scores and the total scores of job happiness and job burnout (physical, mental, burnout). The relationship between self-discipline and emotional job burnout is not obvious. The rest has a negative correlation, and the correlation coefficient has reached a statistically significant level.

3.4. Frequency Table of Ways to Relieve Teachers' Work Fatigue. After classifying the collected questionnaires, the coping methods to reduce work fatigue are summarized and listed in Table 7 according to the frequency.

Table 7: Frequency of ways to relieve teachers' fatigue.

Solution	Frequency
Do sports	87
Objects (towels, etc.) relieved	35
Drink relief	134
Increase rest time	125
Distract attention from playing games	24
Ease	67
Improve lifestyle (more baths, etc.)	43
School organizes outdoor activities	105
School organization party	98
Schools send out more condolences	76
School lunch increases nutrition	69
Humanization of the school system	129
Others (basking in the sun, etc.)	109

4. Discussion

4.1. Job Fatigue Is Related to Teachers' Well-Being and Turnover Intention. Subjective well-being and teachers' turnover intention are the variables of job burnout. Through this study, we can find that the rationality and applicability of the concept of job burnout are influenced by turnover intention. Through the relevant investigation, we found that there is a correlation between teachers' work fatigue and work happiness. Seven aspects (work value, welfare, development prospects, environmental control, self-acceptance, interpersonal relationship, self-discipline) [22] were used to measure job happiness and job burnout (physical burnout, spiritual burnout, emotional burnout). There was no significant relationship between self-discipline and physical burnout except the total scores of self-discipline and emotional burnout. The other factors are negatively correlated with it, and the correlation coefficient is statistically significant.

There is a relationship between teachers' job fatigue and turnover intention. Teachers' turnover intention is related to all aspects of job burnout (physical job burnout, psychological job burnout, emotional job burnout) [23]. The correlation coefficient is statistically significant. There is a negative correlation between teachers' turnover intention and job happiness, between the seven dimensions of job happiness (work value, welfare, development prospects, environmental control, self-acceptance, interpersonal relationship, self-discipline) and teachers' job happiness, and between teachers' turnover intention (physical work fatigue, psychological work fatigue, emotional work fatigue). The correlation coefficient is statistically significant. These results show that job burnout plays an important role in teachers' job happiness and turnover intention [24].

The results show that job burnout has a negative predictive effect on teachers' work, and a positive predictive effect on teachers' turnover intention. Therefore, if enterprises want to improve teachers' job happiness and reduce teachers' turnover intention, they can consider it from the perspective of reducing teachers' job fatigue.

4.2. The Professional Well-Being of Piano Teachers Has Significant Differences. The happiness of female teachers is higher than that of male teachers. One of the reasons is that at this stage of society, the demand for men is much higher than that of women. For example, men's wages are higher than women's, and men's working conditions are generally worse than women's. Another reason is the decision and influence of the concept of ancient Chinese traditional culture [25]. In traditional China, it is generally believed that songs are not performed by boys but by girls. Music teachers must also be women. In this way, male teachers are not recognized by society, resulting in their own cognitive bias for their own identity.

Teachers under 30 have the best professional happiness. This is because young music teachers who have just graduated from universities and other roles have become teachers. They have a strong sense of freshness and pride, and they are very enthusiastic. The work of teachers is also very challenging, so it is easy to meet [26].

The higher the level of education, the lower the happiness of teachers. This is because, although the education background of teachers is low, their position is more correct, but they are most concerned about education, and they are also very competent in education business and satisfied with education. Teachers with higher education levels will have more expectations for work, which makes it difficult to get happiness.

Music teachers with the highest professional title have the strongest professional happiness, the second teacher with the lowest professional title, and the teacher with the middle professional title is between the lowest and the highest. For senior teachers, they are conscientious and responsible for their work, have a strong professional ability, have a higher status and understanding in society, and can win the respect and support of students and parents [27]. Wages and welfare are also guaranteed. The most important thing is to treat life, world outlook, and values correctly. That is to say, they have self-knowledge and have higher happiness. Teachers with primary professional titles, who have just taken office, have enthusiasm, are interested in identity changes, have a fresh sense, and their positioning is very correct, so happiness is very high [28]. Instead, if they are intermediate teachers, they have a rich educational experience, but they are older and have a lower sense of professional happiness due to their lazy education. Therefore, schools and governments should create a platform for teachers to improve their education level, constantly strive to inject positive energy into educational activities, and increase opportunities for teachers to continue research and further research.

The smooth development of educational activities is inseparable from teachers, and the educational activities of schools are closely related to teachers. Teachers' high vocational happiness can improve the quality of education to the greatest extent and enable students to grow up comprehensively [29]. In order to reflect the current situation of music teachers' professional happiness in a certain region, this paper will investigate and study the current situation of music teachers' professional happiness in some regions. A survey was conducted in a certain area by questionnaire. It provides the practical foundation for music teachers to obtain professional happiness.

4.3. Factors Affecting Teachers' Happiness. From the perspective of the whole social system, it is necessary to improve the economic treatment and social status of teachers. Economic treatment and social status are the important conditions and decisive factors to determine teachers' happiness. In essence, the direct reason for the decline of college music teachers' happiness is the widespread prejudice to overload work and society. Because of the particularity of the professional field, music teachers usually carry out school year music courses separately, and sometimes all music courses in the whole school will be implemented. This will bring great problems and pressure to music teachers in universities.

The current education reform originally put students aside but ignored the cultivation of teachers. The teacher's mood was not carefully considered. Music teacher is an awkward social role among teachers. Although university music teachers are engaged in heavy education and management work, their wages are still low. Needless to say, the benefits of welfare are out of proportion to their work intensity. The material basis determines the superstructure. Similarly, the basic prerequisite for teachers to achieve professional happiness is to have a specific material basis. Therefore, it is very necessary for teachers to create necessary material conditions and corresponding social status. Under the background of the market economy, the economic treatment of teachers must determine their professional happiness. Therefore, the most basic thing to really improve the happiness of teachers is to improve the economic and welfare treatment of teachers.

As a national central government, the education department should increase financial support, and the national government should formulate appropriate measures to ensure teachers' wages and gradually increase teachers' wages and social welfare. We should conscientiously implement the national financial expenditure and narrow the wage gap between teachers in different regions. Government departments continue to guarantee teachers' wages, but local autonomous bodies can also increase financial expenditure in order to increase teachers' wages. A powerful country must strengthen education. In order to strengthen education, it is necessary to increase investment in education. The top priority is to effectively improve teachers' wages and social low level. The state and government should narrow the wage gap of teachers in different regions through policy guarantees, and try their best to narrow the wage and subsidy gap of teachers in county-level cities, big cities, and local areas. To really improve the social status of teachers, so that teachers can feel their own value in the actual educational activities, so as to engage in educational activities at ease.

Society should give music teachers a relaxed environment, more understanding and support, less pressure and reprimand, and a reasonable and fair evaluation. Music teachers are not important to ordinary people. In fact, music teachers in universities are quasi-subject teachers. Music teachers are a troublesome social role among teachers, which generally leads to their low sense of self-existence and professional identity. So what do you say about professional happiness? Society should pay more attention to music teachers, treat their profession fairly, and create a good atmosphere of national trust. Let music teachers find their own professional identity in this atmosphere, urge teachers to regard education as their lifelong career pursuit, and let teachers get countless happiness in this professional education work.

Society needs to set correct and reasonable expectations for teaching staff. Students, families, and society should treat their responsibilities correctly, and teachers should not be excessively held responsible. Because education is not omnipotent, the cultivation of students is formed by the joint action of various facts, not only depending on teachers, but also the society should form the correct direction of teacher evaluation. Therefore, students, parents, schools, and society should have reasonable expectations for teachers, not too harsh. As social media, we cannot exaggerate individual phenomena unilaterally or convey negative energy to society. We must report it actively and objectively. Now some media exaggerate individual teachers' improper behavior to exaggerate the evaluation, which has a very bad impact on the society and even distorts the correct evaluation of teachers. Education reform is vigorously carried out throughout the country. Strengthening publicity, delivering positive energy to society, and forming a correct social atmosphere can gradually change people's wrong ideas.

4.4. Suggestions for Relieving Work Fatigue in Piano Teaching. In recent years, enterprises have paid more and more attention to the fatigue of teachers' work, but there is still much room for improvement. Therefore, business operators must take measures to solve these problems, including organizing more outdoor activities, such as going out, dinner, singing, and so on, and establishing effective reward and incentive mechanism. For example, when teachers are praised publicly, part of the bonus is used to comfort them, various bonus systems are set up, and more attention is paid to teachers' life and needs, so that teachers' life trends can be understood in detail. According to the operation of enterprises, within the limited scope of rights, teachers' personal requirements should be properly met, and teachers' interests should be maximized. In the daily work meal, give teachers continuous and reasonable nutrition distribution. Improve the company system, reduce inefficient, repetitive work, and effectively reduce the workload of teachers. The practice of "taking care of teachers" is rooted in the hearts of the people so that teachers can really feel the top-down care and respect, reduce the imbalance of teachers, and improve the happiness of teachers' work. Only when teachers feel the concern and respect of the company, can teachers have the best state in their work and will not bring too much pressure on themselves. This can not only improve teachers' working environment, reduce work fatigue, but also improve enterprise efficiency, increase teachers' sense of happiness, reduce teachers' desire to leave, improve teachers' sense of belonging, improve enterprise culture, and strengthen enterprise unity.

Most of the fatigue of teachers' work is related to their own cognition. Teachers can take various countermeasures to reduce and eliminate the fatigue of work. The general methods used are as follows: a combination of work and rest. Many people believe that when you work, you have to work crazily, and you will indulge in it when you rest and play. In fact, I do not recommend this approach. The best way to live a day is to learn how to combine work and rest. Work should be arranged in a reasonable time and priority, pay attention to rest, not to work in your life to rest. Usually, you can take part in sports activities such as running, swimming, playing ball, walking to ensure the rest time. Whether it is work or play, adults should ensure 7 hours of sleep, preferably not to take up sleep time. The best way to eliminate mental fatigue is to have plenty of sleep. Study work reasonable arrangement. Work and learning are the same, but both need to pay attention to the methods. As long as you have mastered the working methods, you can use less energy to do more, which can improve the efficiency of work and not overwork. Interpersonal communication also needs to be noted that people are social animals, and we can be supported and happy in society. When we have a good interpersonal relationship and work fatigue, chatting with friends and relatives helps to regulate and eliminate mental fatigue. Develop your own interests and hobbies. Whether it is concerned about work or ordinary concern for leisure and entertainment, it needs to be cultivated. It is not possible to be bored with the work of interest. Interest outside of work can also help relieve mental fatigue. When working very tired, you can rest properly, drink water, play games, read books, and distract your attention in order to alleviate the fatigue of work.

5. Conclusion

Through investigation and analysis, this study shows that there is no obvious correlation between teachers' professional happiness and their education background, professional title, school type, and educational experience. Teachers' professional happiness is obviously related to gender, age, teaching subjects and grades, school obligations, income, and other factors. In order to change the current situation, there are two main aspects to promote teachers' professional happiness. First, society should make a reasonable and fair evaluation of teachers; schools should take reasonable and objective measures, standardize the system and culture, and use ergonomics to improve teachers' happiness. The other is to improve teachers' own quality and psychological quality and improve their subjective sense of happiness. Although the posture of playing the piano should not be the focus of piano guidance, it is the basis of healthy piano playing. If the piano teachers can guide the learning of piano with the attitude of ergonomics in the basic piano education, reduce the phenomenon of giving up piano due to work fatigue so that more teachers can participate in music practice, improve the quality of music, and then get a sense of happiness. In future research, I will continue to pay attention to the cutting-edge theory of ergonomics and strive to obtain more experimental data to build a framework for the improvement of teachers' well-being.

Objectives. The study aim was to evaluate the empowerment of primary healthcare providers on the prevention and management of dental or oral health issues among postchemotherapy (PC) patients, in selected rural regions, India, during a pandemic. *Methods*. Initially, 240 PHPs were recruited by convenient and snow ball sampling with 90.3% response rate. A descriptive, cross-sectional study was adopted using a self-administered questionnaire with 5 sections: demographics, identification of dental/oral health issues, knowledge, attitude, and practice on prevention and management of dental/oral health problems in PC patients. Statistical Packages for Social Sciences (SPSS) version 23.0 was used for statistical analysis. *Results*. The overall knowledge was better among nurses (64.56%), followed by pharmacists (54.5%). 81.65% of PHPs were willing to learn more and expressed the need for collaboration with dentists. In the past 3 months, 18.81% of them had PC patients with dental/oral health issues, but only 3.5% of nurses and 0.8% of pharmacists treated them. The logistic regression model revealed higher scores in mucositis/mucosal pain (OR = 1.41), altered taste sensation (OR = 1.34), sensitive gums (OR = 1.71), and dental caries (OR = 1.32) domains ($p < 0.05$). Those who had readiness to learn (OR = 5.37), nurses and pharmacists, and having less years of experience (OR = 1.31) and higher degree (OR = 1.4) had a positive attitude ($p < 0.05$). *Conclusion*. PHPs had limited empowerment in terms of knowledge and practice but showed a positive attitude toward the prevention and management of dental/oral health issues of PC patients. For better practice, continuing education and collaboration with dental professionals is essential.

1. Introduction

Cancer is the second leading cause of mortality in developed countries, trailing only cardiovascular diseases. It is still a major public health concern. Oncology management encompasses a wide range of treatments addressing the preventive, curative, and rehabilitative aspects of cancer. Chemotherapy is one of the most effective treatment options [1]. Advances in cancer treatment have resulted in the longer survival of these patients. Nonetheless, the side effects of cancer therapies continue to be a major concern, as they may limit the effectiveness of the treatment and have a negative impact on the quality of life both during and after therapy.

The extent of chemotherapeutic agents' oral toxicity appears to be related to the dose and frequency of administration. They can cause direct damage to the soft and hard tissues of the oral structures, and their systemic toxicity can cause indirect damage. These oral complications, whether acute or chronic, can occur during or after cancer treatment. Many drugs target rapidly proliferating cells; however, they also have the same effect on rapidly proliferating normal tissues, such as the oral mucosa, and destroy the mucosal layer's basal cells. Their replacement or turnover is hampered, resulting in mucosal ulceration and decreased salivary function [2–4]. There is an indirect toxic effect that is caused outside the oral cavity such as myelosuppression or the destruction of immune cells. In general, more than 30–35% of cancer patients will experience mucositis, altered taste, xerostomia, sensitive gums, dental caries, speaking difficulties, and jaw pain [5, 6]. These side effects can have an implication on the patients' quality of life and as a whole clinical outcome.

The Global Burden of Disease Study (2017) reported that oral diseases affect 3.5 billion people worldwide. The prevalence of dental caries in patients who undergo chemotherapy was 37.3%. The oral cavity is extremely vulnerable to the direct and indirect toxic effects of chemotherapy due to the high cellular turnover rate, microflora, and oral tissue trauma associated with daily oral functions [7]. The estimated prevalence of oral complications ranges from 31 to 93% [8].

Effective oral health management prior to, during, and after treatment is therefore critical to improving patient well-being [9]. Each health professional engaged in the cancer care continuum ought to be aware of such specific oral health adverse reactions and be able to give the necessary precautions to avoid them. In 2020, an enigmatic virus known as SARS-CoV-2 confronted the medical community and wreaked havoc all over the world. According to the recently published data, COVID-19 patients have been prioritized over other patients, including cancer patients, due to the unforeseen conditions of the pandemic. The COVID-19 pandemic had a wide-ranging impact on healthcare services, beginning with disrupting regular patient flow to treatment centers, stressing and intimidating healthcare resources, and leading to the deployment of additional protective measures and social distancing with increased use of telehealth and virtual medicine. Access to healthcare and clinical services became difficult for cancer patients as well during the COVID-19 pandemic [10].

Due to the above-mentioned unprecedented circumstances, dental therapies have been halted in a lot of countries due to the role of saliva and aerosols in the spread of COVID-19. This has resulted in a disruption in the allocation of dental care to all patients, including postchemotherapeutic patients, for whom it is absolutely vital [11]. More importantly, postchemotherapeutic patients must have oral re-examinations every month for the first three months, then once in three months during the first year, and then every six months for the next three years. In this situation, the role of primary healthcare centers (PHCs) in providing adequate support for postchemotherapeutic oral ailments is critical.

In fact, in developing countries such as India, PHCs represent the first tier in healthcare system, providing a range of essential outpatient services to people living in the rural, suburban, and hard-to-reach areas. During the COVID-19 pandemic, the preparedness of PHCs in providing safe, patient-centered care and meeting the current health needs of the population is crucial. Hence, determining the empowerment of primary healthcare providers (PHPs) in terms of knowledge, attitude, and practice on the prevention and management of dental or oral health issues among postchemotherapy (PC) patients is the need of the hour.

2. Methods

2.1. Research Approach and Design. The research approach is quantitative. A descriptive, cross-sectional study was adopted for determining the empowerment of Primary Healthcare Providers (PHPs) in terms of knowledge, attitude, and practice on the prevention and management of dental or oral health issues among postchemotherapy (PC) patients.

2.2. Population and Setting. PHPs working in the rural regions of Tamil Nadu, India, were the population of the study. Three rural districts were selected and PHPs working in PHCs and subcenters were selected as samples for the study.

2.3. Sample Size and Sampling Process. The nonprobability convenient sampling technique was adopted to obtain samples from the three rural districts of Tamil Nadu, India.

The minimum suggested sample size was computed by Raosoft, an online sample size calculator having the overall population (approx. 681 PHPs) of three districts, a 95% confidence with margin of error as 5%, and the expected response rate of 60%. The calculated sample size was 240. Initially, 3 PHCs of each district were visited by one of the investigators personally to select the samples and the snow ball sampling technique was used to contact the rest of the participants. Registered nurses, pharmacists, and laboratory technicians who were willing to participate in the study were included in the study. PHPs who had basic professional training of less than 2 years were excluded from the study.

2.4. Data Collection Tools/Instruments. The self-administered tool consisted of 4 sections.

2.4.1. Section 1. Section 1 describes the demographic data of the participants.

2.4.2. Section 2. Section 2 describes a checklist for the identification of dental/oral health issues of post-chemotherapeutic patients.

2.4.3. Section 3. Section 3 describes knowledge on the prevention and management of dental/oral health problems of postchemotherapeutic patients. Among the dental and oral health problems, the most common and vital issues, such as mucositis/mucosal pain, dysgeusia/hypogeusia/altered taste sensation, xerostomia/dry mouth/hyposalivation, sensitive gums, and dental caries, were included in the knowledge questionnaire. It included 15 multiple-choice questions and each question had the score of "1" for the correct answer and "0" for the wrong answer.

2.4.4. Section 4. The attitude of the PHC providers toward the prevention and management of dental/oral health problems was assessed in this section. Participants assessed their attitude by themselves on a 5-point scale, with strongly agree – 5 to strongly disagree – 1. The participants' attitude was assessed by the mean scores of the 5 statements.

2.4.5. Section 5. The practice of PHC providers toward the prevention and management of dental/oral health problems of PC patients was evaluated with seven "yes" or "no" questions.

2.5. Reliability and Validity. The content validity of the tool was obtained from five experts in Nursing and one general physician and a Dental Specialist. The reliability of the tool was assessed by a pilot study by Cronbach's Alpha test (internal consistency) and the r value is 0.813, which was found to be highly reliable. The data were collected from the participants by electronic media such as WhatsApp, e-mail, and Instagram from February to April 2021. The PHPs were circulated with a Google Docs questionnaire and reminders were given thrice to complete and return the docs. Out of the 240 PHPs, 218 (90.8%) participants returned the completed tool.

2.6. Ethical Consideration. Official permission from the Medical Directors of the PHCs as well as ethical permission from the Institutional Ethical Committee with IEC/LCN/2021 was obtained. Consent from the participants was collected before starting the study by explaining the aim of the study, their role, confidentiality of the information, and their right to depart from the study at any point of data collection. The participants were given a soft copy of the study material after the data collection period in the form of a power point presentation on the prevention and management of dental/oral health among postchemotherapy patients for enhancing their knowledge on the same.

2.7. Statistical Analysis. The data were processed and analyzed by the SPSS software using descriptive and inferential statistics. Descriptive statistics, χ^2 tests (for categorical variables), and regression analysis were used to compare knowledge, attitude, and practice with demographics by SPSS 23.0 for Mac. $p < 0.05$ was considered to be significant in this study.

3. Results

3.1. Demographic Data of the Study Participants. The collected data from 218 PHPs were tabulated and the socio-demographic features of the study participants were tabulated in Table 1. Out of 240 PHPs, 218 responses were received with a response rate of 90.83%. Most of the participants (63.3%) were females and 23.4% of the participants were aged between 20 and 25 years. About 51.38% were nurses, 32.57% were pharmacists, and 16.05% were lab technicians. Among the PHPs, almost half (48.17%) of them had a diploma degree, and a small minority (6.42%) held postgraduate qualifications. Their work experience was variable, ranging from less than one year to greater than 10 years. More than half (53.67%) of them were getting 50 to 100 patients per day and more than two-thirds (77.99%) do not get any patients with postchemotherapy treatment. Among the PHPs, 18.81% of them had treated PC patients with dental or oral health issues.

3.2. PHPs' Knowledge on Dental- and Oral-Related Health Issues among PC Patients. Among the PHPs, most of them (88.53%) identified cachexia as one the major health issues among postchemotherapy patients followed by dental caries (85.78%). The least identified problem was mastication/jaw pain(26.15%) (Table 2).

The overall level of knowledge on dental or oral health was better among nurses (64.56%), followed by pharmacists (54.5%); lab technicians scored less (30.03%) comparatively. However, pharmacists had better knowledge (65.2% vs 63.0% and 27.7%) on mucositis/mucosal pain among the PHPs (Table 3).

3.3. PHPs' Attitude on Dental- and Oral-Related Health Issues among PC Patients. Figure 1 shows the PHPs' attitude toward the dental/oral healthcare among PC patients. Among these, 178 PHPs expressed positively of their willingness to learn more and also opined that having collaboration or telemedicine facility with dentists will enhance the PHPs' knowledge and skills to manage the dental/oral health of PC patients (151 PHPs). About the negative attitude, 125 PHPs had a negative opinion to handling the PC patients' dental/oral health issues effectively. This may occur due to inadequate knowledge and practice experience while handling PC patients with oral health problems.

Table 1: Demographic data of the PHPs.

Variables	No.	%
Age (years)		
20–25	51	23.4
26–30	40	18.3
31–35	69	31.7
>36	58	26.6
Sex		
Male	80	36.7
Female	138	63.3
Work experience		
Less than 1 year	84	38.5
1–3 years	77	35.3
4–6 years	37	17.0
7–9 years	11	5.1
≥ 10 years	9	4.1
Profession		
Nurses	112	51.4
Pharmacists	71	32.6
Lab technicians (LTs)	35	16.1
Level of education		
Diploma	105	48.2
Bachelor's degree	99	45.4
Master's degree	14	6.4
Approximate number of patients per day		
<10	51	23.4
10–50	117	53.7
51–100	42	19.3
>100	8	3.7
Do you get any patients with postchemotherapy treatment?		
Yes	48	22.0
No	170	78.0
If yes, did any of them attend the PHC with dental or oral health problems in the past 3 months?		
Yes	41	18.8
No	177	81.2

Table 2: Identification of dental- and oral-related health issues among PC patients.

S. no.	Dental/oral problems of PC patients	Yes	%
1	Mucositis/mucosal pain	137	62.84
2	Dysgeusia/hypogeusia/altered taste sensation	116	53.21
3	Xerostomia/dry mouth/hyposalivation	142	65.14
4	Sensitive gums	153	70.18
5	Dental caries	187	85.78
6	Oral candidosis	121	55.51
7	Bacterial sialadenitis	89	40.83
8	Cachexia	193	88.53
9	Trismus/fibrosis	94	43.12
10	Mastication/jaw pain	57	26.15

Table 3: Level of knowledge of PHPs on dental and oral health among postchemotherapy patients.

Knowledge	Nurses (%)	Pharmacists (%)	Lab technicians (%)
Mucositis/mucosal pain	63.0	65.2	27.7
Dysgeusia/hypogeusia/altered taste sensation	63.3	41.8	21.37
Xerostomia/dry mouth/hyposalivation	69.1	61.4	19.1
Sensitive gums	66.4	51.8	38.8
Dental caries	61.0	52.3	43.2
Overall knowledge	64.56	54.5	30.03

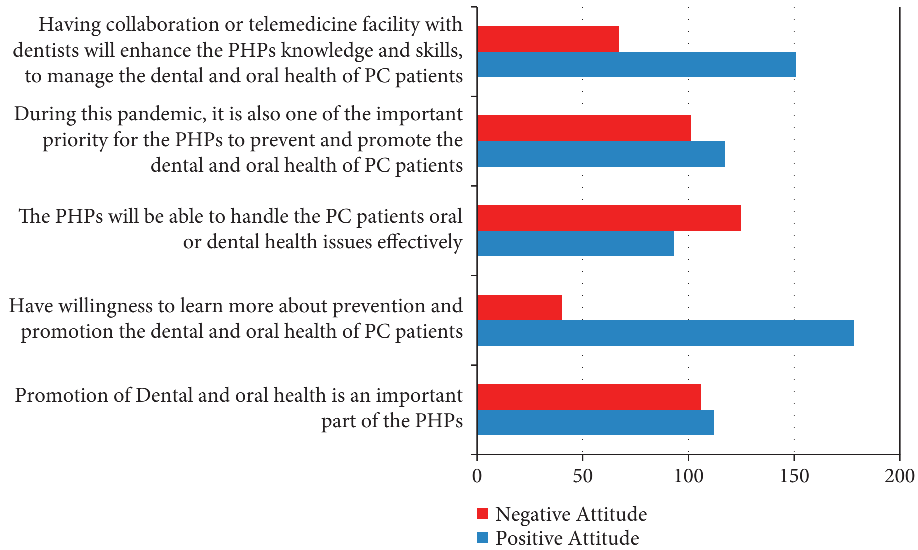

Figure 1: PHPs' attitude toward the dental/oral healthcare among PC patients.

3.4. PHPs' Practice on Prevention and Management of Dental and Oral Health Problems among PC Patients. Determining the practice of PHPs toward the prevention and management of dental/oral health problems of PC patients reveals that though 18.81% of them had PC patients with dental/oral health issues in the past 3 months, 65.1% of the nurses, 71.4% of the pharmacists, and 89.3% of the lab technicians never treated or counselled the PC patients (Table 4). Only 3.5% of the nurses and 0.8% of the pharmacists treated PC patients dental/oral issues often.

3.5. Multivariate Analysis. All variables were used in their continuous form except for profession, readiness to learn, and qualification. Goodness of fit with the Hosmer and Lemeshow test, (HL test) p- value = 0.13.

After controlling the demographic data of the PHPs, the logistic regression model revealed higher scores in the mucositis/mucosal pain (OR = 1.41, 95% CI: 1.13–1.61), altered taste sensation (OR = 1.34, 95% CI: 1.02–1.62), sensitive gums (OR = 1.71, 95% CI: 1.13–1.47), and dental caries (OR = 1.32, 95% CI: 1.27–1.52) domains with $p < 0.05$. Those who had greater readiness to learn more (OR = 5.37, 95% CI: 4.21–7.78) and nurses and pharmacists, i.e., the profession, were associated with a positive attitude toward the prevention and management of dental/oral health problems of PC patients (Table 5). Nurses and pharmacists with less years of experience (OR = 1.31, 95% CI: 1.43–3.11) and those who had higher degrees (OR = 1.4, 95% CI: 1.47–2.27) also had a more positive attitude toward the prevention and management of dental and oral health problems of PC patients than did those with a lower qualification ($p < 0.05$).

4. Discussion

The part of the oral cavity is teeth and gums which allows us to speak, smile, and chew. Cavities (tooth decay), gum (periodontal) disease, and oral cancer are some of the most common diseases affecting our oral health. Oral health is included as one of the 23 leading health indicators in Healthy People 2030. According to the World Health Organization (WHO), oral health is an important component of overall health and quality of life, and improving people's oral health around the world can improve their quality of life [12]. Good lifestyle choices, earlier diagnosis, and improved access to dentists during the pandemic are some of the key challenges in combating dental or oral issues of postchemotherapy, according to the State of Mouth Cancer UK Report 2020/21 [13].

In general, treating malignant diseases affects the mouth both directly and indirectly through effects on immune function or other systemic side effects. Pain, mucositis, salivary gland dysfunction, changes in taste, infections, difficulty in swallowing, fibrosis, soft tissue and/or bone necrosis, exacerbation of dental and periodontal diseases, and recurrent or secondary malignancy are all common oral complications [14]. Cancer survival has improved in recent decades as a result of evolving etiologies and treatment advancements, and the population of cancer survivors continues to grow [15]. This growing number of survivors presents new challenges, particularly in the care of patients with complex medical, oral/dental, and psychosocial needs. Oral complications in this population typically necessitate multidisciplinary collaboration among various professionals and healthcare providers. Primary healthcare professionals, such as nurses, pharmacists, and lab technicians, are "change agents" at the community level, and can thus collaborate to effectively implement oral health promotion strategies, with a key role in early prevention and referral oral health services.

4.1. Knowledge. The current study found that PHPs had a low level of oral health knowledge, as most of them could identify only dental caries as the major issue of PC patients. Other dental or oral issues such as mucositis/mucosal pain,

Xerostomia/dry mouth/hyposalivation	0.09	0.04	0.173	1.03	0.91	1.31
Sensitive gums	0.13	0.06	0.023	1.17	1.13	1.47
Dental caries	0.16	0.21	0.05	1.32	1.27	1.51
Profession	0.7	0.31	0.000	1.59	1.09	2.43
Readiness to learn	1.970	0.22	0.000	5.37	4.21	7.78
Qualification	0.643	0.29	0.000	1.81	1.39	2.74

dysgeusia/hypogeusia/altered taste sensation, xerostomia/dry mouth/hyposalivation, jaw pain, etc. were least identified (Table 2). The overall level of knowledge on dental or oral health was better among nurses (64.56%), followed by pharmacists (54.5%); lab technicians scored less (30.03%) comparatively. However, pharmacists had better knowledge (65.2% vs 63.0% and 27.7%) on mucositis/mucosal pain among the PHPs (Table 3). Another study found similar results among primary care providers [16]. Wooten et al. reported that nurses have limited knowledge of oral health in a study of nurse practitioners' knowledge, opinions, and practice behaviors regarding oral disease and its outcomes [17].

Although the WHO recommends embedding oral health advancement with general preventive medicine and providing expert and policy support to nations to achieve this goal [18], our study found that primary healthcare providers receive limited training in this area [19, 20], notably in patients with postchemotherapy issues. This finding is also consistent with primary care healthcare professionals' lack of knowledge of pediatric OHC in a public healthcare setting in Tehran [16].

The WHO emphasized the importance of providing oral healthcare in developing countries as part of the primary healthcare programs [18]. During this COVID-19 pandemic, PHPs may be the only reliable source of oral health preventive care for PC patients, especially given the limited contact with oncology or dental professionals. PHPs can help diagnose oral health issues in their early stages and preclude their systemic effects in immunocompromised PC patients if they are given appropriate training in this field. According to studies, these PHPs have a significant impact on preventive activities and are a potential target for educational interventions [21–23].

4.2. Attitude. About the PHPs' attitude, most of them expressed positively toward their willingness to learn more and expressed the need for collaboration or telemedicine facility to manage the dental and oral health of PC patients. Nearly half of them had a negative opinion on handling PC patients' oral or dental health issues effectively (Figure 1). This may be due to the fact that they might have inadequate knowledge and practice experience of PC patients dental or oral health issues. The above attitude finding could be related to the PHPs' awareness of their lack of field knowledge. Our findings highlight the importance of adequate training and guidance for PHPs, a process that has proven effective to provide oral health promotion and disease prevention activities. Hence, primary healthcare professionals can make a team effort to effectively implement dental and oral health promotion approaches to PC patients.

4.3. Practice. Determining the practice as a part of empowerment of the PHPs toward the prevention and management of dental and oral health problems of PC patients reveals that though 18.81% of them had PC patients with dental or oral health issues in the past 3 months, Only 3.5% of the nurses and 0.8% of the pharmacists treated these patients' dental or oral issues often (Table 4). The results of a systemic review reported some empirical evidence that a dental health awareness campaign for care home nurses could enhance the nurses' oral healthcare knowledge and attitude [24]. If the PHPs' knowledge improves and gains positive attitude, this will enhance their practical skills as well. Because knowledge and attitude are directly interrelated to practice, there was a significant strong correlation between PHPs' knowledge and their attitude and practice [25–27].

4.4. Multivariate Analysis. The multivariate analysis shows that PHPs with higher knowledge scores, particularly in the mucositis/mucosal pain and dental domains, as well as those who were more willing to learn more about oral health had more positive attitudes toward the prevention and management of dental and oral health problems of PC patients (Table 5). Nurses and pharmacists with less years of experience and those who had higher degrees had a more positive attitude toward the prevention and management of dental and oral health problems of PC patients than did those with a lower qualification. Obtaining a higher degree may have improved their training, possibly due to their ability to search for the required information. In contrast to this study, the study by Rabiei S et al. [16] reported that nurses with a lower education (OR = 1.9) had a more positive attitude toward oral healthcare. Our findings call for training and continuing education for primary care providers about the oral health issues of PC patients, especially during this pandemic.

5. Clinical Relevance

5.1. Scientific Rationale for Study. PHPs not only play a role in the promotion of health, but also have a vital role in four levels of preventive care such as primordial, primary, secondary, and tertiary. In this scenario, information on the empowerment of PHPs in the dental/oral care of PC patients is still limited. In pandemic situations, especially in developing countries, the role of PHCs is important. Though their empowerment of knowledge in the dental/oral care of PC patients is a choice and cannot be ignored, this necessity provoked us to do the current study.

5.2. Principal Finding. The evidence for the role of PHPs in the oral care of PC patients is still limited in terms of knowledge, attitude, and practice on dental and oral health issues of PC patients.

5.3. Practical Implications. It is crucial that dental and oral health issues of PC patients be addressed during PHC visits to reduce the impact of these conditions on patients' morbidity, mortality, and quality of life, especially during this pandemic when there are limited points of referral or care. An educational intervention and continuous reinforcement on identification and management of these issues in collaboration with dental specialists, for the PHPs, can significantly reduce patients' agony, related morbidity as well as improve their quality of life.

6. Recommendations

(i) A similar study with larger samples in a wider population can be done

(ii) To improve the knowledge and skills of the PHPs; educational or training sessions with recent updates on research should be done to improve the quality of life of PC patients

7. Conclusion

Our study found that PHPs had limited empowerment with low level of knowledge in dental or oral health issues of PC patients while also displaying a generally positive attitude and a noteworthy readiness to obtain more training in this field. The findings of our study highlight the critical need for appropriate training and encouragement, particularly among PHPs working in PHCs, to promote oral health and provide appropriate conditions/care for PC patients.

Retraction

Retracted: Efficacy of Crizotinib Combined with Chemotherapy in Treating Advanced Non-Small-Cell Lung Cancer and Effect on Patients' Quality of Life and Adverse Reaction Rate

Journal of Healthcare Engineering

Received 10 November 2022; Accepted 10 November 2022; Published 23 November 2022

Journal of Healthcare Engineering has retracted the article titled "Efficacy of Crizotinib Combined with Chemotherapy in Treating Advanced Non-Small-Cell Lung Cancer and Effect on Patients' Quality of Life and Adverse Reaction Rate" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

Purpose. To explore the efficacy of crizotinib combined with chemotherapy in treating advanced non-small-cell lung cancer (NSCLC) and its effect on patients' quality of life (QOL) and adverse reaction rate (ARR). *Methods*. 90 advanced NSCLC patients admitted to our hospital (from 01, 2019 to 01, 2020) were chosen as the research objects and randomly split into the control group (CG) and experimental group (EG) by flipping a coin, with 45 cases each. Chemotherapy was performed to CG, and the crizotinib treatment was introduced to EG on this basis, so as to compare their clinical efficacy, ARR and 3-year survival rate, and QOL before and after intervention by the Generic Quality of Life Inventory-74 (GQOLI-74). *Results*. Compared with CG, EG after treatment obtained obviously higher total clinical effective rate ($P < 0.001$), lower total ARR ($P < 0.05$), higher GQOLI-74 scores ($P < 0.001$), and higher 3-year survival rate ($P < 0.05$). *Conclusion*. Combining crizotinib with chemotherapy to advanced NSCLC patients can effectively improve the patients' level of quality of life, prolong the long-term survival rate, and present a better effect than single chemotherapy. Further study is conducive to establishing a better treatment scheme for advanced NSCLC patients.

1. Introduction

Lung cancer is currently the most common primary malignancy of the lung, originating from the bronchial epithelium [1, 2]. In recent years, lung cancer has seen a rapid increase in both prevalence and mortality in industrially developed countries [3]. According to statistics, lung cancer currently accounts for approximately 8.5% of all malignancies, and approximately 1.6 million people died of it around the world in 2012 [4, 5]. The lethality rate of lung cancer is also the highest among clinical malignancies at present, seriously threatening the life safety and reducing the quality of life (QOL) of patients [6, 7]. Currently, the pathogenesis of lung cancer has not been clarified, and most scholars believe that it is mostly related to smoking, stone sponges, ionizing radiation, and so on. Early lung cancer has no specific clinical conditions and is not easily sensed by patients, so usually the disease has progressed to the middle to late stage once diagnosed. According to the differentiation degree, it can be classified into small-cell lung cancer versus non-small-cell lung cancer (NSCLC). NSCLC refers to malignant tumors derived from the mucosal epithelium of organs, which mostly arise in the middle-aged and senior people and show the youth-oriented tendency [8, 9]. The clinical symptoms of advanced NSCLC include chest pain, cough, hemoptysis, and dyspnea, and in severe cases, even metastatic sites and other symptoms occur. At present, the main clinical treatments for NSCLC are radiation therapy, chemotherapy, targeted therapy, and surgical resection, but single chemotherapy has some limitations and can only kill a certain amount of cancer cells, resulting in poor treatment effect, which, combined with its greater general toxicity, is difficult in satisfying the clinical needs [10, 11]. It has been found that the introduction of crizotinib based on chemotherapy can largely alleviate the clinical symptoms of patients and enhance the body's immune function, which has a significant efficacy in the treatment of advanced NSCLC. Therefore, to further explore the efficacy of crizotinib combined with chemotherapy in treating advanced NSCLC and the effect on patients' QOL and ARR, 90 advanced NSCLC patients admitted to our hospital (from 01, 2019 to 01, 2020) were chosen as the research objects, with the results summarized as follows.

2. Materials and Methods

2.1. General Information. 90 advanced NSCLC patients admitted to our hospital (from 01, 2019 to 01, 2020) were chosen as the research objects and randomly split into the control group (CG) and the experimental group (EG) by flipping a coin, with 45 cases each.

2.2. Inclusion Criteria. ① Patients' survival was over 3 months after pathological diagnosis; ② the patients had no history of external injury or surgery within one month; ③ the study was approved by the Hospital Ethics Committee (approval no. 2020HC12LS001), and the patients and their family members understood the study purpose and process and signed the informed consent; ④ the patients had not received crizotinib treatment before; ⑤ the study met the World Medical Association Declaration of Helsinki [12]; ⑥ the patients were diagnosed with advanced NSCLC after pathological and laboratory examinations; and ⑦ the patients had measurable lesions after CT or MRI scan, and their clinical manifestations included hemoptysis, dyspnea, and loss of appetite.

2.3. Exclusion Criteria for the Patients. ① Severe brain, heart, kidney, and other organic diseases; ② allergy to the drugs; ③ other primary malignant tumors; ④ pregnant or lactating women; ⑤ confirmed interstitial fibrosis or interstitial lung disease; ⑥ mental disorders; and ⑦ nervous system metastasis and complicated severely impaired bone marrow haematopoietic function.

2.4. Methods. Patients in CG received chemotherapy. The patients were given 1,000 mg/m^2 of gemcitabine (manufactured: Jiangsu Hansoh Pharmaceutical Group Co., Ltd.; NMPA Approval No. H20030104; specification: 0.2 g) by intravenous infusion for 30 min per week for consecutive three weeks, and then the administration was stopped for a week. Such a course was repeated every four weeks. In addition, carboplatin (manufactured: Yunnan PHYTO Pharmaceutical Co., Ltd.; NMPA Approval No. H10950274; specification: 50 mg) was added on such basis, which was dissolved with 5% glucose (concentration: 10 mg/mL) and added to 250 mL–500 mL of 5% glucose injection for intravenous infusion, and the frequency was once per three to four weeks.

Additionally, patients in EG orally took crizotinib (manufactured: Pfizer Manufacturing Deutschland GmbH; Approval No. H20130076; specification: 200 mg × 60 s), with the dosage of 250 mg each time and twice a day.

The treatment duration of both groups was 60 days.

2.5. Observation Indicators. The clinical efficacy before and after treatment was compared between the two groups. Complete response (CR) referred to all measurable lesions disappeared and the diameter of all pathologic lymph nodes was reduced to less than 10 mm for over four weeks; partial response (PR) referred to ≥30% decrease SLD (the sum of the longest diameters) of all targeted lesions for more than 4 weeks; stable disease (SD) referred to no PR – no PD (progressive disease), and PD referred to ≥20% increase SLD compared with the smallest SLD in the study, or a 5 mm increase of SLD or one or more new lesions.

$$\mathrm{TER} = \mathrm{CR} + \mathrm{PR}, \tag{1}$$

where TER = total effective rate; CR = complete response; and PR = partial response.

Follow-up was conducted on all patients by means of telephone, WeChat, and interview for 7 times (once every three weeks) to record their adverse reaction rate (ARR) in detail. The adverse reactions included neurological abnormalities, gastrointestinal reactions, skin abnormalities, vision abnormalities, and liver function damage.

Patients QOL after the intervention was evaluated by referring to the Generic Quality of Life Inventory-74 (GQOLI-74) Scale [13], covering social function (social support, interpersonal skills, work and study, entertainment, marriage and family), physical function (sleep and vitality, physical discomfort, feeding function, sexual function, mobility and sensation function), psychological function (mental strain, negative emotions, positive emotions, cognitive function, and self-esteem), and material life (housing, social service, living environment, and financial situation). The total score was 100 points, with higher scores indicating better QOL.

The 3-year survival rates of the two groups were calculated by outpatient service and telephone followup.

2.6. Statistical Analysis. In this study, the data processing software was SPSS20.0, the picture drawing software was GraphPad Prism 7 (GraphPad Software, San Diego, USA), the items included were enumeration data and measurement data, the methods used were X^2 test, t-test, and normality test, and differences were considered statistically significant at $P < 0.05$.

3. Results

3.1. General Information. No significant between-group differences were presented in the age, gender, BMI, duration of disease, SAS scores, SDS scores, disease stage, or place of residence of patients ($P > 0.05$), which were comparable, see Table 1.

Table 1: Patients' general information.

	EG ($n = 45$)	CG ($n = 45$)	x^2 or t	P
Age (years old)	65.25 ± 3.32	65.33 ± 3.29	0.115	0.909
Gender			0.047	0.829
Male	28 (62.22)	27 (60.00)		
Female	17 (37.78)	18 (40.00)		
BMI (kg/m^2)	26.27 ± 1.59	25.89 ± 1.63	1.119	0.266
Duration of disease (months)	3.12 ± 1.21	3.13 ± 1.11	0.041	0.968
SAS score (points)	47.33 ± 0.51	47.17 ± 0.48	1.533	0.129
SDS score (points)	52.13 ± 1.61	52.21 ± 1.32	0.258	0.797
Disease staging			0.062	0.803
IIIb	35 (77.78)	34 (75.56)		
IV	10 (22.22)	11 (24.44)		
Place of residence			0.050	0.822
Urban area	31 (68.89)	30 (66.67)		
Rural area	14 (31.11)	15 (33.33)		

3.2. Clinical Efficacy. After treatment, the total clinical effective rate of EG was obviously higher than that of CG ($P < 0.05$), see Table 2.

3.3. ARR. After treatment, the total ARR of EG was obviously lower than that of CG ($P < 0.05$), see Table 3.

3.4. GQOLI-74 Scores. After treatment, the GQOLI-74 scores of EG were significantly higher than those of CG ($P < 0.05$), see Figure 1.

3.5. Long-Term Survival Rate. The study results showed that the median survival time of patients in EG was 21 months, with 41 survived cases and 91.11% of survival rate (41/45), and the median survival time of patients in CG was 18 months, with 27 survived cases and 60.00% of survival rate (27/45). The 3-year survival rate of EG was obviously higher than that of CG ($P < 0.05$), see Figure 2.

4. Discussion

NSCLC has a high mortality rate and an incidence rate accounting for 80% of lung cancer patients, which greatly endangers the life health and reduces the QOL of patients [14]. In addition, most patients tend to be at an advanced stage at the time of diagnosis because early NSCLC tumors do not involve the trachea, bronchial mucosa, surrounding blood vessels, and pleura and have no specific symptoms, thereby delaying the diagnosis to a large extent. At present, the clinical treatment modality for advanced NSCLC is mainly chemotherapy, which aims to inhibit tumor cell proliferation and control tumor growth. However, most advanced NSCLC patients are elderly, a group usually has multiple chronic diseases and poor body resistance, so they may obtain certain therapeutic effects but less than ideal remission rates and survival rates [15]. In chemotherapy, gemcitabine is metabolized to active diphosphate (dFdCDP) and triphosphate (dFdCTP) through the action of intracellular transnucleoside kinase, and dFdCDP and dFdCTP inhibit DNA synthesis through two mechanisms of action to achieve the cytotoxic effect of gemcitabine. Carboplatin, whose mechanism of action is similar to that of cisplatin, is a metal coordinating agent and targets the DNA of proliferating cells, which has a similar role of alkylating agent bifunctional groups and can bind the intracellular base, enable DNA molecular intra- and interchain cross bonds and changes of DNA chemical structure, thus affecting cell replication. Such chemotherapy has lower safety, for it can cause greater damage to both the tumor cells and normal cells, so it is aimed at prolonging the patients' survival time and improving QOL in the clinic [16]. As a clinically common antitumor drug, crizotinib has optimal efficacy, low toxicity, and high safety, which can not only inhibit ROS1, EML4-ALK, and other signaling pathways but also suppress tumor cell growth and prevent tumor formation [17]. In this experiment, EG was treated with crizotinib combined with chemotherapy and obtained a clinical overall response obviously higher than CG ($P < 0.05$), indicating that compared with the single treatment modality, the combined treatment presented a significant clinical treatment effect. Besides, chemotherapy treatment is less safe and causes adverse effects that lead to a serious impact on patients' QOL, while also reducing their treatment compliance, resulting in more negative emotions and adversely affecting the prognosis. Therefore, combining crizotinib with chemotherapy can accelerate the apoptosis of tumor cells, hinder the formation of tumors, inhibit the ALK and ROSI genes, and ensure a higher safety, which is easily accepted by clinical patients. The experiment demonstrated that the GQOLI-74 scores of EG were significantly higher than those of CG

Table 2: Between-group comparison of clinical efficacy (n (%)).

Group	n	CR	PR	SD	PD	Total effective rate
EG	45	22.22% (10/45)	37.78% (17/45)	17.78% (8/45)	22.22% (10/45)	60.00% (27/45)
CG	45	6.67% (3/45)	15.56% (7/45)	31.11% (14/45)	46.67% (21/45)	2.22% (10/45)
x^2						13.264
P						<0.001

Table 3: Between-group comparison of ARR (n(%)).

Group	n	Neurological abnormalities	Gastrointestinal reaction	Skin abnormalities	Vision abnormalities	Liver function damage	Total incidence rate
EG	45	2.22% (1/45)	2.22% (1/45)	0.00% (0/45)	0.00% (0/45)	0.00% (0/45)	4.44% (2/45)
CG	45	6.67% (3/45)	4.44% (2/45)	4.44% (2/45)	2.22% (1/45)	4.44% (2/45)	22.22% (10/45)
x^2							6.154
P							$P < 0.05$

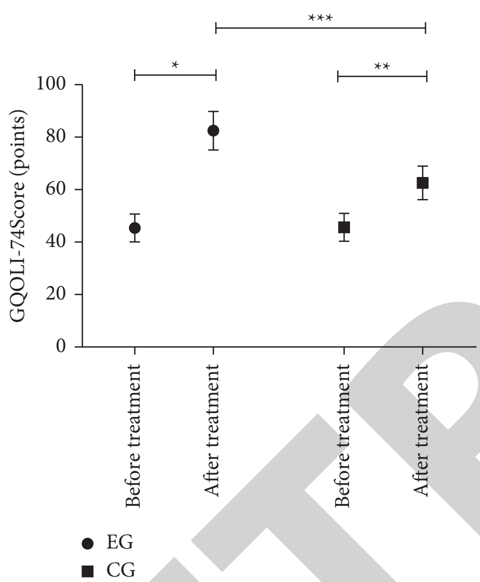

Figure 1: Between-group comparison of GQOLI-74 scores $(\overline{x} \pm s)$. Note: the horizontal axis indicated before and after treatment, and the vertical axis indicated the GQOLI-74 score (points). Before and after treatment, the GQOLI-74 scores of EG were 45.55 ± 5.31 and 82.75 ± 7.35, respectively. Before and after treatment, the GQOLI-74 scores of CG were 45.77 ± 5.32 and 62.77 ± 6.41, respectively. * indicated that the GQOLI-74 scores of patients in EG before and after treatment were significantly different ($t = 27.521$, $P < 0.001$); ** indicated that the GQOLI-74 scores of patients in CG before and after treatment were significantly different ($t = 13.690$, $P < 0.001$); and *** indicated that the GQOLI-74 scores of patients in both groups after treatment were significantly different ($t = 13.743$, $P < 0.001$).

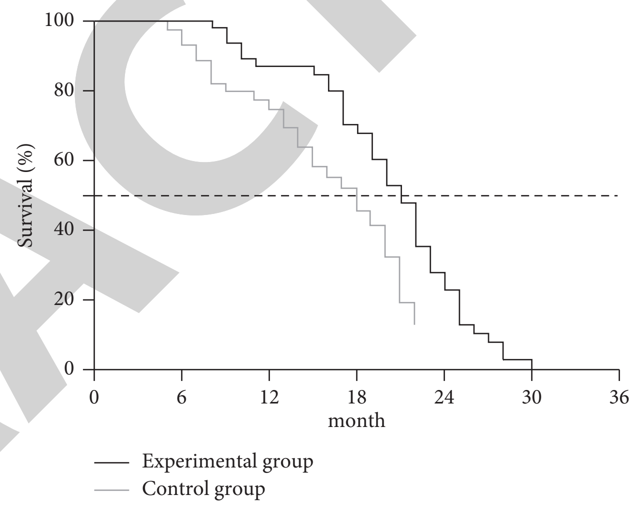

Figure 2: Between-group comparison of patients' long-term survival rates. Note: the horizontal axis indicated the survival time (months), and the vertical axis indicated the survival rate (%). The black line and the light gray line indicated the survival curves of EG and CG, respectively.

($P < 0.05$), indicating that crizotinib combined with chemotherapy could effectively improve QOL for advanced NSCLC patients. In addition, the combined treatment led to a significantly higher median survival time and a 3-year survival rate in EG ($P < 0.05$), implying that it could obviously prolong the survival time and improve the survival rate for patients. Also, the study results presented that the total ARR of EG was obviously lower than that of CG ($P < 0.05$), which was consistent with the founding of Van den Berg [18] et al. In their article, it was pointed out that "the difference in the ARR between the observation group and the control group was significant (8.33% vs 33.33%, $P < 0.05$)," which fully demonstrated that compared with the single treatment, the combined treatment of crizotinib and chemotherapy was safer.

5. Limitation of the Study

This study also has some shortcomings. As a retrospective study, it conducted both qualitative analysis and quantitative analysis, but the results related to treatment effect and ARR of EG were less accurate than in the clinical observational study. In addition, the small number of selected cases may lead to bias in the research results. Also, the cases selected were patients treated in our hospital, so the source of cases lacked diversity, and study design should be completed in the future. Therefore, multicenter, prospective, and large-N studies should be conducted in the future to promote the precision of results.

In chorus activities, the conductor leads chorus members to recreate music works. If you want to interpret music works perfectly with sound, emotion and emotional expression are particularly important. In this paper, a cloud HBD (health big data) integration system based on ensemble learning is designed to realize the high-efficiency and high-precision integration of HBD. An emotional speech database containing three emotions such as pleasure, calmness, and boredom is established, and the corpus problems such as emotional feature analysis and extraction needed for chorus emotion recognition research are solved. It also studies the classification and decision-making in emotional changes, and a DBN (deep belief network) chorus emotion recognition algorithm based on multiple emotional features is proposed. Feature DBN (Deep Belief Network) Chorus Emotion Recognition Algorithm This paper extracts various robust low-level features according to different features' ability to describe emotions and then feeds them into the DBN network to extract high-level feature descriptors. Then, the classification results of ELM (extreme learning machine) are voted and fused with the idea of ensemble learning, and the effectiveness of the algorithm is proved on three public datasets.

1. Introduction

Chorus is a collective artistic activity, which emphasizes the commonality and unity of performers. When it comes to unity in chorus, it means not only breathing, articulation, articulation, speed, timbre, volume, and movement but also the unity of emotion and emotional expression [1]. Because in rehearsal and performance, in order to make the expressive force of chorus more perfect, we should not only train basic skills but also be good at mobilizing and unifying the emotions and feelings of chorus members, thus forming the resultant force of collective singing. However, while emphasizing the common features, we often ignore an important issue in music art: emotional expression [2]. This makes the supposed beautiful voice and ideological connotation lack verve and artistic appeal.

Information technology and Internet technology have been widely used in the field of intelligent medical care, and big data provides an opportunity to deeply explore the value of data in the field of intelligent medical care and health. Literature [3] looks at the scenarios and advantages of the application of IoT (Internet of Things), cloud computing, and big data in smart medical health. Literature [4] expounds on the technical route of big data in the field of intelligent medical health from the perspective of methodology. Literature [5] puts forward the life cycle model of smart medical big data and discusses the goals and measures of smart medical big data governance. Literature [6] puts forward a universal intelligent medical information management and service system, and points out the key problems and future research directions of universal intelligent medical computing. Literature [7, 8] put forward a classification method with pitch frequency related information as its main feature, analyze and study four emotional states: fear, anger, sadness, and pleasure, and point out in its research report that the maximum, minimum, and median pitch frequencies are prominent features in speech emotion recognition. Literature [9] in its experimental research, the cepstrum coefficient feature is used as the emotional feature to classify three kinds of emotions, namely sadness, anger, and calmness, and the recognition rate is about 64%, while the accuracy rate of voice samples used by the subjective judgment of people is only 70%. On the basis of statistical analysis of acoustic features related to duration, energy, fundamental frequency, and formant construction of continuous pronunciation, it is proposed that the difference in feature vector between emotional speech and calm speech is taken as an emotional feature vector. Literature [10–12] use principal component analysis to classify pleasure, surprise, anger, and sadness, and the recognition rate is close to 80%. By analyzing the big data of health intelligent medical care, we can find out the correlation and trend among the data, which is helpful to improve the health service and disease exploration process, to conduct disease diagnosis and treatment more scientifically, to improve the efficiency and quality of health intelligent medical care services, and to continuously meet diversified health needs [13]. However, the application of big data in the field of intelligent medical health is still in its infancy, and there is still a lack of general big data framework and standards, which leads to the inability of large-scale application across industries and regions, and the inability to really play the role of big data.

Emotion is an important instinct of human beings. Like rational thinking and logical reasoning ability, it plays an important role in people's daily life, work, communication, transaction processing, and decision making. Based on HBD (health big data), this paper is applied to the emotion recognition of choir for the first time and identifies six basic human emotions, such as joy, anger, surprise, sadness, fear, and calm. The chorus emotion recognition algorithm based on multifeature DBN has the advantages of fast convergence speed, high robustness, and strong global searching ability so as to optimize the connection weights of the neural network. It can not only give full play to the generalization ability of the neural network but also improve the convergence speed and learning ability of the neural network.

2. Research Method

2.1. HBD Integration System

2.1.1. System Architecture. In some chorus competitions and performances, we hear neat, unified, and beautiful voices without sincere feelings, and the facial expressions of the chorus members are not rich enough, which makes people feel the fly in the ointment. If you want to truly achieve harmony of voice and emotion, you must do a good job of second creation; then, the singer's ideological height, life experience, and artistic accomplishment play a leading role. An excellent chorus player should have rich cultural connotations and literary and artistic accomplishments besides music knowledge and high singing skills. To build a cloud-based HBD integration system, the framework diagram is shown in Figure 1.

The management layer, big data analysis layer, whole cloud HBD integration layer, and whole cloud HBD resource layer constitute a whole cloud HBD integration system. The four layers cooperate with each other to realize the collection, analysis, storage, and operation of the whole cloud HBD.

The interface for users to regulate and use the integrated system is the management operation layer, and the management, regulation, protection, and use of the whole cloud HBD integrated system are realized through the operation of the administrator on this layer [14].

The integrated HBD is stored in the temporary database and metadata of the cloud-wide HBD resource layer and then stored in the cloud-wide HBD integration layer, which is applied to practical application software to complete the integration of cloud-wide HBD based on integrated learning so as to ensure that the cloud-wide HBD resources have higher value embodiment and manageability when integrated [15, 16].

2.1.2. HBD Prediction Method. As chorus art is a form of collective singing, most chorus training emphasizes the common factors of chorus, such as the unity of strength, sound, and expression, to form the resultant force of collective singing. However, while emphasizing generality, emotional expression in music art is often neglected. This makes the sound that should be beautiful and full of ideological connotation lack charm and artistic appeal.

Health informatization has become the core power of innovation and development in the field of big health. Various information systems provide convenient services for the daily work of health and smart medical institutions and at the same time effectively improve their data collection and storage capabilities. Many dynamic nonlinear features are hidden in one-dimensional health sign data, which makes them nonstationary, complex, and unpredictable time series data.

Time series data refers to a series of data values indexed by time. It is common to sample at continuous and equally spaced moments to form a time series. The biggest feature of time series is uncertainty. However, there is a certain mapping relationship within the data. Using intelligent analysis and prediction methods to solve this specific relationship and dig out the potential laws can effectively grasp the future trend of the system.

From a qualitative point of view, if the system parameters and external conditions do not change, then the sampled sequence is stable. However, this kind of analysis is not reliable, and it needs certain statistical characteristics for auxiliary inspection.

For any m time series data $\{Y_t\}$, if its subset $\{Y_{t_1}, \ldots, Y_{t_n}\}$ and subset $\{Y_{t_{1+m}}, \ldots, Y_{t_{n+m}}\}$ are the same, then $\{Y_t\}$ is strictly stationary. The data with strict stationarity have no changing trend. In fact, this kind of data does not exist. Generally, the so-called stationary time series data are weak stationary time series data.

The expectation, variance, and covariance of weakly stationary time series data $\{Y_t\}$ do not change with time [17]. That is,

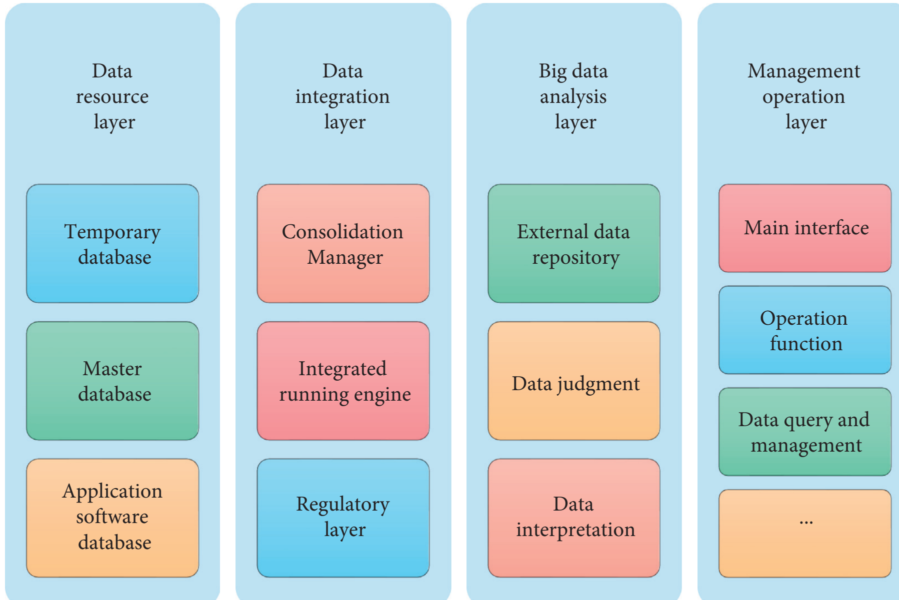

Figure 1: Framework diagram of HBD integration system.

$$E(y_t) = \mu,$$
$$Var(y_t) = \sigma^2, \quad (1)$$
$$Cov(y_t, y_s) = f(t-s).$$

After the time series has passed the stationarity check, the prediction model can be constructed through the relevant fitting model. For nonstationary time series data, it is necessary to process the stationarity and then rebuild the model.

The SARSA (state action reward state action) learning method is a complete state-action transition. When updating the current state action [18], this method does not use the state value function at the next moment but randomly selects actions to update the current state-action space according to a certain probability value and determines the execution action at the next moment when updating, which is the core of the SARSA method [19].The mathematical expression is described as follows:

$$Q(s,a) \leftarrow Q(s,a) + \alpha[r + \gamma Q(s',a') - Q(s+a)]. \quad (2)$$

In the above formula, (s,a) represents the state action at the current moment, (s',a') represents the state action at the next moment, r is the reward obtained after executing the action a, and α is the step size.

In this paper, a deep reinforcement learning method of SARSA based on "in-strategy" is proposed. The method proposed in this chapter is used to calculate the optimal decision. Let the current state be s, $\varepsilon - greedy$ as the selection strategy, the action be a, the current action report be r, and the next state be s'. Then, the current action value function $Q(s,a)$ is described as

$$Q^*(s,a) = E[r + \gamma Q(s',a')|s,a], \quad (3)$$

in which $Q^*(s,a)$ represents the optimal value of the current value function, and a' represents the optimal action selection at the next moment. Combined with CNN (convolutional neural network), if the network parameter is λ, the loss function in the j th iteration is defined as

$$L_j(\lambda_j) = \left(y_j - Q(s,a;\lambda_j)\right)^2, \quad (4)$$

in which $y_j = r + \gamma Q(s',a';\lambda_{j-1})$. By the differential solution of formula (4), the gradient of loss function can be obtained as follows:

$$\nabla L_j(\lambda_j) = \left(r + \gamma Q(s',a';\lambda_{j-1}) - Q(s,a;\lambda_j)\right)\nabla Q(s,a;\lambda_j). \quad (5)$$

The deep reinforcement learning process and its data flow based on the improved SARSA can be obtained from the formula above.

2.1.3. HBD Interpretation. In order to improve the accuracy and stability of the one-dimensional health sign data prediction model based on deep reinforcement learning, the data interpretation process shown in Figure 2 is designed.

Chorus health data analysis and processing system based on big data can provide health management services for chorus members. Through physical measurement, we can learn about chorus members' physical health status, build an interactive basic service and medical ecological platform [20, 21], and realize interactive sharing of key information between the system and the platform so as to provide efficient personalized physical health services for chorus members and promote optimal management of chorus members' self-health [22].

Because of the multifarious types of indicators, the interface display analysis is based on the body mass index. The

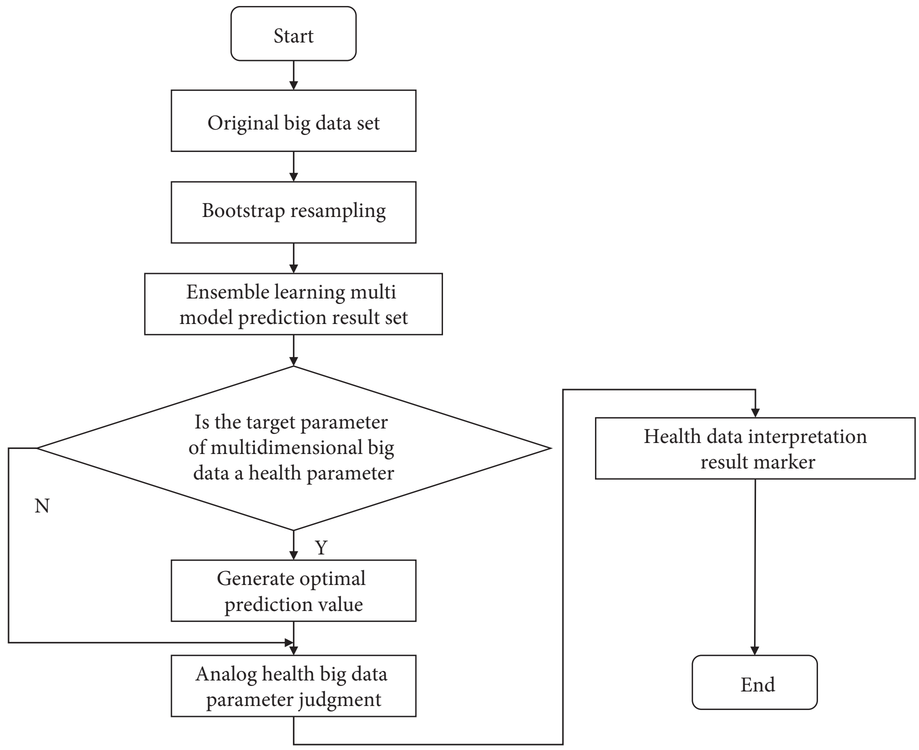

Figure 2: Data interpretation process.

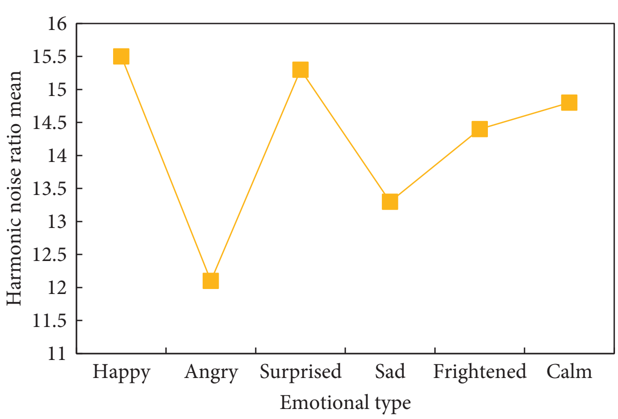

Figure 3: Harmonic noise ratio characteristics of emotion.

function module of weight increase is to increase the physical indicators of chorus members, set the corresponding threshold range reasonably, and dabble in data evaluation standards. In the system, the chorus's physical measurement data, that is, the score calculation, are mainly based on individual indicators and weights, or grades' scoring items and scoring weights, so as to obtain the chorus's total score.

2.2. Emotion Recognition of Chorus Staff. Emotion accompanies every moment of human life. About 38% of the information transmitted during human communication is carried by emotions. When people have a natural oral conversation, they not only convey the voice but also convey the speaker's emotional state, attitude, and intention.

The application of "emotion" in chorus can not only resonate with chorus members and audience but also realize the artistry of the chorus. In essence, emotional unity is a part of chorus unity. In the process of chorus rehearsal, we must follow the principle of chorus unity. The realization of chorus unity plays a very important role in the whole chorus rehearsal process.

In the process of chorus rehearsal, the chorus members should deeply understand the connotation of music and fully reflect the different attributes of each song so as to realize the resonance between the chorus members and the audience. Only in this way can we give full play to the artistry of chorus and achieve a perfect artistic realm.

This study mainly studies the algorithm of chorus emotion recognition. With the help of the excellent performance of neural network technology and the complementarity between different voice features, the idea of ensemble learning is introduced to complete the task of voice signal recognition under different emotions.

2.2.1. Emotional Feature Analysis. In chorus rehearsal, the commander should command the chorus's singing work on the one hand and interpret the music works on the other hand. Before chorus rehearsal, the commander should fully do desk work, get a deep understanding of the works of singing tracks and the background of the times, content forms, and cultures in which the singing tracks are produced, and put himself in another's shoes, understand the aesthetic requirements of songwriters for music, and realize the recreation of music on this basis.

Speech energy is one of the most important features in prosody, which is mainly determined by the vibration amplitude of the signal and reflects the strength of sound. In real life, people can feel that when a person expresses sad feelings, his voice is generally vague and low, while when he expresses happy and angry feelings, his voice is generally loud and bright. Therefore, different emotional voices have obvious differences in speech energy characteristics.

In view of which features in speech signals can effectively reflect emotion, researchers have carried out a lot of research from the perspectives of psychology and phonetic linguistics, but at present, they pay most attention to two types: prosodic features and sound quality features. This kind of feature and its derived parameters are most widely studied and applied in chorus emotion recognition. Sound quality features mainly refer to the timbre and spectrum of speech, so they are also called segmental features, which reflect the change of glottal wave shape during pronunciation (Figure 3).

If music only has notes and rhythms, it is just a shell. Only by giving rich emotions, the expression of music can be fuller and more perfect. Emotion and emotional expression run through the chorus. As chorus conductors, we should fully realize the importance of emotions and emotional expressions when interpreting chorus works and be good at unifying the emotions of members in the chorus process so as to make the chorus art more perfect.

Prosodic features and phonetic features are not isolated. Literature [23, 24] show that there is a certain correlation between prosodic features of speech signals and three emotional dimensions (valence dimension, activation dimension, and control dimension). Among them, the activation dimension is obviously related to prosodic features, and emotional states with similar activation dimensions have similar prosodic features, which are easy to be confused. By judging voiced and unvoiced speech signals, unnecessary calculation of the autocorrelation function of unvoiced frames can be effectively eliminated, and the calculation amount of pitch detection can be reduced.

The purpose of pitch detection preprocessing is to improve the accuracy of pitch detection by the autocorrelation method, which mainly includes band-pass filtering and nonlinear transformation. This paper only introduces the nonlinear transformation method. Commonly used nonlinear transformation methods include center clipping and three-level clipping. In this paper, the towel-center wave elimination method is adopted, and formula (6) is used as the central clipping function expression:

$$y(n) = \begin{cases} x(n) - L, & x(n) > L, \\ 0, & |x(n)| \le L, \\ x(n) + L, & x(n) < -L, \end{cases} \tag{6}$$

where $y(n)$ is the output of the central clipping function, and $x(n)$ is the input, which is the amplitude of n sample points in a frame of speech signal, and is the clipping level, which is a constant related to the maximum amplitude of the current frame. Usually, 60%–70% of the maximum amplitude is taken, and this paper takes 0.68.

The function definition of three-level clipping is

$$y(n) = \begin{cases} 1, & x(n) > L, \\ 0, & |x(n)| \le L, \\ -1, & x(n) < -L. \end{cases} \tag{7}$$

Comparing the expressions (6) and (7), it can be seen that the three-level clipping is a correction based on the central clipping, and the sample points exceeding the clipping level are assigned as 1 or -1, which can effectively reduce the multiplication in the calculation process of the autocorrelation function.

In order to analyze the relationship between formant-related features and emotional state, we extracted the first formant one by one from the emotional voice database. On this basis, the statistical characteristics of the first formant in different emotional states are statistically analyzed. Figure 4 shows the statistical analysis results of the mean value, dynamic range, and change rate of the first resonance peak.

It can be seen from the figure that the mean value of the first formant of pleasure and boredom is higher than that of the dynamic range, while the change rate is pleasure < calm < boredom, and the difference between the change rates of boredom and pleasure emotions is obvious.

2.2.2. Emotion Recognition of Chorus Based on Multifeature DBN. People can fully express their true feelings and thoughts through music. Emotion can be said to be the basic attribute of music. If a song lacks emotional integration, even if it has the best singing skills, it will be difficult for the audience to resonate with it. As music performers, musicians should fully tap the emotions in music, accurately understand the author's thoughts and feelings, and on this basis, organically integrate their feelings with music and recreate chorus music. Only in this way we can fully express the image that music wants to create and arouse the audience's resonance.

In this paper, we consider adopting the method of deep learning, extracting higher-level descriptors to represent more abstract concepts, and extracting more robust feature parameter factors through the multilevel representation of speech signals. The deep learning method has created the latest records in image processing, target location, detection, and other recognition and classification tasks, and DBN is one of the most representative networks.

The Boltzmann machine is an early component of the neural network, and its neurons are divided into two parts: explicit layer and implicit layer. The explicit layer is the input and output layer, which indicates the transmission of data, while the hidden layer is equivalent to the need to adjust the data in the transmission process, adding weight. The standard Boltzmann machine is a fully connected graph, and the complexity of the training network is very high. Therefore, in practice, the RBM (restricted Boltzmann machine) shown in Figure 5 is usually used for simplification.

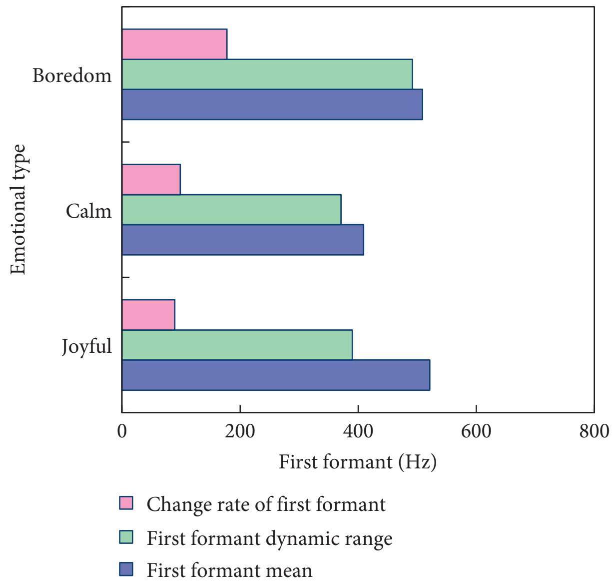

Figure 4: Comparison of the first formant characteristics of three emotions.

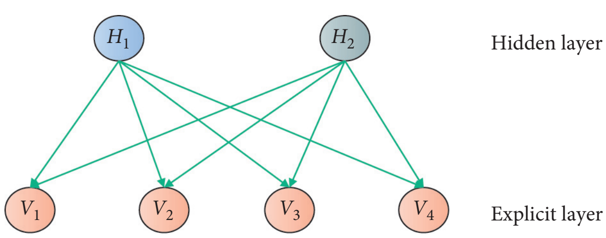

Figure 5: Restricted Boltzmann machine.

The construal divergence (CD) algorithm is often used to train constrained Boltzmann machines. Assuming that there are d neurons in the explicit layer and q neurons in the hidden layer in the network, let v and h represent the state vectors of the explicit layer and the hidden layer, respectively; then, because there is no connection in the same layer, there are

$$
\begin{aligned}
P(v|h) &= \prod_{i=1}^{d} P(v_i|h), \\
P(h|v) &= \prod_{j=1}^{q} P(h_j|v).
\end{aligned} \tag{8}
$$

The connection weight update formula is

$$\Delta w = \eta\left(vh^T - v'h'^T\right). \tag{9}$$

DBN (deep belief network) is connected by multiple RBM stacks, which can be trained effectively in a hierarchical way. Therefore, DBN has a strong learning ability and can learn high-level feature descriptors which are beneficial to the emotional recognition of chorus, as shown in Figure 6.

Firstly, it trains the first RBM with training samples and then uses the output of the first RBM as the input of the second RBM. Similarly, the output of the second RBM is used to train the third RBM. After each layer is pretrained, the whole network is trained by the BP algorithm.

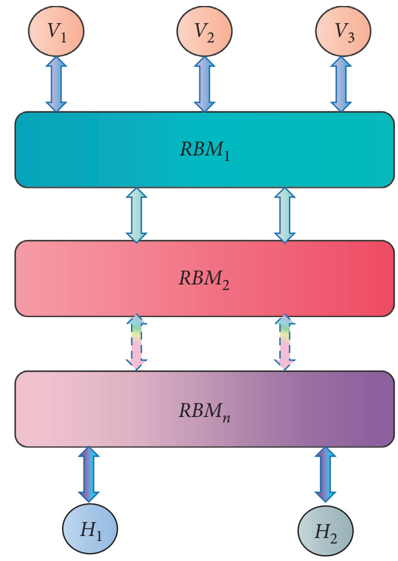

Figure 6: DBN structure diagram.

In this way, we can build a deep network model and then use the network model to obtain more robust high-level feature descriptors from low-level features.

In order to extract higher-level feature descriptors in speech emotion and ensure the diversity of base classifiers, inputting multiple features into the DBN network can solve the above problems. Therefore, this paper proposes a multifeature DBN method for chorus emotion recognition, which is composed of multifeature selection, DBN, and ELM (extreme learning machine) within the framework of set learning. The system framework is shown in Figure 7.

In this paper, we need to use spectrum sequence context (SSC) feature, power-normalized cepstral coefficient (PNCC), rhythm (Rhys) feature, Mel cepstrum coefficient (MFCC), and perceptual linear prediction (PLP), and then input these multiple features into the DBN network after feature selection so as to extract higher-level feature descriptors and create a better classifier.

Traditional hand-designed features do not perform well in emotion recognition tasks, mainly because they are low-level features, and it is difficult to fully describe the deep-seated information hidden in emotions [25]. Therefore, with the help of deep learning methods, a variety of traditional features are integrated with the DBN network to achieve better recognition results in emotion recognition tasks.

3. Discussion and Analysis

3.1. Comparison of Prediction Results. Based on the historical blood pressure data in the database of Literature [22], 221 experimental individuals, aged between 60 and 75 years, were preliminarily screened out. Predicting the blood pressure trend of these kind of people can help them control their blood pressure, guide their medication, and provide early risk warnings for some diseases.

Figure 8 shows the comparison between the actual value of blood pressure time series data and the prediction result of the model, and Figure 9 shows the error prediction model.

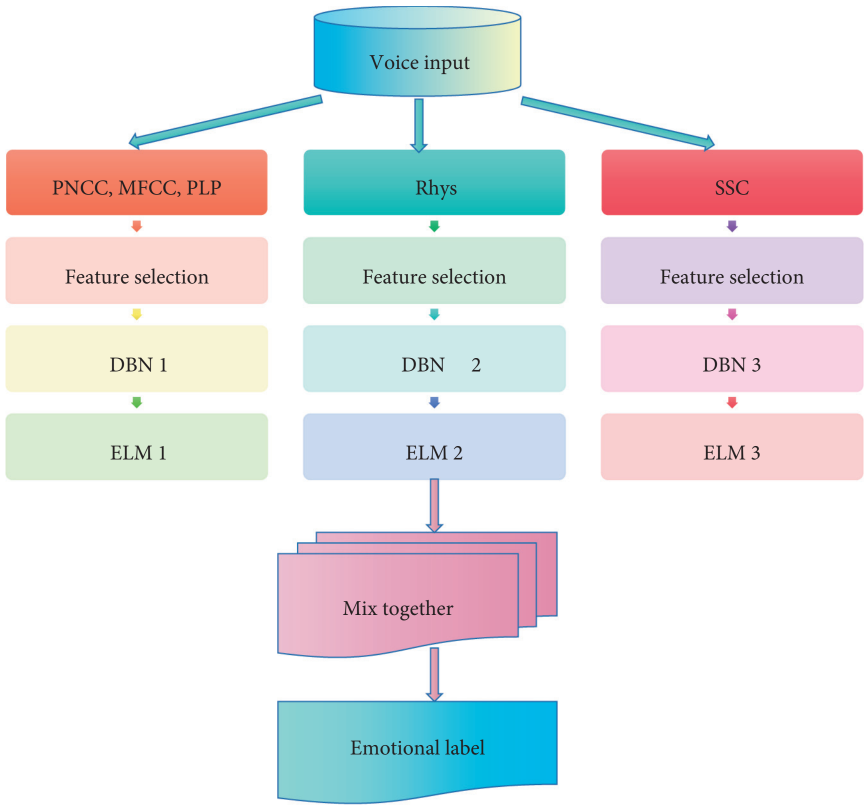

Figure 7: Flowchart of chorus emotion recognition based on multifeature learning.

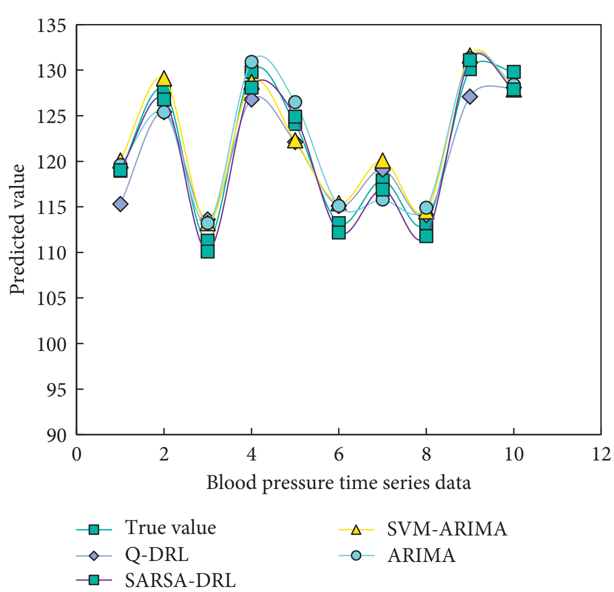

Figure 8: Comparison between actual values and model prediction results.

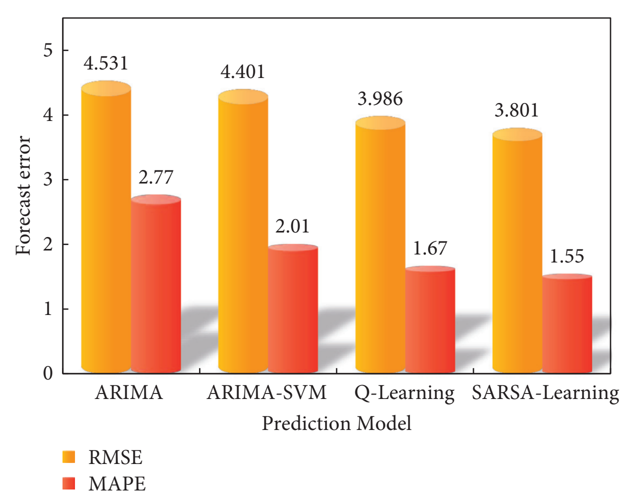

Figure 9: Comparison of final prediction errors of four models.

It can be seen from Figures 8 and 9 that the ARIMA-SVM model has higher prediction accuracy than the traditional ARIMA model and overcomes the limitations of the single model. Q-learning-based deep reinforcement learning and SARSA-based deep reinforcement learning are superior to the former two in high-dimensional spatial prediction, so the prediction accuracy is higher than the former two. Especially, the deep reinforcement learning method based on SARSA learning can fully express the hidden information in the original time series data of blood pressure.

3.2. Efficiency of HBD Integration. When the storage capacity of experimental big data is increasing, the two systems integrate the HBD efficiency of experimental logistics companies. The results are shown in Figure 10.

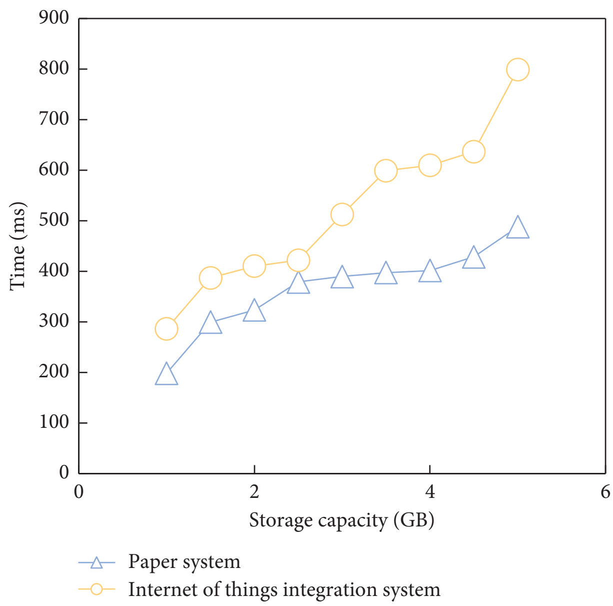

FIGURE 10: Efficiency of HBD integration.

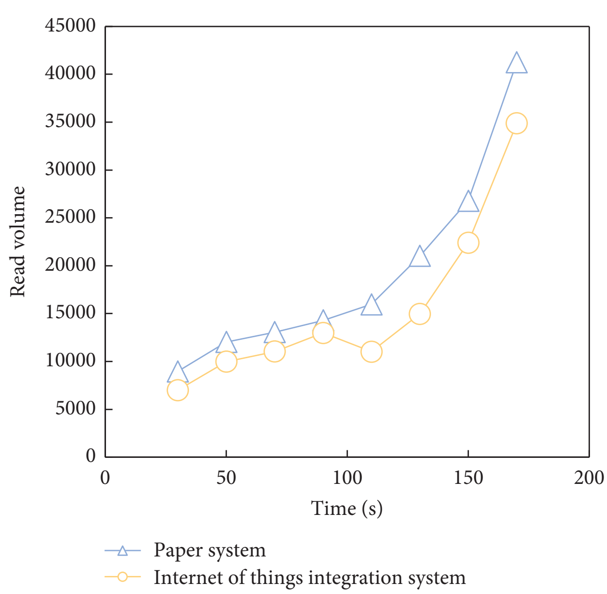

FIGURE 11: Test effect of integration system concurrency.

As can be seen from Figure 10, this system is highly efficient in integrating the whole cloud HBD.

The results of testing the concurrency of HBD integrated in this paper are shown in Figure 11.

According to the analysis of Figure 11, with the increase of time, the system in this paper is much larger than the HBD integration system based on IoT in processing the whole cloud HBD, which shows that the system in this paper has higher performance in processing the whole cloud HBD.

3.3. Analysis of Chorus Emotion Recognition. In order to verify the effectiveness of the spectral context features proposed in this paper in chorus emotion recognition, we compare the classical MFCC features and the combination

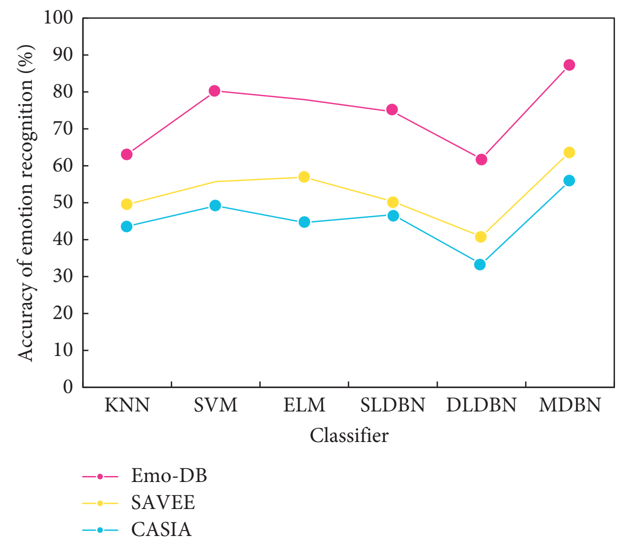

FIGURE 12: Comparison of emotional recognition accuracy of different classifiers.

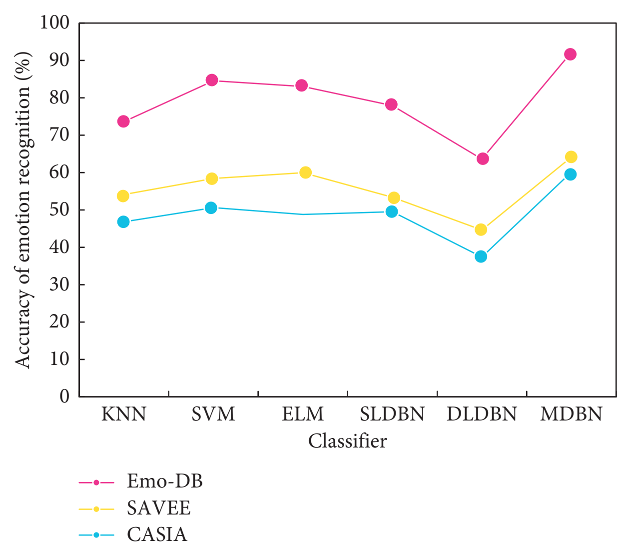

FIGURE 13: Comparison of emotional recognition accuracy of different classifiers.

of MFCC and delta features with the spectral context features on Berlin Emo-DB, SAVEE, and CASIA datasets, respectively. ELM classification is adopted in the classifier, with the number of hidden nodes being 6,000 and the activation function being hardlim. Figure 12 shows the comparison of the emotion recognition accuracy of different classifiers (speaker dependent).

In Figure 12, we compare the algorithm in this paper with KNN, SVM, ELM, single-layer DBN network (SLDBN), and double-layer DBN network (DLDBN). The experimental results show that the accuracy of the algorithm in this paper is greatly improved than the above methods, which shows that the algorithm in this paper can more effectively classify and recognize speech emotions.

In this experiment, 8 chorus samples were randomly selected from the Berlin Emo-DB dataset as the training set and the remaining 2 chorus samples as the test set. In order to avoid the error caused by the randomness of samples, we chose to repeat the experiment 5 times and calculate the average recognition accuracy. Figure 13 shows the comparison of emotion recognition accuracy of different classifiers (speaker independent).

Through Figure 13, we find that in the speaker independent experiment, the algorithm in this paper is compared with KNN, SVM, ELM, single-layer DBN network (SLDBN), and double-layer DBN network (DLDBN). The experimental results show that the algorithm in this paper is better than the above methods. Both have improved, indicating the effectiveness of the algorithm in this paper for the emotion recognition of chorus personnel.

4. Conclusion

If music only has notes and rhythm, it is just an empty shell. Only by giving rich emotions can the expression of music be fuller and more perfect. Emotion and emotional expression run through the chorus. The research work of emotional feature analysis and extraction is carried out in the established emotional voice database, and the changing rules of energy, fundamental frequency, formant, and other features in different emotional states are observed and analyzed. According to the statistical analysis results, the global statistical emotional features with emotional discrimination are selected and extracted. In this paper, according to the different abilities of different features to describe emotions, various robust low-level features are extracted, and then they are fed into the DBN network to extract high-level feature descriptors. Then, the ELM classification results are voted and fused with the idea of ensemble learning, and the effectiveness of the algorithm is proved on three public datasets.

Data Availability

The data used to support the findings of this study are included in this paper.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Objective. To understand the impact of alternate warm and cold therapy (AWCT) on uricemia, sleep, pain, functional ability, and quality of life in gout patients. *Methods*. A quasiexperimental, nonequivalent control group, pre and posttest design was adopted among 120 gout patients. The data were collected on demographics, comorbidities, pain level, joint swelling/joint tenderness, patient global assessment of response to treatment (PGART), health-related quality of life (HRQoL) with SF-36, sleep quality by Pittsburgh Sleep Quality Index (PSQI), and serum uric acid and assessed. Descriptive and inferential statistics were used to analyze the data. *Results*. Patients had mean age of 58 and 61 years, mean number of comorbidities was 1.8 and 1.4, as well as presence of arthritic comorbidities except gout was 1.1 and 0.8 among study and control group participants, respectively. Pain ($p < 0.001$), PGART ($p = -0.01$), HRQoL, sleep quality, and level of SUA (mg/dl) improved significantly ($p < 0.01$) among the study group over study periods. It affirms that the AWCT is effective in reducing pain, functional disability, and SUA, as well as improving the sleep quality and HRQoL of the gout patients. There was a reduced incidence of gout flares ($p < 0.001$), and taking additional medicines for pain ($p < 0.01$) was statistically significant among study participants. Except social functioning, other domains of health were significantly ($p < 0.05$) affected by the comorbidities like hypertension, diabetes, heart disease, renal disease, and asthma/chronic obstructive pulmonary disease. *Conclusions*. Gout is independently associated with higher medical and arthritic comorbidity, and AWCT can be better and cost-effective alternative therapy for gout patients. In addition, it may lead to improved cardiac function, hypertension, and renal insufficiency.

1. Introduction

Gout is the most common form of inflammatory arthritis globally which is a metabolic disease marked by recurrent episodes of acute arthritis caused by inflammation caused by the formation, deposition, and release of monosodium urate crystals in one or more extremity joints [1–3]. It is the most common type of inflammatory joint disease in men over the age of 40, and it can affect women after menopause [4, 5]. Epidemiologic studies confirm a global distribution [5], with an estimated prevalence of 5.1 million people in the United States [6].

Gout is a common chronic crystal deposition disorder that affects 1–6.8% of the population, depending on the population studied. Serum uric acid (SUA) levels have been found to be high throughout the world, including the Philippines and Seychelles: 25%, USA: 21–22%, Japan: 20–26%, Indonesia: 18%, Russia and Nigeria: 17%, Brazil: 13%, Turkey: 12%, Taiwan: 10–52%, Thailand: 9–11%, Mexico: 11%, Sweden: 10–16%, Italy: 9–12%, Iran and Saudi Arabia: 8%, China: 6–25%, Spain: 5–11%, and South Korea: 5–25.8% [7].

Over the last 5–10 years, hospitalizations for gout have increased by 50–100% in the United Kingdom, the United States, and Sweden [8–11]. In these countries, gout now induces more hospitalizations than rheumatoid arthritis, and hospitalizations for gout increased more than for other rheumatological conditions between 2007 and 2012 [8].

The prevalence of self-reported, health professional diagnosed gout was 3.9% in the 2015–2016 National Health and Nutrition Examination Survey (NHANES), a stratified, multistage sample representative of the U.S. adult population [12]. Gout is also commonly associated with comorbidities such as cardiovascular disease (CVD), chronic kidney disease (CKD), obesity, and other conditions. As per a retrospective study in India, hyperuricemia (H.U.) was found in 33.6% of diabetics, 35.1% of hypertensives, and 34.4% of diabetic hypertensives, with the overall incidence of H.U. in patients attending screening programs being 25.8% [7].

Furthermore, cohort studies in the United States, Taiwan, and the United Kingdom have discovered that gout is linked to an increased risk of developing atrial fibrillation, obstructive sleep apnea (O.S.A.), venous thromboembolism (V.T.E.), and pulmonary embolism [13–19].The frequency of gout attacks usually increases with time in untreated patients. Hence, understanding trends in gout prevalence is critical for adequate global healthcare resource planning, not least even though gout can be "cured" with readily available and low-cost therapies.

There is a scarcity of information available on alternative therapies for the management of gout in the Indian population and its relationship with uricemia, pain, sleep, functional ability, and HRQoL. As a result, the current study was designed to evaluate the effect of alternating warm and cold therapy (AWCT) on uricemia, sleep, pain, functional ability, and quality of life (USPFQoL) gout patients: a path forward among Indian populace.

2. Methods

2.1. Research Approach and Design. For this study, quantitative research approach with a quasiexperimental, nonequivalent control group, pre and posttest design was used; only the experimental group received the intervention, while the control group received no intervention.

2.2. Participants and Setting. The study participants were both men and women diagnosed with gout and who were admitted as in patients for a minimum of 10 days and who agreed to participate in the study. Patients with illnesses such as open wounds and diabetic foot ulcers, peripheral vascular diseases, absence of tophi, and patients who are receiving physiotherapy were excluded from the study. The study was conducted in two orthopaedic hospitals, and one setting was used for the intervention group, and the other was for the comparison group to avoid contamination.

2.3. Sample Size and Sampling Process. The minimum recommended sample size was 60, as calculated by Raosoft's online sample size calculator, with a 95% confidence level and a 5% margin of error. In the first and second hospitals, 104 and 121 chronic gout patients were admitted during the study period. Among them, 120 samples were chosen by the nonprobability convenient sampling technique and distributed for experimental (60 participants) and control group (60 participants).

2.4. Data Collection Tools/Instruments. The data were collected on demographics and history of comorbidities, pain level using 10 points numerical scale, joint swelling/joint tenderness with a 4-point scale (0 = none to 3 = bulging beyond joint margins), and patient global assessment of response to treatment (PGART). The PGART was rated by patients using the visual analogue scale (VAS), a 15 cm horizontal line with marked anchors: 0 = very well and 100 = very poor. With these anchors, patients were asked to respond to the following: "Given all of the ways gout affects you, rate your performance on the following scale by placing a mark on the line." The health-related quality of life (HRQoL) was assessed, and the Medical Outcomes Study Short Form-36 (SF-36) consists of eight scaled scores, which are the weighted sums of the questions in their section. Assuming that each question carries equal weight, each scale is directly transformed into a 0–100 scale. The lower the score, the greater the disability, and the higher the score, the better the health. The SF-36 is a 36-item scale that assesses eight domains of health: physical functioning (10 components), physical role limitations (four elements), bodily pain (two elements), general health perceptions (five elements), energy/vitality (four elements), social functioning (two components), emotional role limitations (three elements), and mental health (five elements). Using the Pittsburgh Sleep Quality Index (PSQI), sleep quality was assessed.

Serum uric acid (uricase method) was measured. A high serum uric acid level is currently defined as a value of at least 6.8 mg per dl (405 μmol per L). These data were collected based on the core domains on that outcome measures in rheumatology (OMERACT) [20].

2.5. Assessment. Subjects completed and returned gout symptom diaries between follow-up visits, which the investigators reviewed at the next visit. The journals contained information such as the frequency, dates, duration, and severity of flares; the joint(s) affected; medications (both prescribed and over-the-counter); and whether the gout attack required a medical office contact or visit.

2.6. Intervention. Control group participants received standard care and consistent advice on diet, exercise, and weight management. The intervention group was given routine care and alternate warm and cold therapy twice a day, once in the morning and once before bedtime.Coconut oil was first applied to the lower legs and feet/the affected joints in the arm. The subjects subsequently plunged their toes and then both feet/arms, into 38° water, which was then adjusted to a comfortable temperature near 42°. The basin was covered with a plastic bag, as were the participants' legs/arms up to their knees/elbows. To allow the individual to maintain a comfortable position, a blanket and a pillow was placed beneath the knees/arms and the basin. For 4 minutes, the feet/arms were immersed. The feet/arm was then applied with cold therapy for 30 s until completing 5 cycles. Then, the feet/arms were cleansed with a foaming body shampoo and cotton gloves and dried dry with a towel.The complete procedure took 30 min and comprised a 5-minute oil rub, followed by 20 minutes of AWCT. To keep the techniques as equal as feasible, all AWCT were provided by the same person.This intervention was given for 7 days during their hospitalization, and the participants were advised to follow the same in the home after discharge in 5 days/week for one month. The baseline data and post hoc after one week and one month were assessed for both the control and study groups. Figure 1 shows the CONSORT diagram.

2.7. Ethical Consideration. Official permission to conduct the study and ethical approval was obtained from the Institutional Ethical Committee with ICE/LCN/2021–10 dated 20.09.2021. Consent from the participants was collected after explaining the aim of study, their role, confidentiality of the information, and their right to depart from the study. No harm certificate was obtained from an orthopaedician for the intervention. The control group also ensured that they were following the standard care protocol of the gout treatment. Confidentiality and beneficence were assured throughout the study period.

2.8. Statistical Analysis. The data were processed and analyzed by SPSS software using descriptive and inferential statistics. Analysis of data was by intention-to-treat. Analysis of variance was used to examine the main effects of AWCT among the two groups on the dependent variables. The t-test was used to compare differences between group means. Multiple regression analysis was used to examine the effect of AWCT and comorbidity on health-related quality of life in gout patients. All statistical tests used a significance of 0.05.

3. Results

The characteristics of study participants are given in Table 1. Most of the demographic and clinical characteristics were similar with study and control group, which is shown in the "Goodness of fit" test. Patients had a mean age of 58 and 61 years, 43 and 38 were men among study and control groups, respectively. Mean number of comorbidity was 1.8 and 1.4, as well as presence or absence of arthritic comorbidities except gout was 1.1 and 0.8 among study and control group participants, respectively.

As given in Table 2, the average pain score in baseline, after one week, and one month improved from 8.8 to 5.7 and 8.6 to 6.9 among the study and control groups, which is statistically significant at $p < 0.001$ among the study group.There were no differences between the mean values before AWCT in the score of joint swelling/joint tenderness among the control group. In the experimental group, the PGART score was decreased after the AWCT in the first week (74 (SD, 3)) and after one month (67 (SD, 6)), $p = -0.01$). Similarly, HRQoL, sleep quality, and level of serum uric acid (mg/dl) was improved significantly ($p < 0.05$) among study group participants, but there was no significant difference in the control group.

Table 3 provides the multivariable-adjusted effect of AWCT in gout patients. A multivariable model controlled the age, employment status, marital status, gender, education level, current medications, comorbidities, and arthritis comorbidity other than gout. Among the variables studied, there was a reduced incidence of gout flares ($p < 0.001$), and taking additional medicines, both prescribed and over-the-counter medications for pain ($p = 0.01$), was statistically significant among study participants. The number of joint(s) affected and hospital visits was not related significantly.

The effect of comorbidities on health-related quality of life in gout patients is given in Table 4 and Figure 2. The age, employment status, marital status, gender, education level, current medications, uric acid levels, and arthritis comorbidities other than gout were all controlled in a multivariable model. In this analysis, except social functioning, other seven domains of health status such as physical functioning, physical role limitations, bodily pain, general health perceptions, energy/vitality, emotional role limitations, and mental health were significantly ($p < 0.05$) affected by the comorbidities of the participants such as hypertension, diabetes, heart disease, renal disease, and asthma/chronic obstructive pulmonary disease.

4. Discussion

In the present study, 225 gout patients were screened. Among them, 120 samples were chosen by the non-probability convenient sampling technique and distributed

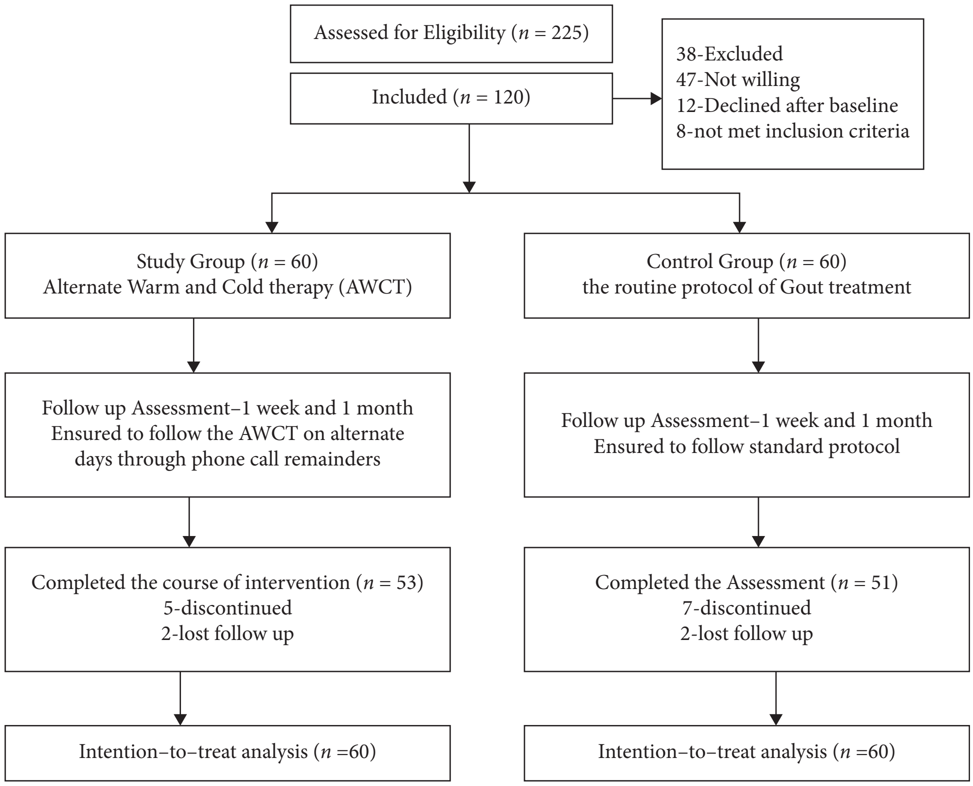

Figure 1: CONSORT diagram.

Table 1: Demographic and clinical data of study and control group participants.

Variables	Study group	Control group	P value
Age (in years), mean (SD)	58 (16)	61 (13)	<0.001
Employment status			
Employed	31	27	<0.001
Unemployed	18	19	<0.001
Retired	11	11	<0.001
Unknown	0	3	<0.001
Married	36	44	<0.001
Male	43	38	<0.001
Education level			
Less than 8th grade	25	21	<0.001
High school	8	14	<0.001
Higher secondary	13	7	<0.001
College	14	18	<0.001
Comorbidity	1.8 (1.3)	1.4 (1.7)	<0.001
Presence or absence of arthritic comorbidities except gout	1.1 (0.7)	0.8 (0.6)	<0.001

for experimental (60 participants) and control groups (60 participants) from two hospitals. The AWCT was given seven days during hospitalization and advised to follow the same at home for one month in the study group. The participants had 1.8 and 1.4 mean comorbidity and presence or absence of arthritic comorbidities, except gout was 1.1 and 0.8 among study and control group participants. A large study looked at the temporal relationships between the occurrence of comorbidities before and after gout diagnosis using data from the U.K. Clinical Practice Research Datalink (CPRD) [21–25]. This study confirmed the well-known association of gout with subsequent CVD and renal disease and hypertension, hyperlipidaemia, CVD, and renal disease as risk factors for gout. Cohort studies from the United Kingdom, the United States, and Canada have also validated the bidirectional relationship between gout and CKD, with CKD predisposing to gout, which increases the risk of CKD progression [26–28]. These findings show that gout can lead to these comorbidities or these comorbidities leads to gout. Hence, identifying and treating gout may be an excellent strategy to prevent the occurrence of these illnesses and can help to reduce the disease burden globally.

Table 2: Changes in the clinical data of study and control group participants over study periods.

Dependent variables: mean (SD)	Group	Baseline	1 week	1 month	P value
Pain score	AWCT	8.8 (0.8)	6.3 (1.1)	5.7 (0.9)	0.001
	Control	8.6 (1.2)	7.1 (1.3)	6.9 (1.02)	0.06
Joint swelling/joint tenderness	AWD	2.1 (0.4)	1.67 (0.13)	1.1 (0.3)	0.001
	Control	2.3 (0.2)	2.0 (0.7)	2.1 (0.5)	0.551
Patient global assessment of response to treatment (PGART)	AWD	81 (7)	74 (3)	67 (6)	−0.01
	Control	79 (11)	76 (9)	80 (4)	−0.971
HRQoL	AWD	57 (16)	61 (11)	69 (7)	0.01
	Control	54 (13)	57 (17)	56 (15)	0.819
Sleep quality	AWD	16 (3.1)	14 (1.8)	11 (0.5)	0.01
	Control	15.4 (4.3)	14.7 (1.8)	15.0 (0.9)	0.907
Serum uric acid (mg/dl)	AWCT	9.9 (1.4)	8.1 (0.9)	7.2 (1.1)	0.05
	Control	9.67 (2.1)	8.7 (1.8)	8.13 (2.2)	0.653

Table 3: Multivariable-adjusted effect of AWCT in gout patients.

	Multivariable adjusted			
	Study	Control	P value	Difference (%)
Incidence	2.69 (2.3–2.7)	3.52 (3.20–3.67)	0.001	34.11
No. of joint(s) affected	1.52 (1.45–1.58)	1.66 (1.27–2.05)	0.06	9.21
Taking additional prescribed and over-the-counter medicines	1.36 (1.48–1.83)	2.07 (1.82–2.33)	0.01	9.52
Hospital visits	2.08 (1.1–2.15)	2.3 (1.34–2.8)	0.21	16.21

Results are shown as mean (99% confidence intervals). Age, employment status, marital status, gender, education level, current medications, comorbidity, and arthritis comorbidity other than gout were all controlled in a multivariable model.

Table 4: Multivariable-adjusted effect of comorbidity on health-related quality of life in gout patients.

	Multivariable adjusted		
	Study	Control	P value
Physical functioning (P.F.)	51.6	47.3	0.01
Role physical (R.P.)	47.3	44.1	0.05
Bodily pain (B.P.)	49.3	43.6	0.001
General health (G.H.)	54.3	45.7	0.01
Vitality (VT)	43.9	40.8	0.05
Social functioning (S.F.)	68.3	67.9	NS
Role emotional (RE)	53.6	42.4	0.01
Mental health (MH)	73.1	66.9	0.05
Physical component summary (P.C.S.)	36.1	32.4	0.05
Mental component summary (M.C.S.)	51.8	42.1	0.01

Age, employment status, marital status, gender, education level, current medications, uric acid levels, and arthritis comorbidity other than gout were all controlled in a multivariable model.

As given in Table 2, pain ($p < 0.001$), PGART ($p = -0.01$), HRQoL, sleep quality, and level of SUA (mg/dl) improved significantly ($p < 0.01$) among study group participants, but there was no significant difference in the control group over study periods. It confirms that the AWAT effectively reduces pain, functional disability, and SUA and improves sleep quality and HRQoL in gout patients. According to Yamamoto and Nagata's study on physiological and psychological assessment of the wrapped warm footbath as a complementary nursing treatment to induce relaxation in patients with incurable cancer, the wrapped warm footbath reduced significantly sympathetic activity in hospitalized cancer patients, which can enhance relaxation and appears to provide pain relief as well as enhanced comfort [29].

Furthermore, a pilot study found a significant antihypertensive effect after 20 minutes of the steam spa. The hypotensive effect could be attributed to improved vascular endothelial function; nitric oxide produced by vascular endothelial cells causes vascular smooth muscle cells to relax [30, 31]. Though it is not the scope of the present study, this is a more significant finding as most of the study participants had the comorbidity of hypertension. This AWCT may help them reduce their blood pressure, and the effect on gout as its impact is bidirectional.

Functional disability [32], impairment of health-related quality of life (HRQoL), and increased mortality have all been reported in gout patients [33]. As a result, gout has emerged as a significant public health concern. The KING study data confirm the impact of gout on disability and

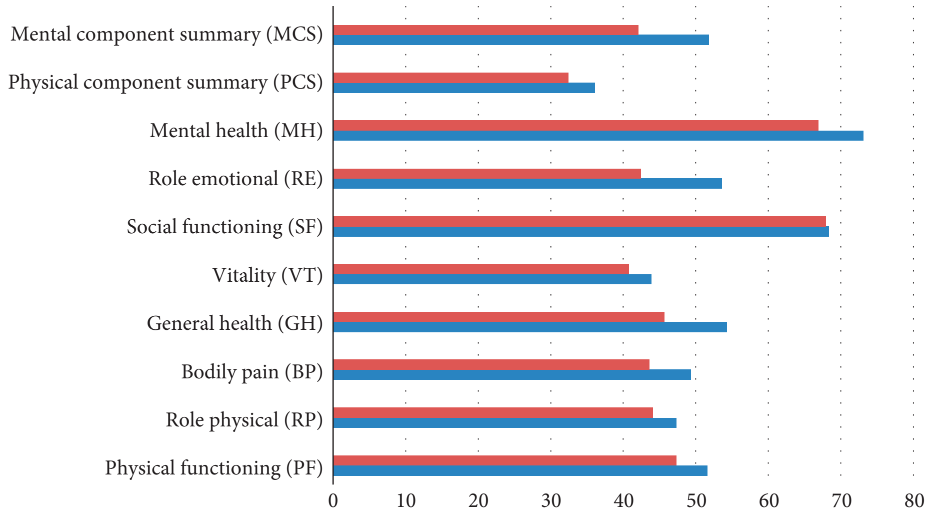

Figure 2: Effect of comorbidities on health-related quality of life in study and control groups.

provide evidence for an independent association of gout and gout-related features with functional outcome and HRQoL. This finding supports the need for better gout treatment [34]. As a nonpharmacological, safe, and simple application, footbaths can improve postmenopausal women's quality of life and prevent problems caused by insufficient sleep quality [35].

All study group patients reported significant pain relief in our preliminary investigation into whether patients receiving AWCT would report pain relief ($p < 0.001$). An increase in parasympathetic activity and a decrease in sympathetic activity would be expected to accompany pain relief-induced relaxation. The cause of the low parasympathetic activity is unknown. Still, the reduction in sympathetic nerve activity in patients may be due to the effects of soaking in warm water, alternate cold application, and tactile stimulation from massage [29]. This pain relief improved the sleep quality, functional ability, and HRQoL of the study group gout patients. However, efferent sympathetic nerve activity is increased by negative feelings in various pain disorders. Accordingly, it is supposed that the reduction in sympathetic nerve activity found in our subjects is the primary mechanism underlying both the relaxation and pain relief effects reported. Negative feelings or depression in patients, usually seen in chronic pain disorders, on the other hand, increase efferent sympathetic nerve activity. As a result, it is assumed that the decrease in sympathetic nerve activity observed in our subjects is the prime mechanism underlying both the reported improved sleep quality and pain relief effects.

Insomnia is a common sleep disorder in adults that can have various negative health effects. The total annual cost of direct and indirect insomnia healthcare costs has been estimated at USD 100 billion. Adding to the societal expenditure, insomnia harms patients' quality of life (QoL), including impaired social and occupational functioning or productivity and impaired cognition or mood. Insomnia can also worsen and increase morbidity and complications from psychological disorders like depression and have severe consequences like an increased risk of suicide [36, 37]. Hence, improving sleep quality is a significant investment in the perspective of the patients and the nation's economy.

In 85–90% of people, hyperuricemia is the major contributor to gout due to under excretion of urate. Sweat fluid comprises sodium chloride, potassium, and nitrogen metabolites like urea, ammonia, uric acid, and creatinine [38]. Besides, reduced sympathetic nerve activity results in increased renal excretory function by affecting the renal vasculature, the tubules, and the juxtaglomerular granular cells and impaired arterial baroreflex regulation. The significant reduction in SUA in the study group may be because of this effect, and AWCT increased sweat and thirst, consequently increasing fluid intake. The cold application increases the voiding sensation, thus enhancing the uric acid elimination in urine and sweat. However, further studies are required to investigate this supposition further.

5. Clinical Relevance

This study results can help healthcare professionals gain greater insight into alternative therapy for gout patients suffering from pain, sleep disturbance, reduced functional ability, and HRQoL. This technique can be used at home to alleviate problems, enhance their overall quality of life, and reduce healthcare costs, and this can provide an avenue for further research studies.

6. Conclusion

To summarize, the AWCT holds promise as a complementary intervention for inducing sleep, pain relief, and as a result, improved functional ability, HRQoL, and uric acid elimination in gout patients. As a result, the AWCT should be a proper adjuvant alternative method for gout patients. In addition, it may lead to improved cardiac function, hypertension, and renal insufficiency.

Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author upon request.

Ethical Approval

Institution Ethical Committee gave an ethical clearance with ICE/LCN/2021–10 dated on 20.09.2021.

Consent

Written informed consent was obtained from the study participants to publish this study.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

All authors have read and agreed to the published version of the manuscript. Premalatha Paulsamy conceptualised, investigated, validated, visualized, and supervised the study, performed formal analysis, developed methodology and software, administered project, collected resources, and wrote and reviewed the original draft. Academic Editor: Enas Abdulhay

The COVID-19 has resulted in one of the world's most significant worldwide lock-downs, affecting human mental health. Therefore, emotion recognition is becoming one of the essential research areas among various world researchers. Treatment that is efficacious and diagnosed early for negative emotions is the only way to save people from mental health problems. Genetic programming, a very important research area of artificial intelligence, proves its potential in almost every field. Therefore, in this study, a genetic program-based feature selection (FSGP) technique is proposed. A fourteen-channel EEG device gives 70 features for the input brain signal; with the help of GP, all the irrelevant and redundant features are separated, and 32 relevant features are selected. The proposed model achieves a classification accuracy of 85% that outmatches other prior works.

1. Introduction

Due to the COVID-19 epidemic, all the governments in the world have to impose a lockdown. This strictness, however, affects the emotions of the people, and lots of people are feeling emotional imbalance [1]. The people are experiencing negative emotions, and their health and performance are degrading day by day. Emotion and mental awarenesses have become the primary concern for all the governments in the world because a lot of people are feeling stressed and alone [2].

To address the challenge as mentioned above, lots of researchers are applying classification algorithms to understand the emotion of the people [3]. Humans cannot classify these types of emotions; whereas, these classifiers can do this task very efficiently [4]. Recently, many expert systems and machine learning tools are gaining importance for the classification of medical data because they can learn from experience, past patterns, and examples [5–7]. Also, a more detailed medical data examination can be done in a shorter time with a reduced number of errors [8–10]. However, the problem with many features is that they are redundant. Because of that, they increase the error rather than reducing it [11, 12]. Feature selection can address this problem by selecting only relevant features for classification [13–15]. This improves the performance of the classifiers by removing similar features, shortening the training time. The techniques like evolutionary algorithms are gaining importance in feature selection because they can efficiently search the entire search space. There are few evolutionary algorithms, but genetic programming has shown good results on classification problems. Another advantage of using GP is that the classifier of GP has a tree structure [16], so we can recognize the features present in the best classifier. This will help, especially in the case of medical diagnosis, because we can determine which features are more important. In the last decade, there have been several reports on applying GP techniques to a range of medical data classification problems [17–19].

However, in this study, the genetic programming-based feature selection (FSGP) technique is proposed. It helps to improve the classification accuracy of the emotion recognition dataset by removing redundant and irrelevant characteristics in a single GP life cycle. An EEG dataset is created using brain signals [20]. The proposed algorithm yielded an accuracy of 85% for 80–20 training-testing partition. The results show that our approach works well with the EEG database and reduces the number of features with increased classification accuracy, confirming that it can be an excellent alternative to the well-known expert system and machine learning methods. The goal of our algorithm would be to correctly classify the samples as positive and negative emotions with an optimal number of features. The following few points highlight the difference between the current study and the existing ones in the literature. (i) How we can reduce the number of features and simultaneously increase the classification accuracy in a single genetic programming life cycle. (ii) The present study contains the result on the emotion recognition dataset created using the 14-channel EEG device. (iii) A reduced number of features are also presented along with the classification accuracy.

The rest of the study is described as follows: Section 2 gives the device and dataset description, Section 3 tells about the proposed algorithm, Section 4 presents the result of the proposed algorithm, and Section 5 compares the proposed algorithm with other machine learning algorithms.

2. Methods and Materials

This part provides information about the device, dataset used, and the classification algorithm.

2.1. Device Description. Emotiv EPOC is a 14-channel wireless headband for collecting brain signals shown in Figure 1. It is a portable device that has 14 electrodes following the American EEG Society Standard, as shown in Figure 2. This device can collect raw EEG data and generate the features from the signals. The total number of signals this device generates is 70. The five features are from every 14 channels, so 70 features.

The EEG signals are generated as a person experiences different emotions or feelings when exposed to situations or scenarios through visual content. We recognize an individual's emotions by analyzing brain waves while watching emotional or situational materials and classify the emotions into two classes, i.e., positive and negative. The elicitation materials included around 60 videos, which depict the dramatic person's predefined personality traits and are therefore recognized as the ground truth of this work's experimental procedure.

2.2. Dataset. Fifty (25 males and 25 females) nonclinical participants were considered for this research. The study was volunteered by participants, and an informed consent form was also concluded. All nonclinical participants from various cultures and education classes were Hindi speaking. However, 5 data samples were dropped as a result of failure in equipment or excessive EEG signal artifacts in the final analysis. The age group of participants is divided into three age groups as 15–20 years, 21–26 years, and 27–35 years.

Figure 1: 14-channel Emotiv EPOC.

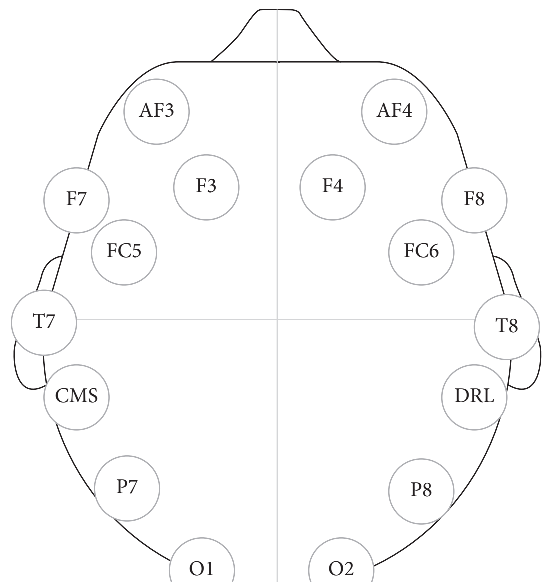

Figure 2: American Society Standard for putting 14-channel electrodes.

3. Proposed Method

For this research, fifty (25 males and 25 females) nonclinical participants involved. Participants volunteered for the study, and an informed consent form was also concluded—all nonclinical participants from various cultures and education classes were Hindi speaking. However, 5 data samples were dropped due to failure in equipment or excessive EEG signal artifacts in the final analysis; in total, 45 participants were considered for this research.

3.1. Initialization and Fitness. We generate the initial population using all features in the feature set and terminals in the terminal set. The ramped half and half method is used for initializing the population. We maintain the structural diversity of the people through all generations. To keep the variety, all the individuals are compared to ensure that no similar trees are generated. After generating the diverse initial population, we calculate the fitness of all the trees using the emotion recognition dataset. During training the individuals, we calculate the fitness using the training dataset.

3.2. Feature Selection. After evaluating the fitness of the classifiers, we perform our feature selection process. In this, we calculate the average fitness of the classifiers in the generation. After that, we select those classifiers whose accuracy (fitness) is more significant than average accuracy and named them Cgaa classifiers (classifier having accuracy greater than average accuracy). Then, we assign the weights to the features present in Cgaa classifiers. Initially, the weight of all the features is 0; then, we evaluate the number of times any feature is present in these Cgaa classifiers. The number of times the feature is present in the Cgaa classifier is the weight of that feature. This process is repeated for all the features, and their weights are evaluated. We repeat this process for 50% of the generation and evaluate the weight of all the features present in Cgaa classifiers. After getting the weight of all the features, we calculate their average. Those features whose weights are more significant than average weight is selected, and we named them suboptimal features (Fso). Then, we got two subsets of features: those whose weight is more significant than average weight (Fso) and those whose weight is not greater (Fno).

In the next generation, we replace all the (Fno) features with (Fso) features. To replace the (Fno) features with (Fso) features, we apply a modified mutation technique, in which we replace the single (Fno) feature with a single (Fso) feature randomly chosen from the (Fso) subset. Then, we compare the fitness of the newly generated tree with its parent. If the fitness of the tree is increased, then we stop; otherwise, we repeat this process till we get better offspring than a parent. In this way, all the unwanted (Fno) features are replaced by (Fso) features. Then, we allowed the GP life cycle to run till the last generation and obtain the best classifier in terms of fitness, and the features present in the best classifier are the optimal feature set. The advantage of this method is that we had done the feature selection and classification in one run of GP. The other benefit is that our process does not suffer from overfitting problems as happens in the case of wrapper approaches because of applying a similar algorithm two times, the first time for feature selection and the second time for classification. The flowchart of the proposed work is shown in Figure 3.

3.3. Genetic Operators. The three operators of genetic programming are applied to generate the following populations. Reproduction copies the best individual to the next generation. Crossover and mutation operators are improved to reduce the possibility of sending the lower fitness individuals to the next generations. The hill-climbing crossover and mutation operators [16] are used in this work. After doing the crossover and mutation, the offsprings are compared with their parents, and if their fitness is better than the parents, only the child is transferred to the next generation. Due to this property only, the exploitation of the solution is maintained.

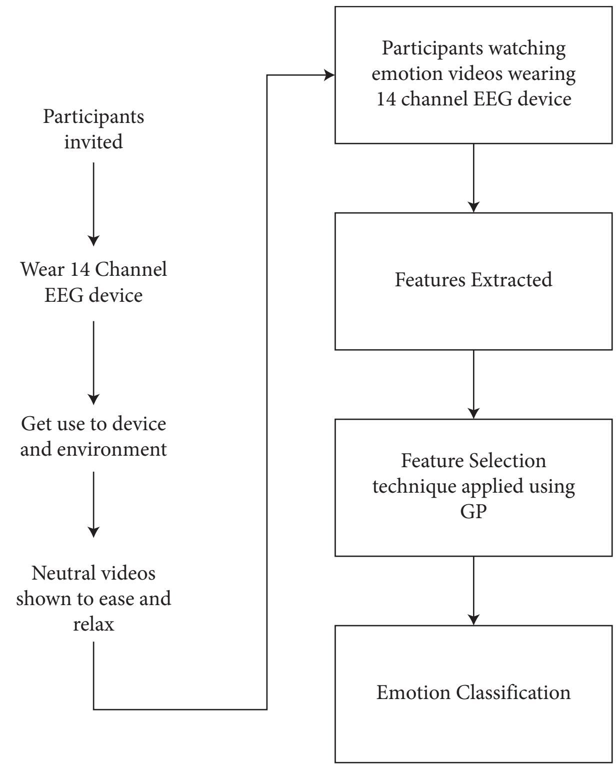

Figure 3: Flowchart of the proposed work.

3.4. Termination Criteria. The GP process is terminated as soon as the fitness reaches 100% accuracy.

4. Results

In this section, the FSGP model results are examined. The computer configuration consists of 64 GB RAM-based Python (3.8) for incorporating FSGP, GPmtfs, and another existing approaches, i.e., neural network, genetic programming, random forest, and SVM. These algorithms were applied to the EEG dataset for emotion recognition. Experimentation is carried out on the datasets with the parameters as given in Table 1.

In this study, the dataset is separated into two parts, i.e., in training and test sets. They are divided into different partitions to compare the training-testing outcomes to existing literature.

The performance assessment is conducted using a hold-out 80–20 validation scheme. In the 80–20 partition scheme, we have divided the dataset into two parts; the first part consists of 80%, which is used for training the model and the second part consisting of 20% is for model testing. The proposed FSGP and GPmtfs architecture were evaluated by calculating the performance metrics such as sensitivity,

Table 1: Parameter and values for the GP model.

Parameter	Value
Crossover probability	60%
Reproduction probability	20%
Mutation probability	20%
Population size	100
Initialization method	Ramped half and half
Initial maximum depth of a tree	10
Initial minimum depth of a tree	5

precision, and specificity values and are given in Table 2, and their mathematical expressions are given as follows.

$$\text{Recall} = \frac{TP}{TP + FN}$$
$$\text{Precision} = \frac{TP}{TP + FP} \quad (1)$$
$$\text{Specificity} = \frac{TN}{TN + FP}.$$

where TP is true positive, TN is true negative, FP is false positive, and FN is false negative.

In this section, we present the experimental results to test the behavior of the proposed genetic programming-based feature selection (FSGP) model, as well as to compare it with the classical multitree genetic programming-based FS (GPmtfs) model [14]. The results of classification accuracy of both the models are given in Table 3, with 80–20 training and testing data for the emotion recognition dataset. It is clear from the results that the FSGP model outperforms the classical GPmtfs in terms of classification accuracy for 80–20 training-testing data. It is also clear from the result that the average number of features selected by the FSGP model is less than the GPmtfs model, which shows that replacing the unwanted features in the middle stage with suboptimal features helps select the optimal set of features and improves the accuracy. Classification accuracy achieved by the FSGP model for 80–20 training-testing samples is 85% with 32 average number of features for the EEG dataset, which is very remarkable. It shows that the FSGP model has good adaptation generation capability and can select the optimal number of features if proper training data are provided. The result confirms the importance of appropriate training data for selecting the optimal features from the dataset.

This concludes that our FSGP can reduce the number of features with improved accuracy and show the important features in the dataset. Thus, our model can be a beneficial tool for physicians to diagnose the patient.

The GPmtfs model' maximum, average, and minimum classification accuracies for 80–20 training-testing partition achieved are 75%, 71%, and 68%, respectively.

The FSGP model' maximum, average, and minimum classification accuracies for 80–20 training-testing partition achieved are 85%, 82%, and 80%, respectively.

Table 4 provides the accuracy of the FSGP model on a different number of fitness evaluations. It is clear from the results that the model gives the best accuracy at 80000 fitness evaluations. The accuracy below those numbers is inferior, and after 80000 fitness evaluation, the accuracy is not improving. This suggests that our model converges at 80000 fitness evaluations.

Table 2: Comparison of performance measures.

Method	Sensitivity (%) Mean ± std	Precision (%) Mean ± std	Specificity (%) Mean ± std
GPmtfs	**70.29 ± 3.16**	**78.50 ± 3.42**	76.47 ± 2.36
FSGP	**84.29 ± 1.16**	**86.50 ± 1.42**	87.47 ± 2.36

Bold shows the maximum values.

Table 3: Classification accuracy comparison of GPmtfs and FSGP models for the emotion recognition dataset.

Method	No. of features	Accuracy		
		Max	Avg	Min
GPmtfs	42	75	71	68
FSGP	32	85	82	80

Table 4: FSGP model accuracy on different numbers of fitness evaluations.

Number of fitness evaluations	Accuracy (%)
50000	66
60000	68
70000	75
80000	85
90000	84
100000	84

Figure 4 shows the comparison of the accuracy of GPmtfs and FSGP on a different number of evaluations. Both algorithms do not seem to produce good results when the number of fitness evaluations is less. On increasing the fitness evaluations, the accuracy of both models increases; however, FSGP outperforms GPmtfs on every comparison. Both the models converged around 80000 fitness evaluations and marked their complete accuracy.

Figure 5 shows the accuracy and features of the FSGP model on a different number of fitness evaluations. The red line indicates the accuracy, and the blue line shows the features. It is clear from the figure that the FSGP model has the highest accuracy and the lowest features at 80000 fitness evaluations. The optimal number of fitness evaluations for the FSGP model is 80000 for emotion recognition data. This fitness evaluation gives the highest accuracy with an optimal number of features.

Table 5 provides the classification accuracy in the form of confusion matrix. It is clear from Table 5 that the sum of true positive and true negative is much better for FSGP as compared to GPmtfs. This again confirms the superiority of FSGP over GPmtfs. The Mann–Whitney confirms the statistical difference in result given in Table 6. The solution produced by our FSGP model is statistically different from the GPmtfs model for 80–20 training-testing partition for the emotion recognition dataset.

5. Discussion

This section compares the proposed model with the standard machine learning algorithms. The conventional algorithms

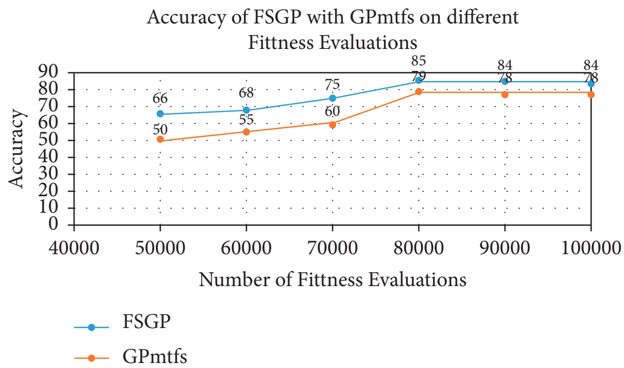

Figure 4: Accuracy of GPmtfs and FSGP on different fitness evaluations.

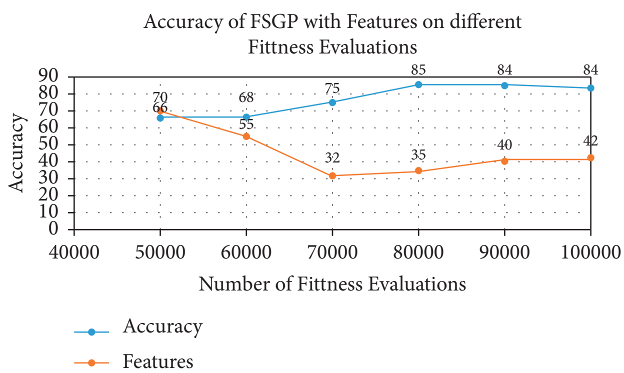

Figure 5: Accuracy of FSGP with features on different fitness evaluations.

Table 5: Confusion matrix of GPmtfs and FSGP models for the emotion recognition dataset.

	GPmtfs		FSGP	
	FP	FN	FP	FN
TP	42	75	71	68
TN	32	85	82	80

Table 6: *P* value for FSGP.

Method	Partition	*P* value
FSGP	70–30	2.871×10^{-11}

are also implemented using the same set of EEG features used to develop the proposed model. Table 7 provides the classification accuracy comparison of the proposed models on the 80–20 partition scheme.

5.1. Comparison. Various works from different authors on emotion recognition datasets are given in Table 7. Our proposed approach, FSGP, in which we have simultaneously done the feature selection and classification, is noteworthy in terms of classification accuracy than other approaches. Observations also show that our method removes the redundant and irrelevant features and finds the optimal number of features to classify the emotion recognition data.

Table 7: Classification accuracy comparison of existing approaches and MLSTM_3 classifier for two class of emotion classification to analyze the mental state during pandemic.

Method	Partition	Accuracy (%) Max
Neural network	80–20	74
Random forest	80–20	70
Genetic programming	80–20	79
SVM	80–20	76
FSGP	80–20	**85**

Bold shows the maximum value of accuracy.

The neural network, random forest, genetic programming, and SVM are the other state-of-the-art approaches used. To guarantee that the conclusions and comparisons given are explicit and accurate, the setting of parameters for all these classifiers has been implemented using the same method. It is evident from Table 7 that in the FSGP model, the classification accuracy was superior to all the other models for 80–20 training-testing partition. The second-best classification accuracy after FSGP is of genetic programming, and for the 80–20 training-test partition, the overall accuracy is 79%. Table 2 provides the values of FSGP and GPmtfs for 80–20 data partitioning scheme for sensitivity, precision, and specificity. It is clear from the result that FSGP outperforms the GPmtfs in all aspects.

Table 6provides the two-tailed Mann–Whitney test which shows the statistical result disparity [21]. The p value is computed using the Mann–Whitney test. If the p value is more significant than 0.05, the results do not alter considerably; nevertheless, if the p value is smaller than the value 0.001, the results are highly effective. The findings in Table 6 show that FSGP model results are statistically separate from GPmtfs for the 80–20 training-testing split. The results show a significant difference when these classifiers' p values are compared to FSGP. According to the evaluation findings, the suggested FSGP model for performance analysis of two classes of emotion, i.e., positive and negative classification, produces accurate output.

6. Conclusion

A novel approach for emotion recognition has been explored to extract important features and improve accuracy. This is done by removing the redundant and irrelevant features during 50% of the generation and forming a subset of suboptimal features rather than finding the optimal features that increase the classifier's accuracy after complete generation. Several experiments have been conducted with the proposed method, and a comparison has been presented with the classical GPmtfs model. The collected EEG dataset was used in this study.

Retraction

Retracted: The Relationship between Thyroid-Stimulating Hormone and Insulin Resistance in Incipient Elderly Type 2 Diabetics with Normal Thyroid Function

Journal of Healthcare Engineering

Received 10 November 2022; Accepted 10 November 2022; Published 27 November 2022

Journal of Healthcare Engineering has retracted the article titled "The Relationship between Thyroid-Stimulating Hormone and Insulin Resistance in Incipient Elderly Type 2 Diabetics with Normal Thyroid Function" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

Objective. To explore correlations between serum thyroid-stimulating hormone (TSH) concentration within the normal range and insulin resistance and its possible mechanism in incipient type 2 diabetes in elderly patients. *Methods*. 453 elderly patients with type 2 diabetes were divided into four groups by the quartile of TSH. Body mass index (BMI), waist-to-hip ratio (WHR), fasting plasma glucose (FPG), fasting insulin (FINS), homeostasis model assessment of insulin resistance (HOMA-IR) and homeostasis model assessment of insulin secretion (HOMA-β), blood lipids, and other indicators were compared among all groups, and correlation and regression analysis were conducted. 3T3-L1 preadipocytes were induced into mature adipocytes in vitro, and different concentrations of bovine TSH were used to stimulate adipocytes. The levels of TNF-α in the culture medium were detected by ELISA. *Results*. (1) With the increase of TSH, TC showed an increasing trend. Compared with the G1 group (4.80 ± 1.08), G2 group (5.13 ± 1.16), G3 group (5.14 ± 1.39), and G4 group (5.38 ± 1.16), the difference was statistically significant ($P < 0.05$ or $P < 0.01$). The LDL also showed an increasing trend. Compared with the G4 group (3.47 ± 0.89), the G1 (3.12 ± 0.82) and G2 groups (3.14 ± 1.05) had a lower LDL, and the difference was statistically significant ($P < 0.01$). The BMI increased between the G4 group (26.7 ± 3.97) and the G1 group (25.6 ± 3.54), and the difference was statistically significant ($P < 0.05$). (2) The serum TSH level was positively correlated with FPG, FINS, HOMA-IR, TC, and LDL ($R = 0.292$, 0.271, 0.394, 0.195, and 0.178, all $P < 0.01$). (3) TSH is the dependent variable, other indicators are independent variables, and multiple stepwise regression analysis is performed; the results show that only HOMA-IR, TC, and LDL enter the regression equation. (4) The TSH stimulated TNF-α secretion of 3T3-L1 adipocytes in a dose-dependent manner. *Conclusion*. The TSH level was positively correlated with the insulin resistance and LDL in the elderly incipient type 2 diabetic patients. Higher levels of TSH may be involved in the development of insulin resistance in the elderly incipient type 2 diabetic patients.

1. Introduction

Type 2 diabetes mellitus (T2DM) is the most common type of diabetes in China, the majority of T2DM patients are middle-aged and elderly people, and the incidence is increasing year by year. Insulin resistance is the main pathophysiological basis of T2DM. In recent years, with the continuous in-depth research on the mechanism of insulin resistance, the role of thyroid-stimulating hormone (TSH) in the occurrence of insulin resistance has attracted much attention. The TSH binds to TSHR on the surface of adipocytes, then activates cyclic adenosine monophosphate-protein kinase A (cAMP-PKA) pathway, activates tumor necrosis factor-α (TNF-α) gene transcription and secretion of TNF-α, and further downregulates the expression of insulin receptor substrate-1 (IRS-1), which plays a role in insulin resistance. At present, under the premise of normal thyroid function, there are still few reports on the role of TSH in the onset of elderly type 2 diabetes patients. This study took newly-onset elderly type 2 diabetes patients as the research object and explored the correlation between serum TSH levels and insulin resistance and other metabolic indicators within the normal reference value range, in order to further understand the relationship between TSH and elderly type 2 diabetes and discuss its possible mechanism.

2. Method

2.1. Patients Test Indicators. From December 2018 to June 2020, 453 elderly patients with type 2 diabetes were enrolled in the study, who were first diagnosed during hospitalization in our hospital, aged 60 to 90 years old, with an average of 70.36 ± 7.19 years old. Among them, 236 were males and 217 were females. The diagnostic criteria for type 2 diabetes are in line with the 2013 American Diabetes Association (ADA). Diabetes is diagnosed by the following factors: fasting blood glucose ≥7.0 mmol/L and/or 2 h postprandial blood glucose ≥11.1 mmol/L [1]. None of the selected patients received any hypoglycemic drugs outside the hospital. Exclusion criteria for the patients include the following: patients with acute infection, diabetic hyperosmolar coma, diabetic ketoacidosis, acute and chronic heart failure, liver and kidney insufficiency, acute stroke patients, and patients with abnormal thyroid function during medication treatment.

Normal thyroid function is defined as TSH levels within 0.27–4.2 mIU/L, FT3 and FT4 are within the laboratory reference range (FT3 is 3.28–6.47 pmol/L and FT4 is 7.64–16.03 pmol/L). According to the patients' serum TSH levels, they were divided into four groups as follows: G1 group (TSH is 0.37–1.17 mIU/L), G2 group (TSH is 1.18–1.67 mIU/L), G3 group (TSH is 1.68–2.45 mIU/L), and G4 group (TSH 2.46–4.20 mIU/L). This study was approved by the Ethics committee of Zhu Xianyi Memorial Hospital, Tianjin Medical University. All patients signed the informed consent.

2.2. Detection of Indexes. Research subjects need to wake up in the morning, fasting, barefoot, and only wear underwear to measure height, weight, waist circumference, and hip circumference and calculate body mass index (BMI) and waist-hip ratio (WHR); at rest, the blood pressure (BP) was measured twice in the sitting position, and the average value was taken; fasting venous blood was taken, and biochemical indicators such as liver function, renal function, and blood lipid were measured by an automatic biochemical analyzer, and fasting plasma glucose (FPG) was determined by glucose oxidase method, and TSH, free triiodothyronine (FT3) and free thyroxine (FT4), fasting serum insulin (FINS), and glycosylated hemoglobin (HbA1c) were determined by chemiluminescence assay; using homeostasis model assessment for insulin resistance (HOMA-IR): HOMA-IR = FPG (mmol/L) × FINS (mIU/ml)/22.5 [2]. The homeostasis model was used to evaluate the insulin secretion index (HOMA-β): HOMA-β = 20 × FINS/(FPG-3.5) [3].

2.3. Culture and Induced Differentiation of 3T3-L1 Preadipocytes. The cells were inoculated in a cell culture flask at a cell density of $1.5 \times 104/\text{cm}^2$, and the cells were placed in a high-sugar DMEM medium containing 10% calf serum at 37°C and 5% CO_2 cell incubator for cultivation. The medium was changed every two days. When the cells grew to 60–70% confluence at the bottom of the culture flask in about 3-4 days, the cells were replaced with DMEM high glucose medium containing 0.5 mM IBMX, 1.0 M insulin, 0.25 M dexamethasone, and 10% FBS for 2 days (48 h). IBMX and dexamethasone were removed so that the complete medium contains only 1.0 M insulin. After 2 days, the medium was changed, and the insulin was removed. A complete medium is used without any inducer. The medium was changed every 2 days, and the differentiation was 8–10 days. Oil red O staining identification of induced differentiation 3T3-L1 cells was carried out.

2.4. Elisa Assay. After stimulation with different concentrations of bovine TSH (0.01 mIU/ml, 0.1 mIU/ml, and 1 mIU/ml) for 4 hours, the culture medium was collected strictly in accordance with the ELISA kit instructions. The enzyme-linked immunosorbent assay (ELISA) method was used to detect the concentration of TNF-α in the culture medium.

2.5. Statistical Methods. SPSS 20.0 software is used for statistical analysis. The data are represented by "". Non-normally distributed data are logarithmically transformed. Comparison between groups is performed by the analysis of variance. Pairwise comparison is performed by the LSD test. Correlation analysis is performed by the Pearson linear correlation analysis. Multivariate stepwise regression analysis was performed. The test level was $\alpha = 0.05$. $P < 0.05$ indicated that the difference was statistically significant.

3. Results

3.1. Comparison of General Information of Patients. There were no significant differences in gender, age, systolic blood pressure, diastolic blood pressure, BMI, WHR, liver function, renal function, FT3, FT4, triglyceride (TG), and high-density lipoprotein (HDL) among 4 groups ($P > 0.05$). With the increase of TSH, the TC showed an increasing trend. Compared with the G1 group, G2 group, G3 group, and G4 group, the difference was statistically significant ($P < 0.05$ or $P < 0.01$). The LDL also showed an increasing trend. Compared with the G4 group, the G1, G2, and G3 groups, the difference was statistically significant ($P < 0.01$). As the TSH level increased, BMI of G1, G2, G3, and G4 groups also showed an upward trend, and the difference between the G4 and G1 groups was statistically significant ($P < 0.05$) (see Table 1).

3.2. Comparison of TSH Levels and Related Indicators of Glucose Metabolism in the Normal Range of Elderly Patients with Incient Type 2 Diabetes. There was no statistically significant difference in LnHOMA-β and HbA1c between groups of patients ($P > 0.05$). With the increase in serum TSH levels, FPG, FINS, and HOMA-IR all showed an

ALP (U/L)	69.5 ± 15.7	71.4 ± 18.4	71.9 ± 19.6	73.3 ± 18.8
GGT (U/L)	35.2 ± 20.9	33.6 ± 20.9	32.8 ± 20.4	32.3 ± 18.8
ALT (U/L)	29.6 ± 18.6	26.3 ± 15.1	26.5 ± 16.6	27.3 ± 17.5
AST (U/L)	23.1 ± 13.3	20.8 ± 9.31	22.6 ± 13.8	20.9 ± 9.52
BUN (mmol/L)	5.60 ± 1.30	5.44 ± 1.32	5.45 ± 1.36	5.45 ± 1.64
Cre (umol/L)	67.2 ± 14.6	63.8 ± 15.4	64.3 ± 14.5	66.1 ± 20.6
UA (umol/L)	307 ± 96.5	305 ± 87.9	314 ± 92.5	312 ± 93.5

Note. Compared with G1, $^{a}P < 0.05$, $^{b}P < 0.01$; compared with G2, $^{c}P < 0.05$, $^{d}P < 0.01$; and compared with G3, $^{e}P < 0.01$.

upward trend. The pairwise comparison of G1, G2, and G3 groups showed no statistically significant difference ($P > 0.05$), while the comparison of the G4 group with G1, G2, and G3 groups showed statistically significant difference ($P < 0.01$), as shown in Table 2.

3.3. Correlation Analysis of Serum TSH Levels and Related Indicators. Correlation analysis of research subjects showed that serum TSH levels were positively correlated with FPG, FINS, HOMA-IR, TC, and LDL ($R = 0.292$, 0.271, 0.394, 0.195, and 0.178, all $P < 0.01$), and no correlation was found with HOMA-β, age, BMI, WHR, TG, HDL, SBP, DBP, and HbA1c, as shown in Table 3.

3.4. Multiple Stepwise Regression Analysis. Using TSH as the dependent variable, using FPG, FINS, HOMA-IR, TC, and LDL as independent variables, multiple stepwise regression analysis was performed. The results showed that HOMA-IR, TC, and LDL entered the regression equation; HOMA-IR, TC, and LDL were independently correlated with TSH. The regression equation was as follows: $Y = 0.393 + 0.187X1 + 0.103X2 + 0.092X3$ ($X1$: HOMA-IR; $X2$: TC; X3: LDL; $P < 0.05$).

3.5. Culture and Induced Differentiation of 3T3-L1 Preadipocytes. The morphology of mouse 3T3-L1 preadipocytes and fibroblasts is similar, as shown in Figures 1(a) and 1(b). After induction to the 10th day, lipid droplets of varying sizes were seen in most of the cells, and the cell volume increased to fill the intercellular space. After oil red O staining, there are bright red particles in the cytoplasm of induced differentiated mature adipocytes. After hematoxylin counterstaining, the nucleus was blue and deviated from the center of the cell. Observed under a 10x light microscope, randomly counted the proportion of adipocytes in the total number of cells in 10 nonrepetitive fields, and more than 95% showed adipocyte phenotype, which was further confirmed to be mature adipocytes.

3.6. Effect of TSH on the Secretion of TNF-α in 3T3-L1 Adipocytes. The 3T3-L1 adipocytes were stimulated with different concentrations of bovine TSH to induce differentiation and mature 3T3-L1 adipocytes for 4 hours, and the TNF-α level in the culture medium was detected. The results showed that, with the increase of TSH stimulation concentration, the TNF-α level showed an upward trend, and the difference was statistically significant as shown in Figure 1(c).

4. Discussion

Insulin resistance is an important pathophysiological basis for the occurrence of T2DM. The previous research centers on the pathogenesis of diabetes, most of the focus was on the secretion of inflammatory factors from adipocytes to cause insulin resistance, and then diabetes, ignoring that factors other than inflammatory factors would also participate in the occurrence of insulin resistance and metabolic disorders. In the past, thyroid disease was considered to be an endocrine metabolic disease independent of diabetes. In recent years, the relationship between TSH and diabetes and diabetic ischemic heart disease has gradually attracted attention. A large number of studies have shown that [4–6], diabetic patients, especially combined among diabetic patients with cardiovascular disease, the prevalence of abnormal thyroid function is significantly higher than that of nondiabetic patients.

In recent years, research on TSH levels and insulin resistance in people with normal thyroid function has gradually attracted attention. A study by Roos et al. on 2703 patients without thyroid disease and diabetes showed that

serum TSH levels were significantly positively correlated with HOMA-IR [7]. Jayanthi R et al. found that serum TSH levels were positively correlated with plasma insulin level and significantly negatively correlated with the insulin sensitivity index with 530 normal, overweight, and obese adults [8]. Similarly, we also found in the previous study that the serum TSH level of T2DM patients was significantly higher than that of the normal control group [9]. In our previous study on diabetic rats, we found that the serum TSH level was negatively correlated with the insulin sensitivity index [10]. Preliminary research suggests that the TSH may be involved in the occurrence of insulin resistance and further development of type 2 diabetes. At present, the correlation between TSH and insulin resistance in elderly T2DM patients is still rarely reported. This study took newly onset elderly patients with type 2 diabetes as the research object, explored the correlation between serum TSH and insulin resistance and related metabolic indicators within the normal reference value range, and explored whether TSH is associated with the occurrence of newly onset elderly T2DM insulin resistance and abnormal lipid metabolism so as to provide a basis for further clinical treatment.

The results of this study suggest that, with the increase in serum TSH levels, BMI, TC, LDL, FINS, and HOMA-IR all showed an upward trend, while HOMA-β showed a downward trend, the TSH was within the normal range, and FNS and HOMA-IR are positively correlated in newly onset elderly patients with type 2 diabetes. Further cytological studies have shown that the TSH can stimulate 3T3-L1 adipocytes to secrete TNF-α in a dose-dependent manner ($P < 0.05$) and TSH can increase the activity of NF-κB. As can be seen from the gel electrophoresis pattern, the NF-κB/DNA probe binding bands gradually increased with the increase of TSH stimulation concentration. This effect was inhibited by a PKA inhibitor (H89). The possible mechanism is analyzed as follows: (1) our previous research results confirmed that there is the expression of thyroid-stimulating hormone receptor (TSHR) on the surface of adipocytes, TSH binds to TSHR on the surface of adipocytes, then activates the cyclic adenosine monophosphate-protein kinase A (cAMP-PKA) pathway [11–13], activates tumor necrosis factor-α (TNF-α) gene transcription and secretion of TNF-α, further downregulates the expression of insulin receptor substrate-1 (IRS-1), and interferes with the normal tyrosine phosphorylation of IRS-1, which plays a role in insulin resistance; (2) insulin resistance can lead to a compensatory increase in early insulin levels, and insulin increases TSH levels by affecting the level of leptin [14]; (3) overweight and obesity are one of the important causes of insulin resistance. This study found that, with the increase of TSH level, the BMI of patients showed an increasing trend, and the difference between the G4 group and the G1 group was statistically significant ($P < 0.05$). The reason may be that obesity leads to leptin resistance, resulting in serum leptin excess, which upregulates the expression of thyrotropin-releasing hormone and further increases serum TSH level [15, 16]. All of these mechanisms can lead to elevated TSH to further aggravate the occurrence of insulin resistance.

This study further found that the TSH is positively correlated with TC and LDL in the normal range. This may be because TSH directly acts on TSHR on liver cell membranes and stimulate cyclic adenosine mono-acyl-CoA reductase, and it also promotes cholesterol synthesis through the cyclic adenosine monophosphate/protein kinase A/cyclic adenosine phosphate response element-binding protein (cAMP/PKA/CREB) signaling system [17, 18]. Abnormal blood lipid metabolism may further damage the body's defense against oxidative stress, cause damage to the function of vascular endothelial cells and accelerate the formation of atherosclerosis, and increase the risk of cardiovascular disease.

To sum up, in the newly onset elderly type 2 diabetes patients with normal thyroid function, serum TSH levels are positively correlated with TC and LDL, and higher TSH levels within the normal reference value range may play a promoting role in the occurrence and development of insulin resistance through the abovementioned mechanisms. The elevated TC and LDL further participate in the pathological process of atherosclerosis occurs and increase the risk of cardiovascular disease in elderly patients with type 2 diabetes.

Therefore, it is necessary to strengthen thyroid function in elderly patients with type 2 diabetes. Monitoring and timely attention to the risk factors related to cardiovascular disease in patients with normal thyroid function and high serum TSH levels will play a positive role in preventing and delaying the occurrence of cardiovascular complications in elderly patients with type 2 diabetes.

Therefore, monitoring of thyroid function in elderly patients with type 2 diabetes should be strengthened, and timely attention should be paid to the risk factors related to cardiovascular disease in patients with normal thyroid function and high serum TSH levels, which will play a positive role in preventing and delaying the occurrence of cardiovascular disease in elderly patients with type 2 diabetes.

Academic Editor: Enas Abdulhay

Internet of Things (IoT) is a successful area for many industries and academia domains, particularly healthcare is one of the application areas that uses IoT sensors and devices for monitoring. IoT transition replaces contemporary health services with scientific and socioeconomic viewpoints. Since the epidemic began, diverse scientific organizations have been making accelerated efforts to use a wide range of tools to tackle this global challenge and the founders of IoT analytics. Artificial intelligence (AI) plays a key role in measuring, assessing, and diagnosing the risk. It could be used to predict the number of alternate incidents, recovered instances, and casualties, also used for forecasting cases. Within the COVID-19 background, IoT technologies are used to minimize COVID-19 exposure to others by prenatal screening, patient monitoring, and postpatient incident response in specified procedures. In this study, the importance of IoT technology and artificial intelligence in COVID-19 is explored, and the 3 important steps discussed such as the evaluation of networks, implementations, and IoT industries to battle COVID-19, including early detection, quarantine times, and postrecovery activities, are reviewed. In this study, how IoT handles the COVID-19 pandemic at a new level of healthcare is investigated. In this research, the long short-term memory (LSTM) with recurrent neural network (RNN) is used for diagnosis purpose and in particular, its important architecture for the analysis of cough and breathing acoustic characteristics. In comparison with both coughing and respiratory samples, our findings indicate poor accuracy of the voice test.

1. Introduction

COVID-19 has been reported as a global epidemic by the World Health Organization (WHO), and it travels out across globe. 8.8 million cases were registered globally on June 30, 2020. With a record of 2.64 million cases and 128 lakhs of accidents, the United States is perhaps the most afflicted country in the region [1–3]. Health practitioners face many challenges such as identify signs, diagnose the condition, and take decisions. To overcome these problems, they use computer programs; they battle to ensure the virus identification, which is successful in this situation. In current trends, AI is a rising innovation; it is close to the intellect of man.

The human brain system illustrates the complex issues, but the lot of concerns increases the cost of solving that issue. AI is capable to concurrently quantify a range of issues and remedies. Many people just assume that AI is just about automation, but it is a computer that imitates human consciousness [4]. IoT connects the people worldwide for transmitting the data to the adjacent devices and systems [5]. The issue is a human who uses some sensors can be tracked regular with automatized devices. Original accusations are written to the framework [6]. IoT device operates with the technology and electronic hardware on the network accessible connected devices for the integrated devices. In recent times, IoT designed a new area of research, specifically in the field of medical services, as a modern subject of study in a broad array of academia and business. IoT development form, i.e., healthcare reform systems combine technical and socioeconomic resources [7]. It progresses from the traditional to much more adapted treatment programs wherein patients could be more easily spotted, managed, and tracked.

IoT is an emerging technology that consists of the set of links provided to interconnects with anything, anywhere, any connection, any device, and any period. IoT technology may affect the whole company range, since every device and entity in the digital Internet network might be identified as having huge benefits. Such benefits often include enhanced connection between services, devices, and systems that go beyond the machine status [8]. IoT delivers suitable solutions to a variety of software and systems. Pollution control, wearables, issues in traffic, defense, intelligent infrastructure, transit, disaster aid, healthcare, and commerce are the examples for IoT. Doctors and community care are one of the most intriguing areas of IoT applications. IoT can generate treatment services such as workout, geriatric therapy, remote monitoring systems, and chronic illness administration.

The emphasis can be made by an IoT framework, integrated with AI. Enhance social protection by using monitoring technologies, image-recognition technology, and the use of AI-enabled software and networks to provide, distribute, trace, and control people's access to the public places [6]. Usually, an IoT health service consists of several server-linked detectors. It provides real-time environmental or user tracking. In an epidemic, AI-assisted detectors can also be used to focus on indicators such as body temperature, respiratory rate, and cough habits of individuals.

A further helpful function might be monitoring people's geolocation. The difference between people could provide helpful info during epidemic of a deadly virus [4]. We will get a fair estimation about how much people share while moving in public spaces using technology like Ethernet.

It is also important to understand the protection and information security extensively during the implementation of certain applications in order to avoid the misuse of confidential data [5]. Authorities may continue to be using these resources and knowledge to continuously observe the actions of individuals after an epidemic. The healthcare sector has long been one of the major areas of application for the IoT. Based on the latest developments in AI and machine learning, eHealth has recently risen to greater heights. The COVID-19 pandemic strategy has provided shudders from several angles across the globe, such as its ability and deliverable, rapid reaction, connected information, and assessment.

The area of eHealth used by IoT and AI to healthcare has mainly become interdisciplinary and offered new horizons to problems during the COVID-19 pandemic [9]. In contrast, technology fields such as IoT and AI have been strongly encouraged to offer rapid and effective medical services, particularly with a view to COVID-19, frequently to automate and facilitate various activities for health professionals.

AI algorithms in particular forecasts play an important role in the study of epidemics. With enormous information on this pandemic, the machine learning methods assist to discover ways to prevent the transmission of the virus from taking prompt action [10]. This search uses the machine learning and deep learning methods to monitor everyday behavior in anticipation of COVID-19' future cross-country accessibility utilizing the official open information source in real-time. These models can predict the near future and help to reduce the harmful consequences of COVID-19. The advent of AI revolutionizes every social and personal sector. AI is designed to behave like a human brain and to mimic its processes of thinking that automate different jobs.

AI is data-driven and makes choices based on the data on which it has been trained. AI is needed to cope with the present epidemic since it has the advantage over the previously mentioned conventional methods. Although AI cannot supplant physicians, it helps them to make diagnostic choices efficient and accurate. Techniques may be used to change the healthcare sector. In pandemic conditions, the healthcare system is overburdened with the enormous number of patient demands, and AI can support them as quickly as practicable with minimal cost for diagnosis and treatment. AI algorithms, such as sensors and cameras, may be readily incorporated into the current infrastructure to automate the contact tracking process. AI helps to do simulations for the prospective medication during the vaccine development process to estimate its efficacy.

The WHO has reported the pivotal symptoms of COVID-19, including body pains, increased heart rate, strong coughing, and severe breathing difficulties [11]. Scientists believe that the respiratory system's audio noises may be identified and examined for the disease's existence. The absurd and stepped-up proliferation of the COVID-19 virus has led to enormous cooperation across many sectors to regulate and prevent the propagation of the virus on a daily basis. In addition, the solution will participate in the fight against COVID-19 in an innovative and the current manner by integrating AI and deep learning algorithms in the digital health district. There have been enormous executions of AI along with the techniques of deep learning (DL), which can be rational during the initial detection and monitoring processes of COVID-19 through the analysis of extracted features of coughing, breathing, and speech using the recurrent neural network (RNN) for coughing, breathing, and speech.

2. Review of Literature

Brem et al. [12] infection predictor to reduce the threat of predictive modeling with regard to sustainability variables has been introduced. They also developed to predict the hazards to the effects of chronic and to identify complications by using SVM classifications to identify the health conditions. Wu et al. [13] introduced a methodology for heart disease diagnosis to solve the medical challenges such as irregular heartbeat. To do this, they use the naive Bayesian method. This intelligent device evaluates and classifies data gathering. Rahman et al. [14] computerized improved teaching approach implemented including IoT computers. They used identities to classify the students' intelligibility and standard. This approach helps the students to evaluate without any public health consequences. Javaid et al. [15] suggested a framework to describe the geographic distribution of COVID-19 disease outbreaks.

Bayindir [16] suggested any IoT application to fight COVID-19. Javaid et al. [15] discussed how various 4.0 industries (e.g., IoT and artificial intelligence) might contribute to decrease the disease spread. Mokbel et al. believed that interaction tracking should be the duty of the utilities and offer a largely automated contact tracking design that is not dependent on user participation. Nasajpour et al. [17] discussed various IoT devices in three major phases: diagnosis, isolation, and healing. The application of ML, AI, and other intelligent methods for COVID-19 prognostics is discussed recently.

Dong and Yao [18] discussed about the promising IoT-based approaches to fight COVID-19 that have been developed. They provide a thorough investigation of current IoT systems at various levels, such as perception layers, network layers, and fog and cloud layers. They also explore uses of IoT in the diagnosis of COVID-19 signs. A four-layered architecture is built on the technology by IoT and blockchain to assist combat COVID-19. The chain-based approach for ensuring the confidentiality and security of physiological information exchanged between IoT nodes is suggested. It also includes the several apps designed to identify and trace the proposed approach with COVID-19. IoT's involvement is in the current digital healthcare system. It also discusses the consequences of IoT-generated data that permitted the healthcare system for policy-makers' choices. Additionally, current facilitators and obstacles to IoT-based healthcare are also included.

They identified the capability of the wireless connection and evaluated the network transfer to diagnose the area at greater hazard. They will also obtain greater attempts to monitor the spreading in some areas. Gupta and Johari [6] planned to identify the resource field utilizing IoT sensors including wireless communication technology 802.11 which was an IoT-based control mechanism. They built a modeling approach for tracking the small spaces. The sensors in light lamps have been fixed to track scheduling and the unnecessary use.

Siriwardhana et al. [4] addressed the production and implementation of IoT-based technology to combat the COVID-19 epidemic effectively. In particular, many scenarios and problems are raised, including how 5G and IoT may be candidates for creative technologies in diverse fields to tackle the pandemic. A systematic analysis has likewise been proposed to minimize the contribution made by big technological innovations including such 5G, artificial intelligence, UAV, Internet of Things, and blockchain.

Hussain et al. [5] emphasized using AI to tackle the epidemic COVID-19. This research offered an outline of different cognitive technologies for various types of epidemics dependent on clinical experience. The study classifies the current AI strategies in medical studies analyzes into neural systems, classical vector assistance, and pervasive processing. Last, a thorough explanation was given about the benefits of AI in the fight against related viruses.

Wu et al. [13] suggested a combined protection and health surveillance framework for IoT. The purpose was to increase safety in the open air. The framework contains two layers: one for gathering user information and the other for aggregating information gathered and over the Web. Wearable systems have been used to collect the public safety metrics and consumer health signs.

Afshar et al. [19] claimed that many research studies have been carried out in support of automatic diagnosis and screening of COVID-19. In the eHealth sector, AI can be gripped and pushed to help identify COVID-19 early by monitoring these three major sound systems, including cough, breath, and speech. In addition, pulmonary noises may include many indicators of the health status of human beings that can be identified and treated by the use of machine learning techniques. Consequently, doctors and experts have recently considered detecting COVID-19 from lung noises since before the large epidemic of COVID-19.

3. Conceptual Framework

3.1. Artificial Intelligence for COVID-19 Pandemic. AI has proven to be a scientific development. It is an incredibly powerful method to solve the COVID-19 epidemic if adequately used [5]. The following are the few present and ability for AI to support the officials in fighting successfully the COVID-19 epidemic:

(i) Monitoring of illness
(ii) Risk forecasting
(iii) Monitoring of surgical examination
(iv) Healing studies
(v) Study and simulation of the virus
(vi) Site recognition
(vii) False news for breaking
(viii) Implement the steps to shut down

Many of the above methods are discussed in depth in the following.

3.1.1. Monitoring of Illness. On December 31, 2019, a Toronto-based city health firm, Blue Dot, announced an imminent coronavirus outbreak. The Blue Dot AI system includes various machines learning and natural language processing (NLP) instruments to locate signs of infections that are developing. This ability allows Blue Dot to control the SARS-CoV-2 spread and predict that it would evolve long before pathologists. But this would not go so far as to suggest that there was no human experience to do so as well. Although your model of AI might forecast the epidemic, human knowledge of the model performance remained key. Figure 1 shows the interfacing of AI for COVID-19 pandemic.

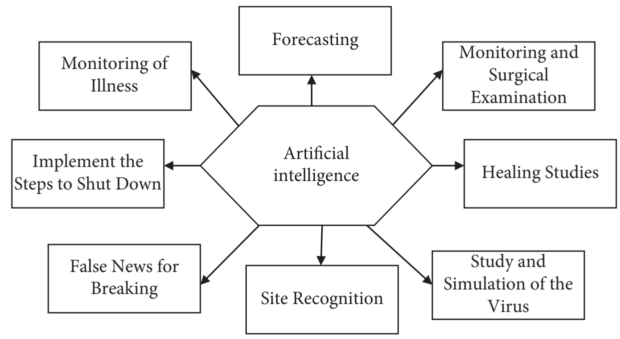

Figure 1: AI for COVID-19 pandemic.

3.1.2. Forecasting of the Risk. An important field of study was the use of prediction techniques to support hospital resource planning. The time-series analysis has been one of the most common methods used to generate short-term demand predictions since it offers thorough treatment for seasonality and serial correlations. For example [16], the prediction of short-term utilization of beds for various time-series techniques and historical average models was assessed [17]. Time-series techniques for predicting occupancy in an urgent ward are analyzed and demonstrated that they can offer meaningful data for up to one week. They exposed that the model generates excellent predictions, but in a crisis, it falls. On a separate line of research [20], patient-level data were used in a computationally expensive model to anticipate the demand at various hospital units.

3.1.3. Medical Diagnosis and Screening. Rapid COVID-19 diagnoses can permit authorities to take appropriate action to restrict the greater dissemination of the infection. Although, the scarcity of reagent kits internationally has complicated the success of huge diagnostic imaging by the officials. Most established AI techniques have been recast, whilst others will be developed to reduce this issue.

3.1.4. Healing Studies. As new, the lack of appropriate virus diagnostic and counseling procedures is one of the largest challenges with SARS-CoV-2. However, AI is known to have an achieve design to accelerate the manufacturing process by evaluating the latest COVID-19 instances as well as ongoing studies into viral infections. A variety of organizations and research laboratories have also used AI to classify new COVID-19 therapies. AI not only can speed things up in clinical trials but can also help to diagnose the established medicines.

3.1.5. Study and Simulation of Virus. Knowing the infection is just the secret to establishing the appropriate cure of COVID-19. Pathogens never replicate on their own, so that they can generate versions of their DNA using cell membranes. For this reason, an infection normally destroys the cell wall through a Keychain system by connecting itself with the host receptors. For most antibody substances, the operational function is to avoid this by removing the cell surface receptors. Therefore, researchers can design the consensus that exists in developing the successful inhibitors.

3.1.6. Site Recognition. The SARS-CoV-2 belongs to the beta-CoV tribe of attention and respect. Genotypes of such diseases usually consist of a combination of populations (bats and rodents). To present, an unexplained element is the biological host that made it easier to relay COVID-19 for humans. To correlate the bacterial vector efficiently and for recognition of differences among recognized viruses, machine learning algorithms have been used. The study proposes that the seasonal influenza species uses the decision tree algorithm. The SARS-CoV-2 can also be expanded to incorporate these versions.

3.1.7. False News for Breaking. Currently, it is unpredictable days since the COVID-19 epidemic have produced some theories and explanations of deception. There has been a lot of disinformation on social networking sites. Technology firms including Google, YouTube, and Facebook have used AI strategies to avoid the dissemination of such false information as well as provide checked facts. Both the networks have sought to filter the material with even the smallest disinformation. In fact, YouTube has put in place tough steps to gather some false video news.

3.1.8. Implement the Steps to Shut Down. A great several nations around the globe are using AI to encourage social dissociations and lock-up initiatives, including China, India, the United States, and the United Kingdom. In China, Baidu has established machine view (CV) operated infra-road monitors to search public areas, making it one of the biggest AI and network companies in the world. These devices not only recognize individuals with elevated physical heat but also distinguish residents who are not adopting the lock-down steps using their built-in face recognition system. A similar CV surveillance system was used to track the public dissociating steps taken by masses in Oxford, England.

3.2. Internet of Things Presence in Procedures for COVID-19. IoT offers strategically advanced forum for tackling the COVID-19 epidemic which overcomes the big lock-up difficulties [9]. This system aims to collect up-to-date information and displays the important functions that IoT is used during COVID-19 in the injured individual. IoT is being used to collect the healthcare information from different infectious patients' positions and to handle all the information through virtual management platforms in the first stage. This system enhances information management and coordination of the study. Figures 2 and 3 show interfacing of IoT to tackle the epidemic of COVID-19.

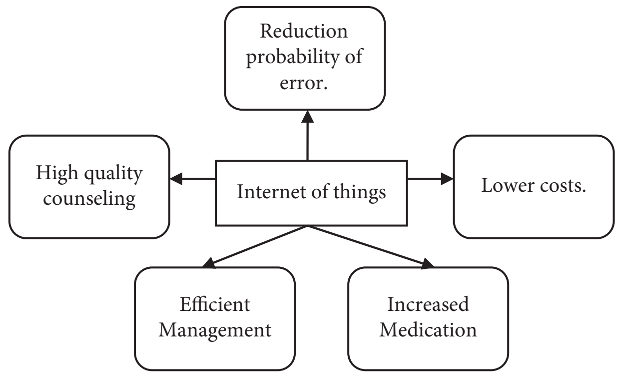

Figure 2: IoT tackles the epidemic of COVID-19.

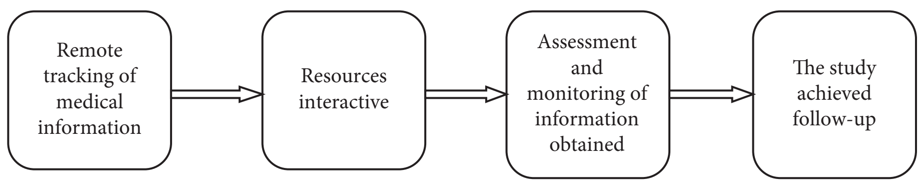

Figure 3: Increase IoT phase map to tackle the pandemic of COVID-19.

3.3. Impact of the COVID-19 Pandemic on the Global Economy. Due to the absence of every clear care plan, the greatest available method of protection against epidemic of COVID-19 was established at the time [5]. Nevertheless, the imperative of social distance forced policy-makers worldwide to implement the lockdowns that have signaled a significant split in the world economy. Both facilities that are nonessential were obliged to close down. It led the supply chain to destroy almost all businesses and thus to hazard losing their homes for people around the world.

3.3.1. Automotive Industry. Due to tight locking policies in many countries of the world, the car sector has undergone huge infrastructure delays to combat the epidemic. With social isolation imposed and people needed to stay at home, the use of vehicles, both commercial and personal, has diminished worldwide. The automobiles affiliated with essential services are the only cars still in use.

3.3.2. Aviation Industry. Atmospheric sector has been hit massively by the COVID-19 epidemic. The affected countries including virtually all states were compelled to both globally and domestically to implement a travel restriction. Critical lines of distribution serving cargo and freight planes are the only operational airways.

3.3.3. Tourism Industry. Since the epidemic of COVID-19, the tourist industry was one of the hardest hit sectors. Tourist industry sales make up to 10% of the worldwide GDP.

3.3.4. Construction Industry. Building businesses are expected to face serious disruptions and setbacks attributable to COVID-19 epidemic in existing ventures. As a result of the strict self-quarantine rules, most building companies will have to suspend their nonessential activities before the epidemic comes to an end. This is expected to lead a massive reprogramming of current programs that could lead to serious damages.

3.3.5. Healthcare and Medical Industry. The epidemic COVID-19 has a major impact globally upon these healthcare services, whereas the overeating induced by lockdown acts and travel restrictions has impacted other industries financially, and the safety sector is far from stagnating. Worldwide clinicians are now experiencing the need for COVID-19 patients to be managed by fans, intensive care units (ICUs), and personal protective equipment's (PPE).

3.4. Major Advantages of IoT for Pandemic COVID-19. Alsaeedy and Chong [21] All extremely dangerous patients are properly monitored via the Internet of Things. This technology is used to estimate biometric problems, such as hyperglycemia, pulse rate, and heart infections [22]. IoT is a creative and powerful phase in the fight against the COVID-19 epidemic and may make enormous problems during lockdown. This innovation is helpful in strengthening the infected patient's infinite data as well as other important data. Figure 4 shows the main advantages of IoT in the battle against COVID-19 pandemics.

3.5. Role of IoT Technologies and Tools in COVID-19 Pandemic. COVID-19 has a unique effect on society, and the economy of the effect of this epidemic nowadays has increased the use of numerous new technologies in combination with other technologies such as AI, data management, and cloud. IoT is of tremendous help in this disaster IoTs, utilized for epidemic monitoring. Important

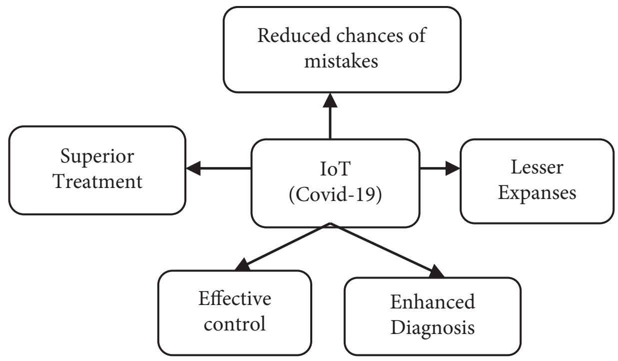

Figure 4: Major advantages of IoT for pandemic COVID-19.

IoT, AI, and big data innovations that assist with the COVID-19 problem and the several problems stated in that effort include telemedicine's for the prevention and management of disease, the prevention of outbreaks and the minimization or even stoppage of the transmission of the virus, the use of drones to monitor for isolation, and mask use. For COVID-19, primary IoT applications are the online clinics, remote consultations, fast screenings, and the smart monitoring of sick individuals and virus prediction [21], the real-time monitoring, patient monitoring, rapid diagnosis, patient education, testing and tracking, protection, and surveillance. There are additional concerns of confidentiality and protection related to the use of CR. The function of IoMT in monitoring patients from a distant location, the ordering of medical products, and the use of smaller devices to communicate patient data to the authorities concerned [4] focus on the peripheral system and improve quarantined sufferers for different metrics such as respiratory rate, air rate, and lung sound rate, tracking devices to identify infections and monitoring for remote access and diagnosing COVID-19 patients with mild symptoms and tele-health innovations. The function of IoT-based technologies in COVID-19 and the existing IoT solutions for the fight against COVID-19 were examined in three major stages; they separated IoT solutions into primary prevention, confinement period, and recovery. Each step was also shown using IoT-enabled devices including IoT controls, wearable, drones, robots, and smartphone apps.

Suraksha Kawach is an IoT device that is utilized by the Defense Research and Development Organization (DRDO), India, to monitor corona-affected individuals and to monitor them. This gadget may be used in the arm or knee and is a GSM and GPS device for reliable monitoring in real-time basis. The prototype of Suraksha Kawach gadget is shown in Figure 5(a).

In order to minimize healthcare personnel' danger, thermal sensors are used to monitor COVID-19 patients' body temperature. Figure 5(b) shows the temperature sensor of the sample. We have got wearable gadgets; next, these sensors measure various parameters such as temperature, heart rate, and pulse rate, and the measurement results may be utilized for action as soon as possible. These devices have an important role in containing COVID-19; the intelligent band is one of the wearable devices, as shown in Figure 5(c).

3.6. Techniques Used for Coronavirus Sample Collection. To prevent its fast spread, it is necessary to establish valid and realistic medications to treat SARS-CoV-2 disease in people. The nucleic acid test (NAAT) is recommended by the WHO which perhaps the most important model of SARS-CoV-2 detection for the effective SARS disease. These studies include the use of the nasopharyngeal swab procedure in which the cleaning solution is used in a specimen. This contains a combination of mucus and saliva.

In the event of significant breathing problems, the WHO advises that samples be taken from the nose and throat as well. Such specimens are taken to a specialist lab, where the polymerase chain reduction method is used to measure the existence of viral RNA. Table 1 provides the various techniques for coronavirus sample collection.

3.7. Using Artificial Intelligence to Detect, Respond, and Recover from COVID-19. AI systems observed that the epidemic of an unpredictable form of disease in the Chinese government before the world was ever conscious of the danger faced by the coronavirus (COVID-19). With the disease becoming a global epidemic, AI tools and techniques should be used to encourage actions by policy-makers. Furthermore, the health community and the society are essential to plan and control any step of the crisis: identifying, stopping, reacting to, and recovering and growing of COVID-19. Figure 6 shows the use of AI to detect, respond, and recover from COVID-19.

3.8. AI with IoT in Healthcare to Treatment of COVID-19. Since the main report of the 2019 coronavirus infection (COVID-19) in Wuhan, China, more than 200 countries and locations have been affected worldwide. Science and technology take on an important role in this perplexing battle. For example, as China began reacting to infection, it zeroed on brain research by monitoring polluted ancient times moving sick people, robots to convey food and medicines, automatons to clean open spots, and by watching and transmitting sound communication to the public to urge them to stay at home. Man-made knowledge was widely used to identify the new particles in transit to assist COVID-19. A number of experts uses AI to find new medicines and remedies alongside certain software engineering analysts that focus on the

(a) (b) (c)

Figure 5: (a) Suraksha Kawach device 5. (b) Sensor 5. (c) Smart band.

Table 1: Various techniques for coronavirus sample collection.

Technique	Analysis
NC	A collection of respiratory secretions from the back of the throat can be used for specific bacterial culture
NS	This approach includes having the breathing tube connected to a syringe, as opposed to nasopharyngeal swab procedure, for the processing of specimens from the nasopharynx
ETA	It is a bottom respiratory screening tool by means of a vertical pipe defined as bronchoscope that extracts the specimen from the lungs
BAL	A fiber-optical bronchoscope is transferred through nasal passage into the bronchoalveolary stress that after initiation of a sterile saline solution, a sample was obtained
Blood test	A pulse in the arm takes a blood sample

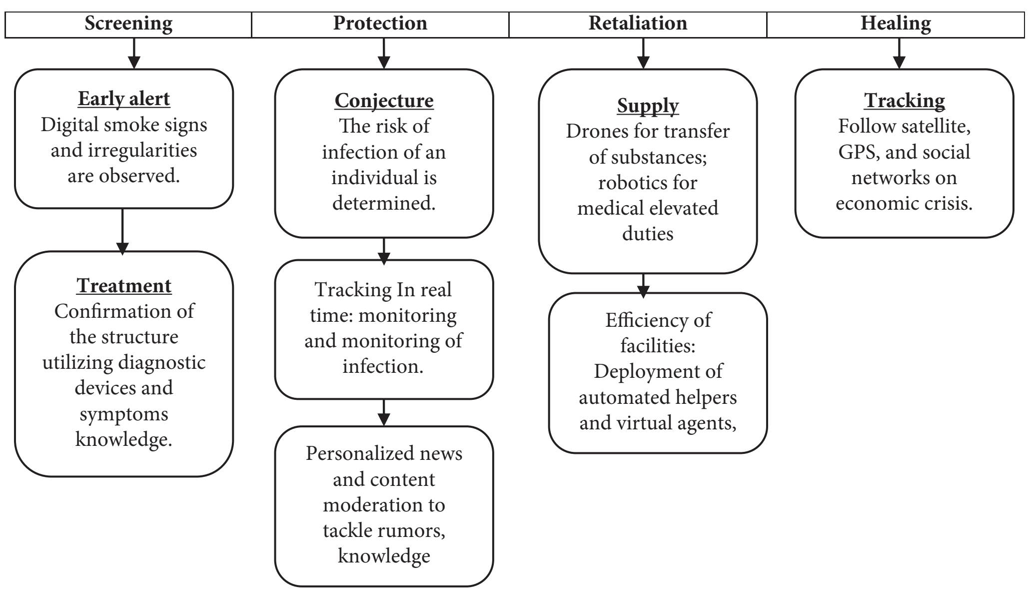

Figure 6: Use of AI to detect, respond, and recover from COVID-19.

identification of compelling patients via the preparation of a clinical image like X beams and CT filters [21].

In any case, computer-based intelligence follows the bands to assist group the isolated rule. Advanced mobile telephones and AI-enhanced heated cameras are being used to recognize fever and tinged people [19]. Nations such as Taiwan have combined the public knowledge based on clinical protection with input from the migration and customs data collection, thereby challenging the travel history and side effects of the COVID-19 patients. In all, AI is used to identify, monitor, and hypothesis flares and helps diagnose the illness.

It is used in the treatment of medical claims. Automobiles and robots are used to transport food and medicines, just as they are used to sanitize public areas. AI helps to create the medicines and COVID-19 antibodies using super PCs [17]. This present study focuses on the use of human-made pushes in the fight against the coronavirus epidemic. It provides an extensive review of the innovative drivers utilized to reduce and conceal the significant impact of the upheaval [5]. The motivation of current study is not only to assess the effect of presented methods but also to suggest their use.

4. Research Methodology

The program process entails the primary analyses and checks for modern sensors and intelligent systems. Research designs with AI techniques are designed to define a mechanism that underlies the number of environments in order to overcome the difficulty of the problem. The goal of the project is to explore the various sensing devices to gather the multiple information and utilizes the AI systems mostly on data sources. The key objective of the proposed work is to gather information upon this thermal and breathing level of the COVID-19 instances from various devices in real-time. In the data preprocessing, the recorded actual statistics shall be believed to reduce the error and extreme values from the principal component analysis (PCA). The third phase resulted in classifying the COVID-19 instances into three groups such as SIR, disease prone, affected and resuscitated (SIR). Then, in the fourth stage, the deep, simple RNN (recurrent neural network) predicts COVID-19 with past health data. Figure 7 shows the flow diagram for detection of COVID-19 using IoT and AI. The four steps of the model suggested are as follows:

(i) Data accession
(ii) Data accusation
(iii) Systemization
(iv) Forecasting

4.1. Recurrent Neural Network. The RNN is a class of the ANN that generates a graph structure for spatial and dynamic characteristics analysis. It assists to modeling the sequence information from transmission systems. The prediction findings are identical to the human brains. The processing of knowledge is clear. Assume an easy and simple given set of data feeding just one neuron. The method provides the performance in a typical neural net by increasing the input with the mass and creates strategies. An RNN returns this performance with the bunch of times. We call timestamp of the period, and the output is entered for the next multiplication of matrices. For illustration, the system consisted of one neuron in the image. The system measures the input/weight mathematical operations and applies nonlinearity with the enabling function. The performance at $t-1$ would be the same. This o/p is the i/p of the multiplication of the 2nd matrix. Figure 8 shows the recurrent neural network.

The proposed system consists of 6 neurons. Two important properties of the ANN are as follows.

(i) Data entered with the first weight set
(ii) Earlier production for a second weight collection

Notice that the quantities of the listed within the first flow forward which are null, and we have no quality present.

4.2. SIR Model. This framework is being implemented by Kermack and McKendrick, and it consists of the various classification COVID-19 situations, including such confirmed, contaminated, and rehabilitation instances. The disease deterministic method (Koike and Morimoto, 2018) is being implemented. The proposed method uses the SIR model as follows:

(i) Suspected (S): patients immediately suspected of disease by others
(ii) Infected (I): victims infected through whatever requires
(iii) Victims healed by infection, and patients accused of infection from others (R)

The design of the outbreak is mathematically written as follows:

$$\begin{aligned}\frac{\mathrm{d}s}{\mathrm{d}t} &= a - \mathrm{d}s - \lambda i + \beta,\\ \frac{\mathrm{d}i}{\mathrm{d}t} &= \lambda i - (d + m)i - T(i),\\ \frac{\mathrm{d}r}{\mathrm{d}t} &= mi - (d + \beta) + T(i),\end{aligned} \tag{1}$$

where a signifies the number of patients being tested; whereas i represent the relative state constant determined by $a1$, $a2$, the infection rate b parameter calculate is the rate of the victims not healed by loss of resistance, m is the normal patient's mortality rate, and T is a natural cure for the actual individuals diagnosed.

5. Result Analysis and Discussion

The table describes that the total population (sample size) of 227 among that population female population of 85 members and male population size of 135 members and other population size of 7 members and 30 members are below 18 years, between 19 and 30 years are 63 members, between 31 and 59 years are 92 members, and above 60 years are 42 members and 33 members having body temperature below 370°C, and 194 members having the temperature (380°C, 390°C, 400°C), and 123 members are infected with COVID-19, and 123 members are in danger zone; they are having different health abnormalities such as breathing problems.

Figure 9 shows COVID-19 effected cases. Figures 10 and 11 show the problematic cases and nonproblematic cases. Table 2 provides the forecasting of COVID-19 with the selective analytical aspects. Table 3 provides the COVID-19 effected cases. Table 4 provides problematic cases. Table 5 provides nonproblematic cases.

6. Conclusion

The threat of the COVID-19 epidemic is still being faced by the universe that attempts complemented by numerous emerging innovations, including such IoT. These are being made by AI to mitigate their impact. Holding that, we have some recent observations of COVID-19 epidemic as the basis for this study. This study is initiated by an exhaustive analysis of COVID-19, wherein we discuss its medical characteristics, dissemination process, and the detection techniques.

For the population analysis, the SIR disease process is employed to identify the events under suspicion; the information is then fed into an LSTM RNN to estimate the COVID-19 instances with past data contained in the secret layer. The two stable problems in electronic enforcement, which requires adjustment, include confidentiality and faith. The migration of data also appears as an additional obstacle to solve interference and complexity by replacing evolutionary methods.

Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Academic Editor: Enas Abdulhay

Mental health essentially refers to a state of mind. It means that an individual can keep a good or normal state in behavior. It is not only related to the overall development of the individual body and mind but also affects the construction of university teachers. This paper mainly studies the career development anxiety of music teachers in colleges and universities in China, analyzes its causes, and puts forward corresponding countermeasures and suggestions to alleviate the pressure and promote the physical and mental harmony of music teachers and the common growth of a good social atmosphere. The purpose is to help music teachers in colleges and universities better manage their mental health. This paper collects the data of occupational stress and mental health of 164 music teachers in many colleges and universities through the method of a questionnaire survey and processes the data with the analysis formula of sample variance and standard deviation. The analysis shows that a considerable number of the respondents have career development anxiety.

1. Introduction

The inequality between social progress and the reform of professional titles in higher education has always been a huge stone in the hearts of all teachers. In the past, we have always unilaterally emphasized that teachers should have the spirit of dedication but ignored the pressure they bear as a special social group and the reasonable demands for normal career development [1, 2].

After entering the new century, the research on the occupational stress of primary and secondary school teachers in China is gradually deepening, but the research on the occupational stress of college teachers has not attracted enough attention. Although university teachers do not face the pressure of students' entrance examinations, the students they face have more mature personalities, and the form of classroom teaching is more open. Students often put forward some problems that teachers cannot explain in class. All of these lead to the fact that college teachers are also suffering from unimaginable social and psychological pressure [3].

According to the survey data, more than 72.3% of young college teachers in China think that their work and academic research pressure is too high, which makes them often fall into more serious mental health problems [4]. In addition, many colleges and universities in our country adopt the incentive policy of "go or not", which makes young teachers in colleges and universities who are in deep trouble feel more confused about their career prospects.

A work stress survey of young university teachers found that the mental health of young university teachers has deteriorated year by year. Especially in recent years, the impact of pressure on young university teachers, such as low wages, difficulty in buying a house, and difficulty in promotion, has gradually increased. The state of mental health is getting more and more severe, as shown in Figure 1.

It can be seen from Figure 1 that the mental health index of young teachers in colleges and universities decreases year by year as the years increase. Taking 2015 as the best starting point for health, by 2021, the average health index has dropped by 30%. It can be seen that the mental health of young music teachers in colleges and universities is deteriorating rapidly.

The psychological state has an important influence on an individual's life and work. The influence of teachers' mental health on the sustainable development of education cannot be ignored [5, 6]. To pay attention to their mental health, and to achieve positive intervention on their mental health by building a good career development space and strengthening psychological counseling is a necessary way to improve the working state of college teachers in China [6, 7]. The mental health of university teachers will not only affect their own work and study but also bring great differences to students' learning moods and even their cognition of the world. There is an obvious positive relationship between the two. College teachers with good mental health will make students feel more sunshine in their studies and life, and vice versa [8, 9]. In many cases, these two opposite learning emotions will accompany students throughout their lives. Human resource management in colleges and universities, as an important entry point to improving the professional development space of college teachers, should not only focus on the teaching work and academic achievements and other hard indicators, but also expand to include the guidance and intervention of teachers' mental health so as to create a more three-dimensional and comprehensive work system of teachers' mental health and help college teachers to work more actively and effectively and improving their healthy psychological state to carry out education and teaching work. [10, 11].

As a nonmusic college, music teachers are a relatively special group. They are more in line with the perceptual cognition of university teachers: brilliant and easy to work with. As a result, their career development anxiety is more easily ignored by society [12, 13]. Paying attention to the mental health regulation of this group not only helps to solve the mental health problems they are facing, but also has a very important reference value for the mental health regulation of the whole team of university teachers.

2. Professional Development Anxiety and Psychological Adjustment of College Music Teachers

2.1. Characteristics of the Professional Development of College Music Teachers

2.1.1. Particularity of Music Teachers. Music teaching pays attention to aesthetics just like dance and art, and music learning is not a day's work. It requires years of learning. In addition, music learning is not only about professional knowledge, but more importantly, experience in life. The profession of a music teacher is different from other teachers, mainly in the following aspects.

First, after becoming a music teacher, you can combine your profession and expertise, find a suitable entry point, combine your expertise with teaching, and promote the continued development of music.

Second, there is a very close relationship between the professional development of music teachers and the school environment. These development environments mainly include the relationship between the internal environment and the external one [14, 15]. The internal environment mainly refers to people's innate sensitivity to music and various physiological conditions such as their voice, while the external environment mainly refers to people's in-depth research and pursuit of music.

Third, the professional development of music teachers has always been a straight line, and there are no other diversions. Despite this, music teachers also face all kinds of difficulties, but they still work hard to form their own unique teaching styles and models.

2.1.2. Features of Professional Development of Music Teachers in Colleges and Universities

Phased. Music teachers are of different ages, and their development will also show different developmental characteristics. At different ages, the problems they face will be different. This is the stage. According to research, 25–60 years old can be called an adult stage. Music teachers between the ages of 25–35. They are young and energetic and have innovative ideas in music. At this time, they are faced with problems in career planning, life planning, and family formation, such as employment, studying abroad, falling in love, and getting married. Music teachers at the age of 35–50 have completed family formation-related issues and accumulated a lot of social experience. They are calm and efficient in their work, and their bodies and spirits are at the peak of activeness. Music teachers at the age of 50–60 may not be as good as the previous two stages, but they have profound professional knowledge, the richest teaching experience, and the highest level of scientific research. According to the statistical results of university research institutions, it is found that the occupational anxiety of college music teachers will increase first and then decrease with age. The specific situation of anxiety is shown in Figure 2.

It can be seen from Figure 2 that the occupational anxiety value of young college music teachers between the ages of 30 and 35 reaches the highest level, and with the increase in age, the occupational anxiety value of college music teachers gradually decreases, reaching the lowest point at the age of 60.

Dynamic. Music teachers are also a group of society [16]. They are also in a social environment. Their career development cannot be separated from the influence of the environment, and this influence is also mutual. The activities of music teachers will also have an impact on the environment [17, 18]. The stages mentioned in the previous article also show that the professional development of music teachers is dynamic and constantly changing, which only shows that different ages lead to different environments, which will have an impact on the professional development of music teachers. In addition, when college music teachers leave the university campus, there are not many career choices. Maybe a certain institution becomes a training teacher. Therefore, it is best for college music teachers not to leave the university campus to develop independently.

Comprehensive. Comprehensiveness means that in the process of professional development, college music teachers

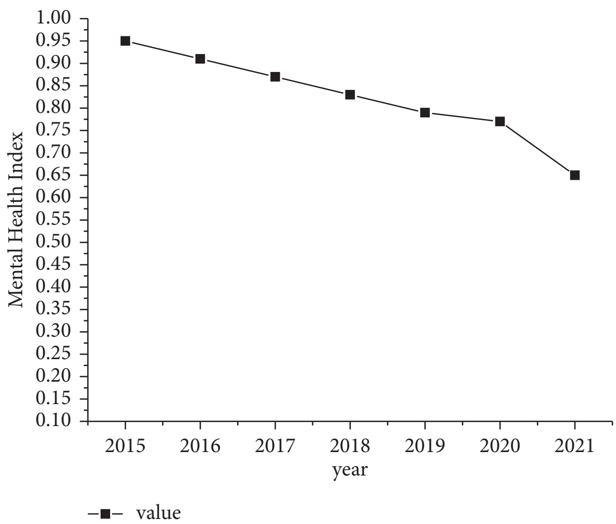

Figure 1: The mental health of young teachers in colleges and universities.

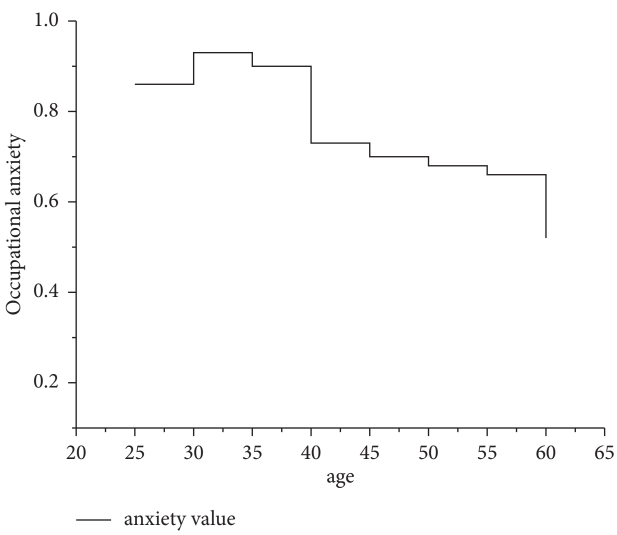

Figure 2: The changing trend of anxiety of college music teachers with increasing age.

must not only have their own unique professional style and authority but also have the knowledge and teaching management capabilities related to other disciplines [19]. As a teacher, they must have at least pedagogy-related knowledge, be good at getting along with students, discover the characteristics of students, and should know how to guide students with different physical conditions to guide their music professional learning. In addition, music teachers must have strong music creation abilities and practical abilities, and constantly improve their level of professional knowledge and innovative teaching methods.

2.2. Performance of College Music Teachers' Occupational Anxiety. Through the analysis of data from different institutions, it is shown that the performance of occupational anxiety of music teachers in colleges and universities is mainly divided into four types. Among them, the degree of influence of different types of anxiety on the teachers' mental health index is shown in Figure 3.

It can be seen from Figure 3 that the performance of college music teachers' occupational anxiety is mainly divided into four types. Among them, grumpy type anxiety has a high impact on teachers' mental health index, reaching 31.58%, while suspicious and uneasy types of anxiety have the lowest impact on teachers' mental health index, at only 19.3%.

It can be seen from Figure 3 that all kinds of anxiety will adversely affect the mental health of college music teachers. The specific types of anxiety involved are as follows.

Emotional Pessimism. When music teachers are dissatisfied with their current work, they will be pessimistic. They often feel exhausted, and it is difficult to show a happy expression about something. Most of the time, they see the negative side of things first. The time spent alone is prolonged, and interpersonal communication is extremely lacking. Too worried about the future and then become gloomy, even during the teaching period, they would not shy away from it. Over time, this emotion will infect students and other teachers.

Grumpy. Music is inherently unique in art, and music teachers also have very obvious personal characteristics. When society, parents, and schools intervene in their teaching too much, they feel that they cannot concentrate on studying music or even become secular. Sometimes they will become very irritable. In teaching, they will be more demanding on students. They will be less tolerant of students who make mistakes. They often become inexplicably angry. They will be self-centered, not cooperate, and not listen to other people's advice, which makes the job impossible. To proceed in an orderly manner, seriously interfering with teaching work.

Suspicious and Uneasy. When teachers are hit, they are prone to self-doubt or feel that others are deliberately targeting themselves, and when they start to think about themselves and their insecurity, the whole person's defensiveness becomes heavier and he is unwilling to communicate with others. In the long run, insomnia and overreaction are prone to occur, which seriously affects normal teaching and life, creates greater obstacles to professional development, and will aggravate teachers' professional anxiety.

Nervousness. Nervousness manifests itself as being overly entangled in something, speculating on the adverse consequences of the event, fear of making mistakes, excessive worry about the past and future, fear of losing face, always being cautious, and pursuing too much perfection.

2.3. Psychological Adjustment Countermeasures of College Music Teachers

2.3.1. Create an Environment Conducive to the Mental Health of Teachers. Teachers bear the heavy responsibility of preaching and receiving jobs, and their mental health has a

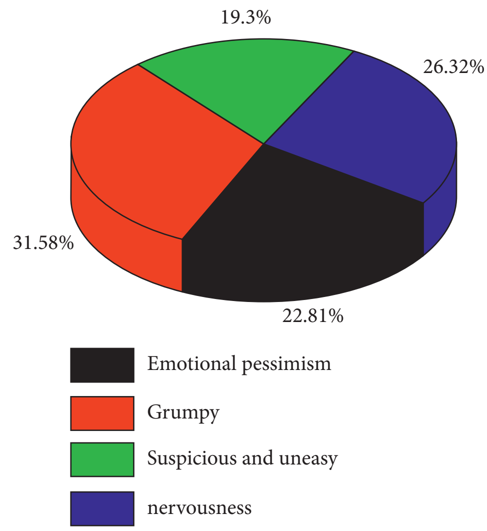

Figure 3: The degree of influence of different types of anxiety on teachers' mental health.

huge impact on society. Local governments should earnestly safeguard the rights and interests of teachers. To solve the psychological problems of music in colleges and universities, it is necessary to find the source of the problem, counter the medicine, create an easy-to-teach working environment for college music teachers, improve the salary and social status of college music teachers, and conduct regular mental health education for college music teachers. Practical actions should be taken to solve the difficulties that teachers encounter in life and work.

2.3.2. Adhering to the People-Oriented Education Management Method. In terms of adjusting the psychological state of music teachers in colleges and universities, it is necessary to optimize management methods and management models through local colleges and universities, always adhering to the people-oriented management philosophy, attaching great importance to the mental health of teachers, and carry out relevant training activities on a regular basis. In addition, formulate more scientific and reasonable teacher assessment standards and prohibit the establishment of standards that ignore reality. When recruiting teachers, we should also pay attention to the mental health of teachers and create a team of teachers with a good atmosphere. Formulate incentive policies that take into account teachers' contributions and achievements at work, and at the same time strictly require teachers' ethics and morality. They must also be rigorous in academic research to avoid mental health problems caused by bad academic habits. Reasonable control of the working hours, advocating the combination of work and rest, and holding faculty sports games or art evenings to provide teachers with more opportunities to show themselves.

2.3.3. Improving the Psychological Quality of Teachers Themselves. At the same time, teachers should also understand that their responsibilities are heavy, introspect in time, and improve their level of professional knowledge for teaching and ideological and moral cultivation. At the same time, they must also understand that they are the object of the students' respect, and they must be able to convey positive energy to the students rather than vent their negative emotions on the students. Survival of the fittest has always been the rule of the world. If they want to develop better, they must improve their overall quality, including psychological quality, in order to strengthen their professional knowledge. This requires teachers to learn to control their emotions and handle things calmly. To have a clear understanding of oneself, they should face up to one's own shortcomings and deficiencies, accept different opinions from the outside world, establish good interpersonal relationships with colleagues, treat students equally, and learn to tolerate others.

When the teachers realize that they are feeling irritable and stressed, they must learn to find solutions. Schools and students are the objects teachers can seek for help. Teachers should not feel ashamed to speak out when they have psychological problems. They should open their hearts to communicate with others. Closing themselves will only make the results worse and worse. They should learn to advance with the times, constantly improve themselves, and adapt to the surrounding environment. Actively participating in school activities, having the courage to show oneself, not caring too much about gains and losses, seeing the false name, teaching and educating people, and academic research are what teachers should care most about.

2.3.4. Developing Good Living Habits. Healthy living habits have always been an important prerequisite for physical and mental health. Music teachers or other teachers in colleges and universities will not change to tie themselves to research and professional titles. They must always be happy so that they can work in order to achieve the effect of getting twice the result with half the effort.

(1) Good sleeping habits can help music teachers in colleges and universities to be energetic and comfortable at work, reducing the intake of unhealthy stimuli such as coffee, tea, tobacco, and alcohol before going to bed, and forming and creating a suitable sleeping environment will also help;

(2) Scientific eating habits and scientific diets provide energy support for teachers to engage in heavy mental work. The specific requirements are timing, quantitative, reasonable collocation, no partial eclipse, and attention to food hygiene;

(3) Appropriate leisure activities can relax teachers' bodies and minds, satisfy hobbies, and experience the function of self-growth. Occasionally, a movie or drama, a walk in the park, a visit to a painting exhibition or a museum, etc., will make them feel physically and mentally happy and stress relieved;

(4) Reasonable physical exercise can strengthen the body, beautify the image, and at the same time help increase teachers' self-confidence, self-esteem, self-control, and self-satisfaction, and more importantly, relieve work and psychological pressure. Physical exercise is the best way to get rid of negative emotions and prevent depression, anxiety, and worries.

3. Investigation and Experiment on the Stress and Mental Health of Music Teachers in Colleges and Universities

3.1. Experimental Content. Music teachers are a group of teachers with distinctive personalities, but they are also prone to psychological problems. This experiment mainly selected 4 colleges and universities in the province as the experimental site, took the music teachers of these 4 colleges and universities as the research objects and investigated their occupational stress and mental health problems. This experiment adopts the experimental method of a questionnaire survey. A total of 175 questionnaires were distributed to music teachers in these 4 universities, and 164 valid questionnaires were returned. The survey tool used the SCL-90 symptom self-rating scale.

3.2. Experimental Process. The survey content was determined and the questionnaire questions were set up. The questionnaire is completed in accordance with the design criteria of the questionnaire. The survey subjects are communicated with before the survey, and after an agreement is made, the survey staff will hand out the questionnaire and the music teacher will fill it out on the spot. It took one week from the issuance of the questionnaire to the collection of the questionnaire. After that, the collected questionnaires were sorted out and the data was collected. The formula used in the data processing stage is as follows:

$$\text{Sample variance formula: } s^2 = \frac{\sum_{i=1}^{n}(x_i - x)^2}{n-1},$$

$$\text{Sample standard deviation formula: } s = \sqrt{s^2} = \sqrt{\frac{\sum_{i=1}^{n}(x_i - x)^2}{n-1}}. \tag{1}$$

4. Survey Results of the Professional Pressure and Mental Health of College Music Teachers

4.1. Survey on the Severity of Occupational Anxiety and Mental Health. The relevant standards of the SCL-90 symptom self-rating scale have stated that the factor score is greater than or equal to 2 as a mild symptom response. When the molecular factor is greater than or equal to 3, it means that the survey subject has a moderate or higher symptom response. Figure 4 shows the statistics based on the relevant standards of SCL-90:

Figure 4 shows that college music teachers may have various possible problems, including psychological problems such as somatization force, Interpersonal sensitivity, depression, anxiety, hostility, terror, paranoid, and psychotic.

Among the 164-people surveyed, 99 people had mild symptoms and 65 people had moderate or above symptoms. From this point of view, the professional pressure on music teachers in colleges and universities in the province is relatively high, and their mental health problems have gradually become prominent.

It can be seen from Figure 4 that among the mild symptom responses, the most prominent is the interpersonal relationship. The number is 90, which is more than half of the sample. Secondly, self-anxiety and physical factors are also compared among them.

Among the above-moderate reaction symptoms, self-anxiety is also the most prominent. The number of people with this factor is 25.

Through further analysis of the results of the questionnaire, the anxiety index is defined in the interval (0, 1), and then the value of a single survey result is quantified, compared with the quantified value of the entire survey sample, and the value of each survey sample is calculated. Anxiety values and the corresponding extreme values, average values, and anxiety states are analyzed and the specific display is shown in Table 1.

It can be seen from Table 1 that the lightest symptom of occupational anxiety for music teachers in colleges and universities is 0.18, and the worst symptom is 0.92. The average of the occupational anxiety symptoms of music teachers in colleges and universities is 0.72. Through the analysis of the mean value, it can be seen that the overall anxiety level of the 164 teachers in this survey is at an upper-middle level.

4.2. Attitudes of Music Teachers to Occupational Anxiety and Mental Health Problems. Figure 5 shows the survey results on the attitudes of music teachers to occupational anxiety and mental health problems. The figure shows that 68% of teachers adopt a positive and optimistic approach, and 16%

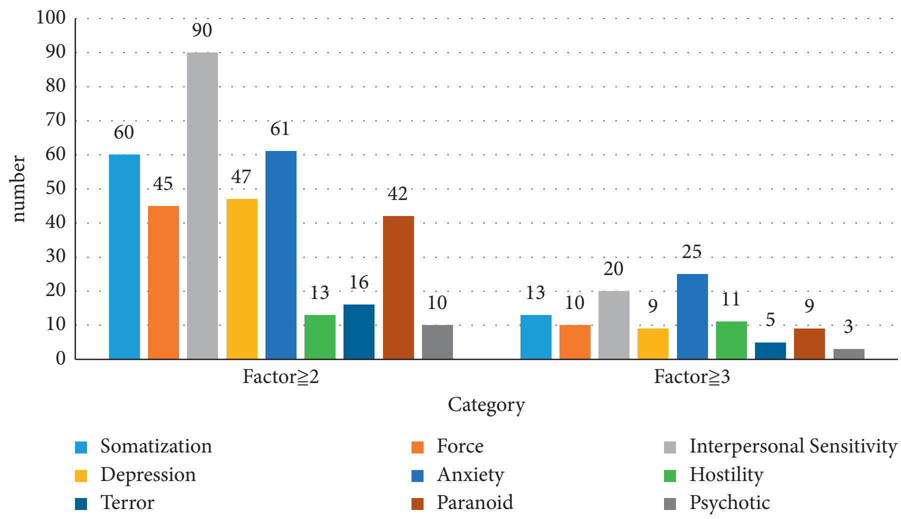

Figure 4: Distribution map of problem severity.

Table 1: Occupational anxiety index of college music teachers.

Number of respondents	Mean anxiety	Maximum anxiety	Anxiety minimal	General anxiety state
164	0.72	0.92	0.18	Middle

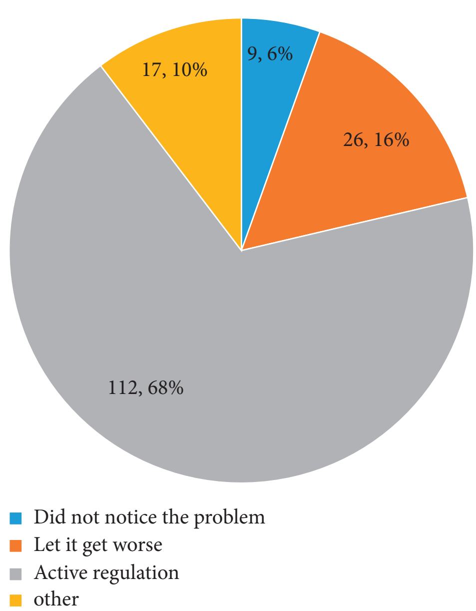

Figure 5: Music teachers' attitudes towards occupational anxiety and mental health problems.

of teachers feel that there is no need to pay attention and just let it develop. 6% of the teachers were unaware of the problem, and 10% of the teachers took other methods to solve it.

5. Conclusion

Music teachers are the most important team force to support music aesthetic education in colleges and universities. Their mental health will undoubtedly have a subtle impact on college students' studies and lives. Taking the opportunity of career development and reform, we must pay attention to the key topics of professional improvement and mental health adjustment of music teachers in colleges and universities. Teachers are humans too. Since they are humans, there are problems of survival and development. If these problems cannot be resolved in a timely and effective manner, psychological diseases may result. Patients suffering from severe psychological diseases may pose a certain threat to their family, society, and school. Music teachers in colleges and universities should pay attention to the improvement of their theoretical knowledge of mental health, and school management departments and society should also pay attention to the mental health of college music teachers, organizing various activities to improve teachers' mental health levels, promoting teachers' physical and mental health, and school education in a harmonious development.

Colleges and universities should create an environment conducive to the mental health of teachers and adhere to a people-oriented education management method. Music teachers in colleges and universities should also take the initiative to improve their own psychological quality and develop good living habits in peacetime. In short, the adjustment of the mental health of college music teachers requires the joint efforts of colleges and teachers. Only by maintaining a good mental state can college music teachers have better professional development.

Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Medical diagnosis is always a time and a sensitive approach to proper medical treatment. Automation systems have been developed to improve these issues. In the process of automation, images are processed and sent to the remote brain for processing and decision making. It is noted that the image is written for compaction to reduce processing and computational costs. Images require large storage and transmission resources to perform their operations. A good strategy for pictures compression can help minimize these requirements. The question of compressing data on accuracy is always a challenge. Therefore, to optimize imaging, it is necessary to reduce inconsistencies in medical imaging. So this document introduces a new image compression scheme called the GenPSOWVQ method that uses a recurrent neural network with wavelet VQ. The codebook is built using a combination of fragments and genetic algorithms. The newly developed image compression model attains precise compression while maintaining image accuracy with lower computational costs when encoding clinical images. The proposed method was tested using real-time medical imaging using PSNR, MSE, SSIM, NMSE, SNR, and CR indicators. Experimental results show that the proposed GenPSOWVQ method yields higher PSNR SSIMM values for a given compression ratio than the existing methods. In addition, the proposed GenPSOWVQ method yields lower values of MSE, RMSE, and SNR for a given compression ratio than the existing methods.

1. Introduction

Modern learning reports that the employment of imaging has increased significantly in the previous two decades [1]. In the United States, for example, there was a study by Smith-Brinman et al. [2]. It was reported in 2008 that CCTV images doubled and MRI images doubled. This growth is the effect of a quick overhaul of hardware as well as software to support imaging systems. In addition, the transition from analog to digital provides fast, stress-free, and accurate image development. All of these factors have supplied significantly to the group of images. Therefore, the byte of these images is received every year worldwide. Imaging technology is implemented by X-ray, ultrasound, MRI/fMRI (functional magnetic resonance image), nuclear medicine, PET (positron emission tomography), CT (computerized tomography) [3], and DXA (dual energy X-ray absorptiometry). The necessity of saving, distributing, and downloading these images in their own appearance has given to the picture archiving along with communication system

(PACS) a medical imaging skill that presents low-cost storage as well as access to useful images from many sources. Unluckily, the huge pixel size of these images severely limits the storage capacity [4–6]. For example, an emblematic NMR matrix dimension is 512×512 with 16 b [7].

A healthcare association that creates hundreds of images a week will need numerous megabytes of storage space. In a year, the total storage needed increases to a few gigabytes. This growth results in various terabit storage volumes per year. Moreover, a 56 kbps MRI band will take 12–15 minutes [8]. A lot of methods have been developed to reduce the size of these images, except that the major desirable novelty is the hybrid image production technique, in which the wavelet transform (DWT) along with vector quantization (VQ) as well as the loss [9] is preferred the most. In numerical analysis and function, DDD is a variation of spectacles in which the spectacles are precisely modeled and designed to process signals with a certain amount of time [10, 11].

In contrast to the discrete cosine transform (DCT) derived from the function of the base cosine, DWT is able to collect a few functions that meet the needs of multidimensional reaction analysis [12]. The origin of the image size reduction algorithm is to get an X input as well as produce an X demonstration that must need less bits for the representation. This went after recovery techniques that work on a compact X representation to produce a recovery , e.g., DWT offers a set of wavelet coefficients at various sizes showing various numerical types.

To propose the quantity for every set using the VQ technique, the bit value can significantly condense, devoid of affecting the excellence. Nevertheless, quantification leads to defeat of signal superiority. Consistent with Sannon, the dimensions of the selected vector have a significant influence on the quantitative efficiency. Larger vectors produce better quality than smaller vectors. For this reason, the purpose of this work is to develop a hybrid approach derived from discrete wavelet transforms and vector quantization to reduce the size of medical images with elevated compression rates and quality.

The main contributions of this paper are summarized as follows:

(i) Recurrent neural network is developed to compress the medical images.

(ii) A novel hybridized approach GENPSO is developed for optimizing the neural network parameters.

(iii) Using GENPSO, the hidden layer of recurrent neural network is compressed in more effective way to increase the compression ratio.

(iv) High compression ratio and better performance were achieved compared to the other existing approaches using wavelet vector quantization.

(v) The proposed method provides good results for real-time medical dataset.

The manuscript of this document is organized as follows: Section 2 discusses some of the relevant contemporary literature. Section 3 presents a detailed description of the proposed architecture. Section 4 presents the experimental results, which include the general operating results of comparing the performance of GENPSO and other compression methods previously published. Conclusion and future work are provided in Section 5.

2. Background

Juliet et al. [13] discussed a new approach, including Ripplet conversion, to ensure better image quality and higher compression levels. In this work, to achieve high compression, the image is presented in various weights and instructions. Cyriac et al. [14] developed a lossless compression technique to address the issue of expanding compression. In this article, the newly developed method is to reduce the image size sufficiently as well as speed up the hardware execution of the software in real time. Brahimi et al. [15] illustrated a new coding method in which both symbols along with images are compressed together with a codec. The major point of this method is to insert a rotten stray signal into the corrupted image, and the resulting image is employed for image size reduction.

Arif et al. [16] introduced an effective approach for minimizing fluoroscopic imaging. The retrieved ROI of this approach is minimized through a grouping of run length as well as hepatic coding. The final outputs show that the newly developed method offers a compression ratio of 400% compared to other traditional approaches. Das et al. [17] described a lossless medical imaging watermark (MIW) procedure that relies on the area of interest concept. The major purpose of this technique is to offer clarification to many issues related to the dissemination of medical data. This article uses seven various methods to display as well as compare outputs to demonstrate that the newly developed approach is easy and obvious in ensuring the security of the medical database.

Lucas et al. [18] introduced 3D lossless compression techniques 3-D MRP for high-volume medical imaging equipment. The presented technique relies on the minimum velocity forecasting mechanism (MRP). This article concludes that the demonstrated method can enhance the probability of error of the MRP as well as achieve higher image size reduction efficiency than ASS along with other standards for the depth of the medical signal. Špelič et al. [19] proposed new algorithms developed as voxel compression algorithms for 3D CT image compression for the broadcasting of graphics information acquired from CT scanners. This work illustrated the Hounsfield size being employed first for partial medicine, and then image size reduction is applied. In this work, a modeling method is employed to evaluate the effectiveness of the newly developed techniques.

Anusuya et al. [20] developed a new, lossless code employing a codec to reduce the size of 3D brain images. In this paper, MRI models are employed to analyze the effectiveness of the newly developed solution, and this paper focuses on sinking utilization time using parallel calculations. Xio et al. [21] introduced integrated tablets for compact image compression without data loss. The proposed technique integrates with integer maps for inefficient compaction. Amri et al. [22] introduced two lossless image size reduction techniques. In this work, demonstrated algorithms are employed to minimize image dimension and code algorithms for lossless image size reduction. It can be seen that the newly developed method can maintain image feature for elevated image size reduction levels and also provide different enhancements to the standard JPEG image size reduction.

Ramesh et al. [23] described a method for predicting wavelengths to minimize medical images. In this method, the forecast equations for each subline depend on the correlation analysis. Evaluation outputs show that the newly developed method offers a superior level of compression matched up to the standard SPHIT and JPEG2000. Ibrahim et al. [24] introduced two novel lossless image size reduction techniques based on logarithmic calculations. The proposed method can offer better image feature compared to conventional DWT. Avramovic et al. [25] developed a new loss-free image size reduction technique using context-based Internet converters. The proposed method relies on the concept of projection to eliminate the need for transparency in the image and to effectively compress the image without losing data. The conclusion is that the newly developed method can attain the similar results as high-class images like previous standard algorithms. Bairagi [26] accounted the idea of symmetry for medical imaging. The method shown here is lossless and can effectively remove unnecessary information from the image.

Zuo et al. [27] introduced an enhanced technique to IMIC-ROI medical imaging for efficient and effective medical imaging. The proposed technique is based on the concept of interest area (ROI) as well as non-ROI area. Srinivasan et al. [28] described encoders for compact electromagnetism (EEG) matrix. The method illustrated first two phases, the lost code layer (SPHIT) and the remaining coded layer. Taquet et al. [29] reported on hierarchical-oriented forecasting methods to allow scaling without loss and near-loss of medical imaging. It can be seen that the newly developed method is best employed for lossless image size reduction as it may offer superior or equivalent PSNR for higher bit rates compared to the JPEG 2000 standard.

Zanaty and Ibrahim [30] introduced a medical image compression technique based on combining region growing and wavelets algorithms. The authors have used a region growing algorithm where an image is portioned into two parts and the capability of the algorithm is justified.

3. Materials and Methods

3.1. Recurrent Neural Network. The recurrent neural network [31] is one of the neural networks which employs precedent data in a closed loop. It can be repeated through merely transmitting the network output or intermediate state as input. For instance, the input image of k-1 might be integrated into a network in kth step. This kind of network is suitable during short-term dependencies as it depends on other and does not perform better for long-term dependencies observed in compression. For this kind of network, there are issues in the training procedure, so throughout reproduction it can "disappear" or "explode." To avoid this limitation, this work uses a new approach called GenPSO and proposed vector quantization required to incorporate with neural network to manage the input and output image data. So in this work the codebook is generated using a novel hybrid GenPSO approach. Then this codebook is used in vector quantization for compressing the number of hidden neurons for increasing the compression ratio [32].

3.2. Updating Weights in Recurrent Neural Network Using GenPSO. In this step, the weight generated from the recurrent neural network is updated through the GenPSO method. The initial constitutive population of a chromosome has an evenly distributed random number. The chromosome represents the weight of the recurrent neural network. A crossover here can be defined as a crossover on a node. It is necessary to construct two springing from the parent node, with each node being retrieved from a hidden layer, and multiple outputs, randomly taken with equal probability. This node is considered a transit node [33]. The value of all input weights for that particular node is changed with the other master. This change can also be considered as a node change, in which all the incoming weights are for randomly selected active nodes. Finally, the PSO process is applied. The initial PSO population was determined by GA decision. Therefore, it can overcome the problem of slow convergence of the GPS network [34].

The algorithm for weights evolution by GenPSo in RNN is as follows.

The following steps are performed to determine the best weight value.

(i) For population of the XiMi, a solution, $i = 1, \ldots, \mu$, is started on area M with $R \in n$.

(ii) Two parents are randomly selected with a parent population distribution and two births will be generated by a crossover operator.

(iii) ereditary mutation of the offspring is performed.

(iv) Repeat step (ii) until the number of offspring μo is μ. Otherwise, go to step (v).

(v) Any parental decision, $i = 1, \ldots, \mu$ and progeny Xo, $o = 1, \ldots, \mu$, are estimated in light of objective function (X).

(vi) For mixed population Xm, m = 1,. . ., 2 μ, both the parent population and the population formed. They are randomly mixed so that parents and children mix up properly.

(vii) Each solution of Xm, $m = 1, \ldots, 2\mu$ is evaluated with 10% of the solutions of the other randomly selected solutions from a mixed population.

(viii) The highest earnings decision is reserved for the next generation of parents.

(ix) If the best chromosome difference for the N number of successive generations is less than the specified brightness, stop the process and the best chromosome of the last generation is the ideal weight. Otherwise, proceed to the next step.

(x) Beginning particle population and location and velocity are derived from the genetic algorithm.

(xi) Estimate the fitness value of all particles depending on the fitness function based on the objective of the optimization problem.

(xii) Compare the values of the fit of each particle and its holes. If the current value is better than pbest, then set the current fitness value to its pbest. Otherwise, the pbest will remain the same.

(xiii) Determine the current best fitness value among all fitness values of all particles in the population. Then, compare this value to Gebel and set the current value to Gebel if the current value is better than Gebet. Otherwise, leave it blank.

(xiv) Update the position and speed of each piece.

(xv) Stop if the best solution is found that matches the predefined minimum error or reaches the maximum number of repetitions. Otherwise, repeat the procedure from steps (x) to (xv).

3.3. Proposed Image Compression Using GenPSO Wavelet Vector Quantization Recurrent Neural Network Approach. The proposed technique for quantifying vectors using backward neural networks is summarized in the following steps:

Step 1. Apply wavelet transform to the image to produce transformed image.

Step 2. Get a pixel value (0 to 255) of the matrix.

Step 3. Now apply these values to the forward neural network. This network must have 64 input nodes since the detector is 8×8. Train the recurrent neural network using the training algorithm as explained in Section 3.2.

Step 4. Weight and tilt, updated by GPS, are fed to a hidden layer that can contain 2, 4, 8, 16, 32, and 64 hidden nodes. Encode these values with GenPSOWVQ

Step 5. Select the 8×8 printer in order after completing the training.

Step 6. Digital bits are now converted into real values.

Step 7. Finally, the call phase shows depressed images (output images) at the output of the nervous system's output layer. The conversion of a pixel to a true value and a true value to a pixel occurs during the compression and compression process.

4. Experimental Results

4.1. Dataset Used. Datasets of images which include chest radiographs, unenhanced brain CTs, mammograms, and abdominal CTs are used for experimenting this work. The performance of the proposed Int OPMICM method is evaluated using real-time medical images in terms of PSNR, MSE, SSIM, NMSE, SNR, and CR values [31]. These results are compared with those obtained by the existing algorithms, namely, FFNN, VQFFNN, optimized FFNN, and optimized VQFFNN. Figure 1 depicts the sample images from the real-time medical database [34].

4.2. Performance Metric. For the assessment of the compression approaches, this paper employs six metrics, namely, PSNR, MSE, SSIM, NMSE, SNR, and CR.

4.2.1. Peak Signal-to-Noise Ratio. The peak signal-to-noise ratio (PSNR) is used to evaluate the quality between the compressed image and the original image. The PSNR formula is defined as follows:

$$\log 10 \frac{255 \times 255}{1/H \times W \sum_{x=0}^{H-1} \sum_{y=0}^{W-1} \left[f(x, y) - g(x, y) \right]^2} \mathrm{d}B, \tag{1}$$

where H and W are the height and width of the image, respectively, and $f(x, y)$ and $g(x, y)$ are the grey levels located at coordinate (x, y) of the original image and compressed image, respectively.

4.2.2. Structural Similarity Index. The structural similarity index is a method for measuring the similarity between the compressed image and the original image.

$$SSIM(y, \hat{y}) = \frac{\left(2_{\mu_y \mu_{\hat{y}}} + c_1\right)\left(2\sigma_{y\hat{y}} + c_2\right)}{\left(\mu_y^2 + \mu_{\hat{y}}^2 + c_1\right)\left(\sigma_y^2 + \sigma_{\hat{y}}^2 + c_2\right)}, \tag{2}$$

where $\hat{Y}$ is the compressed image, Y is the original image, μ is the mean, and σ^2 is the variance.

4.2.3. Mean Square Error. The mean square error (MSE) is used to evaluate the difference between a compressed image and the original image. The MSE can be calculated by

$$\mathrm{MSE} = \frac{1}{n} \sum_{i=1}^{n} \left(\hat{Y}_i - Y_i\right)^2, \tag{3}$$

where $\hat{Y}\hat{Y}$ is the compressed image and Y is the original image.

4.2.4. Root Mean Square Error. The root mean square error (RMSE) is a frequently used measure of the difference between compressed image values and the original image values.

$$\mathrm{RMSE} = \sqrt{\frac{\sum_{i=1}^{n} \left(\hat{Y}_i - Y_i\right)^2}{n}}, \tag{4}$$

where $\hat{Y}\hat{Y}$ is the compressed image and Y is the original image.

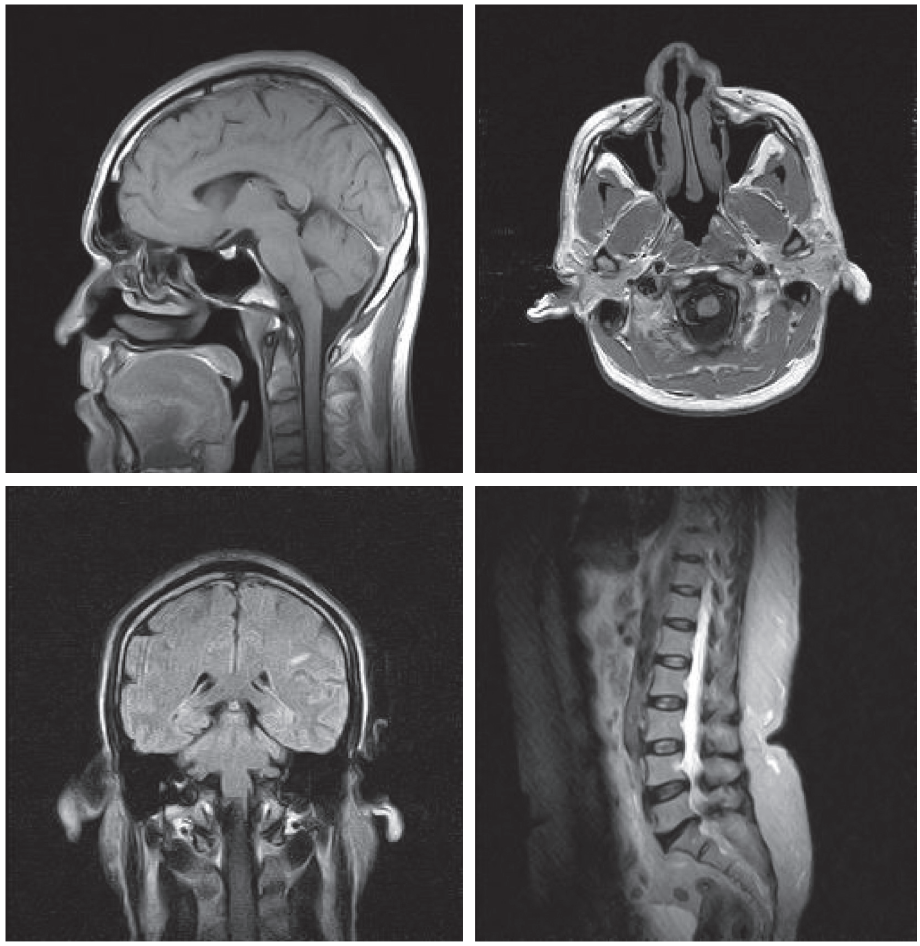

Figure 1: Experimental images.

4.3. Experimental Analysis

4.3.1. Experiment No. 1: Analysis of the Proposed GenPSOWVQ Compression Approach. In this experiment, we will evaluate the contribution of the proposed GenPSOWVQ compression approach. To evaluate the performance of this scheme, the PSNR, MSE, SSIM, NMSE, and SNR against 25% CR ratio are employed. This is shown in equations (1)–(4) correspondingly. This experiment will introduce the concept of GenPSOWVQ compression. It will be performed by estimating the performance of this scheme against a 25% CR ratio. Table 1 lists the PSNR, MSE, SSIM, NMSE, and SNR measures of GenPSOWVQ as well as the existing approaches.

The proposed GenPSOWVQ approach's performance is compared with traditional compression approaches through varying metrics, and the result is illustrated in Figure 2. The performance ratio of GenPSOWVQ has higher value than with traditional compression approaches. So it is proved that GenPSOWVQ is superior to traditional compression approaches.

4.3.2. Experiment No. 2: Performance of Best Chromosome Particles of GenPSO with Population Size of 50. The designed 2-2-1 feed forward architecture and the error value were developed according to the GenPSO method set out above. The population size was 50, and the termination rule is if the best error in the chromosome in the 50 successive generations is less than 0.00001. It is described in Figure 3.

The proposed GenPSO approach's performance is compared with varying population size, and the result is illustrated in Figure 3. The performance ratio of GenPSO has higher value than with traditional compression approaches. So it is proved that GenPSOWVQ is superior to traditional compression approaches.

4.3.3. Experiment No. 3: Performance of Best Chromosome Particles of GenPSO with Population Size of 100. The architecture of the best chromosome particle [35] distribution 2–2–1 was developed using the GenPSO method described above. The population size was 100, and the termination rule is if the 100 best chromosome errors continue to be less than 0.00001. It is described in Figure 4.

The proposed GenPSO approach's performance is compared with varying population size of 100, and the result is illustrated in Figure 4. The performance ratio of GenPSO has higher value than with traditional compression approaches. So it is proved that GenPSOWVQ is superior to traditional compression approaches.

Table 1: Analysis of PSNR, MSE, SSIM, NMSE, and SNR of GenPSOWVQ approach along with 25% CR ratio.

Dataset					
Compression approaches					
Metrics	OFFNN	VQFFNN	VQOFFNN	IntOPMICM	GenPSOWVQ
PSNR	36.80	48.12	49.65	52.4227	60.64
SSIM	0.20	0.43	0.53	0.6736	0.86
MSE	13.57	8.86	6.19	1.4164	0.83
RMSE	3.68	0.001	2.48	1.1901	0.0099
SNR	21.42	16.96	10.65	7.42	5.63

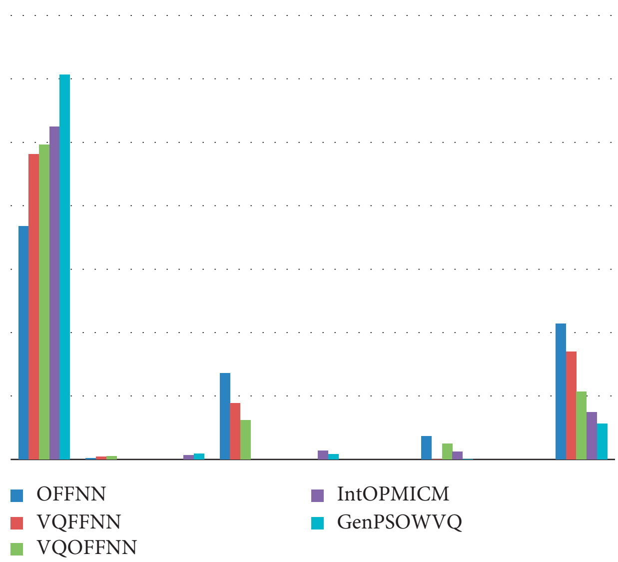

Figure 2: Analysis of PSNR, MSE, SSIM, NMSE, and SNR of GenPSOWVQ approach along with 25% CR ratio.

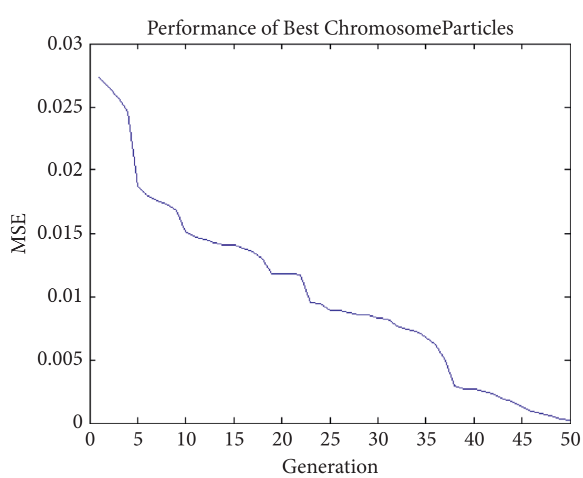

Figure 3: Analysis performance of best chromosome particles.

4.3.4. Experiment No. 4: Performance of Error of GenPSO with Population Size of 50. The designed 2-2-1 feed forward architecture and the error value were developed according to the GenPSO method set out above. The population size was 50, and the termination rule is if the best error in the chromosome in the 50 successive generations is less than 0.00001. It is described in Figure 5.

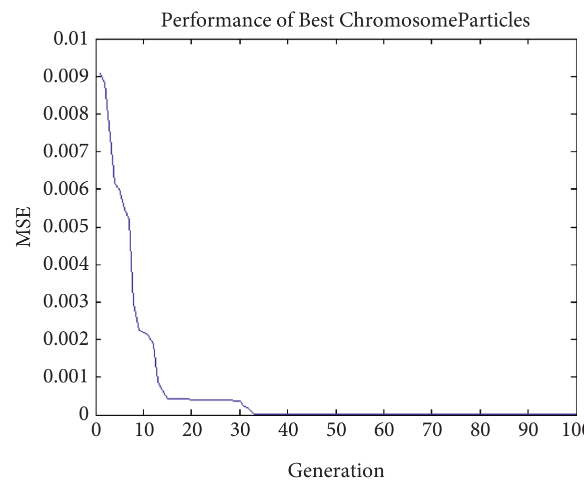

Figure 4: Analysis performance of best chromosome particles with 100 iterations.

The proposed GenPSO approach's performance is compared with varying population size of 50, and the result is illustrated in Figure 5. The performance ratio of GenPSO has higher value than with traditional compression approaches. So it is proved that GenPSOWVQ is superior to traditional compression approaches [36]. The proposed GenPSO achieves high performance against a large population size. This shows that it is superior to traditional compression approaches.

5. Conclusion

This article presents an image compression method for medical image compression using recurrent neural network. This recurrent neural network used a new image compression scheme called the GenPSOWVQ method which has been introduced using GenPSO with wavelet VQ. The codebook is built using a combination of fragments and genetic algorithms. The proposed method was tested using real-time medical imaging using PSNR, MSE, SSIM, RMSE, SNR, and CR indicators. Experimental results show that the proposed GenPSOWVQ method yields higher PSNR SSIMM values for a given compression ratio than the existing methods. In addition, the proposed GenPSOWVQ method yields lower values of MSE, RMSE, and SNR for a given compression ratio than the existing methods. This work can be further expanded to achieve the goal of creating optimal rules. The work can be extended for security in case

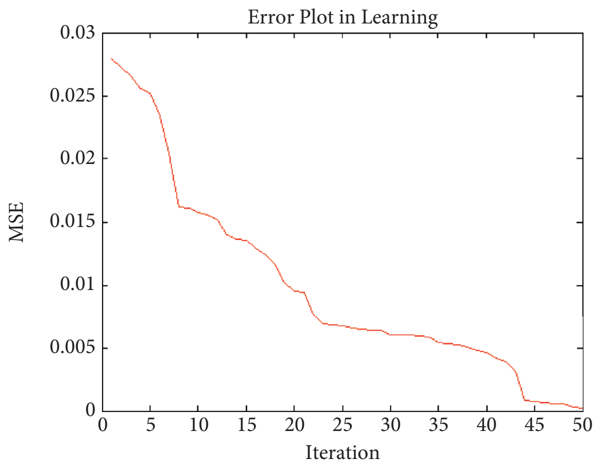

Figure 5: Analysis performance of best chromosome particles with population size of 50.

of image compression. Like the future work for this work, a new code of image compression is proposed using ambiguous logic. This research work has to be tested on large datasets and on a dynamic huge sample that is not tested and storage optimization that is not considered. The article presents a method for image compression using a recurrent neural network known as GenPSO. This method is built using a combination of genetic algorithms and fragments. The test results indicated that the proposed method achieves higher PSNR SSIMM values than the existing methods.

Data Availability

The data that support the findings of this study are available upon request from the corresponding author.

Conflicts of Interest

The authors of this manuscript declare that they do not have any conflicts of interest.

Acknowledgments

The authors extend their gratitude to the deanship of scientific research at King Khalid University for funding this work through research group program under Grant no. R.G.P. 2/48/42.

Retracted: Design and Implementation of Intelligent Monitoring System for Head and Neck Surgery Care Based on Internet of Things (IoT)

Journal of Healthcare Engineering

Received 8 August 2023; Accepted 8 August 2023; Published 9 August 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

As a chronic disease, cervical spondylosis is prone to recurrent attacks as we age if we do not pay attention to protection, which can easily lead to symptoms such as osteophytes and herniated discs. In the early stage of cervical spondylosis, it is possible to alleviate the disease and prevent its aggravation by improving poor cervical posture and increasing cervical activities. This article analyzes the current situation and medical prospect of smart wearable devices with the prevention and treatment of cervical spondylosis in white-collar people as the starting point and smart wearable devices as the focus and provides a detailed analysis of the functions, categories, technologies, and applications of smart wearable devices to provide a technical theoretical basis for the construction of the subsequent research system. For the user's health state, some other physiological parameters are sent to data also through mobile Internet, and the user's physiological information is obtained on the computer database in also, which not only provides the monitoring function for the user's health but also provides the information of medical big data elements for medical and health institutions and so on. This article elaborates the requirement analysis of this system, based on which the system architecture design and module division are elaborated. It provides a practical and theoretical basis for further realizing the seamless integration of IoT technology and nursing information management system and improving its depth and breadth in the application of nursing information management system. From the perspective of the way of quantification of nursing practice activities, real-time monitoring, scientific management, and intelligent decision-making, it provides the basis for achieving the quality of nursing services, reducing errors, reducing labor intensity, and improving work efficiency and clinical research.

1. Introduction

With the rapid development of mobile technology and the widespread use of mobile Internet, the traditional Internet has slowly shifted to mobile Internet [1]. In this high-speed development trend, smart wearable devices are also growing rapidly and becoming a popular industry. In life, people want to use smart wearable devices to sense the outside world and their own information and to be able to process and communicate information more effectively with the help of computers, networks, and even other devices [2]. With the increasing awareness of health and health care requirements, all these are driving the medical model to shift from a symptom-centered treatment model to a prevention-centered, early diagnosis, and early treatment model, which has led to the focus on wearable products for health care. Smart wearable devices in the medical field have occupied an important position, and various medical devices such as smart blood pressure meter, smart blood glucose meter, and wrist-type ECG detector have emerged, making the seemingly professional medical devices start to come into ordinary people's homes [3]. Wearable health devices are devices that can be worn directly on the body or integrated into the user's clothes or accessories. Wearable medical devices can not only monitor blood sugar, blood pressure, heart rate, blood oxygen level, body temperature, breathing rate, and other human health indicators anytime and anywhere but also be used for the treatment of various diseases [4].

At present, wearable devices have made rapid development in the field of medical health, and smart wearable devices are moving from application research to practical application. In addition to monitoring users' personal health, they can also provide new diagnostic and treatment means for medical treatment, effectively solving the practical needs of clinical aspects, with good development prospects and broad market space. At the same time, the market scale of wearable mobile medical devices is expanding, and among the many mobile medical products, the most popular ones are wearable health products that provide medical services and monitoring for hospitals and patients [5]. In recent years, smart healthcare has been developing and growing, and smart ward systems in hospitals have attracted much attention. The construction of smart wards is developing rapidly. In smart wards, nursing staff can quickly access patient medical history information, doctors can use intelligent diagnostic data as auxiliary information for condition assessment and treatment, and patients can easily access health big data information in the process of medical treatment, so smart wards are an important part of realizing smart medical care [6]. Considering the special characteristics that the patient group has lower immunity and is more sensitive to environmental factors, the hospital ward environment is directly related to patients' health, and a good ward environment can create a good recuperation environment for patients. Therefore, a monitoring and control device is needed to monitor the environment in the ward in real time and strictly control the ward environment to meet the needs of patient recuperation. The continuous breakthrough of science and technology, the rise of artificial intelligence, the emergence of cloud computing and the Internet of Things, and the way of life in the ward have undergone further change and transformation, and the Internet of Things monitoring and control system with modern significance has gradually entered the ward [7]. IoT cloud platform is a kind of data processing and management platform that can provide services to consumers and enterprises. After cloud computing has been widely used, IoT technologies in logistics, education, agriculture, and many other fields have progressed. In these applications, the development cost of IoT can be high if it is arranged in local threads, while the cost is dramatically reduced by saving the transmitted data through the IoT cloud platform [8]. To network the physical endpoints, one needs IoT platforms to manage smart devices to achieve communication. The combination of IoT technology and cloud computing becomes inevitable [9]. Cloud computing adds fresh blood to the Internet and IoT development and also combines user applications with the currently popular web development technology, which makes the IT performance of products optimized, and consumers can get a good user experience and realize the cost optimization of enterprises [10].

The traditional intelligent system puts the server in the indoor environment and embeds it directly in the indoor gateway, which calculates, stores, and processes the indoor data, and the performance of the hardware gateway device cannot effectively meet the intelligent demand. On the other hand, due to the storage of data in indoor devices, it causes data disconnection, which is not conducive to the analysis and processing of user data. The rapid development of IoT cloud platform technology has strongly promoted the development of intelligent ward monitoring and control system. Based on the IoT cloud platform, intelligent management and control of equipment in wards can be realized, making the smart ward system solve the problem of data disconnection, and enterprises or users can simply and conveniently manage and control equipment, thus promoting the flow of the system into the market for mass production applications. Under the specific application scenario of the smart ward, the IoT monitoring and control system applied to the ward can integrate the current intelligent instruments, electrical resources, etc. To intelligently monitor and control the ward appliances. Users can view the working status of intelligent devices in wards in real time through cell phones and computers and can manipulate the operating parameters when the physical hardware is running, so as to get a good ward experience. The IoT cloud platform technology and system have scalable storage space and efficient data processing capability, providing a platform for the use of deep learning. The system can train artificial neural networks based on users' historical behaviors and users' interests, resulting in artificial network training models that enable users to understand their own habits of using equipment and also enable data prediction sharing through prediction of changes in environmental parameters, providing a foundation for future construction of intelligent wards. In the long-term direction, the system based on the IoT cloud platform has good security, data sharing, and fault tolerance features and has good development prospects and application value.

2. Related Work

Based on the requirement analysis of the IoT monitoring and control system applied to wards, the thesis designs the overall functional framework of the system. The thesis can be divided into two major parts: IoT hardware module and IoT software module [11]. Among them, the IoT software system includes the cloud platform server and the cloud platform client. Taking the ward application as the design background, different sensors of the ward environment monitoring module are used to collect the corresponding environmental parameters in the ward, including humidity, temperature, carbon dioxide concentration, and light intensity, connect to the network through WiFi wireless communication technology, upload the data to the TCP server inside the cloud server through TCP protocol, create a client in the TCP server, and transmit the data to the MQTT server, and the data information will be forwarded, processed, and stored in the TCP server [12]. The corresponding cloud platform client acts as a client of the MQTT server, and the MQTT client can subscribe to a topic to the MQTT server side, and once subscribed, it can publish messages to that topic, and any message that enters the subscribed topic will be printed to the JavaScript console, and the state changes of the sensor terminal and visual display data will be displayed in the cloud platform client web page in the form of animation. The same is true for reverse communication, which can be completed by the user clicking on the web interface to complete the control of the sensor terminal [13].

The behavior prediction module is based on an artificial neural network, using an attention model to complete the prediction of device usage, which is convenient for patients to understand their habits and provide direction for secondary development later. The system realizes the decoupling of heterogeneous hardware protocols by adding a cloud control software framework, which facilitates the management and control of information and makes the communication modules independent of each other and coordinates their work for easy development and use [14]. The core element and basic composition of IoT is still the Internet, which is an extension and expansion of the Internet and can realize information exchange, communication, intelligent positioning, and monitoring and control. In recent years, IoT has been widely used in production and life, introducing smart city, smart medical, smart energy management, smart transportation, and smart manufacturing into industrial and commercial fields. Currently, IoT platforms mainly consist of nonopen-source and open-source IoT platforms, and the following text briefly describes the two types of IoT platforms [15]. The computing mode of cloud computing is efficient, and IoT performs a lot of and fast computing, so consider combining IoT and cloud computing so that cloud computing provides a good application basis for IoT. Without the development of cloud computing, IoT cannot be successfully realized, and the development of IoT drives the progress of cloud computing technology; the two complement each other and are indispensable. Health care IoT is an important application area of IoT technology in the medical industry [16].

It is clearly proposed to “actively penetrate the medical consortium, use Internet technology to accelerate the interoperability and sharing of medical resources and information, achieve efficient business collaboration, and carry out more convenient telemedicine services” [17]. With the popularization of IoT technology and its full integration and application with 5G communication technology and computer technology such as cloud computing and big data, the influence of health care IoT is growing. Currently, China’s medical-related IoT can be roughly divided into three major application areas: smart hospital services, home health services, and public health services, covering multiple subapplications such as drug traceability, critical care, medical supplies management, and health management [18]. With the increase of people’s need for a better life, people’s demand for home health services is also gradually increasing, and the IoT platform for home health services has been given full attention. However, most of these applications still rely on the developed medical resources in the region to do some support, and the use is also very complicated, and the usage rate of IoT medical services is not high in areas with backward medical level [19]. At the same time, the user’s personal data involve personal privacy and interests; once leaked, they will have a serious impact on the user, and most of the current intelligent medical IoT products do not take into account the data security issues, many will even transfer the user’s data directly to the public cloud, and there are great hidden dangers [20]. Therefore, data security in smart medical is also the focus of attention of governments and researchers in various countries.

3. IoT Intelligent Assisted Head and Neck Care

3.1. Intelligent Monitoring of Head and Neck Wearable Devices. From the current point of view, the development of technology and the improvement of the quality of life also made wearable products available to people’s daily life, so that wearable devices are being known and applied by a large number of people; wearable products health care is the future direction of the development of intelligent wearable products. People use smart wearable devices to monitor various health and physiological indicators in real time, providing users with scientific guidance on health. Although there are many exploratory products in the field of posture monitoring, most of them focus on posture correction monitoring, mainly concerned with posture monitoring of the lumbar spine and other parts, by monitoring the user’s sitting posture, heart rate, breathing, and other data. The controller node can receive control commands sent from the cloud server to the hardware nodes, and the controller node performs the corresponding process according to commands such as switching on and off the fan and switching on and off the air humidifier. A two-directional control of the system is therefore achieved. However, for the user, the lack of data information from the information level to the transformation of action is precisely one of the reasons for the lack of user execution, mostly in giving advice and feedback, and not for the user to develop a corresponding improvement plan, the user needs to find their own way to make up for the shortcomings. At present, wearable monitoring products, monitoring posture, and other body indicators are very helpful to users, but considering that the daily scenarios of white-collar people are relatively irregular, interspersed with meetings, ambulatory work, leisure, study, and other scenarios, a single reminder mode sometimes becomes a disturbance and it may be necessary to consider setting the scenario mode to ensure that users have a good product experience. It is also necessary to integrate the corresponding ergonomics to ensure the comfort of the product.

The arrangement position of the neck ring monitoring node is directly related to the data collected by the sensor device to the model description; the closer to the monitoring target, the better the accuracy. Considering that the smart neck ring mainly monitors the cervical part of the human body, the product identification device can be placed near the cervical vertebrae, using the neck ring structure, which is conducive to the accuracy and fixity of identification. There is also an operation function area at the end of the neck ring, which can be used only through simple operation steps, and the whole process is easy and convenient. Information architecture is the process of normalizing the overall structure and specific functions of the application interface on the basis of the user task model. After the functional requirements of the smart neck ring application system are clear, the logic, hierarchy, and path of each information and element are presented by sorting out the relationship of the content information and elements of the system and constructing the relevant flowchart, making the target function and user’s needs reflected. The smart neck ring will be designed from the four modules of status, movement, discovery, and personal center, as shown in Figure 1.

With the continuous development of smart wearable devices in the medical field, the use of wearable devices to monitor and improve health has become a new way of health management, aiming to remind users to improve their poor lifestyle in real time by monitoring their behavioral data and providing targeted prevention and treatment suggestions. At present, it can detect blood sugar, blood pressure, heart rate, body temperature, human breathing, human posture, and other human physiological health indicators to provide users with scientific health guidance. In terms of cervical spine disease, wearable devices have already realized the monitoring of cervical spine dynamics, which can determine the posture and the activities of the wearer's cervical spine according to the position and angle of the wearer, providing a technical basis for wearable devices in the prevention and treatment of cervical spine disease. Combining with the characteristics and needs of white-collar people, the research and design of guardianship products can prevent and treat cervical spine disease for white-collar people, solve their cervical spine subhealth problems, let them maintain a good lifestyle while pursuing their ideals, and reduce the troubles of subhealth. It not only has social significance but also responds to the development of the times.

3.2. Wearable Device Sensor Node and Controller Node Design. The functionality of a hardware node is divided into two main parts: on the one hand, environmental parameters such as carbon dioxide concentration, light intensity, temperature, and humidity are to be recorded via sensor nodes and the collected data are uploaded to the cloud server via a WLAN module. The hardware notes in this white paper are complex and varied so that you can add new sensors and electrical devices depending on the environment and requirements or remove some sensors and corresponding electrical devices. After changing the devices, only some changes of the physical base interfaces are needed while agreeing on the message format for communication between the two sides, and then the design can be migrated to other physical bases, which is conducive to large-scale rollout. The sensor node includes a main control module, a WiFi networking module, a power and peripheral circuit module, a sensor module, and a controller module. The sensor module collects the environmental parameters in the ward, and the main control module converts the environmental parameters into the required physical quantities. The WiFi networking module can upload the processed data to the cloud server to complete data communication and also receive control commands from the cloud server to perform the corresponding control operations. The energy supply module is to provide various specifications of voltage requirements for each node device. The block diagram of sensor node and controller node structure is shown in Figure 2.

In the context of ward environment, the article requires large communication coverage, high transmission rate, good stability, and easy maintenance. WiFi is chosen as the

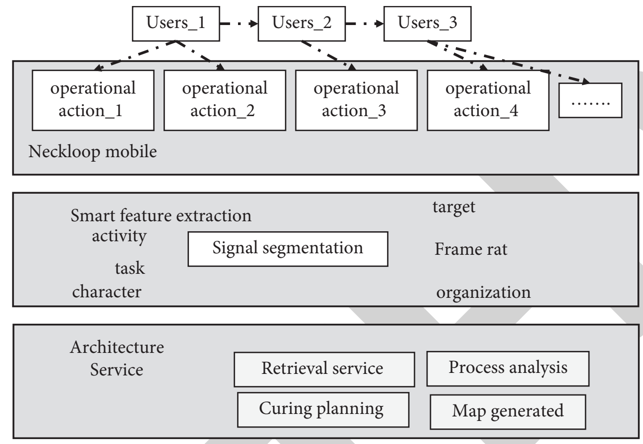

Figure 1: Neckloop mobile application state module information architecture.

wireless communication method for the IoT monitoring and control system in the ward. The USR-WIFI232-A2 is selected as the serial to WiFi communication module. The module is internally encapsulated and simple to set up to complete bidirectional data transmission between the serial device and the WiFi module. USR-WIFI232-A2, as a hotspot, can accommodate 32 WiFi clients at the same time and 32 TCP clients at the same time, providing convenience for the construction of the IoT system.

Several key elements in the recommendation system are defined:

$$T = \frac{\{T_1, T_2 \ldots T_n\}}{\sum_{i=1}^{N} Ti}. \tag{1}$$

User interest set for personalized fuzzy logic is as follows:

$$\mathrm{UT}(t_i) = \{w(u_i, t_i)\}. \tag{2}$$

The user is interested in personalized fuzzy logic set value.

When a user no longer has any user behavior on a resource to which a personalized fuzzy logic belongs after a certain time interval, we judge that the user's learning process for the resource has ended, and the interest value of the personalized fuzzy logic will follow.

$$w(u_i, t_i) = \frac{1}{1 + e^k} * \frac{t - t_0}{T}. \tag{3}$$

T is the time interval for the user's personalized fuzzy logic interest set to transfer; this interval is the time from the user's interest in a personalized fuzzy logic to the completion of the personalized fuzzy logic learning; t is the current time.

After the network parameters are set, restarting the WiFi module will complete the automatic network connection, at which time the WiFi module is accessed as a client and a connection is established with the cloud server. Take the fan as an example; its controller node receives the control command sent by the cloud server and sends the current state of the control node to the cloud server so that the server and the control node stay in sync and realize real-time update of the state information. Pulse width modulation

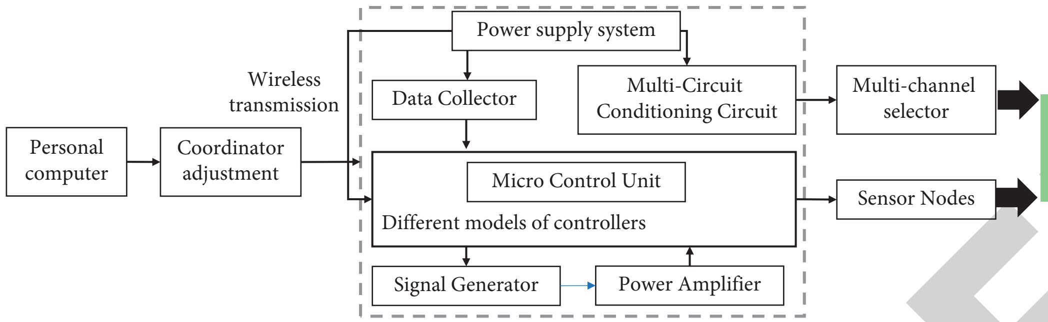

Figure 2: Sensor node/controller node architecture block diagram.

(PWM) technology is used to control the airflow for different gears. PWM technology is used to equate the required waveform by modulating the pulse width and then digitally encoding the analog signal level, i e., adjusting the information, energy, and other changes through the duty cycle to achieve different gears of airflow. At the fan hardware node side, the air conditioner switch is controlled by pressing the on/off button, real-time monitoring of the fan status is achieved by sending heartbeat packets, and the latest status of the node is sent to the cloud server in string format, which is stored, processed, and forwarded to the cloud platform client to achieve the animation display of the front-end page. The controller traffic change curve is shown in Figure 3. The controller nodes are monitored in real time to realize the transmission of status information of different sensor terminals and the execution of control commands from the server side, thus realizing the bidirectional control between the cloud server side and the sensor terminals.

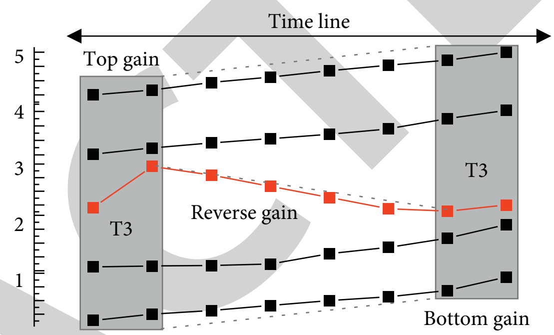

Figure 3: Flow gain selection timing diagram.

3.3. Design and Implementation of Cloud Server. Cloud servers provide interfaces to sensor devices and clients in stations where you can filter, store, and calculate data from sensor nodes and cloud platform clients. The article provides IoT systems on cloud platforms; cloud servers are data request and processing centers for the entire system while communicating with sensor nodes and, on the other hand, with cloud platform clients. Stores and processes requests and response signals from both sides. The two modules of the cloud server side are programmed using Python language to set shared variables and shared addresses in order to complete the communication between modules and realize two-way real-time communication and control transfer, which can be shown in Table 1.

Table 1: Real-time communication and control transfer.

Modules	Real-time communication	Control transfer
Node 1	NA	0.7739 ± 0.157
Node 2	NA	0.7652 ± 0.148
Node 3	0.6213 ± 0.269	0.6220 ± 0.169
Node 4	0.6349 ± 0.253	0.6539 ± 0.165
Node 5	0.7365 ± 0.183	0.8186 ± 0.129

The control transfer layer added between the cloud platform client and the sensor node can separate the client and the sensor node to achieve decoupling, thus allowing the two ends of the system to run separately during development and maintenance, reducing the coupling of the system. After the connection is completed, it is only necessary to negotiate and specify the communication protocol between the two sides and subscribe to it in the prescribed format, and the sensor nodes can quickly connect to the network to receive control commands and upload data to achieve bidirectional transmission of information between them. A block diagram of the cloud server architecture is shown in Figure 4.

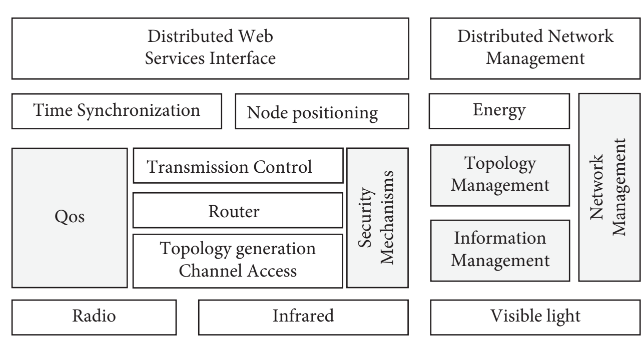

Figure 4: Block diagram of the cloud server architecture.

The cloud platform client acts as a client of the MQTT server and subscribes to the topic to the MQTT server side; once subscribed, it can post messages to the topic and any message that comes into the subscribed topic will be printed to the JavaScript console:

(1) Data messages based on the MQTT protocol are forwarded through the MQTT protocol proxy server to the MQTT client defined inside the TCP server, where they are forwarded, processed, and stored.

Then the data will be transmitted to the sensor nodes through the WiFi networking module via TCP protocol. The final realization of the cloud platform client real-time control sensor terminal execution.

(2) The same is true for the reverse data transfer, which is the transfer of sensor terminal data to the cloud platform client for presentation. The article selects the QoS1 level MQTT protocol, which completes the distribution at least once and ensures that the data from the sensor nodes must be sent out. Since the persistent communication between the client and the server requires constant message transmission, this makes the load on the server side increase.

(3) The article ensures that the signal changes can be listened to in real time by setting the heartbeat interval time, and that when there is no data transmission, the number of transmissions is reduced by lengthening the heartbeat interval time to maintain a continuous connection, achieving both minimizing the load on the server side and maintaining a two-sided connection. In the programming, the focus is on the four methods: connect, subscribe, publish, and disconnect.

4. Head and Neck Care Effectiveness Assessment and Testing

In the training parameters, the learning rate is set to 0.001 and the batch size is set to 128. According to the training curve, the model is better trained when the epoch is 5, and the switch threshold is set to 0.8. After the model training is completed, the trained model is called and tested using the test set. The accuracy of the test set for predicting the fan on/off state was 91.89% (accuracy is expressed as the ratio of the number of correctly predicted fan state samples to the total number of samples in the test set). For each predicted device, a binary model was trained, and a total of four models were trained in the article, each with the same training acquisition, to derive the accuracy of predicting the state of the device under the environmental state of the fan, air conditioner, smart lamp, and humidifier at a certain moment in the future, as shown in Figure 5.

The correlation between the air conditioner switch and the temperature value in the environmental parameters is relatively the greatest, and this chapter focuses on analyzing the correlation between the air conditioner switch and the temperature. The total number of times the air conditioner is turned on in different time periods in a week. The chart of the historical behavior of air conditioner switching in a week shows that the correlation between air conditioner switching and temperature values is low and not easy to predict, resulting in low accuracy of the test set. The results of user behavior prediction show that by fitting the historical serialized data with a neural network using the attention mechanism, the usage status of electrical devices at a future moment can be predicted with an accuracy of nearly 90%, as shown in Figure 6. The prediction accuracy can be improved in the future by improving the network structure and increasing the training set in an appropriate amount.

In several tests, it was found that when a sensor node is connected to the cloud server, when the node is disconnected due to an accident, the server is unable to determine whether the sensor is disconnected due to the lack of feedback. When the unexpectedly disconnected node is repowered, it reports an error because it already has a connection with the same name. The article solves this problem by sending "heartbeat packets," setting the TCP server to send a message to the sensor node every 20s, and if the sensor node receives it, it returns data to the TCP server, indicating that a connection exists. If the sensor node does not return a message to the TCP server after the TCP server sends a message to the sensor node, the connection is broken. At this time, close the connection channel and wait for the next reconnection to create a new channel; as shown in Figure 7, it can be seen that the connection can normally communicate again after the unexpected interruption. The above debugging shows that the two-way real-time communication between the server side and the sensor node is normal. This means that the integration of the two functional modules of the sensor node and the cloud server is successful.

Through research on the cervical spine subhealth of the white-collar population, the research was conducted around the psychological, physiological, behavioral and user needs of white-collar workers, and the real demands of users were discovered through questionnaires, in-depth interviews, and observation visits from which it was found that white-collar workers do not know and pay enough attention to their own cervical spine problems and have a long time of sedentary, lack of physical exercise, and lack of systematic and professional guidance on the prevention and treatment of cervical spine diseas and few of them really seek medical treatment. They usually relieve themselves by pressing the discomfort zone and sitting cervical spine exercises, as shown in Figure 8. Combined with the conclusions of the previous analysis, the overall product system design was carried out. The system includes the following: smart neck ring product hardware, R-neck software application, and the whole product system composition design. Taking into full consideration the actual requirements of white-collar workers in human-computer interaction, the product shape is chosen to be fashionable and lightweight, in line with the preferences and feelings of white-collar workers; in terms of software, according to the definition of product system functions and interaction methods, taking into account the busy nature of white-collar workers, a clear structure and hierarchical interface is designed to avoid interference from too many or overly complex factors, and relevant technical descriptions are made.

The system has several advantages over traditional IoT systems, (1) low coupling between client and sensor nodes, adding more control transfer layer than traditional architecture, which makes both sides function without affecting each other; (2) good platform migration, only needing to make some physical base interface changes and agree on the message format of the two sides of the communication to

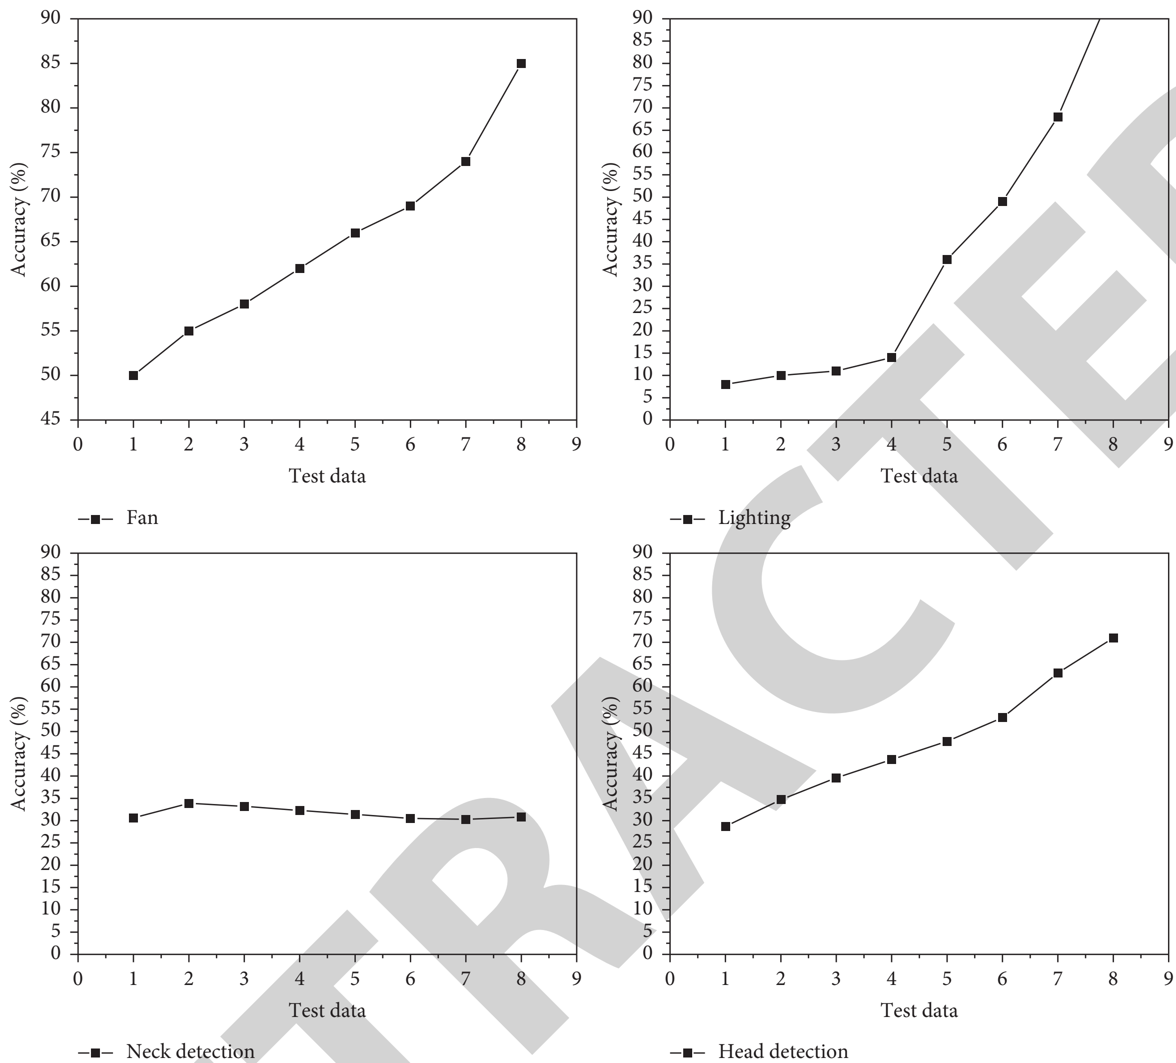

Figure 5: Device on/off test set accuracy.

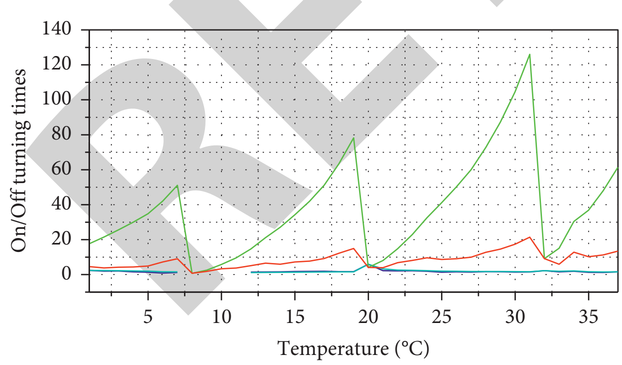

Figure 6: Chart of the total number of opens at different points in the week.

migrate the system design to other physical bases, unlike the traditional architecture which requires a lot of code changes; (3) friendly human-computer interaction, using the grid system to do a responsive layout to adapt to different screen sizes and real-time display of sensor node status through animation effects, you can click the animation to manipulate the sensor nodes. The client page display is further enriched and optimized by throttling and antishake and image preloading, which improves rendering efficiency and increases the dynamic web page effects intuitively and vividly, which improves the interaction friendliness and enhances user experience. (4) The system is predictive and uses an attention mechanism to achieve state prediction for different devices on the basis of artificial neural network. The accuracy rate of the test set is nearly 90%, which can meet the demand of patients and provide direction for the secondary development in the later stage. However, there are still problems in the system, which need to be improved continuously. There are some differences between the hardware and software of IoT devices; there are some delays that lead to miscalculations of information as the data are not updated in time. With regard to the optimization of the IoT control system for stations, there are few studies on scenarios where many users access simultaneously in a short time. Follow-up allows you to provide Nginx proxy web servers for load balancing to improve the responsiveness of your system to a large number of user data attacks in a short time. The behavior forecast

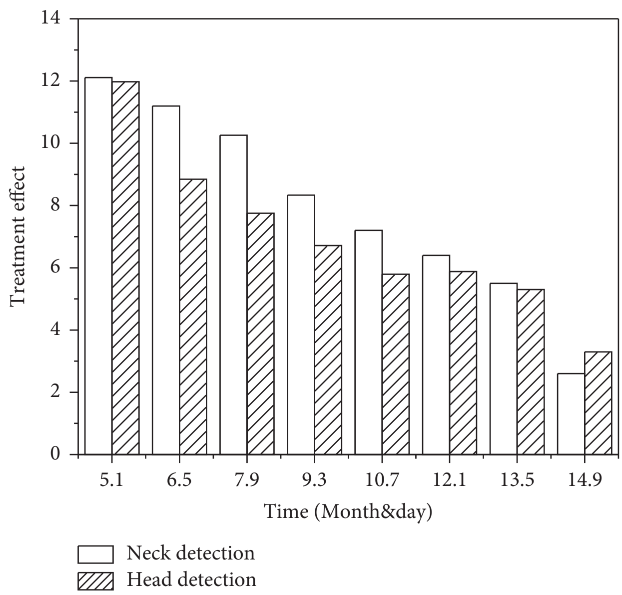

Figure 7: Change in head and neck treatment effect.

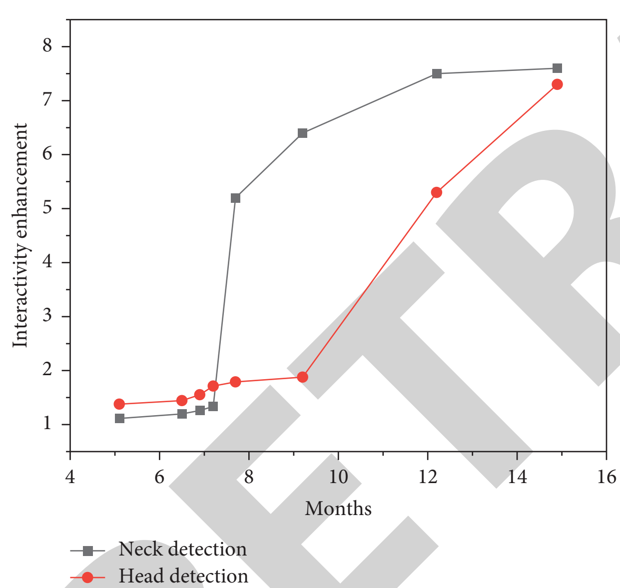

Figure 8: Changes in head and neck treatment interactivity enhancement.

module currently only implements device status forecasting. In later development, different input functions can be added based on the neuronal network model of the current attention mechanism.

5. Conclusion

In the IoT hardware system, the environmental monitoring node and the controller node are designed. The nodes include the main control module, WiFi networking module, power supply and peripheral circuit module, sensor module, and controller module. On the basis of hardware, software programs are written and the sensor node realizes the collection of environmental parameters in the ward, processes the environmental parameters using the main control module, and uploads the processed data information to the cloud service terminal through the WiFi module. In the IoT software system, the server-side publish-subscribe mode message transmission. The service handler is written in Python programming language to control and maintain the information of the management nodes, to complete the two-way communication between the server side of the cloud platform and the sensor terminals, and to realize the storage and management of the collected environmental data by building a database. Real-time animation display and control of sensor node status changes are realized using web development technology, and data are displayed in the form of visual images by ECharts js technology. In order to realize the user's personalized demand and make a differential response to the specified user, the attention mechanism is used to do data mining on the user's historical behavior, capture the key information that is helpful for the current behavior prediction, and complete the behavior prediction with an accuracy rate of 91.89%, which provides the basis and direction for future secondary development. The comprehensive test results of the system show that the system functions meet the expected objectives. The implementation of the IoT monitoring and control system applied to wards and the iterative improvement of its design methodology will be a reference for monitoring the ward environment, manipulating electrical equipment, and predicting future usage.

Retracted: Clinical Care of Hyperthyroidism Using Wearable Medical Devices in a Medical IoT Scenario

Journal of Healthcare Engineering

Received 26 September 2023; Accepted 26 September 2023; Published 27 September 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

This paper presents an in-depth study and analysis of clinical care of patients with hyperthyroidism using wearable medical devices in the context of medical IoT scenarios. According to the use scenario of the gateway and the connectivity of the equipment, the hardware architecture, hardware interfaces, functionality, and performance of the gateway were briefly designed, so as to monitor patients with hyperthyroidism more comprehensively and save labor costs. The gateway can provide access to different devices and adaptation functions to different hardware interfaces and provide hardware support for the subsequent deployment of the proposed new medical communication protocols and related information systems. A medical data convergence information system based on multidevice management and multiprotocol parsing was designed and implemented. The system enables the management and configuration of different medical devices and access to data through the targeted parsing of the underlying medical device communication protocols. The system also provides the automatic adaptation of multiple types of underlying medical device communication protocols and automatic parsing of multiple versions and can provide multiple devices to process fused data streams or device information and data from a single device. The use of event-driven asynchronous communication eliminates the tight dependency on service invocation in the synchronous communication approach. The use of a metadata-based data model structure enables model extensions to accommodate the impact of iterative business requirements on the database structure. Real-time patient physiological data transmission for intraoperative monitoring based on the MQTT protocol and video transmission for intraoperative patient monitoring based on the RTMP protocol were implemented. The development of the intelligent medical monitoring service system was completed, and the system was tested, optimized, and deployed. The functionality and performance of the system were tested, the performance issue of slow query speed was optimized, and the deployment of the project using Docker containers was automated.

1. Introduction

Relatively inexpensive domestic infusion monitoring devices have been marketed, but they can only be monitored individually and cannot be networked for systematic management [1]. Clinical infusion work still suffers from untimely fluid replacement, inaccurate infusion speed, and failure to detect infusion failure in time. With the frequent emergence of problems such as inefficient medical treatment caused by the insufficient and unreasonable allocation of total medical and health resources, inadequate medical risk control, weak primary health service system, imperfect medical security system, disorderly production and circulation of drugs and medical equipment, inflated prices, and serious disputes between doctors and patients, the problem of how to solve the "difficulty of seeing a doctor" and "expensiveness of seeing a doctor" caused by the imperfect medical system has become more acute [2]. The development and application of Internet of Things (IoT) technology in the medical field have emerged in the world, such as medical waste tracking management, special patient monitoring management, baby monitoring, and elderly vital signs' home monitoring. As IoT technology has precise sensing ability for mobile individuals, there are numerous mobile devices in the clinical medical field; thus, with the continuous development of IoT technology, it has successfully integrated into the clinical medical industry and has provided great help to the construction of smart therapy, which has now become one of the hot spots that the IoT field is concerned about [3].

A medical examination device with antidropping function for clinical use in hyperthyroidism and its control system includes a central processing and control module, a human body sensing module, an action recognition module, an overflow detection module, a height detection module, a sound alarm module, an opening and closing control module, a drive module, a status indication module, and a power supply module. The present invention can automatically identify human body movements, can realize automatic unpacking, and is convenient for putting the used syringes into the syringe storage box, making the recovery of the syringes convenient and preventing the inspectors from touching the intelligent storage box. For more safety and hygiene, the test tube holder and the intelligent storage box are fixed by the first electromagnet and the second electromagnet, which can make the placement of the test tube holder and the intelligent storage box more stable and prevent them from falling off during use; at the same time, the electromagnetic field is controlled by the control button. The working state of the body is convenient for taking the test tube holder and the intelligent storage box, and the practicability is higher. Cloud computing, big data, artificial intelligence, and so on have been the hot spots of general concern and technical research in various industries in recent years, and their related technologies have gradually become popular and mainstream application technologies in the process of informatization and intelligence in various industries. At the same time, in the medical field, large-scale regional medical and health information systems and large health care data centers are also under construction in full swing [4]. Nursing is an important part of health care delivery, and the application of information technology in nursing can reduce duplication of effort and nursing errors, allowing clinical nursing staff to spend more time caring for patients and substantially improving the quality of nursing services [5]. Therefore, nursing information competence has become a basic quality that every nurse must possess, and the improvement of information technology in medical services is a great driving force for the development of medical care. Through the study of nursing information competence theory and practice, a set of scientific and reasonable evaluation systems of nursing information competence of clinical nursing staff is developed [6]. The index system of nursing information competence of clinical nursing staff can provide an objective reference basis for clinical nursing staff and nursing managers on the one hand, and provide objective reference indicators for cultivating efficient clinical nursing staff and improve the overall information literacy of nursing staff on the other hand [7].

Wireless sensors used in the field of environmental monitoring such as temperature and humidity sensors are widely used in soil monitoring, infrared sensors are widely used in elevator escalator human detection, light sensors and sound sensors are widely used in intelligent electric lights, smoke sensors and flame sensors are widely used in security warning, and so on. These sensors use different networks to upload data and after processing and analysis to achieve real-time monitoring of human health and real-time monitoring of the environment. People from many remote areas flock to cities in search of a better medical environment and resources; especially in many cases, there is a need to ensure high-definition video call capability for ambulances to enable remote preemption. Establishing healthcare information systems that use Internet technology to connect hospitals to hospitals and hospitals to patients can greatly reduce the potential for unnecessary transportation, lodging, travel, and illness delays. However, there are still many shortcomings in the current healthcare information technology. Medical scenarios such as remote video suffer from certain delays due to limitations in network structure and medical informatics equipment. At the same time, there is a wide variety of medical informatics, which needs to be optimized for specific medical informatics scenarios.

2. Related Work

This section discusses the specific implementation of the Internet of Things in the health field and proposes a construction concept related to the smart hospital based on the Internet of Things [8]. It is considered that smart medicine is a medical system that combines electronic medical records, electronic health records, and medical Internet of Things with medical cloud data as the core and Internet of Things and data transmission and exchange as the technology to build medical and health services and optimal management [9]. Based on the new medical and health service model of "Internet + health care," the shortcomings of the traditional medical service model are analyzed, and the tasks of intelligent medical action are proposed, mainly including medical Informa ionization and medical body construction [3]. The construction of smart medical applications based on IoT technology, including mobile medical care, medical equipment management, and smart hospital service system, was elaborated to gradually realize the combination of IoT and medical services [10]. The purpose of cancer treatment is not only to prolong survival time but also to maintain and improve the quality of survival, which is not only in line with the natural law of cancer development but also consistent with the humanistic concept of "people-oriented" advocated by the state [11]. The evaluation of the quality of survival of cancer patients has become an important aspect of cancer care, but previously it mainly focused on common tumors such as gastric cancer, lung cancer, and breast cancer [12].

Since the incidence of thyroid cancer has shown a trend of increasing year by year in recent years and at the same time, with the advancement of medical screening, diagnosis, and treatment techniques, the postoperative survival of thyroid cancer is more considerable, many scholars have begun to focus on the study of the survival quality of thyroid cancer patients [13]. Medical process monitoring usually still uses manual rounds, transcription of infusion orders, and transcription of inpatient information small card, so the hospital ward nurses also need to blindly run back and forth between the nurse's station and the ward and cannot have a clear sense of the patient's various help but make the planning of the nurses work greatly reduced [14]. With the continuous development of smart mobile devices, mHealth has also begun to influence the way of medical management, doctor-patient communication mode, and health product innovation. Medical services and information are provided using computers, handheld mobile terminals, and software for smart devices combined with mobile communication technology connected to the network [15]. Later, as mobile communication technology continues to develop, increased hospitals are building mobile health care workstations using mobile devices such as PDAs.

The traditional infusion set is still the most used infusion tool in clinical care, and its monitoring method is based on manual inspection. During infusion, the bag or bottle is hung above the needle insertion site of the infuser, and the drip rate is set by the nurse according to experience by manually adjusting the pulley on the infusion tube. When the infusion is about to end or when discomfort occurs during the infusion, the patient or caregiver is required to manually notify the health care worker to come and deal with it in time. This not only increases the labor intensity of health care workers but also makes clinical safety not improved. The management system monitors the infusion status in real time in the field through wireless communication technology, calculates the end time of infusion, and gives an alarm to remind us when the infusion is finished. Any special situation during infusion can be contacted with the nurse main console through the patient call interconnection system. The system can not only reduce the labor intensity of nursing staff and improve work efficiency but also significantly reduce the hidden dangers that may occur during the infusion process, which is the future application trend of clinical medical nursing work.

3. Analysis of Clinical Care of Hyperthyroidism with IoT Wearable Medical Devices

3.1. Medical IoT for Wearable Medical Devices Design. The medical scenario considered in this paper is the scenario where multiple medical devices need to be connected and provide real-time monitoring to the patient, such as an operating room or emergency ward. In existing medical scenarios, it is often necessary to add multiple medical monitoring devices such as monitors, ventilators, and syringe pumps. In addition to this, there are also environmental monitoring devices such as cameras, monitor video encoding boxes, and environmental sensors. All these devices need to be set up independently on the device by the healthcare provider; for example, the monitor needs to be set up for network settings, IP settings, data display item settings, alarm settings, and so on, the syringe pump needs to be set up for push mode, drug settings, channel settings, alarm settings, and so on, the ventilator needs to be set up for ventilation mode, respiratory rate, airway pressure, tidal volume, alarm settings, and so on, and the camera and coding box need to be logged into the device access page for resolution, bit rate, push stream address settings, and so on.

At the same time, the medical process also requires medical personnel to always monitor the operating status of the equipment and alarm information to prevent medical accidents caused by unexpected equipment failures and parameter alarms. In addition, the maintenance of equipment also poses certain difficulties; after the failure of medical equipment, medical staff often need to consult the equipment manufacturer or hospital technicians to recover according to the equipment manual [16]. Environmental monitoring devices such as cameras also require login to the device page to enter a user name, password, and device IP before they can be accessed, as does the setup of the coding box.

At the same time, the unified management of devices such as device registration, device online, and device offline also needs the uniqueness of the device identification to be distinguished, how to ensure the uniqueness of the device is also a problem that needs to be studied, and a more reliable scheme is based on the device address (MAC address, USB address, and serial port address) and device protocol to register the device ID as shown in Figure 1.

There is more overlap in the way these three models apply IoT, and the main component of the project lies in the information system. Existing IoT products are mostly designed to solve specific challenges and hardly meet the needs of most healthcare organizations for system functionality. The deep integration and scale utilization of IoT and healthcare require a mature all-in-one applicable solution.

This paper examines the impact of IoT on the development of medical consortia on a macrolevel. There are various forms of IoT applications, which are currently divided into four categories, care management, medical device management, supply management, and wearable devices, and different applications have different impacts on medical consortia, while medical consortia are divided into four categories, medical groups, medical communities, specialty alliances, and remote collaboration networks, and different medical consortia have different needs for IoT [17]. So microscopic impact of IoT on the development of medical consortia is governed by the form of IoT and the type of medical consortia. In contrast, the study of the macroimpact is not influenced by these factors. In terms of aiding decision-making, the scores of macroimpact are categorized based on factors such as application technology and type of IoT project, and the conclusions of the analysis can be better used as a basis for decision-making. A neural network algorithm is used because our experimental data are limited, and only the algorithm using a neural network can get better results.

The ward call system is a comprehensive system project, which should be considered from various aspects such as its function, performance, cost, and application of modern related technology. Based on such requirements, it is suitable to develop an integrated intelligent medical call system that integrates the functions of bed call, bathroom call, and corridor screen display using CAN bus technology, as shown in Figure 2. As ZigBee technology itself is suitable for wireless data transmission in a small area, in an environment

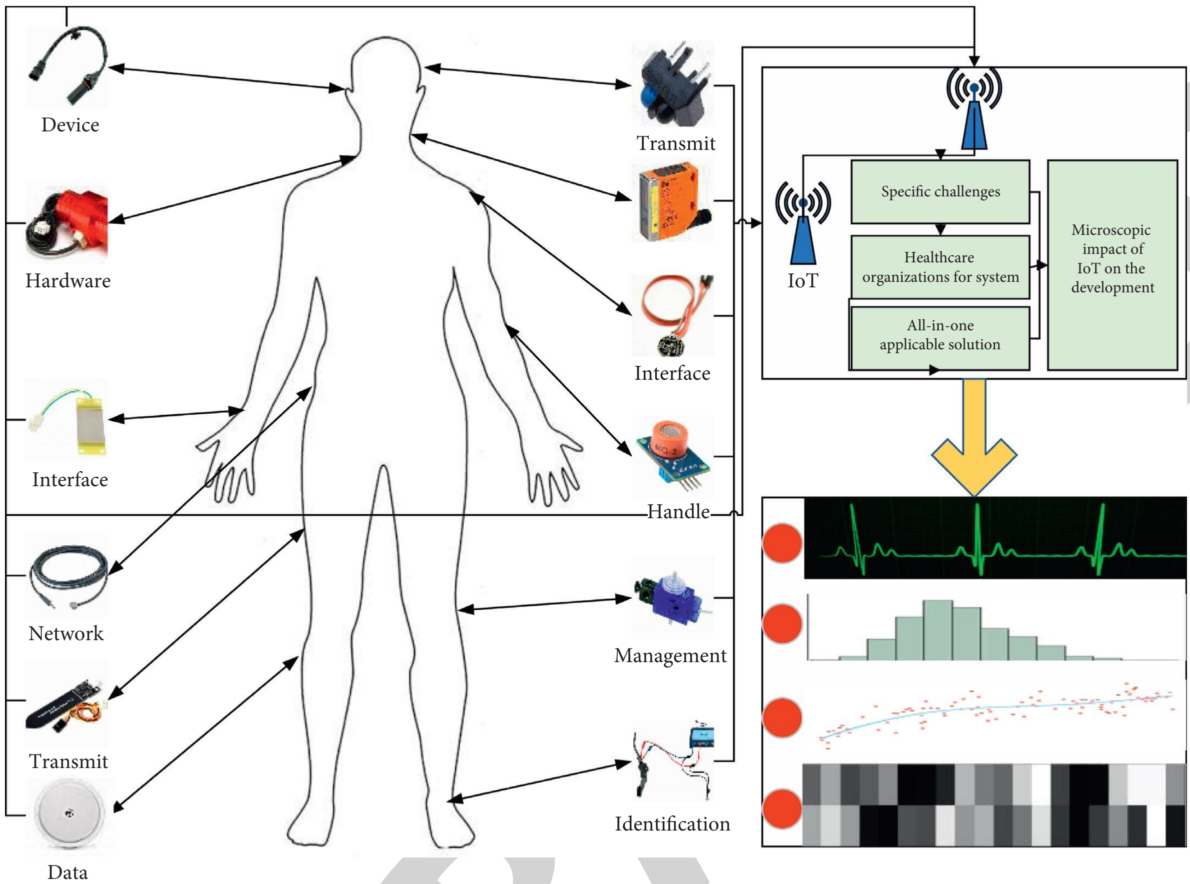

Figure 1: Medical IoT framework for wearable medical devices.

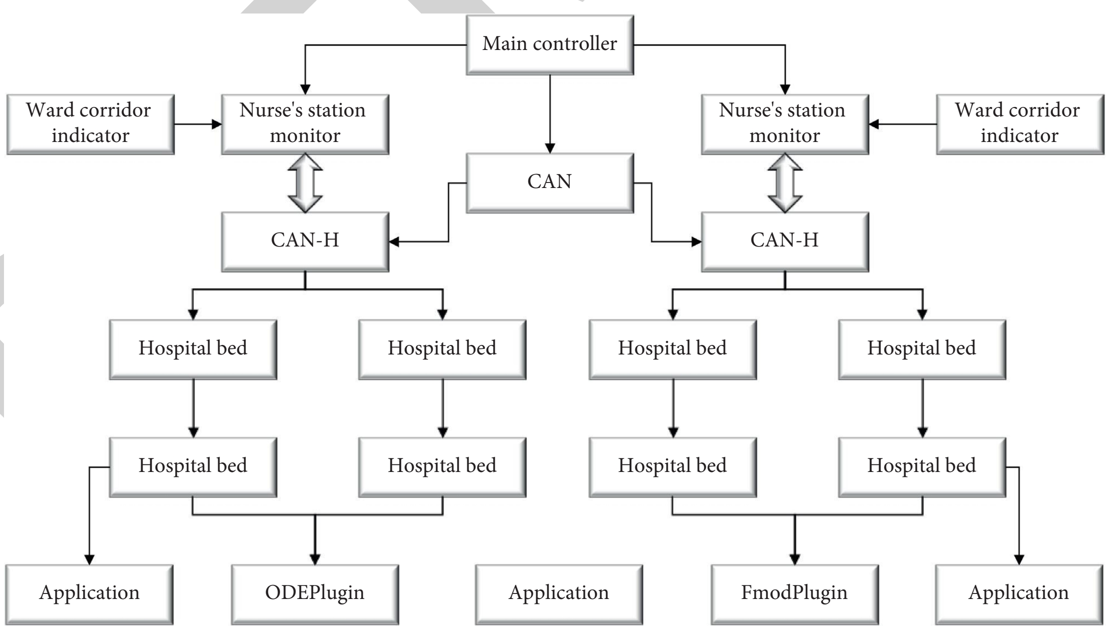

Figure 2: Signal transmission diagram of the call system.

with a large area and relatively complex building structure such as a hospital ward, the loss rate of wireless signals is inevitably high; if the data reception and forwarding capacity are increased by adding terminals, the problems of wireless signal collision and high probability of error codes cannot be solved; it is impossible to set up a large sensing network covering the whole hospital. It is impossible to set up a large sensor network covering the whole hospital.

The ZigBee terminals are wired and powered because they need to forward signals at any time and have high energy requirements. The ward call system uses the CAN bus for data transmission, which is mainly based on security considerations to ensure reliable transmission, but there are disadvantages such as poor system scalability and the need for wiring in the ward.

Any unit connected to the bus can start sending messages if the bus is idle, and if two or more units on the bus start sending messages at the same time, the priority can be determined by receiving or blocking the message according to its ID (identifier). In the ward call system, the call button located in the ward only needs to be pressed when the patient has an emergency to send a call message to contact the nurse and does not transmit the message at all times. The number of nodes that can be connected to the CAN bus is theoretically unlimited, but it is limited by the bus time delay and load capacity. If the number of connected nodes needs to be increased, then the communication speed can be reduced; conversely, if the transmission speed needs to be increased, then the number of connected nodes can be reduced.

For the award, the number of wards is relatively high. The main functions of the clinical medical information management system are to monitor the infusion status of patients in real time, to respond to patients' needs in time, to understand the situation and needs of each ward, and to realize scientific management of the whole ward and ward so that the efficiency of medical and nursing workers can be improved, the overall service quality of the hospital can be improved, and the medical safety and patient satisfaction can be enhanced.

3.2. Analysis of Clinical Care in Hyperthyroidism. With the continuous development of business, the amount of code of the whole system will become increasingly complex, and the system architecture will become increasingly complex. There are many problems faced by using monolithic architecture, such as low development efficiency, increasing maintenance cost, large deployment impact, poor scalability, and high technology selection cost. Therefore, at the beginning of the system design, the system should be split into multiple modules with the idea of microservices [18]. When the system is gradually upgraded with iterations, the vertical expansion of the system can be achieved by upgrading the in-service functionality of individual services. When the upgrade of existing microservices cannot meet the business needs of the system, new microservices can be added to provide new service capabilities to cope with complex business needs.

$$R_1 = \frac{V_{cc}^2 - V_F^2}{I_F^2}. \quad (1)$$

In the formula (1), R_1 represents the serial number 1 resistance, V_{cc}^2 represents the voltage difference, V_F^2 represents the negative voltage, and I_F^2 represents the current of the circuit. The way services communicate with each other also affects the degree of interdependence of the services.

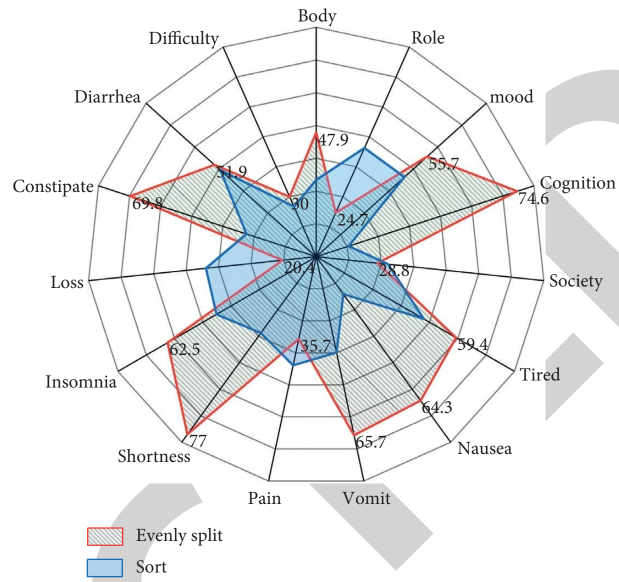

Figure 3: Status of quality of survival.

Synchronous and asynchronous communication are two ways to implement messaging between services. Rest HTTP is a request/response-based synchronous invocation method of communication that encapsulates parameters into JSON format for messaging. Although this communication method is simple to invoke, one party sends a request and waits for the request to be transmitted to the other party and waits until the other party returns after the request has been fully processed before proceeding to the next operation.

Another way of communication between services is asynchronous message invocation, and the message sender only needs to send the message and does not need to care which service is to receive this message; that is, the service does not know who they are called by and does not know which service they will call. Detaching the entire flow of business execution from the module reduces the coupling between the caller and the called, as shown in Figure 3.

It provides edge computing platform services, including support for edge application deployment, providing a unified portal for application deployment. It supports configuration distribution with streaming media equipment, and reports streaming configuration information to the dedicated network operation management platform. It also supportsthe provision of service capabilities, including location services, bandwidth management services, and wireless network information to industry applications through the wireless side or core network side interface. Based on specific business scenarios, it supports providing applications with capabilities such as video streaming and AI algorithm library to meet application requirements.

The scheduler can be seen as a parent node, and the queues/schedulers being scheduled are seen as children. The scheduler can schedule multiple queues and can schedule multiple schedulers. The parent node is the traffic convergence point for multiple child nodes. The classification rules of nodes at different levels can be oriented to different classification needs (e.g., users and business types), each

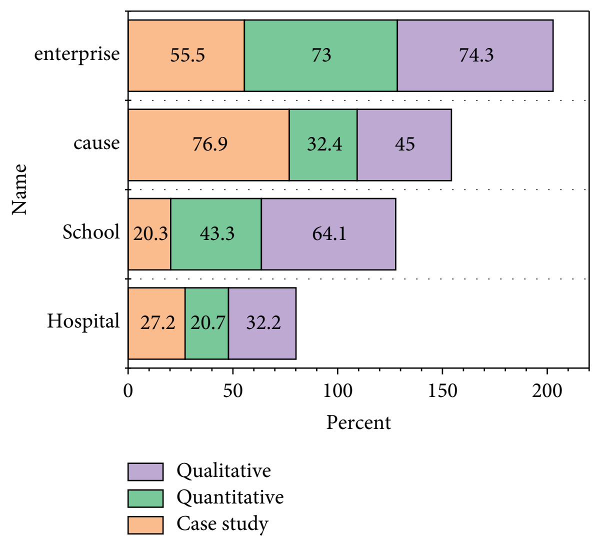

Figure 4: Proportion of data sources.

node can specify classification rules and control parameters to classify and control the traffic once, and different control actions can be done on the traffic at different nodes, thus realizing multiservice, multilevel, and multiuser management of the traffic.

$$\frac{R_{11}}{R_{10} - R_{11}} \cdot V_{cc} = 1000\, mV, \tag{2}$$

$$R_{10} \approx 8R_{11}. \tag{3}$$

In the formula (2), R_{11} represents the resistance between 1 and 2, R_{10} represents the resistance from the initial point to point 1, and the voltage value difference is 1000 mV. First, the subject of assessing the impact of IoT on the development of healthcare clusters is one or more healthcare clusters, with more than ten healthcare organizations in each cluster, and it is practical to use success rates as impact evaluation. Second, the market size in the field of medical IoT has maintained a 25% growth rate in 10 years and is forecast to remain the same in five years. Therefore, the proportion of IoT projects and the future changes in the development trend are not significant.

$$M(x) = w_2 \sigma(w_1 x), \tag{4}$$

where $M(x)$ represents the state at the X position, w_2 represents the weight of the second point, σ represents the state coefficient, w_1 represents the weight of the first point, and x represents the corresponding position. For IoT projects with high technology, the breakthrough products make a certain impact indicator score of 1, but the overall score tends to be close to 0 due to the difference in technology or application focus of other IoT projects. But because IoT technology is in the overall development stage, the overall change in the impact of IoT on healthcare in the next five years is small, and the impact of high technology projects, although growing faster, will not affect the overall statistical level as shown in Figure 4.

Firstly, based on the author's source, the data source, and the type of IoT projects, applied IoT technologies were counted, and percentage stacked bar graphs were plotted to understand the researcher's preference. After analysis, the researchers showed differences in the source of data and the two IoT technologies applied. Researchers from hospitals and schools were more likely to evaluate the impact of IoT on the development of healthcare clusters through qualitative methods, while researchers from the health sector and businesses were more likely to evaluate through case effects. Researchers from hospitals are mainly users of IoT products, researchers from schools are mostly product development designers, and the evaluation of the effects of IoT applications by these two types of researchers is more subjective. The technologies applied by researchers from hospitals and schools are mainly wearable devices, while health authorities and companies focus more on the integrated use of IoT technologies [6]. From Figure 4, it is known that researchers from schools and hospitals together account for 72.9% of the total researchers, so researchers from hospitals and schools will have more influence in the evaluation of the impact of wearable device cases on the development of health care clusters.

$$Q_N(w) = \frac{1}{2} \sum_{i,j} \left(1 + P_{ij}\right)^2 \left(m_i - m_j\right). \tag{5}$$

In formula (5), $Q_N(w)$ represents the state where the weight is w at the position of N, P_{ij} represents the weight component of the i-th row and j-th column, m_j represents the initial component, and m_i represents the end component [19]. The lack of interoperability of medical information systems has always been an important factor constraining the construction of health informatization, and there are two reasons for the difficulty in sharing information [20].

The study on the working status of the study subjects found that 53 cases (30.64%) were currently engaged in domestic work and 44 cases (25.43%) were still working, which was related to the fact that the survey subjects were mostly middle-aged women mainly from rural areas. The types of medical insurance of the survey respondents were mainly new rural cooperative medical insurance and urban employees, with 91 cases and 62 cases, accounting for 52.60% and 35.84%, respectively [8, 21, 22].

4. Analysis of Results

4.1. Performance of Medical IoT Systems for Wearable Medical Devices. As multiple surgeries are performed at the same time in a hospital, multiple monitoring devices are used to monitor the physiological status of the patient during each surgery. The real-time data transmitted from the gateway to the upper layer during the surgery includes both the physiological data of the patient collected by the monitoring device and the alarm information of the monitoring device. In addition to this, the client may also downlink the configuration information of the device at this time, so the concurrency of real-time data information received by the client at the same moment can be large. Using multiple

Figure 5: Real-time data display of the monitor.

threads to receive the patient's physiological data, alarm information, and configuration information separately, and using multiple threads to process the real-time data information, the CPU resource utilization can improve.

Considering that each time the real-time data arrives, a thread needs to be created to process the data, and after processing is complete, the thread must be destroyed to avoid resource usage; this process will keep consuming CPU resources, so a thread pool is used to implement a thread reuse mechanism and eventually interthread scheduling. The real-time curve board for ventilators and syringe pumps is designed according to the real screen of ventilator and syringe pump devices, and the expansion capability is reserved here to switch the display of different content on the page to accommodate the display of content for other types of device access. The real-time data display for the monitor is shown in Figure 5.

A complete test environment is set up in the laboratory as shown in Figure 5. The gateway communicates with the medical devices through the default intranet IP in the gateway, and the gateway, video encoding box, and network pushing camera are then connected to the laboratory LAN to achieve data and video transmission; the server and client are connected to the laboratory LAN to achieve system access and data communication with the gateway. The hardware environment is mainly a monitor connected to the gateway through the network port, a ventilator connected to the gateway through the serial port, and a syringe pump connected to the gateway through the USB port. Real-time data are collected by these three devices and collected by the

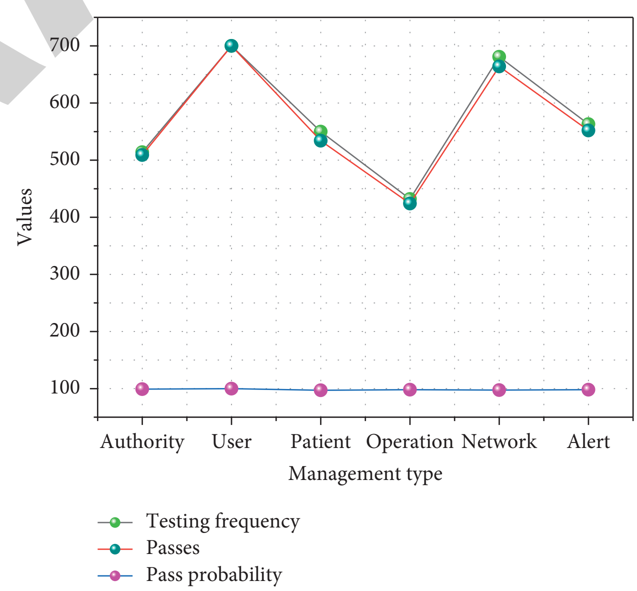

Figure 6: Graph of test results.

gateway, and then the gateway connects to the lab intranet through a wireless connection to realize data transmission with the server.

The video encoding box is connected to the monitor through a VGA port to collect the live video stream of the screen and then connected to the router through the network port to realize the live stream push. The webcam collects indoor scenes and connects to the router through the network port to realize the live streaming push of indoor scenes.

The operation functions of user management are routine operations, so there is no need to consider the concurrency problem, and only the feasibility of the function needs to be tested, as shown in Figure 6. The operation management module can complete the basic operation of the operation room and can realize the basic functions of intraoperative monitoring, which can enter the operation room to view the scene of the operation, perform the operation triggered by the key time points of the operation process, view the monitoring records and quality control records, view the live screen of the monitor screen and the live video broadcast of the scene captured by the camera, and view the real-time collected parameters of the anesthesia machine, the parameters of the syringe pump, the monitor parameters, and so on, and the basic functions of intraoperative monitoring can be achieved normally by changing different models of test devices during testing.

As the underlying gateway realizes the adaptation to different types of medical devices, the data collected by the devices are parsed and processed into a unified format and then sent to the server, and the gateway can realize the transmission of real-time data, so when the data are transmitted to the server, the differences between devices of different manufacturers are already shielded. The gateway and device management module realize the unified control of the gateway and various medical devices, and the system supports the management of various types of medical devices. Alarm management realizes the management of medical device alarms and abnormal alarms of physiological indicators of patients during surgery. In summary, the overall system function test pass rate is 100%, which means that all the modules of the system can be realized normally, and the system is currently applicable to all the gateways that have been successfully adapted to the devices.

4.2. Clinical Care Outcomes in Hyperthyroidism. Informatization of nursing services not only enhances efficiency and allows nursing staff to spend more time facing patients but also leads to higher patient satisfaction with the nursing staff. Therefore, the integration of healthcare services with Internet platforms is becoming the direction of information technology development in medium and large hospitals. Nursing staff plays an important role in hospitals, while some of our nursing staff have not yet been able to acquire some knowledge and skills in nursing informatics. As nursing staff should all need to master the professional knowledge and application related to nursing informatics as well as have the ethics related to nursing informatics.

It was concluded from reviewing a large amount of literature that the evaluation system of nursing information competency in China is necessary because it is less and one-sided compared to foreign studies. The nursing information competence evaluation index system established in this study can provide a theoretical basis for the development of a scientific and reasonable nursing informatics training program for nursing staff. The increasing number of hospitals applying 5G "Internet medicine" shows the importance of establishing a set of nursing informatics evaluation systems suitable for clinical nursing staff. The development of nursing informatics education and the improvement of nursing informatics personnel are effective means to reduce nursing errors and improve work, as shown in Table 1.

This study illustrates that the process of information technology construction must put the legality and security of information in the first place, information security is a prerequisite for the behavior of nursing information technology, and it is urgent to improve the awareness of information security of nursing staff; if there are information security problems, all information construction will be impossible to talk about, so it is necessary to first guarantee the security of nursing information and establish a security barrier to prevent nursing errors and management Vulnerability. The second level indicator is "nursing informatics awareness," and the weight coefficient of nursing staff's "subject awareness" is 0.1295, which indicates that nursing staff needs to constantly realize that they need to continuously learn to make up.

This indicates that nursing staff needs to be aware of the need for continuous learning to make up for their shortcomings, improve nursing information capabilities to enhance work efficiency, and realize the organic integration of information technology with nursing work and nursing management. "Knowledge of nursing informatics" has a low weighting factor compared with other indicators, but it is indispensable in nursing work. Without mastering the concepts, views, and theoretical systems of relevant theories and without a certain amount of relevant theoretical training, it is impossible to put forward any new views and concepts even if the practice time is longer and the practice is more, let alone put forward systemic new theories.

However, considering that all patients were aware of their thyroid ultrasound results before admission and with the increasing accuracy of medical technology, patients had a basic judgment of their condition before surgery; coupled with the health education of the medical staff, they had a scientific understanding of the good prognosis of thyroid cancer, as shown in Figure 7.

Knowledge of thyroid cancer disease is extremely low, and people fail to realize the closeness of these factors to the prognosis of the disease. Finally, the reason for the lack of statistically significant knowledge about the pathology of the disease may be related to the fact that some of the patients have postoperative pathological results of thyroid cancer, although their family members concealed the true nature of their pathology, considering that all patients knew the results of their thyroid ultrasound before admission, and with the continuous progress of medical technology ultrasound results becoming more and more accurate, patients have a basic judgment of their condition before surgery.

In life, the role of women is multiple; on the one hand, like men, they bear the important responsibility of promoting social development, and on the other hand, they also bear the sacred responsibility of taking care of their families and giving birth to and educating their offspring; at the same time, women have special body structure and physiological

Table 1: Multiple linear regression analysis.

Independent variable	B	Beta	FA	P
Constant	0.892	0.617	0.732	0.694
Hospital level	0.484	0.939	0.598	0.769

mechanism; therefore, the physical and mental health of women will be directly related to the harmony of a family or even the whole society. Strengthening the psychological care of female thyroid cancer patients will help to reduce the occurrence of anxiety, improve the quality of survival, and promote the prognosis of the disease.

5. Conclusion

In this paper, a new medical-oriented IoT gateway is proposed for the traditional medical scenario where the underlying medical devices are of various types and the data communication protocols used are closed to each other, the data cannot be processed and aggregated effectively, and the hardware, interface communication protocols, and information system of the gateway are designed and implemented. The gateway can provide a variety of hardware interfaces for device access and is equipped with a high-capacity lithium battery to cope with emergency emergencies. The internal information system can parse the protocols of the underlying medical devices that access the gateway to obtain medical monitoring data, and the interface communication protocol can provide data access interfaces and medical device management interfaces to external terminals. Therefore, the gateway can unify the management and configuration of all medical devices and IoT devices in the ward, automatically resolve the medical protocols of the underlying medical devices to obtain data, and realize the real-time pushing of data streams through the processing and fusion of data. By deploying the gateway in a hospital operating room for field testing, it is found that the gateway can effectively shield the differences of the underlying devices in the ward, the diversity of medical communication protocols, and the isolation of data and realize the unified management and configuration of devices, the automatic parsing of medical communication protocols, the secure encryption of data processing and fusion, and the real-time pushing of monitoring data of multiple devices in the ward. The relevant functions of the gateway have been effectively verified, and good remote real-time monitoring has been achieved. Our research results can be fully applied in practical situations.

The final loss function in the deep learning neural network is composed of other functions in the network. Due to the existence of a large number of non-linear functions such as activation functions in the network, the entire deep learning model presents the nature of a nonconvex function. As optimizing the nonconvex model is more difficult, the solution of the nonconvex function can only represent the local but not the global. The BP algorithm is an algorithm for updating parameters and is mainly applied to deep neural networks. In this article, we will study the volume holographic image library technology, design the basic optical storage path, realize single-point multistorage in the medium, and multiplex technology with simple structure to increase the information storage capacity of volume holography. We have studied a method to read out the holographic image library with the same diffraction efficiency. The test part of the system is to test the entire facial image pattern recognition system. The reliability and stability of the system have been tested for performance and function. Successful testing is the key to the quality and availability of the system. Therefore, this article first analyzes the rules of deep learning, combines the characteristics of image segmentation algorithms and pattern recognition models, designs the overall flow chart of the pattern recognition system, and then conducts a comprehensive inspection of the test mode to ensure that all important connections in the system pass through high-quality testing is guaranteed. Then in the systematic research of this paper, based on the composite threshold segmentation method of histogram polynomial fitting and the deep learning method of the U-NET model, the actual terahertz image is cut, and the two methods are organically combined to form terahertz. The coaxial hologram reconstructs the image for segmentation and finally completes the test of the system. After evaluation, the performance of the system can meet the needs of practical applications.

1. Introduction

Image denoising is to reduce the noise in the image, and the low-resolution image is transformed to form a high-resolution image organically is the image superresolution technology [1]. Both can effectively improve image quality without changing the existing hardware equipment and imaging process [2]. In recent years, deep learning technology has achieved substantial breakthroughs and developments, bringing about tremendous changes in many fields [3]. Deep learning technology is derived from the second generation of neural network technology, which deepens the ability to process data through a deep network structure [4]. In the image field such as image noise and image superresolution, deep learning technology is developing rapidly and has achieved processing effects far exceeding traditional image processing technology. Add the existing deep learning segmentation algorithm to the 2.52 THz coaxial holographic image library for simultaneous processing [5]. Although the number of training samples is insufficient, U-NET can still accurately segment the electron microscope neuron image. According to the experiment in this article, for the real terahertz coaxial digital holographic image library, reconstruct the insufficient number of samples and analyze the U-NET segmentation results of the training set, loss function, and learning rate that affect the real terahertz image, so that it gets the best model. The experimental results show that the optimized U-NET model has the specific ability to distinguish between the image target and the background and at the same time has a specific noise reduction function, which can eliminate the more serious noise in the image [6]. It is proved that in the experiment, the noise in the gear image is basically eliminated, and the target is better retained. The segmentation result is better than the combined threshold segmentation method, but the seal image must be segmented by other algorithms [7]. The powerful Visual Studio development tool completes the development of the facial image pattern recognition system, with a high-quality interface and excellent friendliness. In the process of designing the system software, the confidentiality and special functions of police cases are integrated [8]. The customer adopts modular thinking in the design process to more easily identify the identity of others. It is composed of several important modules and is a kind of user-friendly approach. The database is mainly used to provide the client with interface configuration information, user credentials, and standard facial images. The database deployment in the system research is mainly used to save user credentials and login time and to compare with the recognized images. The design process of this article selects the SQL2008 database based on the skill level of the security assessment and the system survey.

2. Related Work

2.1. DnCNN Network. The literature introduces the application of deep convolutional neural network of DnCNN model to image denoising in terahertz image. First, the principle of noise suppression related to the network structure of the DnCNN network is studied [9]. Then optimize the network model from the relevant parameters of the neural network to obtain the most suitable denoising network for terahertz images [10]. Then the traditional denoising algorithms of NLM and BM3D are introduced, and their related parameters are optimized. Finally, the denoising effect of the DnCNN network is compared with the traditional denoising algorithm, and the denoising effect of the deep neural network model in this chapter is analyzed and compared [11]. The literature introduces the application of densely connected networks in the image superresolution of terahertz images [12]. First, we will introduce the network structure based on tightly connected networks and the principles of high-resolution networks. Then optimize the network model from the relevant parameters of the neural network to obtain the most suitable superresolution network for terahertz images [13]. Then introduced the traditional superresolution algorithm based on sparse representation and anchored neighborhood regression and optimized its related parameters. Finally, the denoising effect of the superresolution network of the dense residual network is compared with the traditional superresolution algorithm. The literature introduces the traditional terahertz image segmentation method and its improved algorithm. The composite threshold segmentation technique is used to characterize the actual holographic reconstructed terahertz image [14]. This means that when trimming and mirroring, the surrounding background will be removed first, and then filtering and denoising will be performed [15]. After the image is improved by grayscale stretching, a polynomial fitting histogram will be performed for threshold segmentation, and the two threshold methods and the Otsu method will be compared step by step [16].

2.2. U-NET Segmentation. The literature introduces the compound U-NET segmentation algorithm. Based on the research of segmentation of the holographic reconstructed terahertz image based on the combined threshold segmentation method and U-NET segmentation algorithm, the trimming and mirroring expansion steps, the NLM filter processing the terahertz image, and then the U-NET segmentation, repeat the experiment to the segmentation result is enlarged, the influence of the existing random features is reduced and the target is better maintained. The literature introduces the U-NET segmentation algorithm as a deep learning algorithm for segmentation of holographic reconstructed terahertz images [17, 18]. The deep learning segmentation algorithm learns and understands data by simulating the learning method of the human brain and can understand the training data before processing any other data. It has been partially applied [19]. U-NET relies on data expansion in order to use training images more effectively and accurately segment electron microscope neuron images from very few training images. This will reduce the sample size of the actual coaxial digital holographic terahertz reconstruction in this experiment [20]. In the experiment, we optimize by comparing and analyzing the results to obtain a model of the actual terahertz image that is particularly suitable for the experiment [21].

After reading the above literature, it can be determined that the main work of this paper includes Figure 1nodes.

3. Deep Learning and Pattern Recognition Technology of Holographic Image Library

3.1. Principles of Deep Learning. Artificial neural network originated from the mathematical bionic modeling of human nerves. Modern artificial neural network models are an important part of machine learning and an important foundation of deep learning.

The output of a single neuron can be expressed as (1)

$$y = f\left(\sum_{i}^{n} w_i x_i + b\right). \tag{1}$$

Artificial neural network fits the model through training, so as to achieve the purpose of learning. The training process of a single neuron can be expressed by (2). The network is trained by updating the weights each time the error between the network's predicted value and the true value. Among them, k represents the k training, i represents the ith data category, and λ represents the learning rate.

$$w^{(k+1)} = w^{(k)} + \lambda\left(y_i - \widehat{y}_i^{(k)}\right)x_i, \tag{2}$$

$\partial C/\partial w_i$ and $\partial C/\partial b_i$ are obtained by the chain derivation rule.

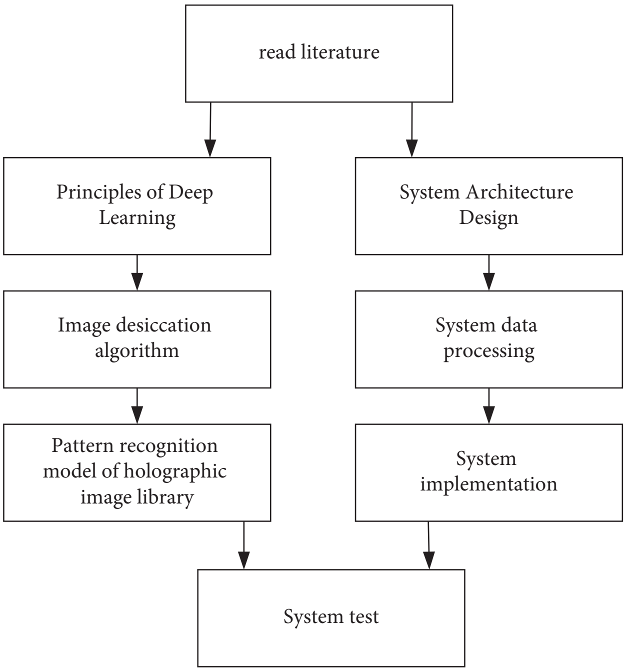

Figure 1: The main work of this paper.

$$w_i^+ = w_i + \Delta w_i = w_i - \lambda \frac{\partial C}{\partial w_i},$$
$$b_i^+ = b_i + \Delta b_i = b_i - \lambda \frac{\partial C}{\partial b_i}. \tag{3}$$

The loss of the network is propagated backward step by step through the chain derivation process, and the value of the parameters of each layer of the network from the back to the front is changed, so that the network can be trained.

$$\frac{\partial C}{\partial w_5} = \frac{\partial C}{\partial \mathrm{Out}_{o1}} \frac{\partial\, \mathrm{Out}_{o1}}{\partial \mathrm{Net}_{o1}} \frac{\partial \mathrm{Net}_{o1}}{\partial w_5}. \tag{4}$$

The formula of mean square error (MSE) corresponds to (4). The characteristic of using squaring to calculate the error is that when the difference between yi and (xi) is greater than 1, the squaring calculation will increase the error, giving it greater punishment, and speeding up the training. And when the difference between yi and (xi) is less than 1, the square calculation will reduce its error, thereby giving it a smaller punishment, and making the training more accurate. But at the same time, MSE will also give higher weight to abnormal points, which will reduce the overall performance of the model and lead to phenomena such as overfitting.

$$\mathrm{MSE} = \frac{1}{n} \sum_{i=1}^{n} \left(y_i - f(x_i)\right)^2. \tag{5}$$

Mean absolute error (MAE), its mathematical expression is as (5), minimizes the absolute value of the error to train the model. Unlike MSE, the gradient of MAE is equal everywhere, which also means that MAE will still give the same punishment to small losses as large losses, which is not conducive to the efficient convergence and learning of the model. But at the same time, because MAE gives all errors the same weight, it is not as sensitive to outliers as MSE. Using MAE to calculate loss is more conducive to learning from data with fewer outliers.

$$\mathrm{MAE} = \frac{1}{n} \sum_{i=1}^{n} \left|y_i - f(x_i)\right|. \tag{6}$$

L0optimizer was proposed by Louizos C et al. in 2017. Its mathematical expression is as in (7), where the term δ is a constant term of a hyperparameter, and δ is taken as 10^{-8} in the algorithm of this paper.

$$L0\mathrm{Loss} = \frac{1}{n}\sum_{i=1}^{n}\left(\left|y_i - f(x_i)\right| + \delta\right)^2,$$
$$L0\mathrm{Loss} = \frac{1}{n}\sum_{i=1}^{n}\left(\left(y_i - f(x_i)\right)^2 + \delta\left|y_i - f(x_i)\right| + \delta^2\right)^2, \tag{7}$$

tanh is a hyperbolic tangent function, proposed by Malfliet et al. in 2005, and its function expression is as (7)

$$f(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}. \tag{8}$$

But at the same time, the zeroing mechanism of the ReLU function also brings its shortcomings. If the back propagation process of the network (including the ReLU function) has large gradient fluctuations, the ReLU input distribution is concentrated in the almost negative area, then such A large number of negative inputs will cause a large number of outputs of the ReLU function to be 0. A large number of neurons are permanently closed because the gradient cannot be updated. This phenomenon is called Dead Relu. At the same time, unsuitable network parameter initialization methods, such as a large number of weights being initialized to 0, will also cause Dead Relu problems. Dead Relu can cause training problems such as vanishing gradients.

$$f(x) = \begin{cases} x, & \text{if } x > 0, \\ 0, & \text{if } x \le 0. \end{cases} \tag{9}$$

The ELU function was proposed by Clevert et al. in 2015. Its function expression is shown in (8)

$$f(x) = \begin{cases} x, & \text{if } x \ge 0, \\ \alpha\left(e^x - 1\right), & \text{if } x < 0. \end{cases} \tag{10}$$

PReLU was proposed by He K et al. in 2015. It is a variant function of the ReLU function. Its principle is the same as that of the Leaky ReLU function, which is to prevent the Dead ReLU problem in the ReLU function by giving a small slope to the negative input. But unlike the slope parameter in Leaky ReLU, which needs to be manually specified, the parameters in PReLU can be optimized through learning. Its function expression is as (9), where λ is a learnable parameter vector with the same shape as x.

$$f(x) = \begin{cases} x, & \text{if } x > 0, \\ \lambda x, & \text{if } x \le 0. \end{cases} \tag{11}$$

For a network that has not undergone batch normalization, take the sigmoid activation function as an example. If the data falls in the area with a small gradient, then the network may cause slow training due to the small gradient, or even cause the gradient to disappear. Training has stalled.

Use the mean and variance of each data batch to batch standardize the data to promote normal data distribution. The processed data are concentrated in the area with a large gradient at the center of the function.

However, the obtained normal distribution data may not achieve the best results. The gradient between the red dotted lines of the sigmoid function does not change much, so the effect of the non-linear transformation of the non-linear function cannot be reflected. Therefore, in the fourth step, the scale factor γ and the translation factor ß are introduced for batch standardization, which can be adjusted through training so that the network obtains the best distributed data. While preventing the gradient from disappearing, the non-linear function of the activation function is better utilized, which is more conducive to training.

3.2. Image Desiccation Algorithm. The DnCNN network is a deep convolutional neural network. It is based on the residual strategy used to remove noise from the image. It better solves the problem of neural network degradation caused by the gradient instability of the deep network and can be achieved at a deeper network depth—a stable convergence of the network under. It has achieved far more effects than traditional image denoising methods in image denoising [22].

The idea of the residual strategy mainly comes from the ResNet network. The ResNet network forms a residual block by adding a fast connection between every two convolutional layers to stabilize the gradient in the network. In the DnCNN network, the residual block design is not used, that is, the output of the network in the output layer is the noise part of the image [23]. And because the image and noise are additive, so to get the denoised picture, you only need to subtract the original picture from the noise picture output by the network. In the residual learning of ResNet, it can be proved that when the residual is very small, the layer-to-layer is close to the identity mapping, and the network at this time is very well trained. Therefore, in the DnCNN network, when the noise level is low, the error between the noise picture and the pure picture is also small, the network residual is also small, and the network training is simpler [24].

The simplified network structure of DnCNN is shown in Figure 2. In the DnCNN network, the main body of the network is the superposition of several identical convolutional layers. No pooling layer is added to the entire network. Each convolutional layer uses the "same" pattern to fill the edge of the feature map and ensures that the step size of each convolution kernel is 1 so that the size of the feature map is in the entire network keep constant. Except for the first and last convolutional layers, BN layers and activation function layers are added after each convolutional layer [25]. The number of convolution kernels in the termination stage of the convolutional layer is 1, and the purpose is to make the dimension of the final output tensor same dimension as the input image [26]. The final output of the network is the difference between the input image and the residual tensor of the last layer of convolution.

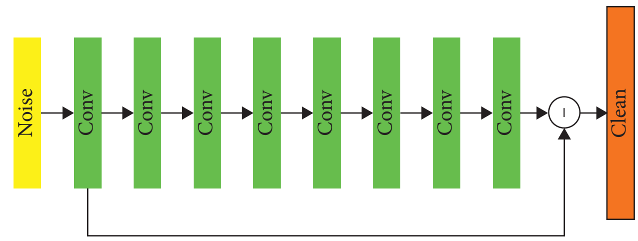

Figure 2: The structure of the DnCNN network.

Using MSE as the loss function training network, its denoising result index is shown in Table 1.

The network trained with MAE as the loss function, the index of the denoising result is shown in Table 2.

Using Looptimizer as the loss function training network, the index of the denoising result is shown in Table 3.

3.3. Pattern Recognition Model of Holographic Image Library. Feasibility study is the first task at the beginning of software development. If the problem cannot be solved, time, resources, and human resources are all wasted on software development. Nowadays, the optical image document recognition industry model has formed a certain theoretical tone through the development of recognition theory and image processing technology. Optical character recognition (OCR) continues to develop based on optical image processing and has taken a place in various fields of social life. Optical character recognition has the advantages of high speed, high efficiency, low error, and low cost of text input. As a new technology, various fields of social life are inseparable from document recognition based on optical character recognition. The characters on the ID card are unique documents, and the development of ID card recognition technology based on optical images has matured [27]. Therefore, the ID card information recognition system based on optical images is technically feasible. Currently, most ID card information is obtained by identifying high-frequency information embedded in the ID card or manually inputting it. The manual input method is inefficient and error-prone, so it will not be possible to obtain photo information [28]. On the other hand, the radio frequency identification method requires the increase of radio frequency chips for system identification and related application development, which promotes the increase of equipment costs. The effective use of computer technology in today's society, comprehensive, effective, fast and cheap access to personal data, verification, and management has become an urgent problem in the current population information flow management [29]. This theme is a very large application value theme and has high requirements in the fields of public safety, transportation, and services. By designing and implementing an ID card recognition system based on image processing and pattern recognition

Table 1: Denoising effect when the loss function is MSE.

technology, we can provide the responsible department with an effective, fast, and cheap method of inputting personal ID card information. This method can facilitate the inquiry and verification of identity information and further promote the network and computerization of government agencies. Improving the cost and labor efficiency of services and government departments has important practical significance [30].

Table 4 shows the histograms of the R, G, and B channels. The histogram divides the illumination of the image into four areas. The first range is 0–25. This area mainly contains the black background and the text information on the ID card, which is the area with low gray value. The second area has a range of 25 to 50 and includes ID-specific information such as "name," "gender," and "ethnicity." The three channels in the third zone are slightly different, the blue channel is 50–120, and the red and green channels are about 50–150. The fourth is the remaining area with few pixels, which is the highlight area caused by uneven light in the image.

The image characteristic comparison table of the standard area and the highlight area is shown in Table 4. Comparing Table 4, it can be seen that in terms of gray mean, standard deviation, and average volatility, the standard area and the highlighted area are relatively close, but there is a big change in the average deviation. Therefore, by changing the average displacement rate, the highlight area of the ID card image can be corrected.

Define the average gray level of each channel as

Table 4: Image characteristics of ID card images.

Feature	Reference area			Highlight area		
	R	G	B	R	G	B
Mean	0.32	0.33	0.35	0.39	0.34	0.31
Standard deviation	0.01	0.03	0.01	0.02	0.01	0.01
Average volatility (%)	1.8	2.3	2.2	2.1	2.5	1.9
Average deviation rate (%)	—	—	—	121.1	95.5	101.0

$$\overline{I_x} = \frac{\sum_x N_x}{,} x = R, G, B. \tag{12}$$

Define the gray volatility rate of each channel:

$$K_x = \frac{l_x}{I_x}, x = R, G, B. \tag{13}$$

Define the color shift rate of each channel:

$$\mathrm{Rate}_x = \frac{I_x^s}{I_x^d}, x = R, G, B. \tag{14}$$

Use the highlight area shift rate to correct the highlight area. First, classify the light according to the intensity of the highlight area, calculate the average deviation rate of each layer, and correct the pixels with high gray values as follows:

$$I_{\mathrm{xnew}}^s = \frac{I_x^s}{\mathrm{Rate}_x}, x = R, G, B. \tag{15}$$

The global threshold method uses a variety of algorithms to determine a threshold T that is independent of pixel position. Methods for determining the value of T include Otsu's method and iterative algorithm. The Ostu method is also called the maximum difference between classes. It provides automatic selection of T by counting the histogram attributes of the entire image. If the threshold between the two categories is t, then the two categories are C_0 and C_1:

$$C_0 = \{0, 1, \ldots t\}, C_1 = \{t + 1, t + 2, \ldots, 255\}. \tag{16}$$

Then the Ostu method finds the maximum value of the following formula:

$$\eta = \frac{\sigma_B^2}{\sigma_T^2}. \tag{17}$$

The Bresen algorithm mainly uses the median between the maximum and minimum values of each pixel area as the segmentation threshold.

$$C(x, y) = G_{\max} - G_{\min} < l. \tag{18}$$

The new judgment criteria are as follows:

$$g(x, y) = \begin{cases} 0 & f(x, y) < (1-\beta)T, \text{ or }, \left(f(x, y) < T_{\mathrm{Bn}}(x, y), \text{ and }, (1-\beta)T \le f(x, y) \le (1+\beta)T\right), \\ 1 & f(x, y) > (1+\beta)T, \text{ or }, \left(f(x, y) \ge T_{\mathrm{Bn}}(x, y), \text{ and }, (1-\beta)T \le f(x, y) \le (1+\beta)T\right). \end{cases} \tag{19}$$

T_{bn} is determined by the following formula:

$$T_{Bn} = \operatorname*{avg}_{\substack{-w \leq \leq w \\ -w \leq j \leq w}} f(x+i, y+j). \tag{20}$$

β is determined by the following formula:

$$\beta = C1 \times \frac{(g2 - g1 + 1)}{128}. \tag{21}$$

The top-down layout analysis method is divided into two steps: row segmentation and column segmentation. The line segmentation can be obtained by analyzing the binarized image and projecting it vertically. Calculate the function as follows:

$$I(y) = \sum_{x=1}^{N} I(x, y), \tag{22}$$

$l_{(i,j)}(d)$ represents the fuzzy stroke length of the semicolon (i, j) of Chinese characters, defined as

$$l_{(i,j)}(d_0) = \max\left(l_{(i,j)}(d)\right). \tag{23}$$

4. Application of Holographic Image Library Pattern Recognition System Based on Deep Learning

4.1. System Architecture Design. Compared with the traditional print recognition, the ID card recognition system has undergone major changes. First, the font and size of the ID card information are already in a specific situation, and the position of the characters is also in a constant state, so the layout analysis of the ID card is relatively simple. However, contrary to ordinary printed Chinese character recognition, the Chinese characters on the ID card contain many rare characters. Due to the importance of identifying ID card information, the identification requirements for ID card characters must be very high, and the mismatch tolerance is also very low. In this article, we will use the following recognition process as shown in Figure 3to design an ID card recognition system based on optical images to realize the ID card recognition function.

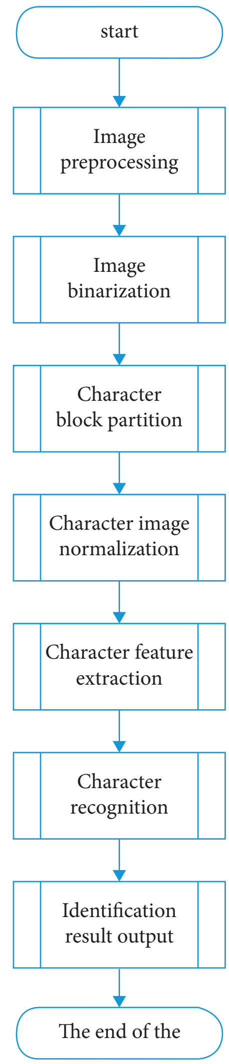

FIGURE 3: Flow chart of ID card recognition system based on optical image.

4.2. System Development Environment. By analyzing and summarizing the above, the ID card recognition software is developed and used. MATLAB is widely used in algorithm development, visualization, analysis, and calculation of data in engineering projects, with excellent interactive environment performance. The input of the software is the color ID card image, and the output is the ID card information that can be displayed. This article develops ID recognition software based on the MATLAB platform, and MATLAB 2013b is the design software.

4.3. System Data Processing. Image preprocessing includes two main parts: uneven light correction and image gray level. When correcting image unevenness, the color change rate is used as a reference for correcting the highlighted area of the image. The functional prototype is

Function Image out = getLightCorrect (Imagein).
%Input parameters:
%Imagein: The color image to be corrected.
%Output parameters:
%Image output: The color image has been changed.
The getLightCorrect function works as follows:

(1) Count the gray histograms of R, G, and B channels
(2) Calculate the forward difference and the backward difference of the gray histogram
(3) The point where the difference between the front and back is greater than 0 is regarded as the peak point
(4) As the starting point of color volatility statistical information, select the point closest to the gray value of 128 from the largest point and select the second largest point from the peak point as the gray value
(5) Starting from the statistical starting point, calculate the average color deviation by searching two

Table 5: The location of relevant information in the ID card (the vertical and horizontal coordinates of the image are all normalized to 1).

Name	X coordinate starting point	X coordinate end point	Y coordinate starting point	Y coordinate end point
"Name" image (name img)	0.1620	0.6173	0.0967	0.2028
"Sex" image (sex img)	0.1620	0.2293	0.2353	0.3317
"Nation" image (nation img)	0.3705	0.6173	0.2353	0.3317
"Birthday" image (birth img)	0.1620	0.6173	0.3514	0.4431
"Address" image (addr img)	0.1620	0.6173	0.4826	0.7616
"ID number" image (no img)	0.3134	0.8976	0.7976	0.9044

Table 6: Function test cases and qualification criteria.

Function name	Test case	Expected output	Eligibility criteria
getLightCorrect	Color ID card image in highlight area	Correct the image	Visually distinguish the corrected image of the highlight area
ImageDiv_ Otsu_ Bersen	ID card image after grayscale	Binarized image	The characters are clearly separated from most of the background
getLineDiv	Binarized image	Character row and column split data	Split characters correctly
getGridDiv	Unit number normalization graph	Character elastic grid segmentation results	The projections within the grid are roughly equal
getHanziLine	Unit number normalization graph	The four fuzzy stroke features of Chinese characters	The four stroke characteristics of Chinese characters are correctly extracted through visual discrimination
getHanziFeature	Unit number normalization graph	Chinese character characteristics	No criterion

directions in the histogram until the grayscale interval contains about half of the total number of pixels in the image as the reference point for color deviation statistics

(6) Use the average color change to correct the brightness of pixels with high gray values

Before binarizing the image on the ID card, first divide it into ID card information area. By using the prior knowledge of the ID card, the trouble of identifying ID card information can be reduced, the background that does not need to be identified can be reduced, and resources can be saved. Table 5 shows the approximate location of ID card-related information on the ID card image. In the identity recognition system, the image is converted according to the approximate position of the identity image where the prebinary ID card information is located.

4.4. System Implementation. The specific implementation of the key algorithm involved in identifying ID card information is described above. However, because the users of the ID card recognition system are not interested in specific recognition methods, the ID card software developed in this article executes the above algorithm in the background of the software, reads the image and outputs the recognition results, and saves the recognition results. The software interface includes three areas. The software title "ID Card Recognition System Based on Image Processing and Pattern Recognition" appears in the software title bar at the top. The center area is the event button, with three buttons: "Import Image", "Start Detection/Detection Complete" and "Save Results". The "Read Picture" button can select the picture on the badge that the user recognizes. The recognition start/recognition completion is used by the user to recognize the ID card information, and the recognition result is displayed on the user interface after the recognition is completed. After confirming that the ID card information has been correctly recognized, "Save Result" is used to save the recognition result in text format. The lower area is an information display area where the recognized image or result is displayed, and after the user determines the image to be recognized, the image to be recognized is displayed in the information display area. After the image is recognized and the user clicks the "Start Recognition" button, the software will start image preprocessing, character feature extraction, character recognition, and other algorithms. When the recognition of the ID card information is completed, the display of the "recognition start" button changes to "recognition end," and the recognition result is displayed in the information display area. This is because the ID card identification information may be incorrectly recognized. Therefore, the "ID Card Information View" window contains an interface for receiving string changes. Finally, the software has developed a function that can save the identification result of the ID card. When the user clicks the "Save Results" button, the software will automatically save the recognition results as a text file that other programs can access [31].

4.5. System Test. The test system has two aspects: basic function test and recognition index test. The basic function test includes some key functions of the test software and the output results of the test software. Test the recognition index by inputting a large number of ID card images to be recognized and statistically analyzing the possibility of correct recognition. The software identification index test does not have to separately test the system software output because the software output has actually been checked. The following is a brief introduction to the input and output test methods of each functional test [32].

As shown in Table 6, the optical image-based ID card recognition system mainly includes the following functional functions, and the functional test of these functions can be carried out using the black box test. In the functional black box test, specific inputs are passed to test whether the output meets the requirements.

5. Conclusion

This technology can provide a variety of conveniences for patients in the medical field. By integrating the data of each medical consortium, building a holographic view of patients based on the medical consortium, so that doctors can access all medical records of patients in the medical consortium, and diagnose the condition of a new patient as early as possible by comparing the diagnosis of other patients. At present, the mainstream application of this technology in the medical field is still in the direction of patient medical image recognition. Other directions such as on-axis holographic imaging detection on lensless sheets also have applications. Terahertz image segmentation based on coaxial reconstruction is an important research field of intelligent image recognition. In the experiment, the actual terahertz image is noisy, and the pixels are divided into target and background. However, when imaging, the laser energy of the seal image is insufficient, so there are grayscale pixels similar to the target pixels around the image. Using composite threshold segmentation method and U-NET segmentation method to segment the true coaxial terahertz holographic image can better maintain the target while eliminating heavy noise and surrounding background. Combine and apply the actual terahertz to segment the coaxial holographic reconstructed image and finally test the segmentation effect of the composite U-NET algorithm on the simulated image. A complete storage is established for the system, an automatic recognition function is added, and the corresponding control software is designed. According to experiments, the accuracy and recognition speed of target recognition based on the large-volume holographic image library are obtained. Based on the two exposure times, the impact of the test results on the detection is studied, and the angle multiplexing is extended to two-dimensional or angle fractal multiplexing, which greatly increases the single-point information storage capacity of the storage medium. Complete the establishment of the basic theoretical storage system, study the exposure method of the hologram with equal diffraction efficiency, analyze the noise source of the system in detail, and quantitatively calculate the influence of SLM and CCD parameters on the page, Using this technology not only costs less but also improves the accuracy of the diagnosis of patients' conditionsand also promotes the application of computer science in the medical field, providing reference for other scholars with experimental data.

Data Availability

The figure and table data used to support the findings of this study are included in the paper. In addition, the data and the models of analysis are available from the corresponding author upon request.

Conflicts of Interest

The authors declare that there are no conflicts of interest regarding the publication of this paper.

Background. The cognitive role of older patients is regularly not investigated in orthopedic rehabilitation, after the elective as well as the nonelective operation. The objective of this research is to investigate the cognitive disorder and its influence over the duration of stay along with the functional consequences of the older patients who were admitted to orthopedic rehabilitation. *Material and Methods*. The inclusion criteria for this study were the patients with age above 50 years; who were admitted with the detection of orthopedic impairment and the surgery both elective and nonelective, investigated utilizing the MoCA (Montreal Cognitive Assessment) over admission, MBI (Modified Barthel Index), and FIM (Function Independent Measure) over admission and discharge status; and were discharged from the hospital. The demography, as well as the clinical data, comprising of the duration of stay, age and the detection was also reported. *Result*. Of the 109 admitted patients, 80 patients were included in the study where $n = 47$ (58.75%) patients were females and $n = 33$ (41.25%) were males. The age group range was 50 to 94 years with a mean age of 78.5 years (SD = 8.27). The diagnostic groups included for the study were fractured neck of femur ($n = 34$; 42.5%), orthopedic surgery ($n = 22$; 27.5%), and other orthopedic surgery ($n = 24$; 30%). The mean duration of rehabilitation stay was reported as 34 (4.39), where the MoCA was reported as 22.17 (2.44); functional independence measures were as follows: motor admission as 53.97 (7.55), motor discharge as 76.27 (5.35), cognitive admission as 30.71 (1.99), and cognitive discharge as 31.85 (1.94). Here, the diagnosis was done over the fractured neck of the femur (i.e., NOF being 34 (42.5%), elective surgeries 22 (27.5%), and other orthopedic as 24 (30%)). *Conclusion*. An excessive percentage of older-age patients in a rehabilitation unit with elective as well as nonelective diagnoses comprises the cognitive disorder. The cognitive screening was advised for all the older age patients in the rehabilitation units to report a specific rehabilitation plan to enhance the consequences along with the duration of stay. There is further study required to explore different cognitive strategies to enhance the rehabilitation consequences among older-age orthopedic patients.

1. Introduction

Cognitive impairment is a well-defined risk element for the damaging falls in older ages [1, 2]. As a consequence, it will be anticipated that chronic cognitive diseases like dementia or Alzheimer's are widely prevailing among older patients depending on multiple factors comprising of characteristic diagnostic parameters and the severity of the clinical manifestations. Postoperative cognitive disorders are frequently observed among elderly patients (age >65 years). These comprise mainly of degraded perception, information investigation, memory, concentrating strength, attention and focus, and the patient's response and reaction [3, 4].

The cases of cognitive disorders have been documented as independent risk measures for delirium, and the total case of the new delirium was remarkably observed higher among the older patients suffering from dementia, as compared to the older patients suffering from no dementia [5, 6]. Furthermore, the prefracture cognitive impairments along with the postfracture suffering of delirium were found to be strongly associated with the higher rate of mortality as well as the risk for the establishment, and the delirium may be an untimely indicator for the postdischarge cognitive degeneration [7, 8]. However, this can generate an outcome in the long-run cognitive degeneration, postoperative cognitive degeneration peripheral to the delirium which does not happen in all the patients.

The cognitive variations in the rehabilitation might be preexisting, which even may be an element causing orthopedic injury in a person [9, 10]. The rehabilitation from a therapy aspect might not individually focus on the cognitive impairment, instead, via the design of the rehabilitation program, assimilate the cognitive role to enhance the participation in the rehabilitation program, as a result of which improving the functional consequences [11]. The evidence proposes that the cognitively impaired suffering older patients can be benefitted from the specialized rehabilitation programs, which is more rigorous, with the patients with average-to-acute cognitive impairment determined to exhibit functional enhancements in the rehabilitation programs [12, 13].

The cognitive status can be a crucial predicting factor of the rehabilitation consequences, along with being aware of the information related to the cognitive abilities of the patient and the dimensions of deficiency facilitating the staff with the retrain in the useful task rendition, comprising of day-to-day activities like walking. To enhance the functional consequences of all the older patients with orthopedic conditions, a better comprehension of the cognitive abilities of the patient and how it can affect their process of rehabilitation is needed [14–16]. Various rehabilitation units implement the cognitive screens to help the decision-making procedure about both appropriateness of a patient who has to be admitted to a rehabilitation unit and the timing as well as assistance needed for discharge, although the screening tools implemented are not steady [17].

The objective of this study is to assess, through a cohort study, the association between the cognitions, calculated with the use of MoCA, and other functional outcomes, calculated using the FIM as well as the MBI, of the older patients with orthopedic condition, who were admitted into the rehabilitation, with the detection of the fractured neck of the femur, elective as well as other related orthopedic operations, and the duration of patient's stay [18]. The occupational therapists furnish the intervention associated to enhance the function in the orthopedic rehabilitation program. The occupational therapy involvement furnished the location of the study conducted and was constant beyond the detection, with the rehabilitation involvement specifically focusing on the requirements of the individuals.

It was hypothesized that the relation between the cognitive impairment and the consequences in the orthopedic rehabilitation may occur for the patients who were admitted with fracture injury, who inclined to be older and weaker, as compared to the ones who were admitted for the elective process.

2. Material and Methods

The audit was verified by the Research and the Ethics Committee, where the patients were recognized via the procedure of admission to the common rehabilitation unit. This unit was facilitated with the staff having a specialized multidisciplinary team, comprising physiotherapy, dietetics, social work, speech pathology, occupational therapy, and medical and nursing.

The inclusion criteria for this study were as follows: (1) the patients with age above 50 years; (2) the patients who were admitted with the detection of orthopedic impairment and the surgery both elective and nonelective, investigated utilizing the MoCA over admission, MBI as well as FIM over admission, and discharge status; and (3) the patients who were discharged from the hospital. The data for this cohort study was gathered through chart data entry and the status of admission and discharge data which is regularly gathered by the occupational therapy group.

The demography as well as the clinical data comprising of the duration of stay and age and the detection was also reported. The diagnosis was classified into subgroups: elective orthopedic surgery of hip as well as knee replacement, fractured neck of femur, and other associated orthopedic injuries comprising the orthopedic injury of the upper as well as the lower limbs along with the fractured pelvis.

The cognition was investigated over the admission utilizing the MoCA and the patients were classified into the groups of severity level as per the scale, to compare the variation between the diagnosis categorized in the range of 26 to 30 in the normal range followed by the range of 18 to 25 as the mild cognitive impairment, the score of 10 to 17 as the moderate cognitive impairment, and the score of 9 or below than that was the less severity of cognitive impairment.

Quantitative values were described using their number, mean, standard deviation, and median; MoCA scores on admission and discharge were compared using ANOVA with repeated measures, with age and education as covariables. Qualitative values were described using their number, frequencies, and centiles and were compared using the Chi^2 test or Fisher's exact test when necessary. To evaluate the change in MoCA score as a function of its baseline value, we split the study population into three subgroups with low (≤21), intermediate (≥22 and ≤25), and high (≥26) MoCA scores. All analyses were performed using SPSS software V22.0 (IBM SPSS Inc., Armonk, NY, USA).

3. Results

3.1. Patients' Characteristics. A total of 109 patients were admitted to the rehabilitation center from January to August 2019 where people with orthopedic injuries and surgeries were selected. Out of these, 29 patients were excluded who did not meet the criteria for inclusion (for not completing the MoCA). Of the 109 admitted patients, 80 patients were included in the study where $n = 47$ (58.75%) patients were females and $n = 33$ (41.25%) were males.

The age group range was 50 to 94 years with a mean age of 78.5 years (SD = 8.27). The diagnostic groups included for the study were fractured neck of femur ($n = 34$; 42.5%), orthopedic surgery ($n = 22$; 27.5%), and other orthopedic surgery ($n = 24$; 30%). The surgeries elected were planned prior to or scheduled. The patient's characteristics are presented in Table 1.

The clinical characteristics of the subgroups which are selected for diagnosis are shown in Tables 1 and 2. Collective MoCA score for the diagnosis was found to show mild impairment. A significant difference in FIM scores (both cognitive and motor), MBI scores at the time of admission or discharge, age, and diagnosis type was noted.

The post hoc analysis showed a significant difference in the scores of cognition where surgery patient scores were higher significantly in comparison to the patients with fractured neck of femur, though there was no other difference between fractured NOF or other orthopedic surgery patients. Statistical analysis has also shown that the FIM scores of cognition between fractured NOF and elective surgery patients were different (0.367). There was no significant change noted between patients with fractured NOF or other orthopedic cases or with elective surgery.

3.2. Significance between MoCA and FIM Scores and Their Functional Outcomes. The functional analysis was done on the basis of the FIM scores (motor) at the time of admission and discharge as well as the MBI scores at the time of admission and discharge were assessed. At the time of admission, a significant change in the FIM motor scores was noted on the basis of the diagnosis type. The post hoc analysis noted that patients with elective orthopedic surgery had a score significantly higher than the NOF cases of patients and with other orthopedic cases of patients.

No significant changes were noted in the FIM scores (motor) at the admission time for patients with fractured neck of femur and other patients with orthopedic cases. The post hoc analysis also revealed that the scores of elective orthopedic patients were higher significantly when compared with patients with fractured neck of the femur or other orthopedic surgery. In the discharge FIM scores (discharge), no difference was noted between orthopedic patients and fractured NOF.

The analysis revealed that the MBI scores were showing a significant difference between fractured NOF and elective orthopedic patients ($P = 0.001$). The analysis has no significant difference when MoCA scores showed no significant differences with the MBI change or FIM motor score (Table 2).

The median of MoCA for NOF and orthopedic surgery was 22 and that of other orthopedic surgeries was found to be 22. The median for FIM motor admission for NOF was 50.5, orthopedic surgery was 65, and another orthopedic surgery was found to be 50. The median for FIM cognition for admission in case of admission for NOF was 30, orthopedic surgery was 32.5, and another orthopedic surgery was 30, whereas the median for FIM cognition discharge for NOF was 31, orthopedic surgery was 33, and other orthopedic procedures was 30.

The median for FIM motor admission for NOF was found to be 71.5, orthopedic surgery was 81.5, and another orthopedic surgery was 76.5 (Table 2). MoCA scores and FIM cognition scores were compared against the functional variables where the association between cognition and discharge was linked significantly with the length of stay in the hospital. A marked association was seen in MoCA scores with FIM admission (motor), MBI discharge, and FIM admission/discharge (cognition, motor).

Table 1: Clinical characteristics of patients included in the study.

S. no.	Characteristic	Mean
(1)	Rehabilitation length of stay	34 (4.39)
(2)	Male	33
	Female	47
(3)	Montreal cognitive assessment	22.17 (2.44)
(4)	*Functional independence measure*	
	Motor admission	53.97 (7.55)
	Motor discharge	76.27 (5.35)
	Cognitive admission	30.71 (1.99)
	Cognitive discharge	31.85 (1.94)
		Number (%)
(5)	*Diagnosis*	
	Fractured neck of femur (NOF)	34 (42.5)
	Elective surgeries	22 (27.5)
	Other orthopedic	24 (30)

4. Discussion

In this study, it can be observed that a higher number of geriatric orthopedic older-age patients in the rehabilitation, in spite of the reason behind their admission, that is, either selective or nonselective operation, have experienced cognitive impairment ($n = 80$), as calculated by the MoCA. In this cohort analysis, we have indicated a median point with faint cognitive impairment, with fewer scores on the MoCA. The NOF group accounts for a larger proportion of fracture types and is associated with cognitive dysfunction in elective and other types of orthopaedic surgery.

There was zero significant variation found between the categories for their total MoCA scores, although there was a significant variation observed between the FIM cognitive score over the admission or the discharge status of patients, thus indicating the lower functional cognition of the patients with a fractured NOF as well as the other orthopedic status. With the scope of diagnosis for other orthopedic states and fractured NOF category, it can be presumed that these were because of the drops for which the precognitive state might have furnished to the risk of fall down.

The MBI was outstandingly varied between the three diagnoses, signifying that the calculation of function via observation, comprising of FIM as well as MBI, inspects the variations in the diagnostic categories. The FIM motor variations for all categories were considered clinically remarkable, thus assisting its implementation as a functional result calculated, on an orthopedic rehabilitation department.

The MBI variation from the status of admission of a patient to the discharge was remarkably varied with the highest development prevailing in the other orthopedic

Table 2: Detailed patient characteristics.

	Total dependence (n %)	1 (2.94)	0	0	

category, densely followed by the fractured NOF category, assisting its utilization as a result measure of role among these patient populations. This also signifies that these patients experienced a better functional result, with alike cognitive capabilities to those allowed for the elective operation. As observed in other researches, the patients who were admitted with a fracture with a history of falls, usually had a failing function before their admission, which affects functional results, but it may even yield more chances for enhancement.

Furthermore, the patients who were admitted for elective operation might be prepared before admitting with social assistance, home set-up and on completion of the prior-admitting exercises, therefore possessing a greater initial point of function with slighter advancements quantifiable after the rehabilitation plan. Moreover, the results of MoCA, FIM movement variation, and MBI nonexpression did not help patients with severe cognitive impairment improvement during rehabilitation. However, a substantial specimen size with more practicality of cognition is needed.

The average duration of stay for those patients who were admitted with fracture NOF was a duration of 34 days and the other orthopedic patient for a duration of 36 days, while the elective orthopedic operation of the patients experienced a 34-day duration of stay. This was above and beyond the range of this project, although it might demonstrate the varied operations in rehabilitation or the patient parameters, like the high rate of cognitive impairment. This should be reported that the average age of these older patients who were admitted to these rehabilitation centers and assessed for this analysis was greater than the national average. Here, the national average age of orthopedic patients turns out to be 78.5 years (SD = 8.27).

The discoveries signify that all the cognitive computations, both MoCA and FIM cognitive scores, were linked with the duration of stay in the group total but not in individual diagnosis. This signifies that beyond both the elective and the nonelective orthopedic recognition, cognition can report the duration of stay. The correlation between cognition and hospitalization time shows that even the slightest reduction in cognition is also obvious, so it is necessary to reduce the cost of medical services.

This aids the advice of the cognitive partitions utilized with all the patients who are admitted to the geriatric orthopedic rehabilitation centers, despite the detection. This process of screening might help the programs to adapt how the rehabilitation is carried out, with respect to the functional context, specific prompts, as well as the assimilation of the cognitive training policies to make as large as possible for the functional results and then possibly diminish the duration of stay.

Cognition is majorly affected by age and it can impact the patient's potential to actively get involved in the process of rehabilitation goal setting, learning and deficient in the remembering skills, tough with the decision making the discharge site and the services needed. The outcomes signify that for the group of fractured NOF along with other groups of orthopedic, the MoCA scores were associated with the functional scores of the FIM (i.e., the admission and the discharge status) and the MBI (i.e., the discharge status), therefore signifying that the MoCA is functional in calculating the cognition before as well as after the rehabilitation as linked to the useful measures at both points.

Although, for the elective operation group, the FIM cognitive and not the MoCA, overadmitting was associated with the functional measures (i.e., FIM motor and the MBI over the admission of patients), but only the FIM motor overdischarge of patients. This proposes that for the elective operation group, the FIM cognitive is more functional in terms of measuring the cognitive potential, which will be associated with the functional behaviour.

There was no significant variation while drawing a comparison of the severity on the MoCA to the detection, and the breakdown of the scores on the basis of the assessing areas was further investigated, which would be advantageous to identify the aspects of cognition associated with the duration of stay. The MoCA scores and the location of discharge were found to be significantly different between those who were discharged directly to their homes and the ones discharged to any other location like a nursing center or an independent care unit or a hostel.

The details of specific cognitive deficiency were experienced by those patients who were admitted to the orthopedic units and would report the design of the rehabilitation program. Furthermore, with the fall as the primary reason for the orthopedic injury among the older patients, the fall prevention programs comprising of the education parameter were needed to count the cognitive elements to enhance their efficacy in lessening as well as preventing the falls. The experts promote the consideration of the role of technology in enhancing the results as well as the assistance of the older people to administer their process of rehabilitation.

Therefore, the implementation of the technology to report the rehabilitation for the people with cognitive modifications in orthopedic rehabilitation needs assessment. The additional study has to be conducted more efficiently to provide rehabilitation to those elder patients with orthopedic conditions, with cognitive impairment, who were likely excluded from the conducted rehabilitation trials.

5. Conclusion

To conclude, the geriatric patients with orthopedic conditions, who were admitted to the rehabilitation, were bestowed with the cognitive impairment beyond the detection and this was linked with the discharge location, useful outcomes, and the duration of stay. The cognitive screening is advised for all the older patients with orthopedic conditions who were admitted to the rehabilitation programs to report an individualized rehabilitation program in order to enhance the results and the duration of stay. Furthermore, the study is needed to investigate the cognitive plans to maximize the rehabilitation results among older patients with orthopedic conditions.

Objective. This study discussed and analyzed the risk factors and nursing countermeasures of ventilator-associated pneumonia (VAP) in the children intensive care unit (ICU). *Methods*. In this study, 155 children with mechanical ventilation in the pediatric intensive care unit from Oct. 2018 to Oct. 2020 were chosen as research objects. We retrospectively analyzed the clinical data of children and divided them into VAP groups and non-VAP groups according to the occurrence of VAP. Subsequently, we adopted a univariate and multivariate logistic regression model to analyze and clarify the risk factors of VAP and formulated the corresponding nursing countermeasures. *Results*. 49 cases of total research objects had occurred VAP, with an infection rate of 31.62%. The primary pathogenic bacteria were Gram-negative bacteria (43/70, 61.43%). According to multivariate logistic regression analysis, the duration of mechanical ventilation, invasive procedures, and application of hormones and antacids are all independent risk factors for VAP in pediatric ICU. The VPA group had longer hospital stay than the non-VAP group, and the difference was statistically significant ((20.92 ± 4.16)d, (15.24 ± 3.77)d, $t = 8.4383$, $P \leq 0.001$). The hospitalization cost of the VPA group was substantially higher than that of the non-VAP Group ((45.8 ± 10.4) thousand Yuan, (33.2 ± 4.3) thousand Yuan, $t = 10.6822$, $P \leq 0.001$). *Conclusion*. Children admitted to the pediatric ICU have a high VAP incidence. The primary pathogenic bacteria are Gram-negative bacteria. As the occurrence of VAP is closely related to a variety of factors, we should take targeted nursing countermeasures to reduce the duration of mechanical ventilation and the frequency of invasive operations and use the hormone and antacids rationally to reduce the risk of VAP and improve the prognosis.

1. Introduction

Most children admitted to the pediatric intensive care unit (ICU) have severe pneumonia, myocarditis, encephalitis, hand-foot-and-mouth disease, etc. Children often need to use respiratory support to get through the dangerous period due to respiratory disorders or respiratory failure, but the application of ventilator is easy to cause complications such as pulmonary injury, displacement of tracheal intubation, septic shock, and respiratory-associated pneumonia (VAP) [1, 2]. VAP refers to pulmonary infection that occurs 48 h after endotracheal intubation or tracheostomy with mechanical ventilation or 48 h after removal of a mechanical ventilation tube, which has high morbidity and fatality rate [3, 4]. VAP prolongs the length of hospital stay and surcharges medical costs and increases the clinical mortality rate and affects the prognosis of children [5]. In recent years, the risk factors of VAP have been the hot spot in the analysis and research of the intensive care field. According to the work in [6–8], the occurrence of VAP is closely related to clinical nursing operations. Therefore, it is of great significance to take effective preventive and nursing measures to reduce VAP risks in the pediatric ICU. This study retrospectively analyzed the clinical data of the 155 mechanically ventilated children in the pediatric ICU of our hospital from Oct. 2018 to Oct. 2020, aiming to clarify the risk factors, pathogen distribution characteristics, and prognosis of children admitted in our pediatric ICU with VAP, meanwhile, to find targeted nursing countermeasures for the pediatric ICU of our hospital, and to provide a theoretical basis for clinical prevention of VAP.

2. Cases and Methods

2.1. General Data. 155 children with mechanical ventilation in the pediatric ICU from Oct. 2018 to Oct. 2020 were chosen as research objects. The objects included 81 males and 74 females, with an average age of (7.83 ± 2.46) years; the average duration of mechanical ventilation was (7.35 ± 3.12) d, and the average length of hospital stay was (18.52 ± 3.05)d. This study was carried out after acquiring approval from the ethics committee of our hospital.

2.2. Inclusion and Exclusion Criteria. Inclusion criteria: (1) the age of the patients ranged from 3 to 12 years; (2) all children were treated with invasive ventilation, and the duration of mechanical ventilation was ≥48 d; (3) children tended to be in stable conditions, or without progressive aggravation; and (4) the clinical data of children were complete.

Exclusion criteria: (1) children that were diagnosed with severe pneumonia before mechanical ventilation; (2) children with other serious diseases; (3) children with conscious or cognitive disorders, or with mental disorders; or (4) those discharged or died during treatment.

2.3. Diagnostic Criteria of VAP. We performed chest X-ray examination on children who have received mechanical ventilation for 48 h or within 48 h of withdrawing the ventilator and intubation. X-ray shows infiltrative shadows or new inflammatory lesions in the lungs, and moist rales could be heard during auscultation. According to the diagnostic criteria of VAP in *Guidelines for the Diagnosis and Treatment of Hospital-Acquired Pneumonia of the Chinese Society of Respiratory Medicine* [9], the child met any of the following two conditions simultaneously: (1) body temperature >38.5°C or <36.5°C, and there were no other obvious external causes; (2) the white blood cell (WBC) $>10 \times 10^9$/L or $<4.0 \times 10^9$/L; (3) increased or purulent respiratory secretions; and (4) new pathogenic bacteria were cultured in secretions.

2.4. Methods. We took 155 children with mechanical ventilation in the pediatric intensive care unit from Oct. 2018 to Oct. 2020 as research objects, retrospectively analyzed their clinical data, and divided them into VAP groups and non-VAP groups according to VAP occurrence. The children's general clinical data include gender, age, underlying diseases, blood transfusion experience, nutritional status, diagnosis, and treatment conditions such as nutritional support methods, intubation methods, application of antibiotics and hormones, and duration of mechanical ventilation retrospectively analyzed. We performed a single-factor analysis on the respective risk factors of the two groups and subsequently incorporated the obtained high-risk factors into the logistic regression model for analysis.

2.5. Statistical Analysis. We adopted the statistical software SPSS19.0 to analyze and process the data included. The measurement data were expressed as $(\overline{x} \pm s)$, and comparison between groups was by the t-test of independent samples; the enumeration data were described by percentage, and the results were taken by χ^2. $P < 0.05$ refers to the statistically significant difference. The multivariate logistic regression analysis included the selected statistically significant variables to determine independent risk factors by steps, and the significance level $\alpha = 0.05$.

3. Results

3.1. General Clinical Data in the Pediatric ICU. 49 cases of real research objects had occurred VAP, the infection rate was 31.62%, and a total of 70 pathogens were detected (Table 1). According to univariate analysis, the general clinical data of patients, including age, underlying diseases, experience of blood transfusion, and malnutrition, were all connected with the occurrence of VAP (Table 2).

3.2. Univariate Analysis of Medication and Diagnosis. Univariate analysis results indicated that the diagnosis and treatment, such as duration of mechanical ventilation, length of ICU stay, and application of invasive operations and hormones and antibiotics, were all concerned with the occurrence of VAP, as shown in Table 3. Variable assignment of VAP in the pediatric ICU: the variable assignment of VAP in the child intensive care unit is shown in Table 4. According to multivariate logistic regression analysis, the duration of mechanical ventilation, invasive procedures, and application of hormones and antacids are all independent risk factors for VAP in the pediatric ICU (Table 5).

3.3. Comparison of Treatment between the Two Groups of Children in the ICU. The VPA group had longer hospital stay than the non-VAP group, and the difference was statistically significant ((20.92 ± 4.16)d, (15.24 ± 3.77)d, $t = 8.4383$, $P \leq 0.001$); the hospitalization cost of the VPA group was substantially higher than that of the non-VAP group [(44.58 ± 1.04) ten thousand Yuan, (3.32 ± 0.43) ten thousand Yuan, $t = 10.6822$, $P \leq 0.001$) (Table 6 and Figure 1).

4. Discussion

Mechanical ventilation is a treatment that applies a ventilator to alter or replace patient's active breathing. It relies on auxiliary equipment to establish the pressure difference between the airway orifice and the alveoli of patient, thus alleviating the respiratory failure or dyspnea of the patient [10, 11]. According to the literature, over 20% children in the pediatric ICU will be treated with mechanical ventilation during treatment [12]. The complication of VAP in children often occurs with the widespread application of mechanical ventilation in the pediatric ICU. For every 24 h increase in

Table 1: Distribution of pathogenic bacteria of VAP in the pediatric ICU.

Species of pathogenic bacteria	Quantity	Composition ratio (%)
Gram-negative bacteria	43	61.43

time of mechanical ventilation, the probability of VAP will increase by 1% to 3%. According to related data [13], the incidence rate of VAP in children with mechanical ventilation was 9%–68%, the mortality was 24%–76%, and the incidence tends to increase year by year. Through the investigation of pathogenic bacteria changes in VAP children, it has been found in related studies that the primary pathogenic bacteria of VAP are Gram-negative bacteria, which have multiple drug resistance [14]. The primary pathogens of VAP in the pediatric ICU, of our hospital during the past 2 years, are *Acinetobacter baumannii*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, and *Pseudomonas aeruginosa*. These results are consistent with those of most research [15–17].

The results of this study's univariate analysis and multivariate logistic regression analysis showed that the duration of mechanical ventilation, invasive operations, and the application of hormones and antacids are all independent risk factors for VAP in the pediatric ICU. The duration of mechanical ventilation is positively correlated with VAP incidence, and the incidence of VAP increases with the extension of mechanical ventilation. This is because the immunity of children under the growing and developing stage is weak due to incomplete body development. During mechanical ventilation, the normal physiological barriers of the nose, throat, and tracheal mucosa of the child are vulnerable to being damaged, which reduces the movement capacity of cilia and increases the viscosity of sputum, as well as chances pathogen invasion and reproduction, thus leading to the occurrence of nosocomial infection [18, 19]. The long-term mechanical ventilation also aggravates lung injury. The long-term upper respiratory tract stimulation of patients increases the accumulation of sputum and oesophagal reflux in children, which increases the probability of pathogens entering the lung tissues and terminal bronchi, thereby further increasing the risk of VAP [20]. Children with invasive operations are prone to VAP, which may be related to the aspiration and regurgitation of colonizing bacteria, the contamination of mechanical ventilation pipes, and the improper operations of medical staff [21, 22]. Glucocorticoids have effects of anti-inflammatory, antiviral, antishock, and immune suppression, but the inappropriate use will reduce the body defence function of children and interfere with electrolyte balance and energy metabolism in

Application of antibiotics	YES = 1, NO = 0

the body. This will increase bacterial infection in children and lead to bacterial resistance, resulting in adverse outcomes such as severe pneumonia and immunodeficiency [23, 24] and rising VAP incidence in the pediatric ICU. The use of antacids increases VAP incidence, and its dominant reason may be that antacids can increase the PH value of gastric juice, thus weakening the gastric acid barrier in children. This can lead to gastrointestinal dysbacteriosis in children, leading to infections with multidrug-resistant bacteria such as *Acinetobacter baumannii* and *Klebsiella pneumonia*. On the other hand, the increased application of antacids may also lead to the displacement of the intestinal flora of children or the migration of colonizing bacteria to the lungs caused by oesophagal reflux, thus increasing VAP's probability [25, 26].

Given the independent risk factors for the occurrence of VAP in the pediatric ICU, our hospital has organized and formed the following targeted nursing countermeasures based on routine care. (1) Strengthening the humidification management of artificial airways and adjusting the total amount of humidification in line with the children's disease stouts and the viscosity of sputum. Appropriate airbag inflating pressure should be used, an adequate airtight artificial airway should be formed, the probability of external bacteria entering the respiratory tract should be reduced, and the respiratory infections caused by hand contamination should be prevented; subglottic sputum aspiration should be used, which can effectively clear the sputum and reduce the probability of pulmonary disease; intermittent shutdowns should be taken, the changes in the children's vital signs should be closely monitored, the intubation and ventilator should be removed as soon as possible to reduce the treatment time of mechanical ventilation, and the recovery of children's spontaneous breathing should be promoted [27, 28]. (2) The aseptic operations should be strictly followed when performing invasive operations. The pipeline should be checked immediately after operation to confirm whether it is polluted, the nursing should be strengthened, and the channel should be disinfected in time to prevent the reproduction of colonizing bacteria, thereby reducing the risk of VAP in children. (3) The sensitive drugs should be selected following the detection results of pathogenic bacteria in children, the changes and drug resistance of infected strains should be monitored by the dynamic method, and timely adjustments should be made to the types, duration, and dosage of hormones. (4) Gastric mucosal protectants instead of antacids should be used according to the child's condition to prevent

gastrointestinal bleeding; dietary guidance and oral care should be strengthened. According to studies, the nursing countermeasures can remarkably reduce the incidence of VAP and prevent secondary infection, which is an effective measure to improve the patient's quality of life [29, 30].

5. Conclusions

To conclude, children admitted to the pediatric ICU have a high VAP incidence; the primary pathogenic bacteria are Gram-negative bacteria. As the occurrence of VAP is closely related to a variety of factors, we should take targeted nursing countermeasures to reduce the duration of mechanical ventilation and the frequency of invasive operations and use the hormone and antacids rationally to reduce the risk of VAP and improve the prognosis.

Glaucoma is the second most common cause for blindness around the world and the third most common in Europe and the USA. Around 78 million people are presently living with glaucoma (2020). It is expected that 111.8 million people will have glaucoma by the year 2040. 90% of glaucoma is undetected in developing nations. It is essential to develop a glaucoma detection system for early diagnosis. In this research, early prediction of glaucoma using deep learning technique is proposed. In this proposed deep learning model, the ORIGA dataset is used for the evaluation of glaucoma images. The U-Net architecture based on deep learning algorithm is implemented for optic cup segmentation and a pretrained transfer learning model; DenseNet-201 is used for feature extraction along with deep convolution neural network (DCNN). The DCNN approach is used for the classification, where the final results will be representing whether the glaucoma infected or not. The primary objective of this research is to detect the glaucoma using the retinal fundus images, which can be useful to determine if the patient was affected by glaucoma or not. The result of this model can be positive or negative based on the outcome detected as infected by glaucoma or not. The model is evaluated using parameters such as accuracy, precision, recall, specificity, and F-measure. Also, a comparative analysis is conducted for the validation of the model proposed. The output is compared to other current deep learning models used for CNN classification, such as VGG-19, Inception ResNet, ResNet 152v2, and DenseNet-169. The proposed model achieved 98.82% accuracy in training and 96.90% in testing. Overall, the performance of the proposed model is better in all the analysis.

1. Introduction

It is important to diagnose glaucoma early on, which can reduce damage and loss of vision and ensure prompt and appropriate care. The worldwide prevalence of glaucoma for people ages 40 to 80 years is 3.54%. Each one out of 200 individuals aged 40 have glaucoma, which ascends to one in eight by age 80 [1]. Various glaucoma-related risk factors have been established, where the elevated intraocular pressure (IOP) that damages the optic nerves and blood vessels is the significant one. It can lead to total damage to the optic nerves and cause vision loss, if glaucoma is left untreated. This gradual and complete damage to the optic nerves is often followed by only mild or no symptoms, so it is known as the "sneak thief of sight" [2].

Glaucoma is one of the most common causes of irreversible vision loss after cataracts worldwide, accounting for 12 percent of all blindness cases each year. The number of people affected by glaucoma between the ages of 40 and 80 is expected to rise to 111.8 million by 2040. Furthermore, 2.4 percent of all people and 4.7 percent of those aged 70 and up are at risk of developing the disorder. Glaucoma is defined as the degeneration of retinal ganglion cells (RGCs) caused by a variety of disorders. RGC degeneration may result in two major health concerns:

(i) Structural changes to the optic nerve head (ONH) and the nerve fiber layer

(ii) Concurrent functional failures of the field of vision

These two glaucoma side effects might induce peripheral vision loss and, if left unchecked, blindness. Besides early detection and treatment, there is no cure for glaucoma. It is essential in developing automated techniques for detecting glaucoma early on [3]. A retinal fundus image is an essential tool for documenting the optic nerve's health, vitreous, macula, retina, and blood vessels. Ophthalmologists used a fundus camera to take the retinal image. The retinal image was used to diagnose eye disease like glaucoma. Glaucoma is a significant cause of global blindness that cannot be cured. Glaucoma disease can change the cup region's shape, which is the center portion of the ONH. The changes can be used as a parameter for the early indicator of glaucoma. The ONH transmits visual information from retina to the brain [2]. Figure 1 shows the retinal fundus images.

There are no initial glaucoma symptoms but will gradually damage the optic nerves and then results in blindness. Thus, it is crucial to detect glaucoma as early as possible so that it can prevent visual damage. Physiologically, glaucoma is indicated by increased optic cup excavation. The increasing size of the optic cup will impact the size of the optic disc, and this relation is known as a cup-to-disc ratio (CDR). It means ophthalmologists can diagnose glaucoma progression using the value of CDR measurement. The optic cup and optic disc segmentation will support to calculate the CDR from the retinal image [3]. The most noticeable symptom of glaucoma is often a loss of side vision, which might go unnoticed as the condition progresses. This is why glaucoma is sometimes referred to as the sneaky thief of vision. In the case of extreme intraocular pressure levels, headache, sudden eye pain, impaired vision, or the formation of halos around lights might occur.

(i) Loss of vision

(ii) Eye redness

(iii) Hazy eyes (specifically in infants)

(iv) Vomiting or nausea

(v) Vision narrowing (tunnel vision) [4]

There are many forms of glaucoma, including angle-closure glaucoma (ACG), primary open-angle glaucoma (POAG), primary congenital glaucoma (PCG), normal-tension glaucoma (NTG), pseudoexfoliative glaucoma (XFG), traumatic glaucoma (TG), uveitic glaucoma (UG), pigmentary glaucoma (PG), and neovascular glaucoma. The forms vary between different ethnicities in intensity, complexity, and occurrence. Open-angle and angle-closure glaucoma are the two major forms of glaucoma [4]. Figure 2 is shown in optic nerve head structure.

The most common form of glaucoma is open-angle glaucoma also referred to as wide-angle glaucoma. It happens as a result of partial drainage canal blockage in which the pressure slowly rises as the fluid is not properly drained. Symptoms start from vision loss in the periphery and may not be detected until central vision is impaired. Angle-closure glaucoma caused by impulsive and aqueous drainage full blockage is often called acute glaucoma. The pressure increases exponentially, which quickly leads to vision loss. It is formed because of the angle of narrow drainage and the small and droopy iris. The iris is pulled inside the anterior angle of the eye against the trabecular mesh network (drainage canals) leading to blockage and bulging of the iris forward [5].

In most situations, this damage is caused by abnormal rise of the pressure inside the eye. The secretion rate is equalised to the drainage rate in healthy eyes. Glaucoma occurs when the drainage canal was partially or entirely blocked, leading to a surge in pressure known as intraocular pressure that affects the optic nerves used to relay signals to the brain where it is possible to perceive visual information. If this damage is left untreated, complete blindness will result. Hence, it is essential to diagnose glaucoma in early stage.

In this research, early prediction of glaucoma using deep learning technique is proposed. In this proposed deep learning model, the ORIGA dataset is used for the evaluation of glaucoma images. For segmentation, the U-Net segmentation model is implemented in this model and a pretrained transfer learning model, DenseNet-201, is used for feature extraction along with deep convolution neural network (DCNN). The DCNN approach is used for the classification, and the final results will be representing whether the glaucoma infected or not.

2. Related Works

Several study models have been developed by various authors for the segmentation and classification of glaucoma detection, each employing a different methodology and algorithm from the others. As will be detailed more, the majority of them are deep learning-based models with varying levels of performance analysis. The fact that retinal disease is such a terrible ailment makes it difficult to detect and distinguish between the two conditions.

The most common approach used in most of the studies to diagnose glaucoma was the acquisition of retinal scans using digital capture equipment for visual content, which was the most common procedure used in most of the studies. The scan images were then preprocessed to equalize the

anomalies. During the preprocessing stage, blood vessels were segmented and depicted in order to create a vessel free image. Furthermore, feature extraction was utilized to efficiently reduce the dimensions of an image in order to represent the interesting areas of an image as a compact feature vector that could be used for precisely classifying the large amount of data collected. Techniques such as textures, pixel intensity values, FFT coefficients, and histogram models were employed in the process of feature extraction and classification. Data analysis and classification were accomplished through the use of image classification, which involved examining the numerical aspects of an image. The data set was divided into several classifications based on the results, such as normal or glaucoma, to facilitate analysis.

Prastyo et al. applied the U-Net segmentation technique to retinal fundus images in order to segment the optic cup. The segmentation of the optic cup and the optic disc aids in the achievement of improved performance in the detection of glaucoma disease. The ROI based on the optic disc image was cropped and segmented with the help of the U-Net algorithm. In order to obtain optimal training, an adaptive learning rate optimization technique was applied, and the model attained a dice coefficient rate of 98.42 percent and a loss rate of 0.15 percent during testing [6]. A model of attention-based CNN (AG-CNN) for identifying glaucoma was proposed by Li et al. and it was tested on a database known as the large-scale attention-based glaucoma database (LAG). The removal of large levels of redundancy from fundus images may result in a reduction in the accuracy and reliability of glaucoma identification. The AG-CNN model took this into consideration and made a decision on it. In this model, subnets of attention prediction, pathological region localization, and classification were combined to form an overall model. When it comes to detecting glaucoma, the model has a 96.2 percent accuracy rate and an AUC of 0.983. In several cases, the ROI was only partially highlighted, and the minor problematic regions were not correctly identified [7].

For the purpose of automatically segmenting the glaucoma images, MacCormick et al. developed a new glaucoma detection algorithm based on spatial detection. The method was developed on the basis of four assumptions: segmentation, deformation, shape, and size of the images were all taken into consideration. After a segmentation of the cup and disc of the retinal fundus images was completed, an estimation of the cup/disc ratio (CDR) in 24 cross sections was performed to generate the pCDR (CDR profile). The results were compared between healthy discs and glaucomatous discs on both external and internal validation, with the AUROC for internal validation being 99.6 percent and for external validation being 91 percent [8].

Juneja et al. proposed an artificial intelligence glaucoma expert system that was based on the segmentation of the optic cup and disc. In order to automate the identification of glaucoma, a deep learning architecture was designed, with CNN serving as the core element. In this model, two neural networks were integrated and used for segmenting images of the optic disc and cup of fundus, which were taken from different cameras. By examining 50 images, the model was able to segment the cup with 93 percent accuracy and the disc with 95.8 percent accuracy [9]. To diagnose glaucoma in retinal fundus images, Diaz-Pinto et al. used five ImageNet trained models, including the VGG-16, VGG-19, ResNet50, Inception-v3, and Xception, all of which were trained using ImageNet data. Performance study revealed that the Xception model outperformed the other models by obtaining better results, and the Xception model was then tested with five publicly accessible datasets for glaucoma diagnosis to confirm its superiority. The Xception model was more efficient than other commonly used models [10] due to its higher level of computing efficiency.

With the help of deep learning, SynaSreng et al. developed an automated two-stage model for glaucoma diagnosis and classification. Initially, the optic disc area was segmented using DeepLabv3+ architecture, but the encoder segment was replaced with several deep CNNs after the initial segmentation. For classification, a trained DCNN was employed with three approaches: transfer learning, feature descriptors learning using SVM, and constructing an ensemble of techniques in transfer learning and feature descriptors learning, respectively. It was possible to segment the optic discs using DeepLabv3+ and MobileNet architectures because of the integration of the two systems. Five separate glaucoma datasets were used in the classification process, which was done using an ensemble of algorithms. Finally, utilizing the ACRIMA dataset, DeepLabv3+ and MobileNet were able to achieve an accuracy of 99.7 percent for OD segmentation and 99.53 percent for classification using DeepLabv3+ and MobileNet [11].

To diagnose diabetic retinopathy, Mateen et al. developed a fundus image classification model that combined the VGG-19 with principal component analysis (PCA) and singular value decomposition (SVD) and used the VGG-19. The model's performance in region segmentation, feature extraction and selection, and classification has been improved by combining the Gaussian mixture model with the VGG, PCA, and SVD [12, 13]. Fu et al. employed two deep learning-based glaucoma detection techniques, multilabel segmentation network (M-Net) and disc-aware ensemble network, to detect the presence of glaucoma (DENet). Initially, M-Net was utilized to solve the segmentations of both the optic cup and the disc, and DENet was used to combine the deep hierarchical context of the global fundus image with the local optic disc region in the initial stages. The CDR was calculated based on the segmentation of the optic cup and disc in order to determine the glaucoma risk. It is possible to get accurate results from an image without segmenting it using the DENet [13].

Jiang et al. developed a new multipath recurrent U-Net model for segmenting retinal fundus image. The efficiency of the model was validated by the performance of two segmentation processes like optic cup and disc segmentation and retinal vessel segmentation. The model achieved 99.67% accuracy for optic disc segmentation, 99.50% for optic cup segmentation, and 96.42% for retinal vessel segmentation by using the Drishti-GS1 dataset [14].

Mahum et al. proposed an early-stage glaucoma diagnosis model based on deep learning-based feature extraction. Images were preprocessed in the first phase before the region of interest was retrieved using segmentation. Then, using the hybrid features descriptors, such as CNN, histogram of oriented gradients, local binary patterns, and speeded up robust features, characteristics of the optic disc were recovered from images including optic cup. Furthermore, HOG was used to extract low-level features, while the LBP and SURF descriptors were used to extract texture features. Furthermore, CNN was used to compute high-level characteristics. The feature selection and ranking technique of maximum relevance minimum redundancy was applied. Finally, multiclass classifiers such as SVM, KNN, and random forest were used to determine if fundus images were healthy or diseased [15].

Gheisari et al. proposed a new method for detecting glaucoma that combined temporal (dynamic vascular) and spatial (static structural) data. A CNN and recurrent neural network (RNN) classification model that extracts not just the spatial features in the fundus images but additionally the temporal features inherent in the consecutive images was developed. Because CNN was designed to diagnose glaucoma, it was built on spatial information encoded in images. CNN was used with RNN for increased performance in detecting glaucoma based on both temporal and spatial features [16].

3. Proposed Methodology

In this research, the deep learning-based models are proposed for segmentation and classification of glaucoma detection using retinal fundus images collected from ORIGA database. For segmentation, the U-Net architecture is used and a pretrained DenseNet-201 architecture was used to extract the features from the segmented image. For classification, the DCNN architecture is used to classify the images for detecting glaucoma.

3.1. Dataset Description. The ORIGA dataset is used in this research for evaluation [17]. The data set contains 650 images of the color retinal fundus with the extension (.jpg) and ground truth with the extension (.mat). The retinal images were collected by the Singapore Malay Eye Study (SiMES). ORIGA database shares clinical ground truth retinal images with the public and provides open access for researchers to benchmark their computer-aided segmentation algorithms. ORIGA dataset is open for online access upon request. After preprocessing, 650 image data were divided into 488 image data as training data, 162 image data as testing data [1, 6, 8, 11, and 13].

3.2. Segmentation Using U-Net. The deep learning algorithm-based U-Net architecture is implemented for optic cup segmentation. The U-Net architecture is the most widely used segmentation architecture for medical images. The architecture of the U-Net segmentation process is shown in Figure 3. The retinal fundus image is given as input; the ROI based on optical disc image is cropped and segmented using deep learning algorithm. The output of the segmentation will be based on the optic cup, where the optic cup outline is masked as shown in Figure 3.

Before segmenting the image, in preprocessing, the ground truth (mask) image was changed to (.png) so that an algorithm could process it. To get the Optic Disk (OD) mask, we used the equation (disc = double (mask > 0)), while for Optic Cup (OC), we employed the equation (cup = double (mask > 1)). After that, we took the region of interest (ROI) from the retinal fundus image by using the ground truth from OD to take OC's closest area.

A contracting path (left side) and an expansive path (right side) are included in this architecture, joined by multilevel skip connections (middle). Input to the contracting path is retinal fundus images, and predictions are generated from a final layer following the expansive path. Each convolution layer has filter banks, each applying 3×3 padded convolutions followed by a rectified linear activation unit whose functional form is $f(z) = \max(0, z)$ [18–20].

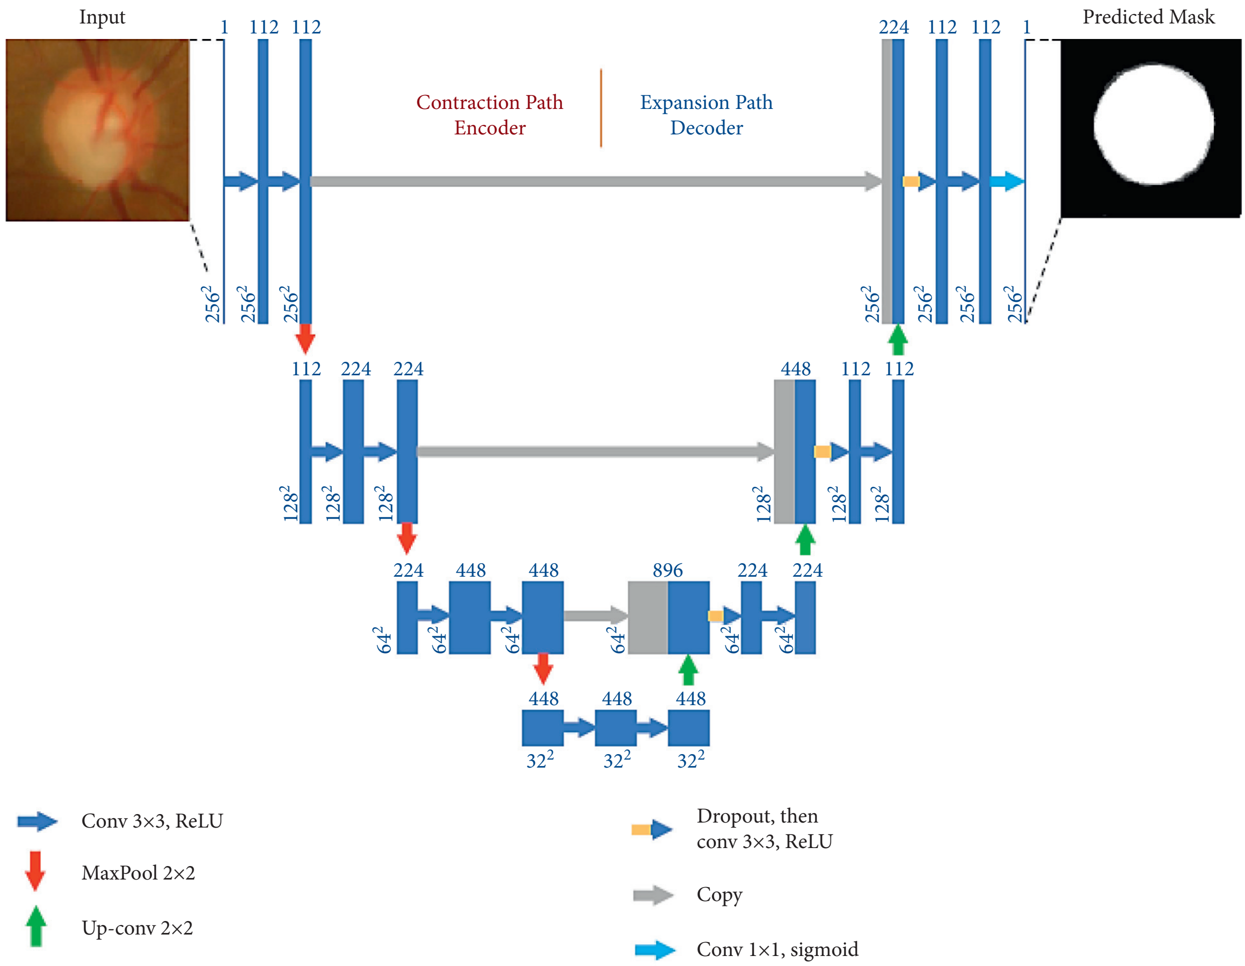

FIGURE 3: U-Net architecture of segmentation [6].

There are three convolutional blocks each in the contracting and expansive paths. Two convolutional layers consist of a block in the contracting path followed by a max-pooling layer with a pool size of 2×2. A block contains a 2×2 upsampling layer in the expansive path, a concatenation from the contracting path with the corresponding block (i.e., a merged layer), a dropout layer, and two convolutional layers. The connecting path includes two convolutional layers. Finally, a 1×1 convolutional layer with a sigmoid activation and a single filter to output pixel-wise class scores is the final output layer. Every convolution layer in blocks 1, 2, and 3 includes 112, 224, and 448 filters in the contracting path, while blocks 5, 6, and 7 include 224, 122, and 122 filters in the expansive path individually. There are 448 filters in every convolutional layer in the connecting path. The proposed DCNN differs from the original U-Net in the number of filters chosen for the model to fit into the GPU memory in each convolution layer and the use of dropouts in the expansive path.

3.3. DenseNet-201 with CNN. A DCNN model with pretrained DenseNet-201 is proposed in this research [21]. This DenseNet-201 model is based on deep transfer learning (DTL) as it is implemented to identify the glaucoma images from the input dataset by classifying the retinal fundus images. To extract features from the dataset, a pretrained DenseNet-201 model is used, and the DCNN model is used for classification. 256×256 is the input image size. The architecture of the DenseNet-201 with DCNN is shown in Figure 4.

DCNN usually performs well with a larger data set over a smaller one. TL could be useful in those CNN applications where the data set is not huge. For applications with comparatively smaller datasets, TL's concept utilizes the learned model from large datasets such as ImageNet. This removes the need for a large dataset and decreases the lengthy training time as needed when generated from scratch by the deep learning algorithm. TL is a deep learning method that uses a model trained for a single assignment as a starting point to train a model for a similar assignment. It is typically much quicker and simpler to fine-tune a TL network than training a network from scratch. By leveraging common models that have been already trained on large data sets, it allows the training of models using similar small labeled data. Training time and computing resources can be significantly decreased. With TL, the model does not need to be trained for as many epochs (a complete training period on the entire dataset) like a new model.

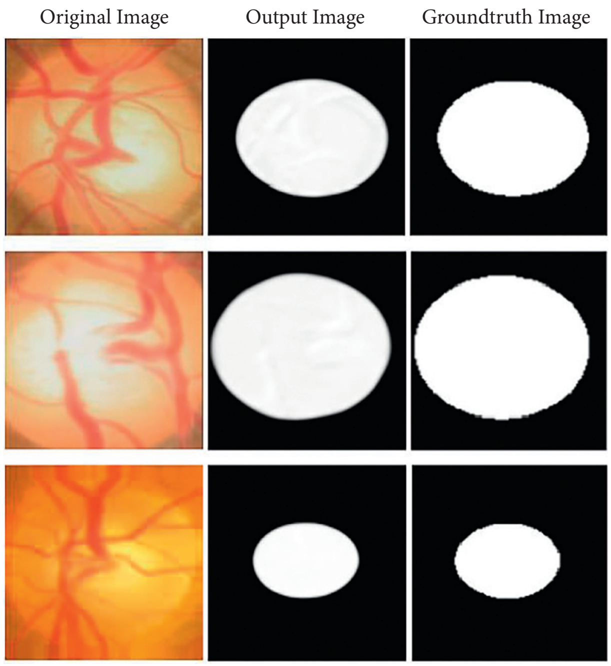

Figure 4: U-Net output image compared with ground truth image.

Because of the feature reuse possibility by various layers, the DenseNet-201 uses the condensed network that provides simple to train and highly parametrical effective models and expands variety in the following layer input and enhances the execution. On various data sets, such as CIFAR-100 and ImageNet, DenseNet-201 has shown remarkable results. Direct connections from each previous layer to every subsequent layer are added to boost connectivity in the DenseNet-201 model as shown in Figure 5.

The concatenation of feature can be mathematically expressed as

$$fc^i = \mathrm{NL}_i\left(fc^0, fc^1, \ldots, fc^{i-1}\right). \quad (1)$$

Here, $\mathrm{NL}_i(\bullet)$ was a nonlinear transformation that could be described as batch normalization (BN) composite function, accompanied by a rectified linear unit function (ReLU) and a (3×3) convolution layer.

For ease of implementation, $[fc^0, fc^1, \ldots, fc^{i-1}]$ indicates the feature map concatenation according to layers 0 to $i-1$ are combined into a single tensor. Dense blocks are generated in the network architecture for downsampling purposes, divided by layers known as transition layer consisting of BN followed by a 1×1 convolution layer and an average 2×2 pooling layer. DenseNet-201's growth rate defines how dense architecture produces better results, and the "H" hyperparameter denotes it. Because of its structure, where feature maps were regarded as a network's global state, DenseNet-201 performs adequately well even with a minimal growth rate. Therefore, all function maps of the preceding layers have access to each successive layer. Each layer includes "H" feature maps to the global state where each count of input feature maps at i^{th} layers $(fm)^i$ was expressed as

$$(fm)^i = H^0 + H(i-1). \quad (2)$$

Here, the input layer channels are given by H^0. A 1×1 convolution layer preceding each 3×3 convolution layer is added to increase computational performance, which reduces the input feature maps that were usually higher than the feature maps of output H. The 1×1 conv layer was known as the bottleneck layer and generates feature maps. FC layers act as a classifier in the classification stage. It uses extracted features and assesses the probability of a segment in the image. The architecture of DenseNet-201 is shown in Figure 6.

To create nonlinearity and to reduce overfitting, the activation function and dropout layer are typically used. Two dense layers of 128 and 64 neurons were implemented for classification. The DenseNet-201 feature extraction model was used for binary classification preceded by the sigmoid activation function to replace the softmax activation function utilized in the DenseNet-201 design. In the FC dense layer, every neuron was FC in the prior layer. The FC layer "i" whose input 2D feature map was extended to a 1D feature vector can be mathematically described.

$$\begin{aligned} v^{i-1} &= \mathrm{Bernoulli}(p), \\ z^{i-1} &= v^{i-1} * d^{i-1}, \\ z^i &= f\left(x^k z^{i-1} + u^i\right). \end{aligned} \quad (3)$$

Here, the Bernoulli function produces a vector $v^i = 1$ randomly with a certain probability that obeys the 0-1 distribution. The dimension of the vector is d^{i-1}. The dropout strategy is used by the initial two layers of the FC layer to randomly block some neurons based on a defined probability, which efficiently avoids overfitting situations in deep networks. The terms "x" and "u" describe the FC layer's respective weighting and offset parameters. The function of sigmoid activation was to convert nonnormalized outputs to 0 or 1 as binary outputs. Therefore, it helps to classify the images as nonglaucoma or glaucoma. The sigmoid function can be expressed as

$$S = \frac{1}{1 + e^{-\left(\sum x_i \cdot z_i\right)}}, \quad (4)$$

where the neuron output is S. The weights and inputs, respectively, represent x_i and z_i.

4. Performance Analysis

The performance analysis of the proposed DCNN with the U-Net and DenseNet-201 model is assessed using the dataset in this section. The model is evaluated using parameters such as accuracy, precision, recall, specificity, and F-measure. Also, a comparative analysis is conducted for the validation of the model proposed. The output is compared to other current deep learning models used for CNN classification, such as VGG-19, Inception ResNet, ResNet 152v2, and DenseNet-169. On the MATLAB 2019a Simulink toolbox, all the experiments are implemented and carried out. The dataset is split into 75% for training and 30% for validating the performance analysis.

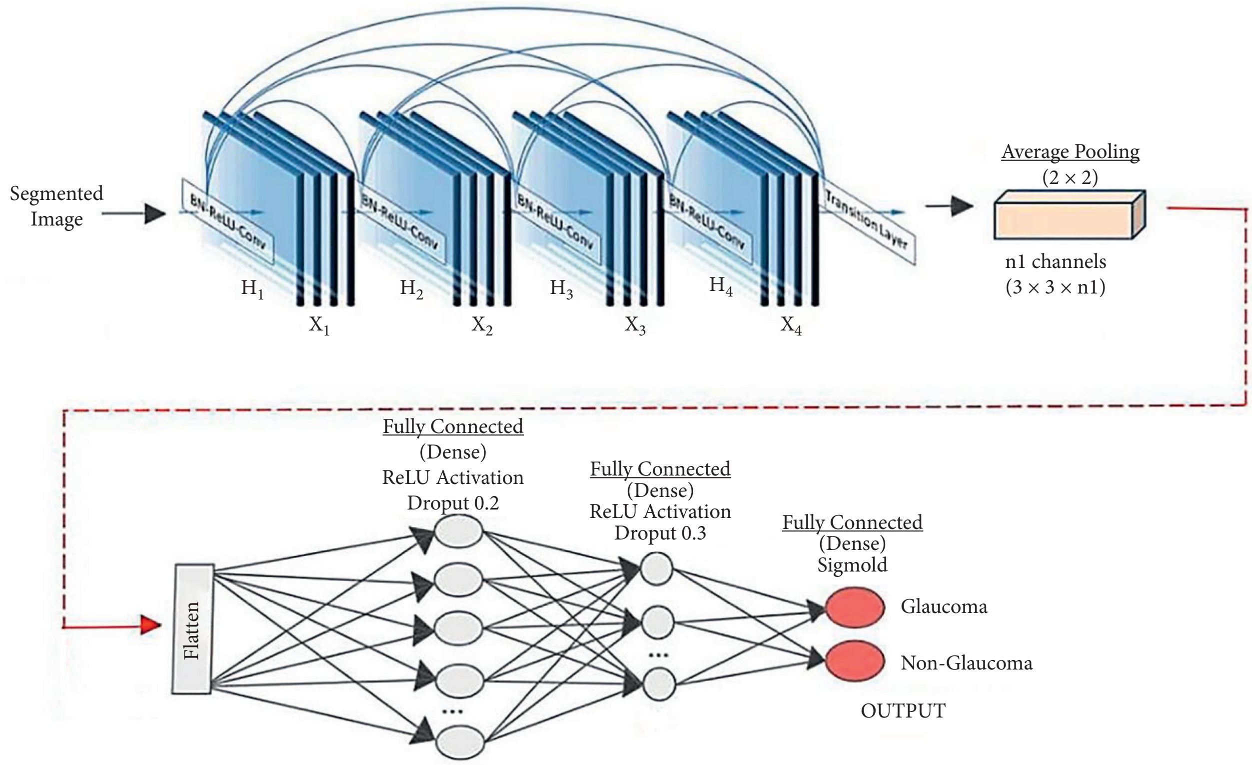

Figure 5: Feature extraction using pretrained DenseNet-201 model and classification using DCNN [21].

4.1. Performance Metrics. The primary objective of this research is to detect the glaucoma using the retinal fundus images, which can be useful to determine if the patient was affected by glaucoma or not. The result of this model can be positive or negative based on the outcome detected as infected by glaucoma or not. The true positive, true negative, false positive, and false negative are properly analyzed to estimate the outcome of this model.

TP: it indicates the total predictions correctly obtained in positive cases

FP: it indicates the total predictions incorrectly obtained in positive cases

TN: it indicates the total predictions correctly obtained in negative cases

FN: it indicates the total incorrect predictions in negative cases

Accuracy is the model's estimation of the performance subset. It is the primary output metric used to calculate the efficiency of the classification process. It is usually used to estimate when both the positive and negative classes are equally important. It is calculated using the following equation.

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}. \quad (5)$$

As shown in Table 1, the proposed model achieved better classification accuracy in both training and testing for classifying the glaucoma fundus images. The model obtained 98.82% training accuracy, which is 1.09% to 3.96% improved compared with other techniques. The testing accuracy is 96.90%, which is 1.36% to 5.26% increased performance than the other existing compared models. The graphical chart of the comparison is plotted in Figure 7.

Precision is a positive predictive value. It is the measure of the cumulative predictive positive value of the correctly predicted positive observation. The lower precision value reflects that a large number of false positives have affected the classification model. The measure of precision can be computed using the following equation.

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}. \quad (6)$$

The estimation of precision is tabulated in Table 2, which shows that the proposed model has achieved better precision value than the compared models. The model obtained 98.63% precision rate in training, which was 1.1% to 4.8% improved compared with other techniques. The precision rate in testing was 96.45%, which was 1.08% to 4.9% increased performance than the other existing compared models. Figure 8 shows the comparison of precision analysis.

The sensitivity is also referred to as recall. It is the ratio of properly predicted positive evaluation of the overall positive predictive value. The lower recall value reflects that a large number of false negative values have affected the classification model. The recall estimation can be calculated using the following equation.

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}. \quad (7)$$

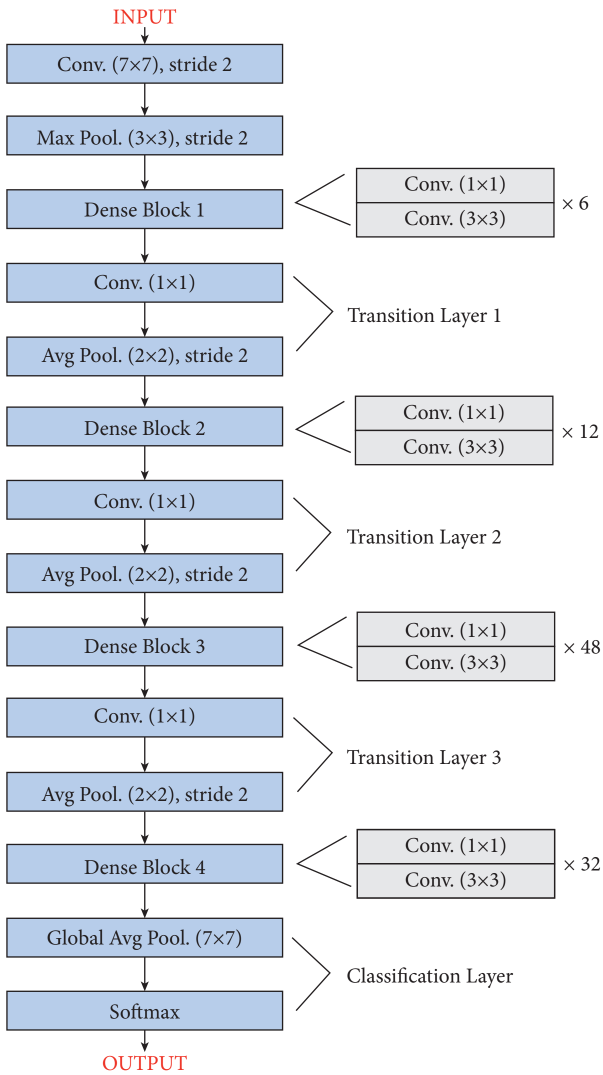

Figure 6: DenseNet-201 architecture [21].

Table 1: Performance analysis of accuracy.

Models	Training	Testing
VGG-19	97.73	95.54
Inception ResNet	94.86	91.64
ResNet 152v2	97.56	93.21
DenseNet169	97.14	95.45
Proposed	98.82	96.90

The proposed model has gained better recall or sensitivity rate as tabulated in Table 3. The model obtained 98.95% recall rate in training, which was 1.1% to 4.05% improved compared with other techniques. The recall rate in testing was 97.03%, which was 1.3% to 5.06% better performance than the other existing compared models. The comparison graph is plotted, as shown in Figure 9.

As per this model, specificity is the prediction that healthy subjects do not have the disease. It is the percentage of subjects with no illness that is tested as negative. The specificity estimation can be calculated using the following equation.

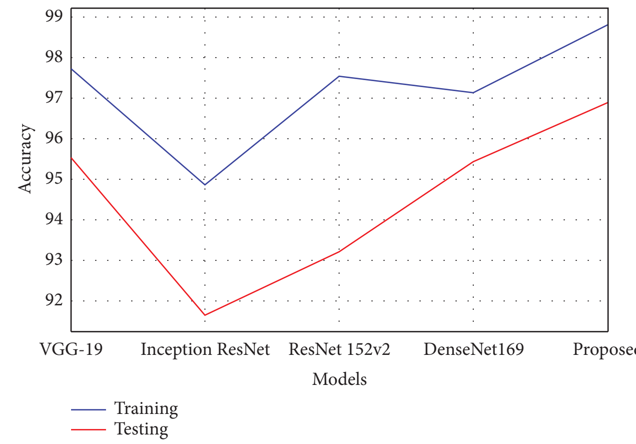

Figure 7: Graphical plot of accuracy.

Table 2: Performance analysis of precision.

Models	Training	Testing
VGG-19	97.30	94.70
Inception ResNet	93.81	91.52
ResNet 152v2	97.28	93.02
DenseNet169	97.49	95.37
Proposed	98.63	96.45

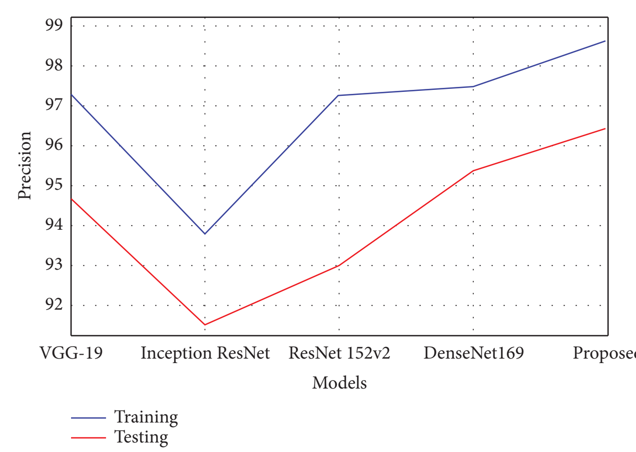

Figure 8: Graphical plot of precision.

Table 3: Performance analysis of recall.

Models	Training	Testing
VGG-19	97.84	95.62
Inception ResNet	94.90	91.97
ResNet 152v2	97.62	94.05
DenseNet169	97.35	95.69
Proposed	98.95	97.03

$$\text{Specificity} = \frac{TN}{TN + FP}. \tag{8}$$

As shown in Table 4, the proposed model has obtained a better specificity rate than the other comparative models of deep learning.

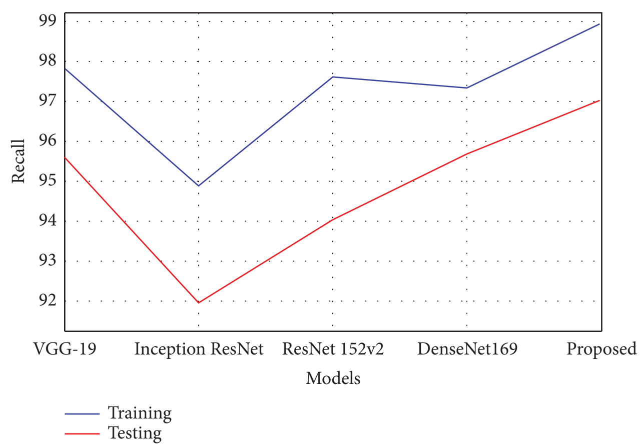

FIGURE 9: Graphical plot of recall.

TABLE 4: Performance analysis of specificity.

Models	Training	Testing
VGG-19	97.24	95.67
Inception ResNet	94.05	89.92
ResNet 152v2	97.28	92.73
DenseNet169	97.00	94.89
Proposed	98.15	96.33

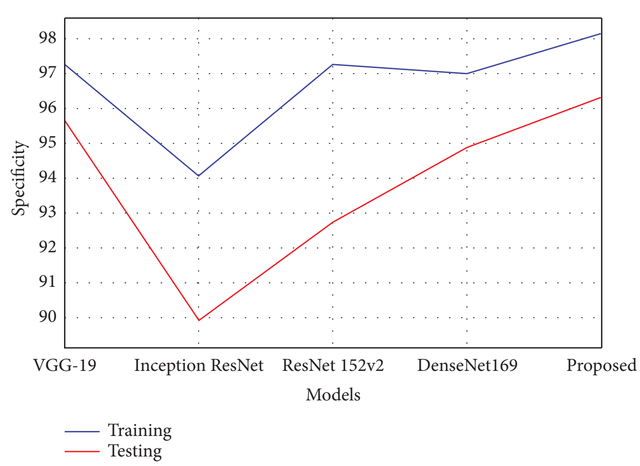

FIGURE 10: Graphical plot of specificity.

The model obtained 98.15% specificity rate in training, which was 0.8% to 4.1% improved compared with other techniques. The specificity rate in testing was 96.33%, which was 0.6% to 6.4% better performance than the other existing compared models. Figure 10 represents the comparison of specificity estimated.

The F-measure estimates the accuracy of the test and is defined as the weighted harmonic mean of the precision of the test and the recall. The accuracy does not take into account how the data was distributed. The F-measure is then utilized to manage the distribution problem with accuracy. When the data set has imbalance classes, it was useful. The F-measure estimation can be calculated using the following equation.

TABLE 5: Performance analysis of F-measure.

Models	Training	Testing
VGG-19	97.52	95.39
Inception ResNet	94.79	91.55
ResNet 152v2	97.35	93.14
DenseNet169	97.07	95.09
Proposed	98.50	96.28

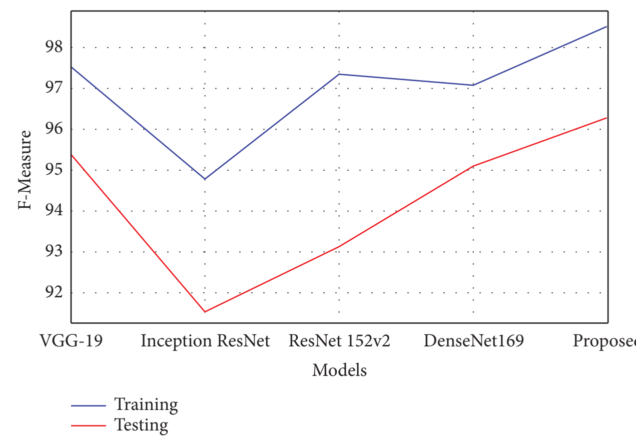

FIGURE 11: Graphical plot of F-measure.

$$\text{F} - \text{measure} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}. \quad (9)$$

The F-measure estimation is tabulated in Table 5, which represents that the proposed model has achieved better F-measure value than the compared models. The model obtained 98.50% F-measure rate in training, which was 0.9% to 3.7% improved compared with other techniques. The F-measure rate in testing was 96.28%, which was 0.8% to 4.7% better performance than the other existing compared models. Figure 11 shows the comparison of F-measure analysis.

In this research, by comparing all the models like VGG-19, Inception ResNet, ResNet 152v2, and DenseNet-169, the proposed model has achieved better performance in both the training and testing stages. The least performance achieved model is Inception ResNet and DenseNet-169 has some close performance to the proposed model.

5. Conclusion

In this research, early prediction of glaucoma detection model using deep learning technique was proposed. In this proposed deep learning model, the ORIGA dataset was used for the evaluation of glaucoma images. 75% of the data was used for training and 25% of data was used for testing. For segmentation, the U-Net segmentation model was implemented in this model and a pretrained transfer learning model, DenseNet-201, was used for feature extraction along with DCNN. The DCNN approach was used to classify the images for glaucoma detection. The primary objective of this model was to detect the glaucoma using the retinal fundus images, which can be useful to determine whether the patient is affected by glaucoma or not. By segmenting the fundus images, the optic cup region was segmented and compared with ground truth images from the dataset. After segmentation, the features were extracted from the images using DenseNet model and classified using DCNN. The proposed model obtained 98.82% training accuracy, which was 1.09% to 3.96% higher compared with other models and the testing accuracy was 96.90%, which was 1.36% to 5.26% higher than the compared models. By analyzing the performance analysis, the results obtained by the proposed model are efficient and the reason for not achieving 100% results was due to the false positives and false negatives. In future, this imbalance issue will be sorted out by improving the classifier and reducing the threshold. This model can be useful for various medical image segmentation and classification processes like diabetic retinopathy, brain tumor detection, breast cancer detection, etc.

Retraction

Retracted: MiR-139-5p Inhibits the Development of Gastric Cancer through Targeting TPD52

Journal of Healthcare Engineering

Received 12 November 2022; Accepted 12 November 2022; Published 26 January 2023

Journal of Healthcare Engineering has retracted the article titled "MiR-139-5p Inhibits the Development of Gastric Cancer through Targeting TPD52" [1] due to concerns that the peer review process has been compromised.

Following an investigation conducted by the Hindawi Research Integrity team [2], significant concerns were identified with the peer reviewers assigned to this article; the investigation has concluded that the peer review process was compromised. We therefore can no longer trust the peer review process, and the article is being retracted with the agreement of the Chief Editor.

Background. Many researchers have confirmed that miRNAs are involved in the pathogenesis of gastric cancer (GC). This study focused on investigating the specific functions of miR-139-5p in GC. *Methods*. MiR-139-5p and TPD52 expressions were observed by qRT-PCR or western blot in GC. The functional mechanism of miR-139-5p was explored by the luciferase reporter assay, transwell assay, and MTT assay. *Results*. MiR-139-5p downregulation and TPD52 upregulation were detected in GC. Adverse clinical features and prognosis in GC patients were related to low miR-139-5p expression. MiR-139-5p overexpression restrained GC cell proliferation and metastasis. Furthermore, miR-139-5p directly targeted TPD52. TPD52 silencing blocked GC progression. And TPD52 upregulation weakened the antitumor effect of miR-139-5p in GC. *Conclusion*. MiR-139-5p inhibits GC cell proliferation and metastasis through downregulating TPD52.

1. Introduction

Gastric cancer (GC) ranks third in human malignancies [1]. Moreover, it ranks first in gastrointestinal malignancies, accounting for 95% of gastric malignancies [2]. Now, surgery is still the most important treatment of early GC, and it is also the main method for the treatment of GC [3]. Due to the late detection of GC, the effect of surgery is not good. And 5-year survival rate is maintained at about 30% [4]. Additionally, patients with early GC have a better prognosis after treatment. The postoperative effect is better for patients over 60 years old, while patients under 30 years old tend to have poor prognosis [5]. Therefore, it is necessary to strengthen the attention to the symptoms of early GC and the monitoring of high-risk groups in order to increase the detection rate of patients with early GC.

MicroRNAs (miRNAs) regulate tumorigenesis by affecting their target genes [6–8]. Recently, more and more miRNAs are found to express abnormally in GC, such as miR-216a [9], miR-937 [10], and miR-1271 [11]. In particular, miR-139 participated in human GC development [12]. Moreover, abnormal miR-139-5p expression often occurs in various cancers and diseases, including neurodegeneration [13], breast cancer [14], glioblastoma [15], and thyroid carcinoma [16]. Recently, it has been reported that obesity was associated with miR-139-5p [17]. Collectively, miR-139-5p is an important biomarker for human diseases, including cancers.

It has been proposed that tumor protein D52 (TPD52), which belongs to the TPD52-like protein family, functions as an oncogene in prostate cancer [18]. Upregulation of TPD52 was first found in human breast cancer [19]. TPD52 overexpression was also detected in various human malignant tumors [20]. In addition, TPD52 expression was associated with the systemic progression of prostate cancer [21]. High TPD52 expression had an association with bad prognosis in breast cancer [22] and ovarian carcinoma [23] patients. More importantly, oncogenic TPD52 regulated cell metastasis in prostate cancer [24]. Nonetheless, the mechanism of TPD52 in GC is still unclear. Here, the functional mechanism of TPD52 and miR-139-5p was investigated in GC. The relationship between miR-139-5p and prognosis in GC patients was also analyzed.

2. Materials and Methods

2.1. Clinical Tissues. Sample tissues were obtained from sixty-seven GC patients in The Affiliated Hospital of Qingdao University. All participators provided informed consent. All GC patients only received surgery. Theses tissues were stored in a −80°C refrigerator. Our research was approved by the Institutional Ethics Committee of The Affiliated Hospital of Qingdao University.

2.2. Cell Culture and Transfection. HGC-27, SGC-7901, MKN-45, and AGS GC cell lines and GES-1 cells (ATCC, USA) were inoculated in the RPMI-1640 medium with FBS and incubated under suitable conditions (37°C, 5% CO_2).

MiR-139-5p mimics and inhibitor, TPD52 vector, and siRNA (GeneCopoeia, Guangzhou, China) were transfected in GC cells by using Lipofectamine 2000 (Invitrogen, Carlsbad, USA).

2.3. Transwell Assay. Transwell chamber (8 μm pore size; Millipore) is used to evaluate the migratory and invasive ability of GC cells. The upper chamber was put with 4×10^4 GC cells with the uncoated membrane. 10% FBS was added in the lower chamber. The coated membrane was used for the invasion assay. These cells were cultured for 24 h. Finally, moved cells were observed by using a microscope.

2.4. MTT Assay. Transfected cells (3×10^3 cells/well) were incubated in 96-well plates at 0, 24, 48, 72, and 96 h. Cell viability was evaluated by the MTT assay. The absorbance (OD = 490 nm) was examined with a spectrophotometer (Thermo Scientific).

2.5. Quantitative RT-PCR. TRIzol reagent (Invitrogen, Carlsbad, USA) was applied to extract total RNA containing miRNA. Quantitative RT-PCR was performed with SYBR Green PCR Master Mix and primers. GAPDH or U6 was used as an internal reference. MiR-139-5p and TPD52 expressions were assessed by the $2^{-\triangle\triangle ct}$ method. The primers are shown in Table 1.

2.6. Western Blot Analysis. RIPA lysis buffer was applied to extract protein samples. Protein was then separated by 10% SDS-PAGE and transferred into the PVDF membrane. Protein was incubated with anti-TPD52 (Abcam, Cambridge, USA) and anti-GAPDH antibodies (Epitomics, Burlingame, USA) at 4°C overnight. Next, the membrane was incubated with the corresponding secondary antibody (Abcam, Cambridge, USA). Finally, protein bands were observed by ECL (ECL, Pierce).

2.7. Dual-Luciferase Assay. pGL3 vectors (Promega, Madison, USA) with the 3′-UTR of wild-type or mutant TPD52 were built. GC cells with miR-139-5p mimics and the above vector were incubated for 48 h. Finally, luciferase activity was detected through the dual-luciferase assay system (Promega, USA).

2.8. Statistical Analysis. Data were calculated by SPSS 19.0 and GraphPad Prism 6. Differences were calculated by the chi-squared test. Survival analysis was performed by the Kaplan–Meier method with the log-rank test. All experiments were performed in 3 replicates. Significant difference indicated $P < 0.05$.

3. Results

3.1. MiR-139-5p Downregulation and TPD52 Upregulation Were Detected in GC. MiR-139-5p expression was evaluated in GC. MiR-139-5p in GC tissues was downregulated compared to the control (Figure 1(a), $P < 0.01$). Consistently, miR-139-5p was downregulated in HGC-27, SGC-7901, MKN-45, and AGS cells compared to GES-1 cells (Figure 1(b), $P < 0.05$ or 0.01). Meanwhile, the expression of TPD52 in GC was also detected. TPD52 upregulation was found in GC tissues (Figure 1(c), $P < 0.01$) and cells (Figure 1(d), $P < 0.05$ or 0.01). Additionally, lymph metastasis and TNM stage in GC patients were related to low miR-139-5p expression ($P < 0.05$, Table 2). And low miR-139-5p expression was related to worse prognosis (Figure 2) in GC patients.

3.2. MiR-139-5p Impeded GC Progression. The specific function of miR-139-5p in GC was investigated in HGC-27 cells containing miR-139-5p mimics or inhibitor. MiR-139-5p expression was enhanced by its mimics (Figure 3(a), $P < 0.01$) and lowered by its inhibitor (Figure 3(b), $P < 0.01$) in HGC-27 cells. Functionally, miR-139-5p overexpression restrained HGC-27 cell proliferation (Figure 3(c), $P < 0.01$). MiR-139-5p downregulation facilitated GC cell proliferation (Figure 3(d), $P < 0.01$). Meanwhile, miR-139-5p overexpression weakened the migratory and invasive abilities (Figures 4(a) and 4(b), $P < 0.01$) in HGC-27 cells, but miR-139-5p downregulation showed an opposite effect (Figures 4(a) and 4(b), $P < 0.01$). Collectively, miR-139-5p impeded GC progression.

3.3. TPD52 Was a Downstream Target of MiR-139-5p in GC. Furthermore, TargetScan (http://www.targetscan.org/vert_71/) shows that TPD52 can bind to miR-139-5p (Figure 5(a)). Luciferase reporter gene assay showed that miR-139-5p mimics blocked wild-type TPD52 luciferase activity (Figure 5(b), $P < 0.01$), which had little effect on that of mutant TPD52. Additionally, miR-139-5p had a negative association with TPD52 expression in GC tissues ($R^2 = 0.7531$, $P < 0.001$; Figure 5(c)). Consistently, miR-139-5p overexpression reduced TPD52 expression in HGC-27 cells when miR-139-5p downregulation accelerated TPD52 expression (Figures 5(d) and 5(e), $P < 0.01$). Therefore, miR-139-5p directly targets TPD52 and negatively regulates its expression in GC.

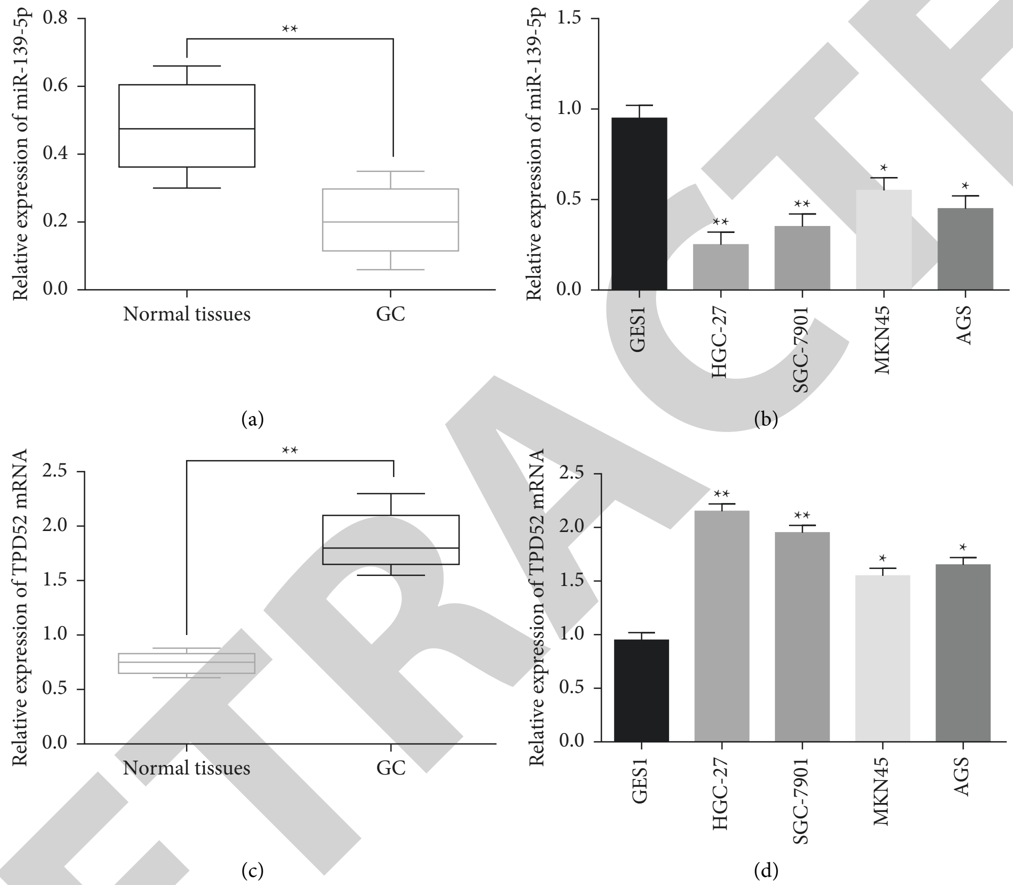

Figure 1: Downregulation of miR-139-5p and upregulation of TPD52 were detected in GC. (a) MiR-139-5p expression in GC tissues ($n = 67$). (b) MiR-139-5p expression in HGC-27, SGC-7901, MKN-45, AGS, and GES-1 cell lines. (c) TPD52 expression in GC tissues ($n = 67$). (d) TPD52 expression in HGC-27, SGC-7901, MKN-45, AGS, and GES-1 cell lines. $^{*}p < 0.05$ and $^{**}p < 0.01$.

3.4. TPD52 Silence Blocked GC Progression. Then, TPD52 function was investigated in HGC-27 cells with its siRNA. TPD52 expression was reduced by its siRNA (Figure 6(a), $P < 0.01$). Functionally, si-TPD52 restrained HGC-27 cell proliferation (Figure 6(b), $P < 0.01$). Meanwhile, HGC-27 cell migration was suppressed by si-TPD52 (Figure 6(c), $P < 0.01$). Similarly, downregulation of TPD52 also inhibited cell invasion in GC cells (Figure 6(d), $P < 0.01$). In brief, TPD52 silencing can inhibit cell proliferation and metastasis in GC.

3.5. Upregulation of TPD52 Partially Impaired the Antitumor Effect of MiR-139-5p in GC. Finally, HGC-27 cells with miR-139-5p mimics and TPD52 vector were employed to further explore their relationship. As we expected, TPD52 vector recovered the reduced TPD52 expression mediated by miR-139-5p mimics in HGC-27 cells (Figure 7(a), $P < 0.01$). Then, TPD52 vector lessened the suppressive effect of miR-139-5p on HGC-27 cell proliferation and metastasis (Figures 7(b)–7(d), $P < 0.01$). In brief, upregulation of TPD52 partially impaired the antitumor effect of miR-139-5p in GC.

4. Discussion

The high tumor recurrence rate and mortality of GC are mainly caused by systemic metastasis. Many researchers have proposed that abnormally expressed miRNAs can affect the occurrence and progression of GC [25, 26]. MiR-139-5p can affect the diagnosis, prognosis, and treatment of malignancy [27]. For instance, miR-139-5p affected cell metastasis in colorectal cancer [28]. Especially, miR-139 was

associated with lymph node metastasis of human metastatic gastric tumors [29]. Moreover, miR-139-5p regulated aerobic glycolysis via inhibiting PRKAA1 in GC [30]. Thus, the role of miR-139-5p was explored in GC.

Here, miR-139-5p downregulation was detected in GC. Adverse clinical features and prognosis in GC patients were associated with its downregulation. The results are similar to previous studies [29]. Moreover, miR-139-5p overexpression restrained GC cell proliferation, migration, and invasion. Furthermore, miR-139-5p directly targets TPD52. More importantly, miR-139-5p hindered GC progression by downregulating TPD52. Similarly, miR-139-5p also repressed cell proliferation in uterine leiomyoma through mediating TPD52 [31]. In addition, we also found that TPD52 was upregulated in GC, and TPD52 silencing can block GC progression.

Previous studies have shown that TPD52 is a target of many miRNAs. Kumamoto et al. reported that TPD52 knockdown can restrain the metastasis of lung squamous cell carcinoma [32]. The same effect of TPD52 on GC was also identified in this study. Moreover, miR-34a and miR-449 repressed breast cancer cell metastasis via targeting the oncogenic TPD52 [33, 34]. MiR-218 also inhibited tumor growth through targeting TPD52 in prostate cancer [35]. These previous research studies are consistent with our conclusions in GC. In a word, the antitumor effect of miR-139-5p is affected by TPD52 in GC.

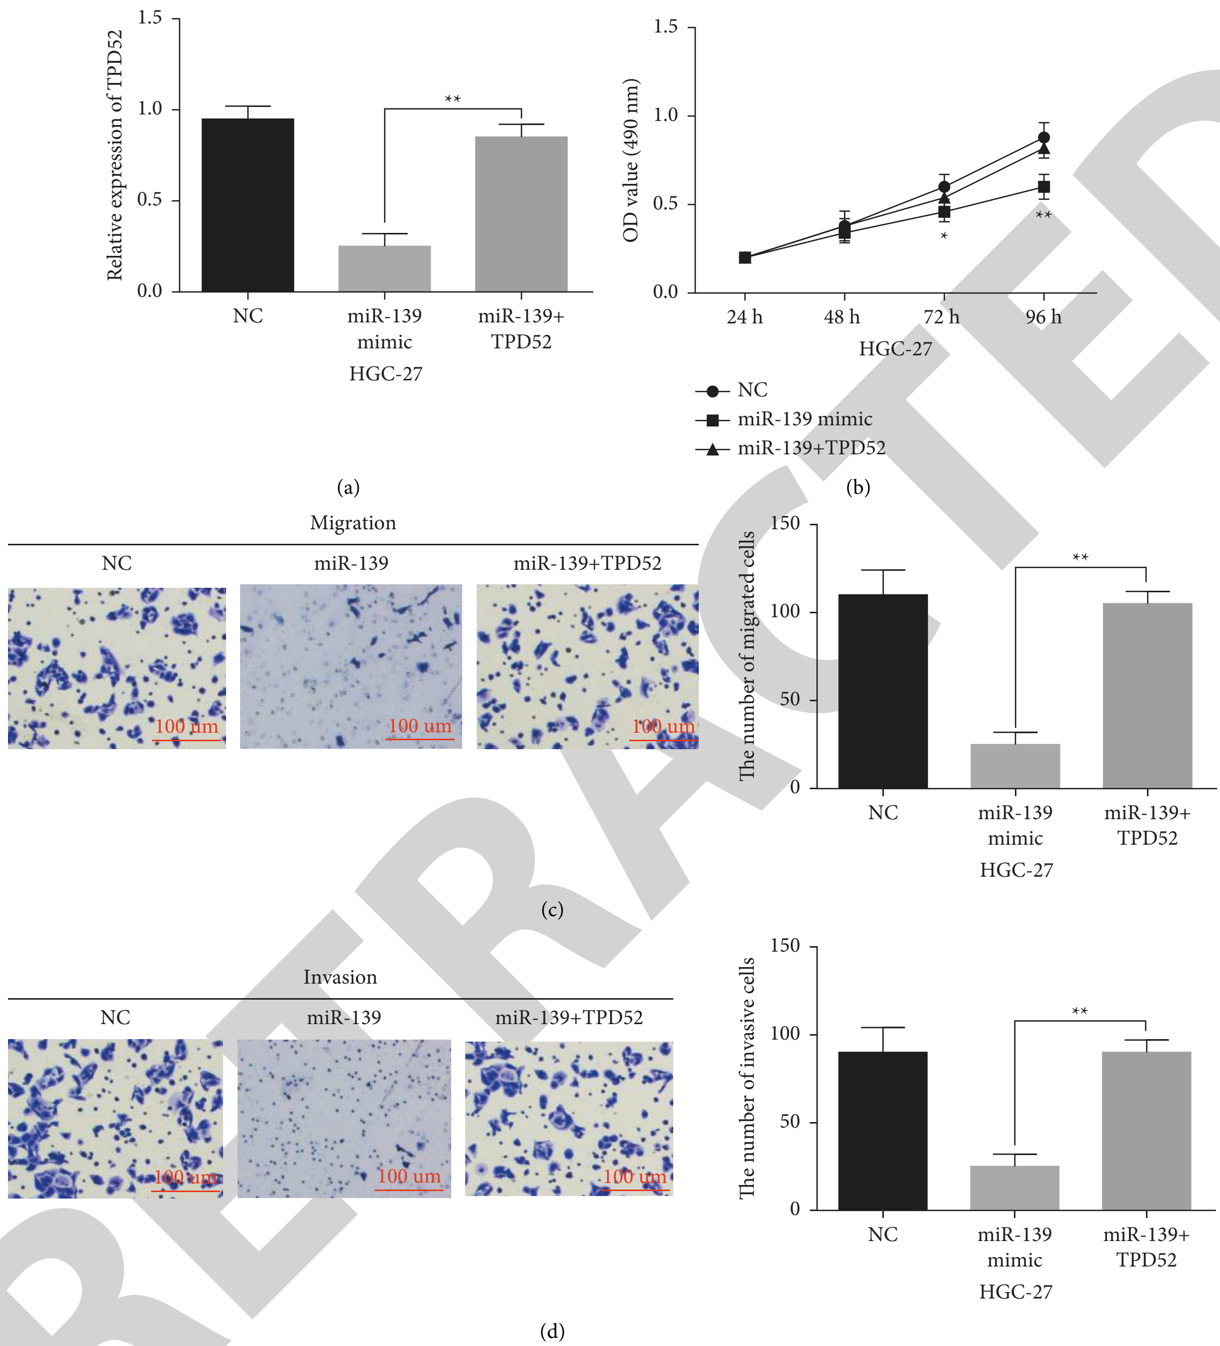

Figure 7: TPD52 upregulation impaired the inhibitory action of miR-139-5p in GC. (a) TPD52 expression in HGC-27 cells containing TPD52 vector and miR-139-5p mimics. ((b), (c), (d)) Cell proliferation, migration, and invasion in HGC-27 cells with the TPD52 vector and miR-139-5p mimics. $^{**}p < 0.01$.

5. Conclusion

In conclusion, miR-139-5p downregulation occurred in GC tissues and cells. Worse prognosis of GC patients was associated with miR-139-5p downregulation. Moreover, miR-139-5p restrained GC cell proliferation and metastasis through targeting TPD52. MiR-139-5p will develop into a therapeutic and prognostic marker for GC. However, the results of this study have not been verified in animals. Therefore, in vivo experiments still need to be done in the future.

The imaging modalities are used to view other organs and analyze different tissues in the body. In such imaging modalities, a new and developing imaging technique is hyperspectral imaging. This multicolour representation of tissues helps us to better understand the issues compared to the previous image models. This research aims to analyze the tumor localization in the brain by performing different operations on hyperspectral images. The tumor is located using the combination of k-based clustering processes like k-nearest neighbour and k-means clustering. The value of k in both methods is determined using the optimization process called the firefly algorithm. The optimization processes reduce the manual calculation for finding K's optimal value to segment the brain regions. The labelling of the areas of the brain is done using the multilayer feedforward neural network. The proposed technique produced better results than the existing methods like hybrid k-means clustering and parallel k-means clustering by having a higher peak signal-to-noise ratio and a lesser mean absolute error value. The proposed model achieved 96.47% accuracy, 96.32% sensitivity, and 98.24% specificity, which are improved compared to other techniques.

1. Introduction

The increasing growth of medical image analysis uses various advanced image processing techniques [1]. Due to this development, incurable diseases can be cured nowadays. This development helps to cure most life-threatening diseases like tumors, blood clots, and cancer at the initial stages. These life-threatening diseases are confirmed with the help of images of the infected region and biopsy. Mostly, the infected region's images are the first step in diagnosing the conditions [2]. The diseases are confirmed with the help of a biopsy. In such a situation, the infected regions' modeling should be highly accurate and easily visualizable.

This paper discusses such modeling, which is called hyperspectral imaging, to locate the abnormal growth of cells in the brain. This hyperspectral image provides an accurate result compared with other images. In general, brain activities are recorded with the help of scanning and radiogram methods. The scanning so far used for the brain is the MRI scan and CT scan [3]. MRI is the abbreviation of magnetic resonance imaging, mainly used for the body's soft tissue analysis [4]. CT is the abbreviation of computed tomography imaging used to analyze the hard tissues of the body.

MRI scanning is mainly preferred for brain analysis. The advantages of this type of scanning are the ability to view the soft tissue clearly. It does not produce any side effects because of not using any ionizing radiation to visualize the brain regions. The MRI scan is highly used to locate the abnormal growth of cells in the brain. This imaging scheme produces the brain's imaging in a greyscale format [5], which medical experts can analyze. An in-depth diagnosis is required in this imaging model to locate the tumor.

Apart from MRI scanning, other types of scanning also produce the images in a greyscale format except for the color Doppler scan. However, alternative techniques like postprocessing for segmenting the tissue regions are not producing desired results. Hence, to overcome this drawback, a new imaging technique called hyperspectral imaging is used to analyze the body's soft tissues.

Hyperspectral imaging is used in remote sensing for vegetation classification by taking pictures of hundreds of bands' regions. This imaging process is also used for capturing the brain with 128 bands. Based on the image processing techniques, the hyperspectral image is classified. These hyperspectral images represent the brain regions in different colors, which effectively understand the brain tissues. This mainly helps the doctor during the surgery process to remove the abnormal tissues. This imaging technique also helps the patient understand the current stage of their diseases due to the representation of tissues in different colors. The high-resolution camera captures the brain tumor [6].

This paper discussed the mapping process of the brain to locate the abnormal tissues. The technique used for the mapping was noise removal to remove any artifacts in the images for postprocessing. The segmentation process was done using a hybrid k-based clustering process [4]. The algorithm for optimization was utilized to choose the value of clusters for the clustering process. The neural-based labelling process was to mention the tissues of the brain in different colors. Based on the image classification accuracy, the mean absolute error value, and the peak signal-to-noise ratio, the results are compared with existing image classification methods and neural network models.

This paper is organized as follows: Section 2 discusses the various research works of tumor localization. Section 3 presents a detailed explanation of the proposed methodologies. Section 4 discusses the comparison of various techniques by practical implementation and evaluation. Section 5 is about the conclusion statement based on the results and analysis.

2. Related Works

Hemanth et al. [1] proposed the abnormal brain image using the deep convolution method. This brain image was classified based on the dataset. The deep convolution neural network was applied to reduce design complexity. The convolution neural network model used a deep learning technique, that is, DCNN. The abnormal brain tumor dataset was used for classifying the image. Here, three layers in DCNN were carried out to perform the classification. The first layer was the convolution layer, which provides the higher-level features with trained parameters. The second layer was the ReLU Layer, which rectifies the linear unit layer. The final one was the Max-Pool layer. It was used after getting the four-cluster region. It classified the terms of metastasis, meningioma, glioma, and astrocytoma.

Deep-seated diseases like MS affect the nerve systems since they would be predicted earlier. Halimeh and Teshnehlab [2] proposed the tumors and MS simultaneous classification and diagnosis with the convolution neural network's help. Here, the image processing technique was used to classify that image, and it was diagnosed. Here, CNN was used. The MRI image was taken for the classification process of the internal image pixel's multiplications. This detects the infected area, lesion, and tumor after diagnosis.

Dong et al. [7] proposed a Farrow structure to apply the time delay filter contrary to a linear FIR structure to fulfill the requirement for real-time updates and be entirely suitable for the FPGA domain. Besides, another off-line approach was implemented to evaluate the Farrow filter coefficient if the coefficient was symmetric. Simulations have been generated to represent the structural model to the Farrow filter developed. The results likewise showed the Frost broadband adaptive antenna with a Farrow filter effectively diminishes the obstacle.

Choi and Jeong [8] proposed a model utilizing Speckle Reducing Anisotropic Diffusion (SRAD), guided filter, and soft thresholding to eliminate SAR image speckle noise while maintaining edge data efficiently. Initially, the generated procedure obtained a filtered image by executing an SRAD filter onto the noisy image. Thus, a logarithmic shift was used to change it to additional noise for future expulsion of the filtered image's multiplicative noise. The filtering image was transformed, using DWT, into multiresolution images. For each high and low-frequency, subimage soft thresholding and the directed filter were used. The denoised images were equipped with Inverse DWT (IDWT) and the exponential transform, showing that the procedure demonstrated superior function over the traditional filtering method and the output was both subjective and objective.

Mafi et al. [9] developed an image denoising technique within related speckle noise and Gaussian noises. The dual-tree complex wavelets transform was used on the images to accomplish a unique coefficient describing these noises. Hence, these isolated coefficients were evacuated by thresholding, and the inverse wavelet transform was executed to achieve the remake image. A connection between the dual-tree and standard wavelet-based denoising filter was applied depending on different basic parameters. Lastly, to expel some other existing noises, a spatial denoising filter was used on the image. The clinical ultrasound images are degenerated by the noise sequences. Such noise sequences helps the researchers' to understand the impacts of Gaussian and speckle noises with the help of most effective speckle and Gaussian denoising filters.

Choi and Jeong [10] proposed an algorithm utilizing SRAD and a guided filter for speckle noise decreasing and edge security. At first, speckle, which was a multiplicative noise, was detached by utilizing SRAD. The existing noise in the filtered image was transformed to added noise using algebraic transform. The additional noise that exists in the filtered image was further detached utilizing a guided filter. Lastly, the image without noise was derived utilizing aggressive transformation, indicating that the model have better noise reduction and edge-preserving capabilities than the standard filtering method.

Marie and Alalyani [11] proposed a novel firefly algorithm-based feature selection process. This also manages the Arabic text classification that was not successfully concentrated because of the Arabic language's inconvenience. This technique has been profitably tested in various complicated issues. Moreover, it has not been included in selecting feature methods to manage the classification of Arabic text. The SVM classifier was utilized as three-calculation parts for approving this method, including accuracy, recall, and F-measure. This work accomplished an accuracy of 0.994 using OSAC dataset.

Narayanan et al. [5] proposed a technique to access the standard EEG signal. At first, the peak EEG signal voltage estimation is computed. Finally, a developed time-frequency transformation method was used to send the signals into an image depending on the wavelet transform. Additionally, the S-transform access was planned to disengage the main features of signals to the classifier scheme. The firefly algorithm-based method was further treated to select the principal features of the signal utilized for training and testing the classifying method. In this method, the SVM, RF, and KNN methods were developed. Hence, the performance obtained an average accuracy of 80.39%. The performance affirmed that this method offered a better outcome on the chosen EEG signal.

Mashhour et al. [12] proposed a new classifier method depending on a firefly algorithm made as a managed learning algorithm. Hence, the analysis depended on the firefly algorithm created by simulating a firefly's character to bring different mates, dependent on intensity and distance. The procedure of this algorithm contained three stages. The feature selection stage was utilized to reduce the features and to select the most valuable features. The model development stage was significant in determining the firefly class moderators. The model forecast stage was utilized to apportion the testing or concealed sample in their related classes using class contributors. A few datasets ended up being related to the Ant-Miner technique. The experiment demonstrated that the firefly algorithm was the best.

Tawahid and Dsouza [13] presented an algorithm known as the Hybrid Binary Bat Enhanced Particle Swarm Optimization (HBBEPSO). In this method, a bat based genetic algorithm is used to analyze the feature space using echolocation and improved rendition of the PSO to achieve better solution in the search place. The algorithm's overall efficiency and technique were identified as the best compared to the other methods examined. Hence, the result has demonstrated the algorithm's capacity to discover the feature space for optimal feature sequence.

Sangaiah and Kumar [14] proposed an algorithm that used a relief attribute reduction with GA based on entropy for breasts cancer identification. This method's hybrid sequence was utilized to deal with the dataset with a higher dimension and concern. The information was accomplished from the WISCONSIN datasets, and the information has been classified depending on various properties. The technique was calculated and compared with the other notable feature selection processes. The experimental outcome indicates that the work has a remarkable capacity to create a decreased subspace of critical features while generating significant classifications accuracy for massive datasets.

Harithaa [15] presented the firefly and cuckoo search-based algorithms of feature selection with detached high accuracy and lower training upward for the PIMA Indian diabetic dataset from UCI. The empirical setup was made with the UCI dataset with the KNN classifier. The precision, accuracy, and recall were analyzed to calculate parameters, and the results were compared with those of the firefly and cuckoo search algorithms. This technique traditionally obtained high accuracy.

Long et al. [16] developed a heart disease diagnostic model with rough sets based on feature reductions and type 2 fuzzy logic (IT2FLS) intervals. Analysis among irregular groups based on feature reduction and IT2FLS targets address the issue and concern of high-dimensional datasets. IT2FLS used a hybrid teaching procedure to compose a fuzzy c-means clustering approach and the adjustment criterion by firefly chaos and hybrid genetic algorithms. This teaching procedure was costly in computational terms, especially when hired with a high-dimensional set of data. The rough set-based quality decline utilizing a chaos firefly approach was analyzed to detect an optimal reduction, reduce computational liability, and improve IT2FLS performance. Results explained remarkable device stability associated with numerous machine learning algorithms like Naive Bayes, ANN, and SVM. This model has been useful in diagnosing heart disease.

Cortes et al. [17] developed an approach for adaptively learning artificial neural networks (ADANET). It was based on analytical methods, including data-dependent generalized, which are proved in detail. The large-scale operations on the various binary division tasks are obtained using the CIFAR-10 dataset. Results explained that this technique could automatically learn network structures with very reasonable work accuracy when related to those obtained for neural networks.

Esfe et al. [18] analyzed nanofluids' thermal conductivity utilizing neural networks, test data, and correlativity for modeling thermal conductivity. Using a KD2-Pro thermal analyzer, the thermal conduction of $Mg(OH)_2$ nanoparticles with a 10 nm mean diameter isolated in ethylene glycol was solved. An experimental collaboration has been developed as far as volume fraction and temperature were concerned, based on observational information at other substantial volume portions and temperature. Therefore, the relative thermal conduction as temperature and volume fraction activities was proposed through a neural network depending on the analyzed information. A system with two layers hidden in each layer and five neurons has the slightest error and a high fitting coefficient. Besides correlating the model and the correlativity obtained from test knowledge, the neural network was highly accurate and predicted the thermal conduction of $Mg(OH)_2$-EG nanofluids.

Erkaymaz et al. [19] researched the work of two various feedforward neural networks (FFNN) for diabetes diagnosis. They used input as PIMA Indians Diabetic Dataset. The previous information indicated that the Watts–Strogatz small world FFNN delivered a good analysis work compared to traditional FFNN. Consequently, the result was associated with the Newman–Watts small world FFNN, and they demonstrated that the latter was even better. However, the Newman–Watts small world FFNN results from better output parameters were validated.

Torti et al. [20] executed an alternative analytical comprehension of the challenge from a smooth optimization perspective. Hence, the specific teaching of limited samples and acceptable conditions was analyzed using a critical point to set up any local minimal to be globally minimal. Additionally, an advanced algorithm, known as the Generalized Gauss-Newton (GGN), was returned as a surmised Newton's algorithm that moves the property of being locally united to a global minimum under the state of accurate teaching.

Hao et al. [21] proposed a glioblastoma brain tumor classification model using HSI images. The spatial and spectral features of HSI images were used by implementing various deep learning models for the detection of brain tumor. These features extracted could support obtaining accurate results in detecting brain tumor. The brain tumor detection process includes the processes like spectral phasor analysis and data oversampling, 1D-DNN-based spectral HSI feature extraction and classifications, 2D-CNN-based spectral-spatial HSI feature extraction and classifications, edge-preserving filtering-based classification results fusion and optimizations, and fully convolutional networks- (FCN-) based background segmentation.

3. Proposed Method

In this paper, a classification and detection model of brain tumor using hyperspectral imaging (HSI) is proposed. The brain tumor mapping technique was used in this work for improving the performance of the proposed model to achieve accurate results in terms of detecting brain tumor. The proposed model includes preprocessing, filtering, optimization, clustering, labelling, and classification processes in order to detect the brain tumor.

Mapping is the process, which represents the different regions of the same properties in different colors. This mapping process is used to understand the areas more effectively. This paper discusses such a mapping process for locating the abnormal tissues in the brain. The term abnormal tissue was the tumor cell whose growth was increasing without any ordered form [22, 23].

The mapping process is done on the hyperspectral image of the brain. The noise removal algorithm to remove any unwanted pixels or disturbance in the image processes the hyperspectral image. This noiseless image is suitable for a better mapping process. The mapping is carried out in two stages. The initial step is to group pixels of the same characteristics using an optimized hybrid k-based clustering process [24]. The second stage is to label the grouped pixels using the neural scheme. Figure 1 is the pictorial representation of the proposed system.

3.1. Image Modeling. The mapping of a brain region is done using hyperspectral images. The image used in this paper is obtained from the in vivo hyperspectral format. The input image consists of 128 bands, and its color wavelength ranges from 400 to 1300 nm, that is, the bandwidth of electromagnetic radiation.

NASA usually performs mapping in hyperspectral images remote sensing application form specifying the different crops. NASA is currently performing this mapping process in the mammogram images using the MEDSEG analyzer to represent the breast region's various tissues to detect the cancer part. The migration to hyperspectral medical imaging helps to capture the images in pixels and their wide range of frequencies.

Hyperspectral imaging's main advantage is to capture the spatial and spectral information of the images through spatial and spectral scanning of the body with different wavelengths.

The information is higher due to the capture of the body of more than eight bands. Each band of the hyperspectral image holds a different story on the brain's particular region, which is impossible in the other imaging models. This paper tests the proposed hybrid firefly and k-based mapping in the dataset used in the parallel k-means clustering process. The HSI brain image is obtained with a hyperspectral camera, and a technique like the one Vivo-based is used. It captures the brain region in 128 bands, and each band consists of different information about the brain. The process of each stage of the proposed method is elaborated in the following.

3.2. Conversion of the Hyperspectral Cube to RGB Format. Our research data preprocessing is one of the common process-forming concepts for the images mapping and noise removal sections. In the HSI RGB form, images have the maximum data in every pixel and color, typically 150 to 400 dimensional vectors were analyzed and configured. The reflection of the pixel consists of each wavelength.

In this preprocessing stage, two processes were performed under the following conditions:

(i) Greyscale process.

(ii) Noise removal process.

Previous research work was performed based on the greyscale process. Noise removal is acting under adaptive and Frost filters to get a better result. The adaptive filter uses an actual pixel integer concept that is replaced with an

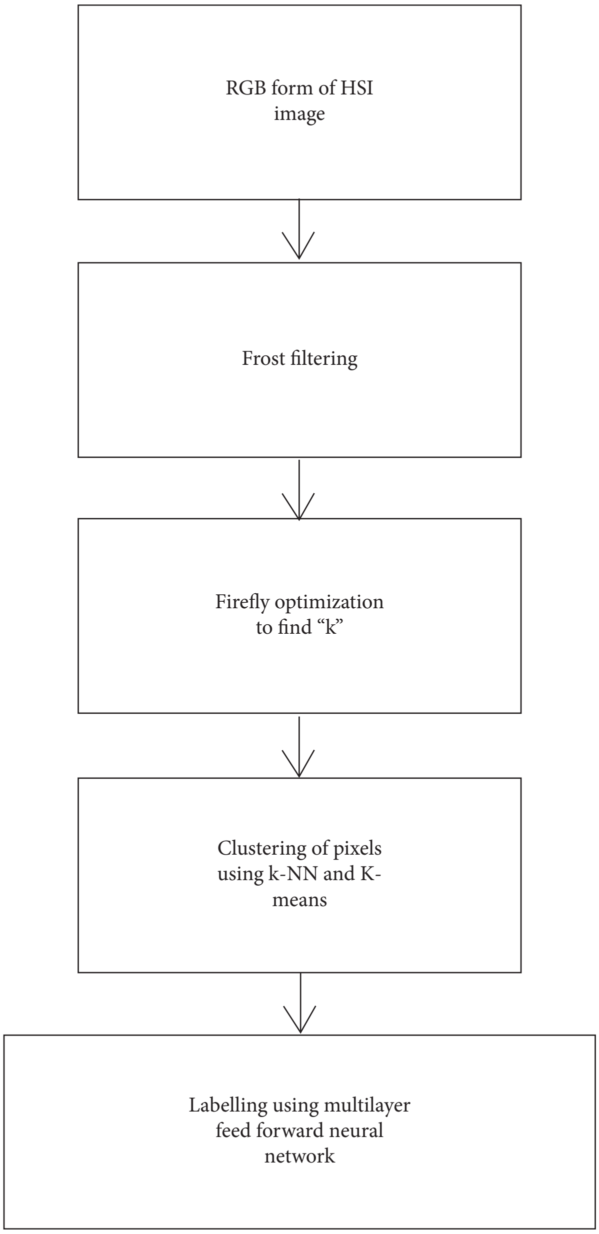

Figure 1: Flowchart for the mapping process.

advanced pixel integer concept, and it presents better results and high performance.

3.3. Frost Filtering. The Frost filter exchanges the pixel of interest with the moving (nXn) kernel's total weighted values. The weighting factor decreases as one moves away from the pixel of interest. As the variance of the kernel grows, the weighting factors for the central pixels will also grow. This filter was based on the statistics of multiplication and stationary noises.

Frost filter minimizes image edges speckle content. This type of filter is a damaged symmetric regular filter used for linear data. It was determining the accurate pixel here, replacing the filter and estimation based on filter distance.

Various order speckle pictures expressed the following equation:

$$J(m,n) = a(m,n).n(m,n), \tag{1}$$

where $J(m, n)$ is the speckle-noise image value corruption, $a(m, n)$ is the actual speckle free signal, and $n(m, n)$ is the speckle noise.

3.4. Feature Extraction. This process is to group the regions of the brain using an optimized k-means clustering technique. The term optimized refers to selecting the optimal clusters value for the k-means clustering process. This optimization approach helps to group the different regions of the brain, along with the tumor part.

Suppose local window size is $N \times N$ means; the result is expressed as

$$s(i, j) = \sum_{K=i-Nj}^{i+Nj} \sum_{i=j-Nj}^{j+N} h(k,l).I(k,l), \tag{2}$$

where

$$\begin{aligned} s(i, j) &= \sum_{K=i-Nj}^{i+Nj} \sum_{i=j-Nj}^{j+N} h(k,l).I(k,l), \\ d_{kj} &= \sqrt{(i-k)^2 + (j-l)^2}, \end{aligned} \tag{3}$$

where k is constant.

3.5. Firefly Algorithm (FA). Firefly algorithm is a meta-heuristic algorithm for the advancement of optimization. This concept is based on the speckle action of firefly insects. Xin-She Yang introduced this algorithm in 2008. Firefly algorithm (FA) uses speckle action to impress another firefly, naturally transmitting signals to differing gender. Firefly is of a similar gender; also, all fireflies can impress another firefly. This consists of brightness for all pairs of fireflies. A brighter firefly attracts another firefly; therefore, the minimum brighter ones are replaced with the brighter ones. The algorithmic flow of the firefly is given in Table 1. The fireflies' beginnings are based on the boundary's integer concept, which is the maximum and minimum limitation statement. The maximum and minimum limitation statements of the fireflies are 1 and 5.

The formula of a pair of two fireflies is expressed as follows:

$$x_i^{t+1} = x^t_{1+\beta\exp\left(-\gamma r_{ij}^2\right)} \left(x_{j}^t {}_{-x_i^t}\right) + \alpha_{t\,\varepsilon_t}, \tag{4}$$

which is optimized by

$$F(x) = (f1(x), f2(x), \ldots, fi(x), \quad i = 1, 2, 3, \ldots, m. \tag{5}$$

3.6. K-Means Clustering. It is the function of a similar pixel integer, and it is synthesis in one part. In our research work, an unsupervised method is referred to as clustering implemented in this section. The undefined address part of a

picture is addressed by presenting the k-means clustering function about a centric portion.

This incorporates the pixel integer term of a picture-based k region, where k is several clusters in the picture and k calculates the firefly optimization function. The entire process is performing under the basis iteration still in the cluster form of every pixel picture. The clustering is one of the pixel properties, and by getting the k value of 3, the mapping region is performed based on the threshold method.

Addressing a function of the pixel term performs a k-cluster state. The centric portion calculated the choosing pixel property concept and the weight of both group concepts under the clustering condition.

The code profiling was performed using the dataset created by original HS images and assuming $k = 24$, min_error $= 10^{-3}$, and max_iter $= 50$.

3.7. Mapping the Regions. The affected region is mapped based on the neural network model, which uses a multilayer feedforward neural network. In the below discussion, the MFNN was described.

3.7.1. Multilayer Feedforward Neural Network (MFNN). Neural networks are computing systems made up of linked nodes that function similarly to neurons in the brain. Using the MFNN method, hidden patterns can be detected, correlations in raw data, cluster, and classifications can be performed, and the proposed MFNN continually learns and enhances over time. This is one of the popularised single-layer feedforward neural networks, naturally used in addressing the operation of the brain molecule. Testing the web is based on the brain's molecule and also the integer of the image. Dataset classification is based on testing and training based on the cross pleat estimation section. The neural network training is based on the training characteristics; the performance process and the results are produced based on those values.

In supervised learning, data labelling is an important component of data preparation. Every error or inaccuracy in this procedure might have a detrimental impact on the quality of a dataset. Furthermore, the overall performance of a predictive model might be lost, leading to errors. Taking this into account, for the ground truth in the tumor identification problem, the MFNN algorithm was applied, which labelled the data.
